# Preface

Tiffany Barnett White  
University of Illinois-Urbana Champaign, Gies College of Business

Andrew Gershoff  
University of Texas at Austin, McCombs School of Business

Robert Kozinets  
University of Southern California, Marshall School of Business

The 49th Annual Conference of the Association for Consumer Research (ACR) was held at the Hilton Anatole Hotel in Dallas Texas from October 11-14, 2018. Our conference theme was “Trust in Doubt: Consuming in a Post-Truth World” and this theme flowed through sessions, events, a forum track, a bundled videography session, and in the conference’s visual and conceptual theming. In addition, for the first time, the conference theme was linked to an upcoming issue of the Journal of the Association for Consumer Research (JACR). This conference also introduced a new conference management software system to help streamline the conference and proceedings process. This volume reports the presentations made in the conference’s special sessions, competitive paper sessions, working paper sessions, invited sessions, forums, and the videography track.

The conference attracted over 1100 participants and had a total of 587 acceptances, which included 116 special session (52% accepted), 242 competitive papers (54% accepted), 267 working papers (72% accepted), 7 forums (78% accepted) and 9 videographies (75% accepted).

We thank our generous sponsors: Journal of the Association for Consumer Research, Journal of Consumer Research, Journal of Consumer Psychology, SAGE Publishing, Stukent, Inc., Palgrave Macmillan, and the University of Chicago Press.

Many wonderful people worked tirelessly to help us make this conference possible. We thank our Program Committee, Competitive Paper Reviewers, Working Paper Reviewers, and Videography Reviewers (who are all listed by name inside these proceedings). We especially wish to thank Fleura Bardhi and Ravi Mehta (Working Paper Chairs), Stephen Spiller, Ashlee Humphreys, and Tonya Bradford (Forum Chairs), Ingeborg Kleppe and Alain Decrop (Videography Chairs), and Donna Hoffman and Tom Novak (Doctoral Symposium Chairs). Many thanks also go to our excellent Associate Editors: Frederic Brunel, Keisha Cutright, Angelika Dimoka, Rosie Ferraro, Peter McGraw, Page Moreau, Stefano Puntoni, Americus Reed, Aric Rindfleisch, and Yael Steinhart.

Special gratitude goes to ACR Executive Director Rajiv Vaidyanathan, who was always willing to patiently and thoroughly help us and answer our questions, and to Paula Rigling, Jiyoung Lee, the platform support staff at All Academic, and the ACR Executive Assistant Brenda Monahan.

Last but not least, we wish to sincerely thank Stacy Wood, ACR President 2018, for gifting us with the opportunity to organize the ACR conference and for her help, wisdom, and support in guiding us through the many steps toward the event.

*Tiffany Barnett White, University of Illinois-Urbana Champaign, Gies College of Business*

*Andrew Gershoff, University of Texas at Austin, McCombs School of Business*

*Robert Kozinets, University of Southern California, Marshall School of Business*

*2018 Conference Co-Chairs*

# Conference Committees & Reviewers

## PRESIDENT

Stacy Wood, North Carolina State University, USA

## CONFERENCE CHAIRS

Andrew Gershoff, University of Texas at Austin, McCombs School of Business  
Robert Kozinets, University of Southern California, Marshall School of Business  
Tiffany Barnett White, University of Illinois-Urbana Champaign, Gies College of Business

## ASSOCIATE EDITORS

Frederic Brunel, Boston University, USA  
Keisha Cutright, Duke University, USA  
Angelika Dimoka, Temple University, USA

Rosellina Ferraro, University of Maryland, USA  
Peter McGraw, University of Colorado, USA  
Page Moreau, University of Wisconsin, USA  
Stefano Puntoni, Erasmus University, Netherlands

Americus Reed, University of Pennsylvania, USA  
Aric Rindfleisch, University of Illinois, USA  
Yael Steinhart, Tel Aviv University, Israel

## FORUMS (PERSPECTIVES, ROUNDTABLES, & WORKSHOPS) CHAIRS

Ashlee Humphreys, Northwestern University, USA  
Tonya Bradford, University of California, Irvine, USA

Stephen Spiller, University of California, LA, USA

## WORKING PAPER CHAIRS

Fleura Bardhi, City, University of London, England

Ravi Mehta, University of Illinois, USA

## DOCTORAL SYMPOSIUM CHAIRS

Tom Novak, George Washington University, USA

Donna Hoffman, George Washington University, USA

## VIDEOGRAPHY CHAIRS

Ingeborg Kleppe, Norwegian School of Economics, Norway

Alain Decrop, University of Namur, Belgium

## PROGRAM COMMITTEE

Linda Zayer, Loyola University Chicago, USA  
Benét Deberry-Spence, University of Illinois at Chicago, USA  
Lisa Penaloza, Kedge Business School  
Julie Ozanne, University of Melbourne, Australia  
Eileen Fischer, York University, Canada  
Jose Rosa, Iowa State University, USA  
Julien Cayla, Nanyang Technological University, Singapore  
Zeynep Arsel, Concordia University, Canada  
Eric Arnould, Aalto University, Finland  
John Schouten, Memorial University of Newfoundland  
Susan Dobscha, Bentley University, USA  
Lan Chaplin, University of Illinois at Chicago, USA  
Silvia Bellezza, Columbia University, USA  
Ashok Lalwani, Indiana University, USA  
David Wooten, Cornell University, USA  
Christina Goulding, University of Birmingham, UK  
Cele Otnes, University of Illinois at Urbana-Champaign, USA  
David Crockett, University of South Carolina, USA  
Markus Giesler, York University, Canada  
Vanessa Perry, George Washington University, USA  
Grant Packard, Wilfrid Laurier University, Canada  
Selin Malkoc, Ohio State University, USA  
On Amir, University of California San Diego, USA  
Katherine Burson, University of Michigan, USA  
James Bettman, Duke University, USA  
Szu-Chi Huang, Stanford University, USA  
Aparna Sundar, University of Oregon, USA  
Danit Ein-Gar, Tel Aviv University, Israel  
L. J. Shrum, HEC Paris, France  
Tina Lowrey, HEC Paris, France

Joey Hoegg, University of British Columbia, Canada  
Zeynep Gurhan-Canli, Koc University, Turkey  
Mitchell Hamilton, Loyola Marymount University, USA  
Jordan Etkin, Duke University, USA  
Pankaj Aggarwal, University of Toronto, Canada  
Barbara Kahn, University of Pennsylvania, USA  
David Mick, University of Virginia, USA  
Simona Botti, London Business School, UK  
Leonard Lee, National University of Singapore, Singapore  
Dengfeng Yan, University of Texas at San Antonio, USA  
Hila Riemer, Ben Gurion University, Israel  
Maura Scott, Florida State University  
Elizabeth Cowley, University of Sydney, Australia  
Bram Van Den Bergh, Erasmus University Rotterdam, The Netherlands  
Klaus Wertenbroch, INSEAD, Singapore  
Keith Wilcox, Columbia University, USA  
Kelly Haws, Vanderbilt University, USA  
Darren Dahl, University of British Columbia, Canada  
Rebecca Reczek, Ohio State University, USA  
Jennifer Argo, University of Alberta, Canada  
Juliano Laran, University of Miami, USA  
Peter Darke, York University, Canada  
Kelly Herd, University of Connecticut, USA  
Kent Grayson, Northwestern University, USA  
Adriana Samper, Arizona State University, USA  
Miranda Goode, Ivey Business School  
June Cotte, Ivey Business School  
Aparna Labroo, Northwestern University, USA

Kristin Diehl, University of Southern California, USA  
Echo Wen Wan, University of Hong Kong  
Erica Van Herpen, Wageningen University, The Netherlands  
Zoey Chen, University of Miami, USA  
Yang Yang, University of Florida, USA  
Alice Wang, University of Iowa, USA  
Nicole Coleman, University of Pittsburgh, USA  
Jennifer Escalas, Vanderbilt University, USA  
Martin Mende, Florida State University  
Aronte Bennett, Vilanova University, USA  
Julie Edell, Duke University, USA  
Stijn Van Osselaer, Cornell University, USA  
Carlos Torelli, University of Illinois at Urbana-Champaign, USA  
Hal Hershfield, University of California Los Angeles, USA  
Alladi Venkatesh, University of California Irvine, USA  
Jeffrey Inman, University of Pittsburgh, USA  
Joann Peck, University of Wisconsin - Madison, USA  
Lisa Cavanaugh, University of British Columbia, Canada  
Helge Thorbjørnsen, Norwegian School of Economics and Business Administration, Norway  
Breaglin Riley, Syracuse University  
Andrea Morales, Arizona State University, USA  
Rui (Juliet) Zhu, Cheung Kong Graduate School of Business, China  
Joseph Nunes, University of Southern California, USA  
Ann Schlosser, University of Washington, USA

**PROGRAM COMMITTEE (continued)**

Alokparna (Sonia) Monga, Rutgers University, USA  
Pierre Chandon, INSEAD, France  
Katherine White, University of British Columbia,  
Canada

Adam Duhachek, Indiana University, USA  
Susan Fournier, Boston University, USA  
Jonathan Levav, Stanford University, USA  
Shai Danziger, Tel Aviv University, Israel

Joseph Goodman, Ohio State University, USA  
Hope Schau, University of Arizona, USA  
Laurie Anderson, Arizona State University, USA

**COMPETITIVE PAPER REVIEWERS**

Fan Liu, Adelphi University  
Nelson Amaral, American University, USA  
Eunjoo Han, Auckland University of Technology,

# Table of Contents

Preface . . . . .	iii
Conference Committees & Reviewers . . . . .	iv

## 2018 ACR Presidential Address

<b>True Story</b> . . . . .	1
<i>Stacy Wood, North Carolina State University, USA</i>	

## 2018 ACR Fellow Addresses

<b>Kids Say the Darndest Things: Insights from Children’s Consumer Research</b> . . . . .	6
<i>Deborah Roedder John, University of Minnesota, USA</i>	
<b>Tribute: Thank You Consumer Research and Marketing!</b> . . . . .	10
<i>Punam A. Keller, Dartmouth College, USA</i>	
<b>On Relevance</b> . . . . .	14
<i>Richard J. Lutz, University of Florida, USA</i>	

## Special Session Summaries

<b>Financial Decisions in the Information Age</b> . . . . .	23
<i>Chairs: Tito L. H. Grillo, University of Texas at Austin, USA</i>	
<i>Adrian F. Ward, University of Texas at Austin, USA</i>	
<b>Paper #1: Financial Education and Confidence in Financial Knowledge</b>	
<i>Stephen Atlas, University of Rhode Island, USA</i>	
<i>Nilton Porto, University of Rhode Island, USA</i>	
<i>Jing Jian Xiao, University of Rhode Island, USA</i>	
<b>Paper #2: From Novice to Know-it-All: How Google-Based Financial Learning Affects Financial Confidence and Decisions</b>	
<i>Adrian F. Ward, University of Texas at Austin, USA</i>	
<i>Tito L. H. Grillo, University of Texas at Austin, USA</i>	
<i>Philip M. Fernbach, University of Colorado, USA</i>	
<b>Paper #3: Product Complexity as a Barrier to Consumer Financial Decision-Making</b>	
<i>Timothy Dunn, University of Colorado, USA</i>	
<i>Philip M. Fernbach, University of Colorado, USA</i>	
<i>Ji Hoon Jhang, Oklahoma State University, USA</i>	
<i>John Lynch, University of Colorado, USA</i>	
<b>Paper #4: Increasing Tax Salience Alters Investment Behavior</b>	
<i>Abigail Sussman, University of Chicago, USA</i>	
<i>Daniel Egan, Betterment, USA</i>	
<i>Sam Swift, Bowery Farming, USA</i>	

**Sharing and Social Connectedness:**

**How Different Ways of Sharing Affect Social Connection . . . . . 28**

*Chair: Heeyoung Yoon, New York University, USA*

**Paper #1: Self-Deprecation Signals Humility, but Not as Much as Self-Deprecators Assume**

*Clayton R. Critcher, University of California, Berkeley, USA*

*Michael O'Donnell, University of California, Berkeley, USA*

*Minah H. Jung, New York University, USA*

**Paper #2: Speaking Ill of Others: When Negatively-Valenced Gossip Fosters Social Connection**

*Alixandra Barasch, New York University, USA*

*Jonathan Berman, London Business School, USA*

*Heeyoung Yoon, New York University, USA*

**Paper #3: Inside Jokes: Humor as Social Exclusion**

*Ovul Sezer, University of North Carolina at Chapel Hill, USA*

*Brad Bitterly, University of Pennsylvania, USA*

*Alison Wood Brooks, Harvard Business School, USA*

*Maurice Schweitzer, University of Pennsylvania, USA*

*Michael I. Norton, Harvard Business School, USA*

**Paper #4: Give Me Something of Yours: The Downside of Digital (vs. Physical) Exchanges**

*Anne Wilson, Harvard Business School, USA*

*Shelle Santana, Harvard Business School, USA*

*Neeru Paharia, Georgetown University, USA*

**The Technological Consumer in an Interconnected World. . . . . 33**

*Chair: Eugina Leung, Erasmus University Rotterdam, The Netherlands*

**Paper #1: Economic Tremors and Earthquakes: Sharing, The Sharing Economy, Crowdfunding, Cryptocurrencies, and DAOs**

*Russell Belk, York University, Canada*

**Paper #2: Searching for the Tree and Missing the Forest: How Broadening Search Promotes Belief Updating**

*Eugina Leung, Erasmus University Rotterdam, The Netherlands*

*Oleg Urminsky, University of Chicago, USA*

**Paper #3: A Computational Social Science Framework for Visualizing the Possibility Space of Consumer-Object Assemblages from IoT Interaction Data**

*Donna Hoffman, George Washington University, USA*

*Thomas Novak, George Washington University, USA*

**Paper #4: Machine Talk: How Conversational Chatbots Promote Brand Intimacy and Influence Consumer Choice**

*Thomas Hilden, University of Geneva, Switzerland*

*Christian Hildebrand, University of Geneva, Switzerland*

*Gerald Häubl, University of Alberta, Canada*

**Tell Me Something I Don't Know: Consumer's Mistaken Beliefs . . . . . 39**

*Chairs: Yuechen Wu, University of Maryland, USA*

*Rebecca K. Ratner, University of Maryland, USA*

**Paper #1: Mistaking the Journey for the Destination: Overestimating the Fruits of (More) Labor**

*Eva C. Buechel, University of Southern California, USA*

*Carey K. Morewedge, Boston University, USA*

*Jiao Zhang, University of Oregon, USA*

**Paper #2: Inferring Personality from Solo vs. Accompanied Consumption: When Solo Consumers are Perceived to Be More Open**

*Yuechen Wu, University of Maryland, USA*

*Rebecca K. Ratner, University of Maryland, USA*

**Paper #3: Handshaking Promotes Deal-making by Signaling Cooperative Intent**

*Juliana Schroeder, University of California at Berkeley, USA*

*Jane L. Risen, University of Chicago, USA*

*Francesca Gino, Harvard Business School, USA*

*Michael I. Norton, Harvard Business School, USA*

**Paper #4: Mispredicting Reactions to Gambling Losses and Their Impact on Consumer Choice**

*Ernest Baskin, Saint Joseph's University, USA*

*Nathan Novemsky, Yale University, USA*

*Robyn LeBoeuf, Washington University in St. Louis, USA*

**Extraordinary Ordinality: Subtle Influences of Numerical Rankings On Consumer Behavior. . . . . 45**  
*Chairs: Mathew S. Isaac, Seattle University, USA*  
*Julio Sevilla, University of Georgia, USA*  
**Paper #1: Assuming Ordinality: Best-to-Worst Inferences in Vertical Lists**  
*Mathew S. Isaac, Seattle University, USA*  
*Shailendra P. Jain, University of Washington, USA*  
**Paper #2: The Victory Effect: Is First-Place Seeking Stronger than Last-Place Aversion?**  
*Steven Shechter, University of British Columbia, Canada*  
*David J. Hardisty, University of British Columbia, Canada*  
**Paper #3: Format Neglect: How the Use of Numerical Versus Percent Rank Claims Influences Consumer Judgments**  
*Julio Sevilla, University of Georgia, USA*  
*Mathew Isaac, Seattle University, USA*  
*Rajesh Bagchi, Virginia Tech, USA*  
**Paper #4: The Rank Length Effect**  
*Fengyan Cai, Shanghai Jiao Tong University, China*  
*Jieru Xie, Virginia Tech, USA*  
*Rajesh Bagchi, Virginia Tech, USA*

**Consumer Experience in the Changing Marketplace of Health and Wellness . . . . . 50**  
*Chairs: Ankita Kumar, University of Wisconsin - Madison, USA*  
*Lez Trujillo Torres, University of Illinois at Chicago, USA*  
**Paper #1: Turning the Titanic: Creating Consumer-Centric Cultures and Improved Consumer Experience in Large, Established Health Care Systems**  
*Gregory Carpenter, Northwestern University, USA*  
*Beth Leavenworth DuFault, State University of New York at Albany, USA*  
*Ashlee Humphreys, Medill School of Journalism, Media, and Integrated Marketing Communications, Northwestern University, USA*  
*Lez Trujillo Torres, University of Illinois at Chicago, USA*  
**Paper #2: Conflicting Institutional Logics and Eldercare Consumers' Coping Strategies in Asymmetrical Service Relationships**  
*Ankita Kumar, University of Wisconsin - Madison, USA*  
**Paper #3: Public Discourse and Cultural Valorization in the Cancer Marketplace**  
*Lez Trujillo Torres, University of Illinois at Chicago, USA*  
*Benét DeBerry-Spence, University of Illinois at Chicago, USA*  
*Søren Askegaard, University of Southern Denmark, Odense, Denmark*  
*Sonya Grier, American University, Washington DC, USA*  
**Paper #4: Trusting the Data, the Self and "the Other" in Self Tracking Practices**  
*Dorthe Brogård Kristensen, University of Southern Denmark, Odense, Denmark*

**In Praise of Badness. . . . . 57**  
*Chairs: Evan Weingarten, University of California, San Diego, USA*  
*Amit Bhattacharjee, Erasmus University, USA*  
*Patricia A. Williams, Wharton School of Business, USA*  
**Paper #1: In Pursuit of Imperfection: How Flawed Products Can Reveal Valuable Process Information**  
*Erin Percival Carter, University of Maine, USA*  
*A. Peter McGraw, University of Colorado Boulder, USA*  
**Paper #2: Repeat Performances Decrease Consumer Perceptions of Authenticity**  
*Rachel Gershon, Washington University St. Louis, USA*  
*Rosanna Smith, University of Georgia, USA*  
**Paper #3: The Upside of Immorality: The Signal Value of Offensive Producer Behavior**  
*Amit Bhattacharjee, Erasmus University, The Netherlands*  
*Jonathan Z. Berman, London Business School, UK*  
*Gizem Yalcin, Erasmus University, The Netherlands*  
**Paper #4: So-Bad-It's-Good: When Consumers Prefer Bad Options**  
*Evan Weingarten, University of California, San Diego, USA*  
*Amit Bhattacharjee, Erasmus University, The Netherlands*  
*Patricia A. Williams, University of Pennsylvania, USA*

**Perspectives on Consumer Trust in Artificial Intelligence** . . . . . 63  
*Chair: Chiara Longoni, Boston University, USA*  
**Paper #1: Consumers’ Trust in Algorithms**  
*Noah Castelo, Columbia University, USA*  
*Maarten Bos, Disney Research USA*  
*Don Lehmann, Columbia University, USA*  
**Paper #2: Robo-Advising: Algorithm Appreciation**  
*Jennifer M. Logg, Harvard University, USA*  
*Julia A. Minson, Harvard University, USA*  
*Don A. Moore, University of California, Berkeley, USA*  
**Paper #3: Consumer Reluctance Toward Medical Artificial Intelligence: The Underlying Role of Uniqueness Neglect**  
*Chiara Longoni, Boston University, USA*  
*Andrea Bonezzi, New York University, USA*  
*Carey K. Morewedge, Boston University, USA*  
**Paper #4: Psychological Reactions to Human Versus Robotic Job Replacement**  
*Armin Granulo, Technical University of Munich, Germany*  
*Christoph Fuchs, Technical University of Munich, Germany*  
*Stefano Puntoni, Erasmus University, The Netherlands*

**Relationship between Visual Perception and Consumer Behavior:**  
**Identifying Effects of Visual Stimulus Characteristics on Product Evaluations** . . . . . 68  
*Chairs: Gunes Biliciler-Unal, The University of Texas at Austin, USA*  
*Rajagopal Raghunathan, The University of Texas at Austin, USA*  
*Adrian F. Ward, The University of Texas at Austin, USA*  
**Paper #1: Communicating a Promise of Change: Visual Steps Enhance Process Imagery**  
*Luca Cian, University of Virginia, USA*  
*Aradhna Krishna, University of Michigan, USA*  
*Chiara Longoni, Boston University, USA*  
**Paper #2: A Simple Step to Go Beyond Present: How Visual Entropy Cues Influence**  
*Gunes Biliciler-Unal, The University of Texas at Austin, USA*  
*Rajagopal Raghunathan, The University of Texas at Austin, USA*  
*Adrian F. Ward, The University of Texas at Austin, USA*  
**Paper #3: How Eyes Pull on the Heartstrings: Averted Eye Gaze Enhances Narrative Transportation and Self-Brand Connection**  
*Ngoc (Rita) To, University of Houston, USA*  
*Vanessa M. Patrick, University of Houston, USA*  
**Paper #4: Visual Perceptual Research in Marketing**  
*Kevin L. Sample, University of Georgia, USA*  
*Henrik Hagvedt, Boston College, USA*  
*S. Adam Brasel, Boston College, USA*

**Do you Think Maybe They’re Compensating for Something? But Why and How?**  
**New Insights into Compensatory Consumption.** . . . . . 74  
*Chair: Patti Williams, University of Pennsylvania, USA*  
**Paper #1: Identity Threats, Compensatory Consumption and Working Memory Capacity: When and Why Feeling Threatened Leads to Heightened Evaluations of Identity-Relevant Products**  
*Nicole Verrochi Coleman, University of Pittsburgh, USA*  
*Patti Williams, University of Pennsylvania, USA*  
*Andrea C. Morales, Arizona State University, USA*  
**Paper #2: The Interdependent Self: High Identity Holism Facilitates Fluid Compensation**  
*Qin Wang, Arizona State University, USA*  
*Monika Lisjak, Arizona State University, USA*  
*Naomi Mandel, Arizona State University, USA*  
**Paper #3: Embracing Experiential over Material Consumption as a Compensatory Response: Thinking about Death Increases Consumer Preferences for Experiences**  
*Yoonji Shim, University of British Columbia, Canada*  
*Katherine White, University of British Columbia, Canada*  
**Paper #4: Tough Crowd! How Observers Influence Compensatory Consumption**  
*Monika Lisjak, Arizona State University, USA*  
*Soo Kim, Cornell University, USA*  
*Sean Blair, Georgetown University, USA*  
*Derek Rucker, Northwestern University, USA*

**Palates, Portions, and Plates:**

**Contextual Cues Shaping Consumers' Food Intake and Enjoyment . . . . . 80**

*Chairs: Nitika Garg, UNSW Sydney, Australia*

*Rhonda Hadi, University of Oxford, UK*

**Paper #1: Don't Stop! Partitioning Increases Satiation to Food**

*Cammy Crolie, University of Oxford, UK*

*Yang Yang, University of Florida, USA*

*Yangjie Gu, HEC Paris, France*

**Paper #2: Snack Portion Size Choice, Expectations and Actual Experiences in Children: The Interplay of Healthiness, Hunger, and Sensory Food Imagery**

*Pierre Chandon, INSEAD, France*

*Celia Hacheffa, Systeme U, France*

*Yann Cornil, University of British Columbia, Canada*

*Sophie Nicklaus, Centre des Sciences du Goût et de l'Alimentation, AgroSup Dijon, CNRS, INRA, Université Bourgogne Franche-Comté, France*

*Camille Schwartz, Centre des Sciences du Goût et de l'Alimentation, AgroSup Dijon, CNRS, INRA, Université Bourgogne Franche-Comté, France*

*Christine Lange, Centre des Sciences du Goût et de l'Alimentation, AgroSup Dijon, CNRS, INRA, Université Bourgogne Franche-Comté, France*

**Paper #3: More Than Meets the Eye: The Influence of Tableware Aesthetics on Food Consumption**

*Chi Pham, UNSW Sydney, Australia*

*Nitika Garg, UNSW Sydney, Australia*

**Paper #4: Flavor Fatigue: How Cognitive Depletion Reduces Enjoyment of Complex Flavors**

*Rhonda Hadi, University of Oxford, UK*

*Dan Rubin, St. John's University, USA*

*Diogo Hildebrand, Baruch College, CUNY, USA*

*Thomas Kramer, University of California, Riverside, USA*

**Uncovering Empirical Generalizations in Consumer Research:**

**Creating New and Synthesizing Accumulated Knowledge . . . . . 86**

*Chair: Mansur Khamitov, Nanyang Business School, Nanyang Technological University, Singapore*

**Paper #1: How Well Do Consumer-Brand Relationships Drive Customer Brand Loyalty? Generalizations from a Meta-Analysis of Brand Relationship Elasticities**

*Mansur Khamitov, Nanyang Business School, Nanyang Technological University, Singapore*

*Xin Wang, Ivey Business School, Western University, Canada*

*Matthew Thomson, Ivey Business School, Western University, Canada*

**Paper #2: Is Congruity Desirable for Brand Extensions? A Conceptual and Meta-Analytic Review**

*Qian Deng, University of Prince Edward Island, Canada*

*Paul Richard Messinger, University of Alberta, Canada*

**Paper #3: The Experiential Advantage: A Meta-Analysis**

*Evan Weingarten, University of California, San Diego, USA*

*Joe Goodman, Ohio State University, USA*

**Paper #4: Using a Meta-Analysis to Unravel Relative Importance of Postulated Explanations for the Endowment Effect**

*Peter Nguyen, Ivey Business School, Western University, Canada*

*Xin Wang, Ivey Business School, Western University, Canada*

*David J. Curry, Lindner College of Business, University of Cincinnati, USA*

# 2018 ACR Presidential Address

## True Story

Stacy Wood, North Carolina State University, USA

So, beloved. Some of you I've never met and some of you are the most important people in my life. I can't tell you how much this organization has meant to me over the course of my career and how much it's given me in my life. But let me try.

I want to tell you a story today and it's a *true* story. I know because I was there. And this story's gotta have a soundtrack because there's always a song playing in my head. And so, while I was putting the slides for this talk together, I thought I'd put some of the lyrics on the slides. I won't mention them. They're very random. I'm a 45-year-old woman from North Florida, so they're not in particularly good taste. It's not like you're going to be impressed with my musical breadth. That's ok.

Now I believe in how the stories we tell shape the culture we have. I hope that some part of my story resonates with you today. I was shocked to be elected president of ACR. I mean *really* surprised. I was shocked and *then* I realized... about half a breath later... that I would have to give this talk! Drive this large automobile! Impossible! I put it off as an unbelievable thing.

But about two weeks later, my husband and I went on a weekend trip to D.C. The first thing that we did was to go see the MLK Memorial, which I had not seen before. If you've been there, you know the power of the place. Because there is the man... with the mountain that he moved. In stone. Larger than life. But the really impressive thing is that surrounding him are all the *words*. All the things he said that we remember. I wandered through and I read the words and I thought about them and I was silent and I maybe cried a little bit, but that's no shame in that. After that Carl and I wandered over to the Lincoln Memorial, which I had seen before, but this time I read the wall that no one ever reads. I was the only person in the large crowd over at the wall on the right, which is Lincoln's *second* inaugural address. It only took him six minutes to deliver! Lincoln! Who was not known for his brevity! A six minutes speech. And yet in that speech are some of the words that resonate through our history. Ah, I was just blown away by the stark truthfulness of it! The honest lovingness of it. Pulling no punches. To say things the way they are...yet always with hope and charity and malice toward none.

Okay, keep in mind MLK Jr., Lincoln, and *then*... that night we went to a U2 concert! So now I'm listening to Bono! Oh, come on! All the songs that inspire...Okay, it wasn't the younger Bono in this picture, but he's still cool. He's still awesome. And his words still resonate. As we're driving home at midnight in the D.C. traffic (as an aside, I do wonder at a place that has traffic at midnight) Carl and I are talking about the power of words and how we've been just *washed* with words all day and just the amazingness of it all. And I said "Gosh, I wish I used words that way, I wish I had a forum. Should I get a Twitter thing?" And Carl said no. Then he said, "But aren't you giving the big speech at ACR?" Oh, yeah, I am. And I got a little nervous.

So, I spent the rest of the year thinking about ACR and what I could say to you that might have impact. I thinking a lot about what I loved about ACR *and* what I *didn't* love about ACR. Both what we are and what we can be. And you might say to yourself, "Okay, who are you, Stacy Wood, to be telling us who we can be?" I am not a professor at a top-10 school, not even a top-50 school. I am not a journal editor. I was an AE once, but haven't been for a long time. And I'm

just *not* the illustrious legend of our field that you might want to take advice from. I am surprisingly old, this being my 24th ACR. I used to be teased for being too young! But I'm not done either. I'm about halfway through my career. I'm going to work until I'm 85. Just be prepared. Someday I'll be the one standing at lunch in that more than 40-year group that Rajiv announces. So, I'm young, but I'm not that young. I have the experience to know what I know. This is important because what I will tell you today is an *intervention*...of sorts.

I see ACR at something of a crossroads. We are this amazing collection of people. But we've gotten larger and larger, and we've wondered what's the meaning of that? And we've seen groups fracture and spin off, sometimes staying within the umbrella of ACR, sometimes going off. And it seems like there's a lot of passion and energy in those smaller groups. So, then, what is the purpose of our larger collection of being? Why should we all come together? I get it.

And yet, every time I hear someone say they're not going to ACR this year, it hurts because *I'm* coming. The only time I didn't come was when I had a baby...and I actually registered for that conference! Even though the conference was two weeks after my due date! It took Gavan Fitzsimons tell me "That is crazy." And, as it turned out, he was right and I couldn't come. But think about ACR. It's where we *meet*... where we meet *diversely* to consider our many perspectives and approaches. That matters.

The other thing that I've seen recently that's really surprised me is (now that I'm invited occasionally to speak at the Doctor Consortium) how *stressed out* our doctoral students and our rookie professors are. I mean, *really* stressed out. I remember being stressed out in my early days, but this still worries me. I see a rise in cynicism. People think that publishing is just a game. They call it a reviewer roulette. You know, I just have to check the boxes, jump through the hoops. It's like it's some kind of Academic American Gladiators to get through to the publishing finish line. And then we have this whole *other* issue that is plaguing us (and other fields) of data integrity and the replication crisis. What trust have we in other people's work? And what trust have we in our own work? Then, as if that weren't enough, we're plagued by the very *label* of marketing. I gave a talk a couple weeks ago to a bunch of surgeons, and at the end of my talk, one particularly well-read surgeon said, "This marketing idea is interesting, but I don't really understand how this is any different from behavioral economics." Whew! I said, "Oh, buddy, you don't even know what you just said!" We were first. We need to use the term marketing proudly...but, in truth, I don't know that I always have. And, *finally*, I worry that some of our bright minds feel shut out and feel shut down. And if you look around, I mean honestly, *look around*. Look at the people around you. Look how smart they are. Look how cool they are. Look how awesome they are. We should not waste the brain power in this room. That would be truly awful.

So, I want to start with what I think is the first problem that we face. And I'm borrowing this from Chimamanda Aditi, who talks about the danger of the Single Story. The danger of the Single Story is the idea that sometimes when you tell one story over and over again, you create a stereotype that de-legitimizes—actually *blocks*—other stories and other paths. Chimamanda Aditi grew up in Nigeria, and when she went to the U.S. for college, she met her American

## 2 / True Story

roommate. Her American roommate said, “You’re from Nigeria. How cool! I’d love to listen to some of your favorite music.” So, she said okay and she pulled out her CD of Mariah Carey! Her roommate was stunned and said, “Oh, I thought you were going to give me some kind of tribal music!” Aditi was surprised even though it wasn’t that that kind of music doesn’t exist. But she realized that people in the U.S. only heard *one* story about living in Africa, and so they didn’t realize that there were *many* stories about living in Africa. We do the same thing with ACR. In some ways, we have created an invisible hegemony whereby we have one clear path of success. One day somebody’s a doctoral student, and then someday that somebody’s a “legend,” getting the big award. And in the 10 years in the middle of that time is promotion at a top school and being on ERBs and research awards. But I think that that’s just *one* story of success in our field. I think there are really *many* stories.

What I’d like to do today is to tell you my story, because my story is *not* the stereotypical story of success. It’s a bit of a roller coaster, frankly. There have been times where I have thought “I can’t even believe how lucky I am to have this job! I can’t even believe that they pay me to do this!” (And I don’t want you to tell my dean that because I always ask for raises too.) But I couldn’t believe I’d be so lucky. But, then, there have been other times where I’ve really thought about dropping out...either to go work for oodles of money in industry, or to be a beach-bum on Sanibel Island in Florida. Rollercoaster.

You have to know that my story started with these two unbelievably amazing people. My parents, Wade Wood and Marcia Vandervliet. Look at how adorable they are! Have you ever seen cuter people in your life? They don’t just look good. Their goodness is all the way through. They met at Hope College--appropriately named--in Michigan. My mom grew up in a very conservative Dutch family—one that didn’t believe in women working outside the house. She was actually disowned by her family when she left to go to college. My father was the first to go to college in his blue-collar Michigan family. They have had an incredible life together. My mom became a nurse. She wanted to be a doctor, but her two options were a nurse or a teacher. My dad became an engineer. And the thing about my parents that has privileged my whole life is that they had a wider perspective than their upbringing. They traveled the world. Their belated honeymoon was to Japan. (You can see by these photos that they spent a lot of time taking pictures of each other looking fantastic.) They had friends of every race and nationality. When my dad hired lawyers or accountants, he always hired female lawyers and accountants with the understanding that, at some point, they would go out to lunch with my sister and me and tell us about their jobs. I didn’t really understand that sexism existed until I was about 11 or 12 because my dad had made me think that there was no difference. There was no difference to him. Now they’re still unbelievable people and kind of hard to live up to. They’re larger than life. Here’s my mom—in this photo, she’s on a “girl’s trip” to camp in the desert that lies between India and Pakistan. Here’s my dad last year, running a half-marathon that involves a bridge at both the beginning and the end of it. He is 76. Sometimes people say to me, “Oh, you’ve done very well for yourself.” I say “You should meet my parents! They’re amazing!”

They did decide to have kids. So, here’s me as a baby. I don’t know that I was that impressed with the world, at first (as you can see by my constantly suspicious look), but I had a really nice childhood. I had a childhood maybe much like yours. I had a little sister who bugged me and made me play with her when all I want to do was read. My dad used to drive me around his engineering construction site when I was little and point out things to me and tell me what they were. My first word was *dragline*. True story! And this photo...

when I asked my mom what her favorite picture of me was, she gave me this one of me crossing an obstacle course in the red bathing suit because she said she always liked that her girls were stronger than anyone else’s. That’s a little bit of pressure, but it’s okay. We were an American family. Very typical. We drank Tab. We ate burritos. We played board games. And if I look back at my pictures, I see that I actually had a really early interest in science. There were a *lot* of photographs of my science projects. There’s one on doing cultures of common objects. I grew germs. And then how light helps a camera. But when I was looking through all these pictures, I see that there is one overarching theme to my entire life, and that is...that I would rather be reading by myself. And I’m a little frustrated with anybody who interrupts my reading for any purpose. I love all of you. And yet I would give this all up in a heartbeat to go read somewhere quietly with a bag of Doritos.

I emerged from high school with my personality formed for better or worse. Someone once told me that I was a perfect example of my Zodiac sign of Cancer. It was in that kind of embryonic state that I headed off to the great world of Gainesville, Florida. It was a magical place! If you’ve not been, it’s truly wonderful. Some of the old places...Burrito Brothers, Leonardo’s. It was a lot of fun. And in my senior year at Florida, as Rich mentioned yesterday, I finally took a marketing course. But I was a Finance and Russian double-major. I thought kids who took marketing were the slower kids, and so I was not a marketing major. But I *had* to take *one* marketing class to graduate and I put it off to my senior year. And then I took Principles of Marketing taught by Rich Lutz. 800 students! Not all in one big room. There were TV replays of the class! I watched Rich Lutz drill a hole in a textbook--that happened. Every time Rich talked, though, about the “principles” of marketing, he would talk about the *research*. He talked so much about research! And while I sat there as a kid, I thought to myself, that research study is so...*wrong*! That may work with some people, but it surely doesn’t work with other people! Or it may work in one place but doesn’t work in another place! It was so interesting, and I had so many counter-theories and I wanted to go talk to Rich all the time. About that time, I had been talking to an Econ professor who was trying to recruit me into a PhD program in economics. So, I went to Rich’s office and I said to him—and remember I’m one of 800 students. I’m a kid at Florida. The kids there, they’re all dressed in tank tops and boxer short bottoms and flip flops—so I walk in in *my* flip flops and tank top, and I say, “You have a PhD program in marketing here? I might be interested.” How *lovely* that he didn’t laugh at me! How lovely that he asked me, “Why are you interested?” And I said, “I really like the research you’re talking about,” and he talked to me and he took me seriously and he said, “I’ll help you. Here are the steps to apply.” My parents were living in India at the time and (this being before cell-phones) we talked infrequently. At our next monthly call, I said, “Guess what? I entered a PhD program in marketing!” My dad, the engineer, said, “What? Marketing?! I thought you were my smart one!” I’ve always fought to explain marketing to my engineering family.

And so, this photo is me going off to a PhD program. I bought a car with a loan from my parents. It was a Pontiac Firebird. (My mom told me she thought I was going to come back with a Honda Accord. I’m like, “Don’t you know me at all?”) I went off in all my bright glory to Florida. These are the people I ran into. These are the people who taught me marketing. It was awesome, but it was tough love. I was no longer the smartest kid in the room. Not by a long shot. I had to work really hard, it took me a bit to get on. Stijn wanted me to tell you the story about how I almost got kicked out of the program for the “Shimp et al paper” story...which I will tell you at a reception somewhere with a drink in my hand. But I remember going to Chris

Janiszewski's office one day with a list of 25 research ideas. Chris told me these 24 are idiotic, but this last one might have some merit. Go think about it for a while. Off I went to think and I came back an hour later and said OK, I thought about it. He said, "No, Stacy! Think for longer than an hour! Come back next week!" Or the time when I went to play basketball. John Lynch and Americus Reed and Kevin Bradford and some other people had a weekly basketball group. I said I played basketball in high school. I'd like to come play with you. And I went. I played. And I was not great. John looked at me kindly and said, "Come back when you can dribble with both hands." Tough love. No pulling punches.

Now I did have *this* amazing pack of people around me. These were my cohort, my colleagues, people who were a year above, and in my year, and a year below. They're all so smart and they had so many different life experiences. It was *amazing*. I think we all realized at the time that this thing called marketing was amazing, but I know that I personally saw through the glass dimly and I spoke as a child and I reasoned as a child... and I'm afraid that I stressed as a child, too. My whole worry was, "Am I doing good enough? What's good? Am I doing good enough? And does everyone else think I'm doing good? Am I good? Is it good?" It was all a bit tricky. Some people may remember if you knew me back in the day, that a lot of people thought that I didn't drink alcohol as a philosophical thing. But the fact of the matter is that for most of my PhD program, I was on some pretty heavy anti-depressants that didn't mix well with alcohol. I struggled not being the smartest anymore and not knowing if I was good enough. To give you a sense of that, this is a photo of me before I started the PhD program. And that's me after... that was year four. Look at that sad pallid person in the gray sweatshirt on a beach!

Now the thing is, is that it wasn't all bad times. There were wonderful times, great times. One of the most impactful things was that Joe Alba, John Lynch, Bart Weitz, Chris Janiszewski, Rich Lutz and Alan Sawyer let me be on a project with them where we talked about what the future of electronic commerce could mean. If we had just called it the Internet, we would have been superstars. There were these high points. And there were these low points. I wasn't selected to be the doctoral consortium candidate for my school. I felt *very* sad, like my career was over and who would ever love me now? I think that sometimes when we're older we forget that when you're in that place, it seems so important. I did get a job and I went to South Carolina and South Carolina was great. I had a paycheck! That was fantastic! But the hard part was that I was no longer around my loving group of fellow students. We weren't like puppies in a little cozy kennel anymore. I was alone and it was a lonely time. So, I put my head down and I worked hard and I got my dissertation published. That was an awesome, awesome moment. It's only looking back that I look at it and I say, "Here's what I wrote: Remote purchase environments: The influence of return policy leniency on two-stage decision processes." Now, I don't know if that's *that* interesting. Was I the queen of return policies? Did I want to become the queen of return policies? No. I never thought about return policies ever again. I was sick of return policies. I was done with return policies. The paper was in *Journal of Marketing*. Box checked, but to what purpose?

Then life got good because I found my community again. Until then, I only had my once-annual trip to ACR. But then Kristin Diehl and Dave Crockett came to South Carolina. And, man, I hope you have your Kristin Diehl and your Dave Crockett because having some friends at your school who have your back is amazing. We threw *so* many parties. This is a picture from a party we called the Idle Rich Party. This party was called Iron Bartender. We went to horse races, as one does in South Carolina. It was a magical time of togetherness and hard work. Here are some of my papers from

that time. Look. "Prior knowledge and complacency in new product learning"—this is actually a more interesting paper, but again, it's not sold very well. You'd think that maybe I could get some help from somebody in marketing! This paper's even worse: "Psychological indicators of innovation adoption: Cross classifications based on need for cognition and need for change." Again, a really interesting idea completely hidden under a bushel of jargon. But I did get tenure, and suddenly, after tenure, I realized that a lot of my earlier anxiety had been for naught. It hadn't even been that close. I wasn't on a precipice of danger. It was fine. I was doing fine. The work was fine.

And so, things progressed onward for me—a kind of progress. I did my thing and I got involved in as many different ways as I could in the field. And as always, I loved ACR. But I *did* start to get a little bored with my work. I *did* find that I was embarrassed to say that I was a marketing professor. I *did* start to entertain the thought of "Am I wasting my life my whole life on this?" But, you know, other things were going on in my life, my real life, at the same time. I met this guy and married him. He's not just the cute guy you see in this photo. He is very intellectually-oriented and has two master's degrees! We thought about starting a family and things like that. We struggled with infertility, which was a big part of my life for five years. In that time, we moved to North Carolina for Carl's job and I commuted for four years to USC. If you've ever commuted for any long time in your career, you know it's not fun. But it was what it was. And eventually these two came along. Here you see I have a three-year-old, Ariella, and a six-year-old, Amalia. They are the cutest kids *ever born*. They are amazing. I don't know what else to say about them other than that they're so crazy and we're so sleep deprived and so consumed with love for them. However, to keep it real, I do feel like I need to show you two pictures from last week. Last week I let my older daughter Amalia, know that it hurt my feelings for her to call me Poop-butt Stacy. So, she wrote me this apology note. Notice she still addressed me as Poop-butt Stacy in the apology note, but she was trying, I think. And this is the face of my youngest last week, after I spent \$26 to take her to one of those special pumpkin patches where you ride the tractor out into the field to choose your pumpkin. And when my daughter understood that she could only take *one* pumpkin home, it became the Worst Day of Her Life. I wish that tractor ride had been free. Sigh.

So, what am I doing? I'm in North Carolina. I'm doing normal things. I'm a professor. I've got a husband. I've got kids. I've got tenure. Auto-pilot. But, something happened at that point that saved my mental life. And I didn't even write it up on this slide because I'm a little afraid even to say it. It's not on the slide - there'll be no evidence. The thing that saved my life was *teaching*. Teaching! The thing that I had grudgingly agreed to do in order to be allowed to do research. When I moved to North Carolina, NC State had no doctoral program, so I had no more PhD students. That was hard. To try to fill the void, I took MBA students who I thought were really bright, and I taught them how to do academic research. All kinds of academic research—experiments, qualitative, conjoint analysis, you name it. We did all kinds of research and I taught them to do it at a level that could be published academically. But we did it for companies. We'd go into a company and say, "What's the biggest consumer problem you're facing? Something that boggles you and you don't have the bandwidth to address it?" And then we tackle it for them and spend a semester studying it. And what I learned is that companies have really big issues and our theories are pure magic. They almost always work! And these companies were so grateful for the things we did for them! We went to big places, and the executives at these places would say, "That was literally the most insightful presentation I've ever seen." I wasn't making the presentation. My *students*

were. It was them making the presentations, using the theories, (I taught them how to do lit reviews!) and they were amazing and they became advocates for marketing research. And if you want to talk to people who are passionate about consumer behavior, I can introduce you to any number of the alumni from this program who love it. In fact, two of my MBA students formed what they call the Syllabus Club, and what they do is they go online and they get the PhD Consumer Behavior seminar syllabi from the most famous scholars in the world. And then they read the papers together and discuss them over coffee. They started with Jim Bettman's class. Can you even imagine an MBA student like that? They are awesome. The jobs they get, the work they do--they're amazing. And we ended up doing all these really neat presentations where we were like, "No, we don't want just do any old presentation. Let's go to a high-tech creativity room where we make a 360-degree curation—it's like a gallery walk of findings. We will take you on a tour around this room and tell you interesting things!" I just really loved it.

And then Teaching Explosion #2 is that I (for the money!) agreed to teach a seminar at the Duke School of Medicine in a program on clinical informatics. My students were doctors and nurses and hospital administrators. When I walked in and I said that I was teaching them marketing every single one of them expected it to be the worst class ever. But by that point, I'd worked with enough companies to know that what we know in marketing is magic, so that I walked in with all the confidence in the world. And I said, "You are going to *love* marketing." And all of the doctors and nurses and hospital administrators rolled their eyes. Yeah, that was Day 1. By the end of the program, they gave me the teaching award—not because of me, but because of the *material*. Talking to them about the issues that they faced and the impact of patient decision making on healthcare was so enlightening that I felt like I had been given a trampoline. I felt like I could jump anywhere. There are just some things where, if it's working, it's frictionless. I started getting lots of invitations to go talk to hospitals. I started having lots of doctors call me up and say, I'd like to work on a project. I didn't even work hard. I wasn't working hard like I always did before to prove how good I was. It was just happening, and it was happening because of the power of our theories. They *work*. So, this photo is me presenting a grand-rounds lecture at UNC's School of Medicine. The couple of people who had heard me before were excited. Every other doctor in that room thought it was a joke. In fact, they sit by seniority at these presentations and the most senior doctors are in the front row. And as I was waiting there to present, three of the doctors were having a purposefully loud conversation about what a stupid thing it was for them to come hear about the "McDonald's of Medicine" from some marketer. But at the end, they felt differently! Again, not because of me, but because of what we *know*. Our marketing knowledge. I wasn't just talking about my work. I was telling them about *all* of our work and they were amazed. They didn't know that this knowledge is out there.

This has started me on a track and it started me thinking about what makes something interesting and important. I realized that one of the real problems with our stress and our cynicism is that, because we have this one path—this Single-Story bias—we feel pressured to stay on it. And so, what I want to suggest is that there are lots of paths. So many paths! And there are lots of purposes. So many purposes! Don't feel like you can't step onto a different path! And *one* of the ways to study things in a way that you feel like you have purpose is to start with the phenomenon, not the theory. I hesitate to say this. I'm wondering if I'm going to have my Florida PhD revoked. But, I think you should sometimes start with the phenomenon and think later about theory. When we love a theory and then we look

around for something that fits the theory, we tend to smooch circular pegs in the square holes. I think if we're truly curious about a phenomenon, we watch it and we wonder about it—carefully, deeply. We've all been trained to know lots of theories. If we have theoretical knowledge and then we watch a phenomenon, we can see what applies. So, this, to me, feels very revolutionary. I know now that the best work that I'm going to do is *in the future*, not in the past. And I know it because of this personal revolution—in fact, I think that this is not that radical of an idea. William Blake, who I absolutely love, said "he who would do good must do it in minute particulars for art and science *cannot exist* but in minutely organized particulars." I don't want us to be "all applied" and forget about theory. I want our applications to make our theories *better*. I want our scholarship to be better because it's linked to something we care about. I want all our work to be a *labor of love*, and that means that when you first start, you gotta *watch* and *think* and *watch* and *think*. And *then* you gotta talk and listen and talk and listen. For an introvert like me, that is actually kind of daunting. And then, finally, you get to read the literature and then go repeat that process. And *only then* you can even think about doing a study.

And so, in my story, I met a doctor, Kevin Schulman, from Stanford, and we started a project in which we looked at how people chose in end-of-life decision making, especially in heroic efforts at last-ditch treatments in cancer. It started because Kevin was interested—he's in cardiology, but he would talk to his friends who are oncologists and they would describe the epic lengths that people (terminal cancer patients) would go to to try one more thing and one more treatment and one more procedure and then a maybe a clinical trial. Whereas he, as a cardiologist, would often say to people, "You know, we could insert this pacemaker and it would give you a year and better quality of life," and they'd be like, "Nah, I've had a good run." Why *is* that? We talked about the language scheme is surrounding different disease states and how cancer has a schema of heroism about it, right? People are *warriors*. They're fighting a *battle* and if you remember Stuart Scott, the ESPN commentator? When he died from cancer, he said, "Don't say I *lost my battle*." I think that's really telling because that "battling" can make you feel strong in the treatment. And it can help raise money. But suddenly there's a bit of a wicked backlash when you come to deciding about hospice. This is very different in many ways from how we can talk about heart disease. Look at this slide with heart disease messaging. Be aware. Take care. It's interesting how the language impacts us. Kevin and I were talking about this and we're planning our studies...and then this...this is my very wonderful friend, Melayne. She was one of our cohort at USC. An economist, but we didn't hold that against her. She was in the thick of every party. She is also a JCR author. She and I and David Norton published this paper. She was diagnosed with breast cancer, triple negative, and she did *everything*. She *fought hard*. She did it all, and I was driving to see her in Colombia a lot because I was living in North Carolina. She had recently stopped doing a treatment at Vanderbilt, a trial that wasn't working. And as I was driving down, I called her to say, "Just letting you know, I'll be there in about 45 minutes." And she said, "Okay, just letting you know. I called in hospice today." I was like, cool. She said, "They're going to bring in a hospital bed this afternoon." I promised to help set it up. So, I got there and we set up the bed. And we tested it out. And she asked me to proof-read the letters that she had written to her daughter, who was 11. And we talked about what kinds of things she'd want me to say at her service. And at the end of the visit, she said, "Thank you so much for not treating this like it's weird." I said of course it's not weird and she goes, "Yeah, but when I told some other people about hospice, they said don't do it, *keep fighting*."

You're *so strong...*" And she said, "I feel a little guilty." And I said, "Don't." But that's the real cost of a language schema.

That moves us to this third problem, the integrity of our data. I mean, there are lots of problems here. Faulty statistics, over-engineered protocols, dubious incentive systems, messy domains. I think that we all know that there is real dishonesty that happens. But there is also a lot of honest error, and often we only have one method, one methodological hammer, and so we don't triangulate on things. But what I really wonder is, do we believe in our studies that *there's a right answer* or we just trying to show it was a "slam dunk" appropriate for a top journal? And if we *do* believe there's a right answer, do we *care* enough to unearth it? Because if we care enough to unearth it, then we will welcome the criticism! We won't want to put a bad answer out there. We will want to talk to anyone who raises their hand and says I don't know that I agree with what you say. Good, good. Sit down with me, show me what to do. Let's work together. You'll *want* to do lots of studies. You *want* to really be the first to examine your work with a critical eye. Because there's a right answer and it matters that it's out there! You will. You're so smart. And a lot of this involves getting out there in running our own studies and observing what happens. This can be hard! Back to my own story of how my work has taken this epic turn. Dr. Julian Yang from Duke approached me and said, I would like to work with you on crafting the decision environment for families who are having to make a decision about "Do Not Resuscitate" or DNR. Because right now it's completely all over the board, and it's really kind of crazy. And I said, Sure, absolutely. We talked about what happens and it sounds just awful. They often take place late in the afternoon because that's when doctors are free. And they just invite anyone who's in the room to be a part of the discussion, no matter whether it's the random Aunt So-and-So who's traveled in. It's so messy. Starting next month, I am going to be on the clinical team that walks in and observes as doctors have this conversation. For those of you who know me well, you know I really fear of a lot of death oriented things. Flying, driving, trains, crossing the street, snakes, spiders. I am a little freaked out, but I really believe there's a right answer and I'm going to find it, even if it's painful.

And so, for the people who are younger in the audience who say, "Yeah, yeah, we've heard a lot about relevance lately, but then come tenure time, suddenly everyone forgets about relevance. So how am I really incentivized to be relevant? I try to get field data, I try to do these hard things and I do it. What have I done to deserve then the cold shoulder afterwards?" I get it! And so, what I did is this: I wrote a little pledge that says that when writing letters for tenure-and-promotion purposes, I pledge to take a holistic view of scholarly contribution, value engagement with scholars outside our field, reward making an impact in the real world, and credit immersion in a substantive domain. And then I emailed it to every full professor that I could think of who I thought probably got asked to write a lot of tenure letters, and I asked, "Would you sign this pledge and let me put your name up on the screen at this speech?" I have never got such quick, enthusiastic responses. I think there may be like 40 people here on this slide. I think my email box had, like, 150 exclamation marks from those 40 people. Some people said they already did it. Some people said this is important. This is about our world shifting to seeing more paths more purposes, more ways to succeed. Not just one path, not just one story! We, as a field, suffer a little bit from some insecurity. I know I did. I felt like I was "just" marketing. I often felt unimportant; it wasn't like I was curing cancer. We suffer from the inability to translate things. Well, my early papers are unusable by practitioners because practitioners can't read them. And,

at the time, I couldn't translate them. But after teaching my MBA students how to translate them, now I can. Now I have that ability, but it took some training. Think about the people who are good at translation. I think of Dan Ariely's book and look at how successful it was! People love our material! People love it and now so many people in our community are writing books. I think that's awesome. I think this is *important*. The world is excited about the knowledge we have. Americus Reed and Barbara Kahn even have a Sirius XM radio show. I mean, stop it! They're on the radio! That's very cool. I think we've got to become a little more fierce. There's an ad that I know all of you have seen from Nike with Colin Kaepernick and it says, "If people call your dreams crazy... if they don't believe what you think you can do, good! Don't change! Because what the non-believers don't understand is that calling a dream crazy is *not* an insult. It's a compliment. So, don't try to be the fastest runner in your school or in the world, be the fastest *ever*. Don't dream of wearing OBJ's jersey, dream of OBJ wearing *your* jersey. Don't choose between being a homecoming queen or a linebacker. Be both! Don't think that you have to be *like* anybody to *be* somebody. If you're born a refugee, don't let it stop you from playing for the national team...at age 16. Don't just become the best basketball player on the planet. Be *bigger* than basketball. If you only have one hand, don't just watch football, but play it at the highest levels. And if you're a girl from Compton, don't just become a tennis player. Become *the greatest athlete ever*. Don't ask if your dreams are crazy. Ask if they're *crazy enough*."

Why do we think that these words are just about *sports*? Why do we think that this is just about athletics? This is our life. We are so talented. *Let's be crazy*. And, so, I have crazy things to do and I don't know how they will work out. But I'm going to go do them. I know that you can do them, too, because we have each other. This is an amazing community. Marketing is literally special because... We like each other. We have fun together. We get together with excitement and passion. They are not just professional relationships. They are friendships. People will lift you up and do it for years and years. I asked Tiffany White if she had any pictures of us in the early days. Tiffany White and I met 24 years ago at ACR in Phoenix...in a hot tub...and Tiffany had the picture. There we are, and here we are 24 years later. But 24 years is not impressive. When you've got 45 years together, you can be the same wild and crazy guys together 45 years later. We do things outside of academics, even athletic things. We attend each other's special moments. We introduce our little ones to their academic grandparents...or they're not just grandchildren. Sometimes they're grand-dogs. (There's no shame in that, David Norton!) But we're there together. We're together. We're *together*. We're always together, making fun of each other sometimes, but always together for the big things, for times when we're just looking super glamorous, times when we visit buildings with columns, eating, drinking, wearing shark hats...but always together. And every year we're excited to see one another. We need to do more than that, though. We need to not only be together, we need to not only socialize, but we need to talk to one another about the things we're doing that we're excited about---whether they're traditional academic stuff, applied academic stuff, teaching academic stuff... I don't care. We need to talk to one another and tell one another what we're doing. We can always play, and I'm sure we will. We're quite good at it! And, so, I have high hopes for us, and I want to take this opportunity to thank all of you who have been a part of my story. It's been wonderful and I love that it's not over. There are a lot of big issues in the world, and it's amazing to know that our knowledge can help every one of them. So, what is the *end* of the story? I don't know. But I do know that everyone lived Happily. Ever. After. *Thank you*.

## 2018 ACR Fellow Addresses

### Kids Say the Darndest Things: Insights from Children's Consumer Research

Deborah Roedder John, University of Minnesota, USA

When I was a young girl, one of the most popular TV shows was called "Kids Say the Darndest Things." The show was hosted by Art Linkletter, who interviewed young children asking them for their views on a variety of topics, such as marriage, family, jobs, and the like. Apart from being cute, and quite funny at times, children's answers often provided an interesting perspective on life. Here's a sampling of children's answers to the question of what they want to be when they grow up (Linkletter 2005):

*"I'd like to be six. I'm tired of being five. I've been five for a whole year."*

*"I want to be a nurse and have all ladies for patients. [Why not men?] Because they complain too much."*

*"Nothing, because I don't want to grow up. [Why?] Because of the bills you have to pay at the end of the month."*

I hadn't thought about this TV show for years, until I started working on this address and began to think about how I could provide a perspective on my career conducting research with children. At first, I thought about the array of topics I've examined—such as children's responses to advertising, developing decision-making abilities, and interactions with brands. Then, I thought about the different theories and empirical findings these investigations produced. But, in the end, what I remember most are my experiences interviewing children, and how they really did say some of the unusual, funniest, and "darndest" things.

And so, with my allotted time, I'm going to tell a few stories about my experiences with children that I still remember to this day—and how they raise questions that go beyond children's research to how we conduct consumer research with any subject population.

#### SETTING THE STAGE

Very few people listening to this address have conducted research with children. Yet, many of you are parents, aunts, uncles, or grandparents who interact with children. Can you imagine what it would be like to conduct a research study with children? When you've conducted studies, I'm guessing that none of you has had the following happen:

- After introducing yourself and explaining you are from a local school, your participant says: "Aren't you kind of old to still be in school?"
- One of your participants doesn't show up, and you get the following explanation: "Steven won't be doing the study today. He's in the principal's office for shoving another boy into a hall locker."
- At the end of the study, you ask a participant if they have any questions for you, and one of them asks "Do you really get paid for doing this?"

Welcome to my world. Here are some of the challenges that await if you want to conduct research with children. It's a world where you can't just give surveys to participants to fill out because many of them can't read. It's a world where a participant's response to a question about why they feel a certain way or chose a certain

option often consists of one word: "Because." It's a world where you can't ask participants to write down their thoughts because...well, they don't know how to write yet or it's too hard to try to explain what a "thought" is to them.

Due to these challenges, most of my research with children has been conducted via one-on-one interviews, with research procedures and tasks specially designed for the age group being studied. Because there is a need to interact closely with your research participants, you have opportunities to observe more than just the answers to your specific research questions. You have an opportunity to see if they struggle, are excited, or interested in your research. You have the opportunity to see how they interact with your research task and materials. And, quite often, you have the opportunity to hear things you never anticipated, which leads me to my first story.

#### STORY #1: RESEARCH ENGAGEMENT

I conducted my first research project with children while I was a doctoral student. Although I had never conducted research with children, I felt relatively confident about running the study because I had conducted numerous studies while working in a marketing research firm prior to beginning my doctoral program.

And, the study seemed easy enough. The objective of the study to examine whether advertising was more persuasive in shaping product choices for younger versus older children (Roedder, Sternthal, and Calder 1983). We showed 4<sup>th</sup> and 8<sup>th</sup> graders an ad for a new product, and then asked them questions about their attitude toward the new product, and asked them to make a choice between the new product versus more established and preferred products. We also included questions about their comprehension of the ad, attitudes toward characters in the ad, overall attitude toward the ad, and preferences in the product category. Nothing extraordinary here for an advertising study.

But, since it involved school-aged children, I did use a different type of response scale for the questions. I selected a smiley face scale, which is often used with children in commercial research contexts. The scale points were variations on a smile and a frown, with a neutral face as the midpoint. I figured answering questions with the smiley face scale would be more interesting and fun, in addition to being easier to understand for children of all ages. The resulting survey was 8 pages long, with four questions and smiley face scales on a page.

When I conducted the study at local schools, it seemed to go well. I ended up having to read the survey, one question at a time, to 4<sup>th</sup> graders because a small number had reading difficulties. But, apart from this unexpected development, I didn't see any red flags. Most of the participants seemed excited as they entered the interviewing room, and loved the idea that they were going to watch something on TV. After seeing the ad, they dutifully marked a smiley face for each question, and were delighted to hear about the gift bag they would receive at the end of the day for helping with the study.

Toward the end of the first day of data collection, I decided to ask a few of the children how they liked participating in the study. The first couple of responses were "OK" or "good." Then, one of the 4<sup>th</sup> grade boys piped up and said: "It was worse than school." I knew

the list of things worse than school was probably pretty short for an 8 or 9 year-old boy....so, this was something to pay attention to.

The next day, when the study resumed, I spent time observing the children....looking for evidence that they were getting tired, bored, or generally less enthusiastic as they filled out the surveys. I did see several children who looked less engaged as they flipped through the survey. I remember one boy who swiped his hand across his forehead, with a motion that indicated he thought it was hard work. Some of the children were losing their focus as the study wore on; they started looking around and seemed less interested. Gee... maybe filling out a survey wasn't as much fun as I thought, even though it had a bunch of smiley faces all over it!

Although the research project was a success, I could see that I was going to need a different approach to do research with children. I was interested in working with much younger children in my subsequent research, and wanted to be able to capture why children of different ages responded in different ways. For children, it seemed that the quality of the data collected, and inferences I could draw, depended on developing research procedures that would be engaging to children. I reasoned that when children were more engaged, they would be more likely to be involved in the questions I would pose, and would be more interested in communicating their thoughts to me. I started developing more interesting tasks, games, and stimuli for my research, specifically meant to engage children.

This story raises a question for all of us, regardless of whether we are conducting research with children or adults: Should we place more importance on designing research that engages our participants? My sense is that really engaging participants in our research tasks is seldom top of mind when we are designing studies, and I wonder if it should be more of a priority. In my experience, it is more difficult to design and implement research with this objective in mind. We need to create our own research protocols and tasks, and we may need to conduct this research in person instead of online. In other words, there could be costs to designing research with participant engagement in mind.

What are the possible consequences of not increasing engagement among our participants? One possible consequence is that our participants pay less attention and are less interested in responding to our queries. The percentage of research participants who cannot answer simple comprehension checks at the end of a study seems to be rising, whether the study is conducted in a lab or online. Sometimes, a significant number of participants can't answer a simple question about something they read or something they did during the study. Of course, there have always been a few slackers in our studies. But, I'm *not* talking about a few people....I'm talking about 10%, 15%, 20%, or more of research participants who didn't pay enough attention to answer a simple comprehension check.

Well, you say, we can just increase the sample size to account for the participants who don't pay attention. Fair enough. But, consider the idea that lower levels of involvement may affect the very nature of our results. Do unengaged participants think and act differently? We know that people with a low level of involvement pay attention to and process more peripheral information, and less central information, than people with a higher level of involvement (Petty and Cacioppo 1981). By extension, perhaps low involvement participants are particularly influenced by seemingly peripheral cues in our studies, including subtle manipulations that would appear inconsequential on the surface. On a related note, perhaps subtle primes have more influence with less involved subjects, who use these cues as heuristics rather than more deeply processing or considering other information. I don't think we know the answers to these questions

about engagement, but I would argue that it is definitely worth our consideration.

## STORY #2: THE VALUE OF DISCOVERY

I had the opportunity to put my newly learned lesson about designing more engaging research as I began a new stream of research on children's decision making. The major question addressed here was whether children were adaptive decision makers, and at what age they begin to exhibit this ability. To begin, I decided to focus on children's abilities to make trade-offs between search costs and search benefits when making a choice (Gregan-Paxton and John 1995).

The standard approach for studying these types of questions with adults was to give them a matrix of information, with columns labeled with the names of different products/brands and rows labeled with attributes of these products. The attribute information for each product would be covered so it could not be seen until the participant asked to uncover it. By observing how participants chose to uncover the attribute information, inferences could be made about the way in which they searched for information. Search costs could also be introduced to observe how search patterns varied when searching for information prior to making a choice was not costless.

Clearly, this research methodology could not be used for young children who couldn't read yet. Further, the idea of decomposing a product into individual attributes, some of which were abstract in nature, would be foreign to the youngest participants in the study. So, a different experimental approach was called for....which resulted in developing a game that we called "House of Prizes."

In this game, children were shown two houses made out of a cardboard box. We cut out four windows on each house and covered them with a cloth curtain to hide what was in each window. Behind each curtain was a small prize, such as a colorful ball. Children were told that they could pick one of the houses, and they would receive all the prizes behind the windows for that house. To manipulate low search benefits, half of the children were told that the same prize was behind each window of a house; thus, there was little to be gained once one of the windows was opened for each house. To manipulate high search benefits, the remaining children were told a different prize was behind each window; thus, there was a lot to be gained by opening each of the four windows of each house before making a choice. To vary search costs, children were given several pieces of candy. For the high search cost condition, children had to give up one piece of candy for each window they wanted to open. For the low search cost condition, children were allowed to open as many windows as they wished, without having to give up any of their candy.

By observing the choices children made to open windows in the houses, we were able to observe how children adapted their search behavior according to the level of search benefits and search costs. The findings were consistent with our predictions for the younger (4-5 years old) versus older children (6-7 years old). There was evidence that the youngest children in the study had emerging abilities to adapt to search costs, but the older children in the study seemed to more readily adapt to both search costs and search benefits. In other words, the older children were more strategic in their search behavior, reducing the number of windows opened when the benefits of search were low *and* search costs were high.

However, something interesting happened that we didn't expect. After the first day of data collection, we noticed an interesting search pattern in the high search benefits condition, where there were four different prizes in each house. A few children opened three or four windows in one of the houses, and then chose the other house

as the one they would receive prizes from. This seemed like a potentially sophisticated way to play the game—find out what prizes are one house, and if you don't really like any of them, pick the other house. To confirm our suspicions, we decided to ask children who exhibited this search pattern about it the next day.

Sure enough, one of the first children we interviewed that day opened all four windows of one house, and then picked the other house. When we asked them why they picked the other house, they said: "I want to be surprised!" We heard the same thing from a couple of other children. Hmm...how puzzling. Isn't the whole idea of searching for information to reduce uncertainty and be able to choose an option closer to our preferences? Why would you want to choose something that you don't know anything about at all? The more we thought about, though, the more it made sense. Surprises are good things when you're a young child—a surprise birthday gift, a surprise trip to get ice cream, or a surprise gift from Santa Claus. Some of the children were simply trying to create a situation where they could have a surprise.

This story raises a question about the role of surprising findings in our research: Should we place more value on the process of discovery in our research? Of course, no one really wants bad surprises—manipulations that fail, participants that don't show up or pay attention, or inexplicable patterns of findings. But, what about good or interesting surprises? Perhaps this is more a question for experimental research given that qualitative research is often focused on the process of discovery. However, regardless of the type of research, should we embrace and communicate surprising empirical findings in our articles and other writings? I would argue that, although most experimental research is rightly focused on findings that relate to our predictions, there is a role for reporting surprising findings that could spark additional research and lead us down interesting pathways for future research.

Take the idea of surprise as a motivation for consumer choice, which was a discovery we made while researching children's decision making. Consider for a moment the idea that this motivation may also exist in adults, but we just haven't explored it as an aspect of consumer choice. I would suggest that there is some evidence to this effect. Consider the popularity of subscription services, such as Birchbox, where subscribers receive small samples of different brands of makeup several times a year. Although marketed on the basis of being able to sample new products, I believe part of the appeal is that each shipment offers a surprise for the consumer. Instead of the tedious process of searching through cosmetic displays in stores or searching through volumes of available cosmetics on online sites such as Sephora, a Birchbox subscriber experiences a surprising collection of new and different cosmetics with every shipment that arrives at their door.

The role of surprise in consumer choice also seems to be alive and well in the travel industry. Firms such as Magical Mystery Tours and Pack Up + Go offer vacation packages to consumers where the destination is a total surprise. You arrive at the airport with your baggage and no idea of where you are going. You only have a sealed letter from the travel agency, which you cannot open until you receive an email from your travel agent with the subject heading "Open Your Envelope!" Only then is your travel destination revealed (Kronsberg 2018).

I'm definitely not in the target market for this experience. I get anxious when my plane takes off 5 minutes late. But, apparently, a significant number of consumers have tired of doing research to pick their destination, checking Trip Advisor for the right hotel, and reading travel guides to plan their tours and activities. Maybe it's all too

tiresome, and what we want is to be surprised every once in a while. Sounds like something worthy of further investigation!

### STORY #3: SHOW ME THE MONEY

My final story is about a research project I conducted to understand whether children could be encouraged to drink more milk if we added new varieties of milk (such as fruit-flavored milk) to the assortment available in stores (John and Lakshmi-Ratan 1992). One school of thought was that adding new varieties would not change the consumption of milk—children would choose to drink the same amount of milk, but would substitute an existing variety (e.g., 2% milk) for any new variety (e.g., peach milk). A different school of thought, and our prediction, was that adding new varieties of milk would increase milk consumption for younger but not older children. Our prediction was based on the idea that younger children haven't yet established strong categorization schemes for products, and would see new varieties of milk as something new to drink, as opposed to seeing it as just another variety of milk.

For this study, we conducted interviews with children from 4 to 12. We showed children a product display of different varieties of milk and different varieties of juice, and asked them to allocate 16 coins of play money to the beverages they would want to drink. Essentially, this was a constant sum allocation task that was designed to make it understandable to young children. Our participants were asked to make their choices using the coins, and were then given gift bags for their participation. Their parents received a cash incentive, as is common in commercial marketing research contexts.

I was waiting near the door of our interview space, talking to one of the parents, when her adolescent son walked up, having completed the study. I thought it would be the perfect time to thank him for his participation, letting him know that he played an important role in our research project. He looked at me, nodded his head, and said: "Hey lady, we're just here for the money."

This story raises a question about monetary incentives in our research: What role do monetary incentives play in our research findings? If people see their participation as a form of work for hire, does that change the way they respond to our questions? Many of us rely on MTurk workers to collect data. Note that they are called workers, not consumers. They give us data in exchange for money. Like all employees, they sometimes complain about the amount of money they are paid or how quickly they are paid.

I wonder if monetary compensation changes the mindset of our participants. Maybe they respond more to our research as workers, not consumers. When I worked in marketing research, we would recruit people for focus groups and surveys by telling them that their opinions were important and would provide important input to the company making decisions about the products. Sometimes, we even mentioned that their opinions would help decide if a product would be produced and sold, or what varieties of the product would be offered. Of course, we also offered a monetary incentive, but the idea was that we wanted them to feel that their participation was important and based on something other than just money. I'm not entirely sure who cooked up this protocol, but it did seem like a good thing to remind participants that we thought of them first as consumers, who had opinions we valued.

I do think it's worthwhile to engage participants in a way that puts them in the mindset of a consumer, not a worker....whether it's an undergraduate student or an MTurk worker. Perhaps it goes back to my first story about engaging participants in our research, and eliciting the mindset of a consumer, not an employee. On occasion, I think we tend to forget about the person staring at a computer screen who is participating in our research. We need to figure out how to

engage our participants as consumers we want to hear from....even if they originally decide to participate for the money.

### **IN CLOSING**

In closing, I would like to thank all the little people that made my research possible. In my case, I'm actually talking about little people.....over 5,000 children and teens who participated in my studies throughout my career. They answered questions, played games, and tried their best to be engaged in the research studies we brought to their schools, day care centers, and community centers.

I would also like to thank all the big people, or adults, that made my research possible. I'm grateful to a wonderful set of co-authors, doctoral students, and colleagues that contributed to my work with children as well as adults. It really wouldn't have happened without you!

# 2018 ACR Fellow Address

## Tribute: Thank You Consumer Research and Marketing!

Punam A. Keller, Dartmouth College, USA

### PREFACE

I prepared this talk two weeks after my mom passed away. A kind colleague who did not know my mom told me my mom must be proud of me. I was taken aback because my mom would never say anything like that to me or any of her children. We all did very different things, and for her to say she was proud on any one occasion might imply she was not proud on other occasions. So her response was always the same—did you like it, did it make you happy? In that spirit of unconditional acceptance and love that my mom gave me, I want to share with you what I like doing and what makes me happy. I do this with the hope that you will continue to find what you like to do, and what makes you happy.

### 1. The role of marketing and consumer research in society

I love being an ambassador for consumer and marketing research. Increasingly, it is important to market how we create consumer and marketing research, and to communicate its value. Business in general, and marketing and finance in particular, is often blamed for lowering well-being by placing profit before people. Advertising and branding are seen as the root causes of a materialistic society, the hallmarks of which are unhappiness and debt. Lack of financial security is blamed on Wall Street greed. And increasingly, consumers are blaming companies for their poor health and rising health care costs. For example, consumers believe advertising encourages people to eat less healthy food and that food companies should provide healthier alternatives. Along the same lines, businesses are blamed for their “take-make-waste” approach toward the environment. There is diminishing trust that businesses will do the right thing, which leads to intense regulatory, political, and public scrutiny of a broad range of commercial activities.

Consumer research has taken a back seat when it comes to solving important consumer problems. Behavioral economics (BE) is frequently touted as offering simple solutions to everyone’s decision-making challenges. BE researchers espouse that policy-makers, managers—indeed anyone—who makes a decision can improve their outcomes by simply being aware of the biases that affect their decisions. Although there is clearly value in recognizing potential decision-making biases that may exist, we continue to put more faith in the concept of BE than in the theoretical underpinnings of biases and the practical guidelines for BE, which are based on rigorous scientific evidence about what really works in the field. To the best of my knowledge, there are no conceptual guidelines on how to use BE to get consumer buy-in.

My Fellows address will connect a much needed conceptual model with empirical support for leveraging the use of marketing and consumer theory to change consumer well-being behavior. Specifically, I demonstrate how we can use deeper consumer insights to enhance consumer empathy and engagement to help consumers achieve their goals.

### 2. A modified Segmentation, Targeting, and Positioning Framework

I’m going to make a bold claim: we cannot change behavior without insights from both marketing research *and* consumer research. Why? Because marketing gives us a behavior change process, while consumer research gives us the theory to help create a robust intervention. There are three reasons for this dichotomy. First, consumer research provides insights on why people are persuaded, and this is a necessary but not a sufficient condition for how to persuade people. Second, we are all familiar with the factors that lead to inconsistencies in attitudes and behavior; the main factor is the impact of contextual factors on behavior. I am being more extreme here than necessary, but I predict that, compared to consumer researchers, marketers who are focused on behavior change are more sensitive to context effects. Third, similar to the why and how of persuasion, consumer research theory is a necessary but not a sufficient condition to help consumers attain their own goals. Marketers are more likely to research consumer goals. Although it is not always evident how theory and application are connected in consumer and marketing research, I am happiest when the link is a goal of the investigation. The figure below describes a four-step process for integrating consumer insights and a marketing process for effective social behavior change.

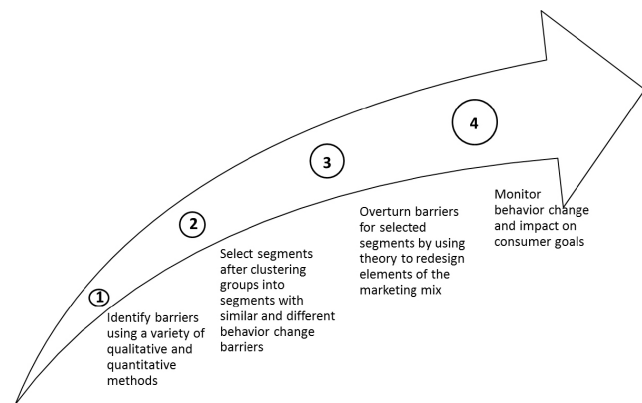

Figure1: Process for designing effective behavior change interventions

#### Consumer barrier segments

despite their avowed consumer centricity, consumer researchers rarely address the challenges their consumers grapple with when making a decision. By contrast, social marketers focus on compliance barriers because the default is status quo behavior. I study avoidant behaviors in the health and wealth domains. So instead of creating benefit segments, I create segments of consumers with similar compliance barriers.<sup>1</sup> I use a variety of qualitative and quantitative methods to identify barriers—I have learned how to be an observer, do in-depth and motivation interviewing, and run focus groups, in addition to taking surveys and gathering secondary data. After clustering barriers, I identify consumer characteristics to help identify segments.

Then I use theory to identify key mediators with corresponding interventions to change behavior. I love attending ACR sessions on

many topics to collect theoretical mediators that influence decision-making. I enjoy sharing consumer research insights with researchers from other disciplines. For example, in a recent project on tailoring medical services, I included a subject expert (in this case a primary care physician), an artificial intelligence expert (because we are using data to learn about consumers' future preferences based on their current consumption habits), a psychologist who is an expert on habit formation, and a health economist who understands electronic health records and health data sources.

Finally, I measure behavior change. As a social marketer, successful behavior change is measured by enabling consumers to achieve their goals.<sup>2</sup>

I would like to share three projects with you to demonstrate this process. In the interest of time, I am going to skip the second step which essentially uses cluster analyses to form barrier segments. Instead I will focus on steps 1, 3 and 4.

### **CASE 1: HOW CONSUMER RESEARCH AND MARKETING WERE USED TO INCREASE ENROLLMENTS AND PARTICIPATION LEVELS IN RETIREMENT SAVING PROGRAMS.**

#### **Background**

My first case is about saving money for retirement. Around half of American households have no retirement accounts at all. No 401(k)s, no IRAs, nothing. You might think that's because they're all expecting pension income in retirement. In fact, according to the Government Accountability Office (GAO), around 29% of households age 55 and older have neither retirement savings nor a pension.<sup>3</sup>

#### **Identify Barriers**

The default setting for retirement saving programs is automatic enrollment because there are too many compliance barriers (such as income, financial literacy, status quo bias, among others) to do the opposite.<sup>4</sup> As a consumer researcher, I and my co-authors hit the pause button and asked if there was an alternative option when it is illegal to automatically enroll people, or when automatic enrollment does not lend itself to engagement and sustainable compliance.

#### **Use Theory to Design Interventions to Overcome Barriers**

We used the anticipatory regret and regret aversion literatures to design an alternative choice format, which we call Enhanced Active Choice.<sup>5</sup> The intervention is a forced choice that highlights the benefits of the communicator-preferred option and the cost of the status quo. Enhanced Active Choice might reframe the alternatives as a choice between: "I want to enroll in a 401(k) plan and take advantage of the employer match" versus "I don't want to enroll in a 401(k) plan and don't want to take advantage of the employer match."

Although it may appear obvious, reminding people of what they will lose if they opt for the non-preferred alternative can have a powerful impact on choice. This is because decision makers are unlikely to seek out information about the costs of remaining with the status quo without prompts (Thaler & Sunstein, 2008)<sup>6</sup>, especially if such thoughts evoke negative emotions like anxiety and regret (Luce, 1998).<sup>7</sup> We believe regret and dislike for the non-preferred alternative will be more marked when the costs of non-compliance are highlighted in the choice format.<sup>8</sup>

#### **Measure Behavior Change**

I partnered with NARPP (National Association of Retirement Plan Participants) to employ Enhanced Active Choice in a new retirement savings enrollment form. The end result was a 25% increase in voluntary enrollment in the Sponsor's 457 plan, and a 600% increase in the use of an auto-escalation program such as SMarT (Save More Tomorrow).

### **CASE 2: HOW CONSUMER RESEARCH AND MARKETING WERE USED TO REDUCE HOSPITAL READMISSION RATES FOR HEART FAILURE.**

#### **Background**

Congestive heart failure (CHF) is a common disease, with an estimate of more than 5.8 million cases in the United States alone, and is one of the main causes of hospitalization in elderly patients. A whopping one-third of these patients return to the emergency room because they experience a heart failure episode every 60 days! Taken together, these factors create significant risks for re-hospitalization; U.S. rates for 30-day readmission for patients with CHF are between 20% and 25%.<sup>9</sup> The CMS (Center for Medicare and Medicaid Services) challenged us to reduce hospital readmission rates for this population.

#### **Identify Barriers**

Most educational programs for CHF during hospitalization focus on increasing motivation to follow recommendations about medications, diet and activity. Heart failure patients face several barriers—patient, disease, professional, and system-related—to self-efficacy and knowledge about their disease condition and needed behavior change. Patient symptoms and co-morbidities prevent them from expressing concerns due to conditions such as fatigue, dementia, and poor eyesight, and patients can omit information due to lack of time during the consultation. Symptoms like confusion and short-term memory loss create problems with maintaining knowledge about the disease condition.

#### **Use Theory to Design Interventions to Overcome Barriers**

Extant educational programs for CHF focus on the benefits of compliance. Less emphasis is placed on increasing the patient's ability to overcome barriers and using external triggers to cue the individual to action. Overcoming challenges that undermine self-efficacy is a key to behavior change and improving health outcomes. Incorporating methods that include patient empowerment by overcoming compliance barriers could improve the hospital to home transition.

To test this hypothesis, we conducted a prospective pilot study to improve patient empowerment in CHF education to see if our tools would improve outcomes of 30-day readmission or death. The first tool, three barrier cards, was intended to increase patient self-efficacy by addressing barriers to compliance.<sup>10</sup> The second tool, a refrigerator magnet, was intended to serve as an external stimulus to behavior change by highlighting the consequences if one does not undertake the recommended actions. We examined the effect of these two tools on readmission and patient and provider satisfaction.

The six-person heart failure education team and study investigators were trained to show each heart failure patient three cards with each key recommendation (daily weight, fluid restriction and medication adherence) written on a card. The team was instructed to tell each patient that they empathized that it was challenging to follow the recommendations and that other patients had also faced

challenges. The team then encouraged patients to share their challenges and barriers. The heart failure education team was provided with a Frequently Asked Questions and Answers sheet for each of the compliance barriers associated with limiting fluids, daily weight checks, and medication adherence.

### Measure Behavior Change

The patients in the two groups were similar in age, gender and risk-for-readmission score. The rate for 30-day readmission in the intervention group was 13.8% versus 19.9% in the matched control group.<sup>11</sup>

## CASE 3: HOW CONSUMER RESEARCH AND MARKETING WERE USED TO REDUCE THE ACQUISITION AND TRANSMISSION OF THE HIV/AIDS VIRUS.

### Background

One in five Africans is infected with the HIV/AIDS virus, with the number being close to one in three in some countries like Zimbabwe.<sup>12</sup> PSI (Population Services International) redesigned their VMMC (voluntary medical male circumcision) program to increase motivation to get circumcised.

### Identify Barriers

Consistent with consumer research on identity and stigma, barriers were categorized into cultural (religious and national barriers), identity (moral/stigma, gender/masculinity), relationship (sexual preferences), and emotional (shame, guilt) barriers.<sup>13</sup>

### Use Theory to Design Interventions to Overcome Barriers

After identifying the target audience barriers, consumer insights were applied to encourage South African males to get circumcised. For example, some men connoted circumcision with reduced masculinity, and this was overcome by asking VMMC ambassadors to wear karate clothes in village theater events. Others believed the circumcision campaign took advantage of those with weak economic status, and this was overcome by using political leaders as role models. Feelings of shame associated with circumcision were counteracted by using entertainment stars as spokespeople, and by disseminating information through new channels such as schools and workplaces. Finally, female significant others were enlisted to reduce morality biases by shifting the emphasis from health to hygiene and fun.

### Measure Behavior Change

The redesigned marketing program has resulted in more than one million males opting-in for the VMMC program.

Communicating the Value of Marketing and Consumer Research

I depend on many other partners in addition to the cross disciplinary investigating team. I work with several government agencies to understand the regulatory environment, to emphasize the importance of education and choice, and to help with dissemination. The cases I share here indicate that my work depends on government agencies like the CDC and OFEFA (Office of Financial Education and Financial Access) at the U. S. Department of Treasury, foundations like NEFE (National Endowment for Financial Education) and NARPP (National Association for Retirement Plan Participants), and firms like CVS Health and Blackrock.

## SUMMARY

My work is about integrating consumer insights and a marketing process for identifying and overcoming barriers to designing successful behavior change interventions. This approach provides a unique opportunity to enhance consumer empathy, engagement, and empowerment by addressing important consumer challenges. If used systematically, this approach can become an indispensable method for increasing the effectiveness of social marketing.

## ACKNOWLEDGEMENTS

To my parents who taught me I could never be denied. To my husband Kevin who is my biggest enabler and teacher. To my daughters, Carolyn and Allison, who are a constant source of inspiration. And to all of you who have encouraged me to not define myself by tenure—to keep going despite being rejected and accepted for tenure multiple times. A BIG thank you to all of you who are vital to my happiness.

# 2018 ACR Fellow Address

## On Relevance

Richard J. Lutz, University of Florida, USA

I am truly both honored and humbled to be deemed a Fellow of the Association for Consumer Research. I honestly thought that my time had passed for being considered for this award, so it came as quite a shock to me when it was announced at last year's conference. In fact, similar to Kubler-Ross's five stages of grieving, I found myself going through the five stages of ACR Fellowship: Shock, Elation, Unworthiness, Bargaining, and Acceptance.

In selecting a theme for my remarks today, I considered and rejected a number of topics. One of those topics that I originally rejected kept nagging at me. Eventually, it won out. The focus of my talk is relevance. Hopefully, it will also be relevant!

The concern about research relevance is hardly a new one for our field. It has been lamented since at least the 1980s, by ACR and SCP presidents, by *JCR* and *JCP* editors, by previous ACR Fellows, and by other leading scholars. Relevance – or more specifically, the lack thereof – has been identified, and diagnosed. Remedies have been proposed. Journals have been launched with relevance in mind (*JACR* and *JMB*). And yet, about a month ago I received a phone call from Jeff Inman, the current editor-in-chief of *JCR*. Would I consider writing a guest editorial for *JCR* on the topic of “What is Relevance?” Say what!?! Being a firm believer that “there are no coincidences,” I took great comfort in Jeff's request that the topic I had chosen is one that is far from settled.

In my remaining time, I shall attempt, first, to answer Jeff's question. Second, I will briefly trace the history of calls for relevance in consumer research, including some very insightful analyses and proposed remedies. Third, I will provide some informed speculation as to why our perceived relevance problem has persisted and what, if anything, can be done about it.

### Relevance Defined

Merriam-Webster defines relevance as: “(1a) relation to the matter at hand; (1b) practical and especially social applicability.” From this simple definition, it is relatively easy to extrapolate to the notion of consumer research relevance. Consumer research should relate to the matter at hand (i.e., consumer behavior) and should have practical applicability (i.e., implications).

However straightforward these extrapolations may appear, neither is without controversy. For instance, with regard to the matter at hand, many have argued for a very broad construal of consumer behavior. Thus, we have seen consumer research on time usage, voting, and even fertility. It seems that the “matter at hand” is quite a handful. At the very least, the matter-at-hand definition permits a very liberal interpretation of relevance.

The practical applicability definition appears to offer more promise in elucidating consumer research relevance. At ACR's inception in 1970, in addition to the obvious academic constituency, consumer research was construed to be of service to marketing practitioners and public policy makers. It was customary for authors to include a “marketing implications” or “public policy implications” section at the end of their papers.

In the mid-1980s things changed. Early pioneers in what was to become the Consumer Culture Theory (CCT) movement challenged the assumption that consumer research should be “industry's handmaiden.” In the words of Tom Tucker (1967), consumer researchers were admonished to study consumers the way a marine biologist

studies fish, not the way a fisherman studies fish. While I firmly endorse that “science *qua* science” philosophy, the unintended consequence of adopting it was that it seemingly devalued consumer research's external constituents. No longer were implications sections a necessity. The only constituents that truly mattered were other consumer researchers (especially editors and reviewers). Ironically, as the “matter at hand” became broader, the audience for consumer research became narrower.

By the early 1990s, concerns about the relevance of consumer research began to surface. In my last *JCR* editorial (Lutz 1991), I identified the need for “greater attention to substantive consumer behavior issues.” In order to achieve this, I recommended initiating research by identifying a substantive consumer behavior problem (rather than beginning with a theory to be tested); interacting with “systems experts” (e.g., marketing practitioners) to identify meaningful problems; and conducting research in natural settings.

In 1993 Bill Wells, one of ACR's founding fathers, as well as a past president and Fellow, wrote a brilliant treatise, “Discovery-Oriented Consumer Research” (Wells 1993), in which he challenged the field to conduct more meaningful, relevant research. He asserted that since the birth of ACR, the field had strayed from its original sense of purpose and had moved “...away from the real world.” He offered five guidelines for making consumer research more relevant: (1) Leave Home; (2) Forsake Mythology; (3) Reach Out, (4) Start Small and Stay Real; and (5) Research Backward. Time does not permit elaboration of Wells' guidelines here, but I strongly encourage you to go back and read his paper. His perspective is as useful now as it was then.

Terry Shimp, in his 1994 ACR Presidential Address, echoed many of Wells' criticisms of the field, concluding, “The call for greater relevance is now an inescapable element of the consumer research landscape” (p.2). He further identified five constituents for whom consumer research is potentially relevant: (1) other academics; (2) students; (3) businesspeople; (4) public policy officials; and (5) society at large (p.3). In other words, relevance is with respect to a target audience; a consumer researcher who aspires to conduct relevant research is wise to begin with an audience in mind. Of course, this is commensurate with the suggestion that consumer researchers should have a close relationship with practitioners and consumers themselves, or what Brinberg and McGrath (1985) denoted “systems experts.”

A final point that Shimp made pertained to the need for “representation-based” research that places greater emphasis on consumer behavior occurring in the actual marketplace. This viewpoint essentially privileges the study of real-world consumer behavior phenomena over the testing of theories that are typically borrowed from other disciplines. Shimp's notion was that greater attention to real-world consumer behavior phenomena would more or less ensure greater research relevance.

Thus, by 1994, the case was closed. The need for greater research relevance was identified, and several useful avenues for achieving it were specified. Relevant research ensued.

Not so fast.

In 2001, Itamar Simonson et al. titled their *Annual Review of Psychology* chapter, “Consumer Research: In Search of Identity.” In

it, they noted some troublesome trends. (Non-CCT) consumer research in *JMR* and *JCP* was largely conducted on student samples (~75%) in laboratory settings (~90%), hardly the real-world settings envisioned by Lutz, Wells, and Shimp. Furthermore, Simonson et al. identified another disturbing aspect:

“... consumer research articles increasingly emphasize the managerial implications of the findings... Yet, few managers (or consumers) read consumer research articles that are published in major journals, and the issues investigated are typically not at a level that is of much use for them” (p.264).

They also observed that, with a few exceptions, “...most articles published in the leading journals have examined more generic topics such as choice and attitudes. *Thus it is sometimes unclear what differentiates consumer research from other disciplines*” (p.263, emphasis added).

Ultimately, Simonson et al. argue for more attention to the substantive domain (i.e., real-world consumer behavior) as well as research that identifies “generalized empirical phenomena” (i.e., descriptive research) as a starting point for theory building.

In 2003, at the end of his term as *JCR* editor, David Mick raised similar concerns. In addition to delineating a number of pressing real-world consumer problems worthy of the field’s research attention (that presaged his subsequent founding of the Transformative Consumer Research movement), he echoed previous calls for greater research relevance. He also noted the imbalance between theory-testing research focused on mental phenomena and research on actual consumer behavior in natural environments.

In his 2006 ACR Presidential Address, “Meaning and Mattering Through Transformative Consumer Research,” David threw down the gauntlet by calling for Transformative Consumer Research (TCR), i.e., research “... framed by a fundamental problem or opportunity, and that strives to respect, uphold, and improve life in relation to ... consumption” (p.2). He went on to argue that ACR had done little to bring its considerable talents to bear on those sorts of topics and laid out a game plan for making TCR a reality. Twelve years later, TCR has enjoyed considerable success (Davis, Ozanne, and Hill 2016). I point you to the TCR tab on the ACR website to learn more about this exciting movement. Similar to a new product launch, it has taken some time for TCR to gain widespread awareness and appreciation. Despite the fact that TCR offers a clear pathway to greater consumer research relevance, only a minority of ACR members are active TCR participants, and the overall field has continued its soul-searching.

In 2007 *JCR* editor John Deighton expressed concern in an editorial that consumer research was not sufficiently differentiating itself from other social sciences and thereby was foregoing the opportunity to make unique contributions to knowledge. He made a plea for more “concreteness” and less abstraction, with the thought in mind that more concreteness would imply a strong focus on unique consumer behavior phenomena. Ultimately, consumer research should be “valued by others.” Of course, who those “others” are is a key question.

In his introduction to the 2008 *JCR* special issue on TCR, David Mick noted that, “over the years, unfortunately, the field of consumer research has generally under-prioritized scholarship for alleviating problems and advancing opportunities of well-being” (p.377). He also recounted the early success of the TCR movement in fostering more broadly meaningful consumer research. The thirteen papers appearing in that special issue have garnered nearly 4,000 Google Scholar citations in the past decade.

My colleague Chris Janiszewski, in his 2009 ACR Presidential Address, addressed the need for consumer researchers to make a unique contribution to knowledge. Utilizing a marketing perspective, Chris analyzed the “market” for consumer behavior knowledge and concluded that a substantive domain focus was essential. Specifically, consumer research should address consumption-specific issues that the more general social sciences overlook. He included examples: consumer satisfaction, attitudes toward advertising, and brand relationships. In Chris’ remarks we once again see the importance of research on substantive consumer behavior phenomena.

Debbie MacInnis and Valerie Folkes, in their 2010 examination of the disciplinary status of ACR, noted that ACR has, since its inception, aspired to be interdisciplinary. Debbie and Valerie cashed out what “interdisciplinary” would really look like. I especially like their diagram depicting the interdisciplinary model. Note the centroid of the diagram: Consumer Behavior Phenomenon. The examples they offer--materialism, gift giving, and obesity--make it clear that substantive consumer behavior phenomena need not be narrowly defined.

At this juncture, it appeared that some progress was being made in the quest for more consumption-relevant research, particularly in the TCR arena. Recall that TCR is avowedly oriented toward research that is beneficial to consumers themselves. In some instances, a spillover effect might be felt on public policy makers, as they seek to promulgate regulations that inform, protect, or otherwise benefit consumers.

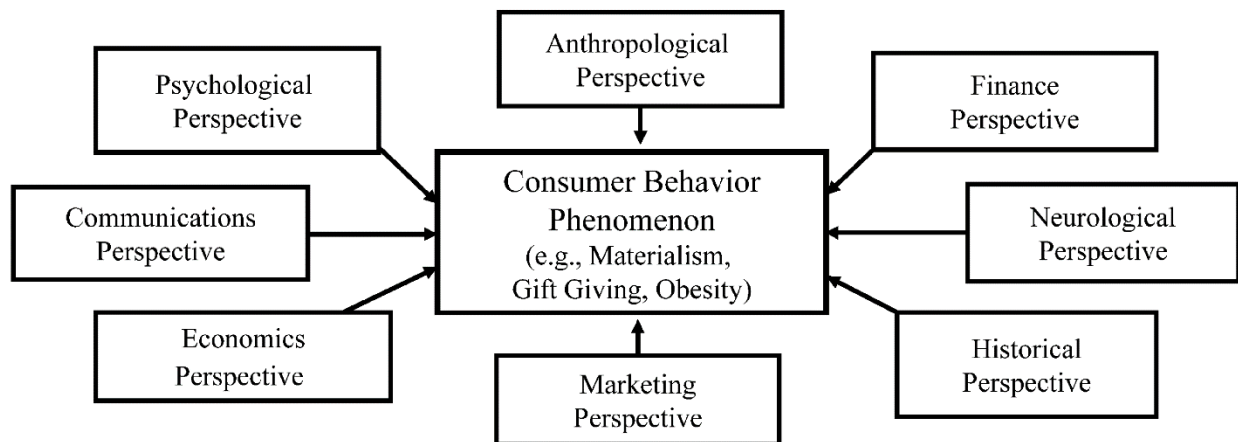

Figure 1: Source: MacInnis & Folkes (2010)

But what about ACR's other constituent--industry? What has been the track record with respect to producing consumer research of relevance to marketing practitioners? Although this question may not be of direct importance to all ACR members, the majority of us are employed in the marketing departments of business schools. It is not too much of a stretch to assert that at least some of us aspire to produce research that is relevant to marketing managers. Indeed, the Consumer Behavior Special Interest Group (CB-SIG) of the American Marketing Association has recently repositioned itself as operating at the interface of consumer research and marketing practice. Last year the CB-SIG initiated the Consumer Research in Practice Award for the best consumer research paper making a managerial contribution, and next summer is hosting its first conference (in Switzerland): "Managerially Relevant Consumer Insights: Crossing Boundaries," with the same emphasis.

Addressing the managerial relevance question head on, Lutz (2011) noted that much academic marketing research intended to address substantive marketing problems appears to fall short of the mark. Others had preceded him with that criticism. As Scott Armstrong (2003) observed, "Few papers in marketing journals would fall into the category of having findings that are useful" (p.71). Daniel (2009) offered an even harsher criticism: "...business journals consist almost wholly of articles written by professors for other professors" (p.3). Although it is certainly a worthy enterprise to conduct research that is primarily aimed at advancing science rather than practice by targeting other scholars, as we will soon see, that defense of our research relevance may be self-delusional.

At the 2010 ACR conference, we were treated to two powerful Fellows' addresses by my former colleague John Lynch and current colleague Joe Alba. Both of them addressed the need for more attention to substantive problems. John counseled:

*"... if we would more often look to the substantive domain as inspiration for our research, three good things would happen. Our work will be of interest to a wider public, we will have more vibrant mutual influence with adjacent social disciplines, and.... benefit more richly from each other's work" (Lynch, 2011, p.15)*

However, it was John's observation that our best researchers (and review teams) appear to think that every paper must make a theoretical contribution. As Brinberg and McGrath's (1985) Validity Network Schema (VNS) illuminates, the likelihood of making a meaningful substantive contribution when one sets out to make a theoretical contribution is severely constrained.

Joe's remarks, subsequently published in *JCR* (2012) as "In Defense of Bumbling," made a strong case for describing the "what" of consumer behavior before tackling the "why." He argues for the use of "abduction" (i.e., "informed curiosity") as a research approach. Note that this is very much in concert with Bill Wells' call for discovery-oriented consumer research. As Joe points out, consumer researchers' penchant for elaborate theories with higher-order interactions militates against communicating with marketing practitioners, whose burning questions more closely approximate main effects. In sum, neither Lynch nor Alba was enthusiastic about the "state of the art" in consumer research with respect to its relevance to practitioners.

In his 2012 ACR Presidential Address, Jeff Inman asserted that "useful, actionable" consumer research was "the elephant not in the room." He cited a recent survey finding that 40% of ACR's membership agreed that more substantive research is necessary and mentioned the TCR initiative as a move in that direction. Critically, Jeff advocated that our research "... should pass the 'So what?' or 'Who

cares?' test and offer useful insights to other constituencies: public policy makers, industry, and yes, consumers as well. Importantly, *relevance to other constituencies should not be a stretch*" (Inman, 2012, p. 2, emphasis added).

In order to generate truly relevant research, Jeff argued, consumer research needs to incorporate "consequential dependent variables" that entail participants' actual resources (e.g., time, money) as opposed to scale responses to a hypothetical scenario. Note that this recommendation tends to favor field research over lab studies or MTurk. Jeff also suggested turning to the substantive domain as a source of research topics, rather than exclusively pursuing theoretically-driven questions.

Jeff concluded his remarks with an important disclaimer, with which I agree wholeheartedly: "Am I saying that we should shift all our focus to research that generates useful insights? Absolutely not. I AM saying that we need to achieve a sustainable equilibrium between research that builds theory and research that applies theory to substantive issues to generate useful insights. Through this, we can form touchpoints beyond our academic colleagues and truly make a difference to practice and to society" (p. 4).

John Lynch and colleagues (2012) echoed Inman's basic thesis and offered some insightful approaches for addressing the perceived imbalance between theory-driven and substantively-driven research. Drawing on Ellison's (2002) analysis, they distinguish *r-quality* (in a nutshell, the rigor of the research in technical terms) and *q-quality* (i.e., "the importance of the paper's main contribution") (p. 474). They argue that it is much more difficult for reviewers to assess *q-quality* than *r-quality* and, consequently, *q-quality* tends to receive short shrift. This has the effect of squeezing out potentially relevant, if not as precise, contributions.

Lynch et al. further argue for greater use of inductive theory-building that originates with a substantive problem. Consequential dependent variables and field studies are suggested as useful mechanisms for pursuing *q-quality*. Recognizing that judgments of *q-quality* are inherently subjective and even idiosyncratic, Lynch et al. advocate a "champion" philosophy in the review process: i.e., at least one member of the review team should be very enthusiastic about the contribution of the research. Assessing the perceived importance of a research topic is thus a central challenge not only for editors but even more significantly for researchers faced with the decision of where to allocate their time and intellectual effort. We shall return to this point.

In his sobering 2013 SCP Presidential Address (and subsequent guest editorial in *JCP*), Michel Pham identified "The Seven Sins of Consumer Psychology." He thoroughly documented those sins as well as potential corrective actions because:

*"Our research findings lack relevance and impact for both our external constituents (i.e., businesses, policy makers, and consumers) and our internal constituents (other consumer researchers and social scientists)" (Pham, 2013, p. 411, emphasis added).*

Excuse me!? What?! The latter charge leveled by Michel sticks a pin (or perhaps a harpoon) into the protective bubble of those of us who have been contenting ourselves to be "relevant" only to academe and eschewing managerial or policy significance.

In support of this perhaps surprising assertion, Michel conducted an exhaustive citation analysis of *JCR* spanning 1994-2008. His findings? A small slice of articles (less than 10%) are "well-cited," averaging over 10 citations per year. But, "the vast majority -- roughly 70% - hardly ever get cited .... [and hence] hardly [have] any measurable scholarly impact" (p. 412). These data points should

be a wakeup call for all of us! Time does not permit a full recounting of the seven sins Michel identified or his proposed remedies, but his paper is a must-read for any serious consumer researcher who wants to have an impact, either inside academe or outside.

While Michel's recommendations echo those of several previous scholars, e.g., the need for inductive theory-building, more attention to content rather than process, and more use of field studies, one recommendation in particular stands out: consumer researchers should "...increase their physical exposure to businesses, policy agencies, and actual consumers in the marketplace" (p.422). He proposes a "field-theory validation path" wherein academic researchers turn to industry consultants or other practitioners as a source of testable hypotheses. Michel's suggestion is reminiscent of Argyris and Schon's (1974) "Theory-in-Practice" approach and would have the desirable effect of grounding our research firmly in the substantive domain.

As we have seen thus far, the decade of the 'teens has witnessed a rash of soul-searching, breast-beating cries for greater relevance in consumer research. But we are not quite through yet. In their introductory *JCR* editorial, "Meaningful Consumer Research," Dahl et al. (2014) pleaded for more meaningful (i.e., "relevant") research. Relying on Wells (1993), they advocated a research approach that begins with a consideration of how useful the findings will be to the audience it addresses. They specifically encouraged considering audiences beyond other academics. Would that exhortation be sufficient to turn the tide?

*JCR* editors were not the only ones encouraging more relevance. In 2015 the *Journal of Marketing Behavior* launched. In his introductory editorial, Klaus Wertenbroch proclaimed "an opportunity for more relevance," with an emphasis on research "...that has relevant and interesting practical implications for decision makers, be they managers, policy makers, or consumers" (p. 1). Klaus drew inspiration from Pham's (2013) "seven sins" and noted that more established journals may have too much cultural inertia in the review process to readily implement an increased focus on q-quality rather than r-quality (in Lynch et al.'s terms).

In her 2017 ACR Presidential Address, Meg Campbell, one of *JCR*'s current editors, made an impassioned plea for greater research contribution, by which she meant "contribute to the understanding of consumer-relevant issues" (p. 1). To do this, she counseled that the research must "...start with a consumer-relevant problem." Being a good marketer, she also emphasized that researchers must actively consider the audience for their research. Meg worries that, as a field, we are not having enough impact, but proposes that a clear focus on understanding consumers is the path to greater research relevance.

Last but not least, earlier this year Meg and Jeff Inman were joined by their fellow editors Amna Kirmani and Linda Price in stating their editorial vision for *JCR*: "It's All about the Consumer." It is evident that they are trying to be change agents, which is certainly within their purview as editors. What are they seeking to accomplish? Among other worthy goals, they "...welcome consumer-focused papers that adopt non-deductive approaches to appropriately document and measure *important* effects... Manuscripts will be evaluated based not only on their conceptual contribution but also on the meaningful, practical insights they generate" (p.956). Thus, we see yet another call for more substantively-driven research.

Inman et al. further note that *JCR* articles "...have trended toward a focus on research topics that are of interest primarily to the academic community – in reality, often only a small portion of the like-minded academics" (p. 957). This observation squares with Pham's disturbing findings about the paucity of citations to much of our work. The *JCR* editorial team recommends careful attention to

the choice of research topic, keeping a firm focus on the consumer. In addition, they advise using "consequential" dependent variables that "...require participants to (a) invest a resource, such as money, time, or effort; or (b) experience a real outcome" (p. 957). Finally, they point to the virtues of field experiments, quasi-experiments, and ethnographic research.

## WHAT IS "RELEVANT" CONSUMER RESEARCH?

Synthesizing the many calls for research relevance, as well as various proposed remedies, I suggest that relevant consumer research has the following properties:

1. A clearly-specified target audience; and
2. A focus on a legitimate consumer behavior phenomenon that is ...
  - a. Interesting (to the audience)
  - b. Important (i.e., not trivial)
  - c. Actionable (i.e., by the audience)
  - d. Potentially generalizable/transferable

Point 1 underscores the basic notion that relevance must be understood in relation to someone other than the researcher him or herself. *Someone* else has to care (Shimp 1994, Deighton 2007, Lynch et al. 2011, Inman 2012, Pham 2013, among others). Point 2 asserts that consumer research must concern itself with *consumer* behavior, not human behavior more generally (Lutz 1991, Wells 1993, Janiszewski 2009, Campbell 2017, among others).

Points 2(a) and 2(b) are self-evident and have been echoed by many, most recently Inman et al. (2018). Point 2(c) deals specifically with the implications of the research. How do the findings alter a marketing manager's decision-making or a public policy official's proposed regulation? Alternatively, how does the research change the way other scholars understand a phenomenon and conduct their own research on it? Ultimately, to be truly relevant, research has to change the target audience's beliefs and/or behavior (Simonson et al. 2001, Mick 2006, Wertenbroch 2015, among others).

Point 2(d) is a necessary recognition that our focus is on scholarly research that advances scientific knowledge. Points 2(a-c) could apply to a consulting project conducted for a firm or government agency. Relevant consumer research must be at least potentially transferable to other consumer contexts.

Two more qualities are not essential, in my view, but nonetheless could contribute favorably to consumer research relevance:

3. Natural settings
4. Effective communication to target audience

Both of those factors may be more applicable with respect to research aimed at influencing external constituents. Point 3 reflects the calls for discovering and/or demonstrating consumer behavior in the real world (Cialdini 1980, Lutz 1991, Wells 1993, Mick 2003, Alba 2012, Inman et al 2018, among others). Point 4 is inspired by the TCR movement's approach wherein research is "taken to the streets" to try to effect desired change. This suggests that the individual scholar should think beyond merely publishing in a top journal if s/he wishes to impact an external constituency. As many have noted, practitioners and consumers do not read *JCR* or *JCP*.

## WHERE DO THINGS STAND – AND WHY?

The foregoing selective review of presidential addresses, fellows' speeches, and journal articles serves to underscore the field's desire for greater research relevance. From early attention to the concern dating back to the 1980s to the recent crescendo of voices (at least a dozen pieces in the past decade), the drumbeat has been steady, if not accelerating. By my rough count, the treatises I have cited herein represent the views of 18 ACR and SCP presidents,

seven ACR Fellows, and seven JCR editors. Yet, judging from the most recent editorial pleas, we are no more relevant in 2018 than we were in 1988!

Why has the perceived deficit in our research relevance persisted in spite of highly-respected scholars calling for corrective action? Are we tone deaf? Incompetent? Misguided? Many factors contribute to the lack of progress, some individual and some systemic. As individual scholars, most of us have been trained to value theory and conduct theory-driven research. (Note: this point does not apply to our CCT colleagues, who ground their research in observed phenomena.) We are naturally drawn to theoretical research; it is what we, and our colleagues, know best. Systemically, the review process at our major journals is ill-equipped to evaluate and nurture research that departs from the norm, as Lynch et al. (2012) persuasively argued. Publishing a substantively-driven piece of research in a major journal is a daunting prospect. The risks have far outweighed the rewards. Unfortunately, our obsession with theory has contributed heavily to our relevance deficit.

In a sense, when the field more or less embraced the “marine biologist” perspective over the “fisherman” perspective and placed little or no weight on actionable implications, it precipitated an unfortunate inward turn. This is rather ironic: that broadening the concept of consumer behavior should lead to a more inward orientation. How so?

Essentially, removing external constituents, whether industry or public policy makers, from the research enterprise has left us talking only to each other (and even that not very pervasively, according to Pham). We have lost a sense of checks and balances on our work. We were able to tell ourselves that we were addressing other academics or, perhaps, consumers themselves, but the real driving force was the review team at our targeted journal. Not unlike the physician who decides on and prescribes various pharmaceuticals to her patients, these four- or five-person review teams are the gatekeepers that determine the fate of our research. And we all know how unbiased, error-free, and uplifting the review process is! (Except for that damn Reviewer B!)

However, for those of us who work in business schools, the traditional reward structure for published research is beginning to evolve toward more attention to ... wait for it ... relevance. The specific term in the 2018 revised AACSB accreditation guidelines is “impact of intellectual contributions” (p. 18). The guidelines further specify that the school “... clearly articulate the contributions to society and are transparent to the public” (p. 19). While citation counts have assumed greater significance of late, citations rest firmly within the academic milieu and are not necessarily indicative of societal impact. The implication of the AACSB standard may be a higher bar for judging the quality of b-schools’ intellectual contributions. It behooves us to stay ahead of the curve. As a field, we may be approaching a true relevance crisis!

### HOW TO BE (MORE) RELEVANT

Let’s suppose for a moment that you are an enterprising young consumer researcher who embraces the need to conduct more relevant research, especially with respect to external constituents. First, I strongly encourage you to read at least three key papers among those I have cited: Wells (1993), Lynch et al. (2012) and Pham (2013). These papers provide an excellent overview of the relevance issue as well as astute guidance on how to address it effectively. From there, how would you proceed? One recommendation that we have seen repeatedly is to initiate your research in the substantive domain. Identify a phenomenon of interest, and apply theoretical and observational tools to address it. However, this seemingly straight-

forward advice addresses only the *necessary* condition for attaining relevance, not the *sufficient* condition. As Wells so aptly put it, “all kidding aside, what does this really mean?” (Wells 1993, p. 498). Not all substantive domain phenomena are of inherent interest or importance. If one is serious about making a relevant contribution to an external constituent (industry, public policy), the most plausible place to begin is by understanding the needs of the audience. How many of us interact with marketing managers or public officials as we decide what to research? How much more productive might our entire research enterprise be if we were to take that step?

As I recommended in my 1989 *JCR* editorial, it would make sense for consumer researchers to “test market” our intended contributions with the audience we hope to influence *before* conducting the research. Furthermore, as advocated by Brinberg and McGrath (1985) and elaborated by Pham (2013), consumer researchers seeking to be relevant should consult with “systems experts” as a fertile source of research ideas. Following this sort of approach would greatly enhance the likelihood that a research project, successfully executed, would make a relevant contribution to its intended audience (Andreasen 1985, Wells 1993). Working “backward” from the audience (i.e., the market) is the mantra that those of us who are marketing professors drill into our students incessantly. We would do well to practice what we preach. Ideally, fostering a collaborative research relationship with marketing practitioners may have the added value of permitting consumer researchers to persuade practitioners of the value of seeking “win-win-win” solutions wherein the firm, the consumer, and society benefit from the firm’s actions.

Of course, as scholars it is incumbent on us to attempt to explain marketplace phenomena, not merely describe them. In that vein, Cialdini’s (1980) “full-cycle social psychology” is instructive. Deftly combining field observations (to establish that a phenomenon is “real”) and laboratory experimentation to elucidate underlying processes is an excellent mechanism for ensuring substantive relevance.

In sum, several action strategies are available that can help an individual consumer researcher achieve greater relevance:

1. Read (at least) these key papers—Wells (1993), Lynch et al. (2012), Pham (2013)
2. Determine the target audience to be influenced by the research
3. Consult with systems experts (i.e., target audience members)
  - a. Source of “theories-in-practice”
  - b. “Test markets” for proposed projects
4. Aim to discover new, important phenomena
5. Use a combination of field and laboratory research (Cialdini 1980)
6. Engage in inductive theory-building
7. Proactively communicate insights to target audience

### WHAT IS ACR DOING TO HELP?

As the primary international association dedicated to furthering consumer research, ACR has a responsibility to assist individual researchers in pursuit of more relevant research. Happily, two terrific examples of this sort of institutional support exist: the Transformative Consumer Research movement and the recently-established *Journal of the Association for Consumer Research (JACR)*.

Founded in 2005, TCR “... seeks to encourage, support, and publicize research that benefits consumer welfare and quality of life for beings affected by consumption across the world” (TCR tab on ACR website). Since its inception, TCR has held six biennial conferences, has awarded thousands of dollars in research grants, and

has been featured in numerous special issues of *JCR* and other journals. Significantly, TCR has attracted more than 500 consumer researchers globally, including some of our most productive scholars, such as one of today’s new ACR Fellows, Punam Keller.

TCR exemplifies many desirable qualities of externally relevant research that I have been espousing today. Consider this graphic from the call for proposals for the 2019 conference.

Note how the process is ultimately solution-oriented, i.e., aimed at making a real-world substantive contribution. The initial step of identifying a significant problem explicitly draws on both internal (to ACR) and external (non-academic stakeholders) expertise. Dialogue and relationships are established that feed directly into theory-guided research. The final step envisions academic-practitioner partnering to implement recommendations. In other words, an entire ecosystem is in place to foster real-world impact of scholarly research. For consumer researchers seeking to make a positive difference in the world through their research, TCR offers a promising community of like-minded scholars.

*JACR* was launched in 2016 with much the same mission as TCR. As stated in the inaugural issue (p. 1, *JACR*’s “... vision [is] that consumer researchers should be conducting research that has significant relevance to consumers, managers, and policy makers.” The explicit aims are to focus scholars on research that is “high in relevance.” *JACR* uses a “special issue” format to attract a critical mass of research on a particular topic, thereby drawing more attention to it, and all ACR members receive *JACR* as part of their membership benefits. A quick perusal of the first few years of issues is enough to easily recognize the more substantive consumer behavior focus. From the initial issue on the science of eating through ownership and sharing, to the evolving retail landscape, *JACR* is strongly focused on real-world phenomena.

These two relatively recent initiatives, both aimed at fostering greater research relevance, are noteworthy and underscore ACR’s global leadership as a consumer research organization. These efforts are to be applauded. However, are they enough? If so, why have we continued to witness so many exhortations for greater relevance in the past few years? Is it possible that TCR and *JACR* and are a

bit too balkanized in their impact? In other words, does their admirable consumer relevance character “spill over” to other sectors in the more general consumer research arena?

**WHAT ELSE CAN ACR DO?**

In considering potential mechanisms whereby ACR might encourage more consumption-relevant research, two possibilities come to mind. One is basically an extension of TCR’s annual call for research proposals, while the other derives from an idea I proposed for marketing scholarship back in 2011 and is a bit more radical. Both ideas are aimed at providing consumer researchers with some guidance in selecting research topics that are interesting, important and relevant.

*Expanding the TCR model.* Since its inception, TCR has been focused on research that has implications for consumer well-being. The 2018-2019 TCR Research Funding Call for Proposals lists more than 20 potential topic areas as examples of the sorts of investigations the TCR community views as relevant. This list represents a terrific starting point for potential TCR researchers. However, since TCR is explicitly aimed at consumer welfare, the topic listing does not include many other legitimate lines of inquiry within the consumer research domain, for example, public policy or marketing practice.

Therefore, I propose that ACR commission a task force to identify and publicize important substantive consumer research priorities. These priorities could be organized by constituency: practitioners, policy makers, consumers themselves, and other academic scholars. In order to fulfill its mission, the task force should include ample representation from each constituency. Similar to the Marketing Science Institute, ACR should revisit and revise the research priorities biannually. Care must be given to having representation of ACR’s base disciplines (e.g., psychology, sociology, anthropology, economics) represented on the task force to ensure consideration of a broad range of potential topics and perspectives.

*Collaborative problem definition.* My more radical proposal draws on an earlier proposal put forth in Lutz (2011, pp. 231-232). ACR should consider establishing a mechanism whereby an author

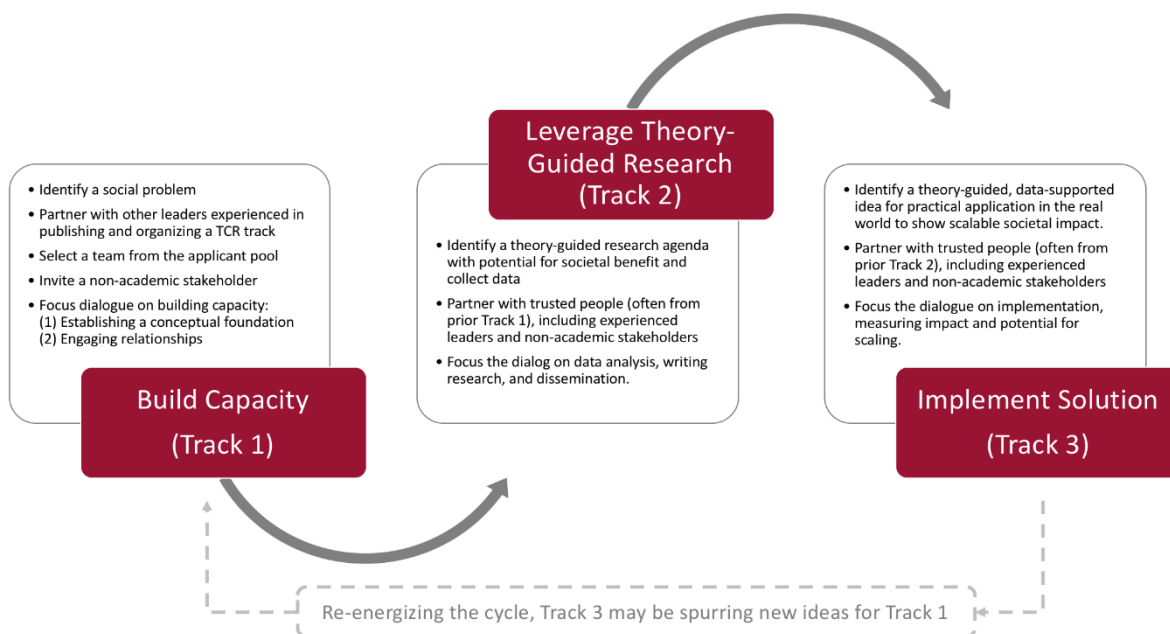

Figure 2: Source: <https://tcr.business.fsu.edu/>

could submit a prospectus for a potential research project and receive feedback from a panel of seasoned consumer researchers and systems experts. The prospectus would specify the intended audience and the nature of the intended contribution. An editor would select a small group of relevant experts and ask them to address this basic question: “If a research study successfully addressed the proposed problem, how important a contribution would it represent?” Suggestions for improvement would also be solicited. Assuming a prospectus passed this basic test, the author(s) could then pursue the project with some degree of assurance that it is a worthy endeavor. Note that it would be important to establish this prospectus review independent of any particular journal in order to avoid any implication of eventual publication. Having reviewed more than a thousand manuscripts for possible publication during the course of my career, it is my strong impression that many of the unsuccessful ones would have failed the initial screening of problem significance I am proposing. Thus, the proposed system would not only have a positive impact on the relevance of consumer research, it would also result in greater system efficiency, as less time would be spent by authors, editors, and reviewers on ill-conceived research problems.

### WHAT CAN THE JOURNALS DO?

I have discussed potential mechanisms whereby individual researchers and ACR can move consumer research toward greater relevance. From a systemic perspective, the third key component is comprised of consumer research journals. In the interest of time, I will focus my remarks on the field’s flagship, the *Journal of Consumer Research*.

As I discussed earlier, the current editorial team has explicitly prioritized relevant, substantive consumer research. Their openness to publishing more substantively-driven research is crucial. However, additional steps need to be undertaken to bring their vision to fruition. As noted earlier, most consumer researchers are trained to conduct hypothetico-deductive research (Lynch, et al. 2012). Relatively few non-CCT consumer researchers (and reviewers) are expert at conducting (and evaluating) inductive research (i.e., research that begins by observing substantive phenomena).

In their *JCR* editorial, Inman et al. (2018) cite the Lynch et al. (2012) paper in support of multiple routes to generating consumer behavior knowledge and note the “strong headwind” that non-deductive, findings-focused research has faced at *JCR*. They continue “... We urge that our associate editors, editorial board members, ad hoc reviewers, and authors...champion rigorous research that provides consumer insight with the use of either standard or ‘nonstandard’ methods and types of meaningful consumer data.” Presumably, this exhortation includes tolerance for an inductive approach.

This may not be enough to steer the *JCR* ship in a more inductive direction. A tremendous amount of inertia is present in the system. Little guidance exists for those who wish to pursue an inductive approach. Lynch et al. (2012) included a brief section, “Criteria for reviewing” non-deductive substantive contributions. Likewise, Pham (2013) devoted a paragraph to criteria for judging descriptive consumer research. However, *JCR* has not yet provided sufficient guidance. For example, the *JCR* website’s “Instructions for Reviewers” is silent with respect to the paradigmatic approach represented in the manuscript. In the “Tutorials” section, we find “A Field Guide for the Review Process,” (Bagchi et al. 2017) that includes a single paragraph on the substantive domain. They state that “... different goals should be judged by different standards,” but do not elaborate. Janiszewski et al. (2016) have an excellent tutorial on “Knowledge Creation and Knowledge Appreciation in Deductive-Conceptual Consumer Research” and note that “...it is

the most popular approach.” Morales et al. (2017) present an insightful tutorial on experimental realism that is implicitly embedded in a hypothetico-deductive paradigm. Surely, a companion tutorial on substantive-inductive consumer research is essential if the current editorial vision is to be realized. Authors and reviewers alike need more guidance. *JCR* and ACR should collaborate on more special sessions at ACR conferences, such as the workshop on consumer relevance scheduled for Saturday afternoon. Another possibility is a special issue or special section of *JCR* devoted to relevant consumer research, similar to the special issue on TCR in 2008. (To be fair, I should note that *JCP* encourages inductive theory-building by welcoming effects-based papers in its Research Reports section.)

In sum, following the lead of the TCR movement, a systemic effort is needed to instill a sustainable stream of substantive, relevant consumer research. It is incumbent not only on authors but also on ACR and *JCR* to effect this welcome change.

### WE ARE NOT ALONE

Lest you feel that my assessment of consumer research relevance is too harsh, or you are left with the impression that ours is a particularly irrelevant collection of scholars, I draw your attention to the Community for Responsible Research in Business and Management (RRBM). (Again, these remarks are of most direct relevance to those of us employed by business schools.) RRBM was formed by a diverse set of 28 scholars from ten countries on three continents, representing all business disciplines (Glick, Tsui, and David 2018). To date, its principles have been endorsed by nearly a thousand other scholars.

In the initial RRBM position paper, “A Vision of Responsible Research in Business and Management: Striving for Useful and Credible Knowledge,” the committee states, “...both the relevance and quality of research in business schools has been under attack for more than two decades” (p.3). They further elaborate what they call the “crisis of relevance” by identifying three pressing issues: “(1) Current research does not produce knowledge relevant for business purposes. (2) A strong orientation toward A-ranked journals distorts incentives towards a narrow focus ... (3) An over-emphasis on theory ... leads to a focus on form more than substance...” (p.11).

Furthermore, they observe, “...research primarily benefits the researchers who conduct it (for career advancement) and those who read it, which consists primarily of other scholars... There is low priority given to how research could benefit business and broader society” (p.12).

All of this sounds painfully familiar. RRBM has as its core mission furthering the collective goal of creating a better society through scholarly research in business. They have promulgated seven fundamental principles of responsible research ([www.rrbm.network/position-paper](http://www.rrbm.network/position-paper)). I invite you to visit the RRBM website and consider joining other leading consumer researchers who have endorsed these ideals.

### PAYING IT BACKWARD ... AND FORWARD

A year ago, as I began thinking about my remarks for this occasion, my first thoughts were ones of gratitude. The ACR Fellow Award means a great deal to me, as ACR has been my primary professional identity for nearly 50 years. Yet I am here today, not due just to my own efforts, but also due to the inspiration and support of so many others. I wish I could have devoted my entire time to thanking them.

I begin by remembering the late Paul Winn, who was my principles of marketing instructor at the University of Illinois and later my Ph.D. colleague, who set me on this path by encouraging me to

pursue my Ph.D. At that point, I was planning to be a market researcher at the *Peoria Journal Star*, so you might say his suggestion made just a bit of a difference in my life! I also wish to acknowledge Jag Sheth, who gave me my first RA position in the Ph.D. program, taught me more than I ever wanted to know about multivariate data analysis, and has entrusted me for the last ten years with membership on the Sheth Foundation Board of Directors. Joel Cohen was a magnificent mentor and dissertation chair who was not only instrumental in launching my scholarly career but also lured me to the University of Florida nine years later. I also benefitted greatly from my other Illinois colleagues Peter Wright, Bobby Calder, Kent Monroe, Bob Burnkrant, Mike Munson, and especially my good friends Mike Houston, Bill Locander, and C.W. Park.

Hal Kassirjian at UCLA is my academic grandfather and set the tone in the department by epitomizing servant leadership. Jim Bettman embodied a scholarly standard of the highest caliber, and still managed to be a “wild and crazy guy.” Noel Capon, Carol Scott, Bart Weitz and a youngster by the name of Debbie Roedder were incredible colleagues. What ever became of Debbie? UCLA was also the home to my first doctoral students – Jack Swasy, Joe Belch, and Scott MacKenzie. Channeling my inner Paul Winn, I literally plucked Scott out of our MBA program and nudged him into our Ph.D. program.

In my 36 years at Florida, I have been blessed with an amazing group of colleagues. In addition to Joel Cohen, who hired me, Bill Wilkie, Dipankar Chakravarti, John Lynch, Joe Alba, and Wes Hutchinson welcomed me in 1982. We were joined over the years by Alan Sawyer, Chris Janiszewski, John Sherry, David Mick, Barb Bickart, Robyn LeBoeuf, David Wooten, and Ratti Ratneshwar. Alan Cooke, Lyle Brenner, Aner Sela, Yang Yang, and Yanping Tu round out the current consumer behavior complement. It has been a true privilege to serve with so many talented scholars over the years.

I have also been fortunate to work with several gifted Ph.D. students at Florida: Doug Hausknecht, Bill Baker, Steve Holden, Chuck Areni, Susan Fournier, Betsy Moore, John Pracejus, Andrew Kuo, and Gia Nardini. In addition to these Florida Ph.D. graduates, there is another group of Florida alums who are near and dear to my academic heart. I met these young people when they were students in my undergraduate principles of marketing course. Most of them subsequently served as undergraduate teaching assistants for me and wrote their undergraduate honors theses under my direction. All of them went on to earn their Ph.D.s, some at Florida, others elsewhere. I am pretty sure that they would say that they would not have considered a Ph.D. in marketing and a career in consumer research without my initial encouragement. More than my scholarly contributions, they represent my legacy to the field, and I am very proud of each of them. Who are these people? Stacy Wood, Chuck Areni, Andrew Kuo, Katie Kelting, Stefanie Robinson, Leigh Anne Novak Donovan, Gia Nardini, Cammy Crollic, Emily Goldsmith, and Irina Toteva. You guys mean the world to me!

In closing, I thank my parents, Willis and Mary Kay Lutz, who encouraged a young farm boy to pursue his academic dream. My wife Rachel has been an unwavering supporter and has balanced my academic focus by nurturing a warm and loving family that has enriched my life immeasurably. Our sons Matt and Jon have blossomed into amazing young men. A contractor and a chef, they ensure a roof over our heads and food on our table! And Matt, in collaboration with his wife Amanda, has filled our lives with the joy and wonder of two precious grandchildren – Claire and Jacob. Sometimes life seems just too good to be true!

Thanks once again to my ACR family for making my ACR Fellows dream come true!

# Special Session Summaries

## Financial Decisions in the Information Age

Chairs: Tito L. H. Grillo, University of Texas at Austin, USA

Adrian F. Ward, University of Texas at Austin, USA

### Paper #1: Financial Education and Confidence in Financial Knowledge

Stephen Atlas, University of Rhode Island, USA

Nilton Porto, University of Rhode Island, USA

Jing Jian Xiao, University of Rhode Island, USA

### Paper #2: From Novice to Know-it-All: How Google-Based Financial Learning Affects Financial Confidence and Decisions

Adrian F. Ward, University of Texas at Austin, USA

Tito L. H. Grillo, University of Texas at Austin, USA

Philip M. Fernbach, University of Colorado, USA

### Paper #3: Product Complexity as a Barrier to Consumer Financial Decision-Making

Timothy Dunn, University of Colorado, USA

Philip M. Fernbach, University of Colorado, USA

Ji Hoon Jhang, Oklahoma State University, USA

John Lynch, University of Colorado, USA

### Paper #4: Increasing Tax Salience Alters Investment Behavior

Abigail Sussman, University of Chicago, USA

Daniel Egan, Betterment, USA

Sam Swift, Bowery Farming, USA

and Lynch used eye-tracking to show that high complexity of the presentation of financial products detracts attention from key information about the options. Decreased complexity, on the other hand, increases time reviewing product information, which improves comprehension of the product and its attributes and positively predicts identification of the best option.

Lastly, Sussman, Egan, and Swift present an investigation of the use of online investment platforms, which can provide unique features to assist consumers in investment decisions. The authors examined the effects of a feature that allows investors to see real-time information on the tax impact of an action before they commit to this action. Results suggest that seeing this information on the investment platform reduces trading behavior, but there are nuances to this effect. Namely, levels of sensitivity to tax information in the platform are different for investors with different political affiliations and vary with tax popularity (inferred based on Google search popularity of the specific tax).

Together, these papers give a snapshot of how factors related to information technologies are shaping financial decisions in the Information Age. This session acknowledges that these factors are incipient and likely to be intensified in the near future. Thus, looking at them and their consequences now serves us as a glimpse of future issues in financial decision making.

## SESSION OVERVIEW

Consumer research has kept a close watch on how personal and household financial decisions are made and their influence on consumer welfare. However, the landscape of financial decisions now changes faster than ever. A large part of these transformations revolves around the rise of forms of access to information never experienced before. The current papers are guided by the question of, “What do financial decisions look and feel like in the Information Age?”

A major hallmark of this age is the ready availability of information—including increased access to expert knowledge about investing through online platforms. Over the course of six months, Atlas, Porto, and Xiao monitored the effects of an online financial education intervention from one such platform on people’s financial knowledge, confidence in this knowledge, and intentions to adopt desirable financial behavior. Increases in confidence in one’s financial knowledge after the intervention were persistent over time, but effects on actual knowledge were negligible and on intentions were short-lived.

Ward, Grillo, and Fernbach focused on another, perhaps more common, approach to accessing knowledge in our time: online search. Using the Internet and tools like Google, many consumers now rely on online search to educate themselves about investing before making financial decisions. The authors explored how using Google to learn basic information related to the “world of investing” inflates financial self-confidence and leads consumers to reject expert financial advice while also adopting riskier investing behavior.

Although the Information Age offers consumers improved ease-of-access to financial information, processing this information is not always such an easy task. This is noteworthy when consumers deal with information about financial products that can be beneficial but, at the same time, are extremely complex. Dunn, Jhang, Fernbach,

## Financial Education and Confidence in Financial Knowledge

### EXTENDED ABSTRACT

Financial literacy is seen as an essential skill as young adults become financially independent and make major financial decisions, yet researchers have found that financial literacy is often low among young adults aged 19-29 (Lusardi et al. 2010; Shim et al. 2010). A recent meta-analysis has found that one challenge limiting efforts to improve consumer financial wellbeing is a short “shelf life” of financial education designed to improve financial literacy and foster beneficial financial behaviors (Fernandes et al. 2014). Consequently, the National Endowment for Financial Education and others have called for greater insight into how financial knowledge decays after financial education and what factors mitigate the decay.

Recent studies found that financial education has positive effects on consumer financial behavior and welfare, from improving financial capability (Xiao & O’Neill 2016; Xiao & Porto 2017) to better credit choices (Walstad et al. 2017), reducing outstanding debt (Brown et al 2016) and positive impacts on family members (Bruhn et al. 2016). A model of financial literacy predicts that consumers seek financial knowledge until marginal cost equals to marginal benefit (Lusardi & Mitchell, 2014). While more knowledge carries benefits by reducing uncertainty around financial choices (Stigler 1961) and promoting beneficial finance practices (Hilgert et al. 2003), recipients of financial education may also benefit from higher financial confidence as part of an overall ability to implement healthy financial behaviors.

This paper reports results from a randomized field experiment assigning young adults to an externally-validated financial education

curriculum, and tracking a cohort for 6 months. We find evidence that following financial education, financial confidence (i.e. subjective knowledge, or how much you think you know) persists longer than objective financial knowledge (how much you are assessed to know) and beneficial financial behavioral intentions.

A panel of 256 young adults enrolled in a northeastern research university completed five surveys over a 6-month period in 2017. 161 (63%) were randomly selected to complete a commonly used 2.5-hour online course providing financial education training. After the intake survey, we collect information from the participants at five other times: at baseline, immediately after financial education, one week post-intervention, three months post-intervention, and six months post-intervention. At each checkpoint, we measured (1) objective financial knowledge using a variety of questions used in previous research such as by Lusardi & Mitchell (2008); (2) financial confidence using five items measuring participants' perception of their financial knowledge; and (3) intentions to adopt desirable financial behaviors (Dew & Xiao, 2011).

We found little evidence that the financial education intervention increased financial knowledge despite slightly higher score results to the treatment group. Our measurement of knowledge was somewhat noisy and not specifically built to test the curriculum, which might help explain the lack of significant results. However, we found a strong and lasting effect of the curriculum to financial confidence. Financial confidence increased after 1 week ( $p = 0.01$ ) and persisted through three months ( $p < 0.01$ ). Even six months after the financial education intervention, those in the treatment group reported a level of financial confidence roughly a third of a standard deviation higher than the control group ( $p = 0.01$ ).

Behavioral intentions are higher in the treatment group by half of a standard deviation after the curriculum ( $p < 0.01$ ), which extended through the 1-week survey ( $p < 0.01$ ), but showed no difference at 3-months ( $p > 0.20$ ) or at the six-month mark. The results indicate that following financial education, subjective financial knowledge persisted longer than behavioral intentions. The initial effect of the intervention on financial behavioral intentions was robust in the very short run – one week after intervention - potentially hinting for the need of regular injections of financial knowledge to help consumer sustain healthy financial habits.

Financial knowledge, financial confidence, and behavioral intentions were all equivalent at baseline ( $p > 0.3$ ). The financial education intervention was successful in increasing behavioral intentions and financial confidence, at the short and long run, respectively. Taken together, while financial knowledge and behavioral intentions returned to baseline levels one week after financial education, financial education has a positive effect on financial confidence, which extends six-months post-intervention. These results are robust when we review different student subgroups by gender, previous exposure to financial education, and being part of a disadvantaged population.

In a second study, we recruited 491 young adult (18-26) participants online in a study involving experimental manipulations of financial confidence and knowledge. We pretested 4 possible knowledge manipulations and 9 confidence manipulations adapted from Wan and Rucker (2012). The main study asked participants to recall 2 financial experiences that made them feel highly confident and certain (high confidence), happy and excited (neutral), or doubtful and uncertain (low confidence). Participants also either completed a financial education curriculum about emergency savings (a 6-minute video and some comprehension questions) or watched an unrelated video, prior to answering questions about intentions to save for emergencies (a 4-item scale). We expected that both the confidence and knowledge manipulations would together influence behavioral

intentions. We found that only confidence influenced behavioral intentions, in particular, that low confidence reduced intentions to save for emergencies, compared to neutral and high confidence conditions ( $p = 0.05$ ). We further found that the education curriculum we expected would manipulate knowledge appeared to more strongly influence confidence, highlighting the practical relevance of considering confidence in the consumer knowledge acquisition process.

The present research provides insight into how financial confidence, knowledge and behavioral intentions evolve following education interventions. While the training had a negligible effect on our measurements of financial knowledge, financial confidence was the clear beneficiary of even a small dosage of financial education. Likewise, the manipulation of financial knowledge from our second study also revealed a positive effect on financial confidence. The impact of financial education on behavioral intentions appears to be more complex: the improvements in financial decision-making are short-lived and dependent upon financial confidence. Altogether, among contemporary young adults, there appears to be a lasting impact of financial education on financial confidence, which contributes to financial behavioral intentions.

### **From Novice to Know-it-All: How Google-Based Financial Learning Affects Financial Confidence and Decisions**

#### **EXTENDED ABSTRACT**

Online search has become an automatic response to the experience of doubt (Sparrow & Chatman, 2013). Because of this, consumers often resort to Google when preparing for decisions in domains where they are not experts. This tendency is particularly notable in the context of financial decisions: since the early 2000s, the Internet is the most popular source of investing-related information, surpassing written material and financial planners (Federal Reserve, 2016). What has been largely overlooked in this context is that fundamental characteristics of Internet search influence memory and self-perceptions in ways that other forms of information access do not. This phenomenon may carry important implications for financial behaviors.

One such effect is Google-induced overconfidence: people misattribute knowledge found through Google to themselves, eliciting a false sense of already knowing information found online. This phenomenon inflates people's confidence in their own cognitive skills (Ward, 2013). We propose that using Google to access basic investing-related information engenders a false sense of mastery in the domain of finance, and demonstrate consequences of this illusory expertise when people make financial decisions. Experiment 1 establishes the phenomenon by revealing positive effects of Google-based financial learning on self-report (Financial Self-Confidence scale - FSC) and behavioral (bets on one's own financial performance) measures of confidence. Experiment 2 shows downstream consequences: Google-induced financial confidence reduces willingness to accept expert advice and increases preference for riskier investments. These effects are moderated by prior financial expertise.

Prior expertise was measured in the beginning of the experiments in an allegedly unrelated questionnaire. Then, participants (MTurk) were randomly assigned to either access financial information via Internet search (Online Search condition) or receive the same information without engaging in Internet search (No Search condition). All participants were prompted with the same investing-related questions (e.g., "What is a 'Bear Market'?"). The Online Search group were instructed to answer these questions using Google. The No Search group were provided with identical information (answers taken directly from Google's "Answer Box"), but without engaging

in search. Thus, both groups were exposed to the same information, but only those in the Online Search condition used Google.

In Experiment 1, after accessing/receiving the financial information, half of the participants ( $N = 246$ ,  $N_{\text{full sample}} = 521$ ) were randomly selected to complete the 5-item Financial Self-Confidence scale (FSC, sample item: "I am confident in my own ability to recognize a good financial investment,"  $\alpha = .91$ ). Next, all participants received instructions about an upcoming investment task for which they could receive a performance-based reward. Participants then bet on their own performance by balancing how much of the reward would be a fixed value and how much would be performance-based (Fox & Tversky, 1995). After completing the investment task and before knowing their reward, they could change their bet.

FSC was higher in the Online Search condition ( $M = 3.86$ ) than in the No Search condition ( $M = 3.45$ ),  $F(1, 244) = 5.57$ ,  $p = .019$ . Online Search participants also bet more on their performance ( $M = 37.38$ ) than No Search participants ( $M = 34.11$ ),  $F(1, 519) = 10.28$ ,  $p = .001$ . A follow-up analysis revealed that the effect of Online Search on betting was driven by participants with little prior financial expertise,  $F(1, 516) = 4.53$ ,  $p = .034$ . For those with minimal prior investing experience, online search increased bet amounts ( $M_{\text{No Search}} = 32.71$ ,  $M_{\text{Online Search}} = 37.36$ ;  $p < .001$ ); for those with more prior experience, it did not ( $M_{\text{No Search}} = 37.39$ ,  $M_{\text{Online Search}} = 37.43$ ;  $p = .981$ ). Actual performance on the investing task did not differ as a result of search ( $p = .169$ ), suggesting that these differences in betting behavior reflect artificially inflated confidence—not improved skill. This inflated confidence persisted after the investment task, as participants were unlikely to change their bets regardless of the experimental group ( $p = .564$ ).

In Experiment 2, the investment task was a simulation in which participants ( $N = 187$ ) opened a new retirement account in a system resembling services like Betterment. They had to allocate an initial amount of \$10,000 between stocks and bonds. The instructions explicitly said that more money on stocks (bonds) is considered a more aggressive (conservative) strategy, alluding to the idea that stocks are a riskier investment. Before choosing how to allocate the money, participants received from the system a recommendation of how much they should invest on stocks based on their age along with a range around the recommended percentage above which their allocation would be too aggressive and below which it would be too conservative.

Only the Online Search group significantly deviated from the recommended allocation,  $F(1, 183) = 16.11$ ,  $p < .001$ . Importantly, this deviation gravitated towards more aggressive (riskier) allocation choices: on average, Online Search participants allocated 14.16% more on stocks than recommended. This allocation on was not statistically different from the bound above which their allocation choice was considered aggressive. In contrast, the average allocation of the No Search group was not different from the recommended allocation. The online search effect on the difference between recommended and actual allocation was moderated by prior financial expertise. Significant deviations from recommendation towards an aggressive investment strategy in the Online Search group were driven by people with low prior expertise in investing,  $F(1, 183) = 4.25$ ,  $p = .041$ .

The Internet makes knowledge more accessible, and accessibility certainly has good implications for financial literacy. For instance, people can now easily access basic training and expert guidance on specialized online platforms. However, too often consumers rely on quick access to target information through Google and this tendency might have less desirable implications for financial behavior. As this research suggests, the use of Google to self-educate oneself in the financial domain unleashes the shortcomings of overconfidence in

decision settings, including too much reliance on one's own performance (Campbell, Goodie, & Foster, 2004) and risky investment choices (Hadar, Sood, & Fox, 2013). Research on these effects can help understand how to benefit from the ubiquitous access to information while avoiding its cognitive traps.

## Product Complexity as a Barrier to Consumer Financial Decision-Making

### EXTENDED ABSTRACT

Economists recommend that most consumers should annuitize a substantial portion of their retirement savings, though purchase rates are very low (Benartzi, Previtro, and Thaler 2011). One potential cause of this "annuity paradox" may be the difficulty associated with attending to and comprehending the details of annuity products (Brown, Kapteyn, Luttmmer, and Mitchell 2017). In the face of complexity, consumers may disengage without fully considering the beneficial attributes of annuity products. This problem may be exacerbated in today's information-rich environment, where consumers have many draws on their time and attention. In the present set of experiments, we investigate how the complexity of an annuity product affects cognitive and behavioral outcomes.

Experiment 1 uses eye-tracking to examine how attention to key information embedded in annuity brochures (e.g., payout information, disclosures about the financial health of the offering firm) is affected by increased complexity. It is well established that as information is more demanding to process (i.e., increased complexity), individuals will devote increased resources to processing to the extent that it is beneficial. Specifically, when cognitive demand gets to be too great, individuals are likely to shift resources to some secondary goal or task (Kurzban, Duckworth, Kable, & Myers, 2013). This shift would then likely lead to missing important information embedded in the complex material. To test this notion, we created a "distraction" paradigm in which individuals read financial products presented on the right side of a screen while distracting websites rotated on the left side of the screen. The paradigm was meant to mimic real decision-making where consumers often have the option to shift attention from a focal decision to some distraction. We manipulated the complexity of a real-world annuity brochure: a *complex* 21-page version, and a *simple* 14-page version which reduced complexity by removing and compressing information (e.g., footnotes, displaying fewer start date, etc.). Importantly, the *complex* version was the simplest real-world version of an annuity brochure that was openly available to consumers. Participants (aged 40-65 years) completed the distraction task with complexity manipulated between-subjects. We measured individuals' eye movements using a desktop eye-tracker. Results demonstrated a marginal effect of complexity on individuals' attention,  $F(1, 27) = 3.76$ ,  $p = .063$ , where less attention was paid to the annuity material with increased complexity. Furthermore, greater attention was allocated to key areas of interest (e.g., the disclosure page) in the simple relative to complex version of the annuity brochure when the disclosure was presented early rather than late,  $F(1, 27) = 10.88$ ,  $p = .003$ . Last, a "wear-out" effect was demonstrated via a within-subject regression analysis where individuals overall paid less attention over time to AOs in the complex relative to simple versions,  $b = -.02$ ,  $t(30) = 2.07$ ,  $p = .047$ . Thus, as expected, an increase in complexity led to resources (i.e., attention) being shifted away from the annuity brochure.

Experiment 2 aimed to extend the general findings of Experiment 1 by examining the effects of complexity on behavioral outcomes. We hypothesized that increased complexity of the annuity brochures would lead individuals to spend less time reviewing. Consequently,

this would be expected to lead to missing beneficial attributes, worse comprehension of the material, increased perceived effort, and have negative effects on preferences when the complex material was associated with high financial benefits. We embedded three annuity attributes in the materials that recently have been shown to be judged as beneficial by consumers: high financial strength, period-certain guarantees, and inflation protection (Shu, Zeithammer, and Payne 2016). These attributes have been shown to be valued by consumers in a highly impoverished conjoint setting. We hypothesized that consumers' preference for these attributes would not always be realized when embedded in more realistic materials, but only when the materials were sufficiently simple.

We utilized the same materials as Experiment 1, as well as an added *minimal* 5-page brochure, and *1-page reference* annuity product. Importantly, all three positive attributes only occurred for one of the annuity products (e.g., the complex material was associated with the highly beneficial annuity whereas the 1-page document did not have the beneficial attributes). Complexity (*complex, simple, and minimal*) and the location of the beneficial attributes (*complex materials, 1-page reference*) was manipulated between-subjects. All participants received the *1-page reference* in addition to one of the complexity conditions. Participants (aged 40-65 years) first read an overview of retirement products that outlined the three above attributes, followed by a self-paced review session of the annuity materials (e.g., the *complex* 21-page brochure and the *1-page reference*). Upon completion of the review portion, individuals then answered several questions regarding their preferences between the annuities, their perceived effort, and answered incentivized comprehension questions. Similar to Experiment 1, results demonstrated that decreasing complexity led to slightly more time spent reviewing the materials,  $F(2, 251) = 2.71, p = .068$ , and better performance on the comprehension questions,  $F(2, 251) = 3.22, p = .042$ . Furthermore, individuals expressed a preference for the more beneficial annuity only when the materials were less complex. However, this result only emerged in the minimal condition,  $t(82) = 3.79, p < .001$ , suggesting that large reduction in complexity are necessary to achieve any benefits on choice.

In conclusion, we demonstrate that complexity has a negative effect on consumers' behaviors when evaluating financial products. Importantly, even relatively large reductions of complexity had small effects on behaviors, causing many individuals to miss important attributes that would be beneficial if the product was purchased. These results have important implications for the design and marketing of financial product information. They suggest that companies should be dramatically reducing the complexity of their marketing materials, to the extent that they want consumers to seriously evaluate and comprehend the options. The results also contribute to our understanding of the annuity paradox and related suboptimal financial decisions where products are complex and hard to understand.

## Increasing Tax Salience Alters Investment Behavior

### EXTENDED ABSTRACT

The recent proliferation of online investment platforms allows for new opportunities to present information to investors in ways that lead to positive behavior change. In the current research, we examine the effect of providing online retail investors with real-time tax impact preview information. The tax impact preview allowed investors could see the tax impact of certain actions before committing to them, allowing them to moderate the change to avoid taxes. We find that highlighting tax consequences significantly changes investment behavior, suggesting that people were not previously incorporating

this tax information into their investment decisions. Furthermore, we provide evidence suggesting that the reaction is specific to taxes, rather than being a reaction to a generic cost. The current research contributes to literature on tax salience and tax aversion (Sussman & Olivola, 2011; see Olivola & Sussman, 2015 for a review and see Sussman & White, 2018 for a discussion of policy implications) as well as to literature examining how the display of information influences investment decisions (e.g., Bazley et al. 2017; Hartzmark & Solomon, 2017; Shaton, 2017).

Views about taxes and tax policy can influence decisions ranging from where to live and how to vote to which store to frequent and which products to purchase, and even whether and to what extent to comply with the law. Research has found that people will alter their behavior more in response to taxes than to equivalent costs, a phenomenon known as tax aversion (Sussman & Olivola, 2011).

Since taxes tend to elicit strong responses, strategically highlighting tax costs could encourage specific behaviors, even without any changes to the presence or amount of these costs. In the current research, we explore investing as a highly consequential setting in which increasing tax salience may be used as a nudge to counter suboptimal investor behaviors. Specifically, we target the behavior of excessive trading as an established bias that is correlated with significantly lower returns than the overall market (Barber & Odean, 2000; Odean, 1999).

We employ a unique data set of retail investors' behavior at Betterment, an online investment advisor, through a period when the availability of real-time tax impact preview (TImP) information was tested and released. Through this feature, investors were encouraged to view the tax impact of certain actions before committing to them. Importantly, while this feature did not change the value of the taxes, it did make taxes salient and allowed customers to moderate their changes to reduce taxes. Our data combines a 20-day window in which TImP was shown to a random subset of customers with a longer term analysis of investor behavior after the feature completed its full launch.

The experimental period allows us to test causally whether varying tax salience acts as an effective nudge. Data support the conclusion that simple provision of real-time, individualized tax information significantly reduced the likelihood of trading among retail investors. Customers in the TImP condition performed 14.5% fewer allocation changes per customer than customers in the control group ( $M_{\text{Control}} = 0.329$ , vs.  $M_{\text{TImP}} = 0.280$  changes during the experimental period;  $t(12,290) = 2.875, d = .05, p = .004$ ).

Next, we examine more than two years of data from Betterment. This analysis allows us to explore whether reactions to salient taxes are consistent with a pure cost-based account or with a tax-specific account, and provides evidence consistent with the latter. We first leverage prior research showing differential sensitivity to taxes as a function of political affiliation (e.g., Hardisty, Johnson, & Weber, 2010; Sussman & Olivola, 2011). We use data on each customer's zip code to infer likely political affiliation based on presidential vote-share in their location from recent elections. We define tax sensitivity as the extent to which an increase in the value of taxes displayed corresponds to a decrease in the likelihood of completing a trade. We find that (1) Republicans are more sensitive to taxes than are Democrats (2) Making TImP viewing mandatory (vs. optional) corresponds to a greater increase in sensitivity among Republicans than Democrats and (3) Sensitivity to tax amount changes (and subsides) after Trump is elected and Republicans take control of the White House. Finally, moving beyond political affiliation to an unrelated correlate of tax aversion, we examine whether investors react more strongly to tax information when taxes are top of mind. We use

Google search popularity for the term “tax” as a proxy for investor consideration of tax-specific costs and find that sensitivity to taxes increases as a function of tax search popularity.

We propose that online investment platforms allow for new ways of presenting information to investors that can help them make better decisions. Our data provides evidence that tax reminders can be used to leverage one bias (tax aversion) and to assist in reducing others (e.g., overtrading and disposition effects).

### SESSION OVERVIEW

Sharing is ubiquitous, and it has become an essential part of consumers' lives. The advancement of social media and smartphones has enabled consumers to share personal experiences, opinions, and resources with others at the click of a button. Facebook Messenger and WhatsApp handle 60 billion messages a day, and firms like H&M and Sephora use these apps for one-on-one real-time conversations with customers. Moreover, consumers can now share money via Venmo and Google Wallet and car rides with other customers via Uber and Lyft.

Given the prevalence of sharing, it is important to understand how it affects consumers' perceptions of and relationship with others. Prior research has shown that sharing is integral to building relationships (Min, Liu, & Kim, 2017; Reis et al., 2010; Belk, 2009). However, not all sharing is created equal; certain types of sharing are more effective at bringing people together than others. Yet we know little about what specific strategies are successful for connecting people, and which may backfire or push people apart.

In this session, we ask: *what sharing strategies do people use to facilitate relationship building?*; *what are the consequences of these sharing strategies?*; and *what factors moderate their effectiveness?* Four papers look at how different types of sharing—from jokes to gossip to goods—influence interpersonal perception and social connectedness.

The first two papers examine the positive and negative effects of sharing negative content. First, **Critcher, Jung, and O'Donnell** examine how self-deprecation, or putting oneself down in a lighthearted way, affects perceptions of the sharer. In contrary to self-deprecators' intuition that making fun of themselves signals humility and authenticity, recipients believe that self-deprecators are actually less good at both skilled and unskilled domains. Next, **Barasch, Berman, and Yoon** show how sharing negative content, in the form of gossip, can sometimes be socially connecting. Specifically, they find

that sharing negative judgments about others can increase liking and trust of the sharer, as long as the recipient agrees and the comments make the speaker seem discerning.

The next two papers look at how sharing positive content can both foster and undermine feelings of closeness. **Sezer et al.** show that sharing inside jokes can make people feel more identified and connected with their group. However, outsiders who witness inside jokes have less motivation to contribute to and interact with the group. Finally, **Wilson, Santana and Paharia** find that the method of sharing also matters. In particular, giving and receiving goods in physical (vs. digital) form can make people feel closer to each other by increasing perceived psychological ownership.

Together, these papers provide a better understanding of how sharing affects consumers' connection with others. We contribute to this topic by examining different sharing strategies (self-deprecation and jokes), the valence of shared content (gossip), and the method of sharing (physical vs. digital). This session will provide guidance for marketers on how to manage customer relationships through various methods of conversation, and will be of interest to consumer researchers studying word of mouth, social connection, and judgment and decision-making.

## **Self-Deprecation Signals Humility, but Not as Much as Self-Deprecators Assume**

### EXTENDED ABSTRACT

Firms' marketing communications, sellers' pitches, and consumers' purchases are all made with an eye to how others will view them. In various ways, they are all in the service of impression management—attempts to influence and mold how one is seen. Although some impression management efforts are fairly explicit and direct, others are more indirect or coy in their attempts to manage impressions. In fact, sometimes the impressions consumers seek to achieve through their own purchases or consumption decisions can be disrupted or even reversed once those signals become too blatant or when attention is called to them (e.g., Han, Nunes, and Dréze, 2010).

In this paper, we examine a subtle impression management signal that has received essentially no attention in the consumer behavior or psychology literatures: self-deprecation. We define self-deprecation as a statement that puts oneself down in a lighthearted way. Although we ultimately examine how self-deprecators believe their own statements are interpreted (and are actually interpreted) by others, this research is conducted against a backdrop of a rise in self-deprecation in marketing communications by Domino's, Buick, Microsoft, and others. When consumers poke fun at themselves, they presumably aim to express humility and authenticity. But what does consumers' self-deprecation actually communicate, and do self-deprecators anticipate that? After all, impression management strategies cannot be used effectively in those attempting to influence impressions don't know how they are managing them.

Our main study was conducted over two waves. In Wave 1, we recruited 183 communicators on Amazon Mechanical Turk. Communicators identified one domain they were skilled at (top 20th percentile) and one domain they were unskilled at (below average). Communicators wrote two short biographies about themselves—one about each domain—in the third person (as though someone else was writing a profile of them). They knew these would be shared with fu-

ture participants—recipients. Communicators' profiles closed with a first-person quote. Half of communicators wrote a quote that was merely descriptive, whereas half were asked to be self-deprecating. Communicators rated their own skill on each domain. They also saw a question that recipients would answer: "How good at [the domain] do you think [the communicator] perceives himself or herself to be?" Communicators guessed how recipients would respond.

In Wave 2, 234 recipients each read a random batch of 20 messages (biography + quote) sent by communicators. Recipients both indicated their own personal guess of the communicator's skill level as well as the question described earlier, their guess of how the communicators truly saw themselves. All analyses used mixed models that included random effects of communicators and recipients.

Note that by allowing communicators to generate their own content, we are prepared to make more generalized (instead of scenario-specific) claims about self-deprecation.

First, recipients assumed that self-deprecating communicators actually were more humble in their self-views,  $t(208.64) = 2.93$ ,  $p = .004$ , which held similarly across both domains,  $t < 1$ . Second, we found self-deprecation was taken at face value. Recipients believed that communicators who self-deprecated actually had less skill than communicators who didn't,  $t(214.47) = 2.85$ ,  $p = .005$ , which again emerged similarly across skilled and unskilled domains. In other words, self-deprecation did not signal a reduction in narcissism or overconfidence, but instead an understanding of one's lower ability.

Did communicators understand the signal they were sending? Self-deprecators appreciated that they were likely communicating lower self-confidence,  $t(797.24) = 4.79$ ,  $p < .001$ , but they (inaccurately) thought this signal was different for skilled and unskilled domains,  $t(4197.49) = 5.90$ ,  $p < .001$ . That is, self-deprecators knew they were sending a signal of lower self-confidence about their unskilled domain. But the significant interaction reflected that self-deprecators thought they were sending an exceptionally strong signal of lower self-confidence in their skilled domain.

Because communicators were guessing the answer to a question we the experimenters know, we can comment on communicators' insight into the signals they are sending. Self-deprecators' accurate understanding of what signal they were sending depended on the domain,  $t(4121.55) = 3.23$ ,  $p = .001$ . Those poking fun of themselves at an unskilled domain knew what they were communicating,  $t < 1$ , but those self-deprecating a domain at which they felt skilled overestimated how much this would make them come off as humble,  $t(399.95) = 3.39$ ,  $p = .001$ .

Additional analyses and scenario studies offered some insight into: 1) why self-deprecators are miscalibrated in the signal they send, and 2) whether recipients always take self-deprecation as a signal of low self-confidence. To the first point, we found when people self-deprecate about a skill they feel skilled on, this does prompt them to call into question somewhat their high self-views. That is, those randomly assigned to self-deprecate showed a reduction in their self-views on their skilled domain but not their unskilled domain,  $t(4197.98) = 3.78$ ,  $p < .001$ . After all, self-deprecating comments typically have some truth in them—a truth communicators are keenly aware of, even if they don't typically focus on it. This reduction in self-confidence partially explains why communicators overestimate self-deprecation's signal of humility. To the second point, we found that when people self-deprecate on a domain that tends to be less important to people, their self-deprecating comments are still believed, but they are not taken to reflect negative self-esteem more generally. Poking fun at one's own intelligence or appearance is assumed to reflect lower self-esteem more generally, but making fun of

one's artistic ability is taken to signal a confident person who is comfortable laughing at themselves about things few find that important.

Although our empirical efforts have focused on the communicative signals consumers send to each other, our ongoing efforts examine how firms' self-deprecation is interpreted by consumers. That is, firms often assume that self-deprecation signals authenticity. But our previous research and preliminary findings suggest that such authenticity comes at the cost of self-deprecation being interpreted quite literally. Poking fun at oneself is not necessarily a way to diffuse a shortcoming, but instead can reinforce that shortcoming as real.

### Speaking ill of others: When negatively-valenced gossip fosters social connection

#### EXTENDED ABSTRACT

Gossip holds a strong negative stigma in almost every culture (e.g., Foster, 2004), yet it still seems an inevitable part of life. If speaking ill of others makes a bad impression, why is it so common? Previous literature has highlighted the social-functional role of gossip in reinforcing cultural norms (Baumeister, Zhang, & Vohs, 2004). Gossip can also deter selfish behaviors while fostering cooperation (Piazza & Bering, 2008). However, little is known about how gossip affects perceptions of the speaker on an individual level. The current research aims to investigate when and how sharing gossip can foster interpersonal closeness.

Research on self-presentation shows, people are motivated to present themselves in a positive light in order to promote a favorable impression onto others (Goffman, 1959). However, this makes it difficult to discover the true nature of others, especially their most negative characteristics. In this regard, sharing negative (vs. positive) character judgments about another person may make gossipers seem more discerning and observant, because negative traits are not as readily observable as positive traits.

Sharing negative judgments about others also has costs, such as potential harm to the target's and the gossipers' reputation. In this sense, spreading negative judgments is risky; it might make one seem discerning, but petty and impolite as well (Bergmann, 1993; Gilmore, 1978). We propose that because sharing puts a gossipers in a vulnerable position, those who risk these potential negative consequences can signal the closeness of the gossipers-recipient relationship by sharing negative judgments of others, thereby increasing liking and trust of the gossipers. In contrast, speaking positively about others is a safer strategy, but without as many potential benefits. While saying positive things about others may signal politeness, it is less likely to provide the recipient with a discerning observation about the character of others.

We further expect the benefits of sharing negatively judgments of others will only occur when a gossipers speaks directly to a recipient, and not from the vantage point of a third party, or if a gossipers is sharing indiscriminately with a large group. Finally, because the benefits of gossip depend on a judgment seeming discerning, we also expect that gossip will backfire if the recipient does not agree with the character evaluation, ruining the gossipers' relationship with that individual.

In **Study 1** ( $N=76$ ), participants were asked to recall a time when they made an observation about someone that was not readily apparent (i.e., it was discerning). Then, they evaluated whether the observation reflected positive or negative traits, qualities, or characteristics about the person ( $-50 = \textit{extremely negative}$ ,  $50 = \textit{extremely positive}$ ). As expected, the results revealed that a majority of discerning observations about others were negative in valence (64.5%;

=6.34,  $p=.012$ ), and that the average evaluation was significantly negative ( $M=-7.46$ ,  $SD=23.64$ ;  $t(75)=-2.75$ ,  $p=.007$ ).

**Study 2** ( $N=300$ ) tested the hypothesis that sharing negative judgments about others can foster liking and trust using a 2 (statement valence: positive vs. negative)  $\times$  2 (target trait: obvious vs. less-obvious) between-subject design. All participants were told to imagine that they started a new job at a company, and that they worked briefly with a co-worker named Peter who held one positive trait (e.g., intelligence) and one negative trait (e.g., self-centeredness). In addition, one of these traits was presented as obvious and one was presented as less-obvious. Participants then imagined that another co-worker, George, made either a positive or a negative statement about Peter: "You know, I really think Peter is intelligent [self-centered]." After reading the scenario, participants rated George on a liking scale (5-items,  $\alpha=.91$ ) and an affective trust scale (7 items,  $\alpha=.89$ ).

An ANOVA revealed that sharing negative (vs. positive) judgments increased liking for George ( $M_{\text{negative}}=4.46$ ,  $M_{\text{positive}}=3.96$ ;  $F(1,296)=13.74$ ,  $p<.001$ ). Moreover, a two-way interaction suggests that while George was liked when he shared the negative judgment regardless of the how obvious the trait was ( $M_{\text{obvious}}=4.44$ ,  $M_{\text{less-obvious}}=4.49$ ;  $F(1,296)<1$ ), people liked George more when his positive remark was less-obvious than when it was obvious ( $M_{\text{less-obvious}}=4.21$ ,  $M_{\text{obvious}}=3.70$ ;  $F(1,296)=6.88$ ,  $p=.009$ ). This occurred even though participants clearly thought that George was less polite when he said negative things (4-items,  $\alpha=.88$ ;  $M_{\text{negative}}=4.42$  vs.  $M_{\text{positive}}=2.68$ ;  $F(1,296)=216.62$ ,  $p<.001$ ). The same pattern of results emerged for the affective trust DV.

**Study 3** ( $N=206$ ) examined whether the positive effect of sharing gossip occurs only with the recipient of the gossip, but not with a third-party. To test this, we employed a 2 (valence: positive vs. negative)  $\times$  2 (audience: self vs. other) between-subject design and used the same scenario as Study 2. Those in the self condition imagined that George told the gossip directly to *them*, whereas those in the other condition imagined George said the same statement to another co-worker. We replicated the positive effect of sharing negative judgments on liking: George was liked more when he spoke negatively than positively of Peter ( $M_{\text{negative}}=4.02$ ,  $M_{\text{positive}}=3.59$ ;  $F(1,202)=8.81$ ,  $p=.003$ ). Also, as predicted, the results revealed a significant valence  $\times$  audience interaction on liking ( $F(1,202)=6.05$ ,  $p=.015$ ). Specifically, participants only liked George more when he said the negative (vs. positive) comments to them ( $M_{\text{negative}}=4.23$ ,  $M_{\text{positive}}=3.44$ ;  $F(1,202)=14.78$ ,  $p<.001$ ), but not when he said them to another colleague ( $M_{\text{negative}}=3.81$ ,  $M_{\text{positive}}=3.74$ ;  $F(1,202)<1$ ). We found the same pattern for the affective trust measures ( $F(1,202)=8.32$ ,  $p=.004$ ).

**Study 4** ( $N=408$ ) tested the moderating role of agreement by manipulating whether the gossiper's remark was consistent with the recipient's perception. Of course, participants liked and trusted the gossiper more when they agreed with his remark. Moreover, the results revealed that our previous results depend on agreement, such that negative statements are punished more harshly than positive statements when the recipient disagrees with them.

These results provide key insight into the type of information that is most likely to spread via WOM across a wide range of business contexts. For example, consumers may choose to gossip about celebrities, CEOs, or politicians in order to form closer bonds with others. Moreover, public personas who present themselves in an overly positive light may be particularly subject to negative WOM as the public gets insight into their true underlying character.

## Inside Jokes: Humor as social exclusion

### EXTENDED ABSTRACT

Humor is central to social life (Gulas & Weinberger, 2006). From intelligence to friendliness, to emotional stability and imagination, a wide range of positive attributes are associated with being funny (Greengross & Miller 2011; Howrigan & MacDonald 2008; Lippa 2007; Martin, 2002). The ability to use humor effectively is a crucial skill, because a good sense of humor offers myriad interpersonal benefits. Effective jokes make it easier to entertain others and have them accept criticism (Dews, Kaplan & Winner, 1995; Fraley & Aaron, 2004; Madden & Weinberger, 1982; Schindler & Bickart, 2012; Schmidt, 2002), enhance liking, status, and perceived leadership effectiveness (Bitterly, Brooks & Schweitzer, 2017; Eisend, 2009; Yam, Christian, Wei, Liao & Nai, 2017), and even facilitate conflict resolution (Fraley & Aron, 2004). In short, humor often fosters social cohesion.

At the same time, however, the consequences of humor depend on the psychological and emotional reaction of the targets of those jokes, and critically on their appraisal of the humor attempt as funny – or not (Cooper, 2008; Warren & McGraw, 2016). While humor typically binds people together, little is known about the effects of humor that is intended to divide, as with humor attempts that require prior knowledge that is available only to certain members of a social group: inside jokes. In the current research, we investigate how an inside joke influences group dynamics, compared to a public joke: a joke that is understood by all members of the group.

An extensive body of research on social exclusion has shown that ostracism threatens people's need for belongings, control, self-esteem and meaning (Williams, 2009), and influences decision-making (Jones & Kelly, 2010). Because social connection is such a fundamental aspect of social life, even minimal forms of exclusion may lead to negative psychological consequences. For example, people feel threat even when they do not receive a ball during a virtual ball throwing game with strangers (Williams, Cheung, & Choi, 2000), when they feel "out of the loop" on pop culture, by being excluded from a domain of information shared commonly by others (Iannone, Kelly, & Williams, 2016), or even when their presence is not acknowledged by eye contact or civil attention from strangers (Wesselsmann, Cardoso, Slater, & Williams, 2012).

Building on past research on humor and social exclusion, we conceptualize inside jokes as humor attempts that create fault-lines within groups. We propose that individuals who witness an inside joke as an outsider would identify with their groups to a lesser extent, contribute to their groups less, and be less willing to interact with their group members on subsequent tasks. Moreover, we predicted that feelings of social exclusion plays a critical mediating role, such that perceived social exclusion drives lower group identification and negative group dynamics. We suggest that although humor is integral to interpersonal relationships, some forms of humor such as inside jokes may actually backfire and hurt social connection.

In **Study 1** ( $N = 208$ ), we randomly assigned participants to either the *joker* or *outsider* conditions in a between-subjects design, asking participants whether they shared an inside joke, or witness someone else share an inside joke in their daily lives. As expected, inside jokes are pervasive, with 74% of participants recalling a time when they shared an inside joke (telling a joke when someone who they knew would not get the joke was present) and 76.9% recalling a time when they witnessed someone sharing an inside joke with another person. The topics of these jokes ranged from boss nicknames to jokes about in-laws to high-school friends. Most importantly, the

joke tellers overestimated how much the outsider would enjoy the experience.

In **Study 2** ( $N=198$ ), we randomly assigned participants to one of two between-subjects conditions: *Inside Joke* and *Public Joke*. Participants in both conditions watched a short stand-up comedy clip, and then imagined that they were having a conversation with their coworkers. We showed participants in the *public joke condition* a dialogue in which employees referred to the same joke in the video that they just watched. In contrast, we showed participants in the *inside joke condition* a dialogue in which employees shared an inside joke that was not related to the video they watched. Participants in the *inside joke condition* identified with the other employees less than did participants in the *public joke condition*. Participants in the *inside joke condition* felt significantly more excluded than participants in the *public joke condition*. Social exclusion mediated the relationship between inside jokes and group identification. Including social exclusion in the model significantly reduced the effect of inside jokes, and social exclusion was a significant predictor of group identification.

In **Study 3** ( $N=202$ ), we asked participants to watch three funny videos and then randomly assigned them to either *Insider* or *Outsider* conditions in which they interacted with two other confederates who referred to a joke that they either watched or did not watch. We found that participants identified with their groups to a lesser extent, contributed to their groups less in a collective brainstorming task, and were less likely to choose the same group members for subsequent tasks when they were an outsider to the joke.

We contribute to the humor and social exclusion literatures by identifying a distinct form of humor: inside jokes. We find that those who share inside jokes underestimate how negative the experience is for the outsider, and that those outsiders feel socially excluded, less motivated to help the group, and more motivated to leave it. In addition being a tool for social cohesion, humor can also be used as a form of social exclusion.

### Give Me Something of Yours: The Downside of Digital (vs. Physical) Exchanges

#### EXTENDED ABSTRACT

Consumers can now give and receive many goods in digital form that could once only be shared in physical form (e.g. money, books, movies). While the increased ease and convenience of exchanging digital goods is in many ways beneficial, we show that it also comes at a cost. In particular, we demonstrate that exchanging digital (vs. physical) goods reduces consumers' feelings of interpersonal closeness to those with whom they exchange the goods. We demonstrate that this effect is driven by perceived psychological ownership and rule out alternative explanations including pain of payment, ease and convenience of payment, and social emotions.

Existing work demonstrates that consumers feel greater psychological ownership over physical versus digital goods, a phenomenon referred to as the "mere-ownership effect" (Atasoy and Morewedge 2017). Accordingly, we predict that when consumers give and receive goods, the mere-ownership effect will lead consumers to also feel more like they are giving something of theirs or receiving something of the other person's when goods are in the physical versus digital form. As a result, consumers will feel interpersonally closer to others when they give or receive physical (vs. digital) goods.

In experiment 1a, 401 participants from MTurk imagined they owed someone \$35 and they either paid that person back in cash or via digital payment application. After, participants rated their perceived closeness to and comfort with the person they paid, which we

averaged to create an index of interpersonal closeness ( $\alpha = .89$ ). An independent t-test showed that participants felt significantly closer to the other person when they gave them money in the form of physical cash ( $M = 5.34$ ) compared to a digital payment ( $M = 4.83$ ,  $t(399) = 3.76$ ,  $p < .01$ ).

We replicate the results of experiment 1a in experiment 1b from the receivers' perspective and across varying amounts of money. Participants ( $N = 403$ ) from MTurk imagined they went on a trip with a friend and they either paid for an activity during the trip for both their friend and themselves or they paid for the flights and hotel for both their friend and themselves, and so their friend owed them either \$25 (low amount) or \$520 (high amount). Participants then imagined their friend paid them back via physical cash or digital payment before completing the perceived interpersonal closeness index. Results of a multiple ANOVA did not indicate a significant main effect of payment amount or an interaction of payment amount and form on any of the DVs. As such, collapsing across payment amount, a t-test indicates that participants felt significantly closer to their friend when their friend paid them back with physical ( $M = 6.38$ ) versus digital money ( $M = 5.97$ ,  $t(401) = 3.87$ ,  $p < .01$ ).

In experiment 2, 203 participants from MTurk imagined they went to dinner with a friend and they paid the bill, but their friend paid them back for their half either via physical cash or digital payment application. Participants then completed the interpersonal closeness questions and an index ( $\alpha = .90$ ) of two items measuring perceived other psychological ownership. Participants also indicated the perceived pain, ease, and convenience of their friend's payment. Results from t-tests indicate that participants felt significantly closer to their friend when they were paid back in physical ( $M = 5.91$ ) versus digital form ( $M = 5.53$ ,  $t(201) = 2.63$ ,  $p < .01$ ) and they perceived their friend as having higher ownership over the physical ( $M = 6.32$ ) versus digital money ( $M = 5.53$ ,  $t(201) = 27.64$ ,  $p < .01$ ). Further, a mediation analysis shows the effect of form of money on perceived interpersonal closeness is fully and significantly mediated by perceived other ownership over the money ( $\beta = -.49$ , 95% confidence intervals do not include zero). Importantly, while form of the payment significantly affected perceptions of pain, ease, and convenience as expected, unlike perceived ownership, none of these measures significantly mediated the effect of form on perceived closeness.

We extend our effects to a non-monetary domain (i.e. books) in experiment 3. We asked 198 participants to imagine a coworker lent them a book in physical or digital, e-book form. Participants then indicated how close they felt to their coworker and their perception of their coworker's ownership over the book. Participants felt significantly closer to their coworker when they were lent a physical ( $M = 5.80$ ) versus digital book ( $M = 5.49$ ,  $t(196) = 2.25$ ,  $p < .01$ ) and they perceived their coworker had higher ownership over the physical ( $M = 6.20$ ) versus digital book ( $M = 4.76$ ,  $t(196) = 8.56$ ,  $p < .01$ ). Further, perceived ownership fully and significantly mediated the effect of form of the book on perceived closeness ( $\beta = -.56$ , 95% confidence intervals do not include zero). Of note, we also asked participants to rate their feelings on a set of social emotions (e.g. pride, thankfulness, embarrassment), and there were no significant effects.

Finally, in experiment 4, we manipulated both form and ownership to demonstrate further evidence for our proposed mechanism. We asked 400 participants from MTurk to imagine their coworker gave them tickets to an event. Participants imagined their coworker gave them the tickets in physical form or over email, and said that they actually bought these tickets a long time ago and can't use them (high ownership) or they were given these tickets earlier that day and can't use them (low ownership). Participants then indicated how close they felt to their coworker. T-tests indicate that participants

felt significantly closer to their coworker when they were given the tickets in physical ( $M = 6.03$ ) versus digital form ( $M = 5.84$ ,  $F(1, 399)$ ,  $p = .04$ ) and when the high ownership ( $M = 5.83$ ) versus low ownership condition ( $M = 6.03$ ,  $F(1, 399)$ ,  $p = .03$ ). There were no significant interactions.

Across five studies, we show that giving and receiving physical (vs. digital) goods enhances feelings of interpersonal closeness as a result of perceived psychological ownership. We rule out alternative mechanisms for our effects such as pain, ease, and convenience of the exchange and social emotions.

## SESSION OVERVIEW

Advances in digital technologies are transforming the way consumers connect with others and with machines. Recent development in crowdfunding and cryptocurrencies allow us to easily share resources. Similarly, search engines provide us with easy access to information. These technologies facilitate the sharing of information and resources among consumers. However, emerging technologies achieve more than connecting consumers together – they connect consumers with machines. Consumers increasingly interact with machines, from a connected network of devices to online chatbots. In short, technological innovations create an ever-more interconnected world.

Nonetheless, despite the transformational impact on everyday consumption of recent technological progress, we know surprisingly little about the interaction between consumers and technology. For instance, does interaction with machines shape consumption experience? Does interaction with others using these technologies facilitate the sharing of information and resources? If these technologies do facilitate information sharing, do they improve the quality of judgement consumers make?

This special session brings together papers spanning different aspects of emerging technological innovations to showcase this exciting research domain. The papers feature research on crowdfunding and cryptocurrencies, search engines, the Internet of Things, and chatbots. This special session will contribute to the consumer behavior literature by providing timely insights into the value of technology. It complements the literature on the consumption experience of technological products. Previous research shows that interaction with technological products can create both positive and negative experiences (Etkin 2016; Mick and Fournier 1998; Wilcox and Stephen 2013). This special session complements this research stream to present these experiences from different perspectives.

Given the lack of research on these new technologies, new theory is needed in order to define foundational constructs and processes and provide direction for future research. The overarching goal of the special session is to understand how interaction with technology shapes consumption experience. In particular, these papers aim to provide insights into how technology connects consumers with oth-

ers and with machines. This special session starts with a review paper on how technological innovations are transforming the way we share resources and information. The first paper “Economic Tremors and Earthquakes: Sharing, The Sharing Economy, Crowdfunding, Cryptocurrencies, and DAOs” discusses how new digital phenomena, such as crowdfunding, cryptocurrencies, and Distributed Autonomous Organizations, are promising to be seen as major tremors for future consumption and economies. The second paper “Searching for the Tree and Missing the Forest: How Broadening Search Promotes Belief Updating” investigates empirically how consumers’ belief updating is constrained by the search terms they use on search engines. The third paper “A Computational Social Science Framework for Visualizing the Possibility Space of Consumer-Object Assemblages from IoT Interaction Data” develops a computational science approach for understanding consumer experience from Internet of Things interactions. The final paper “Machine Talk: How Conversational Chatbots Promote Brand Intimacy and Influence Consumer Choice” empirically examines how interaction with conversational chatbots can impact consumers’ brand perceptions and purchase decisions. Together, these papers will advance our understanding of the technological trends in the marketplace and their significance. The session would be particularly of interest to researchers interested in technology, computer network, and experiential consumption.

## Economic Tremors and Earthquakes: Sharing, The Sharing Economy, Crowdfunding, Cryptocurrencies, and DAOs”

### EXTENDED ABSTRACT

Earthquakes and tremors sometimes jolt us from our business-as-usual complacency. Likewise, certain digitally-facilitated phenomena promise to shake up our economic landscape. We are beginning to appreciate the tremendous economic and social impact of social media, online selling, and digital giants like Google, Amazon, Apple, and Facebook. But the internet has also facilitated challenges to the ways our economies work. They offer ways that we can acquire goods without purchasing or making them, acquire funds without banks or venture capitalists, buy things without state-backed currencies or financial intermediaries, and run corporations without managers or employees. These changes offer potentially foundational changes in the ways we have come to assume that an economy must operate.

Sharing is as old as humankind, but it has been aided by the internet. We can set up online neighborhood clearinghouses to share tools, toys, games, and clothes our children have outgrown. We can take the danger out of hitchhiking and facilitate carpooling through online informal ride-sharing. Cities offer free access to bikes and thereby reduce traffic congestion. Through Couchsurfing we can offer and find free lodging in others’ homes around the globe. And we can share opinions with unseen others about the best restaurants, service people, travel destinations, movies, music, and much more.

While Napster is no longer a way to freely share music and film files online, a number of for-profit alternatives have arisen to acquire such files for a fee or to stream them to our devices without our ever owning or possessing them. While the music and movie industries did not respond quickly or well to sharing, commercial sharing has sprung up via iTunes, Spotify, Hulu, Netflix, and others. Services such as Airbnb, Zipcar, Uber, and Lyft offer short-term housing, cars,

and rides. The automobile industry is becoming involved in making cars and rides available without buying a car or using public transit. German auto makers like Mercedes, Audi, and BMW are prominent among these companies, but French and American car makers have also started or acquired car and ride sharing services. Self-driving cars promise to further shake-up these services.

Like non-profit neighborhood sharing, crowdfunding initially started as a way to crowdsource needed resources, but in this case money was what was sought. Kickstarter began following the 2008 financial meltdown and focused on raising money for artists and creative projects. While initially crowdfunded creative projects like music albums and films raised money by promising copies of the end product and merchandise such as t-shirts, crowdfunding has grown and proliferated into a variety of forms and areas of application. Popular projects involving products have included the Pebble smart watch, Villy glow-in-the dark bicycles, and Oculus Rift VR goggles (subsequently acquired by Google for \$2 billion). In these cases, part of the incentive for contributors was to receive the product before others (termed reward-based crowdfunding). This is similar to advance pre-production subscriptions for a new product as Gutenberg's did before printing of the world's first Bibles. Villy bicycles didn't need the money, but used crowdfunding to gauge market demand. In other cases, the contribution to crowdfunded projects is more of a donation. Crowdfunding has been used to raise money for college tuition, medical costs, funeral and memorial expenses, amateur sports team equipment and transportation, scientific studies, school equipment, wilderness preservation, political campaigns, and many other non-profit causes. Civic crowdfunding aids city services and building. This too is an old model and was used to secure funds to build the base for the Statue of Liberty. In the US, after the JOBS Act of 2012, equity crowdfunding became legal and entailed more of an investment model with financial returns expected. Equity crowdfunding is an alternative to entrepreneurs seeking venture capital funding. Within Islamic sharia finance the model is one of risk-sharing rather than investment. And debt-based crowdfunding relies on peer-to-peer (P2P) lending to pooled applicants who bypass banks and other corporate lending institutions.

Crypto-currencies are another way to bypass the banking system using blockchain technology to transfer funds and keep a shared online ledger of transactions through computers around the world. Prominent cryptocurrencies include Bitcoin and Ethereum. Although Bitcoin was associated with the "dark net" of illegal drug and weapon on the "Silk Road" site and has also been the currency demanded as ransom by malicious hackers, it soared in value, popularity, and price volatility in 2017, despite cases of Bitcoin exchanges being hacked and the virtual currency of Bitcoins being stolen. Cryptocurrencies allow transactions without the intermediaries of financial institutions, government guarantees, and credit card companies. It offers great promise (as well as risk) to consumers and threats to financial institutions who could be bypassed as well as governments who fear a threat to their authority and ability to manipulate the economy through fiscal policy. The institutions threatened are examining ways to use blockchain technology themselves.

Another use of blockchain technology is to enable Distributed Autonomous Organizations (DAOs), which operate like corporations, but without a human power structure or facilities for production, marketing, and distribution. Instead, such a venture, like the Ethereum-based "The Dao" which operated in 2016 and 2017, effectively crowdsources capital to begin a virtual corporation that uses "smart contracts" to outsource normal business functions. The organization has a charter and mandate and could conceivably share revenues with many crowdsourced funders or a few who start such a

virtual company. Imagine a super version of Uber or Lyft using autonomous vehicles, 24-7 hours of operation, lower costs (no human drivers or payment and software intermediaries), and excellent service to take over this industry and others. But The DAO shut down in 2017 after hackers stole several million dollar worth of Etherium currency and the US Securities and Exchange Commission initiated investigations.

I will discuss the degree to which each of these concepts and technologies should be seen as tremors or major earthquakes for future economies and consumption. While prediction can be hazardous, the impact of these developments is being felt now and will continue to shake things up in months and years ahead.

### Searching for the Tree and Missing the Forest: How Broadening Search Promotes Belief Updating"

#### EXTENDED ABSTRACT

The use of search engines has revolutionized information search. Consumers increasingly rely on search engines to answer their questions across different domains, from exploring whether a medicine is safe for consumption, whether to buy a particular stock, to whether an election candidate is corrupt. However, previous research suggests that search engines provide narrow results and over-represent confirming evidence (Kayhan 2015; White 2013). We propose that people fail to sufficiently take into account the limitations of their search terms. As a result, in seven studies, we demonstrate that people's inferences are biased by their search terms, with implications for choices. Additionally, we show that people believe that search can bias inferences when prompted to consider the possibility, but do not sufficiently or spontaneously correct for this bias.

Study 1 tested whether people's initial attitudes influenced the search terms they generated, with implications for inferences. 201 MTurkers were first asked to rate their initial attitudes towards caffeine, and then asked to generate a search term to learn about the effects of caffeine. Half of the participants were randomly assigned to conduct a Google search using the spontaneous search terms they had just generated, while the other half were asked to use a neutral search term ("caffeine health benefits and risks") instead. Then they were asked to spend 5 minutes to look briefly at the search results on the first page, click on the links that seem informative and write a short summary on what they found on the topic of the effects of caffeine based on their information search. All participants uploaded a screenshot of their search.

Afterwards, participants indicated how they thought caffeine affects the body. Initial attitudes were more strongly correlated with final attitudes for participants in the spontaneous search condition ( $r=.67, p<.001$ ) than those in the assigned neutral search condition ( $r=.31, p<.001$ ), indicating that participants were more likely to retain their initial judgements when they used self-generated search terms. The neutrality of the self-generated search terms (as rated by a separate group of 146 MTurkers) mediated the effect of initial attitudes on final attitudes towards caffeine for participants in the spontaneous search term condition ( $b=.046, 95\% CI=.0038$  to  $.13$ ), but not for participants in the assigned neutral search term condition ( $95\% CI=-.045$  to  $.024$ ), suggesting that the use of non-neutral spontaneous search terms yielded the biased inferences.

Study 2 ( $N=206$ ) examines whether external cues shift people's spontaneous search terms based, subsequently biasing inferences. Half of the participants were asked to read a commentary about the positive effects of caffeine while the other half were asked to read a similar commentary about the negative effects. Participants then generated a search term, conducted a Google search with their

## A Computational Social Science Framework for Visualizing the Possibility Space of Consumer-Object Assemblages from IoT Interaction Data

### EXTENDED ABSTRACT

The consumer Internet of Things (IoT) connects everyday objects to the Internet. The recurrent and complex interactions of these objects give rise to new consumer (and object) experiences (Hoffman and Novak 2018; Novak and Hoffman 2018). IoT interactions generate extremely large amounts of data in a variety of forms. These include sensor data, human-device interaction data, human-place interaction data, device-to-device interaction data, chatbots and other discourse data. These data are very high dimensionality and consist of often millions of ongoing interactions among objects and consumers. This makes IoT data big in two ways: 1) their size, in terms of the number of objects that are interacting with each other, and 2) their complexity, in terms of the number of attributes or features describing each object.

The challenge for consumer behavior research is how to extract meaningful insights about the kinds of consumer and object experiences that emerge from IoT interactions, along with the very identity of the multi-level assemblages that emerge from these interactions. But, the complexity of such data poses significant challenges for hypothesis testing in a predictive analytics framework. Also, conventional approaches for data reduction and visualization (e.g. PCA, MCA, and MDA) explain only a small percent of the variation and have difficulty revealing the underlying structure.

To address the challenge, we develop a computational social science approach (Lazer, et.al. 2009) for understanding consumer experience from IoT interactions. Computational social science involves the quantitative modeling of data from digital environments. While computational social science tends to focus on digital captures of social media and related behaviors, an emerging area of inquiry is the computational analysis of the massive amount of IoT interaction data for consumer behavior insight.

Our computational social science analysis of IoT data is anchored by strong theory. Our approach operationalizes the concept of an assemblage's underlying topological space of possibilities (DeLanda 2006) – the space associated with capacities from which IoT interactions and resulting consumer experience emerge (Hoffman and Novak 2018). In this paper, we focus on the structure of the possibility space that underlies individual consumer-object assemblages that have actually emerged.

We use structured IoT discourse data from the web service IFTTT. IFTTT applets are assemblages that combine the capacity of one component to affect (“if this” trigger) with the capacity of another component to be affected (“then that” action). The realized possibility space is operationalized as the set of unique IFTTT applets that have been created by IFTTT users. Between 2011-2016, a total of 331,391 IFTTT applets have been published by users and made available for others to use. Of these published applets, 20,675 comprise the possibility space of unique combinations of a set of four categorical variables representing the trigger channel (Amazon Alexa, Fitbit), trigger event (say a phrase, goal achieved), action channel (Philips Hue, Nest), and action event (turn on lights, lower temperature). The 20,675 unique published applets use 347 different trigger channels using 1110 different trigger events, and 297 different action channels using 591 different action events.

Our approach, which uses assemblage theory concepts to guide decisions about pre-processing, model selection and interpretation. In the first stage, we use a natural language processing (NLP) approach to uncover meaning in the “if-then” applets by training shal-

search term and rated their attitudes towards caffeine as in Study 1. Participants in the positive commentary condition held more positive attitudes towards caffeine after search than those in the negative commentary condition ( $M_{\text{positive}}=4.49$  vs.  $M_{\text{negative}}=3.68$ ;  $t(204)=3.67$ ,  $p<.001$ ). The neutrality of the keywords (rated by a separate sample of 148 MTurkers) mediated the effect of condition on attitudes towards caffeine ( $b=.23$ , 95% CI=.05 to .53).

In Study 3 ( $N=248$ ), participants were assigned either a neutral search term (“caffeine health benefits and risks”), a negative search term (“caffeine health risks”) or a positive search term (“caffeine health benefits”) for their Google search. Participants who used the positive search term to conduct the google search held more positive attitudes towards caffeine post-search than those who used the neutral search term ( $M_{\text{positive}}=5.04$  vs.  $M_{\text{neutral}}=4.40$ ,  $t(162)=2.88$ ,  $p<.01$ ). Similarly, participants who used the negative search term ( $M=3.45$ ,  $SD=1.56$ ) were less positive post-search than those who used the neutral search term ( $M_{\text{negative}}=3.45$  vs.  $M_{\text{neutral}}=4.40$ ,  $t(165)=3.96$ ,  $p<.001$ ).

Study 4 replicates the results of Study 3 with a consequential choice. 348 Dutch undergraduates were assigned either a negative search term or a positive search term, as in Study 3. After participants conducted their search and rated their attitudes, they were asked to choose between a caffeinated or decaffeinated energy drink. Participants assigned to searched a positive keyword were more likely to choose the caffeinated energy drink (52% vs. 36%, Chi-square=9.07,  $p<.01$ ). Post-search attitudes towards caffeine mediated the effect of condition on choice ( $b=.58$ , 95% CI=.34 to .91).

Lastly, we tested whether people were aware of and corrected for bias from search. In Study 5 ( $N=384$ ), participants were assigned to use either the negative or positive caffeine search term, rated their caffeine attitudes, and estimated what their attitudes would have been if they had used the opposite search term. Participants in the positive search condition predicted more negative attitudes had they conducted the negative search ( $M_{\text{actual}}=5.11$  vs.  $M_{\text{predicted}}=3.17$ ,  $F(1, 179)=120.92$ ,  $p<.001$ ), and vice versa for those who had conducted negative search ( $M_{\text{actual}}=3.74$  vs.  $M_{\text{predicted}}=5.03$ ,  $F(1, 179)=56.35$ ,  $p<.001$ ). When prompted, people recognized that using different search terms shifts inferences.

In Study 6 ( $N=396$ ) participants were assigned to use either the negative or positive search term and, either before or after conducting their search, predicted their attitudes towards caffeine if they were to conduct the positive or negative search. The effect of assigned search terms was reduced when participants first considered the counterfactual effects of search ( $M_{\text{difference before}}=.89$  vs.  $M_{\text{difference after}}=1.67$ ,  $F(1, 392)=7.02$ ,  $p<.01$ ). However, this correction was insufficient and the effect of search term persisted ( $M_{\text{positive}}=3.87$  vs.  $M_{\text{negative}}=4.76$ ,  $F(1, 392)=18.55$ ,  $p<.001$ ) even when the prompt was shown before the search task. Likewise, Study 7 ( $N=190$ ) finds that the difference in attitudes after being assigned to use positive vs. negative search terms was reduced, but remained significant when participants engaged in a second non-assigned search ( $F(1, 188)=7.79$ ,  $p<.01$ ). These results suggest that people can only partially correct for the biasing effects of search.

This paper makes several contributions. First, despite the prevalence of information gathering using search engines, how search terms affect inferences is understudied. Second, while the information system literature has examined confirmation bias in search engines, this research shows that people's inferences and choices are biased by their search terms but they correct for this bias when prompted, even if insufficiently so.

low neural networks (word2vec) (Mikolov 2013a; Mikolov 2013b) to learn distributional representations (embeddings) of the 1085 words contained in the text of the trigger and action categories, channels, and events of the 20,675 unique applets. We trained a word2vec model using the skip-gram formulation with negative sampling to learn a 50-dimensional space of 1085 word embeddings. 20,675 applet embeddings were then constructed as the normed weighted average of the word embeddings for all words in each applet (Mikolov, et.al. 2013b).

Second, we used unsupervised machine learning based on t-distributed stochastic neighbor embedding (t-SNE) (van der Maaten and Hinton 2008) to reduce the word and applet embeddings into latent constructs that serve as dimensional lenses for the third step, and for spatial representations.

In the third step we use topological data analysis (TDA) (Carlsson 2009; Lum, et.al. 2012; Singh, Memoli, and Carlsson 2007) to summarize the high-dimensional applet embeddings into three-dimensional topologies of simplicial complexes that represent the shape and structure of the applets. We used the Ayasdi software platform (ayasdi.com) to implement the TDA mapper algorithm (Singh, Memoli and Carlsson 2007). The topological model of the possibility space of applet embeddings, shows 19 overlapping groups of applet assemblages.

Because a weighted average of word embeddings does not distinguish trigger from action, the “if this, then that” applet embeddings do not differentiate “this” from “that.” Thus, we also created separate capacity embeddings for the trigger text (capacity to affect) and action text (capacity to be affected). A horizontal concatenation produced what we call a “trigger+action” embedding doubling the number of columns of the data. A vertical stacking produced a “trigger/action” pair of capacity embeddings, doubling the number of rows.

We used these additional embeddings to investigate the structure of 2238 smart home applets (group 15). Follow-up TDA using the “trigger+action” embeddings, accounts for the separate roles of triggers and actions and shows clearly how smart home experience is distributed across 8 distinct groups. To visualize how the paired capacities are connected for each of the 2238 smart home applets, we performed a t-SNE of the stacked “trigger/action” paired capacity embeddings and plotted the coordinates for each of the 8 smart home groups. The results reveal further insights regarding smart home experience. For example, groups B and D contrast the effects of distant external vs. proximal internal trigger events on the smart home. Our theory suggests distant triggers will lead to more abstract communal self-expansion experiences, while proximal triggers will lead to more concrete agentic self-extension experiences.

### **Machine Talk: How Conversational Chatbots Promote Brand Intimacy and Influence Consumer Choice**

#### **EXTENDED ABSTRACT**

The use of natural language and more conversational interfaces gradually transforms how consumers interact with firms (Dale 2016; Hirschberg and Manning 2015). The use of messenger systems as a new interaction paradigm between human consumers and intelligent bots has been declared as the “next operating system in commerce” (Economist 2016; Suri, Elia, and van Hillegersberg 2017) and is expected to transform how humans search, shop, and express their preferences (Feldman, Goldenberg, and Netzer 2010).

Research on the impact of these novel forms of messenger-based interaction modalities on consumers is both scarce and predominantly concerned with design and technology-related issues

rather than the consequences for consumer behavior. Specifically, the majority of prior work on anthropomorphic agents and conversational bot systems examined either factors related to optimizing the design features of such interfaces (Landis 2014; Lokman and Zain 2010), factors related to user perceptions and acceptance (Boden et al. 2006; Comendador et al. 2015), or how systems can learn in an unsupervised fashion through interactions with a user (Serban et al. 2017).

The current work examines how conversational bot interfaces affects consumers’ perception of customer-firm interactions and how the properties of a bot interface (such as the employed communication style or the level of personalization) can influence consumers’ product choices. Based on a series of four incentive-compatible experiments in a car rental context, we show that consumers perceive a conversational bot interface as substantially more human-like compared to traditional booking interfaces and that this greater perception of human-like characteristics creates both more intimate consumer-brand relationships (even for an entirely unknown brand) and makes consumers more likely to select higher-priced premium offers (such as accepting costly fuel service upgrades).

Study 1 was designed to test our hypothesis of whether a conversational bot interface is perceived as more human-like and promotes a more intimate customer-brand relationship compared to a traditional booking interface. We developed a conversational rental car interface based on the flowXO bot technology across all studies. A total of 236 consumers who regularly rent a car online were recruited from a European consumer panel ( $M_{Age}=37.14$ ,  $SD_{Age}=11.26$ , 49% females). Participants were randomly assigned to either a traditional booking interface or a conversational bot interface. In the traditional booking interface condition, participants first chose their preferred pick-up and return location, time and date, and their preferred vehicle class (compact car, sedan, SUV). In the conversational bot interface, participants specified the same rental options in the same order but a conversational bot asked participants to indicate their preference for each aspect of the car rental by typing into the chat console of the interface. We used regular expressions in the bot backend to verify entries and the bot had no obvious human characteristics. Immediately after the booking process was completed, we assessed the perceived humanness of the system (example item: “This configuration system has human properties”,  $\alpha_{human}=.96$ ) and how intimately they feel connected to the brand (example item: “I feel like AI.Rental really cares about me”,  $\alpha_{BrandIntimacy}=.92$ ). In line with our prediction, we find that prospective car buyers perceived the conversational bot interface as significantly more human-like compared to the traditional booking interface ( $M_{Bot}=4.89$ ,  $M_{Traditional}=3.14$ ;  $t(234)=7.654$ ,  $p<.001$ ) and also reported greater intimacy with the brand compared to the traditional interface ( $M_{Bot}=4.42$ ,  $M_{Traditional}=3.91$ ;  $t(234)=2.248$ ,  $p<.001$ ). As predicted, brand intimacy was significantly mediated by greater perceptions of humanness (5000 bootstrap resamples;  $CI_{95\%}=[.86;1.59]$ ), rendering the residual direct effect nonsignificant.

Study 2 further examined whether greater intimacy can be induced by altering the type of communication style employed by the system. A total of 214 regular car rental customers participated in this study and were randomly assigned to either a traditional booking interface, a bot interface using a formal communication style (identical to Study 1), or a bot interface using an informal communication style (as identified by a pre-test). A one-way ANOVA revealed a significant effect on both perceived humanness ( $F(2,214)=26.87$ ,  $p<.001$ ) and perceptions of brand intimacy ( $F(2, 214)=4.283$ ,  $p<.05$ ). Follow-up contrasts with Tukey HSD correction confirmed that the more informal communication style was perceived as more human-

like compared to both the interface using a formal communication style ( $M_{\text{Bot\_informal}} = 5.15$ ,  $M_{\text{Bot\_formal}} = 4.49$ ;  $t(214) = 2.239$ ,  $p = .07$ ) and compared to the traditional booking interface ( $M_{\text{Traditional}} = 3.11$ ;  $t(214) = 7.198$ ,  $p < .001$ ). The findings on brand intimacy mirrored the findings on perceived humanness and also replicated the pattern of mediation results revealed in Study 1.

Studies 3 and 4 further examined the impact of a conversational bot interface on consumers' downstream consequences on choice. Study 3 tested whether consumers are more likely to accept a premium offer during a booking process and revealed that consumers were more likely to accept a costly fuel service upgrade compared to a traditional booking interface ( $P_{\text{Bot}} = 47.4\%$ ,  $M_{\text{Traditional}} = 29.2\%$ ;  $z(257) = 2.257$ ,  $p = .05$ ) and this effect was amplified when the interface was personalized such that the bot matched participants' gender and the initial letter of their first name ( $P_{\text{BotPersonalized}} = 54.5\%$ ,  $P_{\text{Bot\_NotPersonalized}} = 44.1\%$ ). Study 4 extended these findings across a range of typical car rental upgrades (fuel service upgrade, pre-installed GPS navigation, and in-car wifi) ( $P_{\text{Bot}} = 42.6\%$ ,  $M_{\text{Traditional}} = 25.4\%$ ;  $F(1, 157) = 10.13$ ,  $p < .001$ ). This effect was robust even after controlling for domain expertise ( $p > .61$ ) but was weaker when consumers had a low need for human interaction in a service process ( $\beta_{\text{Bot} \times \text{LowNeedInteraction}} = -.11$ ,  $t(155) = 3.272$ ,  $p < .01$ ).

To the best of our knowledge, this is the first work that explores the consequences of conversational bot interfaces on consumers. We provide evidence that these interfaces can systematically alter consumer brand perceptions and consumers' likelihood to accept costly upgrades that are provided by a service provider. The current research also provides a new look on research on constructed preferences and reveals that the modality of expressing one's preference through interactive, text-based interfaces with a non-human agent (or bot) can alter consumers' credibility perceptions of offers that are often rejected when interacting with human agents (as in Studies 3 and 4).

### SESSION OVERVIEW

Though consumers (like lay psychologists) develop and use theories to help them understand and respond to the social world, their beliefs are not always aligned with actual experiences (Wilson and Gilbert 2003). In fact, consumers often fail to maximize utility derived from consumption due to their mistaken beliefs. For example, consumers are not skilled at predicting the duration and intensity of future emotional reactions (Kahneman and Snell 1992; Wilson et al. 2000). The discrepancy between forecasted and actual experiences can go beyond affective experiences, and occur in domains such as judgments of others' beliefs (DePaulo et al. 1987), choice alternatives (Iyengar and Lepper 2000), or the evaluation mode (Hsee 1996).

This special session explores consumers' mistaken beliefs and highlights the recent developments across different domains including interpersonal context, gambling context, and goal pursuit. The session brings together four papers that offer insight into the underlying mechanism for this discrepancy and demonstrates interesting and important downstream consequences for consumer well-being.

The first paper by **Buechel, Morewedge and Zhang** begins by discussing consumers' misbeliefs in goal pursuit. Consumers intuit that working harder toward a goal makes attaining it sweeter ("sweat-equity"). However, exerting more effort during goal pursuit actually does not increase the happiness associated with goal achievement. Outcomes are less affect-rich and capture less attention when forecasting them than when experiencing them, leading forecasters to overestimate the role of effort in producing happiness.

Moving from goal pursuit, the next two papers examine consumers' mistaken beliefs in interpersonal contexts. **Wu and Ratner** examine consumers' beliefs about others' evaluations about them if they engage in a public leisure activity alone versus accompanied, and compare these beliefs with people's actual evaluations. Consumers think that others will perceive them negatively when they engage in leisure activities alone. However, people actually make more posi-

tive inferences about the openness of solo relative to accompanied consumers, which is not anticipated by consumers themselves.

Next, **Schroeder, Risen, Gino and Norton** examine the impact of handshake, a ubiquitous form of greeting in interpersonal contexts, on cooperation, and consumers' beliefs about its effects. The authors show that although consumers do not expect handshakes to affect negotiation outcomes, handshakes can actually induce cooperation in adversarial contexts, positively influencing dealmaking outcomes.

Finally, **Baskin, Novemsky and LeBoeuf** identify consumers' mispredictions of their own decisions in a gambling context. While people predict that they will spend less on hedonic products after a gambling loss based on lowered wealth, losers actually spend as much as winners on expensive products. This is because consumers attempt to repair their mood through these purchases after experiencing a gambling loss.

Together, this session investigates consumers' mistaken beliefs in various domains including interpersonal contexts, goal pursuit and gambling. These papers shed light on the underlying mechanism of these discrepancies, and provide important implications for consumers well-being. We expect this session to appeal to a broad audience, including researchers interested in social influence, interpersonal contexts, affective forecasting, consumer lay theory and decision making.

### **Mistaking the Journey for the Destination: Overestimating the Fruits of (More) Labor**

#### EXTENDED ABSTRACT

*... climbing a mountain is different from taking the tram to the top, even if you end up at the same place.*

*- Wu 2018: New York Times*

*You will enjoy the fruit of your labor. -- How joyful and prosperous you will be*

*- Psalm 128:2 NLT*

People believe in "sweat-equity"—that working harder toward a goal makes attaining it sweeter. Indeed, putting effort into producing a good can yield utility (Buechel and Janiszewski 2014) and successfully completing a good makes people value it more (Norton, Mochon, and Ariely 2012). Even the erroneous perception that a painting, for example, took more effort to produce improves its perceived value (Wirtz et al. 2004). Despite these benefits, we propose that the belief in sweat equity creates systematic affective forecasting errors. Specifically, we propose that belief in sweat equity leads affective forecasters to overestimate the extent to which exerting *more* effort during goal pursuit increases the pleasure associated with goal achievement.

We argue that the bias of overestimation of sweat equity emerges due to forecasters being better able to consider effort specifications than experiencers. Outcomes are typically less affect-rich when forecasting them than when experiencing them, leading the outcome to capture less attention when forecasting it than when experiencing it (Buechel et al. 2014; Hsee and Rottenstreich 2004). We suggest that, consequently, forecasters are better able to consider cognitive

features of the outcome such as the effort it required to produce than are experiencers.

A pilot study provides first evidence that people hold a strong belief in sweat equity across a variety of goals. For ten kinds of goals drawn from previous literature, (from creating art, to hiking, to completing a home renovation project) participants indicated that they would be happier achieving that goal if its achievement required more or less of their effort ( $\beta = .24$ ,  $Z = 3.58$ ,  $p < .001$ ).

By comparing forecasts and experiences, four experiments then show that this belief leads to a systematic affective forecasting error. Forecasters in Experiment 1 predicted their happiness and enjoyment (averaged to an index of pleasure) about receiving a chocolate for unscrambling either 2 or 20 sentences. Experiencers reported their happiness and enjoyment after unscrambling 2 or 20 sentences. A 2 (role: forecaster, experiencer)  $\times$  2 (effort: high, low) interaction ( $F(1, 231) = 7.97$ ,  $p = .005$ ) revealed that forecasters predicted that they would experience greater pleasure receiving the chocolate after unscrambling 20 ( $M = 6.14$ ) than 2 sentences ( $M = 5.45$ ;  $p = .005$ ), but experiencers reported equal pleasure independent of the effort they exerted ( $M = 6.05$ ,  $M = 6.71$ , respectively,  $p = .25$ ).

Forecasters in Experiment 2a predicted their happiness about creating a difficult (many steps) or an easy (few steps) origami animal. Experiencers reported their happiness upon creating the difficult or easy origami. A 2 (role: forecaster, experiencer)  $\times$  2 (effort: high, low) interaction ( $F(1, 218) = 8.73$ ,  $p = .003$ ) revealed that forecasters predicted they would be happier having created the difficult ( $M = 4.83$ ) than the easy animal ( $M = 4.11$ ;  $p = .01$ ) whereas experiencers were equally happy having created the difficult or the easy animal ( $M = 1.91$  and  $M = 2.38$ ; respectively,  $p = .10$ ).

Experiment 2b conceptually replicated Experiment 2a, but manipulated the *perceived* difficulty of making the animal, while holding the actual difficulty constant via a contrast effect (i.e., all participants made the same animal instead of an easier vs. difficult animal). The results mirrored those of Experiment 2a.

Providing process evidence, Experiment 3 and 4 examined whether increasing affect-richness during forecasts would reduce forecasters' sensitivity to sweat equity. Experiment 3 manipulated the affect-richness of the task. In the control (affect-poor) condition, participants unscrambled the same 2 [20] sentences as in Study 1. In the affect-rich condition, they unscrambled sentences from the erotic romance novel "Fifty Shades of Grey". A 2 (role: forecaster, experiencer)  $\times$  2 (effort: high, low)  $\times$  2 (affect-richness: control, affect-rich) interaction revealed that the difference in sensitivity to sweat equity was moderated by affect-richness ( $F(1, 380) = 5.37$ ,  $p = .02$ ). In the control condition, the results replicated the pattern from Study 1 ( $F(1, 184) = 7.63$ ,  $p = .007$ ). Forecasters in the affect-rich condition predicted that they would be similarly happy regardless of the effort they exerted, therefore resembling experiencers who were equally happy regardless of the effort exerted in both conditions,  $F_s < 1$ .

In Experiment 4, all participants first unscrambled 5 or 20 sentences. They then either reported their happiness (experiencers) or forecasted how happy they would be about completing the same task again one week later in two forecasting conditions. Specifically: Forecasters in an immediate forecaster condition made their predictions immediately after completing the task (while still in an affect-rich state). Forecasters in a delayed forecaster condition made their predictions after watching a 3-minute neutral video (after their affect had subsided). Experiencers reported their happiness immediately after completing the task (while in an affect-rich state). A 3 (role: experiencer, immediate forecaster, delayed forecaster)  $\times$  2 (effort: low, high) interaction revealed that sensitivity to sweat equity was moderated by affect-richness ( $F(2, 242) = 3.47$ ,  $p = .03$ ). Experienc-

ers and forecasters without delay reported and predicted they would be equally happy in both the high and low effort conditions ( $p_s < .29$ ). Forecasters who made their predictions after a delay, however, predicted they would be happier in the high ( $M = 6.71$ ) than low effort condition ( $M = 5.44$ ;  $F(1, 242) = 6.16$ ,  $p = .01$ ).

Together the results provide evidence for a bias whereby people overestimate the rewards of sweat equity. It emerges because an asymmetry in the affective intensity of outcomes being forecasted and being experienced creates a difference in sensitivity to effort specifications.

### **Inferring Personality from Solo vs. Accompanied Consumption: When Solo Consumers are Perceived to be More Open**

#### **EXTENDED ABSTRACT**

Prior research shows that consumers are inhibited from engaging in public leisure activities alone (vs. accompanied) because they believe that others would think they have fewer friends if they go solo (Ratner and Hamilton 2015). The current paper examines how people actually evaluate solo (vs. accompanied) consumers in public leisure settings, and how this compares to consumers' lay beliefs. We explore the possibility that solo consumers are perceived more positively than accompanied consumers on some personality dimensions.

Building on prior research (Miller and Nelson 2002; Trope 1986), we propose that while solo (vs. accompanied) consumers are perceived to be less socially connected, people are also more likely to attribute solo (vs. accompanied) consumers' attendance (e.g., visiting a museum) to an intrinsic interest in seeking intellectual or aesthetic stimulation, leading to positive inferences about solo (vs. accompanied) consumers on openness. For example, a solo consumer is more likely to visit a gallery to enjoy the aesthetic value of art, as opposed to if she goes with friends, in which case she may simply want to socialize. The positive inferences observers make about solo (vs. accompanied) consumers on openness could contribute to the overall favorability towards the consumer, compensating for the negative inferences they make about solo (vs. accompanied) consumers on social connectedness.

Study 1 established that openness and social connectedness are the key dispositional dimensions on which solo (vs. accompanied) consumers are perceived to differ. Participants considered one of three different public leisure activities (blockbuster/comedy show/public lecture) that a target consumer engaged in either alone or accompanied, and rated the consumer on the big five personality dimensions (John and Srivastava 1999) and social connectedness. Across three contexts, respondents perceived solo (vs. accompanied) consumers to be more open, less extraverted and less socially connected. Extraversion and perceived social connectedness were positively correlated. Neither agreeableness, neuroticism nor conscientiousness emerged as significant in distinguishing people's perceptions of solo (vs. accompanied) consumers.

Study 2 examined people's evaluations of solo (vs. accompanied) consumers on openness, social connectedness, as well as overall favorability towards the target, and compared these with consumers' lay beliefs. Participants were either asked to imagine going to a movie by themselves or with company (actor condition) or imagine observing someone going to a movie alone or with company (observer condition). Consumers accurately predicted the extent to which others would perceive them to be more socially connected if accompanied than solo. However, consumers failed to anticipate that observers made positive inferences about solo (vs. accompa-

nied) consumers on openness (actor:  $M_s=4.70$  vs. 4.44, ns; observer:  $M_s=5.64$  vs. 4.80;  $p<.05$ ). Furthermore, solo (not accompanied) consumers underestimated how favorably overall others would evaluate them (solo:  $M_s=4.06$  vs. 5.09,  $p<.05$ ; accompanied:  $M_s=5.08$  vs. 5.11, ns).

Study 3-5 tested situations where solo (vs. accompanied) consumers are not perceived to be more open. Study 3 explores the possibility that when an observer concludes that a target person's behavior is under the influence of potent situational forces, the observer will refrain from making the openness inferences about solo (vs. accompanied) consumers. Participants either imagined seeing a person watch a movie *at a theater* alone or with a friend, or imagined seeing a person watch a movie *on a plane* alone or with a friend. Solo (vs. accompanied) consumers were perceived as more open and less socially connected in the theater condition. However, in the plane condition where observers could easily attribute the target's behavior to a situational constraint (e.g., having nothing else to do on the plane), they no longer perceived solo (vs. accompanied) consumers to be more open or less socially connected. In both theater and plane conditions, solo (vs. accompanied) consumers were evaluated as favorably as accompanied consumers.

In prior research, dining at a restaurant and attending a theater were treated similarly in terms of consumers' anticipation of others' evaluations when they engage in the activity solo versus accompanied. We argue that observers' actual evaluations about solo versus accompanied consumers may differ across these two contexts: though attending a movie alone (vs. accompanied) is perceived to be more open due to stronger attribution to a motive to seek intellectual or aesthetic stimulation, dining at a restaurant alone (vs. accompanied) may not elicit the same trait inference due to the high possibility that the behavior is constrained by a basic physiological need (i.e., hunger) rather than purely discretionary. In study 4, we examine people's evaluations of a solo (vs. accompanied) diner, and compared these with evaluations of a consumer going to an event related to food but not normally to fulfill physiological needs (food sampling along with talks about food history). As predicted, solo (vs. accompanied) consumers were perceived as more open in the food-related event where the psychological constraint was low. In the restaurant condition where the attendance could be attributed to a physiological need, this effect disappeared. The extent to which the attendance was attributed to the intrinsic motive to seek intellectual or aesthetic stimulation mediated the relationship.

Although solo (vs. accompanied) consumers were perceived to be more open in the US, a culture that emphasizes individual autonomy, the same effect may not hold in non-Western cultures that stress interdependence and situational norms. Prior literature suggested that compared to Americans, Chinese are less likely to attribute others' behaviors to internal traits (Miller 1984). In study 5, we recruited participants from China and the US. All participants imagined seeing a person go to a movie either alone or accompanied. Solo (vs. accompanied) movie-goers were perceived to be more open by American but not Chinese participants. Solo (vs. accompanied) consumers were perceived to be less socially connected in both cultures. Overall, Chinese respondents evaluated solo (vs. accompanied) consumers less favorably; US respondents evaluated solo and accompanied consumers equally favorably.

Together, we show that though solo (vs. accompanied) consumers are perceived to be less socially connected, as consumers expected, solo (vs. accompanied) consumers are also perceived to be more open, which is not anticipated by consumers themselves. Contrary to consumers' own predictions, overall solo consumers are perceived as favorably as accompanied consumers.

## Handshaking Promotes Deal-Making By Signaling Cooperative Intent

### EXTENDED ABSTRACT

In adversarial contexts, people often rely on nonverbal signals from partners when deciding whether (or not) to cooperate. We explore the impact of a ubiquitous form of greeting—a handshake—on cooperation. In particular, we predict that shaking hands signals an intent to act cooperatively. As a result of this signal of cooperative intent, handshaking may increase trust between counterparts and consequently induce them to behave more cooperatively. This prediction is based on prior research suggesting that individuals' beliefs about the other party's social motives can predict their own willingness to cooperate (Deutsch 1949; Pruitt and Lewis 1975; Pruitt and Rubin 1986). However, prior research largely measured social motives via individual differences in social value orientation (De Dreu and Van Lange 1995; Deutsch 1949; Kelley and Schenitzki 1972; McClintock 1977; Messick and McClintock 1968; Van Lange and Kuhlman 1994) or manipulated social motives via explicit instructions or incentive schemes (De Dreu and McCusker 1997; Sattler and Kerr 1991). We instead examine how nonverbal behavior can causally influence perceptions of social motives in seven studies using three distinct adversarial contexts: integrative negotiations, distributive negotiations, and economic games.

To first understand people's predictions about how handshakes influence adversarial outcomes, we ran a pilot study with individuals about to engage in a negotiation, and asked them to predict how a handshake would influence their negotiation experience, behavior, and outcomes. The majority of negotiators believed that a handshake would make their negotiation experience more formal, whereas the minority believed a handshake would induce cooperation, almost no negotiators believed that a handshake would meaningfully change their deal-making outcomes.

Studies 1-3 test the actual effect of handshakes on integrative negotiation outcomes. In Studies 1a and 1b, executives engaged in integrative negotiations who shook hands achieved better negotiation outcomes, controlling for whether or not the pair knew each other already. We next tested the causal effect of handshake by randomly assigning pairs to shake hands or not prior to an integrative job negotiation. In Study 2, pairs who shook hands engaged in more cooperative behavior (i.e., open information exchange) and, as a result, achieved higher joint outcomes. Providing further evidence that handshakes signal of a counterpart's cooperative intent, Study 3 demonstrates that merely observing a counterpart shaking hands—but not actually shaking hands themselves—makes participants believe that their counterparts have more cooperative intent, compared to not observing counterparts' prior behavior or observing them avoid a handshake. Furthermore, participants' own cooperative behavior was driven by their inferences about their counterparts' intent.

Study 4 considers a different adversarial context: an economic game. Pairs playing the game have a choice to defect, gaining more for themselves at the expense of their partner, or to cooperate, gaining less for themselves but improving the joint outcome. Whereas integrative negotiations include cooperative incentives, because both parties can benefit mutually, the economic game in Study 4 also examines consequences of handshaking under more competitive incentives. Study 4 further examines whether the effect of handshaking is robust to social value orientation and incentive structure. Finally, to address the issue of experimenter demand effects, we explore whether handshaking affects cooperation among individuals who are instructed or uninstructed to shake hands. Results from this study revealed that participants were less likely to defect when they

shook hands with their partner, and this effect occurred regardless of whether participants were instructed or not to shake hands. The effect of handshaking on defection was also robust to participants' self-reported social value orientation.

Study 5 measures participants' assessments of their partners' intentions following a handshake or no handshake, as well as participants' own behavioral intentions in an economic game. Study 5 further tests whether handshakes promote cooperative behavior only when they communicate cooperative intent, examining whether a countervailing psychological signal of a counterpart's intentions can change individuals' interpretation of, and reaction to, handshaking behavior. Specifically, when participants' counterpart shook hands but reported "feeling sick," participants believed the handshake was malicious and the avoidance of a handshake was caring, but the reverse effect was observed when the counterpart appeared in good health.

Finally, Study 6 tests the effect of a handshake in a distributive negotiation in which we assess an additional aspect of cooperation: lying and truth-telling. Distributive negotiations are zero sum such that parties' interests are completely opposed: If one party gains, the other must necessarily lose. Distributive negotiations therefore represent a strong test of our hypothesis that handshakes can promote cooperation, because cooperation requires one party to sacrifice some of their own potential gain. In Study 6, executives randomly assigned to shake hands at the start of a distributive negotiation engaged in fewer antagonistic behaviors—such as lying—that could benefit themselves, resulting in more equitable outcomes. Therefore, the advantaged negotiator actually showed greater willingness to cooperate after a handshake even to their own detriment.

Across these studies, handshaking promoted cooperative behavior. To many, handshakes that occur at the onset of an adversarial context may seem like inconsequential nonverbal gestures. Yet, as we demonstrate in the present research, in an array of adversarial contexts from negotiations to economic games, shaking hands signaled cooperative intent, thereby leading people to act more cooperatively. Even in more antagonistic distributive negotiations, a handshake can lead the advantaged party to cooperate more, harming their own outcome to create a more equal distribution of the bargaining zone. Together, these studies demonstrate that handshaking can produce cooperation, consequently influencing dealmaking outcomes.

### Mispredicting Reactions to Gambling Losses and Their Impact on Consumer Choice

#### EXTENDED ABSTRACT

Imagine gambling in a casino with a plan to stop when you have either won or lost \$100. Imagine further that you win: will you be tempted to make a purchase at one of the retailers nearby? Imagine instead that you lose: now, how tempting will those retail displays be? Most important, will you have insight into your own behavior, and will you be able to predict in advance how winning or losing will affect you? Can people predict how taking (and resolving) risks will affect their subsequent purchasing behavior?

We examine whether people can accurately forecast how winning and losing will affect their purchase decisions. We show that people may have reasonably accurate intuitions about how winning will affect them: they think that their increased wealth will cause them to spend more than if they had broken even, and they are largely correct about this. However, people have a much harder time forecasting how losing will affect them. In particular, although people predict that they will spend less after losing because of their

decreased wealth, they actually spend more, purchasing hedonic products in an attempt to make themselves feel better.

Predicting when decisions will be made based on affect is vitally important, yet research has documented many systematic failures of predictions of mood effects. People do not predict future moods and their consequences very well, especially in circumstances that revolve around whether or not to gamble more (Andrade and Iyer 2009), how one will feel after indulging (Xu and Schwarz 2009), or how one will feel after experiencing disrupted hedonic experiences (Nelson and Meyvis 2008; Nelson, Meyvis, and Galak 2009). Due to these mispredictions, people may make incorrect decisions based on what they think will happen rather than what will actually happen.

We highlight an important misprediction in gambling contexts. Whereas prior research has shown that people may not accurately predict the extent of the negative emotions they will feel if they lose (Andrade and Iyer 2009), our research suggests that people mispredict whether their mood will affect their decisions at all. In other words, our hypothesis is that people predict that choices after a loss will be based on their lowered wealth level rather than their mood. Therefore, even though people go into a Las Vegas casino thinking that they will not spend much if they lose in the casino, they will actually spend *more* money after losing in the hopes of improving their mood.

In all of our studies, we simulated a gambling environment by having participants gamble a portion of their participant payment. They had 3 equal probability outcomes: winning additional money (winners), having their participant payment unchanged (neutrals), and losing some of their participant payment (losers). Since the gambles are for real money, losses in these scenarios affect their mood negatively.

In Study 1a, we find that gamble losers, as compared to neutrals, are more willing to buy jokes in order to improve their negative mood using money from their own participant payments. Winners are also willing to spend more money on jokes, but their decisions are not mediated by mood. Study 1b shows that participants can correctly predict winners' buying preferences, but not losers' preferences.

Study 2a examines the underlying process by manipulating mood directly. Participants saw either neutral photographs or positive-affect-inducing photographs (Lang, Bradley, and Cuthbert 2008). Among gamble losers, the positive-affect photographs improved their negative mood. As a result, losers in the positive-affect condition reported a lower willingness to buy an indulgent item (truffles) compared to losers in the neutral-photograph condition. Purchases of winners and neutrals were unaffected by the mood manipulation. Study 2b examined predictions about Study 2a. We found only a main effect of picture, such that participants predicted, regardless of gambling outcome, that those who saw the positive photographs would buy more than those who saw the neutral photographs.

Study 3a looks at the process behind winners' decisions. Subjective wealth was manipulated after the gamble by asking participants to recall small or large accounts (Morewedge, Holtzman, and Epley 2007). While losers' willingness to buy truffles did not change based on the subjective wealth manipulation, both winners and neutrals wanted to spend more money when they recalled a large account (vs. small account), suggesting that both winners and neutrals make decisions based on subjective wealth, but losers do not. Study 3b examined predictions about study 3a. Again, participants failed to predict mood repair following a loss, but rather predicted that recalling a large account would increase spending regardless of the gambling outcome.

Studies 4a examined price/quality tradeoffs by asking participants to choose between cheaper/low quality jokes and more expensive/high quality jokes from their participant payments after gambling. Both winners and losers wanted to buy more high quality/more expensive jokes than neutrals. While a separate group of participants in study 4b could predict winner choices, they could not predict loser choices, thinking that losers would buy the less expensive jokes.

Study 5a seeks to rule out that losers experience the “what the hell effect?” (Cochran and Tesser 1996) and just want to buy anything after they lose money. We find that losers, as opposed to winners and neutrals, have a strong preference for hedonic over utilitarian spa massages. Study 5b shows that people predict the opposite – that losers would have a stronger preference for utilitarian products.

In summary, it seems people have the wrong beliefs about how they will behave following gambling. They think that their wealth will drive purchases. While they are correct that winners buy more as a result increased wealth, they are not able to predict that losers also buy more (and buy more hedonic offerings) in an attempt to repair their mood.

## SESSION OVERVIEW

Consumers today have access to an overwhelming amount of information about products and services. Given this, they may feel compelled to sift through endless information on the many options available in the marketplace in order to make appropriate decisions (Leclerc, Hsee and Nunes 2005). Alternatively, consumers may rely on information provided in ranked lists prepared by third parties. Rankings have become increasingly popular because they simplify decision-making by presenting comparative information to consumers in an easily digestible way.

Despite consumers' frequent use of rankings and the power that ranked lists have to sway consumer choice, the literature on rankings remains sparse (for exceptions, see Isaac, Brough and Grayson 2016; Isaac and Schindler 2014; Leclerc, Hsee and Nunes 2005). In order to enhance our collective understanding of how consumers process rankings and lists, this session is devoted to the presentation of some of the latest findings in this important domain.

**Isaac and Jain** show that rankings are so pervasive that even when consumers are merely presented with an unnumbered vertical list of items, they assume that the items have been ranked and listed in "best-to-worst" order of quality or performance. This effect is robust, as consumers infer ordinality from verticality even when they are explicitly informed that order is non-diagnostic.

Rather than examining the inferences that consumers make upon encountering unranked lists, **Shechter and Hardisty** focus their attention on explicitly ranked lists. They explore the intensity of consumer preference for being at the top of a ranked list as well as the degree of aversion for being at the bottom of said list. The authors construct utility functions for ranked lists and find that consumers are risk seeking for first place and risk averse for last place. Additionally, they find that first-place seeking is stronger than last-place aversion.

Whereas the first two papers examined the relative evaluations of different items on a list, the last two papers explore how subtle interventions can influence preference for the same ranked item. **Sevilla, Isaac, and Bagchi** introduce the phenomenon of *format neglect* in the domain of rank claims. They show that consumers

evaluate equivalent rank claims using numerical [percent] formats more favorably when these involve sets of less than [more than] 100 items. This effect occurs because consumers tend to overweight the nominal value of ranking position to the detriment of format and set size information.

**Cai, Xie and Bagchi** show that even when claims involve the same numerical format, the number of items that have been ranked has a substantial impact on consumer preference. They introduce the *rank length effect*, a phenomenon where the same "Number 1" item is evaluated more positively in a longer list (e.g., Top 20 list) than in a shorter one (e.g., Top 5 list). They find that this occurs due to consumers' biases when forming their mental evaluation lines.

We hope that these new findings on rankings and lists spur significant interest and research ideas on this theoretically and substantially rich area of marketing communications.

## Assuming Ordinality: Best-to-Worst Inferences in Vertical Lists

### EXTENDED ABSTRACT

When consumers are presented with a list of items, do they infer that the spatial presentation of the items conveys meaningful information about the items' relative quality or performance? Although prior research has detected presentation order effects (i.e., primacy and recency effects), most of this work has explored how people recall stimuli. In contrast, the present research examines comparative evaluations of items presented simultaneously within a vertical list, when no recall is necessary.

Limited research has examined how consumers use spatial position to make evaluations or choices from a simultaneously presented set of items. This work has found evidence for "edge avoidance" (Rubinstein, Tversky, and Heller, 1997), "centrality preferences" (Shaw et al., 2000), "middle bias" (e.g., Attali and Bar-Hillel, 2003), and a "center-stage effect" (Valenzuela and Raghbir, 2009). The basic finding from past research is that options in the middle of an array are evaluated more favorably (and chosen more often) than those on the edges. Although different mechanisms have been proposed for this effect, it may result from greater perceptual attention being devoted to options in the center of a choice set.

In contrast to edge avoidance (which has not been studied in the domain of vertical lists), we suggest that consumers who encounter vertical lists tend to assume that the items are rank-ordered from best to worst. We posit that because vertical lists are routinely ordered in this way, consumers may overgeneralize this normative tendency and infer that even unordered lists have been arranged from best to worst. In a series of seven experiments (four of which are described here), we provide evidence that consumers infer ordinality from verticality. In addition to identifying a number of boundary conditions for this inference, we show that the presumption of ordinality is so ingrained that the best-to-worst inference may persist even if the provider of a list explicitly communicates that order is non-diagnostic (e.g., that the list is alphabetized, randomized, etc.).

In Experiment 1, we asked 166 online participants to review a list of ten brands that were supposedly the names of popular websites in a foreign country but were actually letter sequences fabricated by a website that generates "meaningless pseudowords." The ten websites

were presented simultaneously as a vertical list but were not numbered. Depending on condition, participants either received no explanation about how the websites were ordered or were informed that the websites were ordered alphabetically. Participants then estimated the relative popularity of the website that was listed second versus ninth from the top on a scale from -100 to +100, with positive values indicative of a best-to-worst inference. This mean relative popularity rating was higher when no explanation about order was given ( $M = +30.10$ ) than when the list was alphabetized ( $M = +9.24$ );  $t(164) = 3.20, p < .01$ . However, mean ratings were significantly higher than zero in *both* conditions, suggesting that consumers made a best-to-worst inference even when they had been explicitly informed that display order was non-diagnostic.

If consumers infer ordinality from vertical position, then they should believe that the evaluative distance between two items is greater when their vertical positions are distant (vs. proximal). We tested this in Experiment 2 by showing 158 consumers an unnumbered list of the best places to work that included nine foreign companies (actually pseudowords) that were shown “in no particular order.” In one condition, a specific company was listed first (from the top) whereas the same company was listed eighth in another condition. Subsequently, participants provided a relative rating of this company versus the company that was listed ninth (again on a scale from -100 to +100). As predicted, the mean relative rating was higher when the two companies were apart in terms of vertical position (i.e., two versus nine) ( $M = +12.25$ ) versus when they were adjacent (i.e., eight versus nine) ( $M = +.51$ );  $t(156) = 2.58, p = .01$ .

Experiment 3 aimed to show that the best-to-worst inference arises because of consumers’ normative expectations about how vertical lists are arranged. A total of 226 consumers were exposed to a series of best-to-worst lists (e.g., lists that go from 1 to 10) or to a series of worst-to-best lists (e.g., lists that go from 10 to 1). Following this task, which manipulated participants’ normative expectations, they were presented with the same unnumbered list as in Experiment 1 and estimated the relative popularity of the website that was listed second versus ninth. The mean relative popularity rating was higher after exposure to the best-to-worst lists ( $M = +29.49$ ) versus the worst-to-best lists ( $M = -2.85$ );  $t(224) = 7.60, p < .001$ . However, whereas the mean rating was significantly higher than zero in the best-to-worst norm condition, this was not the case in the worst-to-best norm condition. This suggests that consumers’ propensity to make best-to-worst inferences when encountering a vertical list is driven by communication norms. More specifically, consumers overgeneralize the tendency of lists to be ordered from best-to-worst and apply this heuristic to lists in which order has not been unspecified. However, when the best-to-worst norm is weakened (through repeated exposures to worst-to-best lists), the effect is attenuated.

Finally, in Experiment 4, we found that the best-to-worst inference is stronger for unordered vertical lists than for unordered horizontal lists. A total of 233 participants encountered an unnumbered list of ten websites, shown in “no particular order,” that were either arranged vertically or horizontally. They then provided a relative evaluation of the website that was listed second versus ninth (either from top-to-bottom, or left-to-right, depending on condition) on a 10-point scale (higher numbers indicating a best-to-worst inference). The mean relative rating was higher when the list was vertical ( $M = 4.92$ ) versus when the list was horizontal ( $M = 4.37$ );  $t(231) = 1.93, p = .05$ .

In sum, this research extends our theoretical understanding of serial position effects by focusing on evaluations rather than recall and by demonstrating the dominance of “best-to-worst” inferences over edge avoidance in the domain of vertical lists.

## The Victory Effect: Is First-Place Seeking Stronger than Last-Place Aversion?

### EXTENDED ABSTRACT

The rise of gamification has increased the number and variety of ways in which people compete. Our research concerns competition with rank feedback. We focus on settings in which rank is a function of effort, competitors can see each other’s (anonymized) performance measures, and no prizes are awarded. Our work builds on past economics and social psychology literature examining optimal contest design and rank preferences (Bull, Schotter, & Weigelt, 1987; Che, & Gale, 2003; Dutcher, Balafoutas, Lindner, Ryykin, & Sutter 2015; Fullerton, & McAfee 1999; Kuziemko, Buell, Reich, & Norton, 2013; Lazear, & Rosen 1981; Taylor, 1995).

We conduct two main studies in this paper. In Studies 1a-1e, we survey individuals to assess their risk preferences for different ranks in a competition. Specifically, we use the probability-equivalent method (Hershey & Schoemaker, 1985) to construct utility curves (over rank) for each individual, and we analyze the patterns observed. Subjects read the following:

*Suppose you and five other people of similar fitness level (either gender) are matched up in a competition to see who takes the most steps over the next month (from a combination of walking, running, and stairs). Imagine that there are no prizes given out in this competition, and that rankings and performance would be displayed through an anonymized leaderboard (i.e., you will not know the identity of anyone else in your competition group, nor will anyone else in your group know your identity; however, you will know which rank is yours).*

*The following questions are designed to assess your preference between using a strategy that would guarantee a certain outcome (e.g., third place out of 6) vs. using another strategy that gives you a chance of finishing in first place (out of 6) and a chance of finishing in last place (out of 6). Assume each of these two strategies involves the same amount of effort. We will vary the chances approximately five times, to estimate the percentage chance that makes you indifferent between choosing the certain rank outcome and the uncertain rank outcome.*

We obtained the indifference point (i.e., utility) for each rank and for each study subject ( $n = 1001$ ). The idea that people are last-place averse, but are even more first-place seeking. We also find statistically significant support for the following hypotheses:

*Hypothesis 1*     *Individuals care about rank in contests without prizes. Specifically, they have greater utility for higher ranks.*

*Hypothesis 2*     *a) Individuals are risk-seeking when in second place, b) risk-averse when in second-to-last place, and c) more risk-seeking in second than risk-averse in second-to-last place.*

*Hypothesis 3 Individuals experience a greater decrease in utility from first to second place, compared to the decrease in utility from second-to-last to last place.*

Study 2 takes the ideas and insights of Study 1 to the lab, to observe if and how individuals' effort and performance change in response to rank feedback provided half-way through a contest. Participants in the treatment group arrive to the lab in round 1 and read the following on a computer screen:

*Today you will be grouped with 5 other students in a continuous step climbing competition. You will be doing the first round of the study and repeatedly climbing a step for 5 minutes, taking as many steps as you can. You will then need to return to the lab at a future date to participate in the second round of the study. Before you start your second round, we will show you the rankings and scores from the first round. You will then proceed to complete the second round of the study, in which you will again climb as many steps as you can in 5 minutes.*

*We will use participant identification numbers to anonymize the results. We will show you your own participant identification number so that you can see where you are ranked and how you scored. However you will not know the identity of anyone else in your competition group, nor will anyone else in your group know your identity.*

*Once your second round score is tabulated, we will send you an e-mail announcing the final rankings and scores (based on both rounds) of every contestant in your group. There are no prizes given out in this contest.*

We had 231 subjects go through the treatment arm. We also had 162 control subjects, who also stepped as many times as they could in two rounds of 5 minutes each. However, they were told the purpose of the study was to evaluate their individual performance, and they were not shown other subjects' performance measures.

We observe that first-place seeking behavior is significant among male participants, whereas there is nearly no difference in performance change between female treatments and control at the higher ranks. On the other hand, female subjects appear to try very hard to get into the "top half", as shown by their response to placing in the middle ranks after round 1. We do not find evidence of last place aversion in this actual competition; treatments and controls have similar responses to learning they placed in the bottom two ranks after round 1.

Our results support the notion that individuals inherently care about rank in competitions. Our study of risk preferences using hypothetical competitions showed that individuals consistently demonstrate last-place aversion as well as first-place seeking behavior. Interestingly, the latter effect appears even stronger than the former. Our study of an actual physical contest showed support for first-place seeking behavior among men, but not among women. Neither gender demonstrated last-place aversion behavior. This may have to do with the anonymized display of our contests results. Future work may consider the effects of displaying leaderboards that include ac-

tual contestant names, the effect of different competition group sizes, and the effect of prize money on contestant effort.

### **Format Neglect: How the Use of Numerical Versus Percent Rank Claims Influences Consumer Judgments**

#### **EXTENDED ABSTRACT**

When marketers promote their products and services, they often claim to be part of an exclusive tier within their competitive set (e.g., "Product X is in the top 10"). Although recent behavioral research has investigated how consumers respond to rank claims (e.g., Isaac, Brough and Grayson 2016; Isaac and Schindler 2013), this work has focused exclusively on claims having a numerical format (e.g., "top 10"). But marketers often communicate ranking information using percentages—such as "top 20%." In the present research, we explore how the use of a numerical format claim (e.g., Product X is in the top 10 out of 50 products) versus an equivalent percentage format claim (e.g., Product X is in the top 20% out of 50 products) influences consumer judgments and decisions. We find robust evidence of an effect whereby consumers respond more favorably to numerical rank claims when set sizes are smaller (i.e.,  $< 100$ ) but more favorably to percent rank claims when set sizes are larger (i.e.,  $> 100$ ), even when the claims are mathematically equivalent. This finding represents a violation to normative theory.

We further suggest that this preference reversal occurs because consumers who encounter rank claims fail to fully account for claim format (i.e., numerical vs. percentile) and set size, a phenomenon we describe as *format neglect*. As a result, they rely predominantly on the nominal position conveyed in the claim (e.g., 10 in "top 10" or 20 in "top 20%"). Our theorizing is consistent with past research showing that consumers often overweight focal and specific information about a case while neglecting other relevant general information (e.g., Bar-Hillel 1980; Kahneman and Tversky 1973; Lyon and Slovic 1976; Nisbett and Ross 1980; Yan and Sengupta 2013). However, whereas previously identified biases in the processing of percentage information have been largely attributed to attentional oversight or calculation complexity (e.g., Bagchi and Ince 2016; Kruger and Vargas 2008), we posit that format neglect stems from consumers' conscious belief that nominal position is more important to the evaluation task than set size, despite the fact that they are equally important and must be considered in conjunction in order to appropriately judge ranking position information. As a result, we predict that consumers, rather than fully integrating both pieces of information to arrive at their evaluation, will rely relatively more [less] on nominal position [set size].

We report findings from five experiments across different consumer contexts that provide evidence for an interaction effect between rank claim format and set size on consumer evaluations and demonstrate that this interaction arises because of format neglect. Experiment 1 provides initial evidence of our basic effect by showing that participants respond more favorably to a numerical rank claim when the item referenced in the claim is part of a small set, but that they respond more positively to a percent rank claim when the item is part of a large set ( $F(1, 229) = 16.76, p < .001, \eta_p^2 = .068$ ). This study also provides evidence for the existence of format neglect as the underlying mechanism, by showing that participants rely on nominal values more than format and set sizes when formulating their evaluations. Experiment 2 provides further support in favor of format neglect ( $F(2, 462) = 4.03, p = .018, \eta_p^2 = .017$ ) and demonstrates that the inflection point for this effect occurs when set size is approximately 100. This occurs as percentages are by definition expressed with relation to the number 100, hence, set sizes of this

magnitude generate identical ranking positions regardless of format (e.g. top 20% out of 100 is equivalent to top 20 out of 100).

In experiments 3 and 4, we identify interventions that can be used to debias consumers. These interventions also provide additional support for our proposed format neglect mechanism by demonstrating that when the importance of set size on evaluations is highlighted perceptually, as in Experiment 3, or cognitively, as in Experiment 4, the effects found in our earlier experiments are attenuated. We found the debiasing task to be effective for both, Experiment 3 ( $F(1, 296) = 4.21, p = .041, \eta_p^2 = .014$ ), and Experiment 4 ( $F(1, 358) = 9.02, p = .003, \eta_p^2 = .025$ ). Finally, Experiment 5 is a field experiment conducted at a cheese shop over a 12-week period. It demonstrates that the manipulation can increase real sales for a product that is ranked within a large set, when its ranking is stated in percentage as opposed to numeric format or when no ranking information is presented altogether ( $F(2, 81) = 9.71, p < .001, \eta_p^2 = .19$ ). Together, these studies provide robust evidence for format neglect and its underlying mechanism. Together, these five studies provide robust evidence in favor of our proposed effect and underlying mechanism.

In summary, the present research introduces the concept of percent rank claims to academic research and contributes to the numerical rankings literature by elucidating how different rank claim formats—such as numerical and percent claims— influence consumer evaluations. Our research uncovers a novel bias—when processing ranked list claims, people rely on the nominal position communicated in the claim (e.g., 10 in “top 10” or 20 in “top 20%”) to make inferences and neglect other equally diagnostic information, such as the ranking format employed and the size of the considered set. Hence, through a subtle manipulation such as ranking format, we uncover an unexpected exception to normative theory and a marketing relevant and actionable effect.

### The Rank Length Effect

#### EXTENDED ABSTRACT

Advent of modern technology and competition has led to the age of choice abundance. Within any category, and for any product, there are multiplicity of options. When selecting a movie to watch, a restaurant to visit, or even a product to purchase, a consumer may have to sift through hundreds of choices. To make these comparisons tenable, several organizations such as Rotten Tomatoes, Yelp.Com, and Consumer Reports offer rank lists, which aid decision-making. These rank lists often vary on the number of items ranked—for e.g., Top 100, Top 20, or Top 5. We investigate how the number of items in the list affects evaluations.

Consumers use an item’s rank to make inferences (Sorensen 2007; Pope 2009; Isaac and Schindler 2014). We propose that evaluations of an item in a rank list not only depends on its rank, but also on the number of items ranked. Specifically, we posit that the Number 1 item will be evaluated more positively in a list with more items (Top 20 vs. 5). However, the difference between items will be smaller in the longer list.

Recognize that, at its core, a rank is a number. Past research suggests that consumers construct mental number lines to make sense of numbers (Dehaene 1997; Restle 1970). We believe that consumers may construct such mental number lines when evaluating ranked items. The mental number line is labile and is usually constructed during task execution (Pinhas and Pothos 2013; Fischer, Mills and Shaki 2010). We posit that the position of items on this evaluation scale will be constructed based on the number of items in

the list—when more (less) items are in a rank list, the corresponding items will be placed further away from (closer to) each other.

We propose that when people transfer ranks from a rank list to their mental evaluation line, they try to accommodate all the items on this list. A Top 20 (vs. 5) list has more items so consumers use more of their mental number line when representing these items. This leads to two consequences—first, consumers use the extremities of their mental number line to place items when the rank list is longer (vs. shorter). Therefore, the top ranked and the bottom ranked items are farther apart with a longer rank list (Top 20 vs. 5). Consequently, the top ranked item in a longer (vs. shorter) list will be evaluated more positively. Secondly, because a longer rank list has more items, consumers will compress these items to fit them on their mental number line. Consequently, the distance between the different ranked items will be compressed more with a Top 20 (vs. 5) list. Results from four studies support these propositions.

In experiment 1A, we randomly assigned 85 participants to one of two conditions, where they saw a Top 20 or a Top 3 movie list. Participants then rated the Number 1 film by providing their overall evaluations (0 = Not good/100 = Very Good), liking (0 = Not at all/10 = Very much), and recommendation intentions (0 = Definitely no/10 = Definitely yes). The Number 1 movie was rated more positively when the rank list was longer (vs. shorter). One possible alternative explanation could be that people may have inadvertently confused the length of the rank list with the total number of movies the Top 20/3 list was chosen from. To rule this explanation out, in Experiment 1B, we used a 2 (Rank range: Top 20 vs. Top 3) by 2 (Information about total number of movies: available vs. not available) between-subject design. In the information (not) available condition, we explicitly told (did not tell) participants that the Top 20/3 list was chosen from 102 movies. The results of a two-way ANOVA (see Table 1) showed that participants judged the Number 1 movie more positively in the Top 20 (vs. 3) condition, and these evaluations were not influenced by whether or not information about the total number of films was provided or not.

In two subsequent experiments, we explored the underlying mechanism. In Experiment 2, we used a similar movie ranking context (Top 20 vs. 5), but we asked participants to evaluate both the Number 1 and the Number 3 movie. If the scale points of the mental evaluation line contract (expand) when the list length increases (decreases), then the difference in evaluations between the Number 1 and the Number 3 movie should shrink (increase). As shown in Table 1, evaluations of both the Number 1 and 3 movies were significantly higher in the Top 20 (vs. 5) condition. However, the difference between the Number 1 and Number 3 movie was lower in the Top 20 (vs. 5) condition.

Experiment 3 replicates these results in a product evaluation context. Participants ( $N = 86$ ) were informed they were considering purchasing hiking boots and were randomly assigned to one of two conditions—and shown either a Top 20 vs. 5 list of hiking shoes. In the Top 20 (5) condition, participants were presented a scale printed on a piece of paper and were asked to indicate their evaluations for all 20 (5) pairs of hiking shoes. After finishing this task, all participants indicated their evaluations (0 = Not good at all/10 = Very good), willingness to pay, and assessments of how much better the Number 1 ranked shoes were relative to the Number 5 ranked shoes. As shown in Table 1, participants’ responses (including willingness to pay) for both the Number 1 and the Number 5 shoes were higher in the Top 20 (vs. 5) condition. However, the difference between the Number 1 and the Number 5 shoes was smaller in the Top 20 (vs. 5) condition. Moreover, evaluations mediated the effect of rank

length of rank on willingness to pay, demonstrating downstream consequences.

In summary, we introduce a novel effect that has both theoretical and practical implications. We show how consumers make sense of rank lists and how deviations in length can influence evaluations.

## **Paper #4: Trusting the Data, the Self and "the Other" in Self Tracking Practices**

Dorthe Brogård Kristensen, University of Southern Denmark, Odense, Denmark

### **SESSION OVERVIEW**

In the spirit of this year's ACR theme of Trust in Doubt? we bring together four projects that examine the rapid evolution of today's health care market, including the important dynamics of how consumer trust may be gained, lost, and re-established. The papers in this session blend multiple methodologies to explore different health and wellness contexts, viewing these service industries as a nexus of cultural and institutional forces and actors embedded within broader market dynamics. They offer insights into how market actors (consumers, organizations, service providers, regulators, legislators, popular culture) shape each market and their interpretations and actions within them.

Across micro to macro levels, they ask the following questions: how does a health care system change organizational culture to become more consumer-centric; what sensemaking and coping strategies do consumers use, when a commercial logic replaces a care logic in the health care market; how is the 'worthy' health consumer culturally produced; and what is the role of the "other" in consumer wellness empowerment.

The first paper studies the transition process in five large United States health care systems from entrenched, traditional culture to a more consumer-centric focus, to find what factors have facilitated or impeded change. The authors find that trust is an important factor in organizational culture change both at the institution level and for patients/consumers. The post trust world is evident in the tension between the bonds of trust patients want to have in their medical providers vs. the responsabilization they do not necessarily want as newly empowered consumers of medical care.

The second paper examines how consumers endowed with different combinations of resource capabilities navigate the eldercare

services market around Alzheimer's Disease. Based on archival data and interviews with various stakeholders across the network of care for the aging, the authors find myriad market factors, such as facility profit-motives, chronic staff shortages and poorly motivated workers, that contribute to consumers' feelings of betrayal and loss of trust in this prolonged service relationship.

The third paper studies how public discourse impacts cultural valorization in the cancer marketplace between 1987 and 2016, and, thus, offers a historical view of the dynamic nature of value processes. The authors find a system of "hopeful uncertainty" driven by public discourse mediates reconfigurations in the cultural value of, which includes trust in, consumer subjects, practices, and services in the marketplace, as well as the triggers and implications of these changes.

The fourth paper analyzes consumers' trust in data as they communicate and articulate health and well-being through self-tracking practices in fitness and Quantified Self communities and the role of "data mediators" (data coaches and personal trainers) as they assist in reading and setting up frames of action. By locating the roles of consumer, coaches and social media, this study questions self-tracking as a highly individual practice.

Across a variety of domains, spanning two ideologically disparate cultures, these studies capture the discursive, market-mediated shaping of medical consumers, their subjective experiences, and the role of trust in the fast-changing health care and wellness landscape.

## **Turning the Titanic: Creating Consumer-Centric Cultures and Improved Consumer Experience in Large, Established Health Care Systems**

### **EXTENDED ABSTRACT**

#### **Introduction**

The battle is on to disrupt the multi-billion dollar health care industry—and many of the battle lines have been drawn around consumer experience. Large, established, traditional health care systems are facing unprecedented competition from new market entries and different models of care. In recent news, CVS has partnered with Aetna to create a mega-entity health care payer and medical provider. Jeff Bezos, Warren Buffett, and Jamie Dimon of JP Morgan have joined forces to start their own health care company. Visionary entrepreneurs have launched stand-alone "doc in the box" clinics with easy and convenient open access, unaffiliated with existing health care systems, yet extremely popular with patient consumers. Such examples of increasing disruption abound.

In this fast-evolving market, health care systems understand that they must become more consumer-centric in order to survive and thrive, as patients exercise their increasing choice in the marketplace, and demand a better care experience. But understanding and implementing are two very different things, especially for large systems with entrenched cultures. As these entrenched systems work to respond to consumer demand for better experiences, informants within them self-report this cultural change akin to "turning the Titanic". In this study, we ask: 1. How can such health care systems implement processes to become more consumer centric? And 2. What is the consumer experience in these systems as they are attempting change?

We analyze five large United States health care systems to find what has made this transition successful, and what has impeded it.

## Background

Health care professionals and the industry as a whole have accepted the need for care to be patient-centered (Epstein and Street 2011). Patient-centered care has been linked to better patient outcome (Oates et al. 2000; Robinson et al. 2008); increased patient satisfaction (Maizes et al. 2009; Malingers et al. 2005); greater perception of value (Epstein and Street 2011); and decreased medical costs (Charmel and Frampton 2008). However, there are many obstacles and many different possible approaches to creating change, and the most effective path forward for those systems seeking change remains unclear.

A corollary to patient centered care is seeing the patient as consumer who is involved in the coproduction of their medical care, decision-making, and delivery (Gallen et al. 2013; Joiner and Lusch 2015). This mindset has been a more difficult one for the medical community to embrace (Hyatt 2003; Newman and Vidler 2006). However, ignoring the consumer focus leads to decreased patient satisfaction, lower reimbursement rates, loss of revenue, and lower new customer acquisition due to word of mouth and negative public reviews. However, the literature on the processes of a transition to a more consumer centric approach within health care is even more sparse than the literature on the process for achieving true patient centered care success.

## Methods

We gained entry to five large health care systems (>\$1 billion/annum revenue each) that have made it a leadership priority to transition to a consumer-centric model. The systems are situated across the US in the Northeast, the Southeast, the Midwest, the West, and the Sunbelt. Cross-sectional varied observation sites were chosen within all systems--these ranged from small rural, suburban or inner-city clinics, to large flagship medical centers, to specialty care centers such as sports medicine and cardiac rehab, to administrative support sites. Over a period of 10 months, all four authors traveled to each system for naturalistic observation and in situ interviews. All four authors also visited all system headquarters and various satellite sites for unstructured depth interviews (n= 72) ranging from 45 minutes to 3 hours each. Informants were distributed vertically (e.g. CEOs, CMOs, Chief Experience Officers and other C-suite executives, middle management, front line care providers, ancillary and support staff) and horizontally (e.g. employees from medical services, marketing, strategy, billing and finance, insurance). We also held depth interviews with patients from each system (n=17) to triangulate their experiences with system data.

## Findings

Using the framework of process implementation during transition (Gebhardt, Carpenter, and Sherry 2006) to find what processes are associated with the success of implementation of patient-centered/consumer centric care practices, we find that this follows a similar process in health care as a transition to a consumer-centric focus in other industries. Gebhardt and his coauthors found that organizational culture had to change via a four-stage process model for a transition to market-oriented, consumer-centricity: 1. Initiation 2. Reconstitution; 3. Institutionalization and 4. Maintenance. In addition to seeing strong evidence that this model holds in our case, we also find that it must occur in order. As an example, it appears that a major impediment to cultural change in a health care system trying to transition to a more patient/consumer centric focus is attempted

institutionalization of new cultural values and “norming” or proceduralizing them before the reconstitutive efforts had succeeded—e.g. before achieving buy in by all stakeholders across the institution.

We also find that the cultural values needed for successful consumer-centric shifts in the Gebhart et al work on non-health care industries are necessary for the systems to successfully transition to a consumer-centric model. Higher or lower levels of empathy, respect, collaboration, trust, openness, and a shared vision of “consumer first” appear to relate directly to system-wide success or difficulty in transition.

Interviews with patients in these systems reveal a number of themes that mirror the institution, such as the importance of respect, empathy, trust, and openness. However, we also see dramatic tensions that persist and are deepened between patient desired empowerment vs. unwanted responsabilization (DuFault et al. 2016; Botti et al. 2009; Joiner and Lusch 2015; Thompson 2004; Veresiu and Giesler 2014). Further, we find a large array of patient preferences that do not match what providers and/or leadership believe their newly envisioned consumers want.

In conclusion, we find that we can effectively analyze the transition of health care systems as they move to a more consumer-centric focus by utilizing the framework of process implementation during transition. However, we also find that extensive challenges remain in incorporating the “voice of the consumer” into these systems.

## Conflicting Institutional Logics and Eldercare Consumers' Coping Strategies in Asymmetrical Service Relationships

### EXTENDED ABSTRACT

#### Introduction

An estimated 5.7 million Americans of all ages and 1 in 10 persons over the age of 65 years are living with Alzheimer's and other dementias in 2018. With numbers projected to rise to 7.1 million by 2025 (Alz.org), and little hope for a cure in sight (Dilts 2018), the care and management of Alzheimer's patients is a major public health concern. Many of these seniors with cognitive and functional limitations need assistance at home, or in community and institutional settings (cbo.gov). Current senior care is in a state of crisis, which is guaranteed to grow as the boomers age. Much of this industry, especially since Wall Street entered the picture in the 1990s, views eldercare as an emerging commercial opportunity and strives to maximize shareholder profit, expansion and pursues workforce and other efficiencies. Conversely, care facilities are experiencing shortage of care workers which directly impacts quality of care. Consumers experience a dearth of alternatives, poor care, high cost and retrenchment of long-term care insurance and welfare support.

Prior research on elderly consumers has looked at post-retirement identity reconstruction (Schau et al. 2009), technology adoption behaviors (Gilly and Zeithaml 1985), age-related changes in consumption behaviors (see Moschis 2012) and old age consumption as a group phenomenon (Barnhardt and Peñaloza 2013). However, our understanding of the market serving elderly consumers, how structural conditions, resource endowments and competing institutional forces constrain and shape their service experiences, is limited.

This research examines the issue of how consumers, endowed with different combinations of resources, cope in a market where institutional interests have produced conditions where consumers face now just the effects of Alzheimer's on a loved one but also shortfalls in services provisioning. It explores the interpretive framings various stakeholders use to make sense of their subjective positions and

experiences, and the consequent interpersonal dynamics between service providers and consumers in the often-protracted service experience of long-term care.

## Methods

I use the concept of institutional logics to analyze the broader macrosocial environment of the eldercare market. These are the sociohistorically patterned beliefs, values and practices that stakeholders (organizations and actors) pursue (Thornton et al. 2012). To initially parse the various institutional logics, archival data was collected on eldercare, medical and pharmacological news, and debates on health care policy. Further this research uses Bourdieu's theory of cultural capital (Bourdieu 1986) to examine the role of resources in how families cope with Alzheimer's disease and Elias's figurational sociology (Elias 1978) to examine the micropolitics of power in asymmetrical service relations. For this, in-depth interviews were conducted with 42 stakeholders across the aging network to understand subjective experiences of eldercare (Thompson et al. 1989). Participants included family caregivers, directors of care facilities, care workers, lobbyists, legislators, social workers and eldercare attorneys. Additionally, participant observation was conducted at support-group meetings, conferences and fundraising events. Data analysis followed a hermeneutic approach (Thompson 1997).

## Findings

The analysis reveals that plural institutional logics are at play in this unstable market (Fligstein 2002). The logic of care, followed by family caregivers, advocates helping the elderly through their evolving needs. Eldercare facilities follow a self-reproducing commercial logic and strive for shareholder profit and future expansion. The commercial logic (in the health care domain) has not gained legitimacy from all stakeholders but the most reputable service providers have strategically coupled the commercial and care logics. The regulatory logic designed to ensure safety, pursued by regulatory and legislative agencies, has prompted manipulative industry tactics such as unnecessary use of psychotropic medications and elimination of Medicaid beds. Care workers, who are mostly female, perform the bulk of this low-skilled, underpaid, physical and affective labor, cite these contradictory logics when explaining quality of care. Together with the waning social welfare logic that seeks to reduce public health expense, the situation favors a market transformation towards at-home care, though the social costs for families will remain prohibitive.

Value is created when a consumer's well-being is improved (Porter 2010). The divergent institutional logics explain the value proposition-outcome gap experienced by eldercare consumers. Their search for value emerges as a contested process embedded within broader market dynamics (Venkatesh et al. 2006). Myriad market factors, such as facility profit-motives, chronic staff shortages and poorly motivated workers, contribute to consumers' feelings of betrayal. Better resourced consumers still experience challenges in service encounters with care workers because of their high level of dependence and lack of alternatives (Elias 1978). As their care goals are frustrated, family caregivers are often forced to intensify monitoring and care labor to extract 'value' - a tactic that I designate as 'value salvage'. Among families lacking resource endowments (economic, social and cultural capital), the caregiving journey produces experiences of poorer care, challenges in various service interactions, more constrained choices, family sacrifices and susceptibility to moral judgments.

## Contributions

This research contributes to understanding of health care disparities (e.g., Lee et al. 1999) and the dilemmas of attenuated access (e.g., Crockett and Wallendorf 2004) as well as the detrimental effects of marketization of health care (Varman and Vikas 2007). It examines the trickle-down effects of neoliberal socio-economic policies which have produced conditions of heightened risk.

It also empirically and critically examines the concept of value co-creation (Vargo and Lusch 2004), which proposes that value propositions attract stakeholders to share their resources during collaborative service exchanges. Challenging the view that a service ecosystem is a self-governed, self-adjusting entity with ties of coordination and reconciliation of conflict (Vargo and Lusch 2016), this research brings to bear, the discordant, conflictual side of value co-creation by highlighting the social costs of divergent stakeholder interests (Arnould 2007; Gummerus 2013; Peñaloza and Venkatesh 2006).

Unlike most of health care, which is moving towards the ideology of consumer-centric care (Epstein and Street 2011), much of the eldercare services industry lags. Our participants seek a service experience that justifies the high cost of care; frustrated by shortfalls, they try to salvage value. From the consumers' perspective, it is a service relationship failure and creates a situation that threatens the welfare of vulnerable seniors. The misaligned institutional interests and practices also interfere with the attainment of identity projects (e.g., the performance of role of caring family or competent care worker) (Deighton 1992; Epp and Price 2008).

## Public Discourse and Cultural Valorization in the Cancer Marketplace

### EXTENDED ABSTRACT

#### Introduction

In the year 2001 cancer became the most urgent health care problem that Americans felt the country faced (Gallup 2018). Given that AIDS had been viewed as the top priority for over 15 years (Gallup 2018), this represented a significant shift in public opinion. An interesting and important question this raises is "What social process enables changes in cultural value?" Scholars point to cultural valorization; that is, the "creation and operation of systems of (e)valuation," (Corse and Griffin 1997, p.174) which enable reconfigurations in the cultural value of institutions, practices and actors (Crane 1987; DiMaggio 1987; Lang and Lang 1988; Lamont 2012). For instance, Corse and Griffin's examination of Zora Neale Hurston's novel "Their Eyes Were Watching God" illustrate the cultural valorization process that transformed this novel from 'average' to 'canonical' status. However, historical processes that illuminate how public discourse reconfigures value (e.g., worth, merit, meaning, status) in the marketplace are limited in the marketing literature.

Prevailing theoretical views of value in marketing examine value at the micro level. These perspectives highlight that value emerges from the intrinsic characteristics of products and changing individual perceptions (e.g., Zeithmal 1988), co-creative efforts between consumers and firms (Vargo and Lusch 2004), and collective efforts of and reflexivity in consumers (e.g., Figueiredo and Scaraboto 2016; Parmentier and Fischer 2015; Schau, Muniz, and Arnould 2009; Thompson 2005). Sociocultural perspectives that examine macro-level emergence or changes in value remain scarce. A notable exception is the growing literature on legitimation (Dowling and Pfeffer 1975; Humphreys 2010a; Suchman 1995), which is considered a valorization sub-process that focuses on the "recognition...

of the value of an entity” (Lamont 2012, p.8). Our study builds on the literature that investigates the legitimation of new markets (e.g., Humphreys 2010a), stigmatized practices (e.g., Humphreys 2010b; Karababa and Ger 2010), and brand discourses (e.g., Giesler 2012).

Our examination of cultural valorization is important because learning about the mechanisms and triggers behind such value shifts can enhance our understanding of *how* marketplace entities experience dramatic changes in valorization while others do not. Thus, by studying cultural valorization we gain a more comprehensive view of the dynamic nature of value processes and how these may intersect and/or influence micro value processes in a variety of contexts. Additionally, understanding value reconfigurations have practical implications as these can marginalize or stigmatize marketplace actors by creating hierarchies or categories of “worthy” consumers, consumption practices, and markets, as some studies with baseball players (Allen and Parsons 2006), popular music (Regev and Seroussi 2004), and intellectual reputations (Lamont 1987) have shown. Our study, in particular, examines how public discourse impacts the cultural valorization of the cancer marketplace. We consider the following research questions: How is a service-centered market valorized by public discourse? What triggers influence cultural valorization changes in this market? What are the implications of value reconfiguration in this market?

## Method

We employ a multi-method approach to address these research questions. Specifically, to look at changes in historical discourses, developments and actions, we use archival data that include articles and advertisements (1987-2016) from mainstream U.S. newspapers (New York Times, Wall Street Journal, USA Today), popular books, TV shows and films, and informational materials such as pamphlets, videos, and documents from a variety of sources (e.g., library repositories, U.S. congress, regulators, trade organizations, non-profit organizations, and consumer groups). We utilize automated content analysis (Humphreys and Wang forthcoming) and co-occurrence network analysis (Koyama and Matsumoto 2004) to examine changes in macro discursive and affective structures in newspaper articles. We also use semiotic analysis (Chandler 2007; Mick 1986; Christensen and Askegaard 2001) and guidelines from Belk, Fischer, and Kozinets (2013) to conduct an iterative examination of all other textual and visual materials.

## Findings

We find that cultural valorization in the cancer marketplace relies on the operation of a system of discursive and affective (e) valuation. This system is based on discourses of collective hopeful uncertainty, with the emotions of fear and hope becoming paradoxical identifying features of this bioscience-based market. We also find three types of triggers that influence this system of (e)valuation: 1) ideological influences on meanings of hope by various marketplace actors at different points of time (e.g., government, expert systems, consumer advocates); 2) historical sociocultural developments (e.g., AIDS crisis, breast cancer activism, cause marketing); and 3) scientific discovery and commercialization efforts (e.g., AIDS cure; cancer treatment developments; cancer service innovations). Together, these triggers fuel changes in the system of collective hopeful uncertainty; thus, reconfiguring public perceptions of cultural value of the cancer marketplace over time. Lastly, we find that the operation of and changes to a system of collective hopeful uncertainty have implications for the consecration, reproduction, and hierarchy of consumer subjects in public discourse, and the emergence, growth,

and perceived financial valuation of this market’s services and treatments over time.

## Contributions

First, we contribute to the value literature by showing that an emotion-driven discursive system underlies the emergence, change, and reproduction of value in public discourse. Our study responds to calls by Arnould (2014), Figueiredo and Scaraboto (2016), and others for more process-based perspectives of value. Second, we show that notions and processes of value are subject to sociocultural historical construction and influences, responding to Askegaard and Linnet’s (2011) call for contextualizing marketplace phenomena. These two major contributions expand our current perspectives of value beyond products, individual or groups experiences and cognitions, and direct interactions of consumers with providers of good or services. Our work also contributes to the literature on cultural discourse and ideologies in health (e.g., Barg and Grier 2008; Thompson 2005) by highlighting their interrelatedness with affective structures. Last, our study has implications for the transformative consumer research literature as it underlines how cultural valorization and changes in contextual meanings (DeBerry-Spence 2008) can influence regimes of historical categorization, worth, and/or hierarchy of consumers, consumption practices, and markets.

## Trusting the Data, the Self and “the Other” in Self Tracking Practices

### EXTENDED ABSTRACT

#### Introduction

This paper focuses on the role of “the other” in usage of and trust in self-tracking data. Due to demographic pressures and the rhetoric of crisis in the health care sector, increasingly consumers are encouraged to take responsibility of their own health in order to gain control over the body and well-being (Fotopoulou and O’Riordan 2016). The emergence of self-tracking technologies has increased the possibility for lay people to access, evaluate and manage their own health – to become the master of their own health and well-being (Lupton 2013). Through the use of wearables and commercial apps on smartphones, tablets and computers, people have acquired the opportunity to monitor and track sleep, eating habits, weight, sports activities, calorie intake etc. (Etkin 2016; Kristensen and Ruckenstein 2018; Pantzer and Ruckenstein 2015). The data can be connected to social media sites, where, for example, one’s running route, speed, or diet can be shared amongst users.

#### Background

Among many self-trackers, it is assumed that the production of numbers or objective outcomes is a viable way to assess and represent the value of one’s life, to enhance personal health and well-being, that is both objective and freed of human bias (Daston and Galison 2010, Kristensen and Ruckenstein 2018). This insight leads to an understanding of tracking data as a very individualized form of health practice and as an example of self-help. But then, what is the role of personal coaches and data coaches that assist people in using and relating to data output? And what is the role of the audience - the people who link with and comment on data through likes etc. on social media platforms where self tracking data are shared?

#### Contribution

The aim of the paper is to analyse how self-trackers communicate and articulate health and well-being through data output tracking their physical activities, sleep and food consumption. Moreover,

the paper analyses the role of “data mediators” i.e., data coaches and personal trainers that use data visualization to communicate and keep track of their clients. While the role of the audience has been addressed (Baym 2013; Rettberg 2018), in the area of self-tracking there are only a few studies that consider social relationships (Depper and Howe 2017; Fotopoulou and O’Riordan 2016; Lomborg and Frandsen 2015). These studies, however, do not specifically address the role of social relationships in perception, trust and use of data

### Method

The paper is based on an ethnographic study of self-tracking among fitness users and personal trainers (15 informants). The overall methodology of the project involved ethnographic studies of self-trackers’ experiences and everyday practices, with focus on social relations and media platform that form part of self tracking practices. Departing from post-phenomenological approaches (Verbeek 2011), we seek evidence of how technologies mediate perceptions and action, and condition experience. We furthermore demonstrate that self-tracking technologies become participants in the transformation of self-experience, but that social relationships also play a crucial role. An additional focus is on the role of “likes” associated with the sharing of self-tracking technologies on social media platforms. More specifically, we analyse the feedback loop (Patzer and Ruckenstein 2015) provided by data, coach and likes.

### Findings

Departing from these questions, the paper will analyse the mutual constitution of a kind of mechanical objectivity (Daston and Galison 2010) and the subjectivity of the self-tracker (Verbeek 2008). The study shows that the relationship with the coach and “likes” on social media platforms provides a “hook” or a reward structure through which consumers are moulded (Kristensen et al. 2017; Schüll 2012). Quantification and visualization provided in self-tracking can provide visibility to certain aspects of self and performance, and by so doing, can provide a frame for action. Personal trainers here assist by providing advice on how to use self-tracking in a balanced and sound way and by offering feedback on the overall process of training in a fitness center. They assist their clients in reading data, responding to data, and using or discarding data as useful frames of action. They also aid their clients in managing the tension between being “in control” through quantified measurement for performance, and opening up for an embodied feeling of being “in contact with oneself”. Social media audience also play a role, as they provide feedback on data output visualizations and confirm the actual frame of action set up by personal trainers and their clients. Based on these findings, this research questions the notion of self-tracking as an individual practice. Furthermore, this research has the implication that management of health may be located outside the health care sector.

## SESSION OVERVIEW

Almost by definition, consumers should prefer good product options to bad ones. All else equal, people tend to prefer options that are higher in quality, free of flaws, consistent, and morally acceptable over those that are worse, flawed, inconsistent, or morally objectionable (Kruger et al. 2004; Kunda 1990; Levin and Johnson 1984; Lord et al. 1979; Tetlock et al. 2000). However, recent research demonstrates that mistakes in the design process can bolster product preference (Reich, Kupor, and Smith 2018), that horrible movies often attract devoted fans (Sarkhosh and Menninghaus 2016), and that consumers often seek out hedonically unpleasant experiences (Keinan and Kivetz 2011).

Why would consumers ever prefer to spend their limited time and money on bad options? Though some initial investigations have started to chronicle when these preferences might emerge, many unanswered questions remain. What do flaws, inconsistencies, or offensive qualities signal about products or producers, and when are these qualities important enough to drive consumer preference? What factors drive consumers to choose bad options rather than good options, and where do consumers derive their utility in each case?

This session seeks to provide new insights about when and why bad qualities can improve the value of products and services. First, **Carter** and **McGraw** showcase five studies demonstrating when product flaws are appealing. When product flaws reveal desirable information about the creation process (i.e., a singer forgetting a lyric proves a concert isn't lip-synced), they can boost rather than diminish preference. Second, **Smith** and **Gershon** discuss how inconsistency in performance can enhance perceptions of authenticity. In four studies, they provide evidence that people perceive performers who repeat performances as less authentic, reducing consumer evaluations. Third, **Bhattacharjee**, **Berman**, and **Yalcin** present evidence that offensive behavior by artists (e.g., personal racism or producing content with racist themes) can arouse greater consumer interest in their work. Across four studies, people perceived offensive artists as more authentic and creative than those who behaved acceptably. Finally, **Weingarten**, **Bhattacharjee**, and **Williams** present evidence

for so-bad-it's-good consumption, or consumer preferences for extremely bad options over mediocre ones. In nine studies across several content domains, people were more likely to choose options they expected to be extremely bad rather than merely bad or average.

Together, these papers provide a more nuanced understanding of how consumers gain utility from seemingly bad qualities. This session explores what traditional notions of product quality fail to capture: the costs of badness may help signal the presence or authenticity of other desirable sources of value.

All four presentations are developed and have at least four completed studies. We expect this session to generate interest among researchers spanning a broad range of topics, including consumer preference, experiential consumption, signaling and symbolic consumption, authenticity, taste and quality, aesthetics, and humor. And given the presentations' relevance to fundamental assumptions about consumer preference and notions of value, we hope to stimulate a fruitful discussion.

### **In Pursuit of Imperfection: How Flawed Products Can Reveal Valuable Process Information**

#### EXTENDED ABSTRACT

Can a product be too perfect? Can marketing communications be too polished? Can packaging be too pristine? Although decades of marketing research and business best practices assert that consumers prefer flawless consumption experiences, we show that consumers sometimes prefer flawed experiences. Concertgoers, for instance, may be pleased to hear a singer flub a lyric because the error reveals the performance isn't lip synced. Or an uncle may be delighted by a badly wrapped present because he knows that his six-year old niece did the wrapping.

Marketers are trained to identify, improve, and highlight marketing tactics that consumers care about. Because consumers prefer consistent color, symmetrical shape, and a smooth texture in their produce, for example, it is logical for marketers to assume that people prefer unblemished apples to blemished apples. Indeed, after crops are harvested, culling aesthetically imperfect produce is the primary reason for losses of fresh produce (Gunders, 2012). However, consumers can also care about how a product came to be (Newman and Bloom 2012; Rozin 2005). Organically farmed produce, for example, is preferred by some segments to conventionally farmed produce.

Consumers who value how a product originated may seek information to verify what production processes were used (Meyer 1982). Process information, however, is often scarce or difficult to verify (e.g., Darby and Karni 1973; Sun, Keh and Lee 2012). Unable to observe the process (e.g., without making a trip to the farm) and dubious of a retailer's claims (Friestad and Wright 1994; Campbell and Kirmani 2000), would-be buyers act as detectives, using the clues available to them to infer the presence of a valued production process (Harris 1981; Huber and McCann 1982; Kirmani and Rao 2000). Although flaws typically hurt product evaluations, we propose that they enhance product evaluations when a flaw provides a clue that the product was produced via a desired process. Minor blemishes can indicate that an apple was grown without pesticides. We suggest that whether a flaw signals a desired process or not is dependent on the

consumers' causal understanding of how the flaw originated (Fernbach, Darlow and Sloman 2011; Fernbach and Erb 2013; Garcia and Koelling 1966; Krynski and Tenenbaum 2007; Tversky and Kahneman 1977 & 1980).

We test our hypotheses in five studies that use products and marketing communications as stimuli.

In study 1, we randomly assigned half of the sample ( $n=107$ ) to read a statement suggesting that some produce labeled organic is not actually grown according to organic standards. When subjects doubted organic claims, they reported being more likely to select apples from bins containing flawed apples compared to bins containing flawless apples (39% versus 20%,  $\beta_{\text{doubt}} = .95$ , Wald = 4.3,  $p = .04$ ).

In study 2, we randomly assigned half of the sample ( $n=108$ ) to read a statement suggesting that many concerts are lip synced. When subjects doubted that the show was live, they preferred a flawed performance more often than subjects in the control condition (58% versus 20%,  $\beta_{\text{doubt}} = 0.887$ , Wald = 4.1,  $p = .04$ ).

Study 3 was designed to test a prediction that flaws should improve evaluations when subjects: 1) value the process and 2) have the knowledge necessary to infer a process. We randomly assigned subjects ( $n=282$ ) to a 2 (product: flawed apples vs. flawless apples) by 2 (knowledge: control vs. non-organic methods more effective at controlling pests) design. We also measured the extent to which subjects preferred organic produce. Our analysis revealed a significant three-way interaction between flaw, knowledge, and preference for organic products,  $t(274) = 2.0$ ,  $p < .05$ . A floodlight test (Spiller et al. 2013) showed that whereas flawed apples were always less desirable among subjects who did not generally favor organic produce (regardless of the knowledge manipulation), flawed apples were evaluated more positively among subjects who preferred organic apples and who were informed that pesticides are more effective at controlling pests. A bootstrapped mediation analysis (Preacher and Hayes 2008) revealed that certainty that the apples were organic mediated the effect, and the competitive mediation pattern was consistent with our predictions (Zhao, Lynch and Chen 2010).

In study 4, we examine how the severity of a flaw and presence of an alternative (non-ideal) process explanation for the flaw moderate our effect. Using a 3 (flaw severity: flawless, mild flaw, severe flaw)  $\times$  2 (process: ideal vs. non-ideal) design, we find that flaws (typos in an email from a favorite celebrity) only improve evaluations relative to flawless alternatives when they are minor as opposed to severe. Furthermore, we find that the positive effect of even a mild flaw on evaluations disappears when the flaw no longer signals the ideal process (that the email was written by the favorite celebrity) and instead signals a non-ideal process (that PR companies write promotional emails with typos so that the emails appear that they may have been written by the celebrity as opposed to a PR professional). The effect was mediated by certainty that the celebrity wrote the email, and moderated by both presence of an alternative cause for the flaw and by an individual difference measure of the importance of the celebrity writing their own email.

Finally, in study 5, we conducted a conjoint analysis on willingness to pay for a number of chairs with different features combined with a 3 (process importance: control, reclaimed, beetlekill) by 3 (knowledge: control, reclaimed wood often shows sign of use, beetlekill wood exhibits blue streaks) between subjects design. Analyzing the utility weights of various product features revealed a significant interaction of our process importance and knowledge manipulations ( $F(4, 505) = 3.06$ ,  $p = .03$ ), such that the utility weight of a flaw was only positive when participants valued a process that was associated with that flaw and had the knowledge necessary to connect the presence of the flaw to the associated process.

We conclude by discussing implications for consumer reasoning, choice models, and marketing tactics.

## Repeat Performances Decrease Consumer Perceptions of Authenticity

### EXTENDED ABSTRACT

Repeat performances are common: celebrities repeat themselves in interviews, entrepreneurs give the same business pitches, comedians often repeat their routines, and politicians deliver the same stump speech across numerous audiences. While behaving consistently or reliability has been found to enhance perceptions of authenticity and evaluations more generally (Cross, Gore, and Morris 2003; English and Chen 2011; Napoli et al. 2014), we find that repeat performances can dampen consumers' perceptions of performer authenticity and subsequent consumer intentions. We theorize that this is because consumers hold similar intuitions about performances (like jokes, speeches, and business pitches) as they do about artworks—there is one authentic, original performance and repetitions are seen as copies. Indeed, for artworks, originality is a salient dimension along which authenticity is assessed (Bruhn et al. 2012; Moulard et al. 2015). We propose that when consumers rate a performer who repeats a performance as less authentic, they are drawing on this originality dimension of the term; the performer now appears less authentic with respect to originality. Importantly, we theorize that this is driven by a lay belief that repeating one's own performance decreases authenticity, rather than by discernible differences between repeated and non-repeated performances. We test these predictions in five studies.

In Study 1, participants viewed the same clip of a business pitch and either read that it was the speaker's first or tenth time giving that exact pitch. Participants then rated how authentic they believed the speaker was using a three-item scale of authenticity perceptions (authentic, sincere, and genuine). Despite watching the same clip, participants who believed they were watching a repeated (vs. non-repeated) performance perceived the speaker as less authentic.

Study 2 was divided into connected studies. First, we created repeat performances by recording individuals answering the same interview questions three times. We found that participants believed their responses became less authentic with each repetition. However, when a separate group of participants (who were unaware of repetitions) viewed a single clip, we did not observe a difference in perceived authenticity. Finally, a third group of participants viewed a single interview clip (1<sup>st</sup>/3<sup>rd</sup> take), and were told either correct or incorrect information about the clip ("This is this person's 1<sup>st</sup> [3<sup>rd</sup>] time recording their answer to this question"). We found a main effect of belief (participants rated the interviewee as less authentic when they believed the clip was a repeat), but no effect of whether the clip was actually a repeated or non-repeated performance. These studies provide converging evidence that this effect is driven by a lay belief that copying one's own performance decreases performer authenticity rather than by discernible differences between repeated and non-repeated performances.

Study 3 tested this effect in a different domain and measured consumer consequences of repeat performances. We used two performances in which a comedian told the same joke in different contexts (repeat condition) or only one of those performances (no-repeat condition). Participants viewed either one clip (randomly assigned) or both clips consecutively (randomized). Participants then answered questions regarding perceived authenticity and consumer intentions for the comedian. As predicted, participants who saw both clips had lower consumer intentions toward the comedian than those

who saw only one clip. Consistent with previous studies, repeat performances decreased perceptions of authenticity. Further, perceptions of authenticity significantly mediated the relationship between repeated performance and consumer intentions.

Finally, Study 4 showed that repeated performances do not always result in negative consumer attitudes. We contrasted the effect of repetitions on performer authenticity for performances in which the content is either highly self-expressive or less self-expressive. In the self-expressive condition, participants viewed another comedian telling the same joke in two different contexts, while in the non self-expressive condition, participants viewed a doctor explaining the same medical findings in two different contexts. We theorized that repetitions lower authenticity perceptions because consumers are hinging on the originality dimension of authenticity when assessing self-expressive acts. However, for non self-expressive material, such as medical findings, we propose that consumers are less concerned with the originality of the performance and more concerned with its accuracy. As predicted, we found a significant interaction between repetition and self-expressive content. In the self-expressive condition, consumer intentions were higher for participants who viewed only one clip, but for the non-self-expressive condition, consumer intentions were higher for those who viewed both clips. Perceived authenticity mediated this interaction.

These studies document a novel effect—identical performances result in different judgments of the performer depending on whether observers believe the performance was repeated. While prior research has established that individuals who behave consistently are generally seen as more authentic (Cross, et al. 2003; English and Chen, 2011; Napoli et al., 2014), this work suggests that exposure to certain kinds of consistency can potentially dampen perceptions of authenticity. This work also shows that the same cue of repetition can create opposing effects on authenticity judgments depending on which dimension is evoked. In this case, we contrasted whether the content of a performance was self-expressive or not. This demonstrates empirical support for the notion that entities are authentic “with respect to” some referent (Carroll and Wheaton 2009; Dutton 2003), wherein, it is critical to identify the dimension people are referencing when forming authenticity judgments.

This work also holds practical implications. Performers often invest significant effort into producing original content, but these findings suggests that if they are recorded repeating a performance, their reputation could suffer. Consumers often observe repeated performances. For instance, as in Studies 3 and 4, YouTube viewers are often directed to similar clips of the same performer. Our work suggests that performers would benefit from controlling the reproduction of their content in order to manage how often they are shown repeating performances.

This research contributes to a body of work that has identified the importance of perceived authenticity in consumer preferences. We find that a cue, such as repetition, of an otherwise identical performance can lead to different assessments of performer authenticity and differential consumer intentions towards the performer.

## The Upside of Immorality: The Signal Value of Offensive Producer Behavior

### EXTENDED ABSTRACT

*“Every great work of art is offensive to someone.”*  
—Gerald W. Johnson

Woody Allen. Louis CK. Ernest Hemingway. Steve Jobs. John Lennon. Hunter S. Thompson. Richard Wagner. Kanye West. His-

tory is littered with luminaries as infamous for their personal transgressions as they are famous for their creative accomplishments. How does morally offensive behavior by producers affect consumers’ evaluations of their work?

A large body of work on halo effects demonstrates that moral assessments of producers often affect the perceived value of their products (Chernev and Blair 2015; Lee and Kwak 2016). Moreover, the negative effects of morally offensive producer behavior tend to be substantially stronger than the positive effects of morally praiseworthy behavior (Trudel and Cotte 2009). Beliefs about contagion further contribute to these effects: objects are thought to assume the essence of their owners, making people willing to pay enormous sums for golf clubs used by JFK but reluctant to try on a sweater worn by Adolf Hitler (Nemeroff and Rozin 1994; Newman Diesendruck and Bloom 2011). Both of these mechanisms may be especially influential in creative domains, where product value depends heavily on the identity of the creator (Bar-Hillel et al. 2012; Newman and Bloom 2012).

In stark contrast to these past findings, we propose that morally offensive behavior by producers can *enhance* the perceived value of their work. While transgressing social norms indicates poor moral character, it might also indicate a strong commitment to honesty (cf. Feldman et al. 2017; Jay 2009). We present four studies demonstrating that a willingness to offend signals authentic producer motives for unfiltered self-expression and a lack of concern for audiences. Accordingly, offensive behavior by producers can increase consumers’ evaluations of their creative output.

In Study 1 (N=166), participants evaluated a painting by an artist known for either mildly offensive sexist behavior or severely offensive racist behavior. In one condition, they read this biography before seeing the painting, coloring their evaluations of the work. In another condition, they saw the painting first, thus forming their initial judgments before learning of the artist’s offensive personal behavior. Participants who knew about the artist’s immoral behavior beforehand evaluated the painting more favorably, compared to those who learned this information afterwards ( $M=6.33$  vs.  $5.71$ ,  $F(1,162)=4.43$ ,  $p=.037$ ), regardless of the severity of the transgression ( $F(1,162)=1.64$ ,  $p=.202$ ). Moreover, participants who knew about the artist’s immoral behavior before seeing the painting were more willing to visit a gallery show featuring the artist (53.0% vs. 32.5%,  $\chi^2(1)=7.11$ ,  $p=.008$ ) and more willing to hang a poster of the painting in their home (59.0% vs. 38.6%,  $\chi^2(1)=6.97$ ,  $p=.008$ ).

We conducted a follow-up study (N=180) to explore individual differences in the willingness to visit a gallery show featuring an immoral artist. Responses were strongly correlated with participants’ beliefs about the importance of a unique artistic perspective ( $r=.41$ ,  $p<.001$ ), their beliefs about the importance of art ( $r=.33$ ,  $p<.001$ ), and the extent to which they personally cared about art ( $r=.37$ ,  $p<.001$ ). These results provide preliminary evidence that individuals’ support for immoral artists is related to the value they place on creative expression.

Study 3 (N=204) further investigated the extent to which offensive behavior is thought to signal creativity. Participants read a description of a high school student and evaluated his aptitude across a variety of subjects. In one condition, he was described as having a history of offensive, disruptive, and problematic social behavior. In another condition, he was described as well-adjusted with no history of behavioral problems. Participants then indicated how they expected the student to perform on standardized tests for logical reasoning and creative expression. Compared to well-adjusted behavior, offensive behavior was thought to indicate worse logical reasoning abilities ( $M=54.14$  vs.  $71.94$ ,  $t(202)=6.82$ ,  $p<.001$ ), but a signifi-

cantly better aptitude for creative expression ( $M=70.89$  vs.  $58.72$ ,  $t(202)=4.82$ ,  $p<.001$ ). While the offensive student was perceived as less moral ( $M=3.08$  vs.  $5.46$ ,  $t(202)=17.66$ ,  $p<.001$ ), he was also perceived as more interesting ( $M=5.31$  vs.  $2.80$ ,  $t(202)=12.52$ ,  $p<.001$ ).

Finally, Study 4 ( $N=305$ ) examined producers' willingness to include offensive product characteristics rather than immoral personal behavior, and sought more conclusive evidence that offensiveness is thought to signal authentic motives. Participants evaluated a movie producer who planned to adapt either a fiction or non-fiction book about a Neo-Nazi gang leader. In the baseline condition, the producer chose to include morally offensive scenes depicting violence, sexism, and racism. In another condition, the producer chose to tone down these scenes by removing offensive content, while in a third condition, he chose to add inoffensive elements (admirable female and minority characters) to make the movie less offensive. There were no differences between these ways of reducing offensiveness, and these conditions are collapsed below for ease of reporting.

Compared to reducing offensiveness, including offensive content increased perceptions of the producer's authentic motives ( $M=4.86$  vs.  $3.87$ ,  $F(1,301)=79.66$ ,  $p<.001$ ), honesty ( $M=5.19$  vs.  $4.61$ ,  $F(1,301)=13.39$ ,  $p<.001$ ), and creativity ( $M=4.27$  vs.  $5.03$ ,  $F(1,301)=43.23$ ,  $p<.001$ ). Only perceptions of authenticity mediated the effects of offensiveness on participants' expected enjoyment of the movie (indirect effect =  $-0.562$ , 95%CI[- $0.850$ ,  $-0.307$ ]). Interestingly, there was no main effect of the fiction manipulation and no significant interaction ( $F_s<1$ ). Regardless of whether the movie concerned true or fictional events, a willingness to incorporate offensive content served as a signal of the producer's commitment to authentic, unfiltered creative expression, thus enhancing the perceived value of their work.

These findings highlight the moral virtue consumers associate with authenticity (cf. Gino Kouchaki and Galinsky 2015). A willingness to transgress other moral norms may signal a commitment to truth, enhancing the value of creative work. Upholding other moral standards, such as concerns about objectionable content or consideration for audiences, may involve direct trade-offs for artistic producers.

## So-Bad-It's-Good: When Consumers Prefer Bad Options

### EXTENDED ABSTRACT

Understanding why consumers seek to consume good content (e.g., movies, TV shows, books) is trivial, even if definitions of good vary considerably and expectations often go unmet. But why would consumers seek to consume content precisely *because* they expect it to be bad? Why did Tommy Wiseau's movie *The Room* become a cult classic for its extreme badness? Why did Rebecca Black's song "Friday" and its disastrous lyrics garner over 100 million views on YouTube? And why did William Hung's atrocious rendition of "She Bangs" on American Idol become a viral sensation?

The phenomenon of "so-bad-it's-good" (SBIG) movies, songs, and other content is almost universally recognized by consumers. Between major media outlets and user-generated sites like BuzzFeed and FAIL Blog, compilations of SBIG content and spectacular failures attract ample attention. In a pilot study ( $N=158$ ), 96% of participants had little difficulty generating multiple examples of SBIG content, and over a third indicated having been sent such content by others.

Yet, the SBIG phenomenon has received little attention beyond initial investigations by humanities scholars (e.g., descriptions of ironic enjoyment of "trash" movies by cinema enthusiasts; Sarkhosh and Menninghaus 2016), and virtually none from consumer

researchers. Prior work on *schadenfreude* over product failures from high-status entities (Sundie et al. 2009), preferences for polarized products (Rozenkrantz, Wheeler, and Shiv 2017), or enjoyment of norm violations (McGraw and Warren 2010; McGraw et al. 2012) appears conceptually similar, but none directly examines when or why people would choose to consume content they expect to be bad over better alternatives.

In what domains and why do consumers exhibit preferences for SBIG options? Though offerings within taste domains are often thought to be horizontally differentiated, consumers also readily perceive and discuss vertical differences in quality in these domains (Spiller and Belogolova 2017). But why would people deliberately choose content that they themselves expect to be inferior in quality?

We examine when and why people may be more likely to pick a very bad option over a mediocre option. We expect that a majority of people will pick the best option available over both bad or mediocre alternatives. But given these alternatives, any choices of very bad options whatsoever (and especially more choices of these options over mediocre options) would serve as a proof-of-concept of the SBIG phenomenon.

To determine which content domains are most characterized by SBIG choices, an initial laboratory study ( $N=173$ ) simply asked consumers where their SBIG preferences are strongest. Participants reported their agreement with the statement "Some \_\_ are so bad they're good" for a wide variety of domains (1 = strongly disagree, 4 = neither agree nor disagree, 7 = strongly agree). While there was overwhelming agreement that certain domains were especially likely to produce SBIG content (e.g., talent show auditions, pickup lines, jokes, reality TV), others were mentioned by only about half the participants (e.g., crime shows, rap songs), and SBIG was seen as particularly unlikely in others (e.g., cakes, cookies).

Next, eight studies examined whether people were indeed more likely to choose very bad content over very good content across these various domains. In all of these studies, participants indicated which option what they'd prefer to consume based on quality ratings we provided.

In domains highly characteristic of SBIG (e.g., American Idol auditions,  $n=100$ ), more participants picked a very bad option (average rating of 1.5/9.0 stars; 36%) than a mediocre option (5.0/9.0 stars; 22%), though a very good option was chosen most frequently (8.5/9.0 stars; 42.0%). This was not true in domains seen as less characteristic of SBIG (e.g., rap,  $n=94$ ; 14.9% vs. 21.3% vs. 63.8%). However, SBIG preferences emerged in both domains in another study asking participants to rank nine options corresponding to each star rating ( $N=194$ ; first-ranked options: 20.1% vs. 6.2% vs. 73.7%). We replicated these results in several other studies: for instance, people were more likely to choose a 1-star option over a 5-star option for both American Idol auditions ( $n=95$ ; 20.0% vs. 8.4%,  $\chi^2=4.21$ ,  $p=.040$ ) and Game of Thrones fan-fiction ( $n=105$ ; 13.3% vs. 3.8%,  $\chi^2=4.88$ ,  $p=.027$ ).

What distinguishes domains that are especially likely to have SBIG content? Initial evidence suggests that the domains most associated with SBIG consumption are perceived as more low-brow ( $F(1,192)=73.64$ ,  $p<.001$ ), with content more focused on immediate hedonic enjoyment than learning or other utilitarian benefits ( $F(1,192)=316.76$ ,  $p<.001$ ). Indeed, a within-subjects study found that these domain differences significantly predicted the proportion of 1.2-star choices ( $N=156$ ,  $z=3.09$ ,  $p=.002$ ).

Two subsequent studies tested whether choices of low-rated options depend on their status as the worst option available, as well as the extremity of their badness. Participants ( $N=241$ ) asked to select an Olympic ski run to watch based on judges' ratings selected a

low-rated run more frequently when no worse options were available (25.0% vs. 1.3%), and choices of the worst option increase when it was extremely bad rather than somewhat bad ( $\chi^2=7.23, p=.007$ ). We replicated these results with choices of clips of the reality show "So You Think You Can Dance" (N=193): low-rated options were chosen more when they were the worst option, and extreme badness increased choices of the worst option ( $\chi^2=6.07, p=.014$ ).

Our findings are the first to quantitatively document SBIG preferences, as characterized by systematic choices of bad over mediocre content. The variation we observe across domains, as well as evidence from a variety of measures, provides initial insights about what drives SBIG and how enjoyment of bad content differs from enjoyment of good content. However, it is worth noting that these effects are apparent both within domains evaluated in terms of quality as well as those evaluated in terms of taste (Spiller and Belogolova 2017). Given the prevalence of this phenomenon, as well as the lack of relevant research, we hope these initial findings can lay a solid foundation for future research.

## Paper #4: Psychological Reactions to Human Versus Robotic Job Replacement

Armin Granulo, Technical University of Munich, Germany  
Christoph Fuchs, Technical University of Munich, Germany  
Stefano Puntoni, Erasmus University, The Netherlands

### SESSION OVERVIEW

Artificial intelligence (AI) is becoming ubiquitous in our society. AI-based technologies are manifold and pervade just about every aspect of consumers' lives. Dating sites use algorithms to match people looking for love. Hospitals use IBM's Watson to diagnose cancer and heart disease. Companies use chatbots to deliver customer care. Financial institutions use algorithms to automate trading and investment decisions.

What are the implications of AI-based applications for consumer trust? This session features research offering a wide range of perspectives on this question. In particular, this session showcases the most up-to-date research that examines what factors hinder versus foster consumers' trust in AI and what psychological processes are at play when consumers interact with AI.

The topics covered in this session include: (1) when do consumers prefer the input of an algorithm over the input of a human; (2) when do consumers rely on algorithmic advice, (3) what is consumer receptivity to artificial intelligence providing medical care; and (4) what are the psychological consequences of robotic replacement of human labor.

Castelo, Bos and Lehmann investigate when and why consumers trust algorithms more than expert humans. Trust in algorithms depends on three main factors: objectiveness of the task, performance of the algorithm, and reliance on feelings versus reason.

Logg shows that algorithm aversion might not be as pervasive as we thought, as people are willing to rely on algorithms depending on factors such as the role of the self and the expertise of the decision maker.

Longoni, Bonezzi and Morewedge examine consumer receptivity to a AI as provider of medical care. Consumers exhibit a robust reluctance toward medical AI, which is driven by *uniqueness neglect*, a concern that AI providers cannot account for a person's unique characteristics as well as human providers.

Granulo, Fuchs and Puntoni investigate the psychological repercussions of robotic job replacement. Whereas observers prefer human job replacement to robotic job replacement, workers whose jobs are threatened prefer robotic to human job replacement, as the former is viewed as a stronger long-term threat to one's profession.

Overall, the research featured in this session examines a timely and important topic: the multi-faceted impact of AI on consumer trust. These papers raise and answer questions that are both practically relevant and theoretically interesting, such as: How does AI influence choices and behaviors across various consumer contexts? What processes explain these influences? Under what conditions can policy makers ensure that A.I. improves consumer and social welfare? We hope that this session will spur new research delving deeper into how AI affects consumer trust.

We expect this special session to attract a wide audience, including scholars whose theoretical interests fall at the intersection of prediction, attitudes, advice giving/taking, and medical decision making. Due to the breadth of the domains investigated (i.e., AI, recommendations, robotics), this session is also likely to attract researchers interested in innovation.

None of the papers here included have been presented at ACR before, and they are all at an advanced stage of completion.

### Consumers' Trust in Algorithms

#### EXTENDED ABSTRACT

Prior research suggests that consumers rely on algorithms less than on humans, even when algorithms outperform humans. We explore when and why this is true and show how to increase trust in and use of superior algorithms.

#### Study 1

387 MTurk users indicated how much they would trust an algorithm or an expert human for 26 tasks, using 0–100 scales. Overall, participants trusted algorithms ( $M = 52.8$ ) less than humans ( $M = 70.2, p < .001$ ). However, was not true for all tasks.

250 separate participants rated how objective and consequential each task seems, and how much the use of algorithms for each task seemed to blur the line between humans and machines (i.e. human distinctiveness threat). Trust in algorithms was higher for tasks that seemed more objective,  $\beta = .77, p < .001$ , for tasks that seemed less consequential,  $\beta = -.34, p = .054$ , and for threatened human distinctiveness less,  $\beta = -1.49, p = .004$ .

#### Study 2

Can trust be increased simply by providing data showing that algorithms outperform humans? 404 participants reported whether they would rather use an algorithm or a human for 9 tasks, using a scale with 0 labeled as "prefer algorithm," 100 as "prefer human more," and 50 as "trust both equally." In the "performance data" condition, participants read about a real study demonstrating that the algorithm could outperform humans for each of the 9 tasks. We provided links to each study and specified how much better the algorithm performed compared to the humans. In the "no performance data" condition, this information was not provided.

Preference for using algorithms was higher when performance data was provided ( $M = 50.48$ ) compared to when it was not ( $M = 70.95, p < .001$ ). Note that preference for humans was observed for only 2 tasks when performance data was provided: predicting personality and joke funniness, two of the most subjective tasks.

### Study 3

Can framing subjective tasks as being objective increase trust in algorithms? 756 participants reported trust in algorithms vs. humans for the two tasks where participants trusted humans more than algorithms. The tasks were either described neutrally, as in Study 2, or as being objective (i.e. quantifiable, data-driven.) The objective frame increased trust in algorithms (collapsing across both tasks,  $M_{\text{control}} = 63.4$  vs.  $M_{\text{objective}} = 58.3$ ,  $p = .008$ ; lower numbers indicate greater trust in algorithms relative to humans).

### Study 4

To apply these findings, 14,997 Facebook users were exposed to 1 of 2 ads for algorithm-based dating advice: either a neutral ad that simply presented “algorithm-based dating advice,” or one describing dating as benefiting from objective, quantifiable data. Click-through-rate was higher for the objective ad (0.87%) compared to the control ad (0.39%,  $p = .053$ ). Advertising algorithm-based advice for a subjective task was therefore improved by framing the task as being objective.

### Study 5

To confirm the effects of task objectiveness and performance data in an incentive-compatible paradigm, 601 participants estimated the market share that a new product had captured after one year, then saw the same estimate from a marketing expert or from an algorithm and could then revise their initial estimate. The difference between their two estimates provides a measure of reliance the algorithm or human’s estimate. A bonus was given to the most accurate participants.

We informed some participants that the algorithm was 80% more accurate than expert humans, and we framed the task as either objective or subjective. When the task was framed subjectively, there were no differences in reliance on advice ( $M_{\text{algorithm}} = 10.5$ ,  $M_{\text{algorithm+performance}} = 11.2$ ,  $M_{\text{human}} = 10.7$ , all  $p$ 's  $> .65$ ). When the task was framed objectively, participants relied more on the algorithm than the human when they were aware of the algorithm’s performance ( $M_{\text{algorithm+performance}} = 14.5$ ,  $M_{\text{human}} = 10.6$ ,  $p < .001$ ) but not when they were unaware ( $M_{\text{algorithm}} = 10.4$ ,  $p = .871$ ). Thus, participants relied on an algorithm more than a human only when the task was framed objectively and they were aware of the algorithm’s performance. In all other conditions, participants relied on algorithms and humans equally.

### Study 6

Beyond objectiveness, the consequentialness of a task also correlates negatively with trust in algorithms, as does the algorithm’s perceived threat to human distinctiveness.

Changing the latter is more feasible for marketers and may also improve trust in algorithms for consequential tasks. In this study, 351 participants reported trust in and preference for algorithms vs. humans for creating a treatment plan for a complex disease. In the high threat condition, the algorithm was said to create the treatment plan and also “takes care of the human aspects of medicine, like answering patient’s questions.” In the low threat condition, the algorithm was said to create the treatment plan which “frees the doctor to take care of the human aspects of medicine...” Participants trusted the algorithm more in the low threat condition ( $M_{\text{low}} = 67.7$  vs.  $M_{\text{high}} = 61.3$ ,  $p = .020$ ), and preferred to use the algorithm vs. the human more ( $M_{\text{low}} = 52.2$  vs.  $M_{\text{high}} = 58.4$ ,  $p = .058$ ). Trust mediated the effect of condition on preference ( $\beta = 4.79$ , 95% CI = .95–9.06).

Consumers are increasingly presented with a novel choice: should they rely more on another human, or on an algorithm? Algo-

ritms often outperform humans, but algorithm aversion sometimes persists. We identified three sources of this aversion and showed the effectiveness of three interventions for overcoming it.

## Robo-Advising: Algorithm Appreciation

### EXTENDED ABSTRACT

Algorithms, scripts for sequences of mathematical calculations, are powerful. As humans interact more with algorithmically programmed agents in their cars, homes, and workplaces, we need to understand their “theory of machine.” By theory of machine, I refer to lay perceptions of how algorithms and humans differ in their input, process, and output, a flavor of theory of mind (Dennett, 1987). This tests when people are willing to rely more on algorithmic than human advice. Anecdotal evidence has led to a widespread idea that people are resistant to allowing a numerical formula to make decisions for them, even though algorithms often outperform human judgment in accuracy (e.g., Dawes, Faust, & Meehl, 1989). Yet, the empirical evidence is mixed and complicated (e.g., Dietvorst, et al., 2014; Dzindolet, et al., 2002; Yeomans, et al., 2017 vs.: Dijkstra et al., 1998; Dijkstra, 1999). In eight experiments, I test whether people are as distrustful of algorithms as prior work suggests.

Experiments 1A (N = 202) and 1B (N = 77 MBAs) tested if people are willing to rely on algorithmic advice. In Experiment 1A, participants guessed someone’s weight in a photograph answered the Numeracy Scale (Schwartz, et al., 1997). Participants were more influenced by advice when they thought that it came from an algorithm (M = .45, SD = .37) than from other people (M = .30, SD = .35),  $F(1, 200) = 8.86$ ,  $p = .003$ ,  $d = .39$ . Higher numeracy correlates with greater reliance on algorithmic advice,  $r(100) = .21$ ,  $p = .037$ . 1B replicated the effect with MBAs,  $F(1, 72) = 13.21$ ,  $p = .001$ , and two geopolitical forecasts,  $F(1, 72) = 5.52$ ,  $p = .022$ . Algorithm aversion may not be as widespread as prior work suggests.

Experiments 2A (N = 276 decisions) and 2B (N = 555) tested a mechanism of reliance on algorithmic advice: subjectivity of the decision. Participants provided three decisions for which they expected reliance on an algorithmic and three for reliance on a human advisor. Decisions were coded by assistants. Participants listed more objective decisions for the algorithmic advisor,  $\chi^2(1, N = 144) = 87.11$ ,  $p < .001$ ,  $r = 0.78$ , and more subjective decision for the human advisor,  $\chi^2(1, N = 136) = 16.03$ ,  $p < .001$ ,  $r = 0.34$  (Overall:  $\chi^2(1, N = 276) = 92.66$ ,  $p < .001$ ,  $r = 0.58$ ). Subjectivity of the domain appears to explain why people are willing to rely on algorithmic advice for objective estimates and forecasts.

Experiment 2B tested how subjectivity interacted with expertise of the human advisor. The experiment had a 2 (subjectivity: subjective vs. objective) X 2 (expertise of person: expert vs. non-expert) mixed design where participants imagined making twelve decisions. Subjectivity was within-subjects and expertise was between-subjects. Controlling for importance, there is an interaction between subjectivity and expertise,  $F(1, 550.98) = 124.98$ ,  $p < .001$ . Perceived subjectivity of the decision mediates the relationship (sober for between:  $z = -3.18$ ,  $p = .001$ ). Expert advice was preferred, regardless of subjectivity,  $F(1, 719.23) = 0.87$ ,  $p = .352$ . These results suggest that although subjectivity mediates reliance algorithmic advice, expertise of the human advisor moderates it.

Experiment 4 examined how the expertise of the decision maker influenced perceptions of algorithmic advice. Experiment 4 (N = 301 lay, 77 experts) compared how lay people and experts who worked in National Security for the U.S. Government (who made geopolitical forecasts regularly) differed in their response to algorithms. Participants made an estimate, one business forecast (the

samples were expected to have low expertise on both) and two new geopolitical forecasts (the experts were expected have more expertise). Controlling for familiarity with what an algorithm is, there is a main effect of advisor,  $F(1, 338) = 9.46, p = .002$ , and expertise,  $F(1, 338) = 32.39, p < .001$ . The effect of advisor is driven by the lay sample, as evidenced in the interaction,  $F(1, 338) = 5.05, p = .025$ .

### Consumer Reluctance Toward Medical Artificial Intelligence: The Underlying Role of Uniqueness Neglect

#### EXTENDED ABSTRACT

Artificial Intelligence is revolutionizing healthcare. IBM's Watson diagnoses heart disease, chatbots dispense medical advice for the United Kingdom's National Health Service, and smartphone apps detect skin cancer with expert accuracy. With AI pervading all facets of healthcare, gauging consumer receptivity to medical AI bears important implications for consumer welfare. However, whereas much is known about medical AI's efficacy, cost-efficiency, and scalability, little is known about consumers' receptivity to medical AI. Across eight studies we show that consumers exhibit a robust reluctance toward medical AI, and that such reluctance is driven by *uniqueness neglect*, a concern that AI providers cannot account for a person's unique characteristics and circumstances as well as human providers.

A first set of four studies examined consumer preferences for medical care provided by AI as compared to care provided by a human physician. Consumers were reluctant to utilize medical care delivered by AI providers, relative to their propensity to utilize comparable care delivered by human providers. Furthermore, consumers were more reluctant to choose an objectively superior medical provider, if that provider was automated than human.

Study 1 (N=228) showed that consumers were less likely to utilize medical care when the provider was automated than human, even if the providers' performance was objectively equivalent. In an incentive-compatible setting and separate evaluations, participants chose whether to use a diagnostic service carried out by either a human or an automated provider. Whereas 39.8% of participants chose to utilize the service when it was carried out by a human, only 26.7% chose to utilize it if carried out by an automated provider ( $c^2=4.4, p=.03$ ).

Studies 2A-2C (N=744) showed that consumers were less prone to choose an AI provider when a human provider was available, even if the former was more accurate than the latter, and this difference in accuracy was explicit. We selected existing applications of AI to various types of preventive (i.e., AI analyzing images for early detection of skin cancer), diagnostic (conversational chatbots triaging an emergency) and treatment care (robotic-assisted surgery to implant a pacemaker) and investigated consumer choice of care provider in joint evaluations (i.e., choice between two human providers vs. choice between a human and an automated provider). Robust across medical decisions and framing of accuracy as success or failure, participants were more reluctant to choose an objectively superior medical provider if that provider was automated than human.

Additional four studies provided empirical support for *uniqueness neglect* as a psychological mechanism underlying reluctance toward medical AI. Building on the notion that consumers perceive automated providers to be rigid, inflexible, and capable of operating only in a standardized fashion (e.g., Haslam 2006; Loughnan and Haslam 2007), we propose that the prospect of being cared for by AI providers results in a concern that a person's unique symptoms, circumstances, and characteristics will be neglected. We refer to this concern as *uniqueness neglect*. We provide converging evidence of

uniqueness neglect as a psychological driver of reluctance toward medical AI via mediation and moderation.

Study 3 (N=286) showed that reluctance toward medical AI was moderated by the extent to which a consumer perceives herself to be unique (measured using the Sense of Uniqueness scale, Simsek and Yalınçetin 2010): greater perceptions of self-uniqueness were associated with greater reluctance to choose an AI provider ( $p=.01$ ).

Study 4 (N=215) showed that concern that an AI provider cannot account for a consumer's unique symptoms and circumstances—*uniqueness neglect*—mediated reluctance toward medical AI. Participants rated the likelihood to use a diagnostic service that allowed them to chat with either a human or an automated nurse to diagnose an emergency. A 3-items scale measured uniqueness neglect (beliefs about the ability of the provider to accommodate a person's uniqueness). Participants were more likely to use the service when the provider was human ( $M=4.15$ ) than automated ( $M=3.16, p < .001$ ) and uniqueness neglect mediated the effect (LLCI=-0.70 ULCI=-0.18, Sobel  $z=-3.2, p=.001$ ).

Studies 5 and 6 provided further converging evidence for uniqueness neglect via moderation. Study 5 (N=222) shows that when uniqueness neglect is curbed (e.g., when medical care is framed as personalized to one's unique needs), reluctance to choose AI is attenuated (process evidence via moderation). Participants rated the likelihood to use a preventive service carried out by either a human or an automated provider. Half of the participants read that care was personalized to "each patient's biological characteristics." When care was not personalized, participants were more reluctant to use the service if the provider was automated ( $M=3.77$ ) than human ( $M=4.80, p = .005$ ). However, such effect disappeared when care was tailored to one's unique circumstances ( $p = .79, F_{int}=4.9, p=.02$ ).

Finally, study 6 (N=333) showed that when uniqueness concerns do not apply (e.g., when choosing a provider for another person), reluctance to choose A.I. was curbed (process evidence via moderation). Participants rated the likelihood to use a diagnostic service either for themselves or for somebody else. When choosing for themselves, participants were less likely to use the service if the provider was automated ( $M=5.64$ ) than human ( $M=6.31, p=.002$ ). However, when choosing for somebody else, stated likelihood was the same irrespective of provider ( $p=.70; F_{int}=4.7, p=.03$ ).

Together, our findings demonstrated a consequential reluctance to medical AI likely to influence several medical decisions consumers make, identified uniqueness neglect as psychological underlying driver of reluctance toward AI, and revealed how to curb such reluctance. As such, we contribute to research on the psychology of automation by extending its scope to the study of consumers in medical settings. Second and more broadly, our research advances our theoretical understanding of consumer decision making in the medical domain by identifying a novel psychological mechanism that shapes an increasingly common class of medical decisions related to consumer utilization of healthcare. Finally, our research provides timely and reaching insights for industry and policy efforts aimed at increasing acceptance of AI-based technological advancements that greatly benefit people's health.

### Psychological Reactions to Human Versus Robotic Job Replacement

#### EXTENDED ABSTRACT

Today's advances in robotics and artificial intelligence increasingly enable firms to fully replace employees with intelligent machines and algorithms. Forecasts predict that, in the coming years, these new technologies will have a major impact on society and will

affect millions of workers in a wide range of occupations (Brynjolfsson and McAfee, 2014). Despite the intense debate around these issues within economics, sociology, and other social sciences, research has not examined how people—both employees and society at large—react to technological replacement of human labor. We address this gap by examining how people react to losing their jobs to modern technology (e.g. robots or algorithms).

In Study 1A (N = 90), we experimentally test whether people prefer human over robotic job replacement. Half of the student participants read that a firm needed to cut costs and therefore had the option to replace existing employees either by other (new) employees or by robots. We find that more participants preferred the employees to be replaced by new employees than by robots (67% vs. 33%,  $Z = 2.20, p < .05$ ). The other half read the same text but adopted the perspective of the employees about to lose their own job. This subtle manipulation of perspective taking, from an observer to an employee perspective, shifted participants' preferences: when participants were told that their own job was at risk, only 40% of the respondents (vs. 67% in the observer condition) preferred being replaced by humans rather than by robots ( $\chi^2(1) = 6.59, p < .05$ ).

In Study 1B (N = 86), we replicated these findings with a sample of qualified workers from an online labor market: 63% of the participants preferred human replacement in the observer perspective condition, whereas only 40% preferred human replacement in the employee perspective condition ( $\chi^2(1) = 4.65, p < .05$ ).

We posit that this effect of perspective taking occurs because being replaced by robots (vs. other humans) is less threatening to one's self-identity, i.e. how individuals evaluate their self-worth and capabilities (Tesser, 1988). This is because being replaced by, or "losing" against "infallible", robots (vs. other humans) should trigger less identity-relevant social comparisons. Thus, to avoid this self-threat and maintain a positive self-image, people have a short-term psychological incentive to prefer being replaced by a robot (vs. another human). However, while comparing to an "infallible" robot might offer little information for people to evaluate their self-worth, people nevertheless evaluate whether differences in capabilities can be reduced (Arnkellson and Smith, 2000). Thus, if people are replaced by robots, and predict that the gap in abilities is permanent, they should be more concerned about one's future professional prospects.

In Study 2 (N = 85), we test these predictions empirically. We used a "white-collar" working context. Participants were asked to imagine working as lawyers for a reputable law firm. The firm was reorganizing its business processes and they were going to lose their job. In line with our predictions, we find that participants rated robotic replacement as less threatening to their self-identity than human replacement ( $t(84) = -10.70, p < .001$ ) but more threatening to their economic future ( $t(84) = 2.26, p < .05$ ). Moreover, a linear regression of preferences on self-threat ( $\beta = -.845, SE = .104, p < .001$ ) and on future concerns ( $\beta = -.196, SE = .091, p < .05$ ) reveals that participants preferred the replacement option that induced less self-threat, namely robotic replacement.

In Study 3 (N = 89), we examine feelings of self-threat and future concerns in a between-subjects design and a different occupational context. In one condition, participants were asked to imagine working for a logistics firm and read that, in the course of a reorganization, the firm had decided to replace them with modern robots. Participants in the other condition read that the firm had decided to replace them with other warehouse workers. Consistent with our results from Study 2, being replaced by a robot (vs. by another warehouse worker) led to less self-threat ( $t(87) = -3.78, p < .001$ ) but

greater concerns regarding one's own economic future ( $t(87) = 3.0, p < .01$ ).

In Study 4 (N = 216), we test whether the effects documented in the previous experiments replicate in a correlational design among people who recently lost their job. Therefore, we recruited workers from an online labor market who indicated to have lost their job within the last two years. We measured the extent to which these workers attributed their job loss to robotic or human replacement, as well as job-loss related self-threat and future economic concerns. To test how the latter two are related to attributions of human and robotic replacement, we ran a series of linear regressions, including a set of control variables (e.g. other reasons for job loss, duration of unemployment, former and current income). Consistent with our previous findings, self-threat was consistently related to perceptions of human replacement (all  $p$ 's  $< .05$ ) but not to perceptions of robotic replacement. Conversely, future economic concerns were only consistently related to perceptions of robotic replacement (all  $p$ 's  $< .05$ ).

Despite the societal importance of workplace automation in the coming decades, no prior research has investigated how people – both employees and society at large – react to technological replacement of human labor. We show that, while the public tends to prefer human workers to be replaced by other human workers than robots, the workers whose jobs are threatened might prefer to be replaced rather by robots. This is because technological (vs. human) job replacement has unique psychological consequences, which support programs for the unemployed should take into account. Our findings may also inspire novel predictions regarding broader societal consequences of technological unemployment. For example, based on our results, it is conceivable that customers react particularly negative towards companies automating tasks they believe could and should be done by workers (Waytz and Norton, 2014). On the other hand, organized resistance among workers to job losses might be weaker when the job losses are attributed to automation than to human replacement.

visual. To and Patrick research the visual characteristic of gaze direction, hypothesizing that when an ad's model has an averted, versus direct, gaze, consumers feel as if they are part of the narrative in the ad. As such, averted gazes enhance narrative transportation, which in return boosts self-brand connection. Finally, Sample, Hagtvedt, and Brasel develop a conceptual model for understanding consumer visual perception. Their synthesized framework indicates three primary constructs to visual perceptual research: visual processing, visual stimulus dimensions and holistic visual perception. This model combined with a synthesis of extant literature identifies considerable opportunities for future research in this realm.

In summary, the papers in this session (all in advanced stages): (1) examine the impact of several characteristics of visual stimuli—presence of intermediate steps (Cian, Krishna and Longoni), level of disorderliness (entropy) (Biliciler-Unal, Raghunathan and Ward), and gaze direction (To and Patrick)—on product evaluations, and (2) suggest a framework for synthesizing the visual perception literature (Sample, Hagtvedt and Brasel). Overall, the session offers important theoretical insights in understanding how visuals affect consumer behavior—a topic that is likely to be of substantial interest to a broad audience at ACR.

## SESSION OVERVIEW

The world is witnessing an unprecedented explosion of visual images (Kane and Pear 2016). This rising importance of visuals in daily life and their heightened use for marketing purposes necessitates further research into how various characteristics of visual stimuli influence consumer behavior. The literature on visual perception has steadily grown over the last two decades; however, many links between visual perception, cognition, and consumer behavior remain to be explored (Krishna 2012). Thus, the goal of this session is to both explore characteristics of visual stimuli that influence consumer behavior and construct a conceptual framework to understand developments in this area of the field.

The four papers in this session examine how visual stimulus characteristics, including presence of visuals showing the intermediate steps in advertisements promising change, level of disorder (entropy) in visual content, and gaze direction of an ad model, impact evaluations of associated products. Specifically, in the context of advertisements promising change, Cian, Krishna and Longoni examine the effect of including visuals of the intermediate steps between visuals of the before and after states (e.g., a person at the beginning and at the end of a weight loss program). The authors propose that including these intermediate steps facilitates mental imagery of the change process. Results demonstrate that presence of intermediate steps increases ad credibility and leads to more favorable attitudes toward the product. Biliciler-Unal, Raghunathan and Ward study how the level of disorder (entropy) in visuals affects temporal focus (i.e., whether consumers think of the past or the future) and thereby, product evaluations. They show that visuals with high levels of disorder (e.g., a crumbled cookie) make consumers focus on the past, while those with low levels of disorder (e.g., a full cookie) make them focus on the future. Therefore, consumers evaluate past (vs. future) related products more positively when presented with a high (low) entropy

## Communicating a Promise of Change: Visual Steps Enhance Process Imagery

### EXTENDED ABSTRACT

Humans often desire change: we want to be thinner, look younger, have more hair. Marketers respond to such desires by offering products promising to deliver the corresponding changes: weight-loss programs, wrinkle removers, hair regrowth solutions. The visuals in the advertisements (ads) for these products typically focus on the desired final outcome by featuring a before and an after visual (e.g., a person at the beginning and at the end of a weight loss program; *before-after ads*). Very few *change-ads* include visuals of the intermediate steps between the before and the highly desirable after (e.g., a person gradually slimming down throughout the weight loss program; *progression ads*).

Although neglected in the marketplace and by future marketers, across seven studies we show that progression ads are superior to before-after ads across multiple consumer domains. We theorize that, to be effective, ads promising transformation should facilitate mental imagery of the trajectory of the change, i.e., the consumer should be able to imagine herself going through the transformation from “before” to “after.” Progression ads (but not before-after ads) evoke this kind of spontaneous process *imagery* -- thoughts and images about the means and ways leading to a change. In turn, spontaneous process imagery increases the credibility of the ad and leads to more favorable attitudes toward the product (serial mediation).

Through a content analysis of 250 ads of the top five weight-loss programs in the US (source: Consumer Affairs) we show that before-after ads are more common than progression ads: 36% were “before-after” whereas only 0.8% were “progression.” Another a pilot study asked participants (N=122) to draw the ad for a weight loss program. While 22.95% of participants drew before-after ads, only 1.64% drew progression ads ( $z = 5.07, p < .001$ ; remaining ads coded

as “others”). Overall, these pilot studies show that progression ads are neglected by both current and future marketers.

In studies 1a (N=116) and 1b (N=139), we show that adding intermediate steps to a before-after ad increases the credibility of the ad. In both studies and using different stimuli (stylized figures and actual photographs), the progression ad was more credible than the before-after ad. One pretest ensured that the stimuli used did not differ on visual appearance, informativeness, complexity, familiarity, and novelty (all  $p$ 's > .1).

In study 2 (N=134), we test the downstream consequences of credibility on attitudes toward the product. Participants rated credibility and reported their attitudes toward one of two versions of an ad for a fictitious hair growth product. The before-after ad featured a drawing of a person before using a hair growth treatment and a drawing of the same person at the end of the treatment. The progression ad contained an identical drawing with the addition of drawings of four intermediate outcomes. As predicted, the progression ad was associated with higher credibility ( $M_{\text{before-after}}=2.91$ ,  $M_{\text{progression}}=3.79$ ;  $F(1, 132)=5.99$ ,  $p < .05$ ) and more positive attitudes ( $M_{\text{before-after}}=3.71$ ,  $M_{\text{progression}}=4.73$ ;  $F(1, 132)=7.35$ ,  $p < .05$ ) than the before-after ad. In a mediation model, credibility fully accounted for the effect of ad type on attitudes (95% CI: .16, 1.43).

Studies 3a (N=143) and 3b (N=80) we use open-ended and close-ended responses to show that progression ads evoke greater process imagery than before-after ads, even though both ads only have visuals of outcomes. In study 3a we coded the content of the spontaneous thoughts and images that either a before-after or a progression ad evoked in participants. Indeed, the progression ad generated more spontaneous process imagery than the before-after ad ( $z=5.11$ ,  $p < .01$ ). The two ads did not differ on outcome imagery ( $p > .5$ ) or amount of imagery (i.e., response length,  $p > .5$ ). In study 3b participants rated the extent to which a before-after ad or a progression ad evoked process and outcome imagery (through six randomly presented statements, three reflecting process imagery ( $\alpha = .89$ ) and three reflecting outcome imagery ( $\alpha = .70$ ) adapted from Taylor et al. 1998; Escalas and Luce 2004; Zhao et al. 2007; 2011. Again, the progression ad led to higher process imagery than the before-after ad ( $M_{\text{before-after}}=4.11$ ,  $M_{\text{progression}}=6.92$ ;  $F(1, 78)=41.53$ ,  $p < .01$ ) and to the same outcome imagery ( $p > .5$ ).

Study 4 (N=142) tests the links between the constructs investigated in the previous studies. Results show how the progression ad leads to greater process imagery than the before-after ad, which then results in higher credibility and consequently more positive attitudes toward the product (full serial mediation, 95% CI: .18 and .89).

Study 5 tests a boundary condition and shows that ambiguity (operationalized through size of change) moderates the effect of ad type on attitudes. We expected to replicate study 4 in the large change condition (high ambiguity because the transformation is large), with a full serial mediation whereby the progression ad leads to greater process imagery, credibility, and ultimately better attitudes than the before-after ad. However, when the change is small (low ambiguity because the transformation is trivial), the progression ad should no longer be more persuasive than the before-after ad. Indeed, within the large change condition, there was a full serial mediation (95% CI: .45 and 1.86). However, and as predicted, within the small change condition, the serial mediation was not significant (95% CI: -1.00 and .20). Importantly, the full mediations in studies 2, 4, and 5 via process imagery indicated that the process mechanism driving the observed effect is not the amount of information contained in the ad (or these mediations would be partial).

Theoretically, and differently from prior research on mental simulation, we bring attention to an understudied yet important ty-

pology of mental imagery: spontaneous mental simulation of process (*process imagery*), and highlight its critical role in the persuasiveness of advertised change. Second, we add to the literature on process versus outcome focus by showing how process imagery can be spontaneously generated through outcome visuals. Substantively, we show that before-after ads, currently prevalent in the market place, may be an ineffective way to credibly promise positive change.

## A Simple Step to Go Beyond Present: How Visual Entropy Cues Influence Temporal Focus and Consumer Behavior

### EXTENDED ABSTRACT

With the rising importance of social media as a marketing platform, marketers have begun to use more visual content. In 2017, 85% of marketers indicated that they use visual images in their social media marketing (Stelzner 2017). A growing body of research indicates that even subtle visual cues such as orientation of the objects (Elder and Krishna 2012) and dynamism of the icons (Cian, Krishna and Elder 2015) can influence consumer attitudes and behavior.

In this research, we explore how a particular aspect of visuals—the degree of (dis)order in them—affects evaluations and preferences for products. We merge insights from physics—in particular, the concept of “entropy” (operationalized in our studies as the level of disorder)—with insights from the psychological literature on time perception to frame our investigation of how entropy cues (the degree of (dis)order in an image) can influence customers’ (i) temporal focus and (ii) product evaluations.

The second law of thermodynamics states that the level of disorder (entropy) in a closed system can only increase with time. As such, with time, things (e.g., a bookshelf, a cookie) become less orderly. Interestingly, even 8-month-old infants appear to be intuitively aware of some of the manifestations of this law (Friedman 2001; 2002). For example, when 8-month-olds are presented with forward and backward versions of videos showing objects falling apart, they prefer the forward version better. Since people learn from very early on that entropy increases with time, we hypothesize that they will expect a high entropy state to follow a low entropy one. Further, because people find a sense of meaning in connecting points in time (Sarial-Abi et al. 2017), we suggest that when people are shown a low entropy picture (e.g., a full cookie), their thoughts automatically focus on future—high entropy state (a crumbled cookie). Likewise, when people are shown a high entropy picture (e.g., a crumbled cookie), their thoughts focus on past—low entropy state (a full cookie).

Because of these effects of entropy on temporal focus, and based on the idea that people find it easier to process images that match, we expect evaluation of a past-related product (e.g., a vintage product) to be more positive when it’s paired with a high entropy visual, since such visuals prompt people to become past-oriented, and vice versa. Similarly, we expect participants to report higher interest in visiting a store which is presented with high (vs. low) entropy visuals when looking to buy a past-related product (e.g., an old book), and vice versa.

Study 1 provides evidence that people expect entropy to increase with time. Participants ( $n=56$ ) were presented with 8 pairs of visuals where one image was more disorderly than the other. For each pair, participants selected the visual that came first in time. As hypothesized, the low entropy images were, on average, judged to have preceded the high entropy ones ( $t(55)=5.659$ ,  $p < .001$ ).

Studies 2a and 2b show that participants exposed to high (vs. low) entropy visuals are more likely to focus on the past (vs. future),

and vice versa. In study 2a, participants ( $n=71$ ) were presented with 6 visuals differing in level of entropy. After each visual, they were shown a 100-point slider scale with end-points marked as “past” and “future” and the middle-point marked as “present”. Using the slider, they indicated whether the image made them think of past, present or future. As predicted, we found that while high entropy visuals make people think about past ( $t(70)=5.14, p<.001$ ), low entropy visuals make them think about future ( $t(70)=3.44, p<.001$ ). Study 2b replicated these results using a between-subjects entropy manipulation and non-student sample.

After establishing that entropy cues influence temporal focus, we turn our attention to exploring whether past (future) oriented products are evaluated more positively when displayed alongside high (low) entropy visuals. In study 3a, we manipulated both the level of entropy in background visuals and the time orientation of products. Participants ( $n=175$ ) saw a low or high entropy poster; after a brief delay, either vintage or futuristic piece of furniture appeared in front of the poster. Participants then indicated how much they liked the furniture. As hypothesized, there was a significant interaction between entropy and time orientation ( $F(1,694)=5.51, p=.019$ ). When paired with high entropy posters, futuristic furniture was evaluated less positively than vintage furniture, ( $M_{\text{futuristic}}=3.50, M_{\text{vintage}}=4.00, F(1,346)=5.55, p=.019$ ); conversely, when paired with low entropy posters, the same futuristic furniture was rated, not significantly but directionally, more positively than vintage ones ( $M_{\text{futuristic}}=4.10, M_{\text{vintage}}=3.95$ ). Study 3b replicated study 3a’s results using a subtler manipulation of time orientation of products.

Study 4 demonstrated that the hypothesized match between entropy and product’s time orientation works in a different product category. It showed that when considering purchasing an old (vs new) book, participants are more interested in visiting a bookstore promoted with high (vs low) entropy visuals ( $F(1,436)=12.46, p<.001$ ).

Study 5 established that shifts in temporal focus mediate the link between visual entropy cues and product evaluations. Participants ( $n=170$ ) saw high or low entropy visuals of bookstores and reported their temporal focus while looking at them. Later, they indicated how willing they would be to purchase a book from that store that will be published in future relative to a book that was published in past. Last, they estimated how old the bookstore is. Results revealed that participants in the high (vs. low) entropy condition focused significantly more on past ( $M_{\text{high}}=41.99, M_{\text{low}}=46.10, F(1,168)=6.25, p=.013$ ), but not judged bookstore as older. Moreover, participants in low (vs. high) entropy condition were more interested in buying a future-oriented book ( $M_{\text{low}}=5.25, M_{\text{high}}=4.55, F(1,168)=6.176, p=.014$ ). Mediation analysis revealed a significant indirect effect of entropy on product preference through temporal focus, 95% CI[-.3131, -.0126].

Across seven studies, we explored how visual entropy cues influence temporal focus and product evaluations, and found that high (low) entropy visuals lead to focusing on past (future), and thereby, elicit higher evaluations for past (future) related products. The paper thus contributes to the literature on visual perception and consumer behavior, and to that on temporal focus.

### How Eyes Pull on the Heartstrings: Averted Eye Gaze Enhances Narrative Transportation and Self-Brand Connection

#### EXTENDED ABSTRACT

Narrative transportation is defined as the extent to which an individual is immersed and absorbed into a visual narrative (adapted from Green and Brock 2000). We propose that the averted gaze (vs. direct gaze) of a model in an advertisement heightens the viewing

experience by facilitating greater narrative transportation, which helps forge a stronger consumer self-brand connection (henceforth SBC). In order to provide theoretical support for our hypothesis, we next discuss how gaze enhances narrative transportation in the arts and theatre domain. In the following exposition, we will use the term ‘audience’ to refer to the viewers or spectators of an artwork or theatrical performance.

In theatre, when performing a narrative on stage, performers on stage often avert their gaze away from the audience in order to create an authentic dramatic world (Gray 1964). By averting their gaze from the audience, the performers create the existence of an invisible imaginary wall (i.e., the fourth wall) that separates the audience from the staged performers. This imaginary wall works to heighten the naturalism of the fiction being presented on stage by letting the audience engage with the fictional world as if they were observing real events. On the other hand, when performers direct their gaze towards the audience, the imaginary fourth wall is momentarily suspended and the audience is made aware of their role as spectators observing the performers’ enactment of fictional events (Wallis and Shepherd 1998). Thus, the averted gaze (vs. direct gaze) of performers in a theatrical performance appears to influence the degree to which the audience is immersed in the work presented. Similarly, gaze also manifests in the domain of fine art, particularly in how portrait paintings engage with the audience (Kern 1996). When analyzing historical portrait paintings, art historians have documented the gaze of the art subject and how such gaze influences the way the audience’s engagement (Simons 1988).

Compared to direct gaze, averted gaze is often considered an aesthetic feature that absorbs the viewers in “the act of looking” (Morgan 2005, p. 4). In contrast, direct gaze of an art subject is considered to be a signal from within the image that the audience is on the outside of the visual narrative (Alpers 1983). These analyses on the role of gaze (direct vs. averted) in both the domains of theater and art suggest that averted gaze is more likely than direct gaze to immerse and engage the audience to feel as if they are part of the narrative, and as such generates greater narrative transportation. Thus, we hypothesize that an ad model’s averted gaze (vs. direct gaze) will enhance narrative transportation, which in turn will facilitate greater SBC (Escalas 2004).

Because of the differences in social perceptions elicited by direct vs. averted gaze, we propose that the visual effect hypothesized will be moderated by the verbal appeal of the ad (rational vs. emotional). Since direct gaze is associated with increased perceptions of trustworthiness (Argyle and Cook 1976), we hypothesize direct gaze will lead to greater transportation when rational appeals are featured. On the other hand, we expect that averted gaze is associated with greater affective responses (van der Weiden et al. 2010) and thus, averted gaze will lead to greater transportation under emotional appeals are featured.

In Study 1, we examined the influence of gaze on SBC and transportation as the underlying mechanism. Participants were randomly assigned to one of the two gender-appropriate ad conditions in which they were shown a fictional perfume/cologne advertisement that featured a female/male model with a direct or averted gaze. Results revealed that participants in the averted gaze condition felt significantly higher self-brand connection ( $M_{\text{averted}} = 4.18$ ) than participants in the direct gaze condition ( $M_{\text{direct}} = 3.65, F(1,174) = 7.53, p < .01$ ). Further, participants in the averted gaze condition also felt significantly more transported ( $M_{\text{averted}} = 4.41$ ) than participants in the directed gaze condition ( $M_{\text{direct}} = 3.19, F(1,175) = 66.82, p < .001$ ). Mediation analysis revealed a significant indirect effect of

gaze on self-brand connection through ad transportation,  $b = -.40$ , 95% CI [-.67, -.15].

Study 2 was designed to replicate the hypothesized role of narrative transportation, but via manipulating narrative transportation. Specifically, in one condition we present no explicit instructions to encourage narrative transportation (similar to Study 1), but in the other condition, we facilitate narrative transportation using ad instructions to encourage participants to imagine themselves as part of the advertisement. Our results revealed that when participants are encouraged to 'transport' themselves into the ad, direct gaze will also enhance self-brand connection, thus mimicking the effects of averted gaze on self-brand connection seen in Study 1.

In Study 3, we examined the moderating role of ad appeals (rational vs. emotional) in the influence of gaze on transportation. Participants were randomly assigned to one of the two gender-appropriate ad conditions in which they were shown a fictional watch advertisement that featured a female/male model with a direct or averted gaze. Each ad also featured either rational/emotional tagline. Results yielded a significant interaction between gaze and ad appeals on transportation ( $F(1, 189) = 10.58, p < .001$ ). When the ad featured a rational appeal, participants felt significantly more transported when the model's gaze was direct ( $M_{\text{direct}} = 4.39$ ) than averted ( $M_{\text{averted}} = 3.86, p < .05$ ). When the ad featured an emotional appeal, participants felt significantly more transported when the model's gaze was averted ( $M_{\text{averted}} = 4.38, p < .05$ ). Our mediated-moderation analysis revealed that when rational appeals are featured, transportation mediates the influence of direct gaze on SBC (95% CI: [-.60, -.08]). When emotional appeals are used, transportation mediates the influence of averted gaze on SBC (95% CI: [.05, .57]).

From a theoretical perspective, this research contributes to the extant literature by 1) demonstrating the novel influence of gaze on narrative transportation and SBC and 2) introducing the interplay between ad appeals and gaze in enhancing consumer transportation when viewing print advertisements.

## Visual Perceptual Research in Marketing

### EXTENDED ABSTRACT

The visual perception of products, places, and promotions is critically important to understanding consumer behavior in the marketplace (Krishna 2012). Despite considerable research focusing on consumer cognitive functioning regarding visual stimuli, our field lacks a unifying framework for understanding the nuances of visual perception. We provide a conceptual model and systematic review of visual perceptual research within marketing, focused on what occurs during perception and which dimensions influence consumer behavior and are consequently important to marketing researchers. By so doing, we present practical and theoretical insights and identify avenues for future research that draw upon the centrality of vision to the consumer experience.

To develop our conceptual framework, we systematically reviewed approximately twenty high-quality marketing and marketing-related journals since 1970, including JCR, JCP, JM, JMR, and JAMS. Papers were chosen that contained an exploration of visual sensory processing; articles exploring imagery only as a prime, or manipulation, were excluded, as were papers that solely focused on the back-end cognitive effects of vision. Additionally, relevant articles from core disciplines bridged gaps and provided synthesis.

Across the literature and over 375 articles, no consistent definition of visual perception emerged, and the term is applied to quite varied stages in the act of vision, perception, cognition, and memory. Thus, we provide the following definition: the processing and

comprehension of focal and non-focal visual stimuli within the perceptual field as influenced by context and experience. Though the perceptual field of figure (i.e., the focal area of interest) and ground (Wagemans et al. 2012) is constantly updated as consumers navigate the world around them (Mace 1977; Rock 1983; Uttal 1981), we provide a momentary snapshot of this process, which fits with most marketing research conducted to date.

When considering this model and the act of consumer visual perception, three primary constructs of interest to marketing emerge: visual processing, visual stimulus dimensions, and holistic visual perception. We define visual processing as the internal comprehension of visual stimuli through the visual cortex as it is informed by cognition. There are numerous research endeavors examining aspects of visual processing, such as attention (Janiszewski 1998; Pieters, Rosbergen, and Wedel 1999; Rosbergen, Pieters, and Wedel 1997). Visual versus verbal processing is another area of interest (Childers, Houston, and Heckler 1985; McQuarrie and Mick 2003; Mitchell 1986; Townsend and Kahn 2013). However, relatively few researchers have examined cross-modal processing, such as how sound influences visual focus (Hagtvedt and Brasel 2016) or how haptics can alleviate erroneous visual estimations (Krishna 2006). Though many papers explore effects of stimulus attributes on processing by the consumer, little research explores the effects of consumer attributes, such as location, on the processing of the stimulus (Raghubir and Krishna 1996).

The second construct of interest is visual stimulus dimensions (Bloch 1995). Shape differences can alter perceptions of prototypicality (Veryzer and Hutchinson 1998), volume (Ordabayeva and Chandon 2013), brand judgments (Jiang et al. 2016), and the innovativeness and trustworthiness of firms (Hagtvedt 2011). Color can influence outcomes ranging from bidding behavior (Bagchi and Cheema 2012) to size estimations (Hagtvedt and Brasel 2017), and research has uncovered stark differences between colored versus black-and-white stimuli (Lee et al. 2014; Meyers-Levy and Peracchio 1995). Lighting can exacerbate default affective responses (Xu and Labroo 2014) and increase consumer retention in stores (Summers and Hebert 2001). Furthermore, the interaction between figure and ground (Meyers-Levy and Tybout 1997; Zhu and Meyers-Levy 2009), the glossiness of products (Meert, Pandelaere, and Patrick 2014), and the motion of visual stimuli (Brasel and Hagtvedt 2016; Roggeveen et al. 2015) play a substantial role in consumer perceptual determinations and consequently behavior.

The third and final construct of interest is holistic, or Gestalt, visual perception. A considerable amount of marketing research has focused on holistic perception of packaging, products, or the environment. For instance, holistic package design shapes consumer brand impressions (Orth and Malkewitz 2008). Holistic product perceptions influence consumer word of mouth engagement and purchase intentions (Bloch 1995; Homburg, Schwemmler, and Kuehl 2015). Furthermore, holistic perception of environments can result in varying behavioral influences (Bitner 1992; Mattila and Wirtz 2001), although much research in this area focuses on general cognition rather than visual perception per se.

Despite the existing literature, we argue that the sensory aspect of vision remains under-explored, and much work remains to better understand the process whereby visual inputs are transformed into perceptual outputs. Our framework, which incorporates visual processing, stimulus dimensions, and holistic perception, provides a useful synthesis of the current literature on consumer visual attention and reveals numerous avenues for future work.

### SESSION OVERVIEW

Recently, a growing body of research has suggested that threatening self-discrepancies can motivate consumers to reduce or eliminate the discrepancy via compensatory consumption (see Mandel et al. 2017). This session examines threatening self-discrepancies and their impact on consumption via several different perspectives. In so doing, the session seeks to understand: What are the psychological processes that drive compensatory consumption? And, what are the different paths through which consumers choose to compensate?

The first paper examines the cognitive implications of self-discrepancies that lead to compensatory consumption. Most research in this domain has treated compensatory consumption as evidence for the unobserved internal process associated with threat. In contrast, this paper directly investigates the intervening psychological processes that drive compensation. Results suggest that threatening self-discrepancies reduce working memory capacity. These decrements further cause consumers to selectively attend to and process identity-relevant products more quickly and positively than neutral products, resulting in heightened attitudes toward items within the domain of the threatened self.

The second paper investigates when consumers cope with a threatened self via fluid compensation processes, which affirm the self in important domains unrelated to the threat. Little research to date has examined when consumers are more likely to choose one type of compensation over another. This paper finds evidence that cultural differences in self-identity lead to a greater tendency to make use of fluid compensation. They find that when interdependent individuals experience a self-threat, holistic thinking about their many different identities is activated, leading them to better see the relations among those identities as sources of global self-esteem, and thus offering paths for fluid compensation processes. This paper

identifies cultural psychology as an important predictor of the paths consumers take to compensate in response to a self-discrepancy.

The third paper examines mortality salience as a threat to personal meaning. Consistent with the view that mortality salience leads to a heightened desire to maintain and restore a sense of personal meaning, they argue that it will also lead consumers to prefer market-place options that imbue one's life with a sense of meaning. Experiential goods have been found to be more self-defining and more socially connecting. Thus, they find that mortality salience will prompt compensatory consumption via experiential choices, while also showing that individuals who can restore meaning via another path do not show preferences for experiential over material goods.

Finally, the fourth paper examines inter-personal effects on processes of compensatory consumption. Prior work has largely focused on compensation in individual decision-making settings, devoid of social context. This research examines how compensatory consumption varies in the presence of observers who are perceived to be judgmental and critical versus those who are benevolent and accepting. They find that judgmental observers drive consumers to compensate in an important domain unrelated to the threatening self-discrepancy, whereas benevolent observers motivate within-domain compensation, offering insights to both the processes driving compensatory consumption and the paths available for such compensation.

Collectively, these four papers provide a deeper understanding about when, why and how consumers compensate through their consumption choices.

## **Identity Threats, Compensatory Consumption and Working Memory Capacity: When and Why Feeling Threatened Leads to Heightened Evaluations of Identity-Relevant Products**

### EXTENDED ABSTRACT

Despite the abundance of papers documenting consumers' reliance on symbolic self-completion after experiencing a self-discrepancy (Mandel et al. 2017), surprisingly little research has investigated the underlying psychological processes that drive this type of compensatory consumption. We address this gap by demonstrating that self-discrepancies triggered by identity threats reduce working memory capacity (WMC), and these reductions in WMC mediate compensatory consumption.

We test our conceptual model using identity-threatening negative emotions as the source of threat (Coleman and Williams 2013), thereby also demonstrating that negative emotions can be critical inputs into the identity maintenance system. We show that individuals experiencing identity-threatening negative emotions express higher evaluations of identity-relevant products (Experiment 1), that identity threats lower WMC (Experiment 2), that lower WMC mediates identity-relevant product evaluations (Experiment 3) because identity-relevant products are processed faster (Experiment 4), and that global self-affirmation can prevent the reductions in WMC resulting from identity threats (Experiment 5).

In Experiment 1 (N = 296), participants were assigned to an athlete, volunteer or romantic partner identity and engaged in an autobiographical writing task to elicit anger, sadness, guilt or a neutral emotion. Then, participants rated twenty products, three relevant to

each identity, and ten filler products. In a repeated measures ANOVA, the predicted three-way interaction of product type, identity and emotion emerged. As predicted, athlete identity participants who experienced the identity-threatening negative emotion of sadness ( $M = 6.55$ ) and guilt ( $M = 6.11$ ) had higher attitudes toward athlete-relevant products compared to those experiencing anger ( $M = 5.26$ ,  $ps < .051$ ) or a neutral ( $M = 5.53$ ,  $ps < .03$ ) emotion. Volunteer identity participants who experienced the identity-threatening negative emotion of anger ( $M = 6.87$ ) and guilt ( $M = 6.00$ ) expressed more favorable attitudes toward volunteer-relevant products than those who experienced sadness ( $M = 5.56$ ,  $ps < .03$ ) or neutral ( $M = 5.73$ ,  $ps < .05$ ). Romantic-partner participants who experienced anger ( $M = 7.07$ ) or sadness ( $M = 6.85$ ) expressed higher attitudes than those who experienced guilt ( $M = 5.42$ ;  $ps < .05$ ) and neutral emotions ( $M = 5.73$ ,  $ps < .03$ ). This study demonstrates that identity-threatening emotions can be a source of identity threat.

Experiment 2 ( $N = 176$ ), a 3 identity (athlete, volunteer, control) x 3 emotion (anger, sadness, neutral) between-subjects design, examines the impact of these identity-threatening emotions on WMC, using the operation-span task (OSPAN; Turner and Engle 1989). In the OSPAN, participants complete two simultaneous activities: solving math problems and maintaining a list of words to recall. Accurate word recall is the primary measure of WMC. Results reveal the predicted two-way interaction ( $F(4, 167) = 9.432$ ,  $p < .001$ ). Athlete identity participants experiencing sadness had lower OSPAN scores ( $M = 14.29$ ) than those experiencing no emotion ( $M = 21.17$ ;  $F(1, 167) = 5.923$ ,  $p = .016$ ) or anger ( $M = 28.35$ ,  $F(1, 167) = 11.22$ ,  $p < .001$ ). Similar results emerged for volunteers experiencing identity-threatening or identity-affirming emotions (v. neutral). We also find a facilitation effect; athletes experiencing anger ( $F(1, 167) = 6.303$ ,  $p = .013$ ) and volunteers experiencing sadness ( $F(1, 167) = 8.518$ ,  $p < .005$ ) had higher OSPAN scores than those in the neutral emotion conditions.

Experiment 3 ( $N = 523$ ) is a 3 identity (environmentalist, volunteer, control) x 3 (emotion (disgust, sadness, neutral) between-subjects design and directly links the reductions in WMC with compensatory consumption. A two-way ANOVA reveals the same pattern of results on WMC as in E2, wherein identity-threatening emotions result in worse OSPAN scores compared to the neutral and identity-affirming emotion conditions. We further replicate the results of E1, such that experiencing an identity-threatening emotion leads to enhanced evaluations for identity-consistent products. Importantly, we find, using Model 8, 10,000 bootstrap samples and a 95% confidence interval that the OSPAN scores in response to identity-threatening emotions mediate evaluations of identity-relevant products.

Experiment 4 ( $N = 488$ ), a 3 identity (athlete, romantic partner, control) by 3 emotion (anger, guilt, neutral) design, examines how these decrements in WMC result in more favorable attitudes toward identity-relevant products. Specifically, we examine processing fluency, finding that after experiencing an identity-threatening emotion, identity-relevant products receive an ease-of-processing boost, which increases evaluations (Bornstein and D'Agostino 1992; Winkielman et al 2003). We predict that response times will be faster for identity-affirming items, particularly when respondents are experiencing an identity-threatening emotion and are therefore seeking opportunities for compensatory consumption. Results reveal a significant interaction of identity, emotion and product type ( $F(8, 946) = 3.005$ ,  $p < .002$ ); across both identities, contrasts reveal individuals experiencing an identity-threatening emotion were faster in recognizing identity-relevant products than individuals experiencing identity-affirming or neutral emotions.

Finally, Experiment 5 ( $N = 508$ ) examines the impact of global self-affirmation on these cognitive processes. Prior work suggests that global self-affirmation can protect individuals from a domain-specific threat (Kim and Gal 2014). However, self-affirmation may merely create the opportunity for fluid compensation across other identity domains, thus negating the need for compensatory compensation, without eliminating the threat itself. Using a single (athlete) identity, E5 is a 2 self-affirmation (yes/control) x 3 emotions (anger, sad, neutral) design, with the OSPAN (WMC) as DV. Results reveal the predicted two-way interaction ( $F(2, 453) = 22.589$ ,  $p < .001$ ). The non-self-affirmation conditions replicate the results found in E2 and E3. However, after self-affirmation, we find no significant differences in WMC across the emotion conditions (all  $p > .09$ ), suggesting that global self-affirmation buffers and eliminates the cognitive costs associated with the domain specific threat.

In sum, we investigate the intervening basic cognitive processes that lead consumers experiencing self-discrepancies to evaluate identity-relevant products more favorably. In five studies, we demonstrate a causal chain linking self-threats, WMC, heightened attention toward identity-consistent stimuli, and compensatory consumption. In addition, rather than being only a consequence of self-threat as in prior work (e.g., Burke and Stets 1999), this research shows emotions can also serve as an important source of self-threat that is not only impactful, but easily manipulated by managers through advertisements.

## The Interdependent Self: High Identity Holism Facilitates Fluid Compensation

### EXTENDED ABSTRACT

A growing body of research suggests that people often purchase products and services as a means to fill the void created by a self-threat (Rucker and Galinsky 2008; Mandel et al. 2017). Consumers may seek products or activities that signal success in the domain in which they experienced the threat, known as within-domain compensation (Lisjak et al. 2015). For example, consumers whose self-perception of intelligence feels "shaken" might want to purchase an intelligence-related book or magazine to bolster their sense of intelligence (Gao, Wheeler and Shiv 2009). Alternatively, they may seek products or activities that signal success in an important domain unrelated to the threat, known as fluid compensation (Steele 1988). To illustrate, Sobol and Darke (2014) found that after experiencing a threat to their appearance, consumers engaged in more effortful decision making to signal their intelligence.

Little is known about when people would actively take the advantage of fluid compensation when available. In this research, we try to address this gap. Specifically, we propose that following a threat (vs. control), people with an interdependent (vs. independent) self-construal would be more likely to use fluid compensation. We propose that this happens because the motivation to mitigate the threat activates interdependents' holistic thinking about their different identities, so that they are better able to see the relations among their different identities as sources of global self-esteem. This higher level of identity holism should lead interdependents to affirm aspects of the self unrelated to the threat.

In Experiment 1, we operationalized interdependence via differences in nationality (Chinese vs. North American). Participants in the threat condition recalled a time in which they felt incompetent in their professional career, and participants in the control condition recalled a neutral episode. Then participants indicated their willingness to engage in three activities that were pretested to represent either within-domain compensation (give professional career tips to others, buy professional clothing, and engage in continuing job edu-

cation) or fluid compensation (have a spa treatment, participate in volunteer activities, and donate money to a charity). A 2 (threat)  $\times$  2 (culture)  $\times$  2 (compensation) ANOVA revealed a marginal three-way interaction ( $F(1,507) = 3.67, p = .056$ ). Following a self-threat (vs. control), Chinese participants reported higher willingness to engage in both within-domain and fluid compensation ( $F(1,507) = 2.72, p = .10$ ), whereas American participants reported higher willingness to engage in within-domain ( $F(1,507) = 2.91, p = .088$ ), but not fluid compensation ( $F(1,507) = 1.66, ns$ ).

In Experiment 2, we measured interdependence among US participants recruited from M-Turk, and we focused only on fluid compensation. We first manipulated self-threat and measured participants' willingness to engage in the same three fluid compensation activities from Experiment 1. We then measured self-construal (Singelis 1994) and subtracted independence from interdependence score so that higher numbers indicate more interdependence (Hong and Chang 2015). There was a predicted 2 (threat)  $\times$  continuous (interdependence) interaction ( $\beta = -.28, SE = .11, t(117) = -2.49, p = .014$ ). Following a self-threat (vs. control), interdependents were more willing to engage in fluid compensation ( $t(117) = 3.04, p = .003$ ). In contrast, there was no such effect for independents ( $t(117) = -.50, ns$ ).

Experiment 3 examined the impact of manipulated self-construal, using the Sumerian warrior story (Trafimow, Triandis and Goto 1991). Next, our undergraduate participants recalled a time when they felt incompetent in the academic domain versus a neutral episode. Finally, we asked participants to report their willingness to engage in three new activities that represent fluid compensation (shop for a pair of running shoes, shop for an activity tracker, and go to the hair salon/barber). A 2 (threat)  $\times$  2 (interdependence) ANOVA revealed the predicted two-way interaction ( $F(1,416) = 4.61, p = .032$ ). After self-threat (vs. control), participants primed with interdependence were more willing to engage in fluid compensation ( $F(1,416) = 7.21, p = .008$ ). There was no such effect for those primed with independence ( $F(1,416) = .13, ns$ ).

Experiment 4 provides initial evidence for the underlying role of identity holism by showing that following a threat (vs. control), interdependents exhibit higher level of identity holism than independents. We manipulated self-threat of academic competence as in Experiment 3 and measured interdependence as in Experiment 2. Afterwards, participants rated the extent to which they associated six identities (e.g., athletic, creative, and friendly) to their sense of self. The average of these ratings forms an index of identity holism, with higher scores indicating participants viewing different aspects of the self as more connected to their global self-esteem. There was a 2 (threat)  $\times$  continuous (interdependence) interaction ( $\beta = .21, SE = .11, t(115) = 1.89, p = .06$ ) on identity holism. Following a self-threat (vs. control), interdependents had a more holistic view of the self ( $t(115) = 1.94, p = .05$ ). There was no such effect for independents ( $t(115) = -.72, ns$ ).

Experiment 5 provides further evidence for our proposed mechanism by showing that following an identity threat (academic competence), interdependents are more likely to affirm an unrelated identity (altruism) because they perceive this identity as being more connected to their global self-esteem. We first manipulated self-threat and measured interdependence as in Experiment 4. Afterwards, participants indicated the amount of money they would like to donate to a charity if they were selected to get \$20 bonus in the lab. Finally, we measured the extent to which participants connected their moral identity with their global self-esteem. Specifically, we asked participants to indicate the extent to which they associated altruism with their sense of self using a four-item scale ( $\alpha = .85$ ).

We found a 2 (threat)  $\times$  continuous (interdependence) interaction on moral identity ( $\beta = .22, SE = .06, t(371) = 3.69, p < .01$ ) and donation ( $\beta = .87, SE = .43, t(371) = 2.04, p = .04$ ). Importantly, a moderated mediation analysis (Model 7, Hayes 2013) showed significant mediation ( $\beta = .40, CI_{95\%}: .12, .72$ ).

In sum, the current research contributes to the literature on compensatory compensation by investigating whether and how cultural differences influence consumers' propensity to engage in fluid compensations.

### Embracing Experiential over Material Consumption as a Compensatory Response: Thinking about Death Increases Consumer Preferences for Experiences

#### EXTENDED ABSTRACT

Past research on compensatory consumption finds that when consumers experience threat, they tend to seek out and value products that symbolize the specific dimension of the threat such as intelligence (Gao, Wheeler, and Shiv 2009; Kim and Rucker 2012), personal freedom (Levav and Zhu 2009), and power (Rucker and Galinsky 2008). In the current research, we pose the question of whether consumer preferences for experiences (vs. material goods) can be used to cope with threat to a particular domain: a sense of meaning in one's life.

Interest in the pursuit of meaning dates back at least to existential philosophers who claimed that one of the core aspects of human nature is the motivation to create the perception that one's existence is significant and purposeful (Becker 1973; Frankl 1963; Sartre 1947). This insight that people have an innate drive to find meaning in their lives was further elaborated upon by Terror Management Theory (TMT; Greenberg, Pyszczynski, and Solomon 1986). TMT suggests that reminders of one's own eventual death (i.e., mortality salience) create existential anxiety, leading people to endorse and adhere to their existing cultural worldviews (e.g., self-relevant beliefs, values, norms) in order to maintain and restore a sense of meaning (e.g., Arndt, Greenberg, and Cook 2002; Pyszczynski et al. 2006). Building on this, we suggest that mortality salience (i.e., threat to meaning) will lead to meaning restoration in the consumer domain such as seeking out options that imbue one's life with a sense of meaning. Specifically, we propose that morality salience will lead to preferences for experiential options (i.e., those made with the primary intention of acquiring a life experience) over material options (i.e., those made with the primary intention of acquiring a tangible material good; Van Boven and Gilovich 2003) because experiential options are more likely to be a source of meaning for individuals.

There are good reasons to hypothesize that experiential consumption is a source of meaning in life. Compared to material goods, experiences are more important in forming, defining, and representing one's true self, which refers to one's intrinsic sense of who one is (Carter and Gilovich 2012). In addition, compared to material options, experiences are more likely to facilitate social connections (Caprariello and Reis 2013; Howell and Hill 2009). This component is likely to constitute a driving force for one's sense of meaning, in that social relationships are primary sources of personal meaning in life (Baumeister 1991).

Drawing on this, we argue that mortality reminders will lead to the selection of relatively more experiential (vs. material) options due to a desire to seek out meaning. We test for this proposed mechanism in two ways. First, we examine whether a reported desire to seek out meaning mediates the observed effect. In addition, we demonstrate the role of meaning by testing a theoretically relevant boundary condition for the predicted effects. We examine whether or

not the individual has had the opportunity to restore meaning through some other means. For example, if the individual has had the opportunity to fulfill the desire for meaning via an alternative route (e.g., recalling a past meaningful experience), this should satiate the desire to seek out meaning, and the tendency to prefer experiential over material purchases in response to mortality salience will be mitigated.

A series of four studies provided support for our predictions. In Study 1, we sought direct causal evidence in support of our prediction by conducting a consequential choice study in which we asked participants to make a real choice between receiving a bookstore gift card or cash following mortality salience (vs. control). We held the product category constant (e.g., gift card) and manipulated the degree to which it is positioned as being relatively more experiential versus material. We found a significant interaction ( $\chi^2(1) = 3.40, p < .05$ ), indicating that participants who focused on thoughts about their own death (vs. control) were more likely to choose a gift card rather than cash when the gift card was positioned as being experiential versus material ( $\chi^2(1) = 4.15, p < .05$ ). However, this tendency was not observed among participants who thought about grocery shopping ( $\chi^2(1) = .06, p > .49$ ). In Study 2, we asked participants to focus on thoughts of their own death (vs. social rejection vs. physical pain vs. a neutral topic) and measured their willingness to pay (WTP) for future experiential and material purchases. We found that participants who thought about their own death indicated higher WTP for experiential than material purchases, and this tendency was only caused by mortality salience but not by social rejection, physical pain, or the control condition ( $F(3, 388) = 3.99, p < .01$ ). In Study 3, we investigated the underlying mechanism by demonstrating that an activated desire for meaning mediated the effect ( $b = .0744, SE = .0555, 95\% CI [.0040, .2516]$ ). Lastly, in Study 4, we demonstrated the moderating role of meaning-fulfillment. We found that the tendency to pay more for experiential than material purchases in response to mortality salience was mitigated when people were given an opportunity to fulfill their meaningfulness via an alternative route (i.e. recalling a past meaningful experience;  $F(1, 226) = 5.88, p < .05$ ).

The present research provides evidence for compensatory consumption by demonstrating that people prefer and choose relatively more experiential (vs. material) options when their sense of meaning is threatened by mortality salience. Furthermore, the implications of our research point to the possibility of subtly reminding people of the limited amount of time left to them to do everything they ever wanted to do when marketers promote more experiential (vs. material) options. Taken together, we would like to summarize the takeaway from this research with a quote from Brazilian novelist Paulo Coelho on his Twitter (@paulocoelho; 2012): “One day, you will wake up and there won’t be any more time to do the things you’ve always wanted. Do it now.”

## **Tough Crowd! How Observers Influence Compensatory Consumption**

### **EXTENDED ABSTRACT**

Ample research has found that symbolic consumption is a means for consumers to offset their insecurities (Wicklund and Gollwitzer 1981; Mandel et al. 2017). However, prior work on compensatory consumption has largely utilized settings devoid of social context (e.g., Gao, Wheeler, and Shiv 2009; Rucker and Galinsky 2008). This limited focus seems surprising given that observers often play a significant role in consumer decision-making (Argo, Dahl, and Manchanda 2005; Ashworth, Darke, and Schaller 2005). Moreover, prior research has proposed that the effectiveness of products and other symbols in resolving self-discrepancies depends on others acknowledging and pro-

viding “social validation” of their intended meaning (Wicklund and Gollwitzer 1982).

To fill this social vacuum, the current research examines how compensatory consumption varies in the presence of others. We draw on past research in personality psychology to distinguish between observers who are perceived to be judgmental and critical in their evaluation of others versus those who are benevolent and accepting (Ashton and Lee 2007; Lee and Ashton 2004). Building on this distinction, we investigate how judgmental and benevolent observers influence consumers’ compensatory consumption. With respect to this question, one possibility is that the presence of judgmental observers might motivate consumers with a self-discrepancy to redouble their compensation efforts in order to elicit social validation from such a “tough crowd” (Wicklund and Gollwitzer 1981). On the other hand, it is also possible that the presence of judgmental others might have the opposite effect, prompting consumers to refrain from compensating for concern of revealing their compensatory motive and thus preventing social validation (Ferraro, Kirmani, and Matherly 2013; Lisjak et al. 2015; Wicklund and Gollwitzer 1981).

We propose that the impact of observers on compensatory consumption depends not only on their characteristics but also on the type of compensatory consumption opportunity available. Specifically, we posit that judgmental (vs. benevolent) observers lessen efforts to compensate in the same domain as the self-discrepancy (within-domain compensation) but not in important domains unrelated to the self-discrepancy (across-domain compensation). This is because the direct relation of the product to the self-discrepancy in within-domain compensation increases concerns that others will suspect a compensatory motive. By contrast, the lack of direct relation in across-domain compensation makes it relatively unlikely that observers would suspect compensation. We test our predictions in five experiments.

Experiment 1 ( $n = 205$ ) examined people’s within-domain compensatory consumption in front of judgmental (vs. benevolent) others. Participants recalled either a time when they felt incompetent (self-discrepancy) or a neutral episode (control). Next, participants in a shopping scenario task reported their willingness to purchase three competence-signaling products (museum gift card, fountain pen, Newsweek magazine) when observed by a benevolent or judgmental other. A self-discrepancy  $\times$  observer interaction was significant ( $p = .05$ ). As predicted, threatened participants (vs. control) reported greater willingness to purchase competence-signaling products when the observer was benevolent ( $p < .01$ ) but not when the observer was judgmental.

Experiment 2 ( $n = 155$ ) examined this effect in a live social context. First, participants recalled a time when they felt incompetent versus a neutral episode. Then, all participants interacted individually with an observer (i.e., research assistant) who was unaware of their reported self-discrepancy. The observer followed a script to act in either a judgmental or benevolent manner. Finally, we offered participants an opportunity to compensate within-domain asking them whether they wanted to sign-up for a research newsletter and by measuring their willingness to pay for a \$10 gift card for a local museum. A self-discrepancy  $\times$  observer interaction was significant ( $p = .012$ ). Replicating experiment 1, threatened participants (vs. control) engaged in more competence-signaling behavior when they interacted with a benevolent observer ( $p = .019$ ), but not when they interacted with a judgmental other.

Experiment 3 ( $n = 197$ ) tested our proposition that consumers refrain from within-domain compensation in the presence of judgmental (vs. benevolent) others due to concerns that they will suspect compensatory motive. After recalling a time when they felt incompetent,

participants indicated their willingness to purchase a competence-signaling gift card in front of a benevolent or judgmental observer. Finally, they reported whether they thought that the observer would think they were compensating by purchasing the gift card. Consistent with our theorizing, participants were less willing to purchase a competence-signaling product ( $p = .049$ ) and more concerned about being labeled a compensator ( $p < .01$ ) when the observer was judgmental (vs. benevolent).

Experiment 4 aimed to show that when consumers were presented with an opportunity to compensate across-domain, they would engage in compensatory consumption regardless of whether the observer was judgmental or benevolent. The procedure was identical to experiment 2 with one exception: our dependent measure was participants' decision to sign-up for a newsletter that signaled compassion (across-domain compensation). As predicted, threatened participants (vs. control) were more likely to sign-up for the compassion-signaling newsletter ( $p < .01$ ). Importantly, the self-discrepancy  $\times$  observer interaction was non-significant ( $p = .78$ ), suggesting that participants compensated across-domain regardless of whether the observer was judgmental or benevolent.

Finally, Experiment 5 ( $n = 197$ ) sought to replicate the within- and across-domain findings in a single experiment and show the effect could occur spontaneously without directly manipulating the observer. We first manipulated self-discrepancy. Then, participants imagined shopping in front of an observer and reported their willingness to purchase three competence-signaling (within-domain) or three creativity-signaling (across-domain) products. Finally, participants rated how benevolent or judgmental the observer was. The three-way interaction was significant ( $p < .01$ ). When compensating within-domain, threatened participants (vs. control) reported greater purchase intentions for competence-signaling products when the observer was less judgmental ( $p < .01$ ), but not when the observer was more judgmental (interaction:  $p < .01$ ). When compensating across-domain, we observed only a main effect of self-discrepancy ( $p = .03$ ), such that threatened participants (vs. control) were more likely to purchase creativity-signaling products.

These findings expand the literature via a recognition of the role others play in compensatory consumption and through the demonstration that within- and across-domain compensation are not used as interchangeable strategies to resolve self-discrepancies.

### **SESSION OVERVIEW**

With abundant food and increasing choices available in today's developed societies, a paradox has emerged for consumers. While on the one hand, they seek to maximize their enjoyment from consumption experiences, on the other hand, they seek to minimize the negative effect of potential overconsumption in such episodes. This difficult balance is exacerbated by the fact that food consumption is susceptible to contextual factors (e.g., packaging, advertising, affect). This motivates research to better understand the factors influencing consumers' enjoyment of food, the antecedents driving consumption volume, and how these two might interact. Understanding such drivers and addressing them is not only of concern to practitioners in the food industry, but also of great interest to policy makers, health professionals, and consumers themselves.

Our special session addresses these concerns by exploring a range of factors influencing consumers' consumption and enjoyment of food, and thus presenting a more holistic view of the research in this domain. Across four papers, all involving actual food consumption, we document how various contextual conditions shape not only consumers' enjoyment of various consumption experiences but also, the types of foods they prefer and how much they actually consume. The papers examine various dimensions of the consumption experience, including partitioning (Paper 1), portion size (Paper 2), tableware aesthetics (Paper 3) and flavor complexity (Paper 4). Accord-

ingly, while each paper individually documents the importance of a specific contextual variable, collectively the session demonstrates that the behavioral outcomes and contingencies linked to food consumption can vary widely. Further, we demonstrate the manifestation of such effects on a wide range of audiences, spanning three continents and a broad age distribution- including children (Paper 2), undergraduate students (Papers 1 and 3), and a broader adult population (Paper 4).

In the first paper, Crolic and colleagues demonstrate that people satiate more quickly to hedonic food experiences when the experience is more (versus less) partitioned. In the second paper, Chandon and colleagues demonstrate that while children are moderately accurate forecasters of how portion size will impact their food enjoyment, they neglect to account for its effects on a snack's healthiness. However, sensory imagery can reduce unhealthy snack consumption. In the third paper, Pham and Garg find that while aesthetically pleasing tableware increases consumption of hedonic food among men, it reduced food intake among women. Finally, Hadi and colleagues demonstrate that cognitive depletion decreases consumers' evaluations for complex (but not simple) flavored foods.

Importantly, these papers highlight the different mechanisms through which situational cues might influence consumption experiences. We accordingly draw upon various theoretical processes to explain the behavioral outcomes, including feelings of repetitiveness (Crolic et al.), sensory imagery (Chandon et al.), self-monitoring (Pham and Garg), and perceived interestingness (Hadi et al.). All papers are in advanced stages of completion with multiple studies completed. The novel results and consequential nature of this research is sure to induce a lively discussion and is likely to appeal not only to researchers interested in food, but to a broader audience interested in either hedonic appreciation and/or consumer health.

## **Don't Stop! Partitioning Increases Satiation to Food**

### **EXTENDED ABSTRACT**

Three experiments demonstrate that people satiate more quickly to hedonic food experiences when the experience is more partitioned (versus less partitioned). This effect is driven by a feeling of repetitiveness resulting from identical partitions. Reducing the feeling of repetitiveness mitigates the effect of partitioning on satiation.

Hedonic food experiences occur frequently, yet, people rarely engage in these experiences all at once. People purchase individually-wrapped or bite-sized foods and food manufacturers frequently introduce mini versions of their flagship products such as mini M&Ms, mini cans of soda, and fun-sized chocolate bars. Yet little is understood about how partitioning, or dividing a continuous experience into multiple parts, influences the consumption experience. Take for example the simple pleasure of eating a piece of chocolate. Some may choose to pop the entire chocolate into their mouth and others may nibble at the chocolate and partition the hedonic experience into multiple smaller parts. This research explores who enjoys the experience more.

Prolonged or repeated consumption usually leads to satiation, or a decrease in enjoyment (Coombs and Avrunin 1977). The rate of satiation can be slowed when the consumption episodes are categorized more specifically (Redden 2008), by introducing variety (Ep-

stein et al. 2009; Galak, Redden, and Kruger 2009), and when the rate of consumption is slowed (Galak et al. 2013), and when what to consume is randomly selected (Redden, Haws and Chen 2017).

In the current research, we explore another critical antecedent to satiation – the extent to which a stimulus is partitioned. Specifically, we compare situations where people experience a stimulus as a whole to situations where the food is partitioned into smaller portions. Contrary to the notion that partitioning may interrupt the satiation process and cause dishabituation (Nelson and Meyvis 2008; Nelson, Meyvis, and Galak 2009), we argue that partitioning a food experience with frequent, brief breaks leads to more satiation. Across three experiments, we find that people satiate more when the hedonic food experience is more partitioned (versus less partitioned). We further show that this effect is not driven by partitioning per se, but rather by the feeling of repetitiveness resulting from identical partitions. When the feeling of repetitiveness is mitigated, the effect of partitioning on satiation disappears.

Study 1 is an initial demonstration of the partitioning effect on satiation to food stimuli. 108 students participated in a between-subjects design (degree of partition: low, high) with repeated measures. The low-partitioned condition had .49 ounces (15) of regular-sized M&Ms. The high-partition condition had .49 ounces (45) of mini M&Ms. Note that one regular M&M is equivalent in weight to three mini M&Ms. Participants in the low-partitioned condition were told to eat one M&M. Participants in the high-partitioned condition were told to eat three mini M&Ms one at a time. Participants were asked, “To what extent was it pleasant or unpleasant to eat the chocolate candy, just now?” (-4=extremely unpleasant, 4=extremely pleasant; Time 1 measure). Next, participants ate the remaining candies one at a time. Participants answered the Time 2 measure and reported repetitiveness (Redden 2008; “How repetitive was your experience in the study?” 1=not at all repetitive, 7=extremely repetitive). Time 2 was subtracted from Time 1 to determine hedonic change. Results showed that participants in the high-partitioned condition showed greater hedonic satiation (reflected by greater hedonic change,  $M=1.55$ ) than the low-partitioned condition ( $M=.44$ ;  $t(106)=-3.19$ ,  $p<.001$ ). The feeling of repetitiveness mediated the effect (indirect effect=.09, 95% CI: .002, .28). Thus, partitioning hedonic experiences increases satiation (greater decline in pleasantness) driven by feelings of repetitiveness.

Study 2 tests the proposed mechanism by manipulating the similarity (i.e., evenness) of the food consumption episodes. Notably, this study manipulates the evenness of the partitions while holding the number of partitions constant, showing that the effect is not driven by partitioning per se, but rather by the feeling of repetitiveness resulting from even partitions. This study rules out alternative explanations such as distraction and annoyance. 102 students participated in a between-subjects design (low-partition, high-partition-even, high-partition-uneven) with repeated measures. The low-partition condition had .69 ounces (7) jumbo M&Ms. The two high-partition conditions had .69 ounces (63) of mini M&Ms. Note that one jumbo M&M is equivalent in weight to nine mini M&Ms. Participants in the low-partition condition were told to eat one jumbo M&M. Participants in the high-partition-even condition ate three mini M&Ms at a time, three times. Participants in the high-partition-uneven condition ate five mini M&Ms at a time, then one, and then three at a time. Thus the high-partition conditions ate the same amount but varied in their evenness. After giving their Time 1 rating, participants ate the remaining candies. Those in the high-partition-even condition always ate three M&Ms together whereas those in the high-partition-uneven condition ate between one and five M&Ms each time. Participants gave their Time 2 rating. Consistent with our predic-

tion, participants in the high-partition-even condition satiated more quickly than the low-partition condition (Bonferroni post-hoc mean difference=1.32,  $p<.05$ ). There was no difference in satiation rate between the high-partition-uneven condition and low-partition condition (mean difference=.64,  $p>.05$ ).

Study 3 demonstrates that mental partitioning can influence satiation. Specifically, if the person perceives the experience as a series of identical parts (versus part of a whole) it leads to greater satiation to the experience. This study holds the actual consumption experience constant to rule out the possibility that annoyance, perceived quantity or higher variety, or differences in attention increased satiation. 228 students participated in a between-subjects design (focus on repetition: high, low) with repeated measures. Both conditions had .98 ounces (30) of regular M&Ms. Participants in the low-focus condition were told that the candy was “one serving of M&M candies”. Participants in the high-focus condition were told that the candy was “30 pieces of M&M candies”. Thus in the low-focus (high-focus) condition, the 30 M&M candies were framed as unpartitioned (partitioned) which decreases (increases) the focus on repetitiveness. All participants ate one M&M and gave their Time 1 rating. Then participants ate the remaining 29 candies and gave their Time 2 rating. As predicted, participants in the high-focus condition satiated more quickly to the food ( $M=1.41$ ) than the low-focus condition ( $M=.94$ ;  $t(226)=-2.10$ ,  $p<.05$ ).

Three studies demonstrate that partitioning decreases enjoyment of hedonic food experiences. Partitioned (versus unpartitioned) experiences increase focus on the uniformity of the parts, increase repetitiveness, hasten satiation, and decrease enjoyment to food.

### Snack Portion Size Choice, Expectations and Actual Experiences in Children: The Interplay of Healthiness, Hunger, and Sensory Food Imagery

#### EXTENDED ABSTRACT

8-11 year-old children can anticipate the effects of portion size accurately when it comes to post-intake hunger, moderately accurately for eating enjoyment, and not at all for perceived healthiness. Food sensory imagery reduces how much energy-dense snacks these children choose and eat, without affecting their intake of a healthier alternative.

Consumers generally view sensory pleasure and portion size as complements, expecting that larger portions will increase eating enjoyment, especially if the food is palatable (Sorensen et al. 2003). However, some studies suggest that larger quantities of food do not necessarily increase eating enjoyment (Rode, Rozin, and Durlach 2007; Rolls et al. 1981). Errors in anticipating the effects of portion size on eating enjoyment may explain why people eat more when they are served larger portions and why they choose portions that are too large from a pure eating enjoyment perspective (Cornil and Chandon 2016). This raises the question of how we can help people—especially children—better anticipate the effect of portion size on enjoyment and realize that they will be happier with less food.

Recent research has investigated the effect of food sensory imagery (creating a mental image of the multi-sensory experience of eating) on portion size choice (Cornil and Chandon 2016). Consistent with research on mindful eating, sensory imagery helps adults better anticipate the effect of sensory-specific satiety, and thus leads them to choose smaller portions while anticipating greater enjoyment from these smaller portions. However, the evidence is mostly limited to adults and calorie-dense foods, whereas a recent study has shown that people are actually well calibrated when it comes to predicting how they will feel after consuming varying amounts

of fruits or vegetables but not after consuming energy-dense foods (Brunstrom et al. 2018).

In the current research, we aim to further investigate the interplay between portion size and both expected and experienced eating enjoyment in young children, as well as the effect of food sensory imagery on their portion size and eating decisions. We also extend past research by testing whether the effect of sensory imagery replicates across two foods that vary in energy-density, and in their symbolic value. Funding was provided by ANR (ANR-15-CE21-0014).

In Study 1, we recruited 91 children (54% female) aged 8 to 11 years old from three primary schools in France. Following pretests, we selected two products familiar and similarly liked by children for afternoon snacks: Brossard® chocolate brownie (high calorie density) and Andros® applesauce (low calorie density). Three portions were selected for each food: the recommended serving size by the manufacturer, a 50% larger portion size, and a 125% larger portion size, so that each portion is 50% bigger than the preceding one. During a first afternoon session, we measured children's expected food enjoyment, post-intake hunger, and healthiness for each portion of each product using validated scales. In six further afternoon sessions, children evaluated actual eating enjoyment, post-intake hunger, and healthiness after eating one portion of each food. We also measured initial hunger during all seven sessions (ranging from moderate to very high).

We found a significant interaction between initial hunger and portion size for both expected and experienced eating enjoyment for brownies (respectively  $p < .05$  and  $p < .01$ ), but only for the latter for applesauce (respectively  $p = .20$  and  $p = .05$ ). Among moderately hungry children, portion size was unrelated to either expected or experienced eating enjoyment (respectively  $p = .09$  and  $p = .96$  for brownie and  $p = .29$  and  $p = .10$  for applesauce). Among very hungry children however, portion size increased both the expected and experienced enjoyment for brownie ( $p < 0.01$  for both), but only increased expected (not experienced) enjoyment for applesauce (respectively  $p < 0.01$  and  $p = .43$ ). The effects of portion size on the other measures were not moderated by hunger nor snack type: both anticipated and experienced post-intake hunger decreased with portion size, for both snacks (all  $p$  values  $< 0.01$ ). Finally, the perceived healthiness of eating each portion was not influenced by its size, either before or after intake (except after eating the brownie).

We examined the effects of food sensory imagery in a second pre-registered study. For Study 2, we relied on the cohort of 91 children who had participated in Study 1 and added 82 additional children of the same age recruited from one of the same school and three other similar schools. The sample size was determined based on a power analysis of the results of Study 1 in Cornil and Chandon (2016). A total of 173 children were randomly assigned to one of two conditions. In the food sensory imagery condition, children were reminded of the five senses and were asked to imagine the multisensory experience of eating three hedonic foods shown on pictures (chocolate candies, waffles, and cereals). In the control (non-food sensory imagery) condition, children were also asked to engage in multisensory imagery but following exposure to non-food pictures (building a sandcastle, making a snowman, playing with dead leaves). After measuring initial hunger, both groups were then asked to choose between the recommended serving size, a 50% larger portion, and a 125% larger portion of either brownie or applesauce. One week later, the children went through the same procedure (with three different images) but were asked about the second food. Eaten quantities were also measured.

We found a significant interaction between the intervention and the type of snack ( $p < 0.01$ ). Compared to the control condition, sen-

sory food imagery led children to choose 7.1 % less brownie ( $p < 0.01$ ) and reduced intake by 8% (about 22 calories,  $p < 0.01$ ). However, it had no effect on either the quantity of applesauce chosen or consumed ( $p = 0.32$  for both). In addition, hungrier and heavier children chose and ate more, but there no differences between boys and girls. Overall, Study 1 shows that 8-11 years old children are accurate forecasters of the effects of portion size on their post-intake hunger of two common snacks (brownies and applesauce) and relatively accurate forecasters for eating enjoyment. Study 1 further shows that eating enjoyment is unrelated to portion size, but only when children are moderately hungry. When they are very hungry, both expected (pre-intake) and experienced (post-intake) eating enjoyment increases with portion size. Importantly, the children neglected the effects of consumption quantity when rating the health impact of eating a snack, only considering its average nutritional quality. In addition, Study 2 further demonstrates the effectiveness of food sensory imagery may be a useful tool to nudge children towards healthier eating since it reduces intake of a hedonic snack, without reducing the consumption of a healthier one.

### **More Than Meets the Eye: The Influence of Tableware Aesthetics on Food Consumption**

#### **EXTENDED ABSTRACT**

This research examines the influence of tableware aesthetics on food consumption. A series of four studies suggest that while aesthetically pleasing tableware increases food salience which increases hedonic consumption among men but triggers monitoring among women, reducing their intake. Plate type, food type, and goal primes moderate these effects.

Obesity has become an alarming global issue. More than 39% of adults are overweight, 13% are obese, and the prevalence of obesity has more than doubled between 1980 and 2014, worldwide (WHO 2016). Past research on food consumption has examined various contextual factors including assortment variety, food shape, labeling, emotions, and packaging, among others. Given that aesthetics of the tableware used in consumption episodes is closely tied to the consumption experience, there is a surprising dearth of research linking the two. Thus, the current research seeks to examine the relationship between tableware aesthetics and food consumption and the different moderators and mediator of this relationship. Particularly, it studies the influence of tableware aesthetics (aesthetically pleasing versus plain tableware) on food consumption, and whether this relationship is moderated by gender, food type (hedonic versus less hedonic food), and eating goal (healthy versus hedonic). The mediating role of self-monitoring is also examined.

Our research makes three important contributions. First, we contribute to the growing literature on the effect of contextual factors on food consumption by linking it to tableware aesthetics and establishing the process underlying this relationship. Current research often focuses on the utilitarian aspects of the tableware, such as its size, color contrast, and weight (e.g., Piqueras-Fiszman et al. 2011), while neglecting its aesthetic aspects. Second, we establish gender as an important moderator of the aesthetics-consumption relationship. While prior research in aesthetics does not highlight gender differences in response to product form or aesthetics, more recent studies have highlighted the need for further examination of gender effects in this domain (Patrick and Hagtvedt 2011). Finally, our findings lead to important implications, which will be of interest to marketers and health professionals, as well as consumers who are interested in balancing hedonic and health goals in their consumption.

In the current research, we argue that tableware aesthetics presents two opposing effects on consumption. Aesthetics has the ability to draw attention; greater attention to food can increase the desire to eat and stimulate greater level of consumption. In contrast, tableware aesthetics can also direct consumers' attention toward monitoring their intake. The amount of food consumed depends largely on whether consumers monitor their consumption – that is, whether they pay attention to how much they are eating (Polivy et al. 1986). Males and females process information related to product designs differently (Meyers-Levy and Maheswaran 1991). Females treat design as an environmental cue and react more strongly to it than males. Further, existing research finds that women are more concerned with dieting and healthy eating than men (Rozin, Bauer, and Catanese 2003) and that they often feel the obligation to eat according to social norms, making them more cautious of their eating habits (Chaiken and Pliner 1987).

Taken together, we predict that gender will moderate the relationship between tableware aesthetics and consumption. Specifically, when hedonic food is presented on aesthetically pleasing tableware, the heightened attention will lead females to monitor their consumption, depressing their food intake. In contrast, aesthetically pleasing tableware will draw the attention of males to the attractiveness of the hedonic food, leading them to consume more.

Study 1 employed a one factor, two levels (plate type: more versus less aesthetically pleasing) between-subjects design to test the relationship. Results found a significant interaction of gender and plate type on consumption ( $F(1,67)=8.79, p<.01$ ). As predicted, while the aesthetically pleasing tableware increased consumption among males ( $M_{\text{aesthetic}}=33.42, M_{\text{plain}}=24.30, p<.05$ ), it had the opposite effect on females ( $M_{\text{aesthetic}}=20.54, M_{\text{plain}}=28.58, p<.05$ ). Further, while males eat more than females, they enjoy the consumption experience less ( $M_{\text{male}}=4.77, M_{\text{female}}=5.50, p=.04$ ).

Study 2 replicated the results of Study 1 and further investigated the underlying mechanism driving the relationship. As predicted, a one-way ANOVA revealed that females (vs males) monitored their consumption to a greater extent, when using aesthetically pleasing (versus less pleasing) tableware. Mediation analysis confirmed that monitoring mediated the influence of tableware aesthetics on consumption among females ( $b=2.48, SE=1.85; 95\% CI=.0915$  to  $5.7975$ ), but not among males.

Study 3 assessed whether eating goals moderated the effect. Hedonic, healthy or neutral goal were primed first, followed by an opportunity for food consumption (presented as a taste test). Results show that among males, consumption was higher under hedonic ( $M_{\text{hedonic}}=31.53$  vs.  $M_{\text{healthy}}=20.62, p=.01$ ) and neutral goals ( $M_{\text{neutral}}=31.19$  vs.  $M_{\text{healthy}}=20.62, p=.01$ ), when using the aesthetically pleasing tableware. In contrast, females consumed less under hedonic ( $M_{\text{hedonic}}=19.15$  vs.  $M_{\text{neutral}}=27.32, p<.05$ ) as well as healthy goals ( $M_{\text{healthy}}=14.10$  vs.  $M_{\text{neutral}}=27.32, p<.001$ ), when using plain tableware. Further analyses revealed that females monitored to a greater extent in the hedonic ( $M_{\text{hedonic}}=3.48$  vs.  $M_{\text{neutral}}=2.72, t=2.1, p<.05$ ) and healthy goal ( $M_{\text{healthy}}=3.64$  vs.  $M_{\text{neutral}}=2.72, t=2.45, p=.01$ ) conditions, which correlated with lower quantities consumed. Among females, mediation analyses comparing neutral goal with hedonic (or health) goal confirmed increased monitoring as the underlying mechanism driving the influence of tableware aesthetics on food consumption. Finally, increased consumption with plain tableware among females was attenuated when either hedonic or healthy goal, was active.

Study 4 aimed to test the potential moderating effect of food type (hedonic vs less so). A three-way ANOVA showed a significant interaction between plate type, food type, and gender ( $F(1,107)=4.36,$

$p<.05$ ). Importantly, while the results replicated findings from Studies 1-3 for the hedonic food product, these differences in consumption across gender and tableware were non-significant with the less hedonic food product; thus, establishing an important boundary condition.

Our findings not only advance the theoretical understanding of the relationship between tableware aesthetics and consumption but also, have important implications for stakeholders such as consumers and policy makers. While aesthetically pleasing tableware help women monitor their consumption of unhealthy foods, it backfires among males. By reinforcing different goals, one might intervene in the consumption process and nudge consumers toward healthier consumption habits.

## Flavor Fatigue: How Cognitive Depletion Reduces Enjoyment of Complex Flavors

### EXTENDED ABSTRACT

This research examines how cognitive depletion influences consumer enjoyment of complex-flavored foods. We find that depleted individuals show decreased evaluations for complex (but not simple) flavored foods due to a reduction in perceived interestingness that can otherwise be derived from flavor complexity and establish substantive boundary conditions for the effect.

Food options often exhibit multi-dimensional flavor profiles: mint chocolate and strawberry cheesecake are as commonly encountered as plain chocolate and cheesecake. In fact, trends in the food and beverage industry suggest that consumers' palatal preferences are becoming progressively more intricate, and "flavor layering" is now prevalent among bartenders, restaurant chefs, and food manufacturers alike (Crawford, 2016). However, taste appreciation is largely a cognitive activity (e.g., Lee, Frederick, & Ariely, 2006; Elder & Krishna, 2010), and complex stimuli can be especially cognitively demanding to process (Carbon & Albrecht, 2016). Therefore, a question that naturally arises is if, or more specifically, under which conditions, consumers actually enjoy complex-flavored food.

We propose that the enjoyment of complex-flavored foods depends on the degree to which consumers are cognitively depleted. While research has demonstrated that cognitive constraints lead individuals to choose indulgent over healthy foods (Baumeister & Vohs, 2007; Bruyneel et al., 2006), we are the first to test if and how depletion influences enjoyment of foods regardless of their hedonic or utilitarian characteristics, focusing on their flavor composition instead. We argue that because depletion reduces the reward value consumers assign to cognitively demanding tasks (Inzlicht & Schmeichel, 2012), it should impose momentary constraints on consumers' willingness to engage in the cognitive processing required to derive interestingness and extract pleasure when tasting complex flavors. Thus, we expect cognitive depletion to reduce enjoyment of complex-flavored (but not simple-flavored) foods. We test our hypotheses in three experiments with actual food consumption and manipulate flavor complexity by varying the number of distinct flavor components in foods (Levy et al; Olabi et al. 2015).

Study 1 ( $N=106$ ) was a 2 (cognitive depletion: low vs. high) x 2 (flavor: simple vs. complex) between-subjects design. Cognitive depletion was manipulated using a standard protocol (Neal, Wood, & Drolet, 2013): participants in the low depletion condition retyped a short passage, while those in the high depletion condition retype the same passage without using the letter "e" or spacebar. Participants then sampled a square of either dark chocolate (simple condition) or dark chocolate with mint (complex condition). Both chocolates were unwrapped, visually indistinguishable, and did not differ in

perceived healthiness, calorie content, novelty, or familiarity (as per pretest results). Participants then indicated their enjoyment of the chocolate (on a 4-item scale, e.g., "I enjoyed tasting this chocolate,"  $\alpha = .89$ ). As predicted, ANOVA results revealed a significant interaction of cognitive depletion and flavor complexity on enjoyment ( $F(1, 102) = 8.80, p < .01$ ). Depletion reduced enjoyment of the complex-flavored chocolate ( $F(1, 102) = 5.00, p < .05$ ). Interestingly, cognitive depletion also increased enjoyment of the simple-flavored chocolate ( $F(1, 102) = 6.57, p < .05$ ).

Study 2 ( $N=86$ ) was a 2 (cognitive depletion: low vs. high)  $\times$  2 (flavor: simple vs. complex) between-subjects design. Mental depletion was manipulated via an anagram-solving task (Park, Glaser, & Knowles, 2008). Afterwards, participants were asked to taste either simple-flavored (salt) or complex-flavored (salt and vinegar) potato chips. As in study 1, the stimuli were pretested to insure the foods differed in their flavor complexity, but not on other potentially confounding dimensions (including perceived novelty, familiarity, and healthiness). After tasting the chips, participants indicated their enjoyment using the same measures as in study 1 ( $\alpha = .93$ ). Next, they rated the interestingness of the chips using two semantic differential items (1 = uninteresting, boring; and 7 = interesting, exciting; Silvia 2005), averaged to form an interestingness index ( $r = .83$ ). As expected, ANOVA results revealed a significant interaction of cognitive depletion and flavor complexity on enjoyment ( $F(1, 82) = 4.53, p < .05$ ). Participants in the high depletion condition preferred the simple-flavored (vs. complex-flavored) chips ( $F(1, 82) = 6.62, p < .05$ ), whereas complexity did not impact evaluations among those in the low depletion condition ( $F(1, 82) = .10, p > .10$ ). Results also revealed a significant cognitive depletion  $\times$  flavor complexity interaction on perceived interestingness ( $F(1, 82) = 7.44, p < .01$ ), mirroring the results on enjoyment. A moderated mediation analysis (model 8; Hayes 2013) demonstrated that the indirect effect of depletion on enjoyment through interestingness was significant among those who tasted the complex-flavored chips ( $\beta = -.51, CI: [-1.09, -.12]$ ), but not among those who tasted the simple-flavored chips ( $\beta = .44, CI: [-.06, 1.01]$ ). Thus, findings from study 2 demonstrate that cognitive depletion reduces enjoyment of complex-flavored foods, and that the decrease in enjoyment is due to lower derived interestingness.

Study 3 ( $N=114$ ) was a 2 (cognitive depletion: low vs. high)  $\times$  2 (tasting speed: fast vs. slow) between-subjects design. Participants completed the cognitive depletion task from study 2. Next, all participants tasted a complex-flavored juice (a blend of mango, orange, apple, and passion fruit). Tasting speed was manipulated by instructing participants to take either a quick sip of the juice, or to slowly savor the juice (Crolic & Janiszewski, 2016). Research suggests that speeding up the act of consumption prevents people from having discriminating taste experiences (Peron and Allen 1988). Therefore, we only expected to see the effect of cognitive depletion on enjoyment in the slow condition. Consistent with this expectation, results revealed a significant interaction on enjoyment ( $F(1, 109) = 6.43, p < .05$ ). As predicted, depletion reduced enjoyment of the juice in the slow speed condition ( $F(1, 109) = 4.04, p < .05$ ), replicating the effect found in studies 1 and 2. Interestingly, for participants in the fast condition, cognitive depletion marginally increased juice enjoyment ( $F(1, 109) = 2.89, p = .09$ ). Consistent with our theorizing, lower processing opportunity significantly reduced enjoyment among those low in depletion ( $F(1, 109) = 4.71, p < .05$ ), but did not affect highly depleted individuals, who did not have the motivation to derive interest from the experience regardless of processing constraints ( $F(1, 109) = 2.24, p > .10$ ).

This research offers practical implications for food establishments (e.g. consumers may prefer simpler food items at the end of

a mentally exhausting workday) and invites additional research on how consumer responses to particular flavor characteristics might be circumstantially determined.

### SESSION OVERVIEW

Much of consumer research has focused on developing theories of consumer behavior (Rapp and Hill 2015; Wang et al. 2015) and testing theoretically-derived predictions by examining novel consumer-relevant phenomena (Dahl et al. 2015). However, the field lacks a concerted integration of accumulated consumer-relevant findings (Grewal et al. 2018). Despite sheer magnitude and richness of consumer research, scant efforts have been made by consumer researchers to synthesize extant research on focal phenomena and provide novel empirical generalizations. By abstracting from clusters of related empirical findings, consumer researchers can contribute to ongoing debates, and perhaps more importantly, generate new theoretical directions moving forward.

The aim of this session is to move beyond a narrative summary of extant empirical work and generate novel empirical generalizations in consumer research. Specifically, the four papers in this session address the following questions: 1) What empirical generalizations can be uncovered from extant research on specific consumer-relevant phenomenon, and 2) how does the nature of these generalizations vary as a function of theoretically important moderators and boundary conditions? Session attendees will learn about novel insights generated from four large-scale consumer research meta-analyses in this session, factors nuancing and/or influencing these insights as well as current best practices related to application of meta-analytic method to tackling important consumer-relevant phenomena.

The first two papers aim to generate empirical generalizations related to the domain of consumers' connections with brands. The authors of the first paper examine how well different consumer-brand relationships (CBRs) drive customer brand loyalty. They show that while affective CBRs emerged the strongest drivers of loyalty overall, identity CBRs yielded stronger effects using behavioral, retrospective loyalty, and non-students while trust CBRs dominated among

Americans. In terms of the second paper, researchers meta-analyze and review the congruity literature for brand extensions. They document a consistent positive effect of congruity on consumers' responses to brand extensions and a series of factors that interact with and moderate congruity to influence consumers' responses (e.g. parent brand characteristics, flexibility of the categorization process).

The last two papers strive to provide empirical generalizations with respect to two classic topics in consumer research: experiential consumption and endowment effect. The third paper meta-analyzes the experiential advantage literature comparing material purchases to experiential purchases, and show that while measures of happiness had a "small-to-medium" effect size overall, measures of impressions and personal identity had directionally larger effect sizes. Lastly, the authors of the final paper meta-analytically test the relative explanatory power of drivers of the endowment effect, finding that biased information processing is the leading explanatory account, relative to ownership and misrepresentation accounts.

Taken together, this session provides multifaceted insights into how the field of consumer research can systematically synthesize existing findings and generate new insights. Exploring important consumer-relevant phenomena through application of powerful meta-analytic method can enrich consumer theories. We expect this session to be of interest to consumer researchers across different areas (branding, experiential consumption, BDT), consumer methodologists, and practitioners who want to use academic empirical generalizations and apply them to practice.

## **How Well Do Consumer-Brand Relationships Drive Customer Brand Loyalty? Generalizations from a Meta-Analysis of Brand Relationship Elasticities**

### EXTENDED ABSTRACT

Customer brand loyalty is one of the most important concepts to consumer researchers

and marketing practitioners. A considerable amount of research over the last 20 years documents

that different consumer-brand relationship constructs (CBR), such as those characterized as primarily affective (e.g. attachment and love), identity-based (e.g. self-brand connection and identification), and trust-based, are positive predictors of customer brand loyalty. For instance, it has been demonstrated that brand attachment predicts a brand's purchase share (Park et al. 2010), brand identification impacts behavioral intentions (Einwiller et al. 2006) and brand trust leads to repurchase intentions (Mazodier and Merunka 2012). CBRs can hence be portrayed as invaluable assets that develop and solidify customer brand loyalty.

Given the importance of consumer-brand relationship constructs as a customer brand loyalty-solidifying mechanism, it is not surprising that branding scholars and practitioners want to know what CBRs to focus on and what performs best and when. However, there is little consensus on what CBR constructs are superior predictors of loyalty and under what conditions each construct performs relatively better. Theoretically speaking, while there is a general understanding that all CBR constructs that we examine are positively associated with customer brand loyalty, there is no systematic understanding regarding what CBR construct is the most effective driver of loyalty, and

even more critically, under what specific circumstances and settings. For example, research focused on the *same* CBR construct (e.g. attachment) has revealed relatively small ( $= .09$ ; Goode, Khamitov and Thomson 2015), medium ( $= .30$ ; Thomson 2006) and large ( $= .64$ ; Hudson et al. 2016) estimates of the path to customer brand loyalty. At the same time, research on *different* CBR constructs (i.e. love, identification and trust) has documented nearly equally powerful paths to customer brand loyalty (Bergkvist and Bech-Larsen 2010; He et al. 2012; Hudson et al. 2016). Relatedly, in light of differing tactical objectives in the field of solidifying customer brand loyalty (e.g. repeat purchase vs. attitudinal loyalty), it is unclear which CBR construct is likely to be superior driver of customer brand loyalty. From a practical standpoint, marketers invest billions into fostering relationships with consumers in the absence of a solid understanding of their actions (Avery, Fournier, and Wittenbraker 2014). Clearly, as a field we do not yet know the answer.

In response, we start to address this gap. To advance understanding of how well different consumer-brand relationship constructs drive customer brand loyalty and to help companies improve the effectiveness of their relationship building investments, we conduct a meta-analysis of the link between three CBR constructs and customer brand loyalty. To generate our database, we undertook a search of all relevant literature that touched on the linkage between CBRs and customer brand loyalty. We initially identified relevant papers through a search of multiple electronic databases, such as ProQuest, Google Scholar, PsycINFO, ABI/Inform, Business Source Complete, Web of Science, JSTOR, and Science Direct using keywords (e.g. brand relationship, brand attachment, brand love, self-brand connection etc... and combinations of these terms) related to customer brand loyalty and the focal antecedents. For inclusion in our meta-analysis, we retained articles published in a journal that appeared on the *Financial Times* (i.e. FT 50) or *UT Dallas' Research Rankings* list or rated in the *Academic Journal Guide* (Chartered Association of Business Schools 2015) as a 2 or higher (out of 4\*). We used this 2+ criteria to ensure a broad range of publication outlets while maintaining quality control. In addition, other criteria for inclusion required that (1) a study measured one or more CBR constructs using a multi-item scale, (2) the study included a measure that was interpretable as customer brand loyalty (e.g. attitudinal loyalty, behavioral loyalty, "mixed" loyalty, etc...), and (3) the study presented empirical consumer-level responses (typically based on survey and/or experimental data). Finally, the results had to enable the unambiguous estimation of effect sizes linking one or more pairs of variables of interest or report other statistical information from which we could calculate effect sizes.

We also identified a series of control variables corresponding to brand, sample, consumer, journal and methodological characteristics, and performed several checks to ensure the robustness of the results. To account for a nested or hierarchical structure of meta-analytic data (i.e. subjects nested within studies; Denson and Seltzer 2011) and associated within-study error correlations between effect sizes, we conduct the meta-analysis with hierarchical linear modeling (HLM) (Bijmolt and Pieters 2001; You et al. 2015). In line with prior meta-analyses in marketing (e.g. Rubera and Kirca 2012; You et al. 2015), we estimate the model employing the maximum likelihood estimation method.

The analysis of 304 effect sizes from 143 studies reported in 127 publications over 21 years ( $n = 179,395$  across 35 countries) reveals that all three consumer-brand relationship constructs positively drive customer brand loyalty and that the aggregate CBR elasticity is .404. More importantly, our results demonstrate under what conditions various CBR constructs increase loyalty. For example, the links

between CBR constructs and customer brand loyalty are generally highest for affect-based CBR constructs and when customer brand loyalty is operationalized in attitudinal (vs. behavioral), absolute (vs. relative) or retrospective (vs. prospective) terms. Additionally, identity-based CBR constructs are stronger predictors of customer brand loyalty when such loyalty is measured behaviorally, retrospectively, or among non-student consumers, while trust-based CBR constructs are better drivers of American consumers' customer brand loyalty.

Drawing on these findings, we advance implications for scholars and managers. We make three main contributions. First, we identify the average elasticity between consumer-brand relationship constructs and customer brand loyalty. In so doing, we extend the field's knowledge base by quantifying the link between various CBR constructs and customer brand loyalty. Second, we identify which of three CBR constructs (i.e. primarily affect-based vs. identity-based vs. trust-based) are relatively better at boosting loyalty. Third, we identify a series of variables (e.g. brand type, sample and consumer characteristics) that moderate these effects, providing important information about when and where each CBR construct appears to be relatively more effective, which implies a series of actionable recommendations for marketing managers.

### Is Congruity Desirable for Brand Extensions? A Conceptual and Meta-Analytic Review

#### EXTENDED ABSTRACT

The literature on brand extensions has come a long way since 1990. In this literature, a key question is how to maximize the success of brand extensions, and an important part of this question involves choosing a product category for a brand to extend to. The extensive literature on congruity suggests that consumers will more readily accept an extension of a brand if the extension product is congruent (or fits) with the parent brand (or category). This is a powerful idea that has stood the test of time.

With growth of this literature, researchers have pushed the boundaries of research on the congruity effect by discussing and examining various moderators of the congruity effect, and various alternative effect patterns (e.g., the moderate incongruity effect pattern). Given the range of results from this large body of literature, a systematic and comprehensive review and synthesis can help organize the various findings to date to facilitate future work and to provide a resource for practitioners.

This paper addresses three sets of research questions: (1) *How large is the congruity effect for brand extensions? And how much variation is there?* (2) *What are the relevant factors, in addition to congruity, that influence the success of brand extensions? And how do they interact with congruity?* (3) *Can moderate incongruity generate more favorable responses to brand extensions from consumers than congruity? And under what circumstances?*

Our theoretical review summarizes the work on congruity since 1990, including various factors studied that work together with congruity to influence consumer reactions to brand extensions. We provide a conceptual framework that synthesizes this work, by putting a focus on the theoretical mechanism of categorization theory and affect transfer, which has frequently been argued to underlie the congruity effect. This theoretical review provides necessary background for our empirical analysis.

Our empirical analysis consists of a meta-analysis to measure the impact of congruity (between a parent brand and an extension category) on consumers' reactions in the brand extension research. This method is particularly useful here, because it can directly contrast and combine different study results via effect sizes, so that pat-

terns, relationships, and even source of variation among studies' results can be identified. After conducting an extensive literature search, screening and coding the data, and applying meta-analysis methods, we generated 269 effect sizes of congruity, each of which represents an effect size arising from a comparison of two levels of congruity. The data came from 37 journal articles in 11 academic journals in fields related to marketing or business.

Our findings help answer some fundamental questions about this topic.

(1) Our review of the literature on congruity in brand extensions shows a consistent positive effect of congruity on consumers' responses, and our meta-analysis reveals that the overall mean effect size of congruity ( $=0.211$ ) is of small to medium size. There is also support for the *Congruity Hypothesis* effect pattern (consumers respond better to congruity than to moderate incongruity, which they respond better to than to extreme incongruity), particularly when the dependent variable is consumer attitudes toward the brand extension. But the variation of the congruity effect sizes across studies is large. This directly speaks to the relative importance of congruity. Although congruity is significant and very relevant from a managerial perspective, it is far from being the sole determinant of success for brand extensions.

(2) Our conceptual review of moderators of the congruity effect identifies and proposes some key factors that may interact with congruity to influence consumers' responses. Our meta-analysis finds a very significant positive effect of congruity for attitudinal dependent variables, that negative information about the parent brand nullify the congruity effect, and that parent brand attitude and brand familiarity positively interact with congruity. For practitioners, these results suggest that parent brand characteristics are important factors interacting with congruity to influence consumers' responses.

(3) Our conceptual review and meta-analysis together identify two important sets of factors that may moderate the congruity effect into a *Moderate Incongruity* effect pattern (consumers respond better to moderate congruity than to congruity, which they respond better to than to extreme incongruity): those factors that increase elaboration to resolve incongruity, and those that increase flexibility of the categorization process. These results provide an alternative brand extension strategy for practitioners. Other than the simple "more congruent, the better" strategy, the company could extend to a moderately incongruent product category, and employ marketing campaigns designed to induce flexibility of categorization or greater elaboration about any perceived incongruity.

(4) In addition, larger effect sizes of congruity are identified for studies using general consumers as samples (vs. student samples) and for studies with a successful manipulation check (vs. unsuccessful or no manipulation checks). These findings have methodological implications for this research area. In particular, the use of student samples may lead to under-estimation of the congruity effect sizes, which suggests that general consumer samples may lead to a more realistic estimation of the congruity effect. Moreover, the use of manipulation checks may be an important element in research design.

Overall, as guidance for managers and researchers in this area, congruity alone is not enough to drive the success of a brand extension, but it can tip the balance together with other factors.

## The Experiential Advantage: A Meta-Analysis

### EXTENDED ABSTRACT

The types of purchases consumers make and the way they perceive those purchases

matters. They affect a consumer's happiness and wellbeing, and they have important implications for satisfaction and repeat pur-

chase. For instance, more than a decade of research suggests calling purchases hedonic or utilitarian can influence happiness (Dhar and Wertenbroch 2000; Khan and Dhar 2010), and many studies demonstrate how consumers trade off products they perceive as vices and virtues (Dhar, Huber, and Khan 2007; Kivetz and Simonson 2002). More recently, studies have focused on another continuum on which consumer expenditures may differ: whether a purchase is more experiential (i.e., for obtaining an experience) or material (i.e., for obtaining a tangible object; Van Boven and Gilovich, p. 1194).

An expanding literature argues that in terms of happiness, there is an "experiential advantage." Experiential purchases lead to more consumer happiness than comparable material purchases (Van Boven and Gilovich 2003). Further, there is evidence that experiences can have other positive benefits beyond happiness. Experiences have been shown to be better for forming bonds with gift givers and receivers (Chan and Mogilner 2017), providing insight into our true self (Carter and Gilovich 2012; Kim et al. 2016), giving off positive impressions (Valsesia and Diehl 2017), and increasing the enjoyment of discussions (Kumar and Gilovich 2015). However, some research has argued that these effects might have boundaries. The benefit of experiential purchases is limited to those that turn out positively in retrospective studies (Nicolao, Irwin, and Goodman 2009), and this advantage may not always hold in day to day life (Weidman and Dunn 2016).

In this research we meta-analyze the literature on the experiential advantage to study what types of factors affect the strength of this benefit and its applicability. We examine whether different procedures and methodologies might affect the effect size of the experiential advantage, and test whether certain dependent measures (e.g., hedonics, social factors, or identity) lead to a larger experiential advantage. Researchers have used several different procedures to test the experiential advantage, which provides a natural experiment to investigate potential moderators. In perhaps the most common procedures, participants are asked to recall a purchase that was either experiential or material in nature (Van Boven and Gilovich 2003). Other procedures have asked participants to think of a product in more experiential or material terms (e.g., a 3D television; Mann and Gilovich 2016), or present participants either an experiential or material good (Van Boven et al. 2010). Researchers have also used varying dependent measures, and little attention has been given to the nuances of what the experiential advantage means. For instance, researchers have asked participants to respond to questions about happiness (Nicolao et al. 2009), impressions of people with said goods (Van Boven et al. 2010), relationships with others (Chan and Mogilner 2017), or several other related, but distinct, dependent measures about hedonics or social elements (Kumar and Gilovich 2015).

We included any comparison between an experience and material condition in which the measure could be construed as the outcome being better in terms of happiness, building social bonds, leading to greater donations, improving perceptions of yourself/your identity, and related measures. We divide the dataset into those about hedonics and those about social/identity types of dependent measures to test primary explanations of the experiential advantage (i.e., social currency, identity centrality, and positive reinterpretation; Van Boven and Gilovich 2003). We excluded studies in which the dependent measure was not interpretable as having an "advantage" (e.g., discount factors; Goodman et al. 2018).

We searched for literature in January through July 2017 on PsycINFO and Proquest Dissertations and Theses, and through a forward search of citations of Van Boven and Gilovich (2003) on Web of Science. We used the following search terms: (experiential OR

material OR material-experiential OR experiential-material) AND (gift OR consumption OR product OR products OR purchase OR purchases OR possessions OR possession). We also searched conference proceedings from SCP, SJDM, ACR, and SPSP. Further, we e-mailed 42 authors for unpublished materials and to verify effect sizes, and we reached out for unpublished materials through the ACR and SJDM listservs and the SCP website.

We use standard formula for computation of effect sizes in terms of Hedges  $d$  with its correction factor (Borenstein et al. 2009; Lipsey and Wilson 2001). We also employ a calculator to account for multiple correlated effect sizes within a study (Hedges et al. 2010; Tanner-Smith and Tipton 2014).

We coded studies based on several criteria. First, we coded studies based on several procedural variables: whether they were run on Amazon Mechanical Turk or not, whether they originated from published or unpublished studies, whether participants were asked to recall a material or experiential good (Van Boven and Gilovich 2003), whether participants were asked to view one or both of two different goods (Van Boven et al. 2010), whether participants were presented a product described in terms of its material or experiential qualities (Mann and Gilovich 2016). Second, we coded studies based on whether the dependent measure was more about hedonics (Nicolaio et al. 2009) or about social (Chan and Mogilner 2017) or identity factors (Kim et al. 2016). Finally, we explored other potential moderators (e.g., year).

The results consistently found evidence for the experiential advantage and we discuss other publication bias methods. We build a  $p$ -curve on the underlying published literature from which we draw effect sizes and find evidential value for the literature (Simonsohn et al. 2014). We find an effect size for the hedonic measures that is smaller ( $d = .26$ , 95% CI [.20, .32],  $t = 8.41$ ,  $Q = 600.25$ ) than for the social and identity measures ( $d = .45$ , 95% CI [.37, .53],  $t = 11.09$ ,  $Q = 322.58$ ) from 129 studies contributing 429 effect sizes. Mturk studies had slightly smaller effect sizes, while other methodological factors only had a weak impact on effect sizes. This result may point to social and identity dimensions being a critical component of the experiential advantage, consistent with the seminal paper's contentions (Van Boven and Gilovich 2003).

## Using a Meta-Analysis to Unravel Relative Importance of Postulated Explanations for the Endowment Effect

### EXTENDED ABSTRACT

The endowment effect (EE) is the tendency for people to value goods that they own disproportionately more than those that they do not. The effect is demonstrated in the valuation paradigm, where sellers' willingness-to-accept (WTA) price is consistently higher than buyers' willingness-to-pay (WTP) price (Kahneman et al. 1990). The effect is important in marketing because it explains many psychologically-based sales tactics, such as free samples and trial periods, and is especially relevant to the burgeoning area of the peer-to-peer economy, where individuals are both buyers and sellers and are subject to the asymmetric price dichotomy associated with the EE.

The EE has been studied for over 40 years. Researchers have theorized and demonstrated various explanations for the effect. The traditional explanation for the effect is loss aversion (Kahneman and Tversky 1979; Thaler 1985), but recent research favors other explanations based on experimental tests. These include psychological ownership (Morewedge et al. 2009; Strahilevitz and Loewenstein 1998), biased information processing (Carmon and Ariely 2001; Morewedge and Gliblin 2015), and strategic misrepresentation (Plott and Zeiler 2005, 2007). The research on the EE suggests that the

phenomenon is *multi-determined*; that is, multiple factors typically work in concert to trigger the effect. However, what remains unclear is the *relative impact* of these factors; rarely has more than one factor been tested at a time.

Further, variations in conceptualizations and manipulations of explanatory accounts have been used across studies. For instance, the psychological ownership account has traditionally been conceptualized in terms of a *possession-self link* (Strahilevitz and Loewenstein 1998; Peck and Shu 2009), but more recently has also been conceptualized in terms of an *implicit self-threat* (Chatterjee et al. 2013; Dommer and Swaminathan 2013). Biased information processing has been experimentally tested with *direct-specific* and *indirect-general* manipulations. Direct manipulations focus on a specific component of the information processing "chain" postulated to be involved in the EE (Irmak et al. 2013; Johnson et al. 2007; Nayakankuppam and Mishra 2005), whereas indirect manipulations do not focus on a specific component, but rather affect information processing holistically (Saqib, Frohlich, and Bruning 2010; Shu and Peck 2011). It is unclear whether and how differences in conceptualizations and manipulations affect the endowment effect.

To deal with these shortcomings, we compiled a comprehensive list of articles on the EE, coded each study within the articles along a number of factors, and conducted a meta-analysis, based on hierarchical modeling and bootstrapping. The hierarchy comprises specific experiments nested within studies in published articles. Bootstrapping is conducted to control for variation in the number of observations associated with each explanatory factor.

In our meta-analysis, we ask two main questions: (i) Of the EE explanatory accounts that have been tested in experimental studies, which is the leading one? (ii) How do the different conceptualizations and manipulations of the ownership and information processing accounts differentially affect the EE?

*Method.* Our data come from articles studying the EE using the valuation paradigm, published in refereed journals in psychology, marketing, and economics, among others. The data consists of 471 observations derived from 188 studies published in 104 separate articles. The dependent variable for our analysis is the natural logarithm of the WTA/WTP ratio. There are two main groups of independent variables: (i) factors hypothesized to trigger the EE, which we label "causal factors", and (ii) moderating factors, which include product-, consumer-, and method-related features.

We use a three-level mixed effects model, in which the first two levels capture variation due to effect sizes across studies and observations and the third level captures variation due to experiments that are cohorts in the same article. Estimates are obtained by maximum likelihood, which facilitates model testing (Hox et al. 2010). Because differences in the number of observations associated with each of the causal factors may influence the observed relative order of the causal factors on the WTA-WTP disparity, we implement a *bootstrapping approach* that maintains a fixed and equal number of observations across each of the causal factors while still using each factor's full range of data.

*Results.* Our model explains 71% of the variance in the WTA-WTP ratio (Nakagawa and Schielzeth 2013). When all moderators are controlled for and causal factors are set to their neutral points, we find that the WTA/WTP ratio is 1.89 ( $p < .01$ ).

According to the mixed effects model, all three factors hypothesized to cause the EE – psychological ownership ( $\beta_1 = 0.090$ ,  $p < .01$ ), biased information processing ( $\beta_2 = 0.126$ ,  $p < .01$ ), and strategic misrepresentation ( $\beta_3 = -0.065$ ,  $p < .01$ ) significantly influence the WTA/WTP asymmetry. To test the idea that biased information processing account might be the leading factor in influencing the

intensity of the endowment effect (Morewedge and Giblin 2015), its estimated beta is compared with those of psychological ownership and strategic misrepresentation. We find that  $\beta_2$  is significantly larger than either  $\beta_1$  or  $\beta_3$  ( $p < .05$ ).

Subsequent analysis of the components of the psychological ownership account reveals that both the *implicit self-threat* ( $\beta = 0.083, p < .01$ ) and *possession-self link* components ( $\beta = 0.051, p < .01$ ) drive the disparity between WTA and WTP. Contrasting beta values, we find the *implicit self-threat* component to play a marginally more extensive role in driving the endowment effect than the *possession-self link* component ( $\beta_{\text{implicit self-threat}} - \beta_{\text{possession-self link}} > p < .13$ ).

Analysis of manipulation types for the biased information processing account show that both *indirect-general* manipulations ( $\beta = 0.115, p < .01$ ) and *direct-specific* manipulations ( $\beta = 0.050, p < .01$ ) influence the WTA-WTP gap. In this case, *indirect-general* manipulations generate significantly larger gaps than do *direct-specific* manipulations ( $\beta_{\text{indirect-general}} - \beta_{\text{direct-specific}} > p < .05$ ).

**Conclusions.** Consistent with existing research, our results validate the multi-determined nature of the EE; however, our results show biased information processing as the leading explanatory account of the effect. The results challenge the traditional conceptualization of the ownership account in terms of a possession-self link and bring to light how different manipulations of biased information processing – direct versus indirect – can systematically affect the WTA-WTP disparity.

### **SESSION OVERVIEW**

Much of consumer research has focused on developing theories of consumer behavior (Rapp and Hill 2015; Wang et al. 2015) and testing theoretically-derived predictions by examining novel consumer-relevant phenomena (Dahl et al. 2015). However, the field lacks a concerted integration of accumulated consumer-relevant findings (Grewal et al. 2018). Despite sheer magnitude and richness of consumer research, scant efforts have been made by consumer researchers to synthesize extant research on focal phenomena and provide novel empirical generalizations. By abstracting from clusters of related empirical findings, consumer researchers can contribute to ongoing debates, and perhaps more importantly, generate new theoretical directions moving forward.

The aim of this session is to move beyond a narrative summary of extant empirical work and generate novel empirical generalizations in consumer research. Specifically, the four papers in this session address the following questions: 1) What empirical generalizations can be uncovered from extant research on specific consumer-relevant phenomenon, and 2) how does the nature of these generalizations vary as a function of theoretically important moderators and boundary conditions? Session attendees will learn about novel insights generated from four large-scale consumer research meta-analyses in this session, factors nuancing and/or influencing these insights as well as current best practices related to application of meta-analytic method to tackling important consumer-relevant phenomena.

The first two papers aim to generate empirical generalizations related to the domain of consumers' connections with brands. The authors of the first paper examine how well different consumer-brand relationships (CBRs) drive customer brand loyalty. They show that while affective CBRs emerged the strongest drivers of loyalty overall, identity CBRs yielded stronger effects using behavioral, retrospective loyalty, and non-students while trust CBRs dominated among Americans. In terms of the second paper, researchers meta-analyze and review the congruity literature for brand extensions. They docu-

ment a consistent positive effect of congruity on consumers' responses to brand extensions and a series of factors that that interact with and moderate congruity to influence consumers' responses (e.g. parent brand characteristics, flexibility of the categorization process).

The last two papers strive to provide empirical generalizations with respect to two classic topics in consumer research: experiential consumption and endowment effect. The third paper meta-analyzes the experiential advantage literature comparing material purchases to experiential purchases, and show that while measures of happiness had a "small-to-medium" effect size overall, measures of impressions and personal identity had directionally larger effect sizes. Lastly, the authors of the final paper meta-analytically test the relative explanatory power of drivers of the endowment effect, finding that biased information processing is the leading explanatory account, relative to ownership and misrepresentation accounts.

Taken together, this session provides multifaceted insights into how the field of consumer research can systematically synthesize existing findings and generate new insights. Exploring important consumer-relevant phenomena through application of powerful meta-analytic method can enrich consumer theories. We expect this session to be of interest to consumer researchers across different areas (branding, experiential consumption, BDT), consumer methodologists, and practitioners who want to use academic empirical generalizations and apply them to practice.

## **How Well Do Consumer-Brand Relationships Drive Customer Brand Loyalty? Generalizations from a Meta-Analysis of Brand Relationship Elasticities**

### **EXTENDED ABSTRACT**

Customer brand loyalty is one of the most important concepts to consumer researchers and marketing practitioners. A considerable amount of research over the last 20 years documents that different consumer-brand relationship constructs (CBR), such as those characterized as primarily affective (e.g. attachment and love), identity-based (e.g. self-brand connection and identification), and trust-based, are positive predictors of customer brand loyalty. For instance, it has been demonstrated that brand attachment predicts a brand's purchase share (Park et al. 2010), brand identification impacts behavioral intentions (Einwiller et al. 2006) and brand trust leads to repurchase intentions (Mazodier and Merunka 2012). CBRs can hence be portrayed as invaluable assets that develop and solidify customer brand loyalty.

Given the importance of consumer-brand relationship constructs as a customer brand loyalty-solidifying mechanism, it is not surprising that branding scholars and practitioners want to know what CBRs to focus on and what performs best and when. However, there is little consensus on what CBR constructs are superior predictors of loyalty and under what conditions each construct performs relatively better. Theoretically speaking, while there is a general understanding that all CBR constructs that we examine are positively associated with customer brand loyalty, there is no systematic understanding regarding what CBR construct is the most effective driver of loyalty, and even more critically, under what specific circumstances and settings. For example, research focused on the *same* CBR construct (e.g. attachment) has revealed relatively small ( $= .09$ ; Goode, Khamitov and

Thomson 2015), medium (= .30; Thomson 2006) and large (= .64; Hudson et al. 2016) estimates of the path to customer brand loyalty. At the same time, research on *different* CBR constructs (i.e. love, identification and trust) has documented nearly equally powerful paths to customer brand loyalty (Bergkvist and Bech-Larsen 2010; He et al. 2012; Hudson et al. 2016). Relatedly, in light of differing tactical objectives in the field of solidifying customer brand loyalty (e.g. repeat purchase vs. attitudinal loyalty), it is unclear which CBR construct is likely to be superior driver of customer brand loyalty. From a practical standpoint, marketers invest billions into fostering relationships with consumers in the absence of a solid understanding of their actions (Avery, Fournier, and Wittenbraker 2014). Clearly, as a field we do not yet know the answer.

In response, we start to address this gap. To advance understanding of how well different consumer-brand relationship constructs drive customer brand loyalty and to help companies improve the effectiveness of their relationship building investments, we conduct a meta-analysis of the link between three CBR constructs and customer brand loyalty. To generate our database, we undertook a search of all relevant literature that touched on the linkage between CBRs and customer brand loyalty. We initially identified relevant papers through a search of multiple electronic databases, such as ProQuest, Google Scholar, PsycINFO, ABI/Inform, Business Source Complete, Web of Science, JSTOR, and Science Direct using keywords (e.g. brand relationship, brand attachment, brand love, self-brand connection etc... and combinations of these terms) related to customer brand loyalty and the focal antecedents. For inclusion in our meta-analysis, we retained articles published in a journal that appeared on the *Financial Times* (i.e. FT 50) or *UT Dallas' Research Rankings* list or rated in the *Academic Journal Guide* (Chartered Association of Business Schools 2015) as a 2 or higher (out of 4\*). We used this 2+ criteria to ensure a broad range of publication outlets while maintaining quality control. In addition, other criteria for inclusion required that (1) a study measured one or more CBR constructs using a multi-item scale, (2) the study included a measure that was interpretable as customer brand loyalty (e.g. attitudinal loyalty, behavioral loyalty, "mixed" loyalty, etc...), and (3) the study presented empirical consumer-level responses (typically based on survey and/or experimental data). Finally, the results had to enable the unambiguous estimation of effect sizes linking one or more pairs of variables of interest or report other statistical information from which we could calculate effect sizes.

We also identified a series of control variables corresponding to brand, sample, consumer, journal and methodological characteristics, and performed several checks to ensure the robustness of the results. To account for a nested or hierarchical structure of meta-analytic data (i.e. subjects nested within studies; Denson and Seltzer 2011) and associated within-study error correlations between effect sizes, we conduct the meta-analysis with hierarchical linear modeling (HLM) (Bijmolt and Pieters 2001; You et al. 2015). In line with prior meta-analyses in marketing (e.g. Rubera and Kirca 2012; You et al. 2015), we estimate the model employing the maximum likelihood estimation method.

The analysis of 304 effect sizes from 143 studies reported in 127 publications over 21 years ( $n = 179,395$  across 35 countries) reveals that all three consumer-brand relationship constructs positively drive customer brand loyalty and that the aggregate CBR elasticity is .404. More importantly, our results demonstrate under what conditions various CBR constructs increase loyalty. For example, the links between CBR constructs and customer brand loyalty are generally highest for affect-based CBR constructs and when customer brand loyalty is operationalized in attitudinal (vs. behavioral), absolute (vs.

relative) or retrospective (vs. prospective) terms. Additionally, identity-based CBR constructs are stronger predictors of customer brand loyalty when such loyalty is measured behaviorally, retrospectively, or among non-student consumers, while trust-based CBR constructs are better drivers of American consumers' customer brand loyalty.

Drawing on these findings, we advance implications for scholars and managers. We make three main contributions. First, we identify the average elasticity between consumer-brand relationship constructs and customer brand loyalty. In so doing, we extend the field's knowledge base by quantifying the link between various CBR constructs and customer brand loyalty. Second, we identify which of three CBR constructs (i.e. primarily affect-based vs. identity-based vs. trust-based) are relatively better at boosting loyalty. Third, we identify a series of variables (e.g. brand type, sample and consumer characteristics) that moderate these effects, providing important information about when and where each CBR construct appears to be relatively more effective, which implies a series of actionable recommendations for marketing managers.

## Is Congruity Desirable for Brand Extensions? A Conceptual and Meta-Analytic Review

### EXTENDED ABSTRACT

The literature on brand extensions has come a long way since 1990. In this literature, a key question is how to maximize the success of brand extensions, and an important part of this question involves choosing a product category for a brand to extend to. The extensive literature on congruity suggests that consumers will more readily accept an extension of a brand if the extension product is congruent (or fits) with the parent brand (or category). This is a powerful idea that has stood the test of time.

With growth of this literature, researchers have pushed the boundaries of research on the congruity effect by discussing and examining various moderators of the congruity effect, and various alternative effect patterns (e.g., the moderate incongruity effect pattern). Given the range of results from this large body of literature, a systematic and comprehensive review and synthesis can help organize the various findings to date to facilitate future work and to provide a resource for practitioners.

This paper addresses three sets of research questions: (1) *How large is the congruity effect for brand extensions? And how much variation is there?* (2) *What are the relevant factors, in addition to congruity, that influence the success of brand extensions? And how do they interact with congruity?* (3) *Can moderate incongruity generate more favorable responses to brand extensions from consumers than congruity? And under what circumstances?*

Our theoretical review summarizes the work on congruity since 1990, including various factors studied that work together with congruity to influence consumer reactions to brand extensions. We provide a conceptual framework that synthesizes this work, by putting a focus on the theoretical mechanism of categorization theory and affect transfer, which has frequently been argued to underlie the congruity effect. This theoretical review provides necessary background for our empirical analysis.

Our empirical analysis consists of a meta-analysis to measure the impact of congruity (between a parent brand and an extension category) on consumers' reactions in the brand extension research. This method is particularly useful here, because it can directly contrast and combine different study results via effect sizes, so that patterns, relationships, and even source of variation among studies' results can be identified. After conducting an extensive literature search, screening and coding the data, and applying meta-analysis

methods, we generated 269 effect sizes of congruity, each of which represents an effect size arising from a comparison of two levels of congruity. The data came from 37 journal articles in 11 academic journals in fields related to marketing or business.

Our findings help answer some fundamental questions about this topic.

(1) Our review of the literature on congruity in brand extensions shows a consistent positive effect of congruity on consumers' responses, and our meta-analysis reveals that the overall mean effect size of congruity ( $=0.211$ ) is of small to medium size. There is also support for the *Congruity Hypothesis* effect pattern (consumers respond better to congruity than to moderate incongruity, which they respond better to than to extreme incongruity), particularly when the dependent variable is consumer attitudes toward the brand extension. But the variation of the congruity effect sizes across studies is large. This directly speaks to the relative importance of congruity. Although congruity is significant and very relevant from a managerial perspective, it is far from being the sole determinant of success for brand extensions.

(2) Our conceptual review of moderators of the congruity effect identifies and proposes some key factors that may interact with congruity to influence consumers' responses. Our meta-analysis finds a very significant positive effect of congruity for attitudinal dependent variables, that negative information about the parent brand nullify the congruity effect, and that parent brand attitude and brand familiarity positively interact with congruity. For practitioners, these results suggest that parent brand characteristics are important factors interacting with congruity to influence consumers' responses.

(3) Our conceptual review and meta-analysis together identify two important sets of factors that may moderate the congruity effect into a *Moderate Incongruity* effect pattern (consumers respond better to moderate congruity than to congruity, which they respond better to than to extreme incongruity): those factors that increase elaboration to resolve incongruity, and those that increase flexibility of the categorization process. These results provide an alternative brand extension strategy for practitioners. Other than the simple "more congruent, the better" strategy, the company could extend to a moderately incongruent product category, and employ marketing campaigns designed to induce flexibility of categorization or greater elaboration about any perceived incongruity.

(4) In addition, larger effect sizes of congruity are identified for studies using general consumers as samples (vs. student samples) and for studies with a successful manipulation check (vs. unsuccessful or no manipulation checks). These findings have methodological implications for this research area. In particular, the use of student samples may lead to under-estimation of the congruity effect sizes, which suggests that general consumer samples may lead to a more realistic estimation of the congruity effect. Moreover, the use of manipulation checks may be an important element in research design.

Overall, as guidance for managers and researchers in this area, congruity alone is not enough to drive the success of a brand extension, but it can tip the balance together with other factors.

### The Experiential Advantage: A Meta-Analysis

#### EXTENDED ABSTRACT

The types of purchases consumers make and the way they perceive those purchases

matters. They affect a consumer's happiness and wellbeing, and they have important implications for satisfaction and repeat purchase. For instance, more than a decade of research suggests calling purchases hedonic or utilitarian can influence happiness (Dhar and

Werthenbroch 2000; Khan and Dhar 2010), and many studies demonstrate how consumers trade off products they perceive as vices and virtues (Dhar, Huber, and Khan 2007; Kivetz and Simonson 2002). More recently, studies have focused on another continuum on which consumer expenditures may differ: whether a purchase is more experiential (i.e., for obtaining an experience) or material (i.e., for obtaining a tangible object; Van Boven and Gilovich, p. 1194).

An expanding literature argues that in terms of happiness, there is an "experiential advantage:" Experiential purchases lead to more consumer happiness than comparable material purchases (Van Boven and Gilovich 2003). Further, there is evidence that experiences can have other positive benefits beyond happiness. Experiences have been shown to be better for forming bonds with gift givers and receivers (Chan and Mogilner 2017), providing insight into our true self (Carter and Gilovich 2012; Kim et al. 2016), giving off positive impressions (Valesia and Diehl 2017), and increasing the enjoyment of discussions (Kumar and Gilovich 2015). However, some research has argued that these effects might have boundaries. The benefit of experiential purchases is limited to those that turn out positively in retrospective studies (Nicolao, Irwin, and Goodman 2009), and this advantage may not always hold in day to day life (Weidman and Dunn 2016).

In this research we meta-analyze the literature on the experiential advantage to study what types of factors affect the strength of this benefit and its applicability. We examine whether different procedures and methodologies might affect the effect size of the experiential advantage, and test whether certain dependent measures (e.g., hedonics, social factors, or identity) lead to a larger experiential advantage. Researchers have used several different procedures to test the experiential advantage, which provides a natural experiment to investigate potential moderators. In perhaps the most common procedures, participants are asked to recall a purchase that was either experiential or material in nature (Van Boven and Gilovich 2003). Other procedures have asked participants to think of a product in more experiential or material terms (e.g., a 3D television; Mann and Gilovich 2016), or present participants either an experiential or material good (Van Boven et al. 2010). Researchers have also used varying dependent measures, and little attention has been given to the nuances of what the experiential advantage means. For instance, researchers have asked participants to respond to questions about happiness (Nicolao et al. 2009), impressions of people with said goods (Van Boven et al. 2010), relationships with others (Chan and Mogilner 2017), or several other related, but distinct, dependent measures about hedonics or social elements (Kumar and Gilovich 2015).

We included any comparison between an experience and material condition in which the measure could be construed as the outcome being better in terms of happiness, building social bonds, leading to greater donations, improving perceptions of yourself/your identity, and related measures. We divide the dataset into those about hedonics and those about social/identity types of dependent measures to test primary explanations of the experiential advantage (i.e., social currency, identity centrality, and positive reinterpretation; Van Boven and Gilovich 2003). We excluded studies in which the dependent measure was not interpretable as having an "advantage" (e.g., discount factors; Goodman et al. 2018).

We searched for literature in January through July 2017 on PsycINFO and Proquest Dissertations and Theses, and through a forward search of citations of Van Boven and Gilovich (2003) on Web of Science. We used the following search terms: (experiential OR material OR material-experiential OR experiential-material) AND (gift OR consumption OR product OR products OR purchase OR

purchases OR possessions OR possession). We also searched conference proceedings from SCP, SJDM, ACR, and SPSP. Further, we e-mailed 42 authors for unpublished materials and to verify effect sizes, and we reached out for unpublished materials through the ACR and SJDM listservs and the SCP website.

We use standard formula for computation of effect sizes in terms of Hedges  $d$  with its correction factor (Borenstein et al. 2009; Lipsey and Wilson 2001). We also employ a calculator to account for multiple correlated effect sizes within a study (Hedges et al. 2010; Tanner-Smith and Tipton 2014).

We coded studies based on several criteria. First, we coded studies based on several procedural variables: whether they were run on Amazon Mechanical Turk or not, whether they originated from published or unpublished studies, whether participants were asked to recall a material or experiential good (Van Boven and Gilovich 2003), whether participants were asked to view one or both of two different goods (Van Boven et al. 2010), whether participants were presented a product described in terms of its material or experiential qualities (Mann and Gilovich 2016). Second, we coded studies based on whether the dependent measure was more about hedonics (Nicolaio et al. 2009) or about social (Chan and Mogilner 2017) or identity factors (Kim et al. 2016). Finally, we explored other potential moderators (e.g., year).

The results consistently found evidence for the experiential advantage and we discuss other publication bias methods. We build a  $p$ -curve on the underlying published literature from which we draw effect sizes and find evidential value for the literature (Simonsohn et al. 2014). We find an effect size for the hedonic measures that is smaller ( $d = .26$ , 95% CI [.20, .32],  $t = 8.41$ ,  $Q = 600.25$ ) than for the social and identity measures ( $d = .45$ , 95% CI [.37, .53],  $t = 11.09$ ,  $Q = 322.58$ ) from 129 studies contributing 429 effect sizes. Mturk studies had slightly smaller effect sizes, while other methodological factors only had a weak impact on effect sizes. This result may point to social and identity dimensions being a critical component of the experiential advantage, consistent with the seminal paper's contentions (Van Boven and Gilovich 2003).

## Using a Meta-Analysis to Unravel Relative Importance of Postulated Explanations for the Endowment Effect

### EXTENDED ABSTRACT

The endowment effect (EE) is the tendency for people to value goods that they own disproportionately more than those that they do not. The effect is demonstrated in the valuation paradigm, where sellers' willingness-to-accept (WTA) price is consistently higher than buyers' willingness-to-pay (WTP) price (Kahneman et al. 1990). The effect is important in marketing because it explains many psychologically-based sales tactics, such as free samples and trial periods, and is especially relevant to the burgeoning area of the peer-to-peer economy, where individuals are both buyers and sellers and are subject to the asymmetric price dichotomy associated with the EE.

The EE has been studied for over 40 years. Researchers have theorized and demonstrated various explanations for the effect. The traditional explanation for the effect is loss aversion (Kahneman and Tversky 1979; Thaler 1985), but recent research favors other explanations based on experimental tests. These include psychological ownership (Morewedge et al. 2009; Strahilevitz and Loewenstein 1998), biased information processing (Carmon and Ariely 2001; Morewedge and Gliblin 2015), and strategic misrepresentation (Plott and Zeiler 2005, 2007). The research on the EE suggests that the phenomenon is *multi-determined*; that is, multiple factors typically work in concert to trigger the effect. However, what remains unclear

is the *relative impact* of these factors; rarely has more than one factor been tested at a time.

Further, variations in conceptualizations and manipulations of explanatory accounts have been used across studies. For instance, the psychological ownership account has traditionally been conceptualized in terms of a *possession-self link* (Strahilevitz and Loewenstein 1998; Peck and Shu 2009), but more recently has also been conceptualized in terms of an *implicit self-threat* (Chatterjee et al. 2013; Dommer and Swaminathan 2013). Biased information processing has been experimentally tested with *direct-specific* and *indirect-general* manipulations. Direct manipulations focus on a specific component of the information processing "chain" postulated to be involved in the EE (Irmak et al. 2013; Johnson et al. 2007; Nayakankuppam and Mishra 2005), whereas indirect manipulations do not focus on a specific component, but rather affect information processing holistically (Saqib, Frohlich, and Bruning 2010; Shu and Peck 2011). It is unclear whether and how differences in conceptualizations and manipulations affect the endowment effect.

To deal with these shortcomings, we compiled a comprehensive list of articles on the EE, coded each study within the articles along a number of factors, and conducted a meta-analysis, based on hierarchical modeling and bootstrapping. The hierarchy comprises specific experiments nested within studies in published articles. Bootstrapping is conducted to control for variation in the number of observations associated with each explanatory factor.

In our meta-analysis, we ask two main questions: (i) Of the EE explanatory accounts that have been tested in experimental studies, which is the leading one? (ii) How do the different conceptualizations and manipulations of the ownership and information processing accounts differentially affect the EE?

*Method.* Our data come from articles studying the EE using the valuation paradigm, published in refereed journals in psychology, marketing, and economics, among others. The data consists of 471 observations derived from 188 studies published in 104 separate articles. The dependent variable for our analysis is the natural logarithm of the WTA/WTP ratio. There are two main groups of independent variables: (i) factors hypothesized to trigger the EE, which we label "causal factors", and (ii) moderating factors, which include product-, consumer-, and method-related features.

We use a three-level mixed effects model, in which the first two levels capture variation due to effect sizes across studies and observations and the third level captures variation due to experiments that are cohorts in the same article. Estimates are obtained by maximum likelihood, which facilitates model testing (Hox et al. 2010). Because differences in the number of observations associated with each of the causal factors may influence the observed relative order of the causal factors on the WTA-WTP disparity, we implement a *bootstrapping approach* that maintains a fixed and equal number of observations across each of the causal factors while still using each factor's full range of data.

*Results.* Our model explains 71% of the variance in the WTA-WTP ratio (Nakagawa and Schielzeth 2013). When all moderators are controlled for and causal factors are set to their neutral points, we find that the WTA/WTP ratio is 1.89 ( $p < .01$ ).

According to the mixed effects model, all three factors hypothesized to cause the EE – psychological ownership ( $\beta_1 = 0.090$ ,  $p < .01$ ), biased information processing ( $\beta_2 = 0.126$ ,  $p < .01$ ), and strategic misrepresentation ( $\beta_3 = -0.065$ ,  $p < .01$ ) significantly influence the WTA/WTP asymmetry. To test the idea that biased information processing account might be the leading factor in influencing the intensity of the endowment effect (Morewedge and Gliblin 2015), its estimated beta is compared with those of psychological ownership

and strategic misrepresentation. We find that  $\beta_2$  is significantly larger than either  $\beta_1$  or  $\beta_3$  ( $p < .05$ ).

Subsequent analysis of the components of the psychological ownership account reveals that both the *implicit self-threat* ( $\beta = 0.083$ ,  $p < .01$ ) and *possession-self link* components ( $\beta = 0.051$ ,  $p < .01$ ) drive the disparity between WTA and WTP. Contrasting beta values, we find the *implicit self-threat* component to play a marginally more extensive role in driving the endowment effect than the *possession-self link* component ( $\beta_{\text{implicit self-threat}} - \beta_{\text{possession-self link}}$ ,  $p < .13$ ).

Analysis of manipulation types for the biased information processing account show that both *indirect-general* manipulations ( $\beta = 0.115$ ,  $p < .01$ ) and *direct-specific* manipulations ( $\beta = 0.050$ ,  $p < .01$ ) influence the WTA-WTP gap. In this case, *indirect-general* manipulations generate significantly larger gaps than do *direct-specific* manipulations ( $\beta_{\text{indirect-general}} - \beta_{\text{direct-specific}}$ ,  $p < .05$ ).

**Conclusions.** Consistent with existing research, our results validate the multi-determined nature of the EE; however, our results show biased information processing as the leading explanatory account of the effect. The results challenge the traditional conceptualization of the ownership account in terms of a possession-self link and bring to light how different manipulations of biased information processing – direct versus indirect – can systematically affect the WTA-WTP disparity.

### **SESSION OVERVIEW**

Market system dynamics are constituted via “discursive negotiations among and the practices of multiple stakeholders” including “a market-shaping consumer” as well as “managers, entrepreneurs, media journalists, policy makers, scientists, technologists, religious authorities and political activists” (Giesler and Fischer 2017, p. 3). These systems encompass a wide range of formal collaborative arrangements such as joint ventures, alliances, and consortiums. There is a rich tradition in marketing of studying interorganizational relationships, and the nature, antecedents and consequences of collaborative partnerships. Studies in this area predominantly focus on relational-, revenue-, and innovation-related outcomes of collaborative relationships (e.g. Fang et al. 2008, Rindfleisch and Moorman 2001, Swaminathan and Moorman 2009). A few studies on market systems have also highlighted the collaborative relations within brand and heterogeneous consumption communities as well as between consumers and institutional entrepreneurs, and examined how such efforts contribute to market change (e.g. Scaraboto 2015, Scaraboto and Fischer 2013, Schau et al. 2009, Thomas et al. 2013). Still, how collaborations between different types of actors shape the dynamics of markets is an under-researched area. This special session seeks to address this gap by showcasing four interrelated studies that examine how collaborations among market actors are instituted, maintained, and disrupted, and in turn, shape dynamics of markets.

The first paper examines how collaborations among market actors can lead to long lasting market-level transformations within the context of the high fashion market. Drawing from framing and social movement theories, the authors introduce the concept of category-based field frame that mobilize actors to enact market-level change and demonstrate how ensuing collaborations result in asymmetric benefits for established versus subordinate market actors. The second paper focuses on the emergence of collaborative arrangements between actors residing in different institutional fields and illustrates how collaborative processes can serve as catalysts for market formation in the context of the ancestral health market. The authors catalogue strategic, learning-related and political types of collaborations and detail the influence of different institutional fields on collaboration dynamics. The third paper examines factors that may undermine continuing collaboration among interdependent, yet, heterogeneous

market actors in the context of the Etsy platform, an online marketplace for unique and primarily handmade goods. The authors identify barriers to collaborative efforts as the actors on the platform become more and more heterogeneous. The fourth paper explores how value is continually cocreated through collaboration in the context of consumption journeys that involve repeated engagement with a practice over extended periods of time. Viewing reflexivity as an important part of this process, the authors identify the kinds of reflexive outcomes that may be leveraged to cultivate collaboration among market actors.

Taken together, these four papers speak to the spirit of this year’s conference theme on “trust in doubt” as the management and building of trust is critical for the success of collaborations between market actors. This session will provide researchers with a theoretically grounded understanding of the role collaborations play in market systems and extend previous research on firm-level and producer-focused collaborations.

## **How Categories Transform Markets through Non-Collective, Non-Strategic Collaboration**

### **EXTENDED ABSTRACT**

A perennial question in social movement theory is how can a group of subordinate market actors foster the power necessary to enact market-level change. Social movement theory has proposed that movement actors resolve this problem by engaging in the creation and maintenance of meanings through the creation of “schemata of interpretation” (Goffman 1974, 21), or frames. These frames organize the world with the intent to “mobilize potential adherents and constituents, to garner bystander support, and to demobilize antagonists” (Snow and Benford 1988, 198). Such “action-oriented sets of beliefs and meanings that inspire and legitimate the activities of movement actors” have been termed collective action frames (Benford and Snow 2000, 614).

These ad-hoc, movement-specific frames are only temporary solutions to help muster the power necessary for subordinate actors to enact market-level change. Once change has been realized, groups of organized actors might dissolve, such as the U.S. civil rights movement, or their orientation might change, such as in the case of car clubs organized around reliability tests during the emergence of the automobile (Rao 2008), and so will the collective action frame. How is a change of frame maintained in a market, then?

To answer this shortcoming and explain how frames acquire durability and stickiness within a market, Lounsbury, Ventresca, and Hirsch (2003) conceptualized that long-lasting market-level transformations can result from field frames, an intermediate concept endogenous to market actors (vs. logics which are often conceptualized as exogenous). We contribute to this perspective by proposing that categories—the cognitive and normative structures that group and separate entities (e.g. actors, products) around common codes and attributes, and enable evaluations and exchanges in markets (Durand and Khaire 2017; Durand and Paoletta 2013)—can be worked upon and used by market actors as field frames to garner the support of market actors and collaborate towards market-level change. How, then, do categories differ from collective action frames when used to enact market-level transformations?

We examine this process and develop our theoretical insights based on an analysis of the changes in the high fashion market that

ensued from the legitimization of and acquisition of dominance by the luxury streetwear category in the mid-to-late 2010s. Findings are mainly based on an extensive archival dataset (3690 pages), and informed by 16 interviews with market actors and a netnography of high fashion and streetwear web forums (between 12 and 72 months).

Our findings highlight four main tensions with existing work on framing and social movements that question some of the main assumptions of collective action frames: (1) collective vs. self-interested collaboration; (2) strategic vs. non-strategic action from market actors; (3) discursive vs. material bases for frames and (4) advantageous vs. disadvantageous benefits for mobilized actors. Despite these tensions, we show that the result of non-strategic and materially-based frames that emerged from the conjoint yet self-interested work of actors is still collaborative work that strive for market-level transformation. First, we show how the conjoint work of market actors result from their respective self-interests, rather than their collective desire to transform a market. For example, we highlight how collaborative work between subordinate market actors—streetwear brands—and high fashion actors—fashion houses—both leverage an emerging category and amplify the field frame. These collaborations happen despite the important boundaries between both markets. Second, and related to our first set of findings, we highlight how the work of actors does not aim at transforming the market, but rather benefiting their market positioning. A consequence of their non-strategic work, that is, their lack of “deliberative, utilitarian, and goal-directed,” is the use of the emerging category-related field frame. This results in the amplification and extension of the frame. For example, we show how luxury retailers collaborate with streetwear brands during co-presentation events. During these events, subordinate and established market actors occupy the same space, which both legitimizes the frame by materializing it in a territorial space (Humphreys 2010a) and facilitates commensuration and comparison between subordinate and established market actors (see Khaire 2014). This has a consequence to extend the frame by mobilizing other, smaller retailers who mimic the practices of more established ones. Third, we show that these collaborative processes are not unfolding through discursive processes, as previously displayed in extant research (e.g. Humphreys 2010a, 2010b; Humphreys and Latour 2013; Humphreys and Thompson 2014; see also Benford and Snow 2000), but rather work at the level of product designs, events, award shows, human resources strategies, and retail stores. Lastly, we show that, when completed, the market-level changes supported by the category-based field frame are disadvantageous to many mobilized, established market actors, who ultimately collaborated against themselves. For example, established fashion houses who contributed to the transformation of the field frame are displaced as other, originally subordinate market actors take their place. Despite these contradictions, this shift in field frames still is supported by the conjoint, collaborative work of subordinate and established market actors who together transform the market.

We thus highlight how the collaborative efforts necessary to achieve market-level change might not demand strategic action and collective intent. It can even result from actors mobilize to a frame, sometimes despite this frame ultimately hindering their symbolic positioning and associated economic benefits. These contradictions with extant research on social movements and framing thus provide theoretical extensions that allow for a better understanding of the processes underlying market-level transformations.

## Collaborative Work as Catalyst for Market Formation: The Case of the Ancestral Health Market

### EXTENDED ABSTRACT

Research on how markets emerge, develop, and change has received increasing attention in recent years (Giesler and Fischer 2017). Work in this area focused on processes of legitimation in market formation (e.g. Humphreys 2010b), highlighted active roles consumers play in market maintenance and change (e.g. Dolbec and Fischer 2015, Martin and Schouten 2014), theorized market evolution as series of contestations and compromises among market actors (e.g. Giesler 2008, 2012), and examined links between competitive dynamics and market evolution (e.g. Ertimur and Coskuner-Balli 2015). In fact competitive forces and dynamics have been a hallmark for understanding development and growth of new markets. From a strategic marketing point of view, marketers are often conceptualized within an antagonistic relationship, in competition to lure consumers to their own products and services. Yet, researchers have also acknowledged and studied contexts within which market actors may compete and collaborate at the same time (e.g., Brandenburger and Nalebuff 1996). This paper focuses on the latter from of relationships and investigates how collaborative work among market actors emerge and serve as a catalyst for market formation/evolution.

We integrate ideas from strategic management literature and organizational network research with an institutional theoretic perspective to examine collaborative processes that contribute to market development. We define collaboration as a cooperative, negotiated relationship among market actors as well as organizations (Hardy, Phillips and Lawrence 2003; Phillips, Lawrence, and Hardy 2000). This definition includes a range of collaborative arrangements such as alliances and associations while distinguishing collaboration from exchange relations that characterize market and hierarchical mechanism of control. That is, collaborative activity is neither governed by the price mechanism, as in the case of a buyer-supplier arrangements, nor by some legitimate authority, as in the case of relations between private firms and state agencies (Phillips, Lawrence, and Hardy 2000). Literature on interorganizational domains examines collaborative formations as response to societal problems that are beyond the means of a single organization to solve. Trist (1983) defines interorganizational domains as “functional social systems that occupy a position in social space between the society as a whole and the single-organization.” These socially constructed cognitive and organizational structures form as individuals view themselves as connected to problems that are shared by others and recognize that they can be addressed collectively. Thus, by pooling expertise and resources, collaborative arrangement can address problems in ways that competition or confrontation cannot (Hardy and Phillips 1998).

The context of our inquiry is the paleo lifestyle movement in the United States, which is an instructive site of collaboration between academic scientists, healthcare professionals, and marketing agents. The premise of this movement is that we can optimize our health by emulating lifestyles of our Paleolithic predecessors. Because “at our biological core we are still largely hunters and gatherers” and our modern lifestyles that commonly involve eating processed foods, sitting in front of a computer all day, exercising in a monotonous manner and sleeping much less than we actually need contradict with how we have evolved as humans (Durant 2013, p. 2). The origins of this movement coincided with the emergence of ‘new health consciousness’ prompted by dissemination of epidemiological studies on chronic diseases and reports on ills of smoking, increasing attention drawn to environmental degradation as well as emergent evidence of carcinogens contained in food products (Crawford 2006). In this

research, we examine how the collaborative work among market actors, evident in the launch of joint projects and the negotiation of a shared meaning system fueled the paleo lifestyle movement and led to the creation of the ancestral health market. This thriving market encompasses products and services ranging from restaurants to vacation retreats, books, and clothing to name a few (Williams 2014).

We employ archival and netnographic data to help us understand the origins of the paleo lifestyle movement and how it contributed to the institutionalization of the ancestral health market. We collected articles from the top ten circulating newspapers in the U.S. that contained the terms “paleo,” “cavemen,” “stone age” and “Paleolithic” using LexisNexis Academic database (n=100). Using the WorldCat network of library content, we gathered the number of paleo related books published in English (n=693). We pulled applications for trademarks related to paleo from the U.S. Patent and Trademark Office (n= 387). We did a close reading of books on the paleo diet and ancestral lifestyle (n=5) written by the so-called “fathers” of the paleo movement and contemporary paleo celebrities (Johnson 2015), and supplemented these with academic paleo lifestyle articles (n=12). A top ranked podcast called *The Paleo Solution Podcast* also constituted a main archival source. The host Robb Wolf discusses topics of health, fitness, and dieting, and features guests that operate in the ancestral health market. Of the 85% of episodes we examined (n=246) over the 2010-2015 time period, 35% of them contained a guest speaker (n=109). We collected additional information on these individuals and recorded their professional and educational backgrounds, credentials, new organizations/brands they launched, and domains of their writings/publications. We supplemented these archival data with a netnography of paleo and ancestral health related websites, forums, and blogs (n=100). Overall, these data allowed us to identify key market actors, how they came to be a part of this lifestyle movement, and the social networks that they belong to.

Through our qualitative analysis, we formed a historical trajectory of the actors and their multiplex relationships. We then catalogued their strategic, learning-related, and political collaborative efforts that served as catalysts for the emergence of the ancestral health market. The findings reveal that the dynamics of these collaborative arrangements are shaped by actors’ institutional affiliations, which at times involve conflicting institutional rules and standards (Phillips, Lawrence and Hardy 2000). Our analysis also illustrates how collaborations amongst market actors are characterized by distributed brokerage and highlight the importance of developing and maintaining a collective identity amongst collaborators. Overall, the findings help us understand how market actors’ collaborative efforts help each actor to attain objectives that would be difficult to accomplish on their own and also serve as catalysts for market formation.

### **Exiting Etsy? When Collaboration Among Market Co-Creators Come Undone**

#### **EXTENDED ABSTRACT**

I know how very difficult life at Etsy has been for so many. I know the struggles are real. What I’m asking is: based on what we have here today, will you still be here a year from now? (Post from Sunny to Etsy Vendor Forum Jul 12, 2017)

Consumer researchers have shed considerable light on the conditions that foster collaboration and continuity among collections of heterogeneous but interdependent market actors in aggregations such as communities (e.g. Thomas, Price and Schau 2013) and hybrid economies (Scaraboto 2015). This research suggests that tensions between heterogeneous actors may be inevitable, but offers multiple possible means for navigating these tensions. These

include, for example, frame alignment practices (Thomas, Price and Schau 2013), negotiations, and collaborating to produce and access resources in ways that allow actors to successfully reconcile their diverse socioeconomic interests (Scaraboto 2015).

While these perspectives on continuing collaborations are invaluable, we as yet lack an understanding of factors that may undermine continuing collaboration among interdependent, heterogeneous market actors – even in the face of tactics to sustain it. In this paper, we attempt to shed light on these factors by an inductive analysis of qualitative data from a platform market from which some actors have exited and many are considering exiting, as the opening quotation suggests.

The Etsy platform is an ideal context in which to investigate this phenomenon because it is one where the market actors – the platform organizer, the clients of the platform who sell goods through it, and the clients who purchase goods through it – are intrinsically interdependent, yet deeply divergent in their interests and values. Using longitudinal netnographic observation methods, we have collected and analyzed data from various online sources, the most important of which is Etsy’s own discussion boards for sellers (<https://www.etsy.com/forums>), from which we have downloaded several thousand discussions archived since Etsy’s inception. Additionally, we collected media articles mentioning Etsy in the title or first paragraph, spanning the period from 2005 to the present.

Etsy was founded in 2005 as part of the “indie” movement and offered unique goods handcrafted by individuals as an alternative to corporate, mass-produced consumption goods. Initially, Etsy’s mission was to reconnect sellers and buyers, and to make commerce more social and fulfilling for its participants. Accordingly, Etsy only allowed participants to sell products they had made themselves or vintage items. It achieved over \$1 million U.S. in sales in its first year of operation.

While Etsy continues to try to honour its original indie ethos, many changes to the market have occurred. New sellers with less of a craft orientation began to place offerings on the platform, buyers with diverse tastes entered the market, and Etsy itself transitioned from an independently owned startup to a publicly traded corporation under pressure to generate profits for its shareholders. For example, vendors who sell goods manufactured by others are now common on the platform. Likewise, the platform now allows sellers to provide goods to wholesalers, who will resell these goods to mainstream retailers. Etsy Studio, a branch of the marketplace, now allows vendors of raw materials to post their goods for sale so sellers who wish to make their own handmade goods can source them through Etsy. All these moves have increased the heterogeneity of actors on the platform. While Etsy ended 2017 with 1.9 million sellers and annual gross sales exceeding \$2.8 billion (<https://www.etsy.com/ca/about>), there is considerable churn among those participating in the platform, which suggests that efforts being made to foster collaboration have been less than completely successful.

Our analysis highlights several factors that have, over time, undermined continuing collaboration among the multiple categories of market actors in this context. One, for example, is *coalition formation*: some categories of actors, whether tacitly or explicitly, act together in coordinated fashion that advances their own short term interests while undermining the interests of others. One instance of coalition formation occurred when Etsy encouraged vendors to put all their offerings on sale, and some subset of Etsy vendors did so; this action served to boost short term turnover for those who participated in the promotional activity, and alienated the more craft oriented vendors who believe that putting their handmade goods on sales devalues them.

The full analysis in this paper offers insight on a broader range of such factors that undermine continuing collaboration among actors in a marketplace. It thereby extends the literatures on marketplace dynamics and collaborative consumption. In particular, it helps shed light on barriers to collaborative continuity.

## Cultivating Collaboration and Value Cocreation in Consumption Journeys

### EXTENDED ABSTRACT

Collaboration is an important means for value cocreation among firms, consumers and consumer collectives. However, cultivating collaboration over time requires a deep understanding of how consumers value perspectives evolve and change. To identify opportunities for collaboration, we explore how reflexivity contributes to the cocreation of value throughout consumption journeys. In particular, we seek to understand how consumers reflexive outcomes can be leveraged to drive collaboration and the continuation of value cocreation through ongoing interactions among multiple actors (e.g., firms, customers, and consumer collectives) – i.e., value cocreation (Vargo, Maglio and Akaka 2008).

The study of consumption-related experiences draws attention to the influence of collectives and collaboration in value creation (e.g., Muniz and O'Guinn 2001; Schau, Muniz and Arnould 2009; Schouten and McAlexander 1995). This research points to practices, “linked and implicit ways of understanding, saying and doing things,” as a critical component of value creation within consumption communities (Schau et al., 2009, p. 31). Applying a systemic approach to value creation (Vargo and Lusch 2011), Figueiredo and Scaraboto (2016, p. 527) provide insights into how value is created through “individual enactments of what may be onetime and haphazard actions.” The authors study the circulation of objects in collaborative consumer networks and find that systemic value creation can occur even without commitment to a particular community or ethos and through individual actions (as opposed to routinized practices).

Although prior research explains how practices (e.g., brand community practices) and processes (e.g., circulation) contribute to value creation, little is known about how value is continually cocreated through collaboration and consumption as individual perspectives change and evolve. Furthermore, the evaluation of an experience is situated within broader social and cultural contexts (Akaka, Vargo and Schau 2015) and the experiences themselves can be extended across time and space (Arnould and Price 2009). Thus, it is important to consider the dynamic context of value (Akaka, Vargo and Lusch 2013), as well as the evaluation of a particular experience (Holbrook 1999), to better understand how value is continually cocreated (or not) through consumption.

Consumption journeys are a useful context for studying continual value cocreation because they involve repeated engagement with a practice over time. We draw on cultural consumption approaches to conceptualize consumption journeys as identity projects that progress over extended periods of time. In other words, consumption journeys are continued engagement with a particular practice (c.f., Warde 2005) through which a person can learn, grow, change and further develop a sense of self (Arnould and Thompson 2005). In this way, consumption journeys provide an extended context through which people engage in particular practices and rely on a variety of market-facing resources to continually cocreate value for themselves and for others. We investigate consumption journeys as the context of continual value cocreation because we are particularly interested in understanding how reflexivity emerges as individuals integrate heterogeneous resources to shape their identities, and, in doing so,

reflect on their association within broader social structures (Thompson, Henry and Bardhi 2018).

Reflexivity is an important aspect of value cocreation because the way in which people assess personal experiences within the world is a major factor in how they act or behave (Solomon 1983). Recent consumer research delineates abstract ideal types of reflexivity – existential, critical and reactive – that assume varying views on the relationships among reflexivity, agency and institutions (Thompson et al., 2018). In our effort to understand value cocreation in consumption journeys, we apply an existential approach to studying reflexivity that “depicts consumers as self-aware agents who make volitional choices from a broad array of identity-constituting resources.” This approach aligns with the sociological views that describe reflexivity as a critical aspect of both practices and institutions (e.g., Archer 2010; Farrugia 2013) and accounts for the dynamics of social and cultural contexts that frame extended engagement with practices throughout consumption journeys.

Rather than investigating how reflexivity mediates structure and agency (Thompson et al., 2018), we seek to understand the personal outcomes of reflexivity within a particular consumer collective and how reflexive outcomes contribute to the continuation of value cocreation. We center our investigation on consumption journeys, rather than an individual experience, because we can trace consumption journeys as evolving value contexts and study the engagement with a practice and its associated market-facing resources over time. Based on this, we focus our research on the following questions: 1) How does reflexivity manifest in consumption journeys? 2) How does reflexivity contribute to the continuation of value cocreation throughout a consumption journey?

The findings from this study further the understanding of collaboration and value cocreation in two important ways. First, we discover that reflexive alignment and misalignment between individual perceptions of the self and the social and cultural context of value cocreation can lead to different reflexive outcomes. Second, we find that different combinations of reflexive (mis)alignment and practice continuity can lead to continuation of value cocreation through practice immersion and adaptation. On the other hand, reflexive (mis)alignment and practice discontinuity can lead to practice dissolution and innovation. Based on our findings, we deepen the understanding of the centrality of practices in consumption and innovation, particularly as they enable or limit continual value cocreation. We offer recommendations for managers striving to cultivate collaboration through continual value cocreation in consumption journeys and propose several strategies for enhancing and extending engagement with a particular practice.

### **SESSION OVERVIEW**

Time and money are two of life's most precious resources. Despite the ubiquity and importance of these resources, many essential questions about time and money are just coming under the lens of consumer research. This symposium will present cutting-edge research on the psychological consequences of time and money, with an emphasis on how these consequences influence prosocial behaviors and consumer well-being. These papers address the question of how understanding the psychology of these resources can be leveraged to improve outcomes in charitable giving and consumer well-being.

First, Costello and Malkoc introduce an unexamined difference between time and money: inseparability of the self from consumption. Across 6 studies, they demonstrate that this difference presents itself when time/money is given (e.g., helping/donating) and shows the implications of this asymmetry on perceived control and subsequently on donation behavior. This asymmetry has important implications—consumers can use donations of time as a way to restore control and their findings provide an understanding of why consumers might make non-traditional donations (e.g., goods).

Our second paper will present work that demonstrates how time can be used to leverage monetary donations. Powell and colleagues study the impact of introducing a time delay to donation pledges. They find that when consumers are asked to make a pledge to donate in the future, the donation amount is higher than immediate pledges. Interestingly, this time delay does not have an effect on the proportion of consumers who are willing to donate. Ironically, when asked to choose timing of donation, participants prefer the immediate option. The authors examine the roots of this paradox.

While our first two papers discuss how time can be harnessed to increase charitable giving, our next paper focuses on how the emotional experience of time spent volunteering is affected by quantifying the value of time in terms of money. Using data from the American Time Use Survey, DeVoe examines how hourly workers—who have a salient heuristic for the monetary value of their time—enjoy engaging in uncompensated volunteer activities when the opportunity costs of their time are especially high; whereas, non-hourly workers enjoy the activities regardless of the opportunity costs.

Rounding out the symposium, Donnelly and colleagues evaluate a common challenge consumers face—how to best communicate their time/money constraints when requested of these resources. Across 4 studies, they find that communicating a money constraint can increase trustworthiness and interpersonal connection because money is seen as outside of one's control. This is not the case for time constraints, where time scarcity is not associated with trustworthiness. Importantly, consumers who communicate time scarcity do not predict the asymmetry in how their message will be received.

Together, these papers identify important and previously unexamined asymmetries in giving time and money (Papers 1 & 4), uncover paradoxes in donation behaviors (Paper 2), and examine when consumers enjoy giving (Paper 3) and how to communicate scarcity in resources when they cannot donate (Paper 4). Combined, these papers present a cohesive view of how, why, and when people give their time/money.

## **My Money is Yours, but My Time is Still Mine: Inseparability of Consumption from the Self Increases Control and Giving**

### **EXTENDED ABSTRACT**

Although time and money are seen in some respects as comparable and interchangeable, there is evidence that these resources are psychologically distinct in a number of ways (e.g., Mogilner and Aaker 2009; Zauberman and Lynch 2005). In this research, we introduce a previously unexamined difference: inseparability of the self from consumption. We contend that this difference presents itself mainly when time or money is given (e.g., helping, donating).

When spending their own money or time, consumers are present and take an active role in how their money/time is being spent. Put differently, they exert similar levels of control over spending of both resources. Conversely, when giving time/money, an asymmetry occurs. When consumers give their money, they are separated from its consumption. The control over the resource (money) no longer lies with the consumer, but the receiver. When consumers give their time however, they are not (and cannot be) separated from its consumption. That is, although conceptually, the resource is given to someone else, the control of the resource (time) still—at least in part—belongs to the consumer.

In 6 studies, we first demonstrate the inseparability of the self from consumption for time and the consequent time/money asymmetry in perceived control. Next, we examine the implications of this asymmetry for decisions to give (i.e., charitable giving).

We first tested the presence of the inseparability asymmetry for time/money. In Study 1a, ( $N=250$ ) imagined planning a party. Half the participants imagined spending their own time/money to plan the party, while the other half considered giving a friend time/money to help plan. Participants answered three questions to measure perceived control over the resource (e.g., “I have the ability to shape how my time/money will be utilized”), combined into an index ( $\alpha = .91$ ). We found the expected interaction ( $p = .036$ ). When considering spending their own money/time, participants’ perceived control over the resource was not different ( $M_{\text{Time}} = 5.03$ ,  $M_{\text{Money}} = 5.15$ ). When giving the resource, an asymmetry emerged such that participants perceived significantly more control over time than money ( $M_{\text{Time}} = 4.96$ ,  $M_{\text{Money}} = 4.46$ ,  $p = .016$ ).

In Study 1b ( $N=222$ ), participants imagined eight situations where they either had control over the resource (e.g., decided how to spend time/money) or lacked control (e.g., a friend decides how to spend time/money). Averaging across scenarios ( $\alpha = .86$ ), we find that decision-makers felt high levels of control for both resources ( $M_{\text{Time}} = 5.00$ ,  $M_{\text{Money}} = 5.13$ ). When they had given up control, however, those considering time ( $M = 3.86$ ) felt significantly more control over the resource compared to money ( $M = 3.19$ ,  $p = .0005$ ). These results suggest that since consumption of time is tied to the self, a certain level of control remains, even if the time is given.

Next, we examined the consequences of this asymmetry for giving behavior. Respondents ( $N=212$ ) participated in two seemingly unrelated tasks. We first induced low or high control (vs. baseline), using an ease of retrieval task. Next, participants considered making a time or money donation to Feed the Children. They indicated their preference for donating time versus money on a 100-point slider scale and the number of dollars/hours they would donate. Consistent with compensatory control theories, we expected and found that participants feeling low control seek situations that restore control and thus will be more willing to donate time. Low control participants ( $M = 68.37$ ) significantly preferred giving time to money as compared to the other two conditions ( $M_{\text{Baseline}} = 58.27$ ;  $M_{\text{HighControl}} = 56.38$ ,  $p = .02$ ), which were not significantly different from one another. As expected, we observed the same significant pattern in donated hours but no differences across conditions in dollars.

In Study 3 ( $N=185$ ), we tried to boost money donations. If inseparability of time consumption from the self (and thus maintaining control) drives time/money asymmetry in donations, then infusing money conditions with control should alleviate the difference. Participants imagined that their college’s alumni association approached them about a time or money donation program. Half the participants were told that they can choose one of five charities for their donation, while the other half were told that their donation would be assigned based on need. Participants indicated interest in donating and perceived control over the resource. As expected, a significant interaction emerged ( $p = .048$ ). Participants were significantly more interested in donating time ( $M_{\text{Time}} = 3.93$  vs.  $M_{\text{Money}} = 3.18$ ) in the baseline condition. When given control over how the resource will be spent, however, this difference disappeared ( $M_{\text{Money}} = 4.54$  vs.  $M_{\text{Time}} = 4.23$ ). A moderated mediation analysis confirmed the role of perceived control.

In Studies 4a and 4b ( $N=181$ ; 205) we test the role of perceived control over the resource, by adding a third form of donation—goods/vouchers. While purchased with money, goods/vouchers are similar to time because they allow donors to better influence how their donation will be utilized. Thus, we expected the goods/vouchers to behave like time, despite being more interchangeable with money. Participants considered donating time, money, or food (4a; gift certificates to a grocery store, in 4b; to a hunger charity) and

answered the same questions as Study 3. Compared to participants who considered donations of money ( $M = 3.77$ ), those considering donations of time and food ( $M_{\text{Time}} = 4.37$ ,  $M_{\text{Food}} = 4.81$ ) were significantly more interested in donating, which were not different from each other. The same pattern emerged in Study 4b ( $M_{\text{Money}} = 3.91$ ,  $M_{\text{Time}} = 4.47$ ,  $M_{\text{Voucher}} = 4.57$ ). Once again, a mediation analysis confirmed the role of perceived control.

Taken together, we demonstrate a previously unstudied time/money asymmetry in perceived control, stemming from inseparability of the self from time consumption. We further show that this asymmetry has consequences for donation behavior. Consumers who lack control are more likely to donate time. Situations that allow consumers to influence how the resource is used (imitating the sense of control experienced when the resource and the self are inseparable) increase donations of money. This asymmetry has implications for non-traditional forms of donations like vouchers and material items.

### **Donate Today or Give Tomorrow? Adding a Time Delay Increases Donation Amount but not Willingness to Donate**

#### **EXTENDED ABSTRACT**

Charitable giving makes people feel good (Dunn, Aknin, and Norton 2008; Andreoni 1989), but comes, quite literally, at a cost. Accordingly, introducing a time delay between committing to a donation and the payment of the donation could increase willingness to donate. This temporal separation might allow donors to highlight the positive aspects of giving while minimizing the impact of future costs.

Indeed, Breman (2011) has shown that current donors are more likely to increase their monthly donation amount if asked to commit to an increase in the future rather than for the next month. Breman suggests that committing to donating more in the future frees people from the immediate temptation of not giving in the present. Andreoni and Serra-Garcia (2016), on the other hand, show that when given the option to donate a fixed amount (\$5), more people choose to donate in the future (in one week) than to donate today. The authors suggest that people feel obliged to donate and committing to giving later provides an opportunity to fulfill that obligation without necessarily having to follow through (i.e., these people plan on renegeing).

These studies demonstrate that adding a time delay can increase donation amounts when the decision to donate is held constant (Breman 2011) and can increase the proportion of donors when the amount donated is held constant (Andreoni and Serra-Garcia 2016). In the present work, we test how and why time delays impact *both* willingness to donate and the amount donated simultaneously. We demonstrate that time delays consistently impact the amount people are willing to donate but not their decision to donate, a finding that cannot be explained by the previously proposed mechanisms.

In Study 1 ( $N=601$ ), participants asked to make a hypothetical donation today donated substantially less ( $M = \$26.80$ ) than those pledging to donate in three ( $M = \$47.14$ ), six ( $M = \$52.23$ ), or twelve months ( $M = \$76.26$ ),  $F(3, 379) = 16.99$ ,  $p < 0.001$ . However, there were no differences in the proportion agreeing to donate today (62.7%), in three (69.8%), six (60.9%) or twelve months (62.3%),  $\chi^2(3) = 3.1$ ,  $p = 0.37$ ). Thus, time delays appear to impact the amount donated, but not the choice to donate.

Study 2 tested the time-delay effect with real monetary stakes. Participants ( $N=601$ ) were recruited to a two-stage study taking place three weeks apart. In both stages, participants were paid a 45-cent bonus. Participants were asked whether they would be willing to donate a portion of one of their bonuses to charity. Participants were

randomly assigned to donate today or to commit today but pay in the future. That is, they donated either from the bonus they received today for completing stage 1 or from the bonus they would receive in three weeks for completing stage 2. We again found that those donating in three weeks ( $M=9.91$  cents) donated more than those donating today ( $M=7.45$  cents),  $F(1, 596)=5.38$ ,  $p=0.021$ . In contrast, the proportion of donors today and in three weeks did not differ ( $p>0.1$ ).

The increase in donation amounts without an accompanying increase in the proportion of donors is consistent with the idea that separating the benefits from the cost of giving increases willingness to donate. The findings are, however, incompatible with Andreoni and Serra-Garcia's (2016) explanation that a time delay allows donors to minimize feelings of social pressure by committing to insincere pledges. According to the latter, time delays should increase the proportion of donors, rather than the amounts donated.

To test whether time-delay facilitates self-control (as proposed by Breman 2011), in Study 3 ( $N=1,342$ ) participants could choose whether, how much, and when to donate. Study 3 was similar to Study 2 except that participants could choose to donate from either their stage 1 or stage 2 bonus (or not at all). The vast majority of participants (76%) chose not to donate. More importantly, of those who did donate, 69% chose to donate today (only 31% chose to donate in the future). Further, those choosing to donate today ( $M=22.92$  cents) gave the same amount as those choosing to donate in the future ( $M=20.76$  cents),  $F(1, 310)=1.49$ ,  $p=0.223$ . These findings are contrary to Breman's (2011) self-control explanation, which predicts that the majority of participants would choose to donate later rather than now. Likewise, alternative accounts focusing on time discounting (Frederick et al. 2002) or resource slack (Zauberman and Lynch 2005) would have predicted more people donating in the future, inconsistent to the observed findings.

Next, we test the conjecture that time delay increases donation amounts by decreasing the cost associated with paying for the donation (i.e., the pain of payment; Prelec and Loewenstein 1998). People are typically more willing to spend windfall gains than earned money, as the former involves lesser pain of payment (Arkes et al. 1994). Hence, if the increase in donation amounts is driven by lower pain of payment, the effect of time delay should be attenuated when windfall gains rather than earned money is donated. To test this hypothesis, Study 4 ( $N=484$ ) employed a 2(delay: now vs. six months)  $\times$  2(source: windfall vs. earned money) between-subjects experiment. The interaction was not significant,  $F_{Interaction}(1, 479)=1.42$ ,  $p=0.233$ . Donations were higher in the future regardless of whether the donation came from a windfall gain ( $M_{Today}=\$113.32$  vs.  $M_{Six\ months}=\$157.68$ ) or from earned money ( $M_{Today}=\$141.82$  vs.  $M_{Six\ months}=\$223.0$ ),  $F_{Timing}(1, 479)=16.46$ ,  $p<0.001$ . This pattern of results suggests that time delays do not increase donations by reducing the pain of paying.

In sum, we find in four studies ( $N>3,000$ ) that a time delay increases donation amounts but not the proportion of donors. However, when given the choice of when to donate, the vast majority prefer to donate today rather than in the future. These results are counter to all previously offered explanations; they cannot be explained by self-control (Breman 2011), avoiding social pressure (Andreoni and Serra-Garcia 2016), time discounting (Frederick et al. 2002), resource slack (Zauberman and Lynch 2005), or reducing the pain of payment (Prelec and Loewenstein 1998). One possibility is that donations today signal greater generosity than future donations and donors make up for this deficit by increasing donation amounts in the future.

## When Does Being Paid an Hourly Wage Make it Difficult to Be a Happy Volunteer?

### EXTENDED ABSTRACT

One of the key questions emerging from the study of happiness is whether we spend our time on the right activities (Aaker, Rudd and Mogilner 2011). In this regard, spending time helping others appears to be a good bet as it is associated with greater self-efficacy and subjective well-being (Mogilner, Chance and Norton 2012; Musick and Wilson 2003). When such freely undertaken uses of time are directed through labor absent any financial remuneration, it enters into the domain of volunteer work (Tilly and Tilly 1994).

Although volunteer work has a persistent positive association with eudemonic and social well-being regardless of the amount of time spent, the positive effects on hedonic well-being (e.g., happiness) is more fleeting and limited to the experience of the activity itself (Son and Wilson 2012). While there are many powerful social motivations for undertaking volunteer work in addition to the subject well-being returns (Clary and Snyder 1999), this type of activity can be especially difficult to justify when viewed through a market-pricing lens for time as it violates the logic of proportionality that one's temporal efforts for work should receive comparable monetary rewards (Fiske 1992; Heyman and Arieli 2004).

Research shows that job practices that make the monetary value of time salient (i.e., billable hours and hourly payment) are associated with a diminished willingness to volunteer and decreased likelihood of actually volunteering (DeVoe and Pfeffer 2007; 2010). Interestingly these effects on the propensity to do volunteer work were observed at both high and low levels of income and hours worked, suggesting that an activity providing zero remuneration is equally difficult to justify irrespective of the monetary opportunity costs of time. While there is experimental evidence that prompting people to consider their hourly wage rate for time decreases the happiness experienced during an unexpected and uncompensated break (DeVoe and House 2012), there has been no externally valid test for the experience of chosen discretionary activities. Boyce et al. (2013) recently showed that income losses decrease subjective well-being approximately twice as much as similar gains increase it. Here we theorize that as potential forgone income (opportunity costs) for volunteering increase, there will be a corresponding decrease in the experience of happiness while volunteering only when people were naturally exposed to payment regimes that made the opportunity costs of time chronically salient.

In this research, we examine the happiness people report experiencing when they do choose to engage in volunteer work. Specifically, we test whether the subjective experience of happiness while volunteering is influenced by how people are paid and the opportunity costs of their time spent volunteering as measured by how much they would be earning in their paid job and the duration of the activity (Freeman 1997; Menchik and Weisbrod 1987). Since people tend not to consider opportunity costs unless externally prompted (Frederick et al. 2009; Greenberg and Spiller 2016), we did not expect the opportunity costs of time to influence how non-hourly workers experienced volunteering. Among hourly paid workers who have a salient heuristic for the monetary opportunity costs of their time (i.e., hourly wage rate), we predicted that the experience of happiness volunteering would be diminished as the opportunity costs of time for the activity increased.

We used time-diary data from the American Time Use Survey for the years when the Well-Being Module (<https://www.bls.gov/tus/wbdatafiles.htm>) was administered (2010, 2012, and 2013). Each respondent reported his/her activities for the day prior to the interview

and three activities of five minutes or more were randomly selected. To capture the experience of allocating time to volunteer work we examined “volunteering” and “travel-related to volunteering.” Among other experiential questions as well as with whom they were interacting, respondents rated how happy they felt during each activity using a scale from 0 (the feeling was not experienced at all) to 6 (the feeling was very strong). To analyze the 1 to 3 volunteer activities nested within each individual ( $M=1.2$ ), we employed multilevel analyses with robust standard errors (Raudenbush and Bryk 2002). We modeled the log of respondent’s income earned per week and the number of minutes spent volunteering ( $M_{minutes}=65.5$ ,  $SD=85.0$ ) as an indicator of the opportunity costs of each respondent’s time. A total 454 respondents employed in the labor force with complete responses on all variables who recorded at least one volunteer activity were included in our analyses. We dummy coded (“0”) for non-hourly wage earners ( $N=250$ , observations=297) and (“1”) for hourly wage earners ( $N=204$ , observations=254) enabling us meet the >250 observations for obtaining stable estimates within each category (Lindsay, 2015).

In order to explore whether the subjective experience of happiness while volunteering is influenced jointly by hourly payment and the opportunity cost of time as indicated the forgone earnings (income) and the time spent on volunteering (duration), we tested a three-way interaction. Specifically, we fitted a multilevel linear model with hourly status, logged income, and duration on happiness. We found a significant three-way interaction among hourly status, income, and duration,  $z=-2.40$ ,  $p=.016$ , 95% CI [-.01, -.001].

Simple slope tests reveal that high income hourly workers felt less happy the more minutes spent volunteering,  $z=-2.34$ ,  $p=.019$ , 95% CI [-.009, -.001]. There was no association between duration of volunteering and happiness for high income non-hourly counterpart for whom there is not a salient heuristic for the opportunity costs of their time. Additionally, there was no association between duration of volunteering and happiness for low income hourly counterpart whose opportunity cost was salient but low in terms of forgone income. Given we were only comparing respondents who are engaged in volunteering, it is perhaps not surprising that many of the job and demographic characteristics controlled for in prior research on hourly status (DeVoe and Pfeffer 2007; Whillans and Dunn 2015) did not emerge as significant predictors of experienced happiness when included in the model. Importantly, the significance of all interactions reported here were robust to a broad set of covariates. In sum, these findings suggest that when opportunity costs are salient and high, volunteers experience less happiness during their prosocial act.

### Communicating Limited Financial Resources Increases Perceived Trustworthiness and Interpersonal Connection

#### EXTENDED ABSTRACT

Consumers regularly engage in a variety of prosocial actions: often giving their money or time to help non-profit organizations, work colleagues, and friends. Giving time and money to others is associated with enhanced psychological well-being (e.g., Dunn et al. 2008), and increased interpersonal connection (Mogilner 2010). However, consumers have limited resources to give—and need to manage their time and money efficiently (Claessens et al. 2007). Therefore, consumers regularly have to withhold giving money and time to others in order to have these resources for other activities. By withholding resources, consumers may need to turn down requests for help and invitations for shared consumption which may negatively impact interpersonal connection and well-being (Baumeister and Leary 1995). In this work we evaluate how communication about

limited money (e.g., “I don’t have money”) vs communication about limited time (“I don’t have time”) influence perceptions of trustworthiness and interpersonal connection.

Money activates a self-sufficient mindset—one less interested in others (Vohs et al. 2006), and in turn, increases the tendency to deceive others (Aquino et al. 2009) and behave dishonestly (Gino and Mogilner 2013). Time, on the other hand, has been found to be more reflective of the self (Mogilner 2010), and is more associated with emotional meaning (e.g. Carstensen et al. 1999). We hypothesize that communication about limited time (in response to a request for help or shared consumption) will be perceived as more interpersonally threatening—resulting in lower perceived interpersonal connection. Further, money is received through an external source—typically through wages from work—and is often distributed unequally (Norton and Ariely 2011), whereas time is distributed equally and not from an external source, therefore, we hypothesize that communication about limited money may be perceived as more trustworthy because access to money is outside of one’s personal control.

In study 1, we scraped a dataset of direct message tweets from the first week of 2018, that contained the phrase “I don’t have money,” or “I don’t have time” resulting in 2,032 tweets. We scraped information about whether the tweet was ‘liked’ by the user who was tagged in the direct message (a signal for endorsement and fondness for the content; see John et al. 2017). We evaluate the tendency to ‘like’ a tweet as a function of message content. A chi-square test comparing scarcity content was significant: users were 105.26% less likely to ‘like’ a tweet that communicated time scarcity than a tweet that communicated money scarcity (24.7% of users liked a tweet in the time scarcity condition and 50.7% of users liked a tweet in the money scarcity condition;  $\chi^2 = 129.09$ ,  $p < .001$ ).

In our second study, lab participants ( $N=270$ ) were asked to reflect on a recent experience in which someone told them they couldn’t do something because they didn’t have money (or time). Participants wrote a few sentences about the circumstance and reported how close they felt to the person before and after hearing this content. Participants also rated the extent to which they felt the communication was trustworthy and honest, and within one’s control. A repeated-measures ANOVA using perceived closeness (before vs. after) as a within-subjects factor and communication content (money vs. time) as a between-subjects factor, revealed a significant main effect for perceived closeness ( $p < .001$ ), which was qualified by a significant interaction ( $p < .001$ ). Prior to the communication event, participants felt equally close to their communication partners, but after the excuse was communicated, participants felt significantly closer to those who communicated scarce money (compared to time). Increased closeness observed in the post-money excuse condition (vs post-time) was mediated by perceived controllability and trustworthiness.

In our third study ( $N=407$ ) we test the moderating role of controllability. We manipulated whether the lack of resource (money or time) was because of a needed (low controllability) versus wanted (high controllability) reason. Participants were asked to imagine that they invited a friend for a fun night out—grabbing drinks, a nice meal and attending a comedy club. Their friend responds, “*Sorry, I can’t go. I don’t have money [time]. I need [want] to spend money [time] buying [reading] books for school.*” Participants rated their perceived closeness, and perceived trustworthiness and controllability of the content. Participants felt closer to their friend when learning of their limited money ( $p=.003$ ), but there was no main effect for controllability ( $p = .74$ ). However, there was a significant interaction in that participants felt equally close when hearing a money or time excuse for a needed reason but felt significantly closer when hear-

ing a money excuse for a wanted reason ( $p=.001$ ). Trustworthiness significantly mediated the difference in perceived closeness for a wanted (CI: .06, .48), but not a needed reason (CI: -.18, .16).

In our final study ( $N=408$ ; 204 dyads), we sought to understand if perceptions of trustworthiness vary as a function of giving or receiving scarcity communication. Half of participants were asked to generate a response to the prompt, “I would give more to charity if...” and were randomly assigned to write about how they would give more if they had more money (or time). Participants rated this self-generated content in regards to how trustworthy they felt it was. The other half of participants were assigned to read the content of the message and rate how trustworthy they thought it was. A repeated-measures ANOVA found a significant main effect for role ( $p<.001$ ), and a main effect for content type ( $p=.002$ ), and a significant interaction ( $p=.02$ ). Authors found their content to be more trustworthy than readers, and overall money excuses were perceived to be more trustworthy. However, authors found money and time excuses to be equally trustworthy, while readers found money excuses to be significantly more trustworthy.

Overall, we find that communication about limited time (vs money) results in lower perceptions of trustworthiness and interpersonal closeness because consumers believe people have more control over how they manage their time than how they manage their money. While consumers believe their constraints are equally trustworthy, they are perceived differently, impacting interpersonal relationships.

### SESSION OVERVIEW

Mobility refers to all forms of territorial movement by people and has been a pervasive aspect of modern life (Bell and Taylor 2004). For example, many people live in one place and work in another. In addition, now more than before, people frequently change their residences in order to pursue a better quality of life (International Migration Outlook, 2018). In spite of its increasing prevalence, our understanding of how mobility changes consumers' psychology and behavior remains limited. Four papers in this session provide novel hypotheses and empirical evidence that demonstrate the impact of different types of mobility on important consumer outcomes. The papers examine different forms of mobility, from relatively infrequent but life-altering mobility (i.e., moving residences or cities) to relatively frequent but innocuous mobility (i.e., changing rooms) to imagined mobility (i.e., mentally simulating a change), thereby imparting a broad yet deep perspective on the effects of mobility. They also explore the impact of mobility on consumer outcomes by investigating what happens during the actual process of being in motion (e.g., being on the train) as well as the consequences that follow from movement. Based on the data from national panel data, field studies and lab experiments, this session highlights the newest research on how mobility shapes consumers' intrinsic motivation, donation behaviors, product preferences and self-control by using a diverse range of theoretical frameworks and measures.

The first two papers examine the consequences of residential moves. **The first paper** examines how residential mobility influences consumers' intrinsic motivation. They show that residential mobility increases individual's self-clarity, and this heightened self-clarity in turn enhances consumers' perceived autonomy and facilitates intrinsic motivation. **The second paper** studies the relationship between residential mobility and donations. A national panel data, field study and lab experiments demonstrate that residential mobility increases one's broadmindedness, which boosts one's helping donations to distant others.

The last two papers explore how mobility influences indulgence and the ability to overcome the desire to be indulgent. **The third**

**paper** investigates how consumers make decisions when they are in the process of being mobile. They reveal that consumers on the move (e.g., on a moving bus) are in an emotional mindset which leads them to prefer indulgent experiences and purchases. Finally, **the fourth paper** tests the role of moving from one environment to another in self-control restoration. They find that changing environments restores consumers' self-control after prior self-control exertion.

In summary, this session demonstrates novel findings showing how mobility can affect consumers. It offers novel, in-depth, empirical and theoretical advances featuring cognitive, emotional, behavioral, and identity outcomes. This session will appeal to a broad set of scholars interested in mobility, consumer motivation, donations, self-control and well-being.

## The Journey that Makes Us: The Impact of Residential Mobility on Self-clarity and Consumer Motivation

### EXTENDED ABSTRACT

Residential mobility can be conceptualized at both the micro/individual and macro/societal levels. At the individual level, it refers to the number of residential moves that an individual experiences during a defined period of time. At the macro level, residential mobility can be defined as the proportion of people within a given community moving their residence during a certain period of time (e.g., Lun, Oishi, and Tenney 2012). Residential mobility has become a pervasive aspect of modern life, due in part to a high number of international migrants, which reached 244 million in 2018 (IOM 2018). Also, more than 10% of the entire U.S. population has moved to a new residence every year since the 1970s (Schmitt 2001). Given its pervasiveness, residential mobility has attracted considerable attention across various disciplines such as sociology (Sampson 1991), education (Tucker, Marx, and Long 1998), and economics (Henley 1998). How residential mobility influences consumer behaviors, however, has seldom been investigated in the marketing literature. The current research addresses this imbalance by examining a novel consequence of residential mobility on consumers' intrinsic motivation. Intrinsic motivation refers to engaging in a behavior or performing an activity for personal, often private or "inner" interests and/or doing something because it is inherently interesting or enjoyable (Deci and Ryan 2000; Laran and Janiszewski 2011).

The current research proposes that residential mobility could serve as an important antecedent that enhances consumers' intrinsic motivation. We argue that this effect occurs because residential mobility can increase consumers' self-clarity and boost their perceived autonomy. Residential mobility involves encountering different environmental surroundings and being exposed to diverse social interactions, providing good opportunities for self-discovery (Markus and Wurf 1987; McGuire 1984). This self-discovery applies to most "learning by doing" activities, which help people develop a clear sense of self-concept and adaptation skills to the new environment (Kealey 1978). In fact, having a clear sense of the self is considered by some to be the foundation for autonomy by perceived control over components of the self-concept (Deci et al. 2015). On the other hand, consumers' perceived autonomy is the basic element for initiating self-determined activities and consequently increases their intrinsic motivation (Deci and Ryan 2000; Kim, Chen, and Zhang 2016). In short, we propose that residential mobility can increase an

individual's self-clarity. This heightened self-clarity then boosts consumers' perceived autonomy and consequently increases their intrinsic motivation. We further predict that the positive effect of residential mobility on intrinsic motivation is mitigated when consumers' self-clarity is boosted experimentally.

Experiment 1 ( $N = 400$ ) using a natural field experiment demonstrates that, rather than enhancing a general tendency to take action, residential mobility enhances only consumers' intrinsic motivation but not their extrinsic motivation. We employed a 2 (mobility vs. stability)  $\times$  2 (intrinsic motivation vs. extrinsic motivation) between-subjects factorial design. We operationalized residential mobility on the macro level by selecting two public universities to represent the high-mobility (91.2% non-local students) vs. low-mobility (20% non-local students) communities. Participants were approached by an experimenter showing a poster about recruiting volunteers for a research task. We framed the task in either an intrinsically motivated or extrinsically motivated way. Then participants indicated whether or not they would sign up as a volunteer. As expected, results revealed that residential mobility was associated with greater intrinsic motivation, but not extrinsic motivation.

Experiment 2 ( $N = 246$ ) establishes the causal link between residential mobility and intrinsic motivation. Participants were asked to visualize the scenarios in which they either move to the different cities (mobility condition) or stay in the same city (stability condition; Oishi et al. 2012), or they described a typical day (control condition; Su et al. 2017). Next, in an ostensibly unrelated task, participants were told that a research center is recruiting some volunteers and there are two types of tasks available. Intrinsically motivated tasks are described as interesting and fun, whereas extrinsically motivated tasks are instrumental and useful (Deci and Ryan 2000). Participants indicated which type of research task they would like to join. Results revealed that the effects were driven by residential mobility increased intrinsic motivation rather than residential stability decreased intrinsic motivation.

Experiment 3 ( $N = 182$ ) provides direct process evidence by showing the sequential mediating roles of self-clarity and perceived autonomy. After participants finished the same visualization task (mobility vs. stability) as in experiment 2, we measured their perceived self-clarity and autonomy as two sequential mediators. Next, participants indicated which type of research (intrinsic or extrinsic) they want to join and left their email address to receive further information. Results showed that the proposed effect of residential mobility on intrinsic motivation is driven by the higher degree of self-clarity and perceived autonomy that are derived from residential change.

Experiment 4 ( $N = 225$ ) provides further process evidence by demonstrating the moderating role of self-clarity boost through a 2 (mobility vs. stability)  $\times$  2 (self-clarity boost: yes vs. no) between-subjects factorial design. We first manipulated the residential mobility via the same visualization task as in the previous experiments. Next, half of the participants went through a "ME/not ME" task in order to boost their self-clarity (Bargh, McKenna, and Fitzsimons 2002). By contrast, participants in the condition of no self-clarity boost did not go through this task. Finally, all participants were presented with two posters that promote blood donation (intrinsically motivated appeal vs. extrinsically motivated appeal) and indicated which poster they found more appealing. As expected, participants in the mobility (vs. stability) condition preferred the intrinsically motivated appeal. However, the difference disappeared in the presence of experimentally boosted self-clarity.

In conclusion, the current research contributes to the existing literature on residential mobility by documenting a novel marketing consequence on consumers' intrinsic motivation. By investigating

the mechanism underlying this effect, this research also extends our understanding of self-clarity and perceived autonomy in the marketing context. Further, our research offers rich practical implications for marketers in terms of how to better utilize intrinsic incentives in their marketing practice.

## How Residential Mobility Influences Donations

### EXTENDED ABSTRACT

With globalization, geographical relocation has become an essential part of life in many parts of the world. How does the experience and mindset of residential mobility impact donations? Previous literature in sociology and psychology has hinted that residential mobility might be negatively associated with prosocial behaviors such as high crime rates and low pro-community actions. We present evidence that high (vs. low) residential mobility can positively impact donations. We propose that residential mobility (vs. stability) leads consumers to have a broader, non-local social identity, which results in donations to distant beneficiaries. While it is natural to want to help those who are close and similar to us, not everyone is motivated to help distant others. Moving experience opens consumers up to new ideas, places, and cultures, so their sense of self likely includes communities other than the local one. This makes them more accepting of distant communities. We argue that such broadened social identity from residential mobility increases donations toward distant others.

In Study 1, we used national panel data (China Family Panel Studies 2010,  $N=29,553$ ) to investigate the effect of residential mobility on donation values toward close vs. distant beneficiaries in an ecologically valid context. The panel data recorded the amounts of respondents' donations given to victims of the severe earthquake in Sichuan Province in 2008 (Wenchuan Earthquake). We used an item asking the current residence of respondents as a measure of distance between the respondents and the donation beneficiaries. Respondents who currently lived in Sichuan Province were coded as *close* since the earthquake occurred in their home town province, and respondents who currently lived in other provinces were coded as *distant*. After controlling for age, gender, annual family income, and the total value of donations to any institutions in the same fiscal year, the results showed that people who had moved (vs. never moved) donated significantly more to the earthquake when they were distant (); however, when the beneficiary was close, residential mobility did not affect the donation amount.

Study 2 aimed to establish the causal relationship between residential mobility and donation intentions a controlled lab setting. Participants from a large university in North American participated this study with a 2 (residential mobility: mobile vs. stable)  $\times$  2 (donation beneficiary: close vs. distant) between-subjects design. Residential mobility was manipulated using a mobility mindset stimulating task (adapted from Lun, Oishi and Tenney 2012), where participants imagined being offered a new job that either required moving to a different location every year (*mobile*) or living in one area for ten years (*stable*). Next, participants were introduced to a campaign helping hungry children either in their home state (*close*) or in another state with similar size and population (*distant*). Then participants were asked to indicate how likely they would be to donate to the campaign. The results replicated Study 1 and confirmed our prediction that for hungry children in a distant state, participants were more likely to donate when they were in the mobile mindset condition compared to the stable condition ( $M=4.74$  vs.  $3.68$ ,  $F(1,139)=6.03$ ,  $p=.015$ ). However, mobility did not impact donation likelihood when the beneficiary was close.

The purpose of Study 3 was to investigate the underlying process that drives the effect of residential mobility on donations toward distant others. We argue that the moving experience opens consumers up to new ideas, places, and cultures, so their sense of self likely includes communities other than the local one. It follows that while people are open to aiding close others' needs regardless of residential mobility, having a broader social identity from residential changes impacts how people respond to distant others' needs. We test this prediction in Study 3. The study employed a 2 (residential mobility: mobile vs. stable) X 2 (donation beneficiary: close vs. distant) between-subjects design. The same task was used to manipulate residential mobility. After the imaged task, participants were asked to indicate their donation tendency to either a UN water local (close others) vs. Africa (distant others) chapter. Next, participants answered a series of measures, among which two items measured broadened social identity ( $r = .74$ ). Consistent with prior studies, the results showed that mobile participants had indicated they would donate more to distant others compared to stable participants ( $M = \$16.93$  vs.  $\$10.77$ ,  $F(1,505) = 7.29$ ,  $p = .007$ ). There was no difference when the beneficiary was close others. A moderated mediation analysis confirmed that broadened social identity significantly mediated the effect of mobility on helping distant others ( $b = 1.55$ ,  $SE = .79$ ,  $CI: [.06, 3.18]$ ), but not close others.

Finally, we conducted a field study to test if residential mobility affected real donation behaviors. Specifically, we coordinated with a national charity foundation, inviting 10,000 students in Shanghai to "Donate Voice," in which donors commit to spending time recording audio books for blind children. In the *close* beneficiary condition, the message was presented as a campaign for blind children in Shanghai. The distant beneficiary condition was presented as a campaign for blind children in Xizang, which is different from Shanghai in geographical location, economy, and culture. Students who signed up for donations were directed to a subsequent survey in which they were asked to report their residential history and how much time they were willing to donate. Results revealed that for students who signed up to donate, those with higher (vs. lower) residential mobility were willing to donate more time to blind children in Xizang (). Again, there was no impact of residential mobility on blind children in Shanghai.

In conclusion, this research makes a novel contribution by demonstrating how residential mobility affects donations, especially towards distant others using national panel data, experiments, and field study.

## Motion, Emotion, and Indulgence: How Movement Influences Consumption

### EXTENDED ABSTRACT

The advent of internet-enabled mobile devices has changed how consumers browse information and make purchases. This technology allows consumers to not only make purchases when they are at home or at work but also when they are traveling. Yet, the major focus of current literature is on understanding how consumers make purchase decisions when they are stationary. We investigate how consumers make decisions when they are in motion.

We posit that when consumers are on the move, they are more likely to be in an emotional mindset. Consequently, they are more likely to prefer indulgent options over utilitarian options. Although we are not aware of research on actual motion, prior research on embodied and grounded cognitions provides useful insights (see Krishna 2012 for a review). This research stream suggests that bodily sensations affect individuals' cognitions. For instance, blinking of eyes

can lower an individual's ability to focus on focal tasks and leads to a "wandering" mind (Smilek et al. 2010). A wandering mindset lowers concentration (Smallwood et al. 2004), and it is well known that an inability to exercise cognitions induces a more emotional mindset (Hock and Bagchi 2018; Shiv and Fedorikhin 1999). We propose that movement of the entire body can also lower ability to process cognitively, and will evoke an emotional mindset, which in turn will increase consumption of indulgent (vs. non-indulgent) experiences and products.

We demonstrate proposed effects in four studies. In Study 1, we provide real world support for our notion that consumers process information more emotionally when they are in motion. We obtained 26,849 tweets posted by individual users from various locations of six cities in the US. A location-based social network application allowed us to identify whether the tweets were posted in locations indicating tweeters were on the move (e.g., on a boat or in a taxi) or stationary (e.g., at home or in a hotel). We used a software (SentiStrength; Thelwall et al. 2010) to code the emotional nature of these tweets and retrieved scores based on their valence and emotional strength. An ANOVA on expression of emotionality supported our proposition that tweets posted when users were on the move contained stronger emotional expressions ( $p < .001$ ).

In the subsequent studies, we investigate the downstream consequences of motion. In Study 2, participants ( $N = 89$ ) were randomly assigned to a moving or a stationary condition, and imagined being on a train or in a café choosing a short video to watch. We provided two choices: an indulgent (from America's funniest home videos) or an informative clip (on financial management). Participants also indicated how they made this decision on two items (1 = used my rational side/used my head; 7 = used my emotional side/used my heart;  $r = .93$ ). As predicted, a logistic regression confirmed that participants on the move were more likely to choose the indulgent video clip ( $b = .97$ ,  $p = .03$ ), and indicated that this decision was driven by their emotional mindset ( $M_{\text{Moving}} = 4.39$  vs.  $M_{\text{Stationary}} = 3.37$ ;  $p = .026$ ). A mediation analysis (Hayes 2013) confirmed that consumers' reliance on emotional mindset mediated the effects of movement on choice (95% CI = .0683, 2.7652).

In Study 3, participants ( $N = 130$ ) were recruited from an online panel based on their current location: currently traveling; located at a public stationary place; or located at a private stationary place. We informed participants that they would be taking part in two ostensibly different studies. In the first study, we asked about their current state of motion. In the second study, participants learned they were shopping for grocery items online (which they could pick up from their local store). We presented 12 items: six were indulgent items (e.g., chocolates, coke) and six were utilitarian items (e.g., oats, water). As in Study 1, participants also indicated how they made their decisions. Because we did not predict or find the two stationary conditions—public and private—to be different from each other, we combined them and treated them as our stationary condition. This also rules out the alternative explanation that our effects emerge because of the public nature of the movement condition. As expected, an ANOVA revealed that those on the move were likely to select more of the indulgent products ( $M_{\text{Moving}} = 1.74$  vs.  $M_{\text{Stationary}} = 1.37$ ;  $p = .046$ ) and this occurred because of their emotional mindset ( $M_{\text{Moving}} = 4.24$  vs.  $M_{\text{Stationary}} = 3.40$ ;  $p = .023$ ). Furthermore, emotional mindset mediated this effect (95% CI = .0336, .5262).

In Study 4, we replicated these effects in the field. Participants ( $N = 70$ ) were recruited from either a public place close to a bus station or when they were traveling on a bus. Participants were provided with an opportunity to participate in a survey, and in return were offered a choice between an indulgent chocolate bar and a healthy

granola bar. In the survey, we asked them to indicate how much they preferred each of the bars ( $-3 =$  Preferred granola bar;  $3 =$  Preferred chocolate bar). Participants then indicated their decision process. Consistent with our predictions, participants preferred the chocolate bar more ( $M_{\text{Moving}} = 1.25$  vs.  $M_{\text{Stationary}} = -.273$ ;  $p = .003$ ) as well as chose it marginally more ( $p = .096$ ) when they were in motion. Further, those traveling made their decisions using an emotional mindset ( $M_{\text{Moving}} = 4.29$  vs.  $M_{\text{Stationary}} = 3.63$ ;  $p = .061$ ), and emotional mindset mediated our results (95% CI = .0105, 1.0206).

Taken together, these studies demonstrate that motion affects how consumers process information and make purchase decisions. We also extend research on bodily sensations to actual movement. Furthermore, this research has important managerial implications: identifying consumers' current state of motion can help managers ascertain which products would be desired and valued more. Therefore, managers may want to provide more indulgent options when consumers are on the move (e.g., on flights, buses; as well as at bus stops, airports). Additionally, emotionally-laden appeals or advertisements are likely to be more successful when consumers are in motion.

### Real or Imagined Changes in Environment Restore Self-Control

#### EXTENDED ABSTRACT

Exerting self-control is an important goal for consumers, but when they are tired and depleted, how can they sustain effective self-control? We propose that mobility—in this case, changing environments—improves self-control performance after prior self-control exertion. This prediction is based on the notion that the brain is highly attuned to its environment. When people change environments, they must understand what is going on, so cognitive resources are redirected from the old to the new setting (Zwaan 1996). In this way, a change in environment may boost executive functioning and self-control performance, even after initial self-control exertion (i.e., offset the ego-depletion effect).

Three experiments tested the mobility hypothesis by randomly assigning participants to complete a task that does or does not require self-control (Task 1) and then assessing participants' subsequent self-control performance (Task 2) in either the same or different laboratory room. We predicted that initial self-control exertion would hinder subsequent self-control performance among those who stayed in the same room, but that changing rooms would restore self-control. Rest replenishes self-control (Tyler and Burns 2008), so the amount of time that elapsed between the two tasks was held constant across all conditions in all reported experiments.

In experiment 1, participants assigned to the depletion condition were forbidden to think of a white bear during a thought-listing task, whereas participants in the no-depletion condition were allowed to think about anything they liked, including a white bear (Wegner et al. 1987). Participants were then given the opportunity to consume a tasty but unhealthy snack (potato chips) under the guise of a taste test. The amount of chips consumed (in grams) during the 10-minute task was the key dependent measure of self-control. Predicting grams of chips consumed, an ANOVA revealed the predicted interaction ( $F(1,153)=4.519$ ,  $p=.035$ ). Replicating previous work, participants in the depletion condition consumed more potato chips ( $M=42.95\text{g}$ ) than participants in the no-depletion condition ( $M=31.78\text{g}$ ;  $F(1,153)=5.133$ ,  $p=.025$ ), but only when participants completed both tasks in the same room. Depleted participants who changed rooms consumed fewer chips ( $M=30.43\text{g}$ ) than their de-

pleted counterparts who stayed in the same room ( $F(1,153)=6.274$ ,  $p=.013$ ).

It is possible that changing contexts improved self-control because of mere distraction or physical movement. To rule out those alternative explanations, experiment 2 added a new comparison condition in which participants completed both tasks in the same room but in between the two tasks they were led halfway to the second room and were then brought back to the original room. Thus, the experiment was a 2 (depletion; no depletion) X 3 (no change; change; movement) between-subjects design.

Participants assigned to the depletion condition wrote an essay that required them to alter their natural way of writing (omitting words containing the letters 'A' and 'N') whereas those assigned to the no-depletion condition were not required to alter their natural way of writing (omitting words containing the letters 'X' and 'Z'; Schmeichel 2007). Then participants completed the Stroop task, a measure of executive functioning and self-control (Stroop 1935). The dependent measure was the difference in time it took participants to complete 30 incongruent trials versus 30 congruent trials (in seconds).

Consistent with the findings reported in experiment 1, mobility (i.e., changing rooms) offset ego depletion. The interaction between change (vs. no change) and depletion condition was significant ( $F(1,283)=4.378$ ,  $p=.037$ ). Mere movement was not sufficient to offset ego depletion as evidenced by the non-significant interaction between movement (vs. no change) and depletion condition ( $F(1,283)=.223$ ,  $p=.637$ ). Dissecting the change (vs. no change) and depletion-condition interaction revealed that depletion-condition participants performed worse ( $M=7.35$ ) on the Stroop task than no-depletion controls ( $M=5.09$ ;  $p=.002$ ). More important, depletion-condition participants who changed rooms performed better on the Stroop task than their counterparts who stayed in the same room for both tasks ( $M=5.07$ ;  $p=.018$ ), and they performed similarly to non-depletion controls who changed rooms ( $M=5.59$ ;  $p=.609$ ).

Mentally simulating an action activates the same psychological processes that are involved in performing the action (Decety and Grezes 2006). If self-control restoration is due to the psychological processes that stem from the environment change, then mentally simulating the room change should also restore self-control. Participants completed the more (vs. less) depleting version of the essay task (experiment 2) and then stayed in the same room, changed rooms, or imagined changing rooms to complete the Stroop task.

Consistent with predictions, changing rooms enhanced self-control among participants who had exercised self-control in the preceding task relative to those who had not exercised self-control in the preceding task. This conclusion was supported by a significant omnibus interaction ( $F(2, 300)=3.314$ ,  $p=.045$ ) and the pattern of simple effects. Conceptually replicating experiments 1-2, depletion-condition participants performed worse on the Stroop task ( $M=7.59$ ) than no-depletion controls ( $M=5.28$ ) when both tasks were completed in the same room ( $p=.004$ ). More important, the change manipulation improved self-control, such that depleted participants performed better on the Stroop task whether they actually changed rooms ( $M=5.03$ ;  $p=.003$ ) or merely visualized changing rooms ( $M=5.88$ ;  $p=.034$ ) compared to depleted participants who stayed in the same room for both tasks. As expected, there was no difference between depleted participants who actually changed rooms and depleted participants who merely imagined changing rooms ( $p=.243$ ). Furthermore, among participants who physically or mentally changed rooms, depletion condition participants performed equivalently on the Stroop task compared to no-depletion controls ( $ps>.298$ ).

In summary, three experiments support the theory that a change in context restores self-control. Alternative explanations such as mere physical movement or disruption were not supported. The studies provide novel insight into how mobility influences a key consumer outcome – the capacity to exert self-control.

## **Paper #3: Emotion, Scientific Reasoning, and Judgments of Scientific Evidence**

Caitlin Drummond, University of Michigan, USA

Baruch Fischhoff, Carnegie Mellon University, USA

## **Paper #4: Green Biases: Consumer Evaluations of Renewable and Non-Renewable Energy Sources**

Nathan Dhaliwal, University of British Columbia, Canada

David J. Hardisty, University of British Columbia, Canada

Jiaying Zhao, University of British Columbia, Canada

### **SESSION OVERVIEW**

Scientists work to develop knowledge or technologies that can improve the world. In order to have an impact, scientific advancements must be adopted—or at least tacitly supported—by the people they are designed to help. However, some people oppose scientific advancements that could objectively improve their lives, despite a clear scientific consensus to the contrary.

The proposed session explores two broad research questions:

1. What are the psychological underpinnings of acceptance of—or opposition to—scientific information and technologies?
2. What interventions can be designed to successfully bring consumers closer to the scientific consensus?

There is a growing body of literature examining public attitudes toward science. For instance, opposition to scientific information and technologies has been attributed to lack of scientific literacy (Ranney and Clark 2016), perceptions of unnaturalness (Scott, Inbar, and Rozin 2016), fears about health risks (Laros and Steenkamp 2004), and values espoused by individuals' social groups (Kahan, Jenkins-Smith, and Braman 2011).

Our session contains four papers that build on this work to shed new light on the consumption of science in the domains of genetically modified food, renewable energy, and the perceived causes of cancer. Each paper offers evidence to identify anti-science biases, judgments, beliefs, emotions, and behaviors.

In the first paper, the authors set out to taxonomize the psychological underpinnings of opposition to genetically modified foods. Using open-ended participant responses, they find five dominant lay reasons. They experimentally test mechanisms related to these underlying psychologies, and end by suggesting differential interventions tailored to each.

In the second paper, the authors take a different approach to the same problem. They examine which types of arguments cause opponents of genetically modified foods to change their minds. Moral arguments shift opponents' attitudes more than arguments about safety,

naturalness, or acceptability in Christian doctrine. These findings suggest that attitudes are based on the moralization of GM foods.

In the third paper, the authors examine how consumers' ability to reason about—and emotional reactions to—scientific evidence relate to their judgments. They find that reasoning ability and emotional reactions to controversial research separately predicts understanding, judgments of quality, and trust in the scientists who conducted it.

In the final paper, the authors explore whether people judge electricity differently due to its generating source. They demonstrate a bias among participants' evaluations of renewable versus non-renewable electricity in hypothetical scenarios, when observing light in a dark or lit room, and when physically experiencing electric shocks.

With this session, we hope to bring the topic of public acceptance of science into the field of consumer research, and we believe the field is uniquely positioned to take it on. With science, consumption has heightened societal *and* commercial importance. We believe the session fits well with this year's conference theme, "Consuming in a Post Trust World," because of clear implications for trust in science and scientists. The proposed session will appeal to researchers interested in judgement and decision making, policy, consumer well-being, emotions, morality, and metacognition.

## **A Taxonomy of Opposition to Genetically Modified Foods**

### **EXTENDED ABSTRACT**

Public discourse today is unsettling, either insular or excessively hostile. Some people maintain vociferous, unshakeable attitudes about complex issues that they do not understand deeply (Caplan, 2011). Nowhere is this more apparent than in disputes around divisive scientific topics. In this work, we build on evidence that many people have strong, enduring attitudes about genetically modified foods despite a remarkably shallow understanding of the mechanisms at play (National Science Board, 2016; Ranney, 2016). There is widespread agreement among scientists that genetically modified (GM) foods are safe to consume (AAAS 2012; European Commission 2010) and have the potential to provide substantial benefits to humankind (Sharma, Kaur, and Singh 2017).

The conventional account of this failure to communicate, the "deficit model," appeals to lack of information (Bodmer, 1986): The idea is that people are too ignorant to appreciate counter-arguments, ignorance leads to reliance on loud voices, which in turn leads to polarization and failure to understand. The standard method to try to overcome these deficits is to use education to change attitudes. Recently, however, the deficit model has been challenged on the grounds that educational efforts rarely work (Miller, 2001).

One critical element that governs discourse but is not a focus of the deficit model is that people are not merely ignorant, but they often fail to realize their ignorance. Asking people to try to explain how a policy works causes them to not only reduce their estimate of their own understanding (Rozenblit and Keil, 2002), but also to moderate the extremity of their attitude. In other words, causal explanation causes people to become aware that they don't fully understand, reducing both hubris and extremism (Fernbach et al., 2013; Sloman & Fernbach, 2017).

This ignorance and lack of awareness suggests that opposition to genetically modified foods may be caused or exacerbated by gaps

between subjective and objective knowledge. It also suggests that people may have specific false beliefs or unfounded concerns that can be targeted with specific interventions (as opposed to broad education efforts).

In our first study, we surveyed a nationally-representative sample of U.S. adults ( $N = 501$ ) to test if subjective-objective knowledge gaps contribute to GM food opposition. Participants were first asked two questions to measure attitudes: extremity of opposition to genetically modified foods (1 = no opposition, 7 = extreme opposition), and concern (1 = no concern, 7 = extreme concern). Responses to these two questions were highly correlated ( $r=.88$ ), and we averaged them to form a measure we call “extremity of opposition”. Next, participants were asked to judge their understanding of GM foods (“subjective knowledge”), using instructions and a single-item rating scale adapted from the cognitive science literature (Rozenblit and Keil 2002). Finally, we measured scientific literacy (objective knowledge) with fifteen true-false questions adapted from the National Science Foundation’s Science and Engineering Indicators survey (NSF 2016), AAAS Benchmarks for Science Literacy (AAAS 1993), and recent work on public understanding of science (Durant, Evans, and Thomas 1989; Mielby, Sandøe, and Lassen 2013; Miller, Scott, and Okamoto 2006).

The results show that as extremity of opposition increases, science literacy decreases ( $\beta_{\text{extremity}} = -1.4$ ,  $t(499) = -4.72$ ,  $p < .0001$ ), while judged understanding of GM foods increases ( $\beta_{\text{extremity}} = .26$ ,  $t(499) = 6.81$ ,  $p < .0001$ ). After z-scoring objective and subjective knowledge, we calculated a difference score by subtracting each participant’s objective knowledge score from their subjective knowledge score. This difference score increases as extremity of opposition increases ( $\beta_{\text{extremity}} = .28$ ,  $t(499) = 8.77$ ,  $p < .0001$ ). We then tested whether objective knowledge predicts subjective knowledge differentially at different levels of extremity of opposition. We regressed subjective knowledge on science literacy, extremity of opposition and their interaction. The interaction is statistically significant, indicating that the slope of science literacy on subjective knowledge differs significantly by extremity of opposition ( $\beta_{\text{interaction}} = -.014$ ,  $t(497) = -4.56$ ,  $p < .0001$ ). Objective knowledge is a significant positive predictor of subjective knowledge up to an extremity of opposition value of 4.77, and turns significantly negative at an extremity of opposition value of 7. For extremists, knowing less is associated with thinking one knows more, and vice-versa.

Our second study was exploratory. The goal was to taxonomize the main reasons people have for being concerned about or opposed to genetically modified foods, independent of the extant literature. To that end, we used the “concern” question from study 1 to capture the responses of only respondents who indicated at least some concern about GM food in a new sample collection on Amazon MTurk, resulting in 506 complete responses. Those participants were presented with the following prompt: “You just indicated some concern about genetically modified foods. In the text box below, describe your concerns in detail and why you have them. Please be as specific as you can.” We then grouped participants’ open-ended responses into five theory-agnostic reasons, which we gave to two hypothesis-blind research assistants, who then coded all responses based on the five reasons. The research assistants’ coding was consistent across 71% of cases, and the remaining 29% of cases were resolved by a third assistant. This resulted in the following taxonomy of psychological reasons for GM food opposition:

- Bodily harm concerns (228 participants)
- Fear of the unknown (93 participants)
- Feelings of unnaturalness (79 participants)
- Environmental harm concerns (34 participants)

- Social or political concerns (17 participants)
- Unintelligible responses (55 participants)

This taxonomy suggests that the psychology of GM food opposition is complex. Therefore it is not surprising that “one size fits all” educational interventions have not been successful in mitigating the prevalence of false, anti-science beliefs. Taken together, these studies suggest that more specific interventions, tailored to different psychological concerns, may be more effective at decreasing concern about and opposition to genetically modified foods. They also suggest that calibration of subjective and objective knowledge may play an important role in opponents’ openness to educational interventions—if those who know the least think they know the most, they may be unwilling to engage in such interventions.

### Moral Arguments Are Most Persuasive in Changing Attitudes of Opponents of Genetically Modified Foods

#### EXTENDED ABSTRACT

Genetically modified food (GMF)—food derived from organisms whose genetic material has been intentionally modified, e.g., through introduction of a gene from a different organism—has been a topic of intense debate. Most consumers in the United States are strongly opposed to GMF, even though the scientific consensus is that GMF is safe for human consumption (AAAS, 2012). We have shown that a plurality of all respondents, and a great majority of GMF opponents in the USA show a moral as opposed to risk-based opposition to GMF (Scott et al., 2016).

Across 4 studies and 1,760 opponents, we systematically manipulate which types of arguments GMF opponents are exposed to and examine attitude change. We are the first to our knowledge to systematically explore different arguments’ effectiveness in the domain of GMF opposition.

In all studies, we defined American GMF opponents’ as individuals who agreed they are opposed to “genetically engineering plants and animals for human consumption”. Opponents answered a set of measures assessing the nature and strength of their opposition, viewed an essay arguing for the acceptability of GMF, then indicated their opposition again on the same set of measures before filling out demographics. Arguments were of four types: moral virtues of GMF, safety, naturalness, and Christian theology.

1. Moral Virtues of GMF: We selected an argument about moral virtues of GMF because prior work suggests that many opponents to GM are moralized opponents (Scott et al., 2016). Moral opponents are typically insensitive to risk-benefit evidence, especially about non-moral consequences (Baron & Spranca, 1997; Tetlock et al., 2000). However, we hypothesized that if moralized opponents saw a *moral* counterargument, they might engage in thinking about tradeoffs and change their minds. In the moral essays, participants were told that “genetically engineered crops can increase health and prevent deaths from malnutrition, especially in the world’s poorest countries” and the example of golden rice which prevents blindness and death from Vitamin A deficiency was explained in depth.
2. Safety of GMF: Much of the literature suggests that risk perceptions are a major predictor of GMF attitudes (Moon & Balasubramanian, 2004). In our safety argument, participants read an essay arguing that GM food isn’t dangerous, and the essay contained polls of scientists and summary statements from reputable scientific organizations.
3. Naturalness of GMF: GMF is considered unnatural, and perceptions of unnaturalness is linked with GMF opposi-

tion (Tenbült et al., 2005). In fact, the unnaturalness of GMF may be one reason why people are morally opposed. Naturalness essays took a few different forms, some arguing that GMF was close to selective breeding and therefore natural, and others arguing that GMF and gene insertion happens in nature.

4. Christian theology: Religiosity has been linked to opposition to GMF, and sometimes GMF is viewed as “playing god” (Brossard, 2012). Therefore, we presented religious arguments that took a few different forms, such as arguing that religious texts permit Christians to cultivate and manipulate the environment or that Christians are called upon since the fall of man to use their talents and innovations (like GMF) to shelter and feed humanity and improve the world.

In study 1 ( $N = 142$ ), opponents were randomly assigned to one of three arguments (two about naturalness, one about Christian theology); In studies 2 ( $N = 213$ ) and 3 ( $N = 692$ ), opponents were randomly assigned to view either a naturalness or Christian theology argument; In study 4 ( $N = 713$ ), participants were randomly assigned to view a naturalness argument, an argument about the safety of GMF or an argument about the moral benefits of GMF.

We operationalized attitude change in two ways. In both cases, arguments about moral virtues of GM were most effective. One measure categorized individuals based on the agree-disagree question “I oppose this” with respect to GMF. All participants had originally indicated they were opposed to GMF, and if they indicated “disagree” after argument exposure, they were coded as 1 (became supporters), else 0 (remained opponents). In a meta-analysis across all four studies, 25.2% of opponents became supporters after viewing arguments about moral benefits of GM (95% CI [19.8%, 31.2%]); 17.6% became supporters after viewing naturalness arguments (95% CI [13.2%, 22.0%]); 14.5% became supporters after viewing safety arguments (95% CI [10.3%, 19.7%]), and 10.4% became supporters after viewing religious arguments (95% CI [7.7%, 13.1%]). A second measure was a pre-post difference score averaged across 12 items measuring attitudes to GMF (9-point likert scale items about desires to strictly regulate GM food, desires to consume GM food (reverse scored) and desires to take actions to protest and oppose GMF cultivation (adapted from Scott et al. 2016; Siegrist, 2000)). On this continuous measure, arguments about moral benefits of GM shifted attitudes by  $d = .44$  (95% CI [.31, .57]). In comparison, arguments about safety shifted attitudes by  $d = .30$  (95% CI [.17, .43]); arguments about naturalness shifted attitudes by  $d = .28$  (95% CI [.20, .36]); arguments about Christian theology shifted attitudes by  $d = .06$  (95% CI [-0.05, .17]).

Across 4 studies and 1,760 GMF opponents, we find that arguing about moral benefits of GMF shifted opponents more than arguments about its safety, naturalness, or acceptability in Christian doctrine. However, consistent with moralization of GMF attitudes, even the best arguments were only moderately effective, with at most 25% of opponents becoming supporters after one of these interventions.

## Emotion, Scientific Reasoning, and Judgments of Scientific Evidence

### EXTENDED ABSTRACT

Although scientists are often stereotyped as cold and distant, scientific research has the power to spark controversy and prompt strong emotional reactions in those who encounter it. Scientific research, in turn, is important to a range of lay consumers’ decisions, from medical decisions (e.g., whether to vaccinate one’s child) to

purchasing decisions (e.g. navigating health claims in advertisements). Although emotions are known to be integral to decision making (Kahneman, 2011), their role in judgments of scientific evidence has been little studied. We investigate how the emotions evoked by scientific evidence are related to three types of judgments regarding that evidence: understanding of it (Drummond & Fischhoff, 2017), judgments of its quality (Broomell & Kane, 2017), and trust in the scientists who produced it (Fiske, Glick, Cuddy & Xu, 2002). We also examine the relationship between these judgments and the ability to reason critically about scientific evidence (Drummond & Fischhoff, 2017), asking whether emotion and reasoning ability make separate contributions to consumer judgments of scientific evidence.

In an online study, 695 participants read a condensed version of a science news report from NPR’s All Things Considered (Harris, 2017) describing research on the role of chance in causing cancer (Tomasetti, Li & Vogelstein, 2017). We chose the article because it involves an emotionally laden topic and presents evidence that sparked controversy, but was not polarized along political or religious lines; we thus believed it would evoke strong, diverse emotions. Participants reported their emotional reactions to the article in terms of six emotions found to affect judgments in other domains (Ekman, 1992; Lerner, Li, Valdesolo & Kassam, 2015; Dunn & Schweitzer, 2005), fear, anger, sadness, surprise, happiness, and disgust, on a 5-level scale from 1= *very slightly or not at all* to 5= *extremely*. Participants then answered a series of dependent measures regarding their subjective understanding of the research, objective understanding (measured by asking participants to summarize the study; responses were coded for correctness by two trained coders), perceived quality of the research, and perceived warmth and competence of the scientists who conducted it, following Fiske et al.’s (2002) conceptualization of trust. Finally, participants completed the Scientific Reasoning Scale ( $M = 6.9$ ,  $SD = 2.7$ ,  $\alpha = 0.72$ ; Drummond & Fischhoff, 2017), which comprises 11 scenario-based problems measuring the ability to critically evaluate the quality of scientific evidence.

We used regressions to predict participants’ responses to our dependent measures as a function of their scientific reasoning ability and emotional reactions. We first modeled each dependent variable as a function of scientific reasoning ability, and found that individuals with greater ability reported greater subjective ( $B = 0.031$ ,  $p < 0.01$ ) and objective understanding ( $B = 0.128$ ,  $p < 0.001$ ), and rated the evidence as of lower quality ( $B = -0.052$ ,  $p < 0.001$ ). Ability was unrelated to judged warmth and competence.

We next added the emotion variables as predictors, assessing whether including them improved model fit. We modeled the emotions in two different ways: (1) we added each emotion as a separate predictor, as in the emotion and decision making literature (Lerner et al., 2015); and (2) we grouped emotions into those with negative and positive valence by creating two indexes: positive emotional arousal (averaging reported happiness and surprise) and negative emotional arousal (averaging reported fear, anger, sadness, and disgust), as in the risk analysis literature (Finucane, Alhakami, Slovic & Johnson, 2000). We found that overall, including emotions as predictors improved model fit, and modeling emotions separately improved model fit more than modeling them by positive and negative arousal, using goodness-of-fit criteria (AIC and adjusted  $R^2$ ) that penalize models for the number of predictors. This finding held for all but one measure: participants’ objective understanding of the evidence was unrelated to emotion, however modeled.

With respect to the specific emotions, we find that sadness is positively associated with subjective understanding of the article ( $B = 0.096$ ,  $p < 0.001$ ), while anger and disgust are negatively associated with subjective understanding ( $B = -0.147$ ,  $p < 0.01$ , and  $B = -0.185$ ,

$p < 0.001$ , respectively). Surprise and sadness were positively related ( $B = 0.077$ ,  $p < 0.01$ ;  $B = 0.144$ ,  $p < 0.001$ ), while anger and disgust were negatively related ( $B = -0.18$ ,  $p < 0.01$ ;  $B = -0.277$ ,  $p < 0.01$ ), to judgments of research quality. Happy and surprised participants judged the scientists as warmer, ( $B = 0.187$ ,  $p < 0.001$ ;  $B = 0.083$ ,  $p < 0.01$ ), and more competent ( $B = 0.089$ ,  $p < 0.001$ ;  $B = 0.112$ ,  $p < 0.001$ ); disgusted participants judged the scientists as less warm ( $B = -0.252$ ,  $p < 0.01$ ) and less competent ( $B = -0.248$ ,  $p < 0.01$ ).

Overall, our results suggest that scientific reasoning ability and emotional reactions to controversial research predict participants' subjective understanding of it and judgments of its quality; emotion but not reasoning predicts trust in the scientists who conducted it. These results are subject to several limitations: because we studied emotions integral to the stimulus, the signal is inherently less clear than in studies that examine the effect of a single emotion; we also cannot separate the emotions that participants expressed from the participants expressing them. Our results have practical and ethical implications for science communications and lay consumers. We found that those with greater scientific reasoning ability understood the evidence better, but thought it was of lower quality, suggest that knowing more about science can help consumers to better understand scientific evidence presented to them in the media, and also to be more critical of such evidence. We also found that surprised consumers thought the research was of higher quality, and placed greater trust in the scientists who conducted it. Evoking surprise could thus be a powerful tool for science communicators, but also one subject to misuse. Further, in this study we deliberately sought a stimulus describing scientific results not (yet) subject to political or religious polarization; future work might examine the effects of emotion in such situations.

### **Green biases: Consumer evaluations of renewable and non-renewable energy sources**

#### **EXTENDED ABSTRACT**

Do people perceive energy from renewable sources as being different than energy from non-renewable sources? If so, this fundamental misunderstanding about energy may explain people's decisions about when and whether to introduce energy from renewable sources into their lives.

Previous survey-based research on green energy products has found that many people hold general positive sentiments around green products but are ultimately reluctant to purchase them due to the belief that they are of higher cost and lower quality (Griskevicius, Tybur, & Van den Bergh, 2010; Lin & Chang, 2012; Luchs et al., 2010). Unlike products that have previously been studied (e.g. laundry detergent) which may in fact differ based on whether they are eco-friendly, electricity has exactly the same physical properties no matter how it is produced. Do people nevertheless view energy from renewable sources as being different than energy from non-renewable sources? Across four studies, we demonstrate that people do indeed view electricity differently due to its generating source. We demonstrate this bias operating when evaluating hypothetical experiences with electricity, when directly observing light in a dark or lit room, and when physically experiencing electric shocks. We also find differences between separate versus joint evaluations (Hsee, 1996). When making separate evaluations, people do not show a consistent preference for products powered by renewable energy and at times judge them to be worse. But in joint evaluations, products powered by renewable energy are judged to be of superior quality. This may indicate that on an unconscious level, people have neutral or slightly negative attitudes towards renewable energy, but

when consciously comparing renewable versus non-renewable energy, people prefer renewable energy.

In Study 1, 332 students were asked about their views of renewable versus non-renewable energy in hypothetical scenarios. Participants reported that being electrically shocked by a renewable energy source would be safer than being electrically shocked by a non-renewable energy source,  $t(305)=9.52$ ,  $p < .001$ , and that a light bulb powered by renewable energy would produce softer light relative to a light bulb powered by non-renewable energy  $t(305)=7.62$ ,  $p < .001$ . In Study 2, 478 participants from Amazon Mechanical Turk (MTurk) also viewed shocks or light from renewable energy as safer or softer than from non-renewable energy. In addition, MTurk participants also viewed renewable energy as more efficient,  $t(478)=4.99$ ,  $p < .001$ , and more reliable,  $t(478)=2.32$ ,  $p = .02$ , than non-renewable energy.

Although Studies 1 and 2 demonstrate a bias in hypothetical surveys, Study 3 tested how people evaluate renewable energy when witnessing electric outputs first-hand. In this study, 164 students evaluated light from two different flashlights, one that had been charged with renewable energy and one that had been charged with non-renewable energy. Participants were first given one flashlight and were asked to evaluate the quality of the light in a dark room and in a lit room (order counterbalanced). Next, participants were given the other flashlight and were again asked to evaluate the light. Participants showed a consistent preference of the light from renewable energy in the within-subjects analysis (e.g. indicated a higher willingness to pay,  $F(1,159) = 37.41$ ,  $p < .001$ ). This was not the case in the between-subjects analysis, where sometimes participants favored the non-renewable energy and sometimes favored the renewable energy. It appears that when people are aware that they are comparing renewable versus non-renewable energy, they answered in such a way to appear pro-renewable energy. But when they are not comparing the two types of energy sources, people do not consistently rate renewable energy as being superior. Given that the way in which a battery is charged has no bearing on the light that is produced, such findings imply that the preference for renewable energy only becomes salient when people are faced with both options.

In Study 4, 165 students experienced electrical stimulation on their arms from two different devices, one that had been charged with renewable energy and one that had been charged with non-renewable energy. Participants first experienced one electrical stimulation device during a fixed round where they experienced the stimulation at a low intensity for 10 seconds. Next, participants experienced the same device during a free round where they were free to take the intensity to a maximum of 60 and were free to test the device for a maximum of 2.5 minutes. Participants then experienced the other device, first during a fixed round and then during a free round. Another group of participants were in a control group where they experienced both devices during both fixed and free rounds, but were not told by which energy source the device was charged. The order in which all participants evaluated the two devices was randomized. This allowed for us to examine the first fixed and free rounds for the between-subjects analysis and examine the first and second fixed and free rounds for the within-subjects analysis.

The results from Study 4 were similar to the results from the Study 3. In the within-subjects analysis participants rated the renewable energy as being safer,  $F(1,84)=5.91$ ,  $p = .02$ , more efficient,  $F(1,84)=3.43$ ,  $p = .07$ , and expressed a greater willingness to pay,  $F(1,84)=7.59$ ,  $p = .007$ . As with Study 3, we see no clear preference of one energy source in the between-subjects analysis. Thus, across both studies people reported renewable energy as being superior only when they were aware that they were comparing it to non-renewable

energy. But when people were not aware that such a comparison was being made, there were no preferences for renewable energy.

This research provides a new way of understanding people's views on renewable and non-renewable energy sources, in the absence of objective differences between the two. The findings reveal new psychological insights that determine the acceptance of renewable energy (Wüstenhagen et al., 2007). Marketers wishing to promote renewable energy it powers would be well-advised to present it alongside a non-renewable option, thus improving consumer evaluations of the renewable energy and the products it powers.

### SESSION OVERVIEW

This special session is unified through a focus on the body. It is through the body that consumers sense the world and develop an understanding of consumption phenomenon. This session traverses embodied understandings of identity, materiality and ultimately how consumers sense “truth” in their everyday interactions. The session asks the questions “What role does the body play in understanding the world?” and “How does foregrounding different elements of embodiment lead to different understanding of consumption phenomenon?”

The first presentation explores the role of the body in aligning and misaligning materials. We ‘break in’ our hiking boots or camping equipment to facilitate the creation of material singular objects. However, the same forces lead to the continual break-down and wearing-in of objects. Through an in-depth ethnographic analysis of shoe repair practices, embodiment is foregrounded in this research through the constant material disintegration of objects. Consumers embodied, material “feel for the game” (Bourdieu 1998, 25) must continually deal with material disruptions that occur relatively slowly and gradually as a natural consequence of their practices.

The second presentation brings the body to the forefront through a focus on experiences of impaired embodiment. The study investigates a group of consumers whose consumption routines have been impaired by a bodily condition—lactose intolerance. The body only became apparent in consumer narratives of eating and drinking after they were diagnosed as intolerant. Here, the embodied know-how over body practices can no longer be taken for granted and must be re-learned. Consumer identity work is shown as a fragmented collection of instances of practical coping.

The third presentation provides an interesting contrast by investigating a context where the body is brought to the forefront after death. Here the “gift of life” of donor transplantation deems body parts as devoid of identity. The research aims to develop an understanding of the ways in which the body is conceptualized and objectified through the eyes of deceased donor families (DDF). Through an exploration of embodied recycling, the study investigates the rare experience of DDFs that contact the organ recipient of their deceased

and the constellation of sensory stimuli that brings them closer together.

The final presentation considers the body as a site of contestation. Drawing on a netnography and interviews with young women who have undergone breast-augmentation, the study explores how plans are disrupted by those who do not agree with their choices. Woman reformulated their body practices, through stuffing their bras to desensitize others to their impending change, or by decided not to have surgery at all. Consumers navigate the tensions between their own desires and the opinions of others when seeking to embody their desired appearance.

This session highlights the broad nature of embodiment. The four papers share the body as a site of consumer research, yet differ in terms of contexts, theoretical lenses and methodological approaches. This session has relevance to theorists of practices, assemblages and non-representational theory through furthering the theorization of embodiment. Furthermore, it has implications for body centric research such as health interventions.

## **The Embodiment of Repair: Consumer Experiences of Material Singularity and Practice Disruption**

### EXTENDED ABSTRACT

Consumers acquire things so they can run, walk, play, cook, eat, work, sleep, be entertained, and perform all of their everyday practices. These objects’ competence, including their capacity to produce and resist material effects, facilitates their interactions with other objects integrated into consumption practices. These interactions generally occur outside awareness, as consumers experience everyday activities through the realization of an embodied memory or habit unconsciously engrained through repeated practice and inseparable from the world they experience (Harrison 2000; Merleau-Ponty 1962; Wallenborn and Wilhite 2014). As Miller observes, “the lesson of material culture is that the more we fail to notice them, the more powerful and determinant of us they turn out to be,” (2010, 54).

These embodied practices are not static, but are in continual motion. Matter constantly becomes something new as interactions between objects create new distributions of competence between them (Bennett 2010; Coole and Frost 2010). As the objects in consumption practices shift, practices shift along with them. In a very material way, “embodiment revolves around an ever-ongoing combination of heterogeneous elements; a continual *collective individuation* of objects, things, contexts, and bodies” (Harrison 2000, 508, emphasis in original). The assembled unity and repeated practices of daily life constitute the elusive nature of embodiment—the tacit way that over repeated practice the body incorporates material arrangements into taken-for-granted actions (Wallenborn and Wilhite 2014). With use we “break in” our seasoned iron skillet, leather hiking boots, outdoor camping equipment, the cushions on our favorite chairs, the fit of our dress slacks, the feel of our new phone with how we contain it, text, e-mail and take photos with it.

However, the same forces that facilitate the creation of material singular objects within embodied practices also lead to the continual break-down and wearing-in of objects integrated within them. Consumer practices are continually threatened by the constant material disintegration of objects that are central to practice performance. Most of these breakdowns occur outside our awareness, only rising

to consciousness as practices get disrupted, shaking us out of our embodied performances (Harrison 2000). A thing which exists “present-at-hand” often does not become noticed until it breaks and is no longer usable or “ready-to-hand” (Heidegger 1962, 103). Similarly, consumer practices, may appear to perpetuate unnoticed until the material elements of the practice get disrupted (Phipps and Ozanne 2017) people experience secure existentially because their practices are unconsciously embedded into stable & “obdurate” materiality that supports the practice. When some of materials that the practice relied upon shifted and became unaligned with the practice, this disruption occurred at the material level. The object (water). We extend prior work on practice disruption to examine how consumers deal with material disruptions that occur relatively slowly and gradually as a natural consequence of their embodied practices.

Through an in-depth ethnographic analysis of shoe repair practices, we find that the continual process of embodied, material practice change leads some objects to become materially singular to a practice. Material singularity describes moments of physical irreplaceability that objects can achieve as embodied components of consumers’ practices. It is a fluid state, constantly changing as objects interact in practice. The fluid state of material singularity often goes unnoticed, as other objects integrated in a practice shift in response to each other and consumers unconsciously adjust their performance in response to these changes. During this “co-evolution of bodies and the material world” (Wallenborn and Wilhite 2014, 56), consumers often develop an embodied, material “feel for the game” (Bourdieu 1998, 25), like a skilled cricket bowler or batsman who instinctively reacts in different ways as ball and field wear down during the course of a match. Consumers typically don’t consciously appreciate the material singularity of an object until it disintegrates sufficiently to disrupt a practice. Repairing a materially singular object maintains the singular flows of competence in the practices and the embodied performance that these flows facilitate. Conversely, replacing a material object would force the consumer to change their practice and the previously embodied flows of competence between objects integrated within it.

To repair and realign disrupted practices consumers must become reflexive about the role of material objects. Repair thus disembodies elements of embodied practices and makes them salient enough for consumers to actively reassemble. We find that consumers respond to practice disruption in several ways. First, anticipating material threats, consumers may protect an object by bolstering or fortifying its coherence in an attempt to prevent or slow its future disintegration. Second, when material singularity becomes salient, consumers can proactively recalibrate an object with their practices as it wears down, maintaining object and practice alignment before disruption occurs. Third, and mostly commonly, faced with the disruption of a practice caused by object disintegration, consumers may reactively repair the practice by restoring sufficient competence to the object that it can be effectively reintegrated back into the practice.

Our research makes several key contributions to research on consumer practice and embodiment. First, we outline the processes by which embodied practices gradually shift and break down outside consumer consciousness, and how inevitable disruptions bring previously unconscious practices into conscious awareness. Second, we introduce the concept of material singularity, which describes moments of physical irreplaceability that objects can achieve as embodied components of consumers’ practices. Finally, we explain how material singularity influences the ways that consumers realign objects within their practices in order to maintain or repair their embodied experiences of practice performance.

## Consumer Identity in the Flesh: Lactose Intolerance and the Erupting Body

### EXTENDED ABSTRACT

It is widely accepted that consumer researchers know a great deal about consumer identity work. Consumer identity work as a research program concerns itself with the ways in which consumers attempt to reflexively fashion or revise a reasonably coherent sense of self by participating in linguistically mediated discourses (Arnould and Thompson 2005; Ahuvia 2005; Hill and Stamey 1990). However, consumer research has neglected to attend to how embodiment is implicated in identity work. Wherever consumer research does attend to the body, it is understood as an expressive vehicle for a bounded, endogenous self, involved in a long-term consumer identity project (Sandikci and Ger 2013; Schouten 1991; See Joy and Sherry 2003 for an exception). Our work provides a systematic elucidation of the body as understood not in contrast to some inner self, but rather as the subject through which we experience and perceive the world around us (Merleau-Ponty 1962).

The purpose of this article is to better understand the relationship between embodiment and consumer identity work. The dominant metaphor of identity project foreshadows reflexive consumer subjects engaged in explicit (Mick and Buhl 1992; Schau and Gilly 2003) or tacit (Thompson and Tambyah 1999) goal-driven pursuits, and conceived of as “identity seekers and makers” (Arnould and Thompson 2005, pg. 871; Thompson and Ustuner 2015; Ustuner and Holt 2012). In contrast, this work aims to provide a fully worked out account of how the situated body serves as a medium and background of immediate identity-oriented consumer experience, how prior to thinking and talking about the world, we embody it (Dreyfus, 1991; Fuchs and Schlimme, 2009;). We employ a cultural phenomenological lens to interpret consumers identity work as a fragmented collection of instances of practical coping, thus showing that embodiment is deeply implicated in processes of identity work (Csordas 1993; Merleau-Ponty 1962). Our work shows that a “paradigm of embodiment can be elaborated upon for the study of culture and self” (Csordas 1990, p. 4) where the body is not a product of culture, but “the existential ground of culture”.

Our guiding research question is: *How does talk about embodied experiences of food consumption constitute identity?* We focus on experiences of impaired embodiment to bring the often-neglected corporeal aspect of identity work into full view. Associated questions are: What is it like to be a lactose intolerant embodied organism? And, what are its implications for processes of identity formation and revision? When refracted through the prism of embodiment, identity work, conventionally regarded as the discursive authoring of preferred selves (Thompson and Haytko 1997; Ahuvia 2005), becomes a successful instance of embodied maximal grip (Merleau-Ponty 1962), i.e. the bodily disposition to “respond to the solicitations of situations in the world” in a way that leverages whatever wiggle-room available therein, with the ultimate end of attaining optimal embodied equilibrium (Dreyfus & Dreyfus 1999, p. 103).

We study a group of consumers whose sedimented consumption routines have been impaired by a bodily condition—lactose intolerance. They cannot consume milk and milk products without experiencing a bodily disequilibrium - involuntary episodes of bodily discharges (burps, farts, stools, vomit), or intense throbbing pain. The particular bodily situation impairs the cohering of bodily experience related to eating and drinking. Embodied know-how that once pervaded eating and drinking can no longer be taken for granted and has to be re-learned.

Fieldwork was carried out in Finland, a socialist democracy embedded in the Nordic “ethos of equality and egalitarianism” (Ostberg and Kjeldgaard 2007, p. 184) that promotes social rights and allows people “social resources, health and education to participate as effective socialist citizens” (Esping-Anderson 1996, 12). We utilized long semi-structured interviews as our predominant mode of gathering our empirical material (Arsel 2017). Our approach to phenomenology is consistent with research that takes embodiment as ‘the starting point for analysing human participation in a cultural world’ (Csordas, 1993, p. 135).

Before being diagnosed as lactose intolerant, the consuming body did not often feature in our respondent’s experiences. However, embodied impairment in the form of LI, collapses the separation between body and identity, so that reflecting on and being aware of one necessarily entails being aware of the other. The sudden eruption of the body leaves valorized identity projects in tatters, as the impaired body breaks out of the intentional arc and threatens achievement of maximal grip on the situation. Identity work from an embodied perspective recreates the cleavage between self and body, redrawing the boundary that had been collapsed by LI. Lactose intolerant people respond with three families of embodiment-oriented identity work, in an attempt to re-habilitate and re-embodiment their lives so as to achieve maximal grip: 1) *Discursive Softening*, where lactose intolerant people respond to the embodied disruption by playing down its meaning and consequence; 2) *Expanded Consumption Repertoire*, where they respond by learning new repertoires of consumption; and 3) *Embodying Expertise*, where they re-intuit and re-habituate themselves to their impaired bodies.

This study attempts to work out the embodiment inherent in identity work, i.e., highlighting the ‘know how’ aspect of identity work, in addition to the previously explicated ‘know that’ aspect of identity work (Luedicke et al 2009). Our research contributes to the growing literature on the lived phenomenological body, explicating the varied ways in which people experience their bodies, and to better understand how these multifarious experiences sculpt identities and selves.

## Understanding Organ Donation: Discourses of Embodied Recycling

### EXTENDED ABSTRACT

In the UK there are 6,500 people on the national transplant waiting list (NHS 2018). Despite steep rises in transplant survival rates, and reductions in the number of people waiting for operations, demand for organs still far exceeds ‘supply’ (Gunnarson and Svenaeus 2012). The metaphor of an organ ‘shortage’ has become firmly embedded in organ donation and transplant (ODT) discourse, and this has powerful implications for the human body as having ‘market value’ (Lock and Nguyen 2010, 234).

The problematics of ODT involve complex attachments to the ‘commodities’ involved; the donor’s relationship with their body, the transplant patient’s body concepts, the sentiments of ODT medics and the emotional trauma experienced by deceased donor families (DDF). It is this last group of people that represent a particularly pressing issue for the ODT community. In approximately 60% of cases, families do not consent to the deceased’s body being used for transplant (NHS 2015). It is this gap – alongside the general reluctance of people to talk about organ donation – that is the impetus for our study: How can an embodied perspective better help us understand people’s propensity to consume and be consumed (or not) by the body of another?

Although organ donation research has begun to consider the interplay between DDF and consent rates (Hulme et al. 2017; Noyes et al. 2016), the specific phenomenon of embodied discourses and the sociocultural structures that enable them to emerge and endure has yet to be subject to significant scholarly attention. Embodiment (Vom Lehn 2006) and sensory stimulation (Hamilton and Wagner, 2014) have become central features of transformative service environments and consumer value cocreation (McCull-Kennedy et al. 2012). As such we see our contribution developing out of the importance of the viscerally experienced emotional labor, sense-making and embodied practices that are central to the patterning of transformational service settings (McCull-Kennedy et al. 2012).

Moreover, whilst the role of the body in ODT process has recently begun to be considered (Blekher, Katz and Gneezy 2014) our understanding of the interplay between emotional attachments to body parts and ODT remains limited. We aim to shed light upon this issue by developing an understanding of the ways in which ‘the body’ - with discrete boundaries between ‘insides’ and ‘outsides’, ‘subjects’ and ‘objects’ and ‘self’ and ‘other’ (Rayner 2003) - is conceptualized and objectified through the eyes of DDF. We consider the corporeal, social and cultural mechanisms that facilitate ODT body concepts in Western society.

There are a range of theoretical resources we can draw on to understand the interplay between embodiment and DDF consent including; medicine (Hulme et al., 2016; Ryckman et al., 2009), medical anthropology (Lock, 1995; Scheper-Hughes, 2001), health marketing (Aldridge and Guy, 2008; Burkell, Chandler and Shemie, 2013; Dijker, Nelissen and Stijnen 2013), consumer research (Blekher et al., 2014; Lai, Dermody and Hanmer-Lloyd 2007), and social psychology (Dijker et al., 2013; Ryckman et al., 2009). Taking a ‘mortal embodiment’ perspective, Lai et al. (2007) investigate how the decision to dispossess body parts for donation challenges the role of the body as the marker of the self. They highlight how embodied projects within consumerist societies are challenged by ‘the gift of life’ discourse where body parts are deemed as devoid of identity (Lock 2002; Ohnuki-Tierney et al. 1994). Moreover, Gunnarson and Svenaeus (2012) note how the ethics of ODT is tied to the relationship we have with our bodies on a societal (and therefore political) level. This article focuses on how the attachments people have to bodies/body parts has a bearing on their market ‘value’ (e.g., to extend life). The value attribution is determined by a constellation of embodied factors that can’t be explained by rationality.

In building the theoretical foundations of our study, we draw from research on thanatopolitics (Foucault and Ewald, 2003), as well as insights from modern biopolitics (Campbell 2009), conceived as the power to ‘make’ live and ‘let’ die (Foucault and Ewald 2003), to help us analyze and understand our research question: How can an embodied perspective help us gain a deeper understanding into people’s propensity to consume and be consumed (or not) by the body of another? We consider how conceptualizations of the body change when it is required to be a source of ‘augmentation’ to another person.

Our paper analyses data collected using interviews with deceased donor family members, organ donors and transplant recipients across the UK to offer new insights into the embodied aspects of donation and contributes to ongoing discussions about the body as an anatomical resource, gift and commodity (Gunnarson and Svenaeus 2012). This study focuses on the ODT experience of transplant patients, DDFs and medical practitioners. Forthcoming interpretive methods will include projective drawing techniques, participant observation, field notes and netnography.

While this may be subject to refinement as the project progresses, early analysis suggests that we contribute to the embodied dimension of the transformational service literature by demonstrating how the death of the body, when it is carefully managed and controlled, enables pride, achievement, self-actualization and mobilization for DDFs, which helps to breathe new life into the loss and grief experienced by DDFs. This challenges the traditional narrative of grief as 'loss.' As a preliminary label for the positive, proactive and proud set of experiences we are using the term 'embodied recycling.' Embodied recycling defines the rare experience of DDFs that make contact with the organ recipient of their deceased and the constellation of sensory stimuli that brings them closer together.

Interviews reveal a rich corporeal portrayal of ODT stories through expressive bodily sounds and movements. Overall, this work aims to extend the ODT, health, and service disciplines by addressing the pressing need to learn more about the transformative impact of family consent. Initial findings show how the embodied pride, achievement, and mobilization felt by DDFs offers an embodied emancipation from the constraints of grief.

### **Contested and Confused: The Influence of Social Others in Disrupting Body Projects**

#### **EXTENDED ABSTRACT**

Close social others, such as friends or family, are likely to have an opinion in consumption contexts. Whether it is choosing clothing or a new hairstyle; or engaging in socially unacceptable behaviours such as excessive alcohol consumption, consumers are likely to hear from others about the efficacy of their behaviours.

In the context of body modification, theorists often employ the concept of a body project to explain how and why consumers work to change their bodies (Askegaard et al. 2002). Researchers conceive of the body as a malleable entity in which consumers are actively managing their body appearance in accordance with their identity (Schilling 2003). This current research extends this line of thinking to explore how decisions involving the body can also be relational pursuits, which are based on the influence of close social others. For instance, consumers rely on others, such as tattooists, in order to help them actualize their desired appearance onto their body (Patterson and Schroeder 2010). We seek to theorize how relationality influences the planning, preparation, and embodiment of an ideal body.

Relationality in body projects are important for body modification practices, such as piercing, tattooing, or elective cosmetic surgery, because these practices are often contested (Giesler 2012). Despite a growing uptake in body modifications, a stigma is still attributed to these practices (Bradshaw and Chatzidaki 2016). More specifically, consumers who seek to change their appearance may be met with resistance within their personal networks or broader society. Therefore, while individuals may feel they have complete control over their bodies, there are times when the body becomes a social pursuit, and this relationality may hinder body practices.

We selected breast augmentation among younger women as a site of body project relationality by close others. Breast augmentation is increasing in popularity and is considered the most popular cosmetic procedure for young women aged 19-34 (ASPS 2017). For this reason, many young women are turning to online communities as a means of gaining support. We conducted a blended netnography, tracing three types of online communities: YouTube recovery vloggers (video bloggers), online forums, and Instagram communities (Kozinets 2015). Data collection also included 18 in-depth consumer interviews with female consumers recruited from online networks.

They are aged between 20-39 years of age and have recently undergone elective breast augmentation surgery.

Findings from this study support that informants consider breast augmentation an increasingly mainstream practice among women their age (i.e., Thompson and Coskuner-Balli 2007). Since many informants personally know someone who had the surgery, they consider breast augmentation to be a socially acceptable body modification practice. Nevertheless, their decision to undergo breast augmentation was often contested within their social networks of support. In particular, negative opinions from close social others played a role in the practices that informants enacted over their own bodies. Exploring these tensions helps us understand how relationality influences consumer's body projects.

Family members and friends met women's desires for change with resistance, commonly telling them to "be natural" or to "love themselves" as they are. Women were told they were shallow for wanting to change their appearance, and their justifications were often scrutinized. Women feared that they were making a mistake given their lack of social support. For example, Phoebe chose not to get breast augmentation because her family members disapproved. This was a common phenomenon in online forums, which revealed dozens of threads from women seeking advice for how to justify the decision for surgery to friends or family members. In Phoebe's case, the fear of a fall out with her family was not worth her changing the body that she was not happy with. In other words, even when women made plans over their own bodies, they were sometimes derailed by unsupportive others or the risk of negative social consequences.

Once women committed to surgery, they prepared themselves and others for the embodied change in their appearance. In order to minimize the risk of a negative reaction to her surgery, Danika slowly filled her bras with socks at work, adding an extra sock each week in order to desensitize her office co-workers to her impending change. Others emotionally prepared for the risks of surgery. This included attempting to reassure apprehensive family members or friends who were not convinced that they had done their research, or were making a rash decision. Sarah went as far as taking her unsupportive mother to meet the surgeon, leveraging his social authority in alleviating her concerns. These examples and others support that preparing others is an integral part of going through with the surgery.

Finally, women reformulated some practices in order to manage the differing opinions between themselves and their support networks. Women often explained that they had parents or romantic partners who did not want them "going too big" or selecting implants that were too large. They feared that they would "show off" their new bodies too much or that their revised appearance would "change" them. For some, informants revised their plans, opting for smaller sized breast implants, to accommodate their partner's desire. This accommodation did not always work well, such as in the case of Olivia regretting her decision to concede to her husband's wishes over her own body. Shortly after their divorce, Olivia started looking into larger implants that were more in line with her ideal appearance. Thus, social tensions play out on the very bodies of these young women.

Prior research exploring body modification theorizes that consumers match their external appearance with an ideal self (Askegaard et al. 2002; Schouten 1991). This study considers the role of important social others in the construction and embodiment of an ideal body. The primary contribution of this research is highlighting that even though the decision to modify may be individualized, body projects can be more fully conceptualized as relational and contested pursuits. We find that consumers navigate the tensions between their own desires and the opinions of others when embodying their desired appearance.

### SESSION OVERVIEW

In today's world, overeating and obesity ironically exist alongside undernutrition and food waste (Block et al. 2016; Mayer 1990; Zlatevska, Dubelaar, and Holden 2014). While increasingly complex nutrition information and unregulated health-claims have been widely implicated as potential culprits of these contradictory outcomes (Kozup, Creyer, and Burton 2003; Roe, Levy, and Derby 1999), little research has examined how the visual aesthetics of food can influence choice, consumption, and waste, which is surprising, given that visual presentation of food is often the most obvious and immediate information that consumers receive.

In this session, four research teams examine how various manifestations of aesthetics produce sensory, cognitive, and affective reactions that can influence food choice and consumption. Each paper touches on a different underlying process, but all four seek to address an overarching question: How can marketers best leverage the aesthetic presentation of food to promote healthier and more sustainable purchase and consumption behaviors?

The first two papers focus on how food aesthetics influence evaluations inherently related to the food in question: the food's perceived healthiness and the consumer's satiation. First, Hagen concentrates on food styling and shows that pretty (vs. less pretty) food presentation leads consumers to judge food as healthier across various aspects of healthiness (e.g., nutrient and calorie content). She demonstrates that this effect is not driven by a halo effect, judgment polarization, or motivated reasoning, but rather by people paradoxically perceiving prettier food as more natural. Next, Sample and Haws change gears and examine changes in visual aesthetics of food as a result of consumption, showing that eating in a messy (vs. clean) manner can simultaneously increase satiation and decrease guilt from wasting food. They find that both of these outcomes can be attributed to messy eating rendering the food less appetizing.

The next two papers move on to explorations of how food aesthetics impact reactions reaching beyond the food itself: feelings of wrongness associated with the act of consumption and consumers' self-perception. Wu, Samper, Morales, and Fitzsimons examine the

practice of customizing food products with lifelike images of people and reveal that, although popular, personalization involving a higher (vs. lower) resemblance to the depicted individual can actually reduce food consumption. They find that this reluctance to consume is driven by superstitious feelings that it is wrong to destroy someone's likeness. Finally, Grewal, Hmurovic, Lambertson, and Reczek investigate reasons for consumers' rejection of ugly produce and show that choosing ugly (vs. pretty) food can undermine people's positive self-perception. Consequently, the authors discover that interventions that protect would-be customers' self-esteem boost their willingness to choose and pay for ugly produce.

Together, the four papers shine a light on the topic of food aesthetics—a subject that is not only of substantive interest given the pressing societal issues surrounding obesity and food waste, but also provides theoretical insight into the various processes involved in “eating with our eyes first.” We believe this session will appeal to a broad audience, including researchers interested in aesthetics, affect, food-related lay beliefs, health, and sustainability.

### Pretty Healthy Food: How Prettiness Amplifies Perceived Healthiness

#### EXTENDED ABSTRACT

Consumers view about 4,010 food and 2,840 restaurant advertisements per year (Statista 2016). In these ads, they continuously see foods that were extensively styled to look pretty, in order to appear appetizing and plentiful. But might consumers also perceive prettier foods as *healthier*? Person perception research shows that prettier people are judged more positively on virtually all dimensions (Feingold 1992). Aesthetics research in consumer psychology indicates prettier products, too, are often evaluated more favorably—for example, they seem more user-friendly (Tractinsky et al. 2000), signal professionalism (Townsend 2017), and suggest high production effort (Wu et al. 2017). Surprisingly, no research has examined whether and how prettiness of food impacts a key food judgment: perceived healthiness. Seven studies show that prettier food is judged as healthier and compare possible underlying processes.

First, prettiness may elicit a generalized halo effect. Beauty elicits positive affect (Winkielman and Cacioppo 2001), and initial positive affective reactions often spill over into judgments of specific attributes, even when those are unrelated to the attribute inducing the initial reaction (Thorndike 1920). Thus, prettier versions of food may, indiscriminately, be judged more positively on all attributes—including healthiness. Second, prettiness may polarize healthiness judgments. Prettier targets are usually more prototypical (Veryzer and Hutchinson 1998), and prototypical exemplars are judged higher on category-defining attributes (Osherson et al. 1990). Thus, prettier versions of healthy foods may be judged as healthier, but prettier versions of unhealthy foods as unhealthier. Third, prettiness may induce specific inferences. Consumers use many (often incorrect) lay theories about attribute correlation (Bruner and Tagiuri 1954), e.g., unhealthy=tasty (Raghunathan et al. 2006) and healthy=expensive (Haws et al. 2017). Thus, prettiness may signal something that, per people's lay theory, is a proxy for healthiness, and prettier versions of food may thus be judged as healthier.

A pilot (N = 803) used a 2(prettiness: pretty vs. ugly) × 8(food replicate) between-subjects stimulus sampling design to test the ba-

sic effect. Participants were asked to find and upload photos of either a pretty or an ugly version of various foods (sandwiches, pizza, salad, omelette), and then rated the food's "perceived healthiness" (healthy, nutritious, good for me, fatty<sup>R</sup>, and high calorie<sup>R</sup>; = .89). People judged the food as healthier when it was pretty than when it was ugly ( $p < .001$ ), supporting the idea that people see prettier food as healthier, but contradicting the polarization account, as both unhealthy and healthy items were rated as healthier.

Studies 1A-1B used single-factor (prettiness: pretty vs. not pretty) designs with more moderate stimuli and held constant photographic quality, food content, and price to show the effect in a controlled manner. In study 1A ( $N = 205$ ), participants evaluated fully controlled experimenter-designed stimuli. They saw the same almond butter & banana (AB&B) toast that was either pretty or not pretty, but equal in terms of perceived amount, tastiness, and price. They rated "perceived healthiness" and gave a numerical calorie estimate. People judged the AB&B toast as healthier ( $p < .001$ ) and estimated it contained fewer calories ( $p = .003$ ) when it was pretty than when it was not pretty. In study 1B ( $N = 154$ ), participants evaluated ecologically valid food stimuli from an "ad-vs.-real" food reportage. They saw the same, equally priced, cheeseburger that was either pretty or not pretty. They provided the same judgments as in study 1A (except for the calorie estimate), and also rated "perceived tastiness" and "perceived amount," because the tasty=unhealthy intuition (Ragunathan et al. 2006) and large portion size may work against the predicted effect. Results fully replicated study 1A, even controlling for the prettier food looking tastier and larger ( $ps \leq .043$ ). Evidently, prettier food is judged as healthier, independent of tastiness, amount, and price.

Study 2 ( $N = 200$ ) used a single-factor (target food prettiness: pretty vs. not pretty) design to test if prettiness-induced healthiness perceptions sway people's choices. Participants had to identify which of two foods contained fewer calories, and correct responses were incentivized via a bonus doubling their pay. They saw an avocado toast (control) plus an almond butter toast that was either pretty or not pretty. People were more likely to (incorrectly) choose the almond butter toast as the lower calorie option when it was pretty than when it was not pretty ( $\chi^2 = 7.87, p = .005$ ). A replication using sandwiches and an unhealthy choice task reproduced the effect.

Studies 3A-3B examined the remaining process accounts. First, per the logic of the halo effect, people with a stronger initial positive affective reaction towards prettiness should exhibit a stronger effect. Study 3A ( $N = 199$ ) tested if the effect is enhanced for individuals highly attracted to beautiful aesthetics and attentive to beauty. People high in "Centrality of Visual Product Aesthetics" (Bloch et al. 2003) did *not* exhibit a stronger, but rather a weaker, pretty=healthy effect for the AB&B toast, contradicting the halo account. Next, per the logic of lay theory-based inferences, having more information should weaken the effect. Study 3B ( $N = 604$ ) tested if the effect is reduced when people have health-related information that reduces the need for guesswork. People exhibited the pretty=healthy effect for the AB&B toast only when given no cue ( $p = .002$ ) or an ambiguous cue ( $p = .014$ ), but not when given a health-related cue ( $p = .275$ ), supporting the specific inferences account. Replications using the ecologically valid cheeseburger stimuli fully reproduced all effects.

Study 4 ( $N = 202$ ) examined the nature of the inferences in-depth. Participants evaluated lasagna that was either very pretty or moderately pretty. They rated "perceived healthiness," and, as viable mediators, "perceived sophistication," "perceived care," and "perceived naturalness." The effect of food prettiness on perceived healthiness was mediated by greater perceived naturalness ( $B = .112$ ;

95% CI: .035, .235), but not by perceived care, sophistication, or tastiness.

This research reveals that pretty food presentation biases healthiness judgments, and also shows that this effect is driven by a perception that prettier food is more natural, from which consumers infer healthiness. Implications for consumer welfare and food branding are discussed.

## The Messy Satiation Effect: The Benefits of Eating Like a Pig

### EXTENDED ABSTRACT

Consumers frequently underestimate satiation, leading to detrimental decisions, mindless eating, and overconsumption (Wansink 2007). Though poor at estimating perceived and actual satiation, consumers are quite adept at appraising visual aesthetics. Even though attractive foods and food presentation strongly enhance likelihood to purchase and consumption (Michel et al. 2015; Zellner et al. 2014), the aesthetics of food presentation can only be controlled before the point of initial consumer acquisition. So, how might changes in attractiveness impact consumption over time, and could food aesthetics help curb overconsumption instead of fanning the flame of obesity?

Over the course of consumption, an initially visually attractive food can become messy and therefore less attractive. We propose that this decline in attractiveness will make a once appetizing food no longer appetizing and this process will lead to an increase in satiation. Satiation perceptions are malleable and strongly influenced by non-physiological factors (Redden 2014); for instance, they are highly susceptible to the available visual cues (Chandon and Ordabayeva 2009; Van Ittersum and Wansink 2011; Wansink, Painter, and North 2005). As such, to the extent that positive evaluations and consumption intentions for an initially attractive food diminish as it loses its attractiveness, satiation should be increased. Thus, we suggest that decreasing the attractiveness of food during consumption by way of eating in a messy (vs. clean) manner may stifle overconsumption while also diminishing guilt associated with not finishing one's food. We test for this "messy satiation effect" across three studies, while exploring the underlying process and the resultant guilt.

In study 1, participants ( $N = 102$ ) were presented with an image of one serving of lasagna and asked to imagine eating. Participants were then randomly assigned either a messy or clean image of the partially eaten lasagna and asked two satiation items (likelihood of eating more of the food, likelihood of finishing the food;  $\alpha = .91$ ). We next assessed how appetizing the food looked and general liking for lasagna. An ANCOVA with our satiation measure revealed greater perceived satiation in the messy condition ( $M_{\text{messy}} = 6.28$  vs.  $M_{\text{clean}} = 6.94$ ;  $p < .05$ ). A mediation model with cleanliness (IV), satiation (DV), and how appetizing the food looked (mediator) indicated full mediation ( $\beta = -.5576$ , 99% CI: -1.2564, -.1017).

In study 2 ( $N = 304$ ), we establish the robustness of the messy satiation effect using a different food item and counterbalancing the order of the satiation and appetizing measures. We also introduce a control condition without a picture of the food in question. We hypothesized that consumers typically plan on cleaning their plate (Collins 2006; Schwartz et al. 2012), and without a picture, satiation should be similar to that in the clean picture condition, whereas those in messy picture condition should show increased satiation. Participants were prompted to imagine eating cake and randomly assigned a messy, a clean, or no image of the partially eaten cake. There was a significant main effect of picture type, driven by increased satiation in the messy condition ( $M_{\text{messy}} = 5.19$ ;  $M_{\text{clean}} = 6.25$ ;  $M_{\text{control}} = 6.03$ ;  $p$

< .01), with significantly greater satiation for messy than clean ( $p = .001$ ) and messy than control ( $p = .01$ ), but equal satiation for clean and control ( $p = .51$ ). This suggests that without a picture, consumers act as if the remaining food is still visually pleasing and will continue to consume in line with our theorizing about cleaning one's plate. There was no main effect of measure order ( $p = .64$ ), so we collapsed results for mediation analysis and again see full mediation from how appetizing the food is ( $\beta = -.2034$ , 99% CI:  $-.4513$ ,  $-.0258$ ).

In study 3 ( $N = 203$ ) we look to another consequence of the messy-satiation effect: guilt relief. Overeating can produce guilt, but so can discarding food. Since consumers engage in rejection behaviors with visual incongruity (Patrick and Hagtvedt 2011) and place less value on distorted products (Trudel and Argo 2013), a consumer should be able to reject (i.e., waste) messy-looking food with significantly less guilt than cleanly eaten food, and to continue to consume (i.e., overeat) clean food with significantly less guilt than messy-looking food. We tested this using a 2(messy vs. clean) $\times$ 2(overeating vs. wasting food) design where participants were shown a slice of cheesecake, told they were close to being full, and to imagine that they began to eat the cake. They were then randomly assigned a messy or clean half-eaten piece of cheesecake and told that they were full and either finished up the cake anyway or had the waiter remove their plate. They were then asked about the guilt associated with their assigned behavior. An ANOVA reveals a significant interaction between visual state of the cake and action of overeating or wasting food ( $p < .05$ ). Those in the clean condition reported significantly less guilt when overeating than when wasting food ( $M_{\text{CleanOvereat}} = 4.42$  vs.  $M_{\text{CleanWaste}} = 5.87$ ;  $p < .01$ ), whereas those in the messy condition indicated the same amount of guilt regardless ( $M_{\text{MessyOvereat}} = 4.81$  vs.  $M_{\text{MessyWaste}} = 4.73$ ;  $p = .88$ ). These results indicate that stopping eating when eating cleanly is possibly a harder thing to do, as consumers are apt to avoid the negative consequences of wasting food. Conversely, eating in a messy manner should not only provide a benefit of increased satiation but less guilt as well.

Together, our studies demonstrate that various forms of changing visual aesthetics during food consumption impacts rates of satiation. Furthermore, a consumer who may not be able to resist ordering a hedonic food can actually "eat like a pig" in an effort to increase satiation, stem overconsumption, and alleviate the guilt from not "cleaning one's plate."

### That's Just Plain Creepy: Understanding Consumer Responses to Personalized Food Products That Resemble People

#### EXTENDED ABSTRACT

From cell phone cases to party favors, consumers are drawn to personalized products (Moreau et al. 2011), a trend that continues to manifest itself across an ever-increasing variety of goods, including food. For instance, consumers now have the option to decorate birthday cakes or even M&M's with images of friends, family, or celebrities. Despite their growing popularity, the downstream effects of such personalization on post-purchase consequences are relatively unknown. We propose that this kind of personalization can actually reduce food consumption.

We draw from the sympathetic laws of magic (Frazer 1890) to examine the impact of food personalization on consumption. Specifically, one such law, the law of similarity, holds that things that resemble one another share essential properties, such that actions taken on an object affect similar-looking objects (Rozin et al. 1986). Given that consumption of personalized food products entails destroying the image of the depicted individual, we contend that eating such

food products would be akin to marring the same individual, an aversive experience that ultimately reduces consumption. Importantly, such effects should only hold for realistic-looking images, but not a cartoon image or the name of the individual. Our work provides new insights on how the sympathetic laws of magic operate in consumption contexts. While prior consumer research on magical thinking has predominantly focused on the law of contagion (e.g., Kramer and Block 2014), we elucidate the influence that the law of similarity can also have on consumption. More broadly, given the mismatch between initial consumer interest and actual consumption, we add to the emerging body of research that explores when and how the drivers of predicted and experienced utility diverge (Wilson and Gilbert 2005). We test our predictions across four studies involving hypothetical and actual consumption.

Study 1 ( $N = 339$ ), which was hypothetical in nature, provides initial evidence for this phenomenon in a 2(portrayal of individual: face vs. name; between) $\times$ 3(M&M type: individual, word, letter; within) design. Participants imagined encountering, at their cousin's graduation party, a bowl of personalized M&M's that depicted their cousin's face (vs. name), "Congrats!", and "M", and were asked to indicate their likelihood of eating each type of M&M. Results revealed a significant portrayal  $\times$  type interaction ( $p < .0001$ ). While participants were less likely to eat M&M's depicting their cousin's face (vs. name) ( $M_{\text{face}} = 5.06$  vs.  $M_{\text{name}} = 5.45$ ;  $p = .0437$ ), the likelihood of eating the other two types of M&M's did not differ by condition ( $p > .22$ ).

In study 2 ( $N = 217$ ), a single-factor 3(portrayal of individual: face vs. name vs. cartoon) design, we generalize our findings to cakes depicting photographs of people, and show that people displayed lower willingness to eat a birthday cake depicting their cousin's face ( $M_{\text{face}} = 4.50$ ), compared to a cake depicting their cousin's name ( $M_{\text{name}} = 5.35$ ;  $p = .0021$ ) or a cartoon illustration of their cousin ( $M_{\text{cartoon}} = 5.21$ ;  $p = .0090$ ). The latter two conditions did not differ from one another ( $p > .61$ ). Further, participants were asked to indicate how wrong it felt to be eating the birthday cake, which underlies the desire to consume the cake depicting the face (vs. name;  $b = .43$ , 95% CI:  $.20$ ,  $.71$ ; vs. cartoon;  $b = .33$ , 95% CI:  $.10$ ,  $.60$ ) (Hayes 2013), thereby providing initial evidence for the underlying process. In other words, we demonstrate that the reluctance to consume was attenuated with a cartoon image of the cousin, which bore lower resemblance to the individual, and hence did not elicit as much negative affect.

Our last two studies replicate study 1's findings with actual consumption. In study 3 ( $N = 167$ ), a single-factor (portrayal of individual: face vs. name) design, undergraduate students were given M&M's featuring the business school dean's face (vs. name) to eat while they watched a video. Conceptually replicating study 1, students ate fewer M&M's that featured the dean's face ( $M_{\text{face}} = 6.39$  vs.  $M_{\text{name}} = 8.34$ ;  $p = .0355$ ), an effect that was driven by feelings of wrongness ( $b = -.43$ , 95% CI:  $-1.05$ ,  $-.02$ ).

Finally, in study 4 ( $N = 120$ ), using a similar procedure as study 3, we find that consumers ate fewer face M&M's, and that inclusion of the face design had negative spillover effects on actual consumption of other M&M's presented alongside the face (vs. name) M&M's. Specifically, using a 2(portrayal of individual: face vs. name; between) $\times$ 2(M&M type: individual vs. school; within) design, students were given M&M's featuring the dean's face (vs. name) to eat, along with M&M's featuring the business school's name. Results revealed that, consistent with study 3, students ate fewer M&M's that featured the dean's face ( $M_{\text{face}} = 3.89$  vs.  $M_{\text{name}} = 5.29$ ;  $p = .0282$ ). However, we also discovered a negative spillover effect, such that people who were given face M&M's alongside the school M&M's

consumed fewer overall M&M's than those who were given name M&M's ( $p = .0501$ ). Thus, for actual consumption, the discomfort of the mere idea of consuming a face appears to reduce overall consumption of related foods.

Taken together, the current research illustrates how the law of similarity can impact consumption in the context of personalized food products. Given the law holds that the image equals the object, and that actions taken on an object affect similar objects, we find that individuals avoid consuming personalized food products that bear a close resemblance to the depicted individual, as doing so elicits feelings of wrongness.

### The Self-Perception Connection: Why Consumers Devalue Unattractive Produce

#### EXTENDED ABSTRACT

Consumers reject unattractive produce, resulting in unsold product that generates billions of pounds of waste (Buzby, Wells, and Hyman 2014). To address this problem, some retailers have started selling unattractive produce, promoting this “ugly food” primarily via two approaches: positively framing its atypical appearance and/or substantially reducing the selling price. It is questionable, however, whether these strategies will be effective or sustainable in the long-term.

We suggest that there are better and more cost-effective ways to market unattractive produce. We ground our arguments in a social-cognitive understanding of *why* consumers reject “ugly” produce. Drawing on self-perception theory (Bem 1972) and self-signaling theory (Bodner and Prelec 2003), we demonstrate that consumers devalue unattractive produce because of *altered self-perceptions*: merely imagining the consumption of unattractive produce acts as a self-diagnostic signal that negatively impacts how consumers view themselves, consequently lowering their willingness to pay (WTP) for the unattractive produce relative to equally safe, but more attractive, alternatives. In line with this theorizing, across three studies and one field experiment, we show that this negative impact can be offset by altering the diagnostic value of the self-signal or bolstering consumers' self-perceptions by boosting self-esteem.

Study 1 tested our proposed self-perceptions process. Participants were randomly assigned in a 2(produce attractiveness: unattractive vs. attractive) $\times$ 2(produce type: strawberry vs. potato) between-subjects design. Participants imagined shopping and viewing an attractive or unattractive produce contained in a package. Participants indicated their WTP and answered a sixteen-item self-perceptions index ( $\alpha = .90$ ) after a filler task, indicating how they perceived themselves after imagining consuming the produce. We found that there was no difference across the two produce types and that produce type did not interact with our attractiveness manipulation, so we included produce type as a covariate. We found a main effect of attractiveness ( $p < .001$ ) where participants' WTP was significantly higher for attractive than unattractive produce. To test our proposed self-perception process, we conducted a mediation analysis estimating the indirect effect of produce attractiveness on WTP, with participants' self-perceptions as the mediator and produce type as a covariate. Results revealed that the indirect effect was statistically significant (95% CI: .07, .21).

In study 2, we tested our first intervention approach: altering the diagnostic value of the produce's self-signal. Participants were randomly assigned in a 2(produce attractiveness: unattractive vs. attractive) $\times$ 2(diagnostic value: diagnostic vs. non-diagnostic) between-subjects design. Taking part in two seemingly unrelated studies, participants completed personality items and a product choice task,

receiving feedback indicating that they had selected products that were either self-diagnostic or not. Then participants engaged in the same strawberry task as in study 1. As expected, there was a significant interaction on WTP ( $p = .048$ ). The simple effect of produce attractiveness on WTP was significant when participants believed their choices were self-diagnostic ( $p < .001$ ), such that those who imagined consuming the attractive produce indicated greater WTP than those who imagined consuming the unattractive produce. The simple effect was not significant, however, when participants believed their choices were not self-diagnostic ( $p = .244$ ). We additionally ran a moderated mediation analysis, with produce attractiveness as the predictor, self-perceptions as the mediator, and diagnostic value of choice as the moderator. We found a significant index of moderated mediation (95% CI: .09, 2.63) such that, when participants believed their behavior was diagnostic, self-perceptions mediated the effect on WTP (95% CI: -2.35, -1.00). Conversely, when participants believed their behavior was not self-diagnostic, the indirect effect became non-significant (95% CI: -.99, .26).

In studies 3-4, we tested our second intervention approach: bolstering consumers' self-perceptions by boosting self-esteem. In Study 3, participants were randomly assigned in a 2(produce attractiveness: unattractive vs. attractive) $\times$ 2(self-esteem: high vs. control) between-subjects design. After earning \$2 for completing an unrelated study, participants completed a self-esteem writing task. Participants then read about a produce box delivery service and saw an image of an open box containing an assortment of attractive or unattractive produce. Participants indicated their real WTP for a similar produce box, using an adaption of the BDM price elicitation method (Becker, DeGroot, and Marschak 1964), and answered our self-perceptions scale. Consistent with our predictions, there was a significant interaction on WTP ( $p = .039$ ), with participants indicating significantly lower WTP for unattractive (vs. attractive) produce when self-esteem was not boosted ( $p = .008$ ), but indifference when self-esteem was boosted ( $p = .979$ ). In fact, enhancing self-esteem effectively increased people's WTP for the unattractive produce by 22.4%. Subsequent moderated mediation analysis, with produce attractiveness as the predictor, self-perceptions as the mediator, and the self-esteem intervention as the moderator, was significant (95% CI: .007, .10). In the absence of the self-esteem intervention, self-perceptions mediated the relationship between produce attractiveness and WTP (95% CI: -.10, -.01). When consumer self-esteem was externally boosted, however, the indirect effect became non-significant (95% CI: -.04, .02), suggesting that momentarily enhancing self-esteem disrupts the negative influence of produce attractiveness on self-perceptions and, as a result, increases participants' WTP for unattractive to produce to be equal that of attractive produce.

In Study 4, conducted in a grocery store, we manipulated in-store advertising messages (self-esteem appeal: high vs. control) posted above a display of unattractive and attractive apples and measured shoppers' subsequent produce choices (i.e., attractive or unattractive) and self-perceptions (using a shortened 5-item index;  $\alpha = .90$ ). We predicted that the in-store self-esteem boosting advertisement would bolster shoppers' positive self-perceptions to a greater degree than the control advertisement, thereby increasing shoppers' likelihood of choosing unattractive produce. Indeed, shoppers exposed to the positive self-esteem ad were significantly more likely to choose unattractive apples ( $p = .006$ ); and this self-esteem marketing intervention increased shoppers' choice share of unattractive apples by 93.3%. Moreover, mediation analysis supported our predicted process, showing a marginally significant indirect effect of self-perceptions (90% CI: .02, .43).

In sum, we demonstrate that consumers systematically devalue unattractive produce because it threatens their self-perceptions. By identifying this novel process mechanism, we derived two methods for effectively offsetting this devaluation response: altering the diagnostic value of the self-signal and bolstering self-perceptions by boosting consumers' self-esteem.

### **SESSION OVERVIEW**

Research on psychological essentialism suggests that consumers may perceive objects to possess an inherent underlying essence that determines the object's identity. While marketing researchers have begun to study how such perceptions impact aspects of consumer behavior (e.g., Morales and Fitzsimons 2007; Newman and Dhar 2014), several intriguing questions require further investigation. For example, what factors make the perception (or transfer) of product essence more likely? How does the salience of a given product's essence influence perceptions and evaluations? Under what circumstances do consumers value (or devalue) products and brands with a strong and salient essence?

These are questions around which this session is focused. Our four papers tackle a range of phenomena surrounding the topic of psychological essentialism, providing new insights into both the antecedents and consequences of essence perception. As we demonstrate, the questions investigated are important for many marketing stakeholders, from advertisers and retailers (see especially the first two papers) to brand managers and consumers (see especially the last two papers).

Kramer, Guo, and Yang open the session by questioning an implicit premise of extant research on essence transfer (i.e., contagion)—that essence transfer is unidirectional. These authors not only show that essence transfer is bidirectional, but they also identify the key determinant of the direction of essence transfer: initial attention allocation. Three studies demonstrate that objects to the left are attended to first and therefore transfer their essence to adjacent objects.

Gunasti, VanBergen, and Irmak study how the physical location of a given product that appears with other identical products (i.e., product replicates) influences perceptions of the target product. The authors propose that product essence is perceived to be concentrated at the center (vs. edge) of a group. Three studies support this proposition, showing that a product from the center (vs. edge) of a group is perceived to be more efficacious and possess greater product essence.

Han and Newman shift the session's focus from the determinants of essence perception to its downstream consequences. Across

four studies, these authors show that consumers are drawn to *atavistic* products (i.e., products reverting to the past) when the broader social system is threatened. Results reveal that this occurs because atavistic products are perceived to possess the essence of their product category, thereby offering stability under system threat.

Finally, Gaustad, Samuelsen, Warlop, and Fitzsimons show that more brand essence is not always better. Their studies show that augmenting (vs. dampening) brand essence can both strengthen and weaken brand identification: When brand connection is linked to an ideal (actual) self-identity, augmenting brand essence increases (decreases) the perceived similarity between the self and the brand, thus influencing brand evaluations.

Together, these studies advance the study of psychological essence in several ways, offering a cohesive set of findings relating to the perception, transfer, and valuation of product essence. Given the range of entities to which psychological essentialism applies and the diversity of its consequences, this session has implications for researchers interested in such topics as branding, spatial processing, advertising, retailing, and consumer-brand relationships.

## **Magical Anchors: Initial Focal Attention Drives the Direction and Content of Essence Transfer**

### **EXTENDED ABSTRACT**

Research has documented essence transfer between objects upon direct or indirect contact, consistent with magical thinking's law of contagion (e.g., Kramer and Block 2014; Morales and Fitzsimons 2007; Rozin, Millman, and Nemeroff 1986). Extant findings have mostly focused on the effect of contagion on a target option or person, and have thus implicitly assumed that essence transfer is one-directional; namely, from a designated source to the designated target, with both designations made by the researcher. For example, Morales and Fitzsimons (2007) found that evaluations of cookies (i.e., the target) are lowered when they come in contact with sanitary napkins (i.e., the source). However, while negative essence of the sanitary napkins demonstrably transferred to the cookies and thereby lowering their evaluations, might some positive essence of the cookies also have transferred to the sanitary napkins, thereby rendering the evaluations of them more favorable? Secondly, if contagion can indeed be bi-directional in nature, such that any option may serve both as the target and as the source of essence transfer, such that contagion may be more prevalent than heretofore demonstrated, then what determines its principal direction?

We propose that the direction of essence transfer, and thereby the content of contagion, depends on the option that receives initial attentional resources, which renders it the contagion source. Specifically, we predict that contagion spreads from left to right, consistent with the reading direction of English and with research showing that individuals attend first in their visual field to the location where the writing system starts (Chan and Bergen 2005). Hence, when two options are encountered simultaneously, the one in the left visual field left will draw consumers' initial attention and thereby determine the content of the essence transfer. Three studies tested our proposition.

In our first study, participants were randomly assigned to conditions in a 2 (source: higher-quality vs. lower-quality) X 2 (contact: touch vs. no-touch) between-subjects design, which also included two control conditions. In the higher-quality source conditions, Johnson's (national brand) was shown to the left of Mannings (private-la-

bel brand) baby oil, whereas in the lower-quality source conditions, Mannings was shown to the left of Johnson's. Furthermore, in the touch conditions the two brands were depicted to be in physical contact, whereas in the no-touch conditions they were separated by one inch of space. In the higher-quality (lower-quality) control condition, Johnson's (Mannings) baby oil was shown on its own. After exposure to the stimuli, participants evaluated the two brands or single brand (in the control).

Analysis showed that attitudes toward the target brand were more favorable when the higher-quality (vs. lower-quality) brand was depicted to the left of the target, receiving initial attention. More interestingly, quality level of the source impacted attitudes towards the target only when the brands were touching, consistent with a contagion-based explanation. Further, when the two brands were touching, attitudes towards the higher-quality brand were less favorable when it was the target (vs. source), consistent with our expectation that the lower-quality option negatively contaminates the higher-quality one when the former draws initial attentional resources. Yet, attitudes towards the lower-quality option were more favorable when it was the target (vs. source). Additionally, attitudes towards the higher-quality target were less favorable when it was (vs. was not) in contact with the lower-quality source, whereas attitudes towards the lower-quality target were marginally more favorable when it was (vs. was not) in touch with the higher-quality source.

Our next study sought to draw attention away from options participants conventionally attend to initially, and exposed them to two brands sequentially. We expected that the left-to-right contagion effect is attenuated or eliminated when reading direction and reveal direction are in conflict with each other. The study had two between-subject factors (anchor: higher-quality vs. lower-quality option; reveal direction: left-to-right vs. right-to-left). We developed four video clips, corresponding to the four conditions. After viewing the video clip, participants were asked to evaluate both brands. Analyses yielded a marginally-significant anchor X reveal order interaction. Specifically, we replicated the results from study 1 when the brands were revealed consistent with the reading direction of English; however, when the brands were revealed from right-to-left, attitudes towards the higher-quality option were significantly less favorable when it was the target versus the source, while attitudes towards the lower-quality option were more favorable when it was the target versus the source.

To examine the role of attentional resources, we tested in our last study if the effect is limited to participants motivated to devote cognitive resources to the task (Petty and Cacioppo 1986). We expected that participants high (but not those low) in attention would rate a regular soup to be healthier when it was in contact with a healthy soup that touches (vs. does not touch) it. We again developed four video clips, in which the two brands were revealed sequentially from left to right, revealing either the healthy soup or the control soup before the target soup, with the two soups either in (or not in) physical contact. The healthy soup was always depicted to the left of the regular soup. After exposure to the soups, participants rated how healthy the target soup was and the amount of attention they paid to the stimuli. Analyses revealed a significant 3-way interaction among the factors: when the soups were touching, the regular soup was rated healthier as participants paid increasingly more attention. Further, reveal direction predicted healthiness ratings task only among those devoting high attention resources.

Thus, our studies confirm that essence transfer can indeed be bi-directional, and that the direction (and thereby content) of essence transfer depends on which option receives initial attentional resources. We thereby not only extend the scope of contagion re-

search, but also provide advice for retailers who may strategically direct shoppers through stores in a direction that renders particular options to be the source of essence transfer, such as national brands, thereby increasing evaluations of private-label store brand they are in contact with.

### **Inside Out: Product Essence is Perceived to be Concentrated in the Center of a Group of Products**

#### **EXTENDED ABSTRACT**

Research on psychological essentialism (Medin and Ortony 1989) suggests that products are perceived to possess an inherent defining essence (Mishra 2009; Morales and Fitzsimons 2007; Newman and Dhar 2014). Our research focuses on the perceived location of this essence when consumers are exposed to multiple units of the same product arranged adjacently (i.e., as a group of product replicates). For example, marketers present multiple facings in store aisles, across rows of vending machines, and on refrigerator shelves. While marketing researchers have studied how the organization (Pizzi and Scarpi 2016) and relative quantity of identical products (Parker and Lehman 2011) in such displays impacts consumer behavior, we know less about how the physical location of a given product impacts product perceptions or evaluations. Do consumers viewing an array of product replicates perceive different levels of essence at different areas of the display? If so, how does the location of a particular product within a set of product replicates (i.e., towards the center vs. edge of the group) impact product perceptions?

We propose that when consumers consider such arrays, they perceive product essence according to a gravitational density metaphor. More specifically, we propose that because product replicates all possess the same essence, when consumers view such replicates as a group, they perceive that the essence of these products is concentrated at the center (vs. edges) of the group. An implication of our conceptualization is that a product taken from the center (vs. edge) of an array will be perceived more favorably in terms of the products' defining characteristic, i.e., the essence.

It has been shown that when presented with a horizontal array of several (different) brands, consumers are most likely to choose the brand in the middle (Atalay, Bodur, and Rasolofoarison 2012; Greenacre et al. 2016; Valenzuela and Raghuram 2009). Two explanations offered for this effect are that the middle brand receives the most visual attention (Atalay et al. 2012) and that consumers have lay beliefs suggesting that retailers put the most popular options in the middle (Valenzuela, Raghuram, and Mitakakis 2013). The studies in this domain have thus focused on preference for different brands due to visual and perceptual cues. We extend this literature by investigating how the location of a particular product in a horizontal array of *identical* products from the same brand impacts the perceptions of individual products in the array. Our work thus builds on previous research in two important ways: First, lay beliefs about popularity no longer apply to a situation in which identical units of a single brand are considered. Second, by focusing on perceptions of a specific product unit, rather than brand-wide perceptions or choice, we develop a novel conceptualization describing how consumers perceive product essence in arrays of product replicates.

We test our propositions across three studies and find consistent support. In study 1, 147 undergraduate business students participated in a single-factor study with three conditions involving purchasing Tylenol. We showed participants a (virtual) shelf with five side-by-side facings of Tylenol, and asked them to imagine taking the leftmost vs. center vs. rightmost package. As the essence of Tylenol is its ability to relieve pain, our DV comprised two nine-point ques-

tions about Tylenol's efficacy ( $r=.77$ ). A one-way ANOVA on this composite revealed a significant effect of product location ( $p=.03$ ): The center product ( $M=7.07$ ) was perceived as more effective than both the leftmost ( $M=6.21$ ;  $p=.01$ ) and rightmost product ( $M=6.43$ ,  $p=.05$ ).

Study 2 built on study 1 by allowing participants to consume the product taken from the left vs. center vs. right of a display. We informed 120 students that they would be participating in a taste test, and they therefore needed to cleanse their palates with saltine crackers. Participants were exposed to five packages of saltine crackers and instructed to take and eat a package from the center vs. edge (left vs. right side was counterbalanced). Next, they rated the effectiveness of the consumed crackers at cleansing their palates on a 7-point agree-disagree scale. An independent-samples  $t$ -test revealed that the center crackers ( $M=3.00$ ) were rated significantly more effective than crackers from either edge ( $M=2.18$ ,  $p<.01$ ). As we described saltine crackers as "an ideal product to cleanse your palate" at the study's outset, these results support our proposition that products from the center (vs. edges) are perceived to possess more product essence.

Our final study built on the prior studies in three critical ways: First, we allowed participants to freely choose a product themselves, instead of asking their perceptions of a product we manipulated them to choose. Second, we manipulated whether participants had a goal to choose a product high vs. low in essence. Third, we measured to what extent the chosen option was perceived to possess the products' essence, aiming to show that essence perceptions mediate choice.

Participants in study 3 were 150 Mturk workers who were asked to imagine buying a brownie for a friend. We manipulated whether their friend wanted vs. did not want to indulge, therefore activating a goal to choose a brownie with high vs. low essence. We showed participants an array of five brownies and asked which they would choose. Afterwards, we asked participants to indicate their agreement with two statements about the chosen piece exemplifying the essence of indulgence (adapted from Newman and Dhar 2014). Results showed that activating a goal to choose the most (least) indulgent brownie led to significantly greater (lower) likelihood of choosing the brownie in the middle ( $p<.01$ ). Further, choice was mediated by perceptions that the center (edge) pieces had greater (less) indulgent essence than other pieces.

Together, these studies show that the horizontal location of even identical products impacts product perceptions. Specifically, consumers perceive that products towards the center of a display have greater product essence than those towards the edge. These results thus both make theoretical contributions (by showing that a gravitational density metaphor describes how consumers perceive the essence of multiple identical products) and have practical implications for retailing and other contexts in which multiple product replicates are displayed together.

## System Justification and the Preference for Atavistic Products

### EXTENDED ABSTRACT

Consumers do not always prefer the most technologically advanced products. In cities throughout the world, one can find shops selling vinyl records, people riding single-gear bicycles and cafes serving pour-over coffee drinks. The popularity of these relatively antiquated products and services is puzzling given the existence of functionally superior alternatives, which are often cheaper. The present research interprets this phenomenon as an instantiation of atavism and seeks to explain it through the lens of system justification theory (Jost and Banaji, 1994; Kay and Zanna, 2009). Atavism is

defined as the "recurrence of, or reversion to a past style, manner, outlook, approach, or activity" (Merriam-Webster, 2016). In its everyday use, atavism often refers to the preference for "retro" goods, services, methods of production, and ways of life. Importantly, the current research proposes that atavism can be distinguished from nostalgia, which typically refers to a preference for products from one's own past (Holbrook and Schindler, 1991).

The current studies investigate how preferences for atavistic products are related to more fundamental psychological motivations to view one's broader social system as just, fair, and good (i.e., system justification theory; Jost and Banaji 1994). Several recent studies have identified an import causal link between system justifying ideologies and a preference toward "essential" explanations. For example, recent experiments have shown that threats to the social system enhance the belief that various social phenomena are due to inherent, essential causes (Brescoll, Uhlmann, and Newman 2013) as well as preferences for products that provide a source of stability, such as national brand products (Cutright, Wu, Banfield, Kay, and Fitzsimons 2011). Drawing on this work, we propose that atavistic products may serve to satisfy system justifying motives because those products are seen as reflecting the core, or *essence* of the particular product category and therefore, consuming them provides a source of stability when the broader social system is threatened.

Study 1 tested the relationship between atavism and system confidence. Specifically, this study examined whether lower system confidence is significantly correlated with the preference for atavistic products. In constructing the stimuli for Study 1, we were mindful of two potential confounds related to inferences about antiques. Therefore, we constructed pairs of actual products (e.g., the choice of a record player versus an mp3 player) that were the same price and were both new. A pretest confirmed that one product was rated as more functional, while the other was rated as more "essential" to the product category.

Participants indicated which product they preferred for eight product pairs. Participants then indicated their perception of system stability-instability using an established eight-item System Confidence Scale (Kay and Jost, 2003). Participants also completed two additional scales. One was a twelve-item Self-Concept Clarity Scale (Campbell et al., 1996), which assesses the extent to which one's self-beliefs are consistent and stable. A second was the Meaning in Life Questionnaire (MLQ; Steger and Frazier, 2005). Consistent with our hypothesis, we observed a significant negative correlation between atavism and system confidence,  $r = -0.15$ ,  $p = 0.05$ . That is, participants who were lower in system confidence showed a greater preference for the atavistic products (over the functionally superior products). However, we did not observe significant correlations between atavism and the other constructs.

Study 2 provided converging evidence for the unique relationship between system-justifying motives and atavism by testing causality. Further, this study provided a source of discriminant validity among consequences by examining whether system-justifying motives also affect established measures of nostalgia. Using an established manipulation of system-justifying motives, participants were randomly assigned to either the system threat condition or the system affirmation condition. (Jost et al., 2005). Then, participants completed atavism proneness (adapted from Holbrook, 1993) and nostalgia proneness scales (adapted from Marchegiani and Phau, 2013). As hypothesized, manipulations of system threat (vs. system affirmation) selectively enhanced atavistic beliefs but not nostalgic beliefs. These results support that system justifying motives is an antecedent of atavism, and theoretically differentiate the concept of atavism, a

general longing and preference for antiquated products, from nostalgia, a general longing for objects associated with one's own past.

Study 3 assessed the role of essentialism in enhancing preference for atavistic products. First, participants read a short paragraph either endorsing or refuting the idea of a product category *essence*. Then, participants indicated their atavistic preferences using the same measure as Study 1. As predicted, participants provided higher valuation of atavistic products when the notion of a product category essence was endorsed than when the same idea was refuted.

Although Study 2 demonstrated a unique effect of manipulating system threat on atavistic proneness index, it did not provide direct evidence that manipulating system threat increases atavistic preferences. In Study 4 participants were randomly assigned to either a system threat or system affirmation condition (cf. Study 2). Then, participants rated their preference for atavistic products (similar to the ones used in Study 1). Replicating previous study results, merely exposing participants to a news article that activated system justifying motives significantly enhanced participant's preference for atavistic products over functionally superior alternatives.

Atavism is a fascinating consumer phenomenon that has been relatively unexplored in the literature. This paper identifies the psychological mechanisms underlying preferences toward atavistic products. In addition to highlighting one of the psychological motives underlying atavism, the current studies also help illuminate the connections between atavism, system justification and psychological essentialism. Consistent with previous research showing that people endorse essentialist explanations in cases of system threat (Brescoll, Uhlmann, Newman, 2013), we show that people show a preference for atavistic products when their broader social system is threatened.

### Too Much of a Good Thing? Consumer Response to Changes in Brand Essence

#### EXTENDED ABSTRACT

The value of consumer-brand bonding is well documented (MacInnis, Park, & Priester, 2009). The current research investigated a potential disadvantage. We investigated consumer responses to modifications in the magnitude of associations central to the brand – changes that either dampen or augment brand essence. For example, suppose that the association most strongly linked to Mountain Dew is “exciting.” Both managerial actions that make Mountain Dew appear less exciting (dampen), and actions that make the brand appear even more exciting (augment), represent a change in brand essence.

We have proposed that consumer responses to such changes depend on the degree of self-brand connection (SBC) (Escalas & Bettman, 2003). We expected high degree SBC consumers to respond negatively to changes that *dampen* brand essence, as such changes reduce the brand's ability to express self-identity. However, we expected that responses to changes that *augment* brand essence depend not only on the degree of SBC, but also on the part of the consumer's self to which that brand connects. If the brand is connected to the consumer's ideal self, then augmentation of that brand's essence increases the brand's ability to signal an ideal identity (i.e., it increases the brand's efficacy as an instrument for self-enhancement). Conversely, if the brand is connected to the consumer's actual self, then such changes can reduce the perceived similarity between the actual self and the brand (i.e., it decreases the brand's efficacy as an instrument for self-verification). We conducted three studies to investigate our predictions.

Study 1 applied a brand acquisition context. The design was 2 (brand connection: low vs. high)  $\times$  2 (self-identity: ideal vs. actual)

$\times$  2 (brand essence change: dampen vs. augment), with consumer response as the dependent variable.

The participants (MTurk,  $N = 526$ ) self-selected individual target brands (according to condition) and reported the three associations they considered most descriptive of “their” brand. Subsequently, the participants read a scenario describing the acquisition of “their” brand. The scenario stated that the acquisition would either dampen or augment (according to the condition) brand essence in terms of the three brand associations the participants had evaluated as most descriptive. The acquirer was a fictitious venture capital company. Finally, we measured the participants' responses to the acquisition.

As expected, the results showed that the participants in the high SBC condition responded more negatively to changes that *dampen* brand associations, compared to participants in the low SBC condition ( $M_{low} = 28.33$  vs.  $M_{high} = 16.09$ ,  $p < .01$ ).

Our theory suggests that self-identity makes a difference only in one situation; that is, when consumers are highly connected to the brand and when associations are augmented. In this situation, the responses of those in the actual SBC condition will be more negative compared to those in the ideal SBC condition. The results supported this prediction ( $M_{ideal\ self} = 54.34$  vs.  $M_{actual\ self} = 44.91$ ,  $p < .01$ ). No such difference was found in the other conditions ( $M_{ideal\ self} = 34.60$  vs.  $M_{actual\ self} = 31.25$ ,  $p = .28$ ).

In Study 2 ( $N = 131$ ), we utilized real changes in brand architecture at a college. The data were collected in two waves. First, two months before the students learned about the changes, we measured their ideal and actual SBC to the college. Subsequently, after the changes were made public, we arranged an information meeting in which we informed the students that the changes would augment the current brand essence of the college to make it even more serious, professional, and business oriented (pretested as the brand's essence). Finally, we measured the participants' responses to the changes.

As predicted, regression analysis revealed a positive effect of ideal SBC ( $b = .36$ ,  $t(128) = 3.33$ ,  $p < .01$ ) and a negative effect of actual SBC ( $b = -.24$ ,  $t(128) = -2.49$ ,  $p < .02$ ) on the response to the brand essence augmentation. The correlation between ideal and actual SBC was only moderate ( $r = .45$ ,  $p < .01$ ), and multicollinearity statistics were acceptable (tolerance = 0.81, VIF = 1.25).

Study 3 applied a brand essence augmentation scenario. Participants (MTurk,  $N = 207$ ) were randomly assigned to two groups of a single-factor (ideal vs. actual SBC) design. We followed a similar procedure as in Study 1, except that all the participants read a scenario about a repositioning that augmented the essence of “their” brand. Finally, we measured the response to the brand essence augmentation, as well as the brand's efficacy for self-enhancement and self-verification.

ANCOVA showed significant differences between groups in response to the repositioning ( $M_{ideal\ sbc} = 65.60$  vs.  $M_{actual\ sbc} = 57.17$ ,  $F(2, 204) = 5.34$ ,  $p < .03$ ). Bootstrapping analysis showed that self-enhancement efficacy ( $a_1b_1$  path:  $b = .13$ , CI 95%: .05 to .23), but not self-verification efficacy ( $a_2b_2$  path:  $b = -.03$ , CI 95%: -.07 to .02), mediated the effect of ideal SBC on consumer response. This result indicates that when consumers learn about changes that augment brand essence, higher degrees of ideal SBC will be associated with an increase in that brand's self-enhancement efficacy, and thus a positive response. Further analyses showed that self-verification efficacy ( $a_2b_2$  path:  $b = -.07$ , CI 95%: -.13 to -.03), but not self-enhancement efficacy ( $a_1b_1$  path:  $b = -.02$ , CI 95%: -.10 to .06), negatively mediated the effect of actual SBC on consumer response. This result indicates that higher actual SBC was associated with de-

creased brand's self-verification efficacy, and thus more negative responses to changes that augment existing brand associations.

Our results show that consumers with a high degree of SBC respond more negatively to changes that dampen brand associations compared to others. Counterintuitively, changes that augment brand associations can also lead to unfavorable consumer sentiments in certain instances. When brand connection was linked to an ideal self-identity, changes that augmented brand essence increased the brand's ability to signal an ideal identity. Conversely, when brand connection was linked to actual self-identity, augmenting brand essence reduced the perceived similarity between the self and the brand, causing brand identification to deteriorate.

Merrie Brucks, University of Arizona, USA

### **SESSION OVERVIEW**

As consumer reliance on digital information increases, it is important that the information is credible. Unfortunately, consumers encounter more fake reviews (Luca and Zervas 2016) and fake news (Byers 2017; Lewandowsky et al. 2017) than ever before. Some websites, like Yelp and Facebook, have employed strategies to decrease the prominence of fake information on their platforms. Do these strategies work? Does it depend on the audience? What about other available information? These are the fundamental questions that are addressed in this session.

While consumers generally accept information they encounter as honest (Gilbert 1991), the prominence of fake information online calls for an investigation into how consumers process this information, given the salient veracity concerns. This session takes a multi-methods approach to exploring this topic by combining traditional experiments with other forms of primary data and secondary data to provide comprehensive accounts of how consumers respond to fraudulent information, such as fake reviews and fake news. Across the four papers, we demonstrate how consumers form perceptions regarding the veracity of the information, and how they respond when it is deemed fake.

In the first paper, Watson and Kirmani investigate consumer responses to fake review alerts. They demonstrate that consumers attempt to correct for fake reviews, but may also seek justice, depending on the valence of the fake reviews. Next, Ding, Mayrhofer, and Johar investigate how “related articles” can help reduce the effects of fake information. They demonstrate that related articles disputing a reader’s political ideology does not decrease the believability of the news, but related articles disputing the findings of news that is counter to their political ideology does decrease believability. Following this, Han and Rao continue the investigation in the political domain and demonstrate an asymmetric response to the acceptance of ambiguous claims. Republicans are more likely to accept, and less likely to fact check, claims in the presence of other Republicans, compared to Democrats. Lastly, Lane and Brucks present a conceptual overview of today’s information challenges, integrating the findings of

prior literature and the other papers in this session to provide a path forward to investigating questions in the “information age”.

Taken together, these four papers contribute to the literature by investigating similarities and differences in information acquisition and processing from the past to today. Practically, they also hold significant implications for current societal issues where fake information is more pervasive than ever before. With a diverse blend of methodologies and theoretic lenses applied to this issue, this session should have broad appeal to audiences interested in word-of-mouth, fake information, and consumer judgments and decision-making, more broadly.

## **Red Flag! The Consequences of Alerting Consumers to Fake Reviews**

### **EXTENDED ABSTRACT**

Defined as those written with the intent to mislead or deceive, fake reviews appear to be a major concern online. Recent research suggests that upwards of 15% of online reviews may be fake (Luca and Zervas 2016). And this seems to be consistent with industry perceptions, as Yelp has disclosed that they remove roughly 20% of their reviews for lacking credibility and helpfulness. Even Amazon, which has sued over 1100 creators of fake reviews, is facing a fake review problem that is “worse than ever” (Tuttle 2015; Woolcott 2017). Indeed, an entire industry has arisen around the creation of fake reviews, as “online reputation management” firms will post positive reviews for your business, and negative reviews for your competitors, for a nominal fee (Segal 2011). This would suggest that the fake review problem may be more pervasive than academics have previously considered.

In an effort to increase transparency, some websites (e.g., Yelp and TripAdvisor) place temporary fake review alerts on a brand’s page when they catch that brand involved with fake reviews. For example, once Yelp identifies that a brand has attempted review fraud (e.g., purchasing fake reviews, incentivizing positive reviews, etc.), that brand’s sub-page within Yelp will feature an alert for the next 90 days (Curtis 2014). These alerts, explain the brand’s infraction to consumers. What happens to the brand during and after such an alert? Do consumers penalize the brand? Do consumers remember brands which previously had alerts? These are some of the questions we address.

Whereas prior research has investigated the characteristics of fake reviews (Feng et al. 2012) or the characteristics of brands that solicit fake reviews (Mayzlin, Dover, and Chevalier 2014; Luca and Zervas 2016), we investigate how fake review alerts affect consumer responses to reviews. Reviews help consumers make informed decisions (Gilbert 1991), but fake review alerts may activate persuasion knowledge (Friestad and Wright 1994), leading consumers to attempt to correct for any perceived sources of bias (Campbell and Kirmani 2000). In addition to accuracy motives, consumers may also seek justice for the manipulation attempt when they can attribute the blame to a source (Ward and Ostrom 2006; Grégoire, Tripp, and Legoux 2009). Fake positive reviews are likely to come from the brand itself, whereas fake negative reviews are likely to come from an unknown competitor, meaning that the desire for justice will be greater in the presence of fake positive, versus negative, review alerts.

Study 1 (n = 1885) uses reviews web-scraped from Yelp to examine brand ratings before, during, and after a fake review alert is

displayed. We also examine the effect of the alert on “recommended” reviews and “not recommended” reviews which Yelp considers more likely to be fake. As such, this study addresses the effect of a fake review alert on both fake and authentic reviews. A 2 (review type: not recommended, recommended)  $\times$  3 (90-day time period: before alert, during alert, after alert) ANOVA on brand ratings yielded main effects of review type ( $p < .001$ ) and time period ( $p < .001$ ), qualified by a significant interaction ( $p = .015$ ). *Before* the alert, ratings were significantly higher for the not recommended reviews ( $M_{\text{not recommended}} = 4.64$ ,  $M_{\text{recommended}} = 4.01$ ;  $F(p < .001)$ ), consistent with the greater likelihood of not recommended reviews being fake. *During* the alert, ratings were marginally higher for the not recommended reviews ( $M_{\text{not recommended}} = 3.26$ ,  $M_{\text{recommended}} = 2.98$ ;  $p = .07$ ), suggesting that the alert decreases the prevalence of fake reviews. *After* the alert, ratings were not significantly different for review types ( $M_{\text{not recommended}} = 4.19$ ,  $M_{\text{recommended}} = 4.04$ ;  $p > .35$ ), which suggests that fake review alerts may have a long-lasting impact in reducing the volume of fake reviews.

Study 2 ( $n = 278$ ) used a controlled lab experiment to test consumer responses to both fake positive and negative review alerts. A 2 (fake review alert: negative, positive)  $\times$  3 (time period: before alert, during alert, after alert) repeated measures ANOVA on brand evaluation yielded a main effect of the alert ( $p < .001$ ), qualified by a significant interaction ( $p < .001$ ). As expected, this study replicated the findings of a fake positive review alert exhibited in Study 1 ( $M_{\text{before}} = 2.62$ ,  $M_{\text{during}} = 2.44$ ,  $M_{\text{after}} = 2.64$ ), while demonstrating the inverse pattern for fake negative review alerts ( $M_{\text{before}} = 2.63$ ,  $M_{\text{during}} = 3.02$ ,  $M_{\text{after}} = 2.82$ ).

Study 3 ( $n = 150$ ) demonstrated our asymmetric mediation process where the perception of average rating accuracy mediates both fake negative ( $\beta = -.08$ ;  $CI_{95\%} = [-.166, -.017]$ ) and positive ( $\beta = -.12$ ;  $CI_{95\%} = [-.252, -.019]$ ) review alerts, but the desire for justice only mediates fake positive review alerts ( $\beta = -.22$ ;  $CI_{95\%} = [-.380, -.117]$ ). While Study 4 ( $n = 310$ ) demonstrates the interaction between a fake review alert and salient aggregate information ( $p < .001$ ). Without the salient aggregate information, our same pattern emerges in the presence of a fake positive review alert ( $M_{\text{negative}} = 2.08$ ,  $M_{\text{positive}} = 3.03$ ;  $p < .001$ ), but this is attenuated in the presence of the aggregate information ( $M_{\text{negative}} = 2.43$ ,  $M_{\text{positive}} = 2.73$ ;  $p = .017$ ). Thus, refocusing consumers’ attention on the authentic information can attenuate their need to correct.

Taken together, the results of these four studies demonstrate the effect of a fake review alert on consumers’ subsequent brand ratings. We show that a bias is created as a result of the fake review alerts, but can be attenuated by re-emphasizing the aggregate information after presenting the fake review alert. These results have significant implications for websites which use fake review alerts and consumers who encounter them. We suggest that websites carefully consider how they deploy fake review alerts to avoid biasing their consumers and creating suboptimal outcomes.

## Can the Presentation of “Related Articles” Correct Misperceptions from False Information on Social Media?

### EXTENDED ABSTRACT

One way in which social media platforms such as Facebook can help build a better-informed populace is to provide information that includes multiple points of view. For example, Facebook provides “Related Articles” in the news feed in the face of potentially false headlines. Can providing “Related Articles” correct beliefs? If so, for whom will those articles be influential? This research aims to investigate these questions.

The majority of American adults consume news that is spread on social network sites (Gottfried and Shearer 2016), putting the quality of this news content in the spotlight. Fake news has become a major concern for society as well as the networks themselves, as users seem unequipped to cope with the vast number of such stories (e.g. Lewandowsky et al. 2017). In the context of the 2016 US presidential campaign, the notion of fake news spreading on social media has been highly discussed and defined as being a threat to our common understanding of the truth (Jun, Meng, and Johar 2017). One possible way to curb the spread of fake news is to encourage users to fact-check information (Amazeen 2017). A few studies investigated interventions that could increase user’s fact-checking behavior (e.g., Pennycook and Rand 2017; Nyhan et al. 2017), and our research aims to contribute to this literature.

One possible way to get consumers to fact-check is to incorporate Facebook’s “related articles” function. Bode and Vraga (2015) showed that corrections to a fake headline, displayed by the Facebook algorithm diminished user’s misperceptions regarding stories related to scientific facts. Misinformation is also, if not more, of a challenge in the context of political topics. Based on the theory of motivated reasoning (Kahan 2016), it is especially difficult to correct misperceptions if they are congruent with a person’s current belief. We aim to advance our understanding of corrective interventions on social media by focusing on how the political orientation of readers interacts with the political stance of news headlines to affect beliefs. Further, we test whether and how the presentation of related articles can correct misbeliefs.

Experiment 1 recruited 72 Republicans and 109 Democrat participants in the U.S. through mTurk. Participants were asked to read six Facebook posts in a random order and to rate the perceived truth of each post’s headline. Four posts were the manipulated target posts and two were filler posts held constant across participants. A pretest showed that Republicans were more likely to perceive two out of four headlines to be true [A: “Obama did in fact unconstitutionally spy on Trump throughout the presidential election.”  $M_{\text{Republicans}} = 3.31$  vs.  $M_{\text{Democrats}} = 1.80$ ,  $t(1,125) = 6.87$ ,  $p < .001$ ; B: “Nearly \$7 of every \$10 donated to presidential candidates in this election cycle from the oil and gas industry has gone to the Democratic party.” 3.07 vs. 2.11,  $p = .01$ ] and Democrats were more likely to perceive the other two headlines to be true [C: “President Trump is cutting the CDC budget by 80 percent.” 2.20 vs. 3.10,  $p < .001$ ; D: “Melania Trump plagiarized her statement on Women’s History Month from Michelle Obama.” 2.40 vs. 3.94,  $p < .001$ ]. Similar to the 4-condition design as in Bode & Vraga (2015), participants read the Facebook headlines with two “related articles” below the headlines. These two “related articles” were designed as follows: either both confirmed the headline, both debunked the headline, one confirmed and one debunked the headline, or both were irrelevant messages. Participants were asked to rate their perceived truth of each headline on a 5-point (1-definitely false, 5-definitely true) scale.

We created matching vs. mismatching conditions based on political affiliation and message. Results showed that “related articles” had no effect on perceived truth of headlines when the headlines matched participants’ political stances ( $F(3,177) = 0.30$ ,  $p = .84$ ). This suggests that Facebook’s efforts to use these headlines to correct false belief are not effective; means are fairly high across conditions ( $M_{\text{irrelevant}} = 3.28$ ,  $M_{\text{confirm}} = 3.35$ ,  $M_{\text{debunk}} = 3.19$ ,  $M_{\text{mixed}} = 3.36$ ). However, when headlines mismatched participants’ political stance, both confirm and debunk articles reduced perceived truth of the headlines, compared to unrelated and mixed articles ( $F(1,177) = 3.72$ ,  $p = .055$ ). In other words, people respond to debunking efforts for claims that they already tend to disbelieve ( $M_{\text{irrelevant}} = 2.64$ ,

$M_{confirm} = 2.37$ ,  $M_{debunk} = 2.21$ ,  $M_{mixed} = 2.5$ ). What is surprising here is that confirming a mismatched headline counterintuitively reduces beliefs, especially for Republicans ( $M_{irrelevant} = 3$ ,  $M_{confirm} = 2.59$ ,  $M_{debunk} = 2.5$ ,  $M_{mixed} = 2.97$ ). Skepticism of the corrective message that goes against one's prior beliefs may be responsible for this effect.

We conducted Experiment 2 with 94 Republicans and 173 Democrats with a similar procedure as in Experiment 1. Results showed no effect for any intervention (compared to the unrelated articles condition) on beliefs in matched ( $M_{irrelevant} = 3.38$ ,  $M_{confirm} = 3.43$ ,  $M_{debunk} = 3.25$ ,  $M_{mixed} = 3.37$ ;  $p = .73$ ) or mismatched claims ( $M_{irrelevant} = 2.40$ ,  $M_{confirm} = 2.58$ ,  $M_{debunk} = 2.30$ ,  $M_{mixed} = 2.26$ ;  $p = .24$ ). The only glimmer of hope is that debunking works for Democrats in this study ( $M_{irrelevant} = 3.49$ ,  $M_{confirm} = 3.67$ ,  $M_{debunk} = 3.24$ ,  $M_{mixed} = 3.42$ ;  $F(1,169) = 2.98$ ,  $p = .086$ ).

After introducing disputed flags in December 2016, Facebook began to use "Related Articles" in August 2017, followed by using "trust indicators" for publications in December 2017 and collaborating with Google from March 2018 (Larson 2017; Bradshaw and Nicolaou 2018), to stem misinformation. More research is urgently needed to find out whether providing additional information in the form of related articles can work under certain conditions. This study highlights the fact that research is also needed to investigate the underlying mechanism of how related articles reduce truth perceptions. Further research is also needed to understand how inferences regarding the source of related articles (sponsored vs. algorithm found) can moderate this effect.

### Asymmetry in Susceptibility to Fake News due to Political Orientation

#### EXTENDED ABSTRACT

Recent Congressional testimony indicates that purveyors of fake news might have reached one hundred twenty six million American users in 2016 (Byers 2017). Further, in the 2016 Presidential election, fake news stories shared over social media substantially favored Donald Trump over Hillary Clinton (Allcott and Gentzkow 2017; Silverman 2016; Narayanan et al. 2018). The observation that fake news favored Trump over Clinton indicates an asymmetry in the supply of fake news, implying that there might be a corresponding asymmetry in the demand for and/or susceptibility to fake news. If there is an asymmetry in susceptibility to fake news, then it would be valuable to identify the cause of this differential susceptibility and the mechanisms that might reduce this susceptibility.

It is well established that conservatives and progressives differ on numerous traits. In particular, conservatives are more likely to accept vague statements as true because they have a low need for cognition and rely on intuitive, heuristic-based cognitive processing. As a consequence, they are less likely to question the truth content of ambiguous claims, and therefore, the manifestation of the truth bias is likely to be higher for conservatives than for progressives. In addition to this main effect, we predict that the manifestation of the truth-bias (and associated reduction in vigilance) will be enhanced when conservatives are in the company of other conservatives. This prediction is based on the finding that conservatives "...possess a stronger desire to share reality with fellow ideologues..." (Stern et al. 2014). An individual's desire to share reality reflects a desire to receive social verification, and in an environment in which shared reality is high because of the presence of like-minded others, perceptions of in-group consensus will tend to be high as well. The presence of the in-group renders the social environment benign since the in-group represents positive social information due to a sense of shared reality. This sense of safety will in turn lead to a decline

in vigilance and an increase in the truth-bias. Since progressives' need to share reality with fellow ideologues is weaker, the differences in vigilance and manifestation of the truth-bias when in the presence of the in- versus out-group will likely be less pronounced among progressives than among conservatives.

Study 1 tests our core premise, that Republicans in the presence of Republicans would display higher levels of truth bias and lower levels of vigilance. Participants logged onto a simulated online news website where they evaluated 36 ambiguous statements (Jun et al. 2017). Participants could identify each statement as true or false, or, they could raise a fact-checking "flag". In Group Republican (vs. Group Democrat) condition, participants evaluated the statements ostensibly in the company of 103 others currently logged in who were largely from "red" (vs. "blue") states. Participants responded to the question about their political affiliation after evaluating all statements. The results revealed that Republicans tended to identify more statements as true ( $p < .05$ ) and flag fewer statements ( $p < .05$ ) in the Group Republican condition compared to in the Group Democrat condition. No significant differences emerged for a similar comparison among Democrats in both true rates and flagging rates ( $p > .70$ ).

Study 2 had two goals: a) to replicate Study 1; and b) to examine whether Republicans' tendency to display the truth-bias is mediated by shared reality and perceived consensus. We included a Group Unidentified condition in which there was no mention of the political orientation of others. We expanded the set of statements into two sets of 25 statements that had either a conservative or progressive tone respectively (Jun et al. 2017). In order to measure shared reality, participants were asked how important it was that they see the world in a similar way as people who generally share their beliefs do, and to measure perceived consensus, participants were asked their perception of the percentage of the others who were logged who had made judgments similar to theirs (Stern et al. 2014). When responses to the two sets of statements were combined, Republicans identified more statements as true ( $p < .02$ ) and flagged fewer statements ( $p < .03$ ) in the Group Republican condition compared to the Group Democrat condition, and the Group Unidentified condition. Democrats did not exhibit significant differences in both true rates ( $p > .80$ ) and flagging rates ( $p > .70$ ) across conditions. Republicans in the presence of Republicans experienced a greater level of shared reality, which was associated with higher perceived consensus, which was ultimately associated with higher true rates.

In Study 3, we test the idea that, because of their higher motivation to share reality and perceive in-group consensus, Republicans would anchor on base rate information provided by Republicans more so. In the High (vs. Low) suspicion condition, participants were told that 103 other participants (Republican or Democrat) had seen 36 statements and concluded that 28 (vs. 4) statements needed to be flagged. We find that Democrats tend to anchor on the flagging rates of prior participants regardless of their party affiliation. However, Republicans anchor on the flagging rates of Republican others more so than Democrat others.

To what extent is the shared reality motive likely to drive Republican's behavior with respect to the truth bias and vigilance not only contemporaneously (Studies 1 and 2) and retrospectively (Study 3), but also prospectively? We examine this issue in Study 4 by making participants accountable to prospective participants. Participants were informed that after they were done, 103 Republican or Democrat participants would evaluate the same statements, and the focal respondent's overall ratings of the statements would be presented to these participants. Focused tests revealed that the true rate displayed by Republicans who were accountable to other Republicans was significantly lower ( $p < 0.02$ ) and their flagging rate was

marginally higher ( $p < 0.07$ ) than that of Republicans accountable to other Democrats, indicating that a sense of accountability to the in-group contributed to a reduction in the truth bias among Republicans. Democrats did not exhibit significant differences in true and flagging rates across conditions.

### Perspectives on “What Can We Trust? Perceptions of, and Responses to, Fake Information” and the Changing Values of Information

#### EXTENDED ABSTRACT

We find ourselves in the midst of the fourth industrial revolution, characterized by increasing velocity, breadth, and depth of information (Schwab, 2017). The explosive growth of digital sources has facilitated access to massive amounts of information while various forms of social media have contributed complexity due to the presence of anonymous, deceptive, and unmediated sources. Live video feeds, consumer review platforms, social media, etc. have allowed consumers to influence the information environment as they are themselves influenced. Prior to the current “Information Age,” communication of the news, advertising, or other information largely proceeded through a limited number of mass media outlets, such as national television networks, radio, magazines, and newspapers, and was filtered by competent, trained media workers governed by regulated standards (e.g., media and advertising regulations) and a widely-held responsibility to inform the public as a whole with little incentive to appeal to or bias information toward micro-niches. This fundamental shift in information creation and communication raises important questions about information behavior in a new age.

Our conceptual framework builds on insights into human information behavior gleaned from decades of research in economics, psychology, and marketing. Seminal investigations questioned the “rational” economic model of information behavior, beginning with Simon’s ideas of bounded rationality (e.g., Simon, 1955). Bettman’s “decision tenets” (1970, 1971) introduced cognitive theories of information processing to marketing and charted the path for research on consumer information behaviors, including the processes of attention, learning, memory, information search, judgment, and decision-making. As this research stream was unfolding, a parallel literature developed in social psychology on attitudinal responses to persuasion attempts (HSM Chaiken, 1980, 1987; ELM Petty and Cacioppo, 1986). This work was closely followed by research which questioned implicit assumptions about the roles of emotion and consciousness, and contributed toward unveiling how emotion affects information search, processing and decisions. For example, researchers demonstrated an important role for mood (e.g., Johnson & Tversky, 1983; for review, Schwarz & Clore, 1996), anticipated regret (Zeelenberg, 1999; Connolly & Zeelenberg, 2002), and other emotion-based motivations in information processing models (e.g., feelings-as-information model, Schwarz, 1990). Furthermore, research on self-image, self-esteem maintenance, etc. indicated that people seek and avoid information for purposes quite orthogonal to accuracy of attitudes and quality of choices. These findings questioned the implicit (and often explicit) assumption that consumers collect and process information to form accurate attitudes and to make better decisions (e.g., Bettman, Luce, and Payne, 1988) given the properties of the human information-processing system and of task environments (Simon, 1990). For example, literature on consumer information avoidance (for review, see Golman, Hagmann, and Loewenstein, 2017; Sweeny et al., 2010) demonstrates that consumers actually avoid information for purely psychological reasons even when it could improve decision quality. In fact, clinical psy-

chologists have argued that errorful decision strategies are necessary for mental health, coining the term “illusions” to replace terms like “error” and “bias” – (Taylor & Brown, 1988).

Beyond these augmentations, we also question the common assumption that people collect and process information for the purpose of forming accurate attitudes and to make better decisions. New provocative findings suggest a novel and important role for social influences in digital information use, past utilitarian value or regulating one’s personal emotions and self-perceptions. For example, Jun, Meng, and Johar (2017) find people are less vigilant, and thus less likely to fact-check, in social settings. Similarly, a recent study finds that the majority of people who share Internet links with others never opened the link themselves (Dewey, 2016). These findings suggest that the social context of information affect how it is processed in fundamental ways. Recognizing the new questions raised by the availability and nature of online social medias, the papers in this session investigate a range of consumer information behaviors related to the value of information that people find in various social media contexts. Together, the findings shed light on situations in which consumers react to differing aspects of deceptive or false information, including the source (Watson and Kirmani, this session) the content (Ding, Mayrhofer, and Johar, this session) and the in- or out-group membership status (Han and Rao, this session). Identifying these findings as being part of a bigger conceptual whole, we integrate recent work in our field with phenomenological observations to organize and envision a new perspective on the role of information in consumers’ daily lives, providing a conceptual contribution, discussion, and framework for future research on the topic (as proposed by MacInnis, 2011).

Building on previous research streams that focused on attitude accuracy, decision quality, and psychological health, we conceptualize information behavior as serving social functions. Specifically, whereas the value of information is the means to achieve accuracy in the economic models and the reaching of a desired emotional state in the more recent psychological models, we highlight the social value of information, such as affiliating or dissociating with reference groups and achieving a “shared reality” (Hardin & Higgins, 1996) with important others. Given the large and growing impact of social media, we argue that placing social value alongside the more deeply-researched cognitive and personal outcomes provides a better understanding of information behavior today. In other words, information behavior may include any single motivation (i.e., utilitarian, emotional, affiliative) or some combination of motivations. Furthermore, we note that these motivations may sometimes be in opposition to each other, such as uncritical consumption of fake news or intentional avoidance of socially disapproved scientific information. We provide a set of propositions that outline when each motivation may or may not be expected to surface, and the behavioral outcomes of these motivations. In this way, we integrate information processing literature with research on group behaviors, primarily from findings in social psychology and sociology. We propose that the accuracy of information is devalued when social considerations are salient, if the information can facilitate connection (dissociation) with desirable (undesirable) others. We will discuss how this view alters the roles of important variables, such as source credibility and self-efficacy.

Xiaoyan Deng, The Ohio State University, USA  
Lei Jia, The Ohio State University, USA

## **Paper #4: The Secrecy Effect: Secret Consumption Polarizes Product Evaluations**

Maria A. Rodas, University of Minnesota, USA  
Deborah Roedder John, University of Minnesota, USA

### **SESSION OVERVIEW**

Secrecy is a ubiquitous part of life (Kelly, 2002), and almost everyone keeps secrets. Prior research on secrecy in psychology has primarily focused on understanding the antecedents and consequences of secrets. However, there is little consumer research on the topic even though hiding consumption-related activities is common (e.g., Goodwin 1992; Vanhamme and de Bont 2008). This session presents a set of papers that address one important question: how will secrecy influence consumer behaviour? These four papers flow nicely from incidental secrecy (paper 1) to inherent consumption-related secrecy (papers 2-4); and are from both interpersonal perspectives (papers 1-3) and intrapersonal perspectives (paper 4).

The first two papers examine the domain-independent impact of secrecy. In the first paper, He, Jiang, and Gorn examine the effect of incidental secrecy on consumer conformity. They find that the experience of secrecy increases consumers' tendency to avoid nonconformity in their consumption choice. They further show that this effect is driven by secret-keepers' desire to avoid social attention, and it is attenuated when consumers perceive themselves as having high self-control capacity. The second paper by Gullo, Brick, and Fitzsimons examines how keeping secrets from one's romantic partner affects a person's relationship satisfaction. It is found that keeping a secret for avoidance-reasons leads individuals to more guilty feelings, compared to keeping a secret for promotion-reasons. And this feeling of guilt can have a positive effect on one's relationship satisfaction for people who perceive distance in their relationship, because it signals that the secret keeper cares about the relationship.

The other two papers examine the influence of secrecy on secrecy-related consumptions. In the third paper, Yang, Deng, and Jia explore how secret consumption affects consumer enjoyment. They show that keeping a consumption activity as a secret has a polarizing effect on consumption enjoyment such that secrecy increases consumption enjoyment when the expected social response from others is positive but decreases consumption enjoyment when their expected social response is negative. From an intrapersonal perspective, the fourth paper by Rodas and John provides converging evidences to this polarizing effect. The authors demonstrate that prompting secret

consumption results in more extreme product evaluations because secret increases preoccupation about the target product. This effect is further found to be moderated by distraction and consumers' need for cognition.

In summary, the four papers in the current special session (all in advanced stages) identify a number of antecedents and consequences of secrecy in the consumption context and examines the impact of secrecy on consumer behaviour in secrecy-related and secrecy-unrelated domains. Given the variety of the questions addressed and the variety of situations examined in the empirical work carried out, this session is likely to appeal to a broad set of conference attendees, including those interested in social conformity, relationship satisfaction, consumer enjoyment, and product evaluation, and the factors that affect them.

## **Secrecy Prompts Nonconformity-Avoidance in Consumption Choice**

### **EXTENDED ABSTRACT**

As human beings, we all have our secrets, be it a surprise party to celebrate a friend's birthday, a poor performance in an exam, or an affair that if exposed might ruin one's marriage. Secrecy is an unavoidable outcome of our socialization process (Kelly 2002; Simmel 1950), and an important concept in the consumption domain (e.g., Goodwin 1992; Vanhamme and de Bont 2008). Consumers often keep consumption-related secrets such as gifts or an adult magazine delivered in a nondescript package. Despite the prevalence of secrecy, relatively little research has explored the consequences of keeping secrets, especially in the consumer arena. In the current research, we examine the impact of incidental secrecy on consumer conformity, a domain that, at first glance, would seem unlikely to be affected if the person is keeping a secret about something that has nothing to do with a product choice that is to be made.

Secret-keepers constantly worry about both their own disclosure of the secret and others' discovery of it (Larson and Chastain 1990; Ragins, Singh, and Cornwell 2007). The likelihood of both types of secret disclosure are intimately related to the amount of social attention the individual receives. Social attention is often a precursor to social interaction, and with social interaction comes the risk of disclosure of the secret (Ashton, Lee, and Paunonen 2002; Sprecher et al. 2013). In the current research we propose that since social attention represents a potential threat to the secret-keeper, secrecy will induce a desire to avoid social attention. Nonconformity, which is generally defined as a behavior or belief that is inconsistent with norms or standards (Nail, Macdonald, and Levy 2000), makes people stand out and attracts more social attention. Putting them together, we hypothesize that secrecy will decrease consumer nonconformity in consumption choices, and the effect will be mediated by the desire to avoid social attention.

One important reason why secret-keeping consumers are motivated to avoid social attention is that they are afraid they may leak out the secret. If this is true, then the effect of secrecy on the tendency to conform should be attenuated or eliminated if consumers worry less about self-disclosure, such as the situations when consumers perceive themselves as having high self-control capacity. People with high self-control capacity tend to be good at managing their lives, saving money, keeping secrets, fulfilling promises, controlling their emotions, and so forth (e.g., Mukhopadhyay and Johar 2005;

Tangney, Baumeister, and Boone 2004; Zhang and Shrum 2008). If consumers believe that they have a relatively high self-control capacity, they should worry less about leaking their secrets to others, and the effect of secrecy on the avoidance of social attention and consumer nonconformity should be weakened.

Three studies provide supportive evidence for our hypotheses. Study 1 tested our basic proposition. To manipulate secrecy, US participants ( $N = 90$ ) first completed a writing task, in which they either wrote about a secret they were keeping (adopted from Slepian et al. 2012) or the food items they ate in a recent day. Next, they proceeded to a shopping task, in which we measured conformity by observing their choice between a majority-endorsed product option (i.e., having a 76% market share) or a minority-endorsed option (i.e., having a 24% market share). We found that secrecy decreases consumer nonconformity by reducing the choice percentage of the minority-endorsed option.

Study 2 tested our proposed underlying attention-avoidance mechanism through a process-by-moderation approach. US participants ( $N=393$ ) were assigned to a 2 (secrecy: secrecy vs. control)  $\times$  2 (perceived social attention: low vs. high) between-subjects design. We first manipulated participants' perceived social attention using a reading task (Wan, Chen, and Jin 2017). In the low (vs. high) attention condition, the article argued that people actually get much less (vs. more) attention from others than they think. After reading the article, participants completed the same episodic secrecy manipulation that was used in study 1, and a nonconformity measure similar to the one used in study 1. Results indicated that the effect of secrecy on consumers' nonconformity avoidance was mitigated when participants were induced to believe that the level of attention others pay to them is low.

Finally, study 3 examined the moderating role of perceived self-control capacity. US participants ( $N=193$ ) were assigned to a 2 (secrecy: secrecy vs. control)  $\times$  2 (perceived self-control capacity: high vs. low) between-subjects design. Participants in the high (low) self-control condition first read a fake scientific article about how human beings are good (bad) at self-control. Then after the same secrecy manipulation as in study 1, participants were asked to imagine that they were shopping for a backpack and reported their purchase intention of four backpacks, one of which being a nonconformity option (Huang, Dong, and Mukhopadhyay 2014). As expected, secrecy decreases participants' intention to purchase the nonconformity option, and this effect is weakened when participants perceive themselves having high self-control capacity.

As the first to investigate the relationship between secrecy and consumer conformity and the social attention-avoidance mechanism driving it, this research extends the secrecy literature by revealing a novel consequence of secrecy in an unrelated domain. The current research enriches our understanding of consumers' tendency to (dis) conform to others in their product choices.

## Secret Consumption in Close Relationships

### EXTENDED ABSTRACT

You watched a Netflix shows, indulged in a candy bar at work, or took the liberty to overspend on a pair of shoes, and chose not to tell your romantic partner about this consumption—a little secret. Secrets are not something you usually keep from your partner, but perhaps keeping your consumption secret helps to avoid a fight or hurt feelings. Are secrets always bad? Research on secrets suggests secrets are always bad for both the self (e.g., guilt, anxiety; e.g., Kelly and Yip 2006) and the relationship (e.g., satisfaction, break ups; e.g., Caughlin et al. 2009).

However, this research has primarily focused on secrets that are highly consequential, such as cheating, and has not examined the role of consumption. How, then, might secrets about consumption impact the self and relationship? Furthermore, how might the motivation for keeping a secret influence outcomes in the relationship? Building on the secrets literature (e.g., Caughlin and Afifi 2004; Easterling et al. 2012; Lane and Wegner 1995; Simmel 1950) and the feelings as information theory (e.g., Schwartz 1990), we suggest that while consumption secrets can have a negative impact on the self, their downstream effects can have either a neutral or an ironically beneficial impact on the relationship. Specifically, we suggest that keeping a secret for avoidance-reasons (e.g., not wanting to be judged) leads to worse outcomes for the self by increasing feelings of guilt than keeping a secret for promotion-reasons (e.g., wanting to help a partner stick to a goal). Further, we predict that those feelings of guilt—which can only occur when you care about the object of guilt (e.g., Tangney and Dearing 2003)—can have a beneficial downstream for people who have ambiguous attitudes or feelings about their relationship: feelings of guilt from the secret will *signal* to the secret keeper that they must care about the relationship (i.e., feelings as information), and therefore they feel more satisfied in the relationship overall. On the other hand, consumption secrets should have no impact (positive or negative) on relationship satisfaction for people who already have strongly positive attitudes toward their relationship—they already know they care about the relationship, so feelings of guilt from the secret should not be informative for them.

We test these hypotheses across four studies that examine different types of relationships and different types of consumption. We first conducted a pilot study with 151 individuals ( $M_{\text{age}}=32.34$ ) who were in a relationship. They described a time when they kept a consumption secret from their partner that their partner still does not know about. If they could not think of an example, participants were asked to imagine one. 98% of participants described a real (vs. imagined) time they kept consumption secret from their partner, suggesting that secret consumption is a prevalent phenomenon in relationships.

Studies 1 and 2 tested how different motivations for keeping a secret affect feelings of guilt. In study 1, 119 couples ( $M_{\text{age}}=40.5$ ) were recruited at a local farmer's market. Both members of the couple completed a questionnaire individually. Couples were randomly assigned to describe a time when they kept consumption a secret from their partner for either promotion- (e.g., wanting to help the partner stick to a diet) or avoidance-reasons (e.g., not wanting a partner to judge the consumption). Then, all participants indicated feelings of guilt after the secret consumption (single, Likert-scaled item) and whether their partner found out. We conducted analyses using multi-level modeling with individuals nested within couples. We examined whether motivation predicted feelings of guilt, controlling for whether their partner found out. In line with predictions, keeping a consumption secret from a romantic partner for avoidance-motivated reasons leads to marginally greater feelings of guilt than promotion-motivated secrets ( $B=.48, p=.07$ ).

Study 2 conceptually replicated these results in a lab setting using a different relationship type: roommates. 118 undergraduates ( $M_{\text{age}}=20.6$ ) who were currently living with a roommate came into the lab during the reading week before finals. They were asked to imagine that their roommate was going to the library with a goal to study and do well on exams. Then, participants imagined that they decided to go to a party (i.e., an experience consumption) that night and chose not to tell their roommate. We manipulated whether the motivation for keeping the secret was for avoidance- (e.g., don't want roommate to judge you) or promotion-reasons (e.g., want help

roommate stay focused on their goal). Participants then indicated how guilty they would feel. In line with the previous findings, keeping a secret for avoidance-reasons ( $M=2.41$ ) resulted in significantly greater feelings of guilt than keeping the same secret for promotion-reasons ( $M=1.86, p<.05$ ).

Study 3 examined the downstream consequences of feelings of guilt from a secret on relationship satisfaction, testing whether guilt has beneficial outcomes for individuals who hold ambiguous attitudes about their relationship by signaling that they must care about the relationship. 249 individuals ( $M_{age}=33.5$ ) who were in a relationship completed this 2Xcontinuous study on Mturk. Similar to study 1, participants imagined keeping a secret from their romantic partner for either promotion or avoidance reasons. In this study, they imagined eating a candy bar and then not telling their partner. Then, participants indicated how guilty they would feel, completed a relationship attitudes measure (Vangelisti et al. 2005) and, as the dependent measure, a relationship satisfaction measure (Rusbult et al. 1998). Moderated mediation analyses, with relationship attitude as the b-path moderator, reveal the predicted pattern of results (95% CI[.004, .189]). Feelings of guilt from the avoidance-motivated secret increase relationship satisfaction for people who have more ambiguous attitudes toward their relationship and have no impact for people who have strongly positive attitudes toward their relationship.

We demonstrate across four studies that, while consumption secrets from close others can have negative outcomes for the self when kept for avoidance-motivated (vs. promotion-) reasons, feelings of guilt from the secret can have either a *neutral* or an ironically *beneficial* impact on relationships depending upon the attitudes about relationship. Additional studies testing the underlying process will be conducted before ACR.

### “A Tale of Two Secrets”: Examining the Diverging Effects of Secrecy on Consumption Enjoyment

#### EXTENDED ABSTRACT

Research on secrecy has painted a largely grim picture of the effects of secrecy on the secret keeper’s psychological and physical well-being (Kelly 2002). Our research, however, investigates conditions under which secrecy leads to positive (and negative) effects on consumption enjoyment. We posit that in consumption settings, although sometimes consumers hide a secret (e.g., binge drinking issues) because they want to avoid the negative responses that could be triggered once people from whom the secret is kept discover the secret, on many other occasions consumers keep a secret (e.g., planning a surprise party) because they want to boost the positive responses that could be obtained from the person from whom the secret is kept upon secret revelation.

Drawing from research on secrecy (Lane and Wegner 1995) and anticipated utility (Kahneman, Wakker, and Sarin 1997), we predict that secrecy has a polarizing effect on consumption enjoyment, dependent on whether the consumption activity is expected to evoke positive or negative social responses. Specifically, when a consumption activity is expected to elicit negative responses from others (“negative social responses”), keeping the consumption activity as a secret (vs. not as a secret) not only creates burden, but also causes consumers to dread the negative consequences of secret revelation, leading to reduced consumer enjoyment. In contrast, when a consumption activity is expected to elicit positive responses from others (“positive social responses”), although keeping the consumption activity as a secret (vs. not as a secret) is mentally depleting, this negative effect stemming from the secret keeping process is often

overpowered by savoring the positive outcomes of secret revelation, resulting in increased consumer enjoyment.

Study 1 ( $n = 169$ ) featured a 2 (secrecy: secretive vs. non-secretive)  $\times$  2 (social response: positive vs. negative) between-subjects design. Participants read a scenario in which a protagonist planned a vacation with the significant other. Social response was manipulated by whether or not the significant other was expected to like the vacation plan. Secrecy was manipulated by whether or not the protagonist planned the vacation (booking flights, hotels, and tickets) secretly and therefore had to suppress the urge to confide the plan to the significant other. Participants assessed the protagonist’s consumption enjoyment, and savoring and dread during the experience (1 = very little to 9 = very much). Results suggested that an interaction of secrecy and social response ( $F(1, 165) = 31.32, p < .001$ ) emerged, such that when the protagonist expected the significant other to like the vacation idea, keeping the consumption activity as a secret enhanced enjoyment ( $M_{secretive} = 8.27$  vs.  $M_{non-secretive} = 7.16$ ;  $F = 15.03, p < .001$ ); whereas when the protagonist expected the significant other to dislike the vacation idea, hiding the consumption activity as a secret reduced enjoyment ( $M_{secretive} = 6.17$  vs.  $M_{non-secretive} = 7.33$ ;  $F = 16.31, p < .001$ ). We also found evidence for a moderated mediation such that secrecy increased (decreased) enjoyment in the positive (negative) condition through the savoring-dread index ( $b = .86, SE = .23$ ; 95% confidence interval [CI] = .50 to 1.46).

In experiment 2 ( $n = 280$ ), which employed a 2 (social response: positive vs. negative)  $\times$  2 (social distance: close vs. distant) between-subjects design, we examine how social distance influences the effects of secrecy on enjoyment. Social distance between the secret keeper and the person from whom the secret is kept should moderate the effects of secret keeping on consumption enjoyment, such that the effects of secrecy on enjoyment are more pronounced when social distance is close. Participants were asked to recall a past secret consumption experience which met our requirements of social response (the consumption is likely to receive a positive [negative] social response) and social distance (keeping a consumption activity as a secret from someone close [not close] to them) and to report their consumption enjoyment. Analysis revealed an interaction of social distance and social response ( $F = 7.83, p = .01$ ), such that participants reported higher enjoyment if they were keeping the secret from someone they felt close to than from someone they did not feel close to ( $M_{close} = 7.92$  vs.  $M_{distant} = 7.18$ ;  $F = 4.40, p = .04$ ); whereas when the recalled secret consumption was expected to elicit negative social response, participants reported lower enjoyment if the secret was kept from close others than from distant others ( $M_{close} = 5.21$  vs.  $M_{distant} = 5.84$ ;  $F = 3.46, p = .06$ ).

Study 3 was designed to examine the moderating role of preoccupation with the secret. For consumption eliciting negative social responses, a negative linear trend between level of preoccupation and consumption enjoyment exists: consumption enjoyment decreases as the level of preoccupation increases. For a secret consumption activity with positive expected social responses, a curvilinear relationship between level of preoccupation and consumption enjoyment exists: consumers enjoy the consumption experience most when they are moderately preoccupied with the secret. This effect occurs because the negative effect of keeping a secret is overwhelming in the high preoccupation condition. Participants took part in a 2 (social response)  $\times$  4 (level of preoccupation: high vs. moderate vs. low vs. control) between-subjects design. The experiment was similar to the procedure of study 1 with the exception that level of preoccupation was manipulated by how often the secret consumption activity came into the consumers’ mind. Trend analyses indicated that, in the negative social response condition, a significant negative linear trend of

level of preoccupation emerged ( $F = 26.49, p < .001$ ) such that the higher the preoccupation with the secret, the lower the consumption enjoyment. By contrast, in the positive social response condition, a significant quadratic trend of level of preoccupation emerged ( $F = 3.55, p = .06$ ) such that the protagonist enjoyed the experience most when he or she was moderately preoccupied with the secret.

Across three experiments, we found support for our theory that keeping a consumption activity as a secret has a polarizing effect on consumption enjoyment, increasing enjoyment when social response is positive but reducing enjoyment when social response is negative.

### The Secrecy Effect: Secret Consumption Polarizes Product Evaluations

#### EXTENDED ABSTRACT

Much of the advertising we see depicts people enjoying the consumption of a product in the company of other people. Recently, however, advertisers are also beginning to depict people consuming products in secret. For example, Breyer's advertises its line of gelato by showing a couple waiting for their children to go to bed so they can keep their gelato consumption a secret. King's Hawaiian's advertises its dinner rolls through a humorous ad showing a man keeping his consumption of dinner rolls secret by hiding them in a hidden wall cabinet. This development raises an interesting question: Is it possible that consumers like a product more if they are prompted to think about consuming it in secret?

We propose and find evidence that prompting secret consumption results in more extreme (polarized) product evaluations, and that this is driven by increased preoccupation about the target product. We define secret consumption as consuming a product with the intent of hiding the consumption from others. Secret consumption is a prevalent phenomenon among consumers. In a study we conducted, 60% of women and 44% of men reported having engaged in secret consumption, across product categories such as chocolate, ice cream, alcohol, and video games.

We look to theories of secrecy (Lane and Wegner 1995) and attitude polarization (Tesser 1978) to explore the effects of secret consumption. In brief, when people are prompted to think about their consumption as secret, they become preoccupied with thoughts about the product they have consumed. Thoughts about the product continue to pop into mind, resulting in increased thinking about the product. This increased thinking leads to a polarization of product evaluations. Thus, increased thinking about a consumed product results in more positive (negative) evaluations for liked (disliked) products.

Support for these conclusions are reported in six studies, where we assigned women to either a secret or non-secret consumption condition, and then asked them to consume and evaluate a familiar food item (chocolate, cookies). Across studies, we incorporate three different manipulations for the secret consumption condition, as well as including measures of preoccupation in later studies. In addition, the later studies (studies 3-6) were conducted in a field setting (at a large State Fair in the U.S.), where we were able to examine the robustness of our findings with a broad population.

The first two studies demonstrate the secrecy effect using two different manipulations for the secret consumption conditions. For study 1, we asked women in the secret condition to imagine eating a brand of chocolate in secret; women in the non-secret condition did not receive this instruction. For study 2, we asked women to read a print ad for a brand of chocolate. Women in the secret condition read an ad encouraging consumption of the chocolate in secret, while women in the non-secret condition read an ad without mention of secret consumption. In both studies, women who were prompted to

think about eating the chocolate in secret had more positive evaluations of the chocolate versus women in the non-secret condition.

In the next two studies, we provide further evidence regarding the effects of secret consumption: (1) the secrecy effect on product evaluations is due to preoccupation; (2) prompting secret consumption has a polarizing effect on product evaluations; and (3) the effects of our secret consumption manipulations are due to prompting the idea of secrecy, rather than the private or public nature of the consumption setting, with a 2 (secret vs. non-secret consumption)  $\times$  2 (public vs. private setting) between-subjects design. Participants were randomly assigned to consume the product in secret (either in a private booth or at a table with others around) or in non-secret (either in a private booth or at a table with others around). We asked them to taste and then evaluate the product. We also included a measure of how preoccupied they were with the consumed product. Mediation analyses confirmed that preoccupation was the mediator of the relationship between consumption setting (secret vs. non-secret) and product evaluations. To provide evidence for attitude polarization, we used a well-liked product in study 3 (cookies) and a disliked product in study 4 (high-cocoa dark chocolate). As expected, we found that prompting secret consumption resulted in more positive evaluations for the liked product (mediated effect=.36, SE=.11, 95%CI=.17 to .61), but more negative evaluations for the disliked product (mediated effect=-.18, SE=.12, 95%CI=-.53 to -.03).

The final two studies examined moderators of the secrecy effect. In study 5, we found that the secrecy effect disappears when people are distracted during consumption. Further, we show that preoccupation with the consumed product mediates the interaction effect between distraction (present vs. absent) and consumption setting (secret vs. non-secret). In study 6, we found the secrecy effect is stronger for people higher in NFC due to greater preoccupation with the secretly-consumed product. Further, our findings show that preoccupation mediates the interaction between NFC and consumption setting (secret vs. non-secret).

Does prompting secret consumption affect product evaluations? Across six studies, we show that it results in more extreme or polarized product evaluations. This effect was observed across different methods of prompting secret consumption, different product categories (cookies, chocolate), consumption settings (public vs. private), and research settings (lab, field).

## Paper #4: Who Gets Credit? Who Gets Blame? The Role of Agency in Ethical Production

Neeru Paharia, Georgetown University, USA

### SYMPOSIUM OVERVIEW

With increasing frequency, consumers are wielding their power in the market through acts such as boycotts and “boycotts” in order to demonstrate their agency, express their views, and hold companies accountable. Brands have also recently been taking active political positions both voluntarily and involuntarily (e.g. in February of 2018 several firms such as Delta Airlines, Dick’s Sporting Goods cut ties with the National Rifle Association). These trends bring up a number of relevant questions: Should brands take active political positions? Should they lobby? Should they give consumers power? From a consumer’s perspective, what are the consequences of such actions? This session explores a wide range of factors related to the topics of consumer agency and brands’ political actions, addressing a number of critical issues in light of these recent trends. The first paper by *Weber, Hydock, Joireman, and Sprott* provides evidence of firm political advocacy (FPA) as a new phenomenon, and demonstrates that FPA interacts with consumers’ political orientation, and differentiates FPA from corporate social responsibility. Because little is known about how consumers respond to potentially-divisive FPA, this work provides novel perspectives on a growing phenomenon.

The second paper by *Vadakkepatt, Martin, and Arora* investigates the role of corporate lobbying on customer satisfaction. Empirical analyses with an unbalanced panel of 164 publicly traded firms, tracked from 1998 to 2014, show that firm lobbying is significantly, negatively related to customer satisfaction. Importantly, customers need not know about a firm’s lobbying activities for it to impact customer satisfaction. However, subsequent analyses with customers shows that when they are made aware, satisfaction suffers further.

The third paper by *Hydock and Paharia* explores the conditions under which firms should (or should not) take active political positions for issues unrelated to their business (e.g. gun control, gender and bathrooms, etc.). This work demonstrates that it depends on how many players are in the market, and whether the firm is a first mover. When there are only a few player in the market, taking a political position can hurt, but when there are many players in the market, it can help. Further, firms benefit most when they are the first mover to

take a political position in a category. If they are the second mover, they should take the opposite political position.

The fourth paper by *Paharia* looks at agency at a more micro-level, demonstrating made-to-order business models increase consumers’ interest in ethical attributes. Because consumers feel more agency in the act of production they are more likely to weigh ethical attributes more heavily.

Taken together, this set of papers opens up several new avenues of research in the area of brands, politics, and agency. Each paper includes a complete set of experiments and provides process evidence that can stimulate new research ideas and provide insights in this emerging area. Given the recent trends, and applicable questions, this session is likely to appeal to a broad set of conference attendees interested in corporate social responsibility, agency, and political action.

## Immigration, Abortion, and Gay Marriage – Oh My!

### EXTENDED ABSTRACT

Firms’ involvement in the political process historically represented a lucrative strategy to pursue a firm’s financial interests by managing policy and reducing risk (Lawton McGuire, and Rajwani 2013). More recently, firms are increasingly taking positions on controversial issues; for example, in July 2012, Chick-Fil-A had donated approximately \$5.5 million to anti-gay groups and more recently, in February of 2018, a litany of major firms (e.g., Delta Airlines, Dick’s Sporting Goods) cut ties with the NRA following their continued fight against laws regulating gun ownership. In conjunction with firms’ increased involvement in divisive political issues, a recent Pew Research Center study (2017) revealed that, since 1994, American political values have shown increasing polarization, shifting from a unimodal distribution (where most people are moderate) toward a bimodal distribution (where most people are either quite liberal or conservative). Firms previously avoided this danger by engaging in less controversial social activism through Corporate Social Responsibility (CSR) initiatives, which resulted in positive outcomes for firms (Sen, Du and Bhattacharya 2016). However, given that consumers increasingly believe social change should come from business (Brownstein 2016), firms may feel heightened pressure to engage in political activism, despite the uncertain consequences. Accordingly, in the present paper, we develop and test an integrative framework capturing consumer responses to FPA.

Juxtaposing CSR and FPA, our core contention is that while CSR and FPA both convey what a firm values, FPA is more likely than CSR to convey the political values of a firm, which interact with consumers own political orientation. We report a series of studies shedding light on the recent rise in FPA (vs. CSR), how consumer political orientation influences responses to FPA, and how responses to FPA and CSR differ. Further, we demonstrate that while the interaction of FPA and consumers’ political orientation produces both positive and negative effects on consumers’ attitude toward a brand, it has disproportionately negative effects on willingness to pay (WTP) for the firms products.

In our first study, we document evidence of a rise in FPA over time, and specifically a greater rise in FPA than CSR. To address this question, we conducted an archival analysis of New York Times (NYT) articles published between 1970 and June 2017 (~4.1 million articles). A Poisson regression based on keyword selection and

coding of CSR vs. FPA articles over time revealed a significant interaction of year and article type ( $b = 0.097$ ,  $p < .01$ ), with simple slopes revealing a positive effect of year for CSR ( $b = 0.019$ ,  $p < .1$ ) and FPA ( $b = 0.103$ ,  $p < .01$ ), but a greater increase in FPA articles over time, motivating further investigation of consumers' response to FPA.

In our second study, we directly compare consumer attitudes to CSR and FPA as a function of consumers' political orientation (PO). Respondents read one of 20 scenarios resulting from a 2 (Type of Action: CSR vs. FPA)  $\times$  2 (Position: Liberal vs. Conservative)  $\times$  5 (Context) between-participants design; a (control) condition read that firm had decided to move offices. Participants indicated their attitude toward the company, which served as the primary measure. A set of analyses was conducted to illustrate the differential response to FPA vs. CSR. First, we fit participants' brand attitudes to unimodal vs. bimodal distributions. In all scenarios, FPA produced a bivalent response, but CSR produced a univalent response. We then compared CSR and FPA on several dimensions likely to differentiate the two actions. Relative to CSR, FPA was seen as significantly ( $p < .001$ ) more controversial ( $M = 5.21$  vs.  $3.23$ ), more likely oriented toward influencing social policy ( $M = 5.11$  vs.  $4.81$ ), less appropriate ( $M = 4.09$  vs.  $5.45$ ), and less oriented toward social responsibility ( $M = 4.43$  vs.  $5.44$ ). Finally, we ran a regression to assess the effect of brand action (FPA vs. CSR), brand position (liberal vs. conservative), and participant PO. The analysis indicates that, relative to CSR, FPA results in less favorable attitudes overall, and that firm FPA ( $\beta = .55$ ,  $p < .001$ ) interacted with consumer political orientation to a greater extent than CSR ( $\beta = .13$ ,  $p < .001$ ). Together, these results suggest consumer responses to FPA and CSR are fundamentally different.

In our third study, we demonstrate that while FPA induces a bivalent effect on attitude, it has a negative effect on WTP. That is while consumers' attitude toward a brand equally reflects the alignment and misalignment between firm FPA and their own PO, their WTP is disproportionately affected by misalignment relative to alignment of firm FPA and participant PO. In a study, participants read about two firms with similar offerings; they then read that one firm supports gender identity based bathroom laws (liberal FPA), biological gender based bathroom laws (conservative FPA), or moved offices (control). Participants then reported their attitude and WTP for each firm. For brevity, we report here that relative to the control condition, there was no effect on average attitude toward a firm engaging in FPA (collapsing liberal and conservative positions); some consumers attitudes increased, some decreased, but the net effect was null. However, relative to the control condition, we see that when a firm engaged in FPA, WTP for their products decreased (22 cents,  $p < .01$ ).

The present work offers four key contributions. First, by examining the intersection between consumers' and firms' political orientation, we complement and extend recent research on political orientation at the consumer and firm levels, which has largely developed along separate lines. Second, we underscore the generalizability of the FPA phenomenon by studying responses across a range of contexts. Third, we examine whether consumers' tendency to avoid politically-misaligned firms outweighs their tendency to gravitate toward politically-aligned firms, highlighting an important asymmetry in responses to FPA. Fourth, in differentiating FPA from CSR, we show that while political orientation does influence responses to CSR, FPA is much more likely to be interpreted through a political lens, resulting in bivalent, more politically-polarized, and less favorable responses.

## Unintended Customer Consequences of Corporate Lobbying

### EXTENDED ABSTRACT

Corporate lobbying, defined as "any communication made on the behalf of a client to a member of Congress, congressional staffers, the President, White House staff and high-level employees of nearly 200 agencies, regarding the formulation, modification or adoption of legislation" (The Center for Public Integrity, Lobbying FAQ, 2006), is the most common form of corporate political investment in the United States (Hillman et al. 2004; Chen, Parsley and Yang 2015). Firms devote millions of dollars to lobbying, with many Fortune 500 companies spending more on lobbying than on taxes (Huffington Post 2012). In fact, lobbying has become such an integral part of a firm's non-product market strategy that today, many firms house their own, internal lobbyists. Although most companies still prioritize spending in their product market environments, lobbying expenditures have swelled to a point that U.S. companies now spend more on lobbying the House and Senate than the amount spent by taxpayers to operate these legislative wings (Drutman 2015). Evidence strongly suggests that lobbying is increasing, and only will continue to do so (Martin et al. 2018).

Given growing lobbying prevalence, understanding whether and how lobbying impacts customers is of crucial importance to academics and practitioners alike. Yet, while studies have examined the impact of lobbying on a firm's financial market performance (e.g., Borisov, Goldman and Gupta 2015; Chen, Parsley and Yang 2015), to date no study has examined the manner in which a firm's lobbying can affect its customers. Indeed, there is reason to believe that a firm's lobbying efforts can have significant customer effects mainly because customers disapprove of business-government interconnections (Public Affairs Council 2017) and a firm's involvement with politics is the number one cited motive for customers to boycott a brand (YouGov 2017; see also Klein, Smith, and John 2004). Against this backdrop, the current research examines the relationship between lobbying and customer satisfaction, a leading measure of customer reactions to a firm's products and a marketing metric that has been shown to impact a firm's accounting and financial measures of performance (e.g., Fornell et al. 2006; Fornell et al. 2016).

More precisely, we examine two pathways through which lobbying can impact customer satisfaction – the firm pathway and the customer pathway. In the firm pathway, lobbying impacts customer satisfaction through its effect on the product market environment and does not rely on customer knowledge of a firm's lobbying efforts. In the customer pathway, lobbying impacts customer satisfaction through customer knowledge and potential customer disapproval of a firm's lobbying efforts. Importantly, while we expect lobbying's impact on customer satisfaction through the customer pathway to be negative, a priori it is unclear how lobbying impacts customer satisfaction through the firm pathway. On the one hand, a firm's lobbying efforts can positively affect customer satisfaction by allowing firms to secure scarce and valuable resources to improve product offerings to the benefit of customers, thereby enhancing satisfaction (Cameron 2012; Duchin and Sosyura 2012). On the other hand, lobbying can also negatively affect customer satisfaction by diverting a firm's attention from product markets to government affairs. Such a shift in focus may either neglect or damage core value producing activities which include those that support customer expectations, perceived quality, and perceived value—widely acknowledged satisfaction determinants (e.g., Anderson and Sullivan 1993).

We examine the effect of lobbying on customer satisfaction through the firm pathway using an unbalanced panel of 164 public

firms tracked over 16 years. We then explore how customers respond to firm lobbying knowledge using experiments with 700 customers and the actual companies and products they use. Findings contribute to marketing theory and practice in four important ways.

First, this research is a foundational study linking firm lobbying (as opposed to other areas of strategic focus) to customer mindset metrics, which are an underutilized but centrally important performance outcomes in marketing (Katsikeas et al. 2016; Kumar 2016). In spite of the many benefits firms seek through lobbying, as well as their heightened spending on it, we find that lobbying hurts satisfaction regardless of whether customers know the extent to which firms lobby. This finding is especially telling given that lobbying has positive effects on firm performance metrics (e.g., Martin et al. 2018).

Second, we disentangle how the particular reasons for which companies lobby can differentially affect customer satisfaction. To the best of our knowledge, this is the first study to examine individual effects of specific lobbying issues on any firm performance outcome. We analyze lobbying issue effects on customer satisfaction in two stages. First, we aggregate all issues into either product market or non-product market classes, and find only product market issues significantly affect customer satisfaction. We then narrow focus to specific product market issues related to a firm's advertising and innovation efforts. We find lobbying for advertising issues increases customer satisfaction while lobbying for patent issues lowers customer satisfaction, supporting our assertion that it is not just how much the firm lobbies but also what the firm lobbies for that matters. Further testing shows key firm stakeholders (i.e., customers and investors), may have different perspectives of what lobbying issues are important.

Third, we contribute to knowledge by demonstrating both a firm-side and a customer-side route through which lobbying can affect satisfaction. The set of effects borne out in our secondary data are closely mirrored through customer experiments where respondents report on lobbying behaviors of companies whose goods and services they already use. For firms, this evidence suggests that it is not just that complacency may shift firm focus away from offering customers greater value, and hence hurting satisfaction. Our findings show that growing disapproval of business-government relationships also may encourage negative customer behaviors.

## Market Structure and Firm Engagement in Divisive Political Issues

### EXTENDED ABSTRACT

Recently, brands have increasingly taken divisive political positions on issues that are unrelated to their core offerings. For example, Chick-fil-a's (Amazon's) CEO came out against (for) gay marriage, Hobby Lobby sought exemptions on covering birth control, Paypal dropped plans for an office in North Carolina following the state's bathroom bill, Microsoft denounced DACA repeal, and a handful of brands dropped programs tied to the NRA, due to their position on gun regulation. While these positions might be spurred by a variety of events, come in a variety of forms, and be attributable to the brand directly or indirectly, they similarly involve taking sides in a divisive socio-political debate.

This behavior makes sense given consumers are increasingly looking for corporations to spur change (Brownstein 2016). However, at the same time, Americans have become more polarized politically, suggesting there are few political positions a brand can "safely" take. Taking a position on a divisive issue by nature results in some consumers supporting/opposing it. What's more, existing research suggests that consumers may react more negatively to brands'

sociopolitical stance that they oppose than positively to brands' sociopolitical stance they support; consumers punish brands more for unethical CSR relative to ethical CSR (Folkes and Kamins 1999; Trudell and Cote 2009).

Given the greater negative response toward brand actions consumers disliked compared to the positive response to brand actions consumers favor, we would anticipate that when a brand takes a divisive political stance (assuming the population is evenly split on the issue) that consumers would be less likely to choose that brand over a competitor, relative to when they did not take a divisive political stance. However, literature on consumer choice tells us that choice context can have an important impact on consumer's decisions (Chernev 2003; Sela, Berger, and Liu 2009). Specifically, when provided with a larger choice set, consumers attempt to make the choices they feel are most justifiable (Sela, Berger, and Liu 2009). Accordingly, we anticipate that market structure, the number of competitors in the market, will moderate the effect of brands' divisive socio-political stances on likelihood of choosing a brand relative to a competitor. Specifically, because larger choice sets drive consumers to make more justifiable choices, in a more competitive market a brand that takes a divisive socio-political position will be more likely to be chosen, relative to when it does not take a divisive political position.

In our first three experiments, we test this hypothesis – with three types of divisive socio-political issues – as participants choose a shirt; participants randomly assigned to a competitive (15 brands each offering on shirt) or oligopoly (2 brands, each offering a shirt) market condition. In the experimental condition, participants read that one of the brands took one side of a divisive socio-political issue; experiment 1a "support Democrats/Republicans," experiment 1b "support gun control/rights," experiment 1c "support gender identity/biological gender." While one position may invoke greater support than its opposite (e.g. 70/30, 40/60) – by collapsing across positions and comparing the net effect of making a politically divisive position to the control, we simulate the response to a brand taking one side of a 50/50 issue.

In each study we see an interaction of market structure and condition (socio-politically divisive issue vs control),  $ps < .05$ ). Further, we see that in an oligopoly, consumers were less likely to choose a brand that took a divisive socio-political position (Experiment 1a and 1c  $ps < .05$ , Experiment 1b  $p = .2$ ), but in a competitive market (15 competitors) consumers were more likely to choose a brand that took a divisive socio-political position ( $ps < .05$ ). Notably, in experiment 1c participants were told that they would actually (2.5% chance) really receive their choice.

In our next study, we provide a boundary condition for the positive effect of divisive socio-political stances on consumer choice. Specifically, because greater choice set size leads consumers to make more justifiable choices, we anticipate that when a second brand follows a first, and makes the same divisive stance, consumers will not be more likely to choose them as doing so would be less justified than choosing the courageous first brand. Following this logic, we should anticipate that if the second brand takes the opposite position, it will improve that brand's likelihood of being chosen relative to in the control condition, because among those supporting this "opposite" side of the divisive socio-political position this is the only justifiable choice. Accordingly, study 2 involved 4 conditions all in a competitive market for running shoes (10 brands) where a first mover takes a position (pro-life or pro choice) and a second mover takes no position (condition 1), the same position (condition 2), or the opposite position (condition 3). There was also a fourth control condition where the first mover and second mover do not take posi-

tions. The first mover increased market share relative to the control (10%) in all conditions (second mover no position: 25%,  $p < .001$ , second mover same position: 25%,  $p < .001$ , second mover opposite position: 30%  $p < .001$ ), but the second mover only increased market share when taking the opposite position to the first mover (22%) relative to the same position (7%,  $p < .001$ ) or the control condition (8%,  $p < .001$ ).

Over four studies, we demonstrate that two important market variables impact consumer choice behavior following brands' divisive socio-political positions. Specifically, because in competitive markets consumers choose more justifiable brands, they are more likely to choose a brand taking a divisive stance relative to in an oligopoly. Further, we find that brands taking divisive socio-political stances are only seen as justifiable choices when they are the first to take a particular side, suggesting that for follower brands to benefit from divisive positions in a competitive market, they must take a unique position.

### Who Gets Credit? Who Gets Blame? The Role of Agency in Ethical Production

#### EXTENDED ABSTRACT

Nike offers consumers the ability to customize their own shoes with Nike ID. Custom Ink allows customers the opportunity to design their own t-shirts. On-demand printing companies allow customers to order out-of-print and rare titles. The dominant wisdom of these made-to-order business models is that consumers want more ability to tailor product attributes to increase preference fit (Franke, Schreier, and Kaiser 2010). However, allowing consumers to have greater control over product attributes also blurs the lines of who is the producer and who is the consumer.

Recent research has looked at how consumers value customized products based on *product attributes* (e.g. style, color, etc.) (Franke, Schreier, and Kaiser 2010). The present research builds on this work by examining how consumers respond to *process attributes* when given more agency. We argue there is an unintended consequence of agency – that consumers will weigh process variables differentially between when they assume the role of a consumer (no control over production) versus when they assume the role of a producer (some control over production). We theorize that when consumers are given agency as producers, they are explicitly given power to tailor their own product attributes, but also experience an unintended consequence of assuming greater responsibility and agency for process attributes. Specifically looking at process variables that have been defined as ethical attributes in the marketing literature (Irwin and Walker Naylor 2009) (e.g. environmental and labor) we explore how consumers view ethical process attributes when they have a role in production. We find that when consumers have “producer agency” (e.g. ordering products on demand, customization, preorders), they disfavor products made with negative ethical process attributes more than if they only had “consumer agency” (e.g. buying what is already in inventory). Furthermore, we find this effect is reversed when there are more positive ethical process attributes (e.g. fair trade production, recycled products). Because consumers feel more responsible for production, producer agency can lead to feelings of anticipated guilt or gratification depending on the favorability of the production process. Finally, we explore how diffusion of responsibility plays a role.

In study 1, with 527 Mechanical Turk participants using a 2 (agency: consumer agency vs. producer agency) X 3 (ethicality: negative vs. control vs. positive) between subjects design, participants considered the purchase of a bag. In the consumer agency conditions participants were told the bag was in inventory. In the producer

agency conditions participants were told the bag would be custom-made after it was ordered. In the positive and negative conditions participants were told whether the company payed a living wage or not. In the control condition no ethical information was given. Participants rated their purchase intentions, and anticipated feelings of guilt and gratification.

We found a significant interaction between agency and ethicality ( $F(1, 523)=5.62, p=.004$ ) on purchase intention. In the negative conditions, participants indicated a lower purchase intention in the producer agency condition than in the consumer agency condition ( $M=2.14$ , vs.  $M=3.02$ ;  $F(1, 523)=9.24, p=.002$ ); there was no significant difference based on agency in the control condition or in the positive conditions. In the negative conditions, guilt mediated the relationship between agency and purchase intentions (guilt: .22, CI: .04, .55).

In study 2 we used a mixed design to better control for a price quality trade-off for ethical products. 361 student participants were randomly assigned to a consumer agency or a producer agency condition and read about both a book printed on standard paper for \$11 and a book printed on recycled paper for \$14. In the consumer agency conditions they were told the book was in inventory, and in the producer agency condition they were told it would be printed on demand. We again found a significant interaction ( $F(1, 356)=9.32, p=.002$ ). Participants indicated a lower purchase intention for regular version of the book in the producer agency condition than in the consumer agency condition ( $M=6.69$  vs.  $M=7.24, t(357)=2.53, p=.01$ ), but indicated a significantly higher purchase intention for the recycled version of the book ( $M=3.94$ , vs.  $3.31, t(358)=2.67, p=.008$ ). Through mediation analyses we found that participants anticipated feeling more guilt with the regular version of the book and more gratification with the recycled version of the book in the producer agency condition compared to the consumer agency conditions.

In study 3, our goal was to attenuate the effect by addressing feelings of consumer diffusion. We predicted that we could reduce feelings of diffusion in the consumer agency condition by limiting the number of items in stock. 242 Mechanical Turk participant were assigned to one of three between subjects conditions (producer agency, consumer agency, and low diffusion). Participants were taken through a process of choosing a shirt to increase realism. In the consumer agency and low diffusion conditions participants were told this shirt was being chosen from inventory. In the producer agency condition participants were told this shirt was being custom made. After making choices about the shirt's physical attributes participants were told they could pay an additional \$4.99 for the shirt to be fair trade. In the low diffusion condition participants were then told there was only one standard shirt and one fair trade shirt left in inventory.

We found a significant effect of condition on purchase intentions ( $F(1, 236)=3.67, p=.027$ ). Participants indicated a higher purchase intention for the fair trade option in the producer agency condition than in the consumer agency condition ( $M=4.0$  vs.  $M=3.13, t(236)=2.44, p=.016$ ). Participants also indicated a higher purchase intention in the low diffusion condition than in the consumer agency condition ( $M=3.94, SD=2.15$  vs.  $M=3.13, SD=2.1, t(236)=2.31, p=.022$ ).

A final study 4 demonstrates a similar effect of producer agency in a field experiment using Facebook's advertising platform. This research demonstrates how agency in production can influence consumer behavior with respect to the production process. We found that producer agency increases the importance of ethical process attributes. Accordingly firms can use producer agency to enhance (or diminish) the importance of ethical attributes.

### **SESSION OVERVIEW**

Size and shape are two basic dimensions of product design and shopping environment. Not only do they influence our perceptions and preferences of products or product assortments (e.g., Maimaran and Wheeler 2008; Raghurir and Krishna 1999), but they also change our decision processes in fundamental ways (Meyers-Levy and Zhu 2007). In this symposium, we present four papers that explore the impact of size and shape, with a focus on two specific outcomes—judgment of products and product sets (papers 1 and 2) and inferences of outcome efficacy and decision efficacy (papers 3 and 4).

**Paper 1** asks whether the shape of a product—slim or normal— influences how luxurious the product appears. The authors propose that, because (1) consumers evaluate products in the same way as they evaluate human body shape and (2) people with higher socioeconomic status are typically slimmer, consumers perceive slim-shaped products as more luxurious than normal-shaped ones. Further, this slim-as-luxury effect is stronger among those who endorse the link between body slimness and high status more.

Moving to evaluations of a set of products that jointly fulfill the same need (e.g., an oral care collection which includes toothpaste, mouthwash and dental), **Paper 2** finds that people perceive a set of products that are placed in a circular (vs. angular) shape to be more complete, and hence perceive each component to be more important. The authors further identify (1) the distinctiveness of visual cues and (2) the degree of familiarity with component items as two boundary conditions.

In the context of prosocial behavior, **Paper 3** documents that when people use a larger font size to fill out a pledge form, they infer their actions will be more impactful, which further leads to a greater prosocial motivation. Importantly, this effect occurs only when the donor’s primary motivation is to influence outcomes, rather than to signal that they care (i.e., focusing on outcome efficacy).

**Paper 4** investigates the consequence of feeling physically small, as a result of encountering larger-than-self stimuli in the shop-

ping environment. The authors reason that, people carry over the belief that a small body size means less control over one’s physical environment to decision making, and experience less decision efficacy when feeling physically small. To cope with this negative state, they delegate decisions (a direct resolution path) when an external decision agent appears to possess efficacy (e.g., group consensus, expert advice), but rely on themselves (a symbolic resolution path) when the agent does not possess efficacy (e.g., a random recommendation algorithm).

This session contributes to the literature on how physical attributes in the marketing environment influence evaluations of products (papers 1 and 2) and inferences about one’s action and decision efficacy (paper 3 and 4). It will appeal to a wide audience interested in sensory marketing, prosocial behavior and compensatory consumption.

## **“Slim-As-Luxury” Effect: Product Shape as Input to Luxury Perceptions**

### **EXTENDED ABSTRACTS**

In an increasingly crowded marketplace, product design plays a critical role in drawing consumer attention and engagement. Product shape is one element of design and different product shapes can be observed within the same product category. For example, different beverage brands use distinct bottle shapes to distinguish themselves from each other. In early 2017, Fiji released its new slim-shaped water bottle to fit consumers’ active lifestyle. Galliano, an Italian herbal liqueur, is well recognized for its notably skinny and tall bottle shape.

Past findings suggest that holding the absolute volume constant, slimmer containers (i.e., greater height/weight ratio) are perceived to be bigger (Raghurir and Krishna, 1999), and therefore consumers believe that they have consumed more liquid from a slim (vs. wide) container (Wansink and Ittersum, 2003). Through its impact on perceived volume, the slimness of a product package has also been found to affect product preference and purchase intention (Raghurir and Greenleaf 2006). However, little is known about how product shape can influence consumers’ perception of the product value. We propose that consumers evaluate product shape in the same way that they evaluate human body shape. Specifically, because of various reasons (e.g., healthier food and more exercise), people who have higher socioeconomic status are more likely to maintain a slim body shape, especially in developed countries (McLaren 2007; Pampel, Denney, and Krueger 2012). Moreover, people have internalized this association between slim body shape and its symbolic value of high status (Rudman 2004). Given that people tend to imbue the features of human beings to objects and nonhuman creatures (Epley, Waytz, and Cacioppo 2007), we hypothesize that people generalize their belief about human body shape and its association with social status onto products.

Therefore, we propose a “slim-as-luxury” effect, such that people perceive slim-shaped (vs. normal-shaped) products as more luxurious, and posit that the effect is stronger for people who believe that high status individuals tend to be slimmer than lower-status individuals. We conducted five experiments to test our hypotheses.

Experiments 1A ( $n = 116$ ) and 1B ( $n = 100$ ) tested the basic slim-as-luxury effect. In Experiments 1A, a within-participants design, participants were asked to draw the contours of two beverage

bottles, one for high-end and one for low-end market. The ratio of height/width served as the dependent measure of the bottle's slimmness. Results showed that participants drew a larger ratio for the high-end (vs. low-end) market beverage ( $M_{high} = 3.71$  vs.  $M_{low} = 2.71$ ;  $t(115) = 5.92, p < .001$ ). Experiment 1B replicated the effect with a between-participant design, holding the height of the bottles constant. Results from both studies demonstrate that people tend to draw slimmer bottles for a luxury beverage than for a non-luxury beverage, supporting our slim-as-luxury hypothesis.

Experiment 2 ( $n = 220$ ) tested the slim-as-luxury effect in a gift-giving context with a choice measure. Participants read a gift-giving scenario that involved making a choice between two fitness trackers. One tracker was more functional with a normal shape and the other one was less functional with a slim shape. Participants were asked to choose between the two fitness trackers for their friend, who was described as either an exercise-lover or an exercise-lover with luxurious tastes. A chi-square test revealed that participants were more likely to choose the slim tracker as a gift for their luxury-oriented friend (40%) than for their non-luxury-oriented friend (16%;  $\chi^2(1) = 15.18, p < .001$ ). Results from Experiment 2 supported our proposed slim-as-luxury effect in a product choice context, suggesting that consumers may choose a slimmer product when they focus on the symbolic value of products, even at the cost of sacrificing functionality.

Experiment 3 tested the proposed mechanism by examining whether consumers' beliefs about status-associated body shapes would moderate the slim-as-luxury effect. A pretest showed that people in the U.S. believe high status people are slim whereas people in India do not hold the same belief. Participants from the U.S. and India were recruited (279 from the U.S. and 384 from India) to evaluate the luxuriousness of a given product, which was either a slim-shaped or a normal-shaped air purifier (1 = *not luxurious at all*, 9 = *extremely luxurious*). U.S. participants rated the slim-shaped (vs. normal-shaped) air purifier as more luxurious ( $M_{slim} = 7.24$  vs.  $M_{normal} = 6.71, F(1,654) = 5.25, p = .017$ ) compared to Indian participants who rated the normal-shaped (vs. slim-shaped) air purifier as more luxurious ( $M_{slim} = 6.30$  vs.  $M_{normal} = 6.86, F(1,654) = 7.47, p = .005$ ). The interaction effect was significant ( $F(1,654) = 12.35, p < .001$ ).

In Experiment 4, we measured participants' beliefs about human body shape and status, rather than using country as a proxy measure. We used a 2 (product shape: normal vs. slim; between)  $\times$  2 (product: chocolate and speaker; within) mixed factorial design and measured beliefs. Participants ( $n = 121$ ) rated the luxuriousness of a chocolate and a speaker, either with a slim or normal product shape, on a 9-point scale. They also indicated their belief about the status-associated with body shapes by selecting the body type that represented high status people (1 = very slim, 7 = very wide). As hypothesized, for both products, the results yielded a significant interaction effect between product shape and people's belief ( $b_{speaker} = -.95, t(117) = 2.76, p = .007$ ;  $b_{chocolate} = -1.12, t(117) = -3.07, p = .003$ ), demonstrating that the slim-as-luxury effect was stronger for participants who believed that high status people tend to have a slim body shape.

Results from five experiments support the hypothesis that people rate slim (vs. normal-shaped) products as more luxurious. The effect is driven by beliefs that high status people tend to have a slim body shape. This belief regarding human body shape is overgeneralized to products. Further research is needed to investigate the boundary conditions for this effect as well as to establish how the shape cue interacts with other cues (e.g., exclusiveness) to affect consumers' luxury perceptions.

## "But, will you think it's important to use mouthwash?" How Visual Communication of a Set Impacts Perceived Set Completeness and Item Importance

### EXTENDED ABSTRACTS

Consumers frequently utilize a "set" of products to achieve an overarching goal. For example, they may use toothbrush, toothpaste, dental floss, and mouthwash to keep their teeth healthy. How can marketers increase the likelihood that all these products that aim to achieve the goal of "keeping teeth healthy" are purchased, and that all necessary actions are performed?

Building on the literature on the perceived completeness of *single* objects (Hagtvedt 2011; Sevilla and Kahn 2014), we propose the concept of perceived *set* completeness, and define it as "the state or condition of having all the necessary or appropriate parts."

In this research, we focus on how visual communication of a set of items can impact perceived set completeness, and thereby affect the perceived importance of the components of the set. Extending recent work on circular (vs. angular) shape effects (Jiang et al. 2016; Zhu and Argo 2013), we propose that circular (vs. angular) shapes are associated with a greater sense of completeness. Therefore, having a set of items placed in a circular (vs. angular) shape would increase consumers' perceived completeness of the set, and in turn increases the perceived importance of each component of the set.

We first conducted a pilot study to test the strength of association between circular shape and completeness. Participants ( $n=118$ ) were shown six shapes (i.e., triangle, square, rhombus, circle, rectangle, and trapezium) and asked to indicate which shape gave them the greatest feeling of completeness. We found that 67.8% of the participants indicated that circle gave them the greatest feeling of completeness (32.2% chose one of the five angular shapes;  $p < .001$ ).

Next, study 1 examined the effect of shape on set completeness perception. Participants ( $n=125$ ) were asked to view a flyer on the prevention measures for the Zika virus. When the study was conducted, the Zika virus was widespread in the city. Four prevention measures were listed in the flyer and each was illustrated with a figure and verbal descriptions. In the circular (vs. angular) condition, the measures were grouped in a circle (vs. square). After the participants have viewed the flyer, they were asked to indicate the extent to which the four measures formed a complete prevention process for the Zika virus (1 = not at all, 7 = very much). An ANOVA revealed that participants perceived the set of measures to be more complete when the measures were grouped in a circular (vs. angular) shape ( $M_{circular} = 4.75, M_{angular} = 4.26; p = .02$ ).

Study 2 tested the effect of shape on behavior. Participants ( $n=82$ ) were shown either a circular or square plate of similar size with four partitions, and were asked to pick as many snacks as they wanted. Each partition contained a type of snack. Using the variety of the snacks picked by participants (minimum = 1, maximum = 4) as the dependent variable, an ANOVA revealed that participants picked more types of snacks when the snacks were placed in a circular (vs. angular) plate ( $M_{circular} = 1.84, M_{angular} = 1.44; p = .035$ ). Similarly, using the total number of snacks picked by participants as the dependent variable, an ANOVA revealed that participants also picked more snacks when the snacks were placed in a circular (vs. angular) plate ( $M_{circular} = 2.21, M_{angular} = 1.54; p = .005$ ).

Study 3 investigated whether set completeness mediates the effect of shape on component importance. Participants ( $n=123$ ) viewed an ad for an oral care product collection (including toothpaste, mouthwash, and dental floss). In the circular (vs. angular) condition, the collection was grouped in a circle (vs. square). Two dependent variables were measured: (1) the completeness perception of the set;

and (2) product importance. We asked participants to rate the importance of mouthwash – which was not in the oral care routine for most participants. We found that a circular (vs. square) shape made participants perceive the product collection to be more complete ( $M_{\text{circular}} = 4.67$ ,  $M_{\text{angular}} = 4.30$ ;  $p < .05$ ), and the mouthwash to be more important ( $M_{\text{circular}} = 4.48$ ,  $M_{\text{angular}} = 3.97$ ;  $p = .05$ ). A mediation analysis further revealed that the completeness perception fully mediated the effect of shape on component importance.

Study 4 ( $n=293$ ) examined the moderating role of distinctive visual cues. We predict that distinctive visual cues (e.g., colors) will reduce completeness perception, and thereby attenuate the effect of circular shapes. We employed a 2 (shape: circle vs. square) 2 (component color: same-color vs. different-color) between-subjects design. In the same-color condition, we used the same design as we did in study 3. In the different-color condition, we used different background colors for the three component products. Participants responded to the same importance measure used in study 3. A two-way ANOVA revealed a significant interaction ( $p = .04$ ). Contrast analyses revealed that when the background of the components had the same color, a circular (vs. square) shape made participants perceive the mouthwash to be more important ( $M_{\text{circular}} = 4.48$ ,  $M_{\text{angular}} = 3.91$ ;  $p = .02$ ); when the components had different background colors, the shape manipulation did not affect mouthwash importance ( $M_{\text{circular}} = 3.96$ ,  $M_{\text{angular}} = 4.07$ ; *NS*).

Finally, study 5 ( $n=200$ ) tested whether familiarity with component items decreases the shape effect. We employed a 2 (shape: circular vs. angular) 2 (have been to New York: yes vs. no) between-subjects design with the first factor manipulated and the second factor measured. Participants first viewed an advertisement for New York City, which included five places. In the circular (vs. angular) condition, the places were grouped in a circle (vs. rectangle). The dependent variable was perceived set completeness. We found a marginally significant interaction ( $p = .08$ ). Contrast analyses revealed that for participants who had never been to New York, circular (vs. angular) shape made them perceive the set to be more complete ( $M_{\text{circular}} = 5.20$ ,  $M_{\text{angular}} = 4.71$ ;  $p = .07$ ); however, for participants who had been to New York before, shape did not affect set completeness perception ( $M_{\text{circular}} = 4.54$ ,  $M_{\text{angular}} = 4.67$ ; *NS*).

## Changing the World, One Word at a Time: The Effect of Font Size on Prosocial Intention

### EXTENDED ABSTRACTS

Expecting to have an impact toward achieving a goal is a powerful motivator. In the context of prosocial behavior, research shows people are motivated to help when they expect to have an impact on the cause under consideration (Duncan 2004; Bartels 2006; Fetherstonhaugh, Slovic, Johnson, and Friedrich 1997; Jenni and Loewenstein 1997). For example, the mere illusion of impact created by providing donors with specific (vs. generic) information about how funds will be used (Cryder Loewenstein, and Scheines 2013) or by describing recipients as nearby (vs. far away; Touré-Tillery and Fishbach 2017) motivates people to give more. The present research goes beyond the content of charitable appeals to examine how the size of the font used to fill out a pledge form can influence people's expectations that they can have a prosocial impact, and hence their prosocial intentions.

Imagine filling out a charitable pledge form online to help provide school supplies to disadvantaged children, such that everything you type is in a font larger than (vs. the same size as) the rest of the form. Would you pledge more money? We propose and find across four studies, that producing such a visual effect increases people's

expectations of impact, leading them to express greater prosocial intentions (e.g., larger monetary pledges). In all experiments, the font-size manipulation started on the first screen of the survey, where participants provided their consent, and participants answer a filler question so they would experience the font size before making their pledges. Participants pledged real earnings or potential raffle winnings from completing the study. We modelled pledge amounts through zero-inflated Poisson regressions.

**Experiment 1** tested the effect of font size on pledge amounts and the self-inferential nature of this process. The experiment employed a 2 (font size: large vs. regular)  $\times$  continuous (self-diagnostics score) between-subjects design. Three hundred fifty-seven residents of a metropolitan area in the United States (219 female,  $Median_{\text{age}} = 35-44$ ;  $Mode_{\text{age}} = 25-34$ ) read a charitable appeal, completed a pledge form in a large (vs. regular) font, and completed the self-diagnostics scale (SDS, Touré-Tillery and Light, 2018) to measure the extent to which they tend to make self-inference from their own behaviors. We found participants pledged higher amounts in large (vs. regular) font ( $b = -1.15$  (.096);  $z = -11.96$ ,  $p < .001$ ). Furthermore, we found the predicted interaction of font size  $\times$  self-diagnostics ( $b = .029$  (.0023);  $z = 12.81$ ,  $p < .001$ ), such that this effect occurred only at higher levels of SDS ( $z$ s between 1.96 and 2.03,  $p$ s between .05 and .043).

**Experiment 2** tested the meditating role of expected impact, employing a 2 (font size: large vs. regular) between-subjects design. Two hundred US-based participants (96 female,  $M_{\text{age}} = 34.46$ ,  $SD_{\text{age}} = 11.07$ ) recruited from Amazon's Mechanical Turk (MTurk) read a charitable appeal, indicated the extent to which they would expect their donation to have an impact, and completed a pledge form in a large (vs. regular) font. We found participants who completed the form in a large font pledged more money ( $M = \$6.85$ ,  $SD = \$6.85$ ) than those who completed it in a regular font ( $M = \$5.80$ ,  $SD = \$5.81$ ,  $\beta = .12$  (.057),  $z = 2.05$ ,  $p = .041$ ;  $r = .16$ ). Finally, this effect was mediated by expected impact (Model 4:  $a \times b = 1.02$  (.38),  $z = 2.70$ ,  $p = .007$ );  $a = 1.01$  (.32);  $t(192) = 3.21$ ,  $p = .002$ ;  $b = .099$  (.015),  $z = 6.62$ ,  $p < .001$ ;  $c = .0073$  (.059),  $z = .12$ ,  $p = .90$ ).

In **Experiment 3** we tested the moderating role of expected impact, which we operationalized through the effectiveness of the charity. The experiment employed a 2 (font size: big vs. regular)  $\times$  3 (charity effectiveness: none/control vs. low vs. high) between-subjects design. Five hundred ninety-five participants (291 female,  $M_{\text{age}} = 54.96$ ,  $SD_{\text{age}} = 13.83$ ) recruited from a large consumer panel read a charitable appeal and completed a pledge form in a large (vs. regular) font. Depending on the condition, they also read that the charity under consideration is highly effective, highly ineffective, or they received no effectiveness information—as in previous studies. We found a predictable main effect of effectiveness, and replicated the font-size effect in the no-information condition: participants pledged larger amounts when writing in large font ( $M = 11.53$ ,  $SD = 7.72$ ) than in regular font ( $M = 8.94$ ,  $SD = 7.91$ ;  $b = 0.099$  (.044),  $z = 2.23$ ,  $p = .026$ ). However, there were no effects in the other two conditions.

Finally, **Experiment 4** tested the moderating role of donors' primary motivation: making an impact (outcome) versus signaling. The experiment employed a 2 (font size: large vs. regular)  $\times$  2 (motivational focus: outcome vs. signaling) between-subjects design. Three hundred and ninety-eight US-based participants (159 female,  $M_{\text{age}} = 32.99$ ,  $SD_{\text{age}} = 11.30$ ) recruited through Prolific Academic read a charitable appeal and completed a pledge form in a large (vs. regular) font. Depending on the condition, the appeal emphasized donating to "make a difference" or to "show that you care." We found the predicted interaction of font size  $\times$  motivational focus ( $b = .24$  (.079),  $z = 3.06$ ,  $p = .002$ ), such that the font-size effect emerged

only in the outcome condition ( $M_{\text{large}} = \$7.38, SD_{\text{large}} = \$6.88; M_{\text{small}} = \$5.67, SD_{\text{small}} = \$5.41; b = .19 (.057), z = 3.37, p = .001$ ).

Taken together, these results show the effect of font size on pro-social intentions stems from fluctuations in expected impact. Specifically, typing in a large (vs. regular) font increases people's expectations that their actions will make a difference, and this assurance in turn increases their motivation to act. These results have obvious implications for charitable organizations that solicit donations online. The results also suggest decision makers should consider font size when measuring pro-social intentions (e.g. voting intentions) to minimize systematic errors.

## The Unbearable Smallness of Being: How Feeling Physical Small Influences Decision Delegation

### EXTENDED ABSTRACTS

Consumers often encounter stimuli that make them feel physically small by contrast, such as when seeing background pictures that feature the vastness of nature during online shopping or standing in shopping malls with high ceilings. Because how consumers perceive themselves influences how they make decisions (Gao, Wheeler, and Shiv 2009; Touré-Tillery and Fishbach 2015), we explore the impact of feeling physically small on consumer decision with a focus on decision delegation.

Since a smaller body size inevitably means less control over one's physical environment (e.g., ant vs. elephant; toddler vs. adult), we propose that the carry-over effect of feeling physically small in the decision-making context is a weakened sense of decision efficacy, an aversive state. Further, we propose that people can either directly or symbolically resolve this "unbearable" state (see Mandel et al. 2017 for a review) by engaging in different levels of decision delegation. Specifically, when an external decision agent appears to possess efficacy (e.g., group consensus, expert advice), people engage in direct resolution by outsourcing the agent's efficacy, resulting in more delegation. On the contrary, when the external decision agent does not possess efficacy (e.g., a random recommendation algorithm), people engage in symbolic resolution by relying more on themselves, as the action of making decisions per se can bolster the sense of efficacy (Langer 1975; Su et al. 2016; Zuckerman et al. 1978), resulting in less delegation. Five studies tested this framework.

Experiments 1-3 tested the direct resolution path. In **Experiment 1**, we had participants select silhouettes of different sizes to represent themselves when the reference objects were larger than the self (e.g., a tall building; small condition) or of similar size to the self (e.g., a desk; control condition) (adapted from van Elk et al 2016; pre-tested), following which participants made brand choices with information on the majority's decisions (i.e., wisdom-of-the-crowd; adapted from Dong and Zhong 2017). We found that participants "copied" the majority's choice more often in the small ( $M=3.25, SD=1.52$ ) than control condition ( $M=2.82, SD=1.66, t(281)=2.28, p=.023$ ).

**Experiment 2** tested the mediating role of decision efficacy in the direct resolution path. Participants imagined shopping for a TV online and viewed images of four TV models, with either photos of the Milky Way (small condition) or a flower (control condition) as screensavers. They then wrote about their thoughts about the screensavers and reported confidence of making a wise TV choice (i.e., self-reported decision efficacy). Next participants read the specification information and learned that they can either make a choice by themselves or "choose the best-seller." Participants were more likely to choose the best-seller in the small (12.2%; 12/98) than control condition (4.1%; 4/101;  $(1)=4.23, p=.04$ ), and self-reported decision efficacy mediated the effect ( $=2.01; p=.044$ ; Iacobucci 2012).

**Experiment 3** used a moderation approach to test the theory, predicting that it only holds for individuals whose decision efficacy is chronically lower in a given context. We had participants make stock decisions (adapted from Huang et al. 2014) with the opportunity to delegate these decisions to a financial company, whose advertisement and brand logo employed images of giant mountains (small condition) or no images at all (control condition). Afterwards, participants took a financial literacy test (James et al. 2012). We found the predicted interaction of feeling small by financial literacy ( $p=.017$ ; floodlight region significant below 4.01), with the effect significant only among those low on financial literacy (i.e., with chronically low decision efficacy in this context).

**Experiment 4** tested the symbolic resolution path, by using a random algorithm which does not possess any decision efficacy as the external decision agent. We first elicited thoughts about feeling small (or not) by having participants view a picture of the galaxy and write down three thoughts in the format "In the vast universe, I..." or a picture of color blocks and wrote in the format "I..." We then offered participants an opportunity to win a lottery and measured whether they would like to select the lottery ticket by themselves or let a random algorithm decide for them. Results show that feeling small reduced the likelihood of using the random algorithm (12.3%; 10/81 vs. 25.4%; 18/71;  $(1)=4.26, p=.039$ ).

Finally, **Experiment 5** tested both the direct and symbolic resolution paths, using a 2 (feeling small vs. control)  $\times$  2 (majority's choice reflects decision efficacy vs. not) between-participants design. We first manipulated perceived self-size as in Experiment 1 and then had participants fill out either a Knowledge or Preference Survey (adapted from Griskevicius et al 2006), with information on the majority's choice. We informed participants that questions in the Knowledge (vs. Preference) survey had correct answers (vs. only elicited personal taste), and thus the majority's choice reflects the collective decision efficacy (vs. no information). We measured the frequency of following the majority's choice and found the predicted interaction ( $F(1, 275)=7.23; p=.008$ ). Whereas feeling physically small led participants to follow the majority's choice more often when answering the Knowledge survey ( $=4.60$  vs.  $=4.23, F(1,275)=2.84; p=.093$ ), the reverse was true when they answered the Preference survey ( $=3.46$  vs.  $=3.91; F(1, 275)=4.50, p=.035$ ). This interaction pattern rules out "feeling powerless" as an alternative since feeling powerless fosters a communal orientation (Rucker, Galinsky, and Dubois 2012) which increase compliance with others' decision regardless of others' decision efficacy.

Taken together, we show that feeling physically small lowers people's perceived decision efficacy and document two seemingly opposite paths that people use to resolve this "unbearable" state. Our research contributes to literature on compensatory consumption (Mandel et al. 2017) as well as offer implications on how subtle cues in marketing environment can influence choice delegation and compliance.

### **SESSION OVERVIEW**

Goals are not easy to attain. People commonly experience difficulty in almost every stage of goal pursuit from the initiation of goal-relevant behaviors, to the maintenance of goal progress, and to the completion of goal pursuit. How can we help people overcome the barriers to achieve success in goal pursuit? And how can we leverage psychological insights to facilitate people’s goal pursuit? This proposed session presents four papers that answer these questions in different stages of the goal pursuit process. From the initiation of goal pursuit (paper 1), to the maintenance of a goal (paper 2), the furthering of progress (paper 3), and to the completion of goal pursuit (paper 4), these four papers provide distinct and critical insights that effectively tackle the barriers in goal pursuit, and present substantial evidence on real behavioral consequences.

Yang, Gounder, and Bagchi examine the initiation stage of goal pursuit. They posit that people find the first step in task initiation to be extra daunting because it is perceived as a big step breaking the psychological barrier between pre-pursuit and in-pursuit phases. To help ease people into the in-pursuit phase, they propose and find that token “break-in” gestures, such as randomly marking task materials, can effectively increase the likelihood of task initiation and reduce the likelihood of goal abandonment.

John, Hershfield, and Shu test a theory of goal maintenance. They theorize that emotions elicited from the perceived discrepancy between the pre-goal self and the current self will keep motivating goal-congruent behaviors during goal pursuit and following goal attainment. In five studies, they find that making salient the past-versus-present contrast of the self in actual weight loss goal pursuits consistently leads to greater success in maintaining the progress achieved after a goal is attained.

Kim and Urminsky explore factors that enhance further progress in goal pursuit. They focus on how perceived similarity between forgone options informs goal progress and thus prompts more goal-congruent choices in subsequent goal conflict situations. In five experiments conducted in a variety of domains, they demonstrate that highlighting the dissimilarity between forgone options increases per-

ceived goal progress, which in turn increases the likelihood of goal-congruent choices.

Ruan, Polman, and Tanner investigate the completion of goals and identify a distinct source of motivation that comes into play near the end of goal pursuit – the pleasure from the mere completion of goal means, which is independent from that of achieving the goal reward per se. They show in a series of experiments how this previously overlooked factor contributes to the motivation towards goal completion and the evaluation of complete versus incomplete goal pursuits, shedding light on when and why people are most driven by goal completion.

In sum, these papers provide a comprehensive view on the process of goal pursuit, suggest new actionable behavioral interventions, and deepen our understanding of the barriers and facilitators to success.

## **The “Break-in” Effect: A Token Gesture Can Increase Task Initiation and Prevent Goal Abandonment**

### **EXTENDED ABSTRACT**

Many goal pursuits fail at the stage of task initiation—starting is half the battle, as many proclaim. Even when an initial task is well within one’s capabilities, the thought of task initiation can feel so overwhelming that people often end up procrastinating and eventually abandoning the goal altogether. How can people overcome their fear of task initiation and be less likely to abandon goals?

In this research, we examine a behavioral intervention for task-initiation failures. We theorize that the identification of a goal prompts people to categorize tasks by goal-relevance, which creates a virtual barrier between pre-pursuit and in-pursuit phases in their mental representation. Consequently, the small first step of task initiation tends to be perceived as a big step that breaks the virtual barrier and enters one into the in-pursuit phase. We thus posit a successful “nudge” intervention may rest in helping people accidentally cross this virtual barrier. In particular, we hypothesize that a token “break-in” gesture—a simple action conceptually irrelevant to the goal pursuit yet perceptually moves people from the pre-pursuit phase to the in-pursuit phase, can facilitate task initiation and reduce goal abandonment. Three experiments demonstrate the effectiveness of “break-in” token gestures (e.g., leaving inadvertent marks on task materials), including two studies with real behavioral consequences and one with process evidence on the role of perceived dauntingness. This research sheds new light on task initiation failures and joins the growing literature on leveraging behavioral insights to improve goal implementation (Dai, Milkman and Riis 2015, Rogers and Milkman 2016, Tu and Soman 2014).

In Study 1, 151 students were recruited to a laboratory for a take-home individual research assignment in exchange for a performance-based \$5 Amazon e-gift card. Participants were randomly assigned to 2 (break-in vs. control) between-subjects conditions. After learning about the topic of the take-home assignment, participants were given an honor code sheet and an answer sheet. The honor code, which participants signed and handed back to the experimenter, stated that participants would only use the internet for the assignment without help from others. The answer sheet, which participants took home inside a folder, contained further instructions about the assignment including questions to answer. After participants wrote down

## A Theory of Goal Maintenance: A Distinct and Vivid Pre-Goal Self Predicts Post-Goal Maintenance Behavior

### EXTENDED ABSTRACT

We develop and test a theory of goal maintenance which posits that individuals who achieve a life-changing goal – such as getting out of debt, becoming sober, or losing a substantial amount of weight – are more likely to maintain the progress achieved during goal attainment if they psychologically distance themselves from their pre-goal self and routinely engage in activities that activate memories of their past, less flattering self. This new model is an extension of self-discrepancy theory (Higgins, 1987), as it relates discrepancies in self-state representation to motivation and intertemporal behavior. We posit that the accessibility and closeness of the prior, pre-goal self, when activated, will continue to elicit emotions that motivate behavior of the current, improved self. We are currently applying this model of goal maintenance to weight loss maintenance. Through five studies, we explore whether accessibility and perceived closeness of the overweight past self predicts successful weight maintenance after a weight loss goal has been achieved.

Study 1, a survey of 400 Amazon Mechanical Turk subjects who reportedly lost at least 10% of their body weight, revealed correlational evidence that weight maintainers are more likely to see themselves as psychologically distant from their past, overweight selves and are also more likely to activate memories of their past, overweight selves compared to weight regainers. Regression analysis was performed on the survey dataset to determine what, if any, behaviors consistent with our proposed theory explain weight loss outcomes when controlling for demographic factors - such as age, race, and gender. Consistent with our theory, the analysis revealed that posting before-and-after pictures of oneself on social media ( $p < 0.1$ ), feeling motivated when thinking about weight regain ( $p < 0.01$ ), and feeling psychologically distant to one's past, overweight self ( $p < 0.01$ ) were predictive of weight maintenance.

Study 2, an online study of 220 participants from the school's Behavioral Lab subject pool who reportedly lost at least 10% of their body weight, provided evidence that manipulating the vividness of the past, overweight self activates implicit goal maintenance behavior, conducive to sustaining weight loss. We used willingness to pay (WTP) for healthy and unhealthy products and services to measure participant's motivation to maintain weight. Eligible participants were randomly assigned to three conditions: a baseline condition, where the past self was not made salient; a past self condition, where the past self was made salient; and a past self contrast condition, where the past self and closeness to the past self were made salient. The DV was a WTP task for specific products and services (e.g. an all-you-can-eat buffet, a pound of grapes, a slice of cheesecake, a one-on-one personal training session, and a one-hour tennis lesson). Figure 1 displays the results for all three conditions. A one-way MANOVA indicated that assignment to condition significantly affected participants' WTP ( $p < 0.0002$ ). Participant motivation levels to maintain weight loss increased when the past self was made salient ( $M = 11.06$ ,  $SE = 0.20$ ) and increased even further when the past self and closeness to the past self were made salient before the WTP task ( $M = 11.45$ ,  $SE = 0.19$ ), as compared to the baseline condition ( $M = 10.40$ ,  $SE = 0.19$ ). Accordingly, accessibility of the past self in memory and evaluations of closeness between the past self to the current self appear to work cooperatively to increase goal-related motivation.

Study 3, a text and sentiment analysis of over 400 blogs from a popular weight management website, demonstrated that those more

the honor code and their name, the experimenter handed them a pen with green ink to complete the answer sheet with, ostensibly for the digital transcription of their answer sheet. Participants were asked to either scribble on the upper margin of the answer sheet (break-in condition) or the honor code sheet (control condition) to test out this pen. Even though the scribble action was irrelevant to the content of the assignment, we theorize that the scribble on the answer sheet would serve as a token "break-in" gesture because leaving a mark on the task material would shift participants from the pre-pursuit phase to the in-pursuit phase and render the assignment task less daunting. By contrast, the scribbles on the honor sheet would not have such an effect because it belonged to the pre-pursuit phase.

Participants had about three weeks to submit their completed answer sheet. We recorded both the time of participants' initial access to the submission link and the time of task submission. The records indicate that more participants in the "break-in" condition initiated the task (52.0%) compared with those in the control condition (35.5%,  $\chi^2(1) = 4.16$ ,  $p = .041$ ,  $w = .17$ ). Moreover, more participants in the "break-in" condition (50.7%) completed the task compared with those in the control condition (32.9%,  $\chi^2(1) = 4.90$ ,  $p = .027$ ,  $w = .18$ ). The "break-in" gesture was effective at increasing both task initiation and goal completion. Among those who submitted the answer sheet, a similar number of questions were answered correctly between conditions ( $M_{\text{break-in}} = 3.61$  vs.  $M_{\text{control}} = 3.56$ ,  $t = .20$ ,  $p > .250$ ), suggesting similar motivation and task difficulty between conditions.

We further examined the effect of "break-in" gestures on reducing goal abandonment as a behavioral intervention in Study 2 and to shed light on the process in Study 3. In Study 2, 255 MTurkers completed two sequential surveys about the adoption of a new exercise routine at the start of a new year. Participants were asked to download a 2-page guideline for the exercise routine and to report back in two weeks. The "break-in" condition differed from the control condition in an ostensible attention check question, which either asked participants to manually highlight each instance of an arbitrary word in the document and save the highlights, or asked them to manually search for the same arbitrary word without highlighting the word. Two weeks later, more participants in the "break-in" condition reported having tried the exercise than those in the control condition, controlling for individual fixed effects (86.3% vs. 77.8%;  $b = .77$ ,  $SE = .37$ ,  $Wald = 4.34$ ,  $p = .037$ ).

In Study 3, 249 MTurkers were asked to imagine having to read a recently published scientific report in the next few days among other job duties. The first page of the printed report was either tainted by an accidental coffee spill or not, the image of which was visually presented to participants. Despite the stain from the spill being obviously goal-irrelevant and explicitly described as incidental, it reduced perceived task dauntingness ( $M_{\text{break-in}} = 4.13$ ,  $SD = 1.96$  vs.  $M_{\text{control}} = 4.67$ ,  $SD = 1.74$ ;  $t = -2.29$ ,  $p = .023$ ,  $d = .29$ ) and increased the self-reported likelihood to start the task as planned ( $M_{\text{break-in}} = 5.57$ ,  $SD = 1.40$  vs.  $M_{\text{control}} = 5.07$ ,  $SD = 1.68$ ,  $t(247) = 2.53$ ,  $p = .012$ ,  $d = .32$ ). Perceived dauntingness mediated the effect of the "break-in" token gesture on the predicted likelihood of task initiation (indirect effect  $b = .10$ ,  $SE = .05$ ,  $p < .001$ ,  $CI [.02, .23]$ ). No difference was found in other dimensions of task perception including difficulty and motivation. Last, an ongoing study was designed to shed more light on the underlying mechanism.

successful in weight loss and maintenance focus less on the future and use more discrepancy language than those less successful. Blog posts were evaluated using the Linguistic Inquiry and Word Count (LIWC) software (Pennebaker, Francis & Booth, 2007); specifically, sentiment categories that may indicate focus on the past self and distinctions between the past and current selves – including discrepancy, verb tense (i.e. past, current, future), compare, and difference scores – were analyzed. The regression results indicate that the blogs of those more successful in weight loss or maintenance express less negative emotions ( $p < 0.01$ ), are less future focused ( $p < 0.05$ ), and are more likely to express the cognitive process of discrepancy ( $p < 0.1$ ). Overall, the natural language processing analysis suggests that successful weight loss outcomes are associated with language that includes greater discrepancy content and is focused significantly less on the future.

Study 4 aimed to test these ideas in a causal setting. Using a longitudinal study of 32 subjects from the school's Behavioral Lab subject pool, Study 4 provided preliminary evidence that constant reminders of a past, overweight self through digital media can lead to more successful weight maintenance over time among individuals who recently met a weight loss goal. Participants assigned to a baseline condition received two inspirational quotes via email each week over a four-week period, and participants assigned to the past self contrast condition received the same inspirational quotes via email, but their messages also included their personal before-and-after weight loss pictures as a vivid reminder of their past selves. Over the four-week period, participants in the baseline condition gained 0.02% ( $SD = 1.52\%$ ) weight on average whereas those in the past self contrast condition lost 0.4% ( $SD = 2.21\%$ ) weight on average. These results are consistent with our theory. However, this effect did not reach conventional levels of statistical significance due to our small sample size. Seven subjects did not complete the study by participating in the final weigh-in.

In Study 5, we used the same methodology as Study 4, but we evaluated effects over 12 weeks instead of four weeks, and we recruited 49 subjects from the Behavioral Lab subject pool to participate in the study. Over the 12-week period, participants in the baseline condition gained 1.01% ( $SD = 2.20\%$ ) weight on average whereas those in the past self contrast condition gained 0.28% ( $SD = 2.68\%$ ) weight on average. The difference in weight change between conditions was not statistically significant at conventional levels; however, the weight increase in the baseline condition was statistically different from zero ( $p = 0.032$ ) whereas the weight increase in the past self contrast condition was not statistically different from zero ( $p = 0.60$ ), suggesting maintenance on average in the latter but not the former.

**Want to Stick to Your Goals?  
Think about “Dissimilar” Alternatives that You’ve  
Forgone!**

**EXTENDED ABSTRACT**

Past research demonstrates that thinking about forgone alternatives influences utility from a chosen option. Consumers obtain higher utility when choosing a virtue from a mixed set that contains both vices and virtues than choosing from a homogeneous set that only contains virtuous options (Dhar & Wertenbroch, 2012). Further, Sagi and Friedland (2007) suggest that when choosing from diverse alternatives, evaluations of a chosen option depend on the summed utility of all of the unchosen alternatives, not just the second-best alternative's utility.

We explore how the similarity of forgone alternatives impacts perceived goal progress and subsequent decisions. Specifically, we find that when consumers consider dissimilar (vs. similar) goal-inconsistent alternatives that they could have chosen, they believe that they have achieved more progress towards their goal. Further, they are then more likely to stick to the goal in a subsequent choice. However, considering dissimilar (vs. similar) unchosen options impacts goal perceptions only when the focal goal is personally relevant. Our findings are replicated in varying goal-conflict situations (saving vs. spending: study 1, donating vs. spending: study 2, healthy vs. tasty food: studies 3 to 5), including real choices (Study 5).

Study 1 ( $N = 124$ ) provides an initial demonstration of the effect of forgone-option similarity on perceived goal progress. We employed saving (vs. spending) as a widely shared goal—in our pre-test ( $N = 142$ ), 96% of people indicated they currently endorse saving as their active personal goal. All participants were first asked to write down how they would like to spend \$150 for themselves. Next, they were asked to briefly list two similar (dissimilar) alternative ways to spend the same amount of money, and explained why the three ways are similar (dissimilar) from one another. After the alternative-listing phase, participants imagined a situation in which they had decided to save an unexpected \$150 of income, instead of spending it on one of the alternatives. Participants then indicated how much progress, contribution, or achievement they think they would have made towards their savings goal (averaged into a perceived goal progress score,  $\alpha = .91$ ), as well as good feeling about themselves, decision satisfaction, and decision difficulty.

The manipulated similarity of considered alternatives significantly impacted perceived goal progress. Despite considering the same objective savings, participants who generated dissimilar alternative ways of spending reported higher perceived progress ( $M_{\text{dissimilar}} = 5.51$  vs.  $M_{\text{similar}} = 5.05$ ,  $p = .04$ ). However, option similarity did not yield any significant differences on the other measures, including choice difficulty.

In study 2 ( $N = 375$ ), we employed donation as a goal context to examine whether the personal relevance of a focal goal moderates the effect of option similarity on goal progress perception. The goal's relevance was manipulated by having participants read an article stressing the importance of either individual donors (like the participants) or of a few wealthy donors, and participants then generated alternative uses for donated money. When the goal was relevant, those who generated dissimilar (vs. similar) alternatives felt that donating yielded greater progress ( $M_{\text{dissimilar}} = 5.97$  vs.  $M_{\text{similar}} = 5.30$ ,  $p < .01$ ). However, when the donation goal was less relevant, similarity of the alternatives did not affect perceptions of donating ( $M_{\text{dissimilar}} = 5.45$  vs.  $M_{\text{similar}} = 5.45$ ,  $p = .98$ ). A 2 (similarity: similar vs. dissimilar) X 2 (salience: high vs. low) ANOVA confirmed a significant interaction ( $F(1, 371) = 5.87$ ,  $p = .01$ ), even after controlling for the attractiveness of the alternatives that participants generated.

Study 3 ( $N = 469$ ) extends the previous findings in three ways: 1) measuring pre-existing differences in individuals' goal relevance, 2) generalizing to a different goal context (dieting), 3) providing pre-set alternatives, instead of using self-generated alternatives. All participants imagined being on a diet and choosing to have apple chips instead of high-calorie snacks. They were shown 3 high-calorie alternative snacks they could have chosen, either in the same category (e.g., 3 different flavors of donuts) or in different categories (e.g., 1 donut, 1 cupcake, 1 chocolate), and evaluated perceived goal progress. Replicating our previous results, we observed a significant interaction between manipulated similarity and measured goal relevance (measured by Concern with Food and Eating subscale of Restraint Questionnaire [Herman and Mack 1975];  $F(1, 458) = 8.92$ ,  $p$

< .01). The more the dieting goal was personally relevant, the higher progress participants felt by forgoing dissimilar (vs. similar) goal-inconsistent alternatives.

Study 4 ( $N = 174$ ) measured subjective goal progress based on individuals' actual experiences, rather than an imagined situation, and tested the consequences for subsequent goal pursuit. As in previous studies, participants showed higher perceived goal progress when they were assigned to consider their own past dissimilar (vs. similar) unhealthy alternatives ( $M_{\text{dissimilar}} = 5.23$  vs.  $M_{\text{similar}} = 4.71$ ,  $p = .01$ ). Furthermore, when making a subsequent hypothetical choice, participants were more likely to choose a healthy food when they thought about dissimilar (vs. similar) unhealthy options to a prior healthy choice (51% vs. 83%,  $p < .01$ ). A mediation analysis revealed that higher perceived goal progress due to considering dissimilar alternatives mediated increased choice share of the healthy option ( $b = .32$ , 95% CI = [.02, .87]).

Finally, in study 5 ( $N = 223$ ), we replicated the effect on consequential choices in a naturalistic setting among people who had actually engaged in their exercising goal. When gym-goers who had just completed their workout were asked to recall dissimilar activities they could have done instead of exercising reported higher perceived goal progress ( $M_{\text{dissimilar}} = 4.73$ ) than 1) those asked to recall similar alternatives ( $M_{\text{similar}} = 4.25$ ,  $p = .05$ ) and 2) those not asked to recall any alternatives ( $M_{\text{control}} = 4.00$ ,  $p < .01$ ). Further, participants were more likely to choose a healthy energy bar subsequently after recalling dissimilar alternatives (64% vs. 39% (similar;  $p < .01$ ) vs. 45% (control;  $p = .04$ ).

Taken together, these results can advance our understanding about the role of choice set in goal-pursuit behavior. Our findings offer practical insight into how to enhance motivation by merely shifting which forgone alternatives people focus on.

## Mere and Near Completion

### EXTENDED ABSTRACT

What motivates people to pursue goals? Extant research converges on the idea that goals are cognitive representations of desired end-states (Bargh 1990; Ferguson and Cone 2013; Fishbach and Ferguson 2007) and the positivity associated with these desired end states is what imbues goals with motivational force (Atkinson 1974; Tolman 1932). For example, in a punch-card-style loyalty program, the acquisition of rewards is a desirable end state and the motivation to collect stamps originates in the desire to acquire rewards.

In this research, however, we suggest an additional source of motivation that is entirely distinct from the particular desired end-state obtained by fulfilling a goal. Specifically, we argue that, quite separate from the reward for completing a goal, people are also motivated by the fact that the mere completion of goal means (e.g., collecting the required number of stamps in a loyalty program) is satisfying in its own right. Put simply, people like to complete things – it feels satisfying. Apparent as it may seem, the motivation to complete per se has been largely overlooked in extant goal research. While it has been shown that people do seek the mere completion of things (Halkjelsvik and Rise 2015; Ovsiankina 1928), we are unaware of any research directly exploring how a motivation to merely complete interacts with the pursuit of a desirable end-state in determining aggregate motivation to pursue the goal. The current research was envisaged to disentangle the two, and to show that a desire for mere completion represents a distinct motivation guiding progress toward goal completion.

Building on the proposition that mere completion is satisfying in its own right, we further propose that 1) people will become

gradually insensitive to the size of goal reward (e.g., \$3 vs. \$10) as the distance to completing a goal decreases, because of the increase in the motivation to seek mere completion, and that 2) people will prefer a goal that is almost complete over one that is already complete, because the former implies that they will get to complete it, and therefore reap the hedonic benefits that accompany a feeling of completion.

We have run 14 studies in total. We will next report five of them that are central to testing our hypotheses.

Study 1 tested the utility of mere completion. It required participants to do a boring task – clicking on buttons on a computer screen. Participants were informed that the computer would tell them to stop when they had reached the total required number of clicks. In the complete-set condition, participants were stopped after they had clicked all nine buttons ten times each. In the incomplete-set condition, they were stopped after they had clicked eight of the nine buttons ten times each. Although complete-set participants repeated the boring task more times, at the end of the study, they felt overall better ( $M = 4.34$ ,  $SD = .80$ ) than incomplete-set participants ( $M = 4.05$ ,  $SD = .73$ ;  $F(1, 120) = 4.43$ ,  $p = .037$ ). Study 1 also included two measures of the feeling of completion, both of which mediated the effect of our manipulation on feelings, with the indirect effects significantly differing from zero ( $\beta s > .09$ , 95% confidence intervals [CIs]  $\subset$  [.01, .77]).

Study 2 tested the hypothesis regarding how much people value a goal that is almost complete vs. one that is already complete. Participants were told that they had collected either six or seven stamps in a loyalty program where they could get \$3 after collecting seven stamps. Contradicting pure economic considerations, participants charged a higher price for six stamps ( $M = 4.98$ ,  $SD = 5.23$ ) than seven stamps ( $M = 3.32$ ,  $SD = 2.27$ ;  $F(1, 183) = 8.01$ ,  $p = .005$ ). We name this effect as the one-away effect. Consistent with our theory, Study 3 found that expected excitement of collecting the next stamp mediated the one-away effect ( $\beta = -.65$ , 95% CI: [-1.33, -.04]), and Study 4 showed that the one-away effect disappeared when the acquisition of reward was not associated with the eventual completion of collecting stamps (e.g., for a loyalty card that has twelve slots and awards \$3 for every 6 stamps collected, the acquisition of the first \$3 reward leaves six slots unstamped.) Figure 1 summarizes the main results of Study 4.

Study 5 tested the hypothesis regarding scope-(in)sensitivity to the size of a goal reward. Study 5 represented a 2 (Progress: 1 stamp vs. 9 stamps)  $\times$  2 (Reward: \$3 vs. \$10) between-participants design. Participants were told that they had collected either one stamp or nine stamps in a loyalty program that offered either \$3 or \$10, depending on the condition they were randomly assigned to. Participants then indicated to which extent they were motivated to collect the next stamp. A two-way ANOVA between progress and reward a significant interaction effect ( $F(1, 654) = 4.82$ ,  $p = .029$ ). Although participants were significantly more motivated by the larger reward (vs. smaller reward) when completion progress was low (1 stamp of 10) ( $M = 4.87$ ,  $SD = 1.51$  vs.  $M = 4.11$ ,  $SD = 1.63$ ;  $F(1, 654) = 19.53$ ,  $p < .001$ ); when completion progress was high (9 stamps out of 10), there was no difference in motivation between the smaller and larger reward sizes ( $M = 5.35$ ,  $SD = 1.56$  vs.  $M = 5.58$ ,  $SD = 1.54$ ;  $F(1, 654) = 1.66$ ,  $p = .198$ ). Thus, as we anticipated, when the goal was near completion, participants became insensitive to reward size. Participants were equally motivated to complete the goal regardless if the reward size was smaller or larger.

The current research has important implications. In theoretical terms, this research demonstrates the important role of mere completion in determining motivation and influencing decision making and

bridges findings in seemingly disparate research domains (e.g., consumer collection, loyalty programs, curiosity, the sunk-cost fallacy, the mere urgency effect). In practical terms, our research explains why consumers sometimes neglect their loyalty rewards, and reveals how marketers can use strategies based on mere completion to increase the persuasiveness of their promotions.

### **SYMPOSIUM OVERVIEW**

The growth of luxury consumption has been one of the biggest trends in marketing over the last two decades. During this time, sales of luxury goods have skyrocketed from \$80 billion to over \$900 billion per year and the number of luxury brand users has more than tripled from 90 million to 450 million worldwide (D'Arpizio 2017). Many new research and practical questions are raised in the new era of luxury consumption: What constitutes of luxury products? What information does luxury products communicate to the audience in different contexts? How do audience perceive luxury consumers? To answer these questions, this session provides new insights and novel findings from four papers that explore the new meanings of luxury and status.

The first paper examines a novel factor, time, and how it interacts with luxury products. Across four studies, the authors show that slow (vs. fast) motion in the advertising for luxury products heightens status perception and leads to more positive evaluations of the brand.

The second paper investigates how luxury products can be used in a new context: in a romantic relationship. The authors propose that women use luxury products as signals about their mating preference to potential romantic partners. Four studies show that women's desire for luxury products are triggered by mate selection motivate.

The last two papers examine how luxury consumers are perceived in the social context. Both paper provide novel theoretical frameworks to reconcile the potential positive and negative social impressions made about luxury consumers. The third paper develops a new framework to examine when consumers are likely to benefit and be punished for luxury consumption. Four studies show that although consumers with luxury products are perceived to have higher status, they are also perceived to be less warm. Finally, the fourth paper explores the underlying reasons behind consumers' negative perceptions of high-end luxury consumption. Despite the fact that luxury goods are actually sustainable, as they last longer and have higher resale value than ordinary goods, four studies demonstrate that luxury consumers are seen as wasteful because their purchases

are deemed unnecessary. Further, this negative bias diminishes when luxuries are framed as long-lasting investments.

Taken together, this set of papers opens up several new avenues of research in the area of luxury and status consumption. Each paper includes a complete set of experiments and provides process evidence that can stimulate new research ideas and provide practical insights in the area of luxury and status consumption. Given the variety of settings and questions, this session is likely to appeal to a broad set of conference attendees interested in luxury goods, status, social signaling, and branding.

## **When Does Slow Mean Luxurious?: The Effect of Product Motion Speed in Brand Communications on Status Perceptions**

### **EXTENDED ABSTRACT**

When asked to define luxury, Christian Blanckaert, former Chairman and CEO of Hermès, responded "It is mastering the balance between timelessness and timeliness." The current research focuses on one prevalent manifestation of time: the motion speed of products in brand communications. Past research has shown that brands can convey status to consumers through various visual means, such as adding art to product packaging and design (Hagtvedt and Patrick 2008), varying the prominence of brand logos (Han, Nunes, and Drèze 2010), and adjusting interstitial space in retailing (Sevilla and Townsend 2016). Despite considerable interest in the visual cues of status, little is known about how motion may also shape status perceptions. This omission is surprising given the growing importance of video advertising in the current multimedia environment (Google/Ipsos Connect 2017).

Although unexplored in the social sciences, anecdotal evidence suggests that slow motion is used in theatre and novel writing to signify high status. For example, consider the following advice from the editors of *Writer's Digest*: "...To make a villain more imposing, let him slow down. Show readers that he's in no hurry to commit his evil deed—he has such high status that he can walk slowly and still catch the person fleeing frantically through the woods" (2017, 112; see also Johnstone 2012). Moreover, advertising textbooks discuss the pervasive use of slow motion as a visual tool to emphasize luxury, especially in car ads (Brierley 1995; Wells et al. 1992).

Building on this potential relationship, we posit that moving products presented at a slower speed are perceived as having higher status—the respect and admiration from an audience (Magee and Galinsky 2008; Dubois and Ordabayeva 2015). As a result, the products are seen as more desirable. We measure a product's desirability through consumers' likelihood to share word-of-mouth (WOM) about the product with others (Angelis et al. 2012). We further show that this effect of motion speed on status perceptions is attenuated for products of non-luxury brands for whom status is not relevant.

In study 1A, 197 Mechanical Turk (MTurk) participants were randomly assigned to one of two conditions (slow vs. fast). Participants watched a video clip featuring a bottle of red wine purportedly made by a small premium winery. They saw the wine being poured into a glass. The clip was three times slower in the slow condition (15s) than the fast condition (5s). Then participants rated the wine on status perceptions using three items (prestigious, luxurious, high status; Ward and Dahl 2014). The wine was perceived as hav-

ing higher status in the slow ( $M=5.20$ ,  $SD=1.16$ ) than fast condition ( $M=4.82$ ,  $SD=1.34$ ;  $F(1, 195)=4.61$ ,  $p=.033$ ).

In study 1B, 197 MTurk participants were randomly assigned to one of two conditions (slow vs. fast). Participants watched a video clip of a rotating ring purportedly made by Chanel. The clip was four times slower in the slow condition than the fast condition. To keep viewing time constant (about 25s) across conditions, the clip in the fast condition was repeated three times. Next, participants were told to imagine that their female friend was thinking of buying a ring and indicated how likely they were to recommend the ring to the friend. Then they rated the ring on status perceptions using the same three items. Participants were more likely to recommend the ring in the slow ( $M=4.56$ ,  $SD=1.69$ ) than fast condition ( $M=3.81$ ,  $SD=1.69$ ;  $F(1, 195)=9.54$ ,  $p=.002$ ). Furthermore, the ring was perceived as having higher status in the slow ( $M=5.67$ ,  $SD=1.29$ ) than fast condition ( $M=5.18$ ,  $SD=1.42$ ;  $F(1, 195)=6.23$ ,  $p=.013$ ). Status perceptions mediated the relationship between motion speed and recommendation likelihood (indirect effect=.23,  $SE=.099$ , 95%  $CI=[.059, .46]$ ).

In study 2, 367 participants on Prolific Academic were randomly assigned to one of two conditions (luxury vs. non-luxury). They were told to imagine that they were marketing managers of a luxury (vs. non-luxury) brand that sells high-end, premium (vs. cheap, affordable) jewelry. They were informed that their task was to create a video ad for the brand's newly released earrings. Participants were given two motion speed options for the ad: a faster option and a slower option. Each option was accompanied by a video clip featuring a pair of earrings going around in circles. The two video clips were identical except the video clip for the slower option was two times slower than the video clip for the faster option. Participants were more likely to choose the slower motion speed option in the luxury (73.47%) than non-luxury condition (62.57%;  $p=.026$ ).

In study 3, 194 MTurk participants were randomly assigned to a 2 (motion speed: slow vs. fast)  $\times$  2 (brand type: luxury vs. non-luxury) between-subjects design. Participants watched the same video clips from study 1B, except the clip was not repeated in the fast condition. Thus, in both conditions, the clip featured the ring once (26s in the slow condition; 8s in the fast condition). Participants in the luxury (vs. non-luxury) condition were told that the ring was made by Chanel (vs. Forever 21). Next, participants rated the ring on status perceptions using the same items as in prior studies.

A two-way ANOVA on status perceptions revealed a significant motion speed  $\times$  brand type interaction ( $F(1, 190)=4.33$ ,  $p=.039$ ). The ring was perceived as having higher status in the slow ( $M=6.11$ ,  $SD=.95$ ) than fast condition ( $M=5.38$ ,  $SD=1.23$ ) when the ring was made by Chanel ( $F(1, 190)=5.93$ ,  $p=.016$ ). However, no difference emerged between the slow ( $M=4.32$ ,  $SD=1.83$ ) and fast conditions ( $M=4.48$ ,  $SD=1.78$ ) when the ring was made by Forever 21,  $F(1, 190)<1$ ,  $p=.60$ . Thus, the effect is attenuated for non-luxury brands presumably because the status benefits conferred by a slower motion speed are less relevant to such brands.

The current research provides evidence that a slower motion speed can enhance status perceptions with consequences for consumers' willingness to share WOM about the product. Future studies will investigate the mechanism(s) underlying this effect.

### **Out of Your League: Women's Luxury Products as Signals to Men**

#### **EXTENDED ABSTRACT**

Conspicuous consumption has been shown to serve an important role in a romantic relationship context. The main findings of this stream of work demonstrate that luxury goods can help men to attract

romantic partners. For example, when a mate attraction motivation is activated, men were found to desire for luxury goods (Griskevicius et al. 2007; Sundie et al., 2011). Although there is less research examining the role of women's conspicuous consumption in romantic relationships, one conclusion from the previous research seems to suggest that mate attraction is unlikely to trigger women's conspicuous consumption desire. Instead, women's luxury consumption is found to be linked with a different mating motivation: to deter female rivals (Wang and Griskevicius 2014). However, we propose that women would use luxury products as effective signals to men in romantic relationships, and it is not intended to attract them.

Besides mate attraction, there is another important task for people to successfully start a relationship: select a mate (Buss and Schmitt 1993). Across history and cultures, women have shown to be the choosers in the relationships and are more cautious in mate selection (Buss 1989, Trivels 1972). Being the chooser seems to require less effort, but it can be costly when there are too many options, especially ones with unclear qualities. Therefore, it is adaptive for women to develop strategies to discern and select men with desirable traits that are associated with important reproductive value (Li et al. 2002; Li and Kenrick 2006). One of the most important values that women look for is men's ability and willingness to provide resources (Buss 1989; Li et al. 2002). Taken together, we propose that a mate selection motive would increase women's conspicuous consumption as a signal to men about their mating standards especially related to financial resources. We further propose that men should be able to read this signal and react as expected: men with fewer financial resources should be less interested in pursuing women with luxury (vs. non-luxury) products. However, men with more financial resources should not be affected by women's conspicuous consumption. We tested our predictions in four experiments.

Study 1 examined whether activating a mate selection motive would trigger women's desire for conspicuous luxury products. 160 female participants were randomly assigned to one of two between-subject conditions: (1) mate selection; and (2) mate attraction. These motivations were activated by manipulating women's perceived sex ratio. In the mate selection condition, participants read an article talking about "more men for every woman for today's students"; whereas in the mate attraction condition, the corresponding article talked about "fewer men for every woman for today's students". Desire for luxury goods was measured by two sets of items: spending relative to peers and preference between two versions (basic vs. luxurious) of the same product (Griskevicius et al. 2007; Sundie et al. 2011). Results of these two DV sets consistently showed that activating a mate selection motive led women to show greater desire for conspicuous luxury products than a mate attraction motive ( $M=4.32$  vs. 3.59,  $p<.001$ ;  $M=4.56$  vs. 3.94,  $p=.005$ ).

Study 2 further demonstrated that a mate selection motive only triggered women's desire for public visible luxury goods but not the ones often used in private. The study had a 2 (condition: mate selection vs. control)  $\times$  2 (product type: conspicuous vs. non-conspicuous) mixed-design. In the mate selection condition, participants imagined they were at a party with men of mixed quality, and she felt a little overwhelmed by too much attention from them. In the control condition, participants imagined a typical day of doing laundry (Griskevicius, Shiota, and Nowlis 2010). Participants were then asked about their preference for the level of luxury for both public and private luxury goods (adapted from Wang and Griskevicius 2014). Results showed that participants in the mate selection condition indicated a significantly stronger preference for public luxury products than the control group ( $M=4.16$  vs. 3.56,  $p<.05$ ). However, there was no

significant difference in the conditions for private luxury products ( $M = 3.67$  vs.  $3.53$ ,  $p = .59$ ).

Study 3 examined the specificity of the audience, testing whether a mate selection motive is most likely to trigger women's desire for conspicuous consumption when they face primarily undesirable (vs. desirable) men. Female participants were asked to imagine that they were single and planned to create a profile for an online dating platform. Due to the high volume of men on the website, the women could design different personal profile versions targeting different visitors. Participants in the desirable audience condition were asked to create the personal profile for men who were primarily above their standards for a mate, whereas participants in the undesirable audience condition were asked to create a personal profile for men who were primarily below their standards. Consistent with our predictions, across three different product categories (e.g., clothes, car, leisure activity), there were significantly more women in the undesirable audience condition who chose to display luxury (vs. non-luxury) items in their profiles than women in the desirable audience condition.

Finally, study 4 examined the effectiveness of the signal, testing whether displaying luxury products is effective as a filter for potential mates based on their financial resources. For such display strategy to be an effective mate selection signal, sporting luxury goods should only decrease the motivation for men with low fanatical capabilities to further engage with the woman. However, such luxury signals should not affect men's interests in the woman if they have affluent financial resources. Consistent with our theory, the results of study 4 showed that men at a lower income level were less interested in asking out the woman with luxury (vs. non-luxury) possessions ( $p < .01$ ). In contrast, for men with higher income levels, the difference was no longer significant ( $p = .67$ ). Furthermore, a moderated mediation showed that men's confidence to support future family mediated the decreased interest only from men with lower (vs. higher) levels of income.

### The Dark Side of Luxury: The Social Costs of Conspicuous Consumption

#### EXTENDED ABSTRACT

Veblen (1899/1981) introduced the term conspicuous consumption in reference to the purchase and display of expensive items by the rich to convey their wealth and standing to others (see also Sundie et al., 2011). Research over the last decade has examined conspicuous consumption more generally in the form of individuals that wear brands with visible logos, parade one's products in highly visible locations, name-drop the brands one owns or likes, and attend events where one's status is recognized (Ferraro, Kirmani, & Matherly, 2013; Griskevicius et al., 2007; McFerran & Argo, 2014; Nelissen & Meijers, 2011; Rivera, 2010; Sundie et al., 2011; Wang & Griskevicius, 2014).

A key finding within the literature is that conspicuous consumption appears to be a powerful social influence strategy to obtain compliance and preferential treatment (Lee, Ko, & Megehee, 2015; Nelissen & Meijers, 2011). For example, Nelissen and Meijers (2011) found that actors received more money from a partner who wore a shirt with a luxury brand logo (i.e., Lacoste) compared with a non-luxury brand logo. Similarly, Lee, Ko, and Megehee (2015) found that individuals who wore luxury brands (e.g., Louis Vuitton) versus non-luxury brands or no logos were viewed as more suitable for an internship, deserving of a higher salary, and received larger charitable donations.

Thus, the current perspective is that conspicuous consumption is a powerful influence strategy. In contrast, the present work explores the idea that such conspicuous consumption can backfire. We draw upon the person perception literature in which the broad dimensions of agency and communion are used to categorize people (Abele and Wojciszke 2007, 2014) the authors hypothesize that (a. High-status individuals such as doctors, professors, and CEOs are often perceived to be warmer or equally warm as less stereotypically prestigious careers such as construction worker and fast food worker (Fiske and Dupree 2014). Despite this relationship, we propose that conspicuous consumption can reduce social influence via communal (e.g., warmth) attributions. We explore two potential underlying mechanisms for this effect: impression management/ulterior motives (Godfrey, Jones, and Lord 1986; Leary and Kowalski 1990) and envy (Fiske et al. 2002). Finally, we propose that the social influence of conspicuous consumption depends on the diagnosticity of the warmth (vs. status) perception.

*Experiment 1.* Participants ( $N = 119$ ) were presented with either a picture of a man in a t-shirt (non-conspicuous condition) or a man wearing an identical shirt displaying a Gucci trademark (conspicuous condition). Replicating prior work, we found that participants perceived the conspicuous (vs. non-conspicuous) consumer to have higher status ( $M = 4.81$  vs.  $M = 3.83$ ;  $t(117) = 4.50$ ,  $p < .001$ ). However, participants perceived the conspicuous (vs. non-conspicuous) consumer to also have lower warmth ( $M = 3.96$  vs.  $M = 4.62$ ;  $t(117) = -3.06$ ,  $p = .003$ ). In addition, we found that participants perceived the conspicuous (vs. non-conspicuous) consumer to have higher ulterior motives ( $M = 5.14$  vs.  $M = 2.20$ ;  $t(117) = 11.10$ ,  $p < .001$ ), but not greater feelings of envy ( $p = .234$ ). Ulterior motives mediated the relationship between conspicuous consumption and warmth perceptions.

*Experiment 2.* The second experiment aimed to conceptually replicate experiment 1, with a different luxury brand. We also measured envy from other people's perspective, to rule out socially desirable responding. Participants ( $N = 120$ ) were presented with a picture of a purse with no label (non-conspicuous condition) or a visible Burberry checkered pattern (conspicuous condition). Participants were then asked to imagine the woman that owns it. Replicating experiment 1, participants perceived the conspicuous (vs. non-conspicuous) consumer to have higher status ( $M = 5.57$  vs.  $M = 5.05$ ;  $t(118) = 2.37$ ,  $p = .019$ ), but lower warmth ( $M = 3.71$  vs.  $M = 4.35$ ;  $t(118) = -2.57$ ,  $p = .011$ ). In addition, we found that participants perceived the conspicuous (vs. non-conspicuous) consumer to have higher ulterior motives ( $M = 5.41$  vs.  $M = 3.89$ ;  $t(118) = 5.19$ ,  $p < .001$ ). As in the first experiment, ulterior motives mediated the relationship between conspicuous consumption and warmth perceptions.

*Experiment 3.* The third experiment demonstrates consequential social influence. Participants ( $N = 115$ ) were assigned to read two questionnaires, presumably filled out by other participants. One of the questionnaires mentioned luxury brands, whereas the other questionnaire did not (counterbalanced in terms of mentioning luxury brands and presentation order). Participants were asked to choose a participant to work with in an upcoming task for either the job of corporate publicist (i.e., status-diagnostic role) or a human resources coordinator (i.e., warmth-diagnostic role). A significant relation emerged between conspicuous consumption and job type ( $\chi^2 = 38.42$ ,  $p < .001$ ), such that more participants chose the actor that engaged in conspicuous (vs. non-conspicuous) consumption for the corporate publicist (vs. human resources coordinator) job.

*Experiment 4.* This final study demonstrates a boundary condition for the dark side of luxury. Participants ( $N = 102$ ) were assigned to one of the two conditions from the first experiment. In addition,

we measured lay beliefs that luxury good consumers typically have ulterior motives. We found that impression management lay beliefs moderated the link between luxury good consumption and warmth inferences ( $B = -.24$ ,  $SE = .11$ ,  $t = -2.15$ ,  $p = .034$ ). Whereas 66% of participants perceived the conspicuous (vs. non-conspicuous) consumer to have lower warmth, 34% of participants perceived the conspicuous and non-conspicuous consumers to be equally warm.

The present work allows for a better understanding of *when* and *why* conspicuous consumption is an effective social influence strategy. Observers infer from conspicuous consumption both higher status and lower warmth. This negative social reaction is primarily driven by perceptions of ulterior motives rather than envy. The social influence of conspicuous consumption depends on what attributes observers view as diagnostic in the decision context. Moreover, the effectiveness of the social influence of conspicuous consumption also depends on observers' own lay theories.

### Sustainable Luxury: a Paradox or a Desirable Consumption?

#### EXTENDED ABSTRACT

Is it better to spend \$1,000 on one high-end luxury product or \$250 on four mid-end ordinary products? What if the high-end product is more durable and lasts much longer? How do we view consumers who choose quality over quantity? In line with the notion "you buy cheap, you buy twice," one may think that buying high-end luxury products is more sustainable as these goods last longer and have resale potential on secondhand markets. Through web-data scraped from multiple retailers and secondhand markets (e.g., Poshmark, Tradesy), we indeed find that luxury products are more diffused and have higher resale value compared to ordinary products ( $M_{luxury} = \$86.5$  vs.  $M_{ordinary} = \$41.2$ ,  $p = .001$ ) on these marketplaces. However, past findings also suggest that users of luxury goods are seen as extrinsically motivated and are not liked by others (Van Boven, Campbell & Gilovich, 2010; Christopher & Barry, 2000).

We seek to directly compare the two spending habits — consumption of luxury, high-end goods versus mid-end, ordinary goods — and deepen our understanding of inferences that consumers draw in response to these buying habits. Across a series of studies, we demonstrate that consumers negatively view purchasers of more durable, high-end products because these purchases are deemed unnecessary and superfluous. Furthermore, we show that this negative bias is attenuated when luxury purchases are framed as investments and we explore boundary conditions of the effect.

In Study 1, we establish that luxury consumption is perceived to be a wasteful and materialistic behavior. In a 2-condition, between-subjects design, participants ( $n = 138$ ; lab) judged a shopper spending \$300 on one high-end pair of shoes (*luxury* condition) versus spending the same amount on three mid-end pairs of shoes for \$100 (*ordinary* condition). Compared to the ordinary shopper, the luxury shopper was viewed as more wasteful and materialistic ( $M_{luxury} = 4.0$  vs.  $M_{ordinary} = 3.1$ ,  $p = .001$ ).

In Study 2, we replicate our finding using more calibrated stimuli (e.g., price of the products, based on a pretest with 225 online and 207 lab participants), while controlling for the end functionality of the product (that is, purchasing shoes for work vs. leisure, Keinan, Kivetz & Netzer, 2016). Participants ( $n = 243$ ; online), split across gender, rated a shopper – Sam or Sally – in a 2 (consumption: *luxury* vs. *ordinary*)  $\times$  2 (function: *leisure* vs. *work*) between-subjects design. Again, we find that the luxury shopper was seen as more wasteful and materialistic ( $M_{luxury} = 5.2$  vs.  $M_{ordinary} = 4.4$ ,  $p = 0.001$ ) regardless of whether the purchase was for work or leisure. In addition, we

coded the open-ended comments and identified four main themes. Mediation analyses based on such themes revealed that luxury consumption was perceived to be more wasteful and materialistic (versus consumption of ordinary products) because the purchase was deemed unnecessary and superfluous (0.31; 95% CI from 0.16 to 0.52). Study 3 ( $n = 400$ ; online) replicates results from previous studies that users of luxury goods, compared to those who buy ordinary goods, are judged more negatively and illustrates that the effect persists even when controlling for the number of products already owned. Because a person spending money on high-end shoes may be more likely to own many pairs of shoes, we controlled for this issue across conditions. Participants rated a shopper – Sam or Sally – in a 2 (consumption: *luxury* vs. *ordinary*)  $\times$  3 (number of products owned: *few* vs. *many* vs. *control*) between-subjects design. Again, we found that buying one pair of high-end shoes for \$300, compared to buying three mid-end shoes for \$100 each, was seen as more wasteful and materialistic ( $M_{luxury} = 5.3$  vs.  $M_{ordinary} = 4.7$ ,  $p = .001$ ), regardless of the number of products already owned. We also test for mediation and, again, find that the extent to which the purchase is perceived as unnecessary mediates this effect (0.24; 95% CI from 0.05 to 0.44).

Study 4 ( $n = 186$ ; lab), explores conditions under which we see a reversal in the perception of luxury consumption. While luxury shoppers are perceived to be more materialistic and wasteful than ordinary goods shoppers ( $M_{luxury} = 4.5$  vs.  $M_{ordinary} = 3.8$ ,  $p = .001$ ), this effect diminishes when the investment aspect of the luxury purchase is emphasized. In addition, when the luxury shopper viewed her purchase as a onetime investment in a high-end product, she was perceived less negatively than the ordinary goods shopper purchasing multiple products for the same time horizon. In fact, when the investment aspect of the purchase was prominent, the luxury shopper was perceived to be less materialistic and wasteful compared to when the investment aspect was not made salient ( $M_{investment} = 3.5$  vs.  $M_{no-investment} = 4.2$ ,  $p = .004$ ).

Across four studies, our findings address the notion of sustainable luxury consumption and demonstrate that sustainable luxury, rather than a paradox, is more of a tautology as luxury products are more durable and long-lasting than ordinary goods. We propose that marketers of high-end products focus on positioning their products as investments to reduce the stigma associated with luxury consumption.

## **SESSION OVERVIEW**

The premise that consumers relate to brands as they do with other humans is a well-documented phenomenon in the consumer behavior field (MacInnis & Folkes, 2017). As with humans, brands sometimes can do bad and, therefore, hurt a consumer–brand relationship. Indeed, brand transgressions have been identified as brand actions that can have negative effects on brand relationships (Grégoire, Tripp, & Legoux, 2009). On some occasions, however, brand transgressions may even yield positive effects (Aaker et al., 2004). These mixed results call for further research on this topic. For example, why are brand transgressions sometimes negative and sometimes positive to a brand relationship? Further, under which circumstances are brand transgressions either positive or negative?

The purpose of this session is to shed new light on the effects of brand transgressions on brand relationships by bringing in new insights and perspectives from recent consumer research. In doing so, we hope to enhance our understanding of how consumers relate to brands and how those brand relationships are either positively or negatively affected by brand transgressions. The four papers discuss different aspects of consumers relating to brands in the face of a brand transgression and will, therefore, contribute to a diversified and vivid discussion. The articles are summarized as follows:

In Paper #1, Kähr, Nyffenegger, Krohmer, and Hoyer show that consumers who were not directly involved in a brand transgression can also feel betrayed by observing a consumer brand sabotage activity from a consumer who indeed was involved in a brand transgression. This research proposes that observing a consumer brand sabotage activity can serve as a substitute for consumers' personal experiences, decreasing their own relationship with the brand.

In Paper #2, Velloso and Fischer argue that consumers may interpret certain types of brand transgressions (those that defy authority but do not cause direct physical harm to individuals) as being either entirely normalized or even admirable. Surprisingly, this research demonstrates that consumers are not averse to maintaining

or forming relationships with brands that conduct this type of brand transgressions.

In Paper #3, Wiggins, Grimm, and Kuchmaner investigate the role that brand communities can play in helping brands recover from brand transgressions. The authors found that within brand communities, higher status and community cohesiveness increases psychological ownership of the brand. Furthermore, when the brand commits a brand transgression, this contributes to a sense of responsibility to help the brand recover and increases consumer likelihood to engage in constructive actions to help the brand recover from the brand transgression.

In Paper #4, Lopez, Reimann, and Castaño propose that brand transgressions interact with relationship metaphors to influence brand relationships. This study demonstrates that in the face (vs. absence) of a brand transgression, consumers who break a pencil (vs. put together a pencil) have a weaker (vs. stronger) brand relationship. Moreover, after a brand transgression that causes a brand relationship breakup, consumers subjected to a puzzle metaphor are more likely to reconcile with the brand than consumers subjected to a breaking metaphor or a neutral condition.

## **When Consumer Brand Sabotage Harms Other Consumers Relationship with the Brand**

### **EXTENDED ABSTRACT**

Recently, researchers conceptualized the phenomenon of consumer brand sabotage (CBS) as hostile aggression where consumers hold the dominant motive of harming a brand by impairing the brand-related associations of other consumers (Kähr et al. 2016). Despite its high damage potential, prior research has not yet examined whether and how CBS affects other consumers who observe such hostile activities. This study addresses this research gap and examines the consequences and processes by which CBS affects other consumers depending on their brand relationship. In contrast to existent literature which studied the role of the consumer-brand relationship among consumers directly involved in a service failure, we focus on the role of the consumer-brand relationship among consumers who are not directly involved in a transgression but observe a CBS activity.

*Hypothesis 1* As more and more consumers rely on other consumers' brand experiences to form their attitude and make purchase decisions (e.g., Sparks, So, and Bradley 2016), we expect that observing a CBS activity could serve as a substitute for consumers' own experiences, decreasing their brand attitude and purchase intention

Considering the psychological processes behind these effects, prior research found that consumers feel betrayed by a company if they assess its behavior as a violation of their relational norms (Grégoire, Tripp, and Legoux 2009), affecting their brand attitude (e.g., Aggarwal 2004).

*Hypothesis 2* Hence, if consumers observing the CBS activity perceive the brand's behavior (criticized by the

*brand saboteur) as a violation of their relational expectations, they may feel betrayed, decreasing their brand attitude*

Regarding consumers' purchase intention, social identity theory states that consumers express their belonging to a brand by purchasing its products (Escalas and Bettman 2003), thereby, communicating their social identities. When individuals can no longer distinguish their in-groups favorably from any outgroup (e.g., when their in-group (here: the brand) was put in a bad light), a state of social identity threat arises (Scheepers and Ellemers 2005), which motivates them to leave the in-group (Tajfel and Turner 1986).

*Hypothesis 3 In our context, consumers may experience a social identity threat after observing a CBS activity, lowering their purchase intention of that brand*

Concerning the consumer-brand relationship, prior research showed that it can have a buffering and an amplifying effect in the context of brand transgressions (e.g., Grégoire et al. 2009; Hess, Ganesan, and Klein 2003). In our context, we examine consumers' brand trust and consumer-brand identification (CBI) as key constructs of the consumer-brand relationship.

*Hypothesis 4 Due to the intimate connection of brand trust to relational expectations (Grégoire et al. 2009), we expect that consumers with high (vs. low) brand trust feel more strongly betrayed after observing a CBS activity, decreasing their brand attitude*

*Hypothesis 5 As brands that consumers identify themselves with help expressing their social identity (Escalas and Bettman 2003), we expect that consumers with high (vs. low) CBI perceive a stronger social identity threat after observing a CBS activity, decreasing their purchase intention*

To test the impact and processes by which CBS affects other consumers, we conducted an online experiment where we randomly assigned 186 consumers (48.9% female, Mage=30.6) to either a CBS ("FitchtheHomeless" about A&F by Greg Karber) or a filler video (control group). We measured all constructs with established scales from prior research using seven-point Likert scales. Based on a MANCOVA, we found a significant negative effect of CBS exposure compared to the control group on consumers' brand attitude and purchase intention ( $\Theta=.13$ ,  $F(2,172)=23.09$ ,  $p<.001$ ), supporting H1. Based on two mediation analyses using PROCESS model 4 (bootstrapping: 10,000 samples; Hayes 2013), we first found a significant indirect effect of CBS exposure (0=control group, 1=CBS) on consumers' brand attitude via their perceived betrayal ( $B=-.30$ , 95% CI  $[-.4938, -.1528]$ , supporting H2) and, second, on consumers' purchase intention ( $B=-.09$ , 95% CI  $[-.2002, -.0086]$ ) via their social identity threat (supporting H3).

To test how the impact of CBS on other consumers depends on their brand relationship (i.e., brand trust and CBI; H4 and H5), we conducted an additional scenario-based experiment with 494 consumers (57.3% female, Mage=26.7). Participants were randomly assigned to the CBS condition (fictitious Facebook post of a consumer publicly criticizing the poor working conditions in PUMA's factories and calling for boycott) or the control condition (no Facebook

post). The same constructs and measures were used as in the first experiment. This study replicated the findings from the first study. Additionally, we conducted two conditional mediation analyses with PROCESS model 7 (bootstrapping: 10,000 samples; Hayes 2013, 2015).

The first analysis revealed that the indirect effect of CBS exposure on brand attitude through perceived betrayal is moderated by brand trust (index of moderated mediation  $=-.04$ , 95% CI  $[-.0881, -.0021]$ ), supporting H4. The Johnson-Neyman technique identifying the range of brand trust where a CBS exposure significantly affects betrayal revealed that consumers with brand trust higher than 1.60 felt betrayed after observing the CBS activity (BJN =.44, SE =.22,  $p=.05$ ) but not for those lower than 1.60. The second analysis showed that CBI moderates the indirect effect of CBS exposure on consumers' purchase intention via perceived social identity threat (index of moderated mediation  $=-.15$ , 95% CI  $[-.2888, -.0390]$ ), supporting H5. The Johnson-Neyman technique revealed that there are no statistical significance transition points within the observed range of CBI. Consumers perceived a social identity threat already with a brand identification of 1.0 ( $B=.32$ , SE=.10,  $p<.01$ ), increasing with higher levels of CBI.

With our study, we show that CBS negatively influences other consumers' brand attitude and purchase intention and, thereby, shed light on the negative consequences of this under-researched phenomenon. By showing that also consumers who were not directly involved in a brand transgression can feel betrayed and threatened in their social identity only by observing the CBS activity, we also contribute to literature on negative consumer behavior (e.g., Klein, Smith, and John 2004). Finally, by disclosing that consumers with high levels of brand trust and brand identification are affected most by a CBS activity, we also contribute to the ongoing debate on the buffering versus love-becomes-hate effect of consumer-brand relationships in the context of brand transgressions (e.g., Grégoire et al. 2009).

## Brand Relationships in a "Post-Fact" World

### EXTENDED ABSTRACT

Much of the consumer-brand relationship literature has argued that brand misbehaviors lead to the weakening or dissolution of relations (Bechwati and Morrin 2003; Grégoire, Tripp, and Legoux 2009; Hemetsberger, Kittinger-Rosanelli, and Friedmann 2009; Johnson, Matear, and Thomson 2011). However, a growing body of research shows that other relationship paths are also possible due to brand-self connections (Lin and Sung 2014), specific brand personality traits (Aaker, Fournier, and Brasel 2004), investments made (Sung and Choi 2010), and particular kinds of relationship dynamics (e.g., master-slave, dealer-addict, and villain-victim) (Alvarez and Fournier 2016; Batra, Ahuvia, and Bagozzi 2012; Fournier 1998; Fournier and Alvarez 2013) the authors investigate the nature and consequences of brand love. Arguing that research on brand love needs to be built on an understanding of how consumers actually experience this phenomenon, they conduct two qualitative studies to uncover the different elements (features) of brand love. The present research aims to extend the literature that explores brand relationships after transgressions by providing a more thorough understanding of consumer-brand relationships in a "post-fact" world.

What is a "post-fact" world? This dystopic vision sees people make claims or take positions without effective concern for providing verifiable evidence. As the boundaries blur between fact and opinion, between real and fake, powerful rhetoric is more likely to settle an argument than objective proof and logic (Loseke 2018).

People immersed in hyper-reality construct their own truths based on their imaginations, ingenuities, and pragmatic needs (Venkatesh 1999). And brands invest in the manufacture of “alternative” facts, deceiving consumers and defying institutional authority.

While such a vision may be exaggerated, evidence points to an increasing belief in the importance of emotion to judge the soundness of a claim (Laybats and Tredinnick 2016). Under such conditions, people filter out what they wish to be false and embrace what they want to be true, even in the face of contradictory empirical evidence (Johnston 2008; Manjoo 2008). Moreover, consumers freely share their views on social media and influence each other’s impressions and behavioral intentions, regardless of whether they anchor their ideas in verifiable facts (Anderson et al. 2014; Lee 2012; Stavrositu and Kim 2015). And even a few dissenting voices on comment sections of news articles and blog posts can shift the perceived range of acceptable views (Lewandowsky, Ecker, and Cook 2017; Sikorski and Hänel 2016).

When competing versions of what is true and what is acceptable vie for attention in this new media landscape, how do consumers react to revelations that brands have failed to be truthful? While research has started to uncover the factors that encourage a post-truth world (Hopkin and Rosamond 2017; Keyes 2004; Lewandowsky et al. 2017; Manjoo 2008), there is still very little investigation on the implications of the present milieu for brands. Berthon and Pitt’s (2018) conceptual paper constitutes one notable effort in this direction. The authors posit that, if brands do not provide consumers with experiences that are authentic and honest, they will fail the “reality” test and face negative consequences.

Our paper picks up empirically where Berthon and Pitt’s conceptual papers leaves off, exploring the extent to which explicit deviation from truth-telling may affect a brand’s potential to preserve existing relationships or form new ones. It proceeds by investigating how consumers react when they discover that a brand has not been truthful. We conducted a case study of Volkswagen’s emissions scandal, which offered the appropriate context to observe consumers’ reactions to the production of “alternative” facts by a reputable brand. On September 18th, 2015, news outlets exposed the U.S. Environmental Protection Agency’s (EPA) and the California Air Resources Board’s (CARB) accusations that Volkswagen had been circumventing federal and state emissions tests. So-called “defeat devices” installed in 2009-2015 models advertised as “clean diesel” let these vehicles exceed lawful nitrogen oxides (NOx) emissions levels on the road while blocking them when undergoing laboratory testing.

Our inductive theory building relied on qualitative and automated content analyses of a longitudinal database of consumer archival and interview data. We analyzed consumer posts about “Dieselgate” in the online comments sections of major US news outlets, automotive magazines, blogs, and brand communities. We also interviewed customers who owned Volkswagen cars at the outbreak of the scandal and consumers that purchased a vehicle in the following months and or who considered purchasing Volkswagens.

Our findings demonstrate that the contemporary “post-fact” ethos influences the way consumers interpret certain types of brand transgressions. In Volkswagen’s case, in which the company defied regulators’ authority and did not cause direct physical harm to specific individuals, some consumers construed the brand’s untruthfulness as being either entirely normalized (“all car makers lie all the time, so what’s the big deal?”) or even somewhat admirable (“Volkswagen lies about conforming to emissions regulations just show how unwarranted the EPA regulations really are”).

We argue that Volkswagen’s success in becoming the highest volume auto seller in the world in less than two years after the

scandal broke (Roberts and Stoll 2017) suggests that, under current conditions, consumers – even those who are not longstanding brand loyalists – may not be averse to maintaining or forming relationships with brands that deviate from being honest about the claims they make. We speculate about how the character of brand relationships under “post-fact” cultural conditions may also be evolving.

### **“My Brand” Behaved Badly: Psychological Ownership and Consumer Responsibility for Helping Brands Recover from Transgressions**

#### **EXTENDED ABSTRACT**

Researchers have studied consumer responses to negative publicity (Ahluwalia et al., 2000), product failures (Aaker et al., 2004), brand transgressions (Grappi et al., 2013; Romani et al., 2013; Xie et al., 2015), and corporate social irresponsibility (Armstrong and Green, 2013). Across these literature streams, consumers are found to respond with negative emotions and punitive actions towards the brand.

These negative effects are attenuated when consumers have strong brand relationships (Johnson et al., 2011; Paulssen et al., 2016), high attitude certainty (Pullig et al., 2006), high brand commitment (Ahluwalia et al., 2000), and high identification with the organization (Einwiller et al., 2006; Lange and Washburn, 2012). Collectively, this research suggests that consumers who perceive a strong connection with the brand, such as members of a brand community, will be less likely to engage in punitive actions in the wake of a brand transgression.

We argue that brand community members are also likely to perceive psychological ownership of the brand (Chang et al., 2015), which creates a sense of responsibility to help the brand recover from the transgression (Pierce et al., 2003; Van Dyne and Pierce, 2004; Shu and Peck, 2015). This sense of personal responsibility is predicted to be higher for brand community members who have higher status in their brand community or who perceive their brand community to be more cohesive (Zhang et al., 2014). These brand community members will be more likely to engage in constructive actions designed to help the brand recover from the transgression.

Higher status (H1a) and greater brand community cohesion (H2a) will increase a member’s perceived responsibility to help the brand, and this effect will be mediated by the individual’s psychological ownership of the brand.

Higher status (H1b) and greater brand community cohesion (H2b) will increase a member’s likelihood to engage in constructive actions to help the brand, and this effect will be mediated by the individual’s psychological ownership of the brand and perceived responsibility to help the brand.

Higher status (H3) and greater brand community cohesion (H4) will decrease a member’s likelihood to engage in punitive actions against the brand, and this effect will be mediated by the individual’s psychological ownership of the brand.

Four field studies tested these hypotheses among members of five real brand communities accessed through Amazon MTurk – Xbox and PlayStation (Studies 1a and 1b), Apple (Study 2), and Jeep and Subaru (Study 3) – using three different transgressions – personal information being hacked due to the firm’s failure to update software (Studies 1a and 2), purposely omitting a known hardware defect from warranty coverage (Study 1b), and a variation on Volkswagen’s “dieselgate” scandal which involved software installed to “cheat” on emissions testing (Study 3). Recommendations set forth by Wessling, Huber, and Netzer (2017) and Goodman and Paolacci

(2017) were followed to minimize concerns about MTurker self-selection and misrepresentation.

Measures included *perceived community cohesiveness* ( $\alpha = 0.80 - 0.89$ ) and *perceived status in the community* ( $\alpha = 0.81 - 0.88$ ) adapted from Antia and Frazier (2001); *psychological ownership* ( $\alpha = 0.90 - 0.93$ ) adapted from Peck and Shu (2009); *responsibility to help* measured on a single item sliding scale ranging from 0-100; *punitive actions* ( $\alpha = 0.86 - 0.93$ ) adapted from Grappi, Romani, and Bagozzi (2013), and *constructive actions* using Johnson and Rapp's (2010) consumer helping behavior scale: expanding behaviors ( $\alpha = 0.941 - 0.957$ ); displaying brands ( $\alpha = 0.871 - 0.923$ ); increasing quantity ( $\alpha = 0.874$ ), and increasing price ( $\alpha = 0.751$ ).

The hypotheses were tested using Hayes' (2013) procedures and the SPSS macro PROCESS (Models 4 and 6; 5,000 bootstrap samples). Results for each model are summarized below:

*Status/Cohesion* → *Psychological Ownership* → *Responsibility to Help*

H1a and H2a are tested and supported across all four studies. Status has both a significant direct and indirect effect on responsibility to help, indicating partial mediation. Cohesion has a significant indirect effect but no direct effect on responsibility to help, indicating full mediation.

*Status/Cohesion* → *Psychological Ownership* → *Responsibility to Help* → *Constructive Actions*

H1b and H2b are tested and supported across Studies 2 and 3. Status had a significant indirect effect on all three included actions. Only increasing quantity and price also showed a significant direct effect. In Study 2, cohesion exhibited both direct and indirect effects for expanding behaviors, displaying brands and increasing quantity. However, in Study 3, only indirect effects were significant for increasing price and expanding behaviors, while both direct and indirect effects were significant for displaying brands.

*Status/Cohesion* → *Psychological Ownership* → *Punitive Actions*

H3 and H4 are tested across all four studies. In Studies 1a and 1b, there were no significant indirect effects of status or cohesion on punitive actions, and a significant positive direct effect of status. This pattern would lead us to reject H3 and H4. However, Studies 2 and 3 show different results. Status has both a significant positive direct effect and a significant negative indirect effect on punitive actions. The pattern indicates partial mediation and supports H3. Cohesion has no direct effect on punitive actions, but a significant negative indirect effect. Collectively, there is mixed support for H3 and H4.

This paper contributes to research on brand communities by examining the role of psychological ownership in mediating the impact of community status and cohesion on responses to brand transgressions. While previous research on brand transgressions argued that consumer-brand connections mitigated negative responses and punitive actions, we find that psychological ownership of the brand contributes to a sense of *responsibility for helping* a brand recover from a transgression and subsequent *constructive actions*. Our results further suggest that punitive actions and constructive actions are not mutually exclusive and may be appropriately viewed as independent responses to brand transgressions. This research suggests that brand communities can play a role in helping brands recover from transgressions within the broader market.

## Metaphorically Transgressing the Brand Relationship

### EXTENDED ABSTRACT

The observation that consumers relate to brands as they do to humans is a well-documented phenomenon (MacInnis & Folkes, 2017). One question of special interest is: What are the features that propitiate or hinder a consumer in forming a brand-relationship? (Fournier, 1998). In this study, we focus on brand-transgressions (Grégoire et al., 2009), which refers to a violation of the implicit or explicit rules guiding brand-relationships (Metts, 1994). We attempt to study the interactive effects of brand-transgressions and relationship-metaphors on brand-relationship strength.

Previous research argues that metaphors are prevalent in everyday life. Hence, metaphors can be thought of as stimuli that, either via environmental or embodied interactions, exercise a great impact on consumer behavior (Marin, Reimann, & Castaño, 2014). Therefore, metaphors structure what we perceive and even how we relate to other people (Lakoff & Johnson, 1997).

We propose that metaphors can also structure how strongly consumers relate to brands in the presence or absence of a brand-transgression. Indeed, recent research in the interpersonal-relationship literature has started to investigate the role of metaphors and relationship conflicts on relationship satisfaction (Lee & Schwarz, 2014) these frames have the power to change the evaluative impact of relational conflicts. We find that thinking about conflicts with one's partner hurts more with the unity (vs. journey). Nevertheless, no research has explored the role of metaphors and transgressions on brand-relationships. In this paper, we address two relationship-metaphors: "breaking-up" (i.e., ending a brand-relationship) and "matching perfectly" (i.e., establishing/maintaining a brand-relationship).

Most of the previous studies have focused on the "cuteness" of the effects, not on explaining the conditions under which people are more and less likely to rely on metaphors compared with literal interpretations in making sense of abstract social concepts like brand-relationships (Landau, Meier, & Keefer, 2010). We attempt to overcome this limitation by providing evidence that consumers only rely on metaphors when certain relationship-metaphors are activated in the presence or absence of a brand-transgression:

*Hypothesis 1a* In the presence of a brand-transgression, a metaphor that conveys a negative relationship meaning (breaking-up a pencil) will decrease the strength of a consumer's brand relationship (compared to not breaking-up a pencil).

*Hypothesis 1b* In the absence of a brand-transgression, a metaphor that conveys a positive relationship meaning (putting together a puzzle) will increase the strength of a consumer's brand relationship (compared to not putting together a puzzle).

*Hypothesis 2* In the presence of a brand-transgression that causes a brand-relationship breakup, a breaking-metaphor will decrease brand-relationship reconciliation (compared to a puzzle-metaphor).

### Experiment 1a

The goal of Experiment 1a was to study the effect of negative relationship-metaphors. The study employed the "We are breaking-up" metaphor and asked participants to break a pencil or to hold it.

Results revealed that when participants were presented with a brand-transgression, they reported a significantly weaker brand-relationship when they broke the pencil ( $M = 3.91$ ;  $SD = .12$ ) compared to when they just held it ( $M = 4.77$ ;  $SD = .21$ ),  $t = 15.98$ ,  $p < .001$ . However, when participants were not presented with a brand transgression, both means were not different,  $t = .49$ ,  $p = .63$ .

### Experiment 1b

The goal of Experiment 1b was to study the effect of positive relationship-metaphors. The study employed the “We are a perfect match” metaphor and asked participants to complete a puzzle or not. Results revealed that when participants were not presented with a brand transgression, they reported a significantly stronger brand-relationship if they put together a puzzle ( $M = 6.13$ ;  $SD = .23$ ) compared to if they did not put together a puzzle ( $M = 5.80$ ;  $SD = .27$ ),  $t = -4.01$ ,  $p < .001$ . However, when participants were presented a brand transgression, both means were not different,  $t = .147$ ,  $p = .88$ .

### Experiment 2

The goal of Experiment 2 was to compare the effect of both relationship-metaphors in the same study. We also aimed to generalize our previous results by employing different manipulations and experimental-stimuli. Replicating findings from experiments 1a and 1b, consumers who experienced a brand transgression reported a weaker brand-relationship when subjected to a breaking-metaphor ( $M = 4.01$ ;  $SD = 1.50$ ) compared to when subjected to a puzzle-metaphor ( $M = 4.82$ ;  $SD = 1.40$ ),  $t = 3.27$ ,  $p < .001$ , or to a control condition ( $M = 4.94$ ;  $SD = 1.42$ ),  $t = 3.68$ ,  $p < .001$ . However, consumers who did not experience a brand-transgression reported a stronger brand-relationship when subjected to a puzzle-metaphor ( $M = 5.94$ ;  $SD = .58$ ) compared to when subjected to a breaking-metaphor ( $M = 5.39$ ;  $SD = .95$ ),  $t = 3.92$ ,  $p < .001$ , or to a control condition ( $M = 5.43$ ;  $SD = .78$ ),  $t = 4.30$ ,  $p < .001$ .

### Experiment 3

Following recent suggestions for employing realistic experimental designs in the discipline (Morales, Amir, & Lee, 2017), the goal of Experiment 3 was to offer further support for our hypotheses by conducting a field-longitudinal study using a new brand and a cell phone App. Besides replicating results from previous studies, it was found that after a brand-relationship breakup, consumers subjected to a puzzle-metaphor are more likely to reconcile with the brand ( $M = 5.11$ ;  $SD = 1.03$ ) compared to consumers subjected to a breaking-metaphor ( $M = 4.24$ ;  $SD = .85$ ),  $t = 3.27$ ,  $p < .001$ , or a control condition ( $M = 4.22$ ;  $SD = .74$ ),  $t = 3.17$ ,  $p < .001$ . Furthermore, employing a trajectory analysis, it was found that the interactive effects of transgressions and metaphors remain over time, even when they are no longer present.

In sum, the current research is the first to highlight the relevant role brand-transgressions and metaphors play in brand-relationships by demonstrating how metaphors conveying a metaphorical relationship meaning and transgressions can affect a brand-relationship. Further, these findings contribute to conceptual metaphor theory by showing that consumers are more likely to rely on metaphors compared with literal interpretations when certain metaphors are activated under certain situations of presence or absence of transgressions. Moreover, we provide insight into the lasting effects that transgressions and metaphors have on consumers regarding their cognitions and behaviors about their interactions with brands.

### **SESSION OVERVIEW**

Consumers have more outlets for supporting charitable causes than ever before. Between the more than 1.5 million charitable organizations in the United States alone (NCCS 2016) and the increasing number of for-profit companies engaging in cause-related marketing initiatives, competition for consumer support is fierce. Thus, it is important to understand the effectiveness of cause-related marketing efforts. Recent work is beginning to document that some cause-related appeals might inhibit rather than increase donor support (e.g., Simpson, White, and Laran 2018). However, there are several unexplored ways in which organizations might be unknowingly reducing consumer support. This session highlights the newest research that examines when and why commonly-used cause-related appeals backfire.

First, **Kang, Leliveld, and Ferraro** examine how the facial expression of a victim in cause-related advertisements can decrease the effectiveness of such appeals. They find that advertisements featuring a victim with a sad facial expression leads consumers to perceive the organization's manipulative intent. This finding provides an important caveat to the literature encouraging organizations to use sympathy-evoking images of victims.

**Daniels, Kristofferson, and Morales** also focus on how facial expressions can affect contributions to charitable organizations; however, they focus on the facial expression of an organization's volunteer rather than the expression of victim. Volunteers frequently post images of themselves performing volunteer work, either of their own volition or at the request of the charity, and often these images include humorous facial expressions. The authors find that such humorous facial expressions are at odds with the serious nature of most causes supported by non-profit organizations, and lead to perceptions of volunteer insincerity, which spillover and reduce support for the referenced organization.

Next, **Castelo, Kristofferson, Main, and White** provide evidence that assuming a consumer's identity in a charitable request (e.g., Hi Animal Lover!) leads to reactance, and lowers the effec-

tiveness of the appeal, even if the assumed identity is correct. This effect is particularly pronounced for individuals who strongly hold the assigned identity. In other words, by assuming a donor's identity, charitable organizations are driving those who should be their largest contributors away. Further, this finding provides a novel setting where activating an identity leads to identity-inconsistent behavior.

**Makov and Newman** show that backfire effects extend to social initiatives put forth by for-profit companies. Specifically, they show that a company's sustainability initiatives can cause negative consumer reactions if they lead to increased profits. This effect is driven by a psychological divide between market and communal relationships and holds even when the organization's actions are truly in line with expressed environmental goals.

Taken together, the four papers (all in advanced stages) demonstrate that frequently-occurring cause-marketing appeals can backfire. In doing so, we not only offer new theoretical insights into cause-related marketing, but also provide practical implications to ensure that cause-related appeals provide the positive impact necessary to encourage consumer support. While this session will certainly appeal to researchers interested in prosocial behaviors, we also expect those interested in other areas such as emotions, identity, persuasion knowledge, and social influence to find the session valuable.

## **When the Face of Need Backfires: The Impact of Facial Emotional Expression on the Effectiveness of Cause-Related Advertisements**

### **EXTENDED ABSTRACT**

In cause-related advertisements that encourage consumer support for charitable causes either by donation or by CRM purchase (i.e., the purchase of a product is linked to support for charitable causes), organizations often display the image of a victim, whose facial expression may vary. Small and Verrochi (2009) showed that an image of a sad-faced (vs. happy-faced or neutral-faced) victim increased sympathy towards the victim, increasing donations. Thus, there appears to be a benefit of displaying a sad-faced image.

However, little research examines the potential negative effects of sad facial expression. We address this gap by demonstrating that a sad-faced (vs. happy-faced or neutral-faced) image evokes consumer inference of the organization's manipulative intent, defined as "consumer inferences that the advertiser is using inappropriate or manipulative tactics" (Campbell 1995). We build on several research streams to make this proposition. First, consumers have a chronic goal to maintain positive feelings and to improve negative feelings (e.g., sadness; Lazarus and Folkman 1984). When consumers encounter a sad-faced image, they may perceive that the organization is forcing them to experience a negative, aversive emotion to achieve its self-interested goal (increasing fundraising/purchase). Second, research in anthropology suggests that organizations' practice of displaying images of others' suffering (e.g., sadness) is viewed as trivializing that suffering as an attention-grabbing hook (Kleinman and Kleinman 1996). Hence consumers will infer more manipulative intent from the sad-faced image.

We propose that the inference of manipulative intent, along with sympathy (Small and Verrochi 2009), mediate the effect of facial expression on ad effectiveness, measured by ad evaluation, organization evaluation, and helping intention (CRM purchase and donation).

Reflecting different characteristics of the effectiveness measures and mediators, we draw different predictions for ad/organization evaluations than for helping intentions. One relevant difference is that helping behavior (vs. ad/organization evaluations) is more directly related to the motivation to enhance the welfare of victims (Bagozzi and Moore 1994). However, all three effectiveness measures are related to how consumers perceive the organization. For example, consumers' inferences that an organization is manipulative reduces their ad/organization evaluation, and their willingness to support the organization by purchasing a product (Campbell 1995). Because inference of manipulative intent is the consumer's response towards the organization, while sympathy is the consumer's response to the victim, we expect that inference of manipulative intent will impact ad/organization evaluations and helping intentions, while sympathy will only affect helping intentions. Importantly, the effects of sympathy and manipulative intent on helping intentions operate in opposing directions with sympathy increasing helping intentions and manipulative intent reducing helping intentions.

We hypothesize that a sad-faced (vs. happy-faced or neutral-faced) image will lower ad/organization evaluations (H1) due to mediation by manipulative intent (H2). Inference of manipulative intent and sympathy will mediate the effect of facial expression on helping intentions, but in opposing directions, which may produce no effect of facial expression on helping (H3). We expect the proposed effects to be the same for advertisements by for-profit and nonprofit organizations because consumers perceive both organizations are persuasion agents, who can be manipulative to achieve their goals (Cotte et al. 2005; Seu and Orgard 2014).

Three studies tested H1-H3 using cause-related advertisements by for-profit and nonprofit organizations, using images of different children. In these studies, participants viewed a one-page advertisement with the image of a child with specific facial expression. Study 1 used a CRM advertisement by for-profit organization, which stated that proceeds from the purchase of a granola bar would be donated to hungry kids. The image of a child with either a happy, neutral, or sad expression was displayed. Study 2 generalized the findings to a non-profit CRM context using a 2(facial expression: neutral, sad) x 2(organization type: for-profit, nonprofit) between-subjects design. Study 3 further generalized the findings by including a condition where the non-profit organization solicited a donation.

In all studies, ad/organization evaluations were significantly lower in the sad (vs. neutral and happy) conditions (H1). There was no difference between neutral and happy conditions. For ad/organization evaluations, only the inference of manipulative intent significantly mediated (H2). For helping intentions, the effect of facial expression was not significant. This was because the indirect effects of inference of manipulative intent and distress were both significant but in opposite directions (H3). Moreover, in studies 2-3, the interaction between facial expression and organization/ad type was not significant, suggesting that the facial expression effects hold in advertising by for-profit and nonprofit organizations. We ruled out several alternative explanations (warmth and competence of the organization, outcome efficacy, and attractiveness of a child).

In studies 4-5, we provide more support for the manipulativeness mechanism by examining two theoretically relevant moderators. Skepticism towards CRM reflects consumers' tendency towards disbelief of CRM claims. More skeptical consumers are more likely to perceive a potentially suspicious tactic (e.g., sad-faced image) as manipulative (Kirmani and Zhu 2007). Thus, the negative effect of sad facial expression should be larger for consumers with higher skepticism towards CRM. As expected, study 4 revealed a significant interaction between facial expression (sad vs. happy) and

skepticism towards CRM on ad/organization evaluation and helping intentions. Cause centrality captures whether the advertisement is cause-focused or product-focused. Cause-focused ads feature the cause (e.g., victim's image) at the focal point of the advertisement and the promoted product at the secondary point, while product-focused ads feature the product at the focal point and the cause at the secondary point (Chang 2012). When the organization positions the cause element as the focal point, consumers will infer that the organization intentionally focused consumers on the sad-faced image, and infer high manipulative intent. Thus, the negative effect of sad facial expression should be stronger in the cause-focused (vs. product-focused) ad. As expected, study 5 revealed a significant interaction between facial expression and cause-centrality on ad/organization evaluations.

Overall, we provide a comprehensive framework of the effect of facial expression by considering the effects of two mediators and by identifying two moderators. By doing so, we uncover a nuanced effect that sad facial expression produces negative effects on ad/organization evaluations but weaker effects on helping intention.

### **I'm Just Trying to Help: How Volunteers' Social Media Posts Can Impact Support for Non-Profits**

#### **EXTENDED ABSTRACT**

Nonprofits lean heavily on social media to raise awareness and funds for their causes (M+R 2017). One common approach is to encourage supporters to share their experiences with the cause to help raise awareness amongst their social networks. Often supporters respond by posting an image of themselves engaging in volunteer work on behalf of the organization on their personal social media accounts. These secondhand appeals promote the charitable organization but do not have the oversight and planning of organization-sponsored promotional appeals. Thus, research investigating the impact and effectiveness of these secondhand appeals is needed.

Previous work in the prosocial domain has examined how sad facial expressions of identifiable victims in promotional appeals can increase support for charities by eliciting greater feelings of sympathy (e.g., Small and Verrochi 2009). However, no research has yet examined how the facial expressions of a volunteer might impact consumer responses. We focus instead serious and smiling volunteer expressions compared to humorous facial expressions, which are used quite frequently on social media to increase the favorability of response (Porter and Golan 2006; Ipsos 2013). Specifically, we argue that because humor does not align with the seriousness of issues addressed by charities, consumers will view volunteer's humorous images as insincere, leading to reduced support for the organization.

Study 1 examines how participants respond to volunteer social media posts featuring either a humorous, serious, or smiling facial expression. Mturk workers (n=224) participated in a 3-cell (Expression: serious, smiling, humorous) between-subjects design. Participants were told that they were going to view a social media post from someone who recently volunteered with the organization HandsOn—a (fictitious) charity whose mission is to help clean up and repair local community property. Participants then saw an Instagram post of the volunteer. In the post, the volunteer either had a serious expression, smiled, or stuck her tongue out for the respective conditions.

After viewing the secondhand appeal, participants responded to questions regarding both the volunteer and the charitable organization. Participants first rated to what extent the volunteer was self-ish and insincere ( $\alpha=.86$ ). Next, participants were asked to rate how

likely they were to donate and volunteer for HandsOn, as well as how much they would like to learn more about HandsOn ( $\alpha=.86$ ).

Participants believed the volunteer was significantly more insincere in the humorous condition compared the smiling condition ( $p=.001$ ) and serious condition ( $p=.001$ ). The smiling and serious conditions did not differ from one another ( $p=.45$ ). Similarly, participants were less likely to support HandsOn in the humorous expression condition compared to the smiling expression condition ( $p=.04$ ) and serious expression condition ( $p=.005$ ). Again, the smiling and serious conditions showed no differences ( $p=.46$ ). Thus, a humorous secondhand appeal from an individual who spent time volunteering with the charity led observers to *reduce* their intentions of supporting the organization. As predicted, the volunteer's insincerity mediated the pathway between facial expression and support of the organization.

Study 2 examines whether this negative spillover consequence holds in the both non-profit and for-profit contexts. We predict that the negative effects of a humorous facial expression will only hold in a non-profit context, as insincerity and selfishness are more at odds with the warmth associated with non-profits than the competence associated with for-profits (Aaker et al. 2010).

Mturk participants ( $n=401$ ) completed a 2 (Expression: smiling, silly) x (Company: for-profit, non-profit) between-subjects design. Participants read about a company called Jessie's Kitchen. In the non-profit (for-profit) condition, Jessie's Kitchen offered cooking classes for a \$30 donation (fee). The food made in each class was donated to local families in need (enjoyed by the class). Participants responded to the same volunteer insincerity ( $\alpha=.84$ ) measures as study 1. The behavioral intention measures from study 1 were adapted for Jessie's Kitchen and to fit either the for-profit or non-profit context. Additionally, because both non-profit and for-profit organizations are interested in increasing customer interaction, we included the participant's likelihood of "liking" the picture on Instagram in our intentions index ( $\alpha=.86$ ).

As predicted, participants in the non-profit conditions were significantly less likely to want to support Jessie's Kitchen in the humorous expression condition compared to the smiling expression condition ( $p=.03$ ). However, in the for-profit condition there was no difference between support intentions across expression ( $p=.73$ ). Similarly, participants in the non-profit conditions directionally thought the volunteer was more insincere in the humorous condition compared the smiling condition ( $p=.11$ ). In the for-profit conditions, perceptions of insincerity did not differ across expression ( $p=.25$ ).

In our final study, we examine a second boundary condition—the amount of information participants have about the volunteer's commitment to the cause. Undergraduate participants ( $n=290$ ) participated in a 2 (Expression: silly, smiling) x 2 (Additional info: yes, no) between-subjects study. The procedure was nearly identical to that of the non-profit conditions from study 2 with two notable changes. First, in the additional information conditions, participants were given more information behind the individual's reasons for volunteering. Second, instead of the previous intentions measures, participants were told that Jessie's Kitchen was attempting to raise funds by selling products featuring their logo. Participants viewed an image of a mug with Jessie's Kitchen's logo, and rated how much they would be willing to pay for it.

Participants in the no additional information conditions felt the volunteer was significantly more insincere in the humorous condition compared the smiling condition ( $p=.03$ ). In the additional information conditions, perceptions of insincerity did not differ across expression ( $p=.44$ ). Participants in the no additional information conditions were willing to pay less for the mug in the humorous

expression condition compared to the smiling expression condition ( $p=.06$ ). There was no difference in the additional information conditions ( $p=.62$ ). As expected, volunteer insincerity mediated the relationship between facial expression and WTP when no additional information was present, but not when additional information was available.

Across three studies, we take the first step in understanding how volunteer's social media posts might affect support for charitable organizations. We find initial support for our hypothesis that humorous expressions can lead to negative consequences for both the volunteer and the organization.

## Don't Tell Me Who I Am! When and How Assigning Consumers an Identity Backfires

### EXTENDED ABSTRACT

Past research suggests that while individuals often have chronically accessible aspects to their identity (Oyserman 2009), different identities can be activated by elements of the decision context (e.g., Forehand & Deshpandé 2001; White & Dahl 2007). Each identity that an individual holds is associated with different behavioral demands and expectations (Grover and Hui 1994). The salience of a particular identity can influence individuals' perceptions, attitudes, and behaviors (Forehand, Deshpandé, & Reed II 2002). Indeed, research supports the notion that a salient identity dominates working memory at a given point in time (Bhattacharya & Sen 2003) and is more likely to affect behavior than an identity that is not salient (Burke 1980).

Given the importance of identity in predicting behavior, we were interested in situations in which a charitable organization assigns an identity to a consumer. We refer to this as identity assignment. For example, imagine you donate to the ASPCA and receive a letter describing you as an animal lover. You may or may not actually hold this identity, but this identity is being inferred by the charity. Organizations who make such assumptions may be attempting to induce identity-consistent behavior in an effort to increase support for their cause, although we suggest that sometimes this strategy will backfire.

Theoretically, this phenomenon is tied to self-verification theory which relies on three important assumptions (Swann 2011). First, over time, patterns of behavior emerge that become part of a person's stable self-view. Second, these self-views provide to the individual a sense of coherence in their identity. Third, these feelings of consistency and coherence cause people to work towards maintaining these self-views. What is novel about the current research, however, is that in the case of identity assignment, we predict that as opposed to responding in an identity consistent manner, consumers will do the opposite. This prediction would be in contrast to self-verification theory as it would demonstrate a situation in which a positively viewed identity leads to a negative downstream consequence. Further, identity-based motivation theories (Oyserman 2009) and social identity theory (Tajfel and Turner 1979) would predict that when one's identity becomes activated, that person should act consistently with their identity. We demonstrate a situation in which this is not the case. We reveal a backfire effect wherein people become less likely to behave in line with the activated identity. We demonstrate this occurs due to reactance, which is defined as the tendency to be less likely to agree to request because one's own feelings of autonomy and freedom to choose are threatened in some way (Brehm 1972).

Study 1 examined whether identity assignment can backfire and reduce identity-consistent choices. Participants ( $n=271$ ) were randomly assigned to one of two conditions: Identity Assignment

vs. Control. Participants were asked to evaluate an appeal from an animal protection charity: The Humane Society. The letter outlined its mission and provided basic facts. Furthermore, participants in the identity assignment condition were presented with an additional line of text: "We know you are an animal lover, and that you are passionate about caring for animals and their welfare." After completion, participants completed five items indicating their behavioral intentions to support the charity (e.g., volunteer, sign a petition). Finally, participants completed measures to assess reactance to identity assignment (e.g., "I do not like that I am being told how I feel about animals"). Participants in the identity assignment condition expressed significantly higher reactance responses to the appeal than participants in the control condition ( $p = .023$ ), and were less likely to support the charity in the future ( $p = .017$ ). Mediation analysis showed that increased reactance mediated the relationship between identity assignment condition and subsequent decreased support.

Study 2 investigated whether this backfire was, counterintuitively, most pronounced among those with stronger identities, and ruled out a general positive attribution as an alternative explanation. Participants ( $n=256$ ) were assigned to conditions in a 3 (Assigned Identity, General Internal Attribution, Control)  $\times$  continuous (Identity Strength) design. Participants in the control and identity assignment evaluated the same letters from Study 1. The appeal in the general attribution condition was: "We know that your values and the kind of person you are makes you passionate about caring for animals and their welfare". Participants next completed the behavioral support items from Study 1. The 3  $\times$  continuous interaction emerged ( $p = .047$ ), and was driven by the identity assignment  $\times$  control interaction ( $p = .012$ ). For those with high (+1.63SD) [low: -.76 SD] identity strength, the assigned identity leads to lower (higher) cause support than the control condition. No effect emerged in the general internal attribution condition.

Study 3 delved deeper into the psychological reactance proposed to drive this backfire effect. We reasoned that this identity inconsistent behavior results from the perception that the organization is taking unfair advantage of the consumer's identity in the solicitation request. Participants ( $n=256$ ) were assigned to conditions in a 3 (Identity Assign, Identity Assign+appeal, Control)  $\times$  continuous (Identity Strength) design. The cover story and manipulations were consistent with previous studies, but participants in the identity assign + appeal condition received an additional appeal that donations were needed or animals might suffer. We hypothesized this condition would amplify experienced reactance. To assess reactance, participants indicated agreement with the following item: The Humane Society is taking advantage of my attitudes about animals to get me to donate". Participants then provided perceptions of the Humane Society using a four-item index. Results revealed the predicted interaction ( $p = .015$ ), showing that those with strong identities (+.28 SD) perceived the organization was taking advantage of them for gain, which in turn lowered overall perceptions of the organization ( $b = -.05$ , CI95:  $-.108, -.001$ , Process Model 7).

We investigate the novel phenomenon of identity-assignment, and show that when an organization assigns to a consumer an identity based on past support behavior, those who hold this identity engage in identity-inconsistent behaviors. We show this backfire effect is due to the perception that the organization is attempting to take advantage of their beliefs for gain.

## Consumer Perceptions of Environmental 'Win-Wins'

### EXTENDED ABSTRACT

Many organizations across a wide range of industries have sought to align their financial goals with environmental ones by identifying strategies that maximize profits while minimizing environmental impacts. Although such 'win-win' strategies are generally thought to reflect positively on companies employing them, in a series of 3 studies we find that people tend to respond negatively to the notion of profiting from environmental initiatives. In fact, observers may evaluate environmental win-wins less favorably than profit-seeking strategies without environmental benefits.

We suggest that this negative response results from a fundamental psychological divide between social relationships that are perceived as communally-oriented versus those that are perceived as market-oriented (hereafter, 'communal' and 'market'). Previous research has demonstrated that communal versus market relationships invoke fundamentally different norms for behavior (e.g., Clark and Mills 1979; Newman and Cain 2014). Specifically, when a communal relationship is established, profits can "taint" the positive value associated with pro-social behavior by violating the norm that one should give without receiving something in return. In market contexts, however, this norm is not present and thus it may be perfectly acceptable to profit from one's actions (Holmes, Miller, and Lerner 2002).

Indeed, past research has demonstrated that blurring the lines between communal and market relationships lowers evaluations of individuals and organizations who behave pro-socially and may even reduce individuals' likelihood of helping others (e.g., Newman and Cain 2014, Vohs, Mead, and Goode 2006). Yet given the differences between pro-social behavior such as charitable giving, and environmental initiatives of for-profit organizations (e.g. no identifiable victim, time discrepancies), it remains unclear if such win-wins are evaluated under the same norms as pro-social behavior.

We examine the distinction between communal and market norms, and how they affect perceptions of companies profiting from environmental win-wins in a series of 3 studies.

Study 1, examined whether an environmental win-win is evaluated less favorably than a 'business as usual' approach. 375 MTurk Participants were presented with a fictitious newspaper article that discussed real advertisements used by the outdoor apparel company, Patagonia. In the environmental conditions, participants read about Patagonia's pro-environmental 'Don't buy this jacket' campaign, in which the company argued that to help the environment, individuals should consume less. In the control conditions, participants read about a more standard 'Try on adventure' campaign, which highlighted the performance capabilities of Patagonia products. The newspaper article either highlighted that the ad campaign resulted in increased profits (which it did; Stock 2013), or an increase in brand recognition (reputational benefit). Thus, the factors of ad type (environmental vs. control) and benefit (monetary vs. reputational) were fully crossed in a 2X2 between-subjects design. Participants then rated the company on several dimensions (moral, ethics, like, approve, trust, manipulative(R), selfish (R), buy, competent).

We found that Patagonia received significantly lower evaluations when the environmental advertisement resulted in profits ( $M=5.41$ ) than when the control advertisement resulted in profits ( $M=6.32$ ),  $p < .001$ ). In contrast to the profit conditions, when the benefit was reputational, participants had equivalent ratings of the company in both the environmental ( $M=5.96$ ) and control ad conditions ( $M=6.18$ ,  $p = .28$ ).

In Experiment 2 we directly test the hypothesis regarding communal versus market norms. 244 Mturk participants were primed to a specific norm (communal/market exchange) with a short writing exercise. Then, participants read about a sustainability initiative in which trash collectors would institute a new pricing model that encourages waste reduction ('pay-as-you-throw'). Half of the participants read the initiative had environmental benefits (environmental benefit only), while for the other half read that the initiative was profitable for the company and also environmental (win-win). Thus, the factors of priming task (communal vs. market) and benefit type (environmental benefit only vs. win-win) were fully crossed in a 2X2 between-subjects design. Participants then rated the company's morality.

Participants primed with communal norms, gave the company significantly lower evaluations in the win-win condition ( $M=5.22$ ) compared to the environmental benefit only condition ( $M=6.89$ ,  $p<.001$ ). However, participants primed with market norms, gave the company equivalent evaluations in the win-win ( $M=6.55$ ) and the environmental benefit only ( $M=6.37$ ) conditions ( $p=.61$ ). Further comparison of the two win-win conditions indicated that profits led to significantly lower evaluations of the company when participants were primed with communal norms vs. market norms, ( $p<.001$ ,  $d=.67$ ).

Experiment 3 tested whether differences in mere temporal order would engender a similar negative win-win effect. Initial categorization of an event may strongly affect the processing of subsequent information such that people tend to resist re-categorizing the event even when they encounter conflicting information (Markman 1987, 1989; Moreau, Markman, and Lehmann 2001). Therefore, we hypothesized that even when people are exposed to identical information about an organization, they may have very different evaluations depending on which benefits are encountered first.

123 participants read two pages containing identical information about the company Patagonia. Half of the participants first read that the company was a very good environmental actor, and on a subsequent page read that the company was also very profitable. The other half of participants first read the information in the reverse order. Participants then rated the company on the same dimensions as in Experiment 1.

Results indicated a significant effect of information order on company evaluations ( $p=.011$   $\eta^2=.05$ ). As predicted, Patagonia was evaluated significantly more positively when participants first read about how they were profitable before reading about their environmental efforts ( $M=7.15$ ) compared to reading about their environmental efforts first ( $M=6.45$ ).

Together these studies suggest that the risk of eliciting negative public response following the adoption of green business practices, is not limited to "greenwashing" or other forms of disinformation previously examined (Delmas and Cuerel Burbano 2011; Walker and Wan 2012). Hence, even if an organization's actions are truly in line with the environmental goals professed and no 'greenwashing' is involved, it is still at risk of drawing a negative reaction if these activities are not carefully communicated. We show that this negative backlash can be avoided by reframing the efforts as market-oriented, or by simply altering the order in which individuals encounter information regarding the initiative.

### **SESSION OVERVIEW**

Robots that interact directly with consumers are becoming increasingly prevalent in many sectors of the economy. Such robots are already being used in retail stores, restaurants, hotels, hospitals, and are being sold directly to consumers for use in the home (Dass 2017; Gibbs 2016; Nguyen 2016; Simon 2015). Indeed, the market for consumer robots is growing seven times faster than the market for manufacturing robots (Business Insider 2015); it reached \$5.4 billion in sales by the end of 2017 and is expected to reach \$14.9 billion by 2023 (Business Wire 2017).

This potentially revolutionary trend raises many fundamental questions for consumer research. How will consumers react to the use of robots in jobs that are normally performed by humans? How should robots be designed and deployed in order to maximize consumers' comfort and trust? How might interacting with robots change downstream consumer behaviors? This special session – the first to our knowledge to focus on consumer robots at ACR – will address these questions and more.

In the first paper, Mende et al. demonstrate that interacting with a human versus a robot in a service setting decreases consumers' comfort, which in turn has downstream consequences for how much food consumers choose to eat.

Kim and Duhachek then explore how interacting with a human versus a robot affects the process of persuasion. They use construal level theory to explain their findings that robots and humans are more effective at different forms of persuasion.

Kim and Schmitt shift the focus of the session to perceptions of a robot's mind. Specifically, they find that the two fundamental trait dimensions of social judgments also apply to robots, and that the perceived competence and warmth have differing effects on consumer attitudes to robots.

The final paper in the session moves from comparing humans and robots to exploring how different kinds of robots affect consumers' experiences. Castelo et al. study how the human-likeness of a robot impacts consumer's reactions to such robots, finding that even

perfectly human-like robots elicit much more negative reactions than do humans, and introducing a new notion of species-ism.

Overall, this session explores a timely and important topic: how the increasingly common use of robots in consumer-facing settings will change consumers' experiences and behaviors. We expect this session to appeal to a broad audience, since the papers cover a broad swathe of theoretical and substantive topics including eating behavior, persuasion, intergroup attitudes, mind perception, and innovation. We hope that this session will also spur others to further study the rise of consumer robots from a consumer research perspective, since the implications of this trend are still largely unknown.

None of the papers here included have been presented at ACR before, and they are all at an advanced stage of completion.

## **Service Robots Rising: How Humanoid Robots Influence Service Experiences and Consumption**

### **EXTENDED ABSTRACT**

Although technology already continuously influences consumers' service experiences (e.g., Giebelhausen et al. 2014; Huang and Rust 2013), the emergence of humanoid robots (i.e., robots with a human-like morphology such as a face, arms, and legs) is likely to be among the most dramatic evolutions in the service realm. For instance, the humanoid robot "Pepper" works as a robot waiter at Pizza Hut in Asia and takes orders and interacts with customers (Curtis 2016), sells coffee machines at 1,000 Nescafe stores in Japan, and worked in a restaurant at the Oakland Airport (Heater 2017). These humanoid robots critically differ from traditional self-serving technologies because they are able to meaningfully engage humans on a social level and may build a relationship with consumers (van Doorn et al. 2017).

### **Impact of Humanoid Service Robots (HSRs) on Service Experiences**

It is currently not clear whether these humanoid service robots (HSR) (relative to human employees) trigger positive or negative consequences for consumers and companies. Although creating robots that appear as human-like as possible is the "holy grail" in robotics (Rubin 2003), consumers may respond negatively to highly human-like robots, due to feelings of discomfort (e.g., eeriness) that such robots can evoke—a phenomenon conceptualized in social robotics as the "uncanny valley" (Mori, MacDorman, and Kageki 2012). Empirical support for the uncanny valley remains mixed and inconclusive (Kätysyri et al. 2015; Piwek, McKay, and Pollick 2014), and it has yet to be tested in consumption and marketing settings. Therefore, the goal of this paper is to investigate whether HSRs trigger discomfort and what the consequences might be for customers' service experiences and their consumption. In particular, we expect that the discomfort elicited by an interaction with a HSR drives a systematic coping response of turning to food (Heatherston and Baumeister 1991).

### **Studies**

Studies 1A, 1B and 1C examine the underlying process related to interacting with a HSR and its downstream effect on consumption behavior, specifically, food consumption. Study 1A (N=215) features a one-way, between-subjects design, with two service provider levels (HSR vs. human). Participants were invited to a cheese tasting test

and sat at individual computer stations, each with a box containing 20 uniformly cut cubes of Gouda cheese. Respondents watched a video with either a HSR or a human behind a table with a cutting board and cheese cubes who told them that they prepared the cheese for them. Participants could eat as much cheese as they wanted while watching a video and answering questions.

The analysis of variance (ANOVA) for the manipulation check index (“The kitchen staff member is like a person [R]/machine-like”) revealed that the manipulation performed as intended ( $M_{\text{HSR}} = 5.74$ ,  $M_{\text{Human}} = 2.26$ ;  $F(1, 208) = 577.49$ ,  $p < .001$ ). An analysis of covariance (ANCOVA) on discomfort with the service provider (“This kitchen staff member is creepy/eerie/unnatural,” 1 = “not at all,” 7 = “very much so”;  $\alpha = .76$ ) and attitude towards the service employee (“dislike/like,” “bad/good,” “negative/positive,” “unfavorable/favorable”;  $\alpha = .94$ ) revealed that consumers felt greater discomfort when told that the cheese was prepared by the HSR rather than the human service provider ( $M_{\text{HSR}} = 3.69$ ,  $M_{\text{Human}} = 2.33$ ;  $F(1, 196) = 67.67$ ,  $p < .001$ ) and were less favorable toward the HSR ( $M_{\text{HSR}} = 5.03$ ,  $M_{\text{Human}} = 5.45$ ;  $F(1, 196) = 7.34$ ,  $p < .01$ ). Furthermore, participants ate more when the cheese was prepared by an HSR rather than a human service provider ( $M_{\text{HSR}} = 7.35$ ,  $M_{\text{Human}} = 5.99$ ;  $F(1, 196) = 4.03$ ,  $p < .05$ ). A serial mediation analysis (Hayes 2015; Process Model 6) confirmed our theorizing that when food is prepared by an HSR (vs. human), consumers feel relatively more uncomfortable, which leads to a less favorable attitude, which triggers increased food consumption ( $a \times b = -.19$ ; 95% confidence interval [CI]:  $-.50, -.04$ ).

Studies 1B and 1C confirm this pattern of results, using a somewhat different study setup. In Study 1B, we filmed a second set of videos with an actual robot or human service provider in an actual restaurant with an all-you-can-eat format. To generalize these findings, Study 1C features another HSR, which was designed to appear identical to its human counterpart.

In studies 2, 3A and 3B we explore important boundary conditions and find that the adverse responses that HSRs elicit are elevated when perceived threat to human identity is high and mitigated when consumer-perceived social belongingness is high. In study 4, we examine whether the common managerial practice of anthropomorphizing a HSR (e.g., by giving it a name) might mitigate consumers’ reactions to HSRs.

## The Impact of Artificial Agents on Persuasion: A Construal Level Account

### EXTENDED ABSTRACT

Whereas more individuals are relying on information provided by non-human agents, such as artificial intelligence and robots, little research has examined how persuasion attempts made by non-human agents may differ from persuasion attempts made by human agents. Drawing on construal level theory, we posit that individuals will perceive artificial agents (AA hereafter) at a low-level construal, which directs individuals’ focus towards “how” these agents implement actions to serve humans. Further, we posit that interactions with such agents drive individuals to adopt a low-level construal mindset more generally. We show these construal-based differences impact compliance with persuasive messages made by AA such that these messages are more effective when the message represents low- (vs. high-) level construal features. We find these effects are moderated by the extent to which an AA can independently learn from its environment (i.e., machine learning), as learning defies people’s lay theories about AA.

In Study 1, one hundred participants from M-Turk (female = 45%,  $M_{\text{age}} = 35.57$ ) were instructed to imagine that the actions

provided in the Behavioral Identification Form (BIF; (Vallacher & Wegner, 1989) were conducted by either a human or an AA, depending upon condition. Then, participants chose the descriptions that they thought were more appropriate for the agent that they were assigned to. We summed the number of high-construal choices made by each participant to create an index of construal level. The index was submitted to a 2 (agent: human, AA) ANOVA. As predicted, the construal level score was significantly lower when participants imagined that the action was conducted by an AA ( $M = 4.04$ ,  $SD = 5.51$ , 95% CI = [2.44, 5.64]) than when the action was conducted by a human ( $M = 11.28$ ,  $SD = 5.88$ ), 95% CI = [9.68, 12.88]),  $F(1, 98) = 40.36$ ,  $p < .001$ ,  $\eta_p^2 = .29$ .

In Study 2, three hundred twenty four participants from M-Turk (female = 54%,  $M_{\text{age}} = 37.30$ ) were randomly assigned to one of the conditions in a 2 (agent: human, AA) x 2 (message: high-construal, low-construal) between-subjects design. Participants filled out a questionnaire that purported to measure their risk of skin cancer (e.g., age, gender, residential area, hours of daily sunlight exposure, skin cancer history in the family etc.) and were told that personalized medical advice will be created based on their answers. In particular, participants in the human (AA) condition were told that they will receive medical advice from a human doctor (IBM’s artificial intelligence Watson) after assessing their answers. The medical advice message either highlighted high- or low-level construal prescriptive statements regarding sunscreen use. The intention to use the sunscreen (e.g., “I intend to use sunscreen”; 1 = very unlikely and 7 = very was measured and served as our dependent variable).

We submitted the intention to use sunscreen to a 2 (agent: human, AA) x 2 (message: high-construal, low-construal) ANOVA. The result only revealed an interaction between agent and message,  $F(1, 320) = 5.92$ ,  $p = .016$ ,  $\eta_p^2 = .02$ . In particular, when the message was coming from an AA, the low-construal message ( $M = 4.98$ ,  $SD = 1.48$ , 95% CI = [4.65, 5.31]) was more effective than the high-construal message ( $M = 4.30$ ,  $SD = 1.72$ , 95% CI = [3.93, 4.68]) in persuading individuals to use sunscreen,  $F(1, 320) = 6.96$ ,  $p = .009$ ,  $\eta_p^2 = .04$ . When the message was coming from a human, there was no significant difference between the low-construal message ( $M = 4.40$ ,  $SD = 1.62$ , 95% CI = [4.05, 4.76]) and the high-construal message ( $M = 4.60$ ,  $SD = 1.58$ , 95% CI = [4.26, 4.93]) in persuading individuals to use sunscreen,  $F(1, 320) = .61$ ,  $p = .437$ ,  $\eta_p^2 < .01$ . These results show that AA are not only perceived as a low-construal agent (i.e., Study 1) but also extends to the persuasion context such that AA’s persuasion is more effective when low- (vs. high) construal message is used.

In Study 3, One hundred and ninety-two undergraduate business students (female = 48%,  $M_{\text{age}} = 20.21$ ) were randomly assigned to one of the conditions in a 2 (AA’s capability: fixed, learning) x 2 (message construal: high-construal, low-construal) between-subjects design. First, participants were instructed to read a description about Alexa, which depicted Alexa as an AA having fixed or experiential learning capability. Then, Alexa instructed the participants to list products they purchased recently on their computers. Then, participants randomly received on their computer either a high- or low-construal message that advertised a gym, which they believed as an individualized message from Alexa. Then, participants indicated the extent to which they intended to visit the gym (1 = not at all likely, 7 = very likely), which was our dependent variable.

Then, the intention to visit the gym was submitted to a 2 (AA’s capability: fixed, learning) x 2 (message: high-construal, low-construal) ANOVA and we only found an interaction between AA’s capability and message,  $F(1, 188) = 5.93$ ,  $p = .016$ ,  $\eta_p^2 = .03$ . In particular, in the fixed capability condition, low-construal message ( $M =$

3.89,  $SD = 1.83$ , 95% CI = [3.38, 4.40]) was marginally more effective than the high-construal message ( $M = 3.27$ ,  $SD = 1.73$ , 95% CI = [2.77, 3.77]),  $F(1, 188) = 3.01$ ,  $p = .084$ ,  $\eta^2 = .03$ . In the learning capability condition, it was shown that the high-construal message ( $M = 4.00$ ,  $SD = 1.91$ , 95% CI = [3.48, 4.51]) was marginally more effective than the low-construal message ( $M = 3.38$ ,  $SD = 1.63$ , 95% CI = [2.89, 3.88]),  $F(1, 188) = 2.93$ ,  $p = .089$ ,  $\eta^2 = .03$ . Therefore, Study 3 showed that beliefs on AA's learning beliefs are capable of overriding the fundamental linkage between low-construal and perceptions of AA, thereby impacting persuasive effectiveness.

Taken together, three studies have shown that AA are not only perceived as a low-construal agent but also AA's persuasion is more effective when the message highlighted low- (high-) construal features. However, such low-construal perception by default was attenuated when the AA was perceived as capable of learning from the environment.

## Ecce Machina Humana: Examining Competence and Warmth in Consumer Robots

### EXTENDED ABSTRACT

Robots are entering the consumer marketplace. Unlike industrial robots, which are employed in factories, these "consumer robots" are capable of being personal assistants and companions in our homes; sales assistants in retail stores; concierges and check-in staff in hotels; caretakers and nurses in medical facilities and nursing homes; and teachers, for example, for mentally disabled and autistic children.

How will consumers evaluate these human machines? Because consumer robots, compared to industrial robots, are designed to behave and even look like humans, we propose that consumers evaluate robots using the same dimensions that they use to evaluate humans. We specifically focus on the trait dimensions of competence and warmth, which are considered the two fundamental dimensions of social judgment (Fiske et al. 2007; Judd et al. 2005). The competence dimension is an intellectual trait dimension including utilitarian traits such as competent, intelligent, efficient and capable. The warmth trait dimension includes desirable social qualities such as being warm, kind, sociable and friendly (Abele et al. 2008; Judd et al. 2005). We propose that both trait dimensions are relevant for judging consumer robots and that both affect attitudes toward consumer robots, albeit in different ways than judgments about humans affect attitudes toward human beings.

Regarding relevance, competence certainly seems to be a relevant dimension to judge both humans and robots because, as machines, robots are designed to perform well in various tasks from an instrumental and utilitarian perspective. On the other hand, warmth seems to be a uniquely human trait dimension; it seems odd to judge a machine on warmth because it does not experience emotions and generally seems to be of a different nature than humans. However, through the process of anthropomorphizing—that is, attributing human traits to nonhuman entities—consumers may still do so, and anthropomorphizing other entities has been shown to occur naturally and automatically in response to a wide variety of stimuli (Epley, Waytz, and Cacioppo 2007; Gazzola, Rizzolatti, Wicker, and Keysers 2007; Hume 1957), including even intangible, non-human entities such as products and brands (Aggarwal and McGill 2007; Aggarwal and McGill 2012; Aaker 1997; Fournier 1998). People seem to anthropomorphize to reduce perceived threat and provide a sense of comfort by introducing an element of the familiar in the context of a less known situation (Guthrie 1993). This seems to fit perfectly with the situation that consumers are facing with robots;

thus, it seems reasonable to assume that for human-like consumer robot, in addition to competence, warmth will be a relevant judgment dimension.

Regarding attitudes, when judging other human beings in a social context, *ceteris paribus* attitudes tend to be more positive the more competent and warm a person is (Wojciszke, Abele, and Barylak 2009). We expect that attitudes toward robots will also be more positive the more competent a robot is because robots are expected to be functionally capable and even surpass humans in competence. However, in terms of the warmth judgments of robots we predict that the effect observed for humans will not hold for consumer robots due to the so-called "uncanny valley" phenomenon: as robots become more human-like affinity increases but when robots' resemble humans too closely, likeability decreases due to a feeling of eeriness or uncanniness (Mori 1970; Wang, Lilienfeld, and Rochat 2015). Thus, we propose that attitudes toward consumer robots will initially increase with warmth; however, robots that behave and appear too warm will be perceived as uncanny and this will decrease positive attitudes.

A pretest and two experiments were conducted to investigate the effects of competence and warmth on consumer attitude toward robots and human beings. The results from a pretest ( $N = 108$  MTurkers) confirmed the relevance of both competence and warmth judgments in consumer attitude toward consumer robots. The results demonstrated that, in forming general impressions, for humans and consumer robots both competence and warmth were perceived as relevant, yet for mechanical robots, only competence was perceived as relevant (see Table 1)

Study 1 ( $N = 484$ ), using a  $2 \times 2 \times 3$  between-subjects design, focused on attitudes for humans and robots, resulting from describing the robots as competent or warm to three different degrees (low, medium, high). A marginally significant three-way interaction ( $F(11, 472) = 2.50$ ,  $p = .08$ ) was revealed. For humans, attitudes increased as competence levels and warmth levels increased. Turning to the more important results for consumer robots (see Figure 1), attitudes increased for competence ( $M = 3.36$  vs.  $M = 4.83$  vs.  $M = 5.18$ ; all  $ps < .05$ ), but for warmth consumer attitudes increased only up to a certain point ( $M = 3.52$  vs.  $M = 5.72$ ;  $p < .001$ ) and then decreased when warmth was really high ( $M = 4.84$ ;  $p < .01$ ). In addition, there was a significant mediation effect of uncanniness in the relationship between warmth and consumer attitude, unveiling uncanniness as the potential mechanism behind the effect.

In Study 2 ( $N = 205$ ) uncanniness was manipulated through human-like appearances of robots, in line with "uncanny valley" phenomenon. Specifically, using a  $2 \times 3$  between-subjects design, participants received either a competence or warmth description for a more human-like robot (an android with a very human-like face and body), or less human-like robot (a toy-looking robot only alluding to human features), or a human. The two-way interaction was marginally significant ( $F(2, 199) = 2.59$ ,  $p = .07$ ). Consistent with the findings of Study 1, the results showed that for more human-like robots (that is, those that induce uncanny feelings), consumer attitudes were significantly less positive when warmth (vs. competence) traits were communicated ( $M = 4.47$  vs.  $M = 5.38$ ;  $p < .05$ ). On the other hand, for less human-like robots and for humans, for whom uncanniness plays no role, the difference between competence and warmth was mitigated (none of the tests comparisons was significant).

Taken together, the current research confirmed the relevance of the two fundamental social judgment dimensions—competence and warmth—for judging consumer robots. Most importantly, two studies demonstrated that competence has an increasing, positive effect on attitudes toward consumer robots, as it does for humans. However, while warmth also has an increasing, positive effect on attitudes

for human beings, attitudes toward consumer robots decreases when warmth is too high, likely due to a feeling of uncanniness resulting from robots usurping this uniquely human trait.

### Human or Robot?

#### The Uncanny Valley in Consumer Robots

##### EXTENDED ABSTRACT

As a robot's human-likeness increases, it may become more threatening to human jobs, safety, and distinctiveness, thereby increasing discomfort in humans. Past a certain threshold of human-likeness, however, robots might be seen as having some degree of human nature, after which further increases in human-likeness may increase comfort. Even perfectly human-like robots, however, are unlikely to be granted full human nature, which is a form of speciesism. We explore these ideas in 4 studies.

In study 1, 200 participants rated images of 25 robots and 2 humans on their human-likeness; an additional 362 participants reported how comfortable they would feel interacting with the robot. We told participants that the humans were either humans or highly human-like robots.

An initial examination of the data revealed a roughly U-shaped relationship between HL and comfort; in order to rigorously test for such a relationship, we used a 2-lines test (Simonsohn 2017). The results of this test are depicted in the Figure below and show that increasing human-likeness leads to lower comfort until the point 8.25; after this point, further increases in human-likeness improve comfort. The 2 black points in the upper-right are humans portrayed as humans and are not included in the regressions.

In Study 2, 200 participants watched one of three videos depicting a robot or a human. The videos featured either Nao (rated as moderately human-like in Study 1), Nadine (a highly human-like robot), or the human being whom Nadine was designed to resemble. Participants who saw the human video were either told that the human was a highly advanced robot, or that she was a human. After watching the video, participants completed a 3-item measure of their reaction to the robots (how much do you feel *uneasy/unnerved/creeped out*,  $\alpha = .95$ ; Gray and Wegner 2012). We excluded 16 participants who did not believe that the human was a robot.

The human portrayed as a human elicited the most positive reactions ( $M = 2.32$ ). Evaluations of the moderately human-like robot were roughly equal ( $M = 2.93$ ,  $p = .209$ ). In contrast, the robot with high human-likeness elicited significantly more negative reactions ( $M = 5.58$ ,  $p < .001$ ), as did the perfectly human-like robot (the human portrayed as a robot:  $M = 3.57$ ,  $p = .037$  compared to the human-as-human). The perfectly human-like robot was evaluated more positively than the highly human-like robot,  $p = .002$ .

Existing research offers many explanations of why human-likeness initially decreases comfort, such as increased threats to safety and human-distinctiveness (Wang, Lilienfeld, and Rochat 2015). However, these explanations cannot account for our finding that higher human-likeness eventually improves comfort. We suggest that highly human-like robots can elicit questions about whether they have some degree of human nature, such as consciousness, free will, and souls, and that subsequent increases in human-likeness increase perceptions of human nature and therefore improve comfort with such robots. Study 3 tests this theory.

155 participants saw an image of either a highly but imperfectly human-like robot, or a human portrayed either as a human or a perfectly human-like robot and were told that a chain of stores was considering employing them. We excluded 8 participants in the human-as-robot condition who did not believe that it was a robot.

Participants expected to feel most comfortable shopping in a store staffed by the human ( $M = 8.44$ ), less comfortable in a store staffed by a perfectly human-like robot ( $M = 5.56$ ,  $t(93) = 4.95$ ,  $p < .001$ ), and least comfortable in a store staffed by an android ( $M = 4.35$ ,  $t(100) = 1.98$ ,  $p = .050$  compared to the perfectly human-like robot). The human also seemed to have the most human nature ( $M = 8.40$ ), while the perfectly human-like robot had less human nature ( $M = 1.86$ ,  $t(93) = 13.10$ ,  $p < .001$ ) and the android had the least ( $M = 1.09$ ,  $t(100) = 1.65$ ,  $p = .102$  compared to the perfectly human-like robot). The robot's perceived human nature was positively associated with comfort shopping in a store staffed by a robot ( $\beta = .81$ ,  $p < .001$ ), controlling for perceived threats to jobs, safety, human distinctiveness, and the perceived unhealthiness of the robots. Thus, perceived human nature is a stronger predictor of comfort shopping in a store staffed by a humanoid robot than any of these other potential predictors.

We conducted Study 4 in both the US and Japan, two cultures in which the belief that robots have a soul is expected to differ naturally. Religions that are common in Japan such as Confucianism and Shinto teach that spirits live in all (animate and inanimate) object. In contrast, Christianity strictly distinguishes objects that do or do not have a soul. Japanese consumers may therefore be more likely to grant human nature to robots. Participants saw a picture of one of two robots (with moderate or high human-likeness) or a human. As in the previous studies, participants who saw the human were told that she was either a human or a robot. Participants completed the same 3-item measure of reaction to the robot from Study 2 and the measure of human nature in robots from Study 3.

Japanese participants saw the robots as significantly less uncanny ( $M = 4.03$ ) than the Americans ( $M = 5.20$ ,  $p < .001$ ), and the effect of robot human-likeness on reactions was three times larger among Americans ( $F = 11$ ) than among Japanese ( $F = 34$ ,  $p < .001$ , see Figure below). Japanese participants perceived robots as having more human nature ( $M = 1.12$ ) than Americans ( $M = .24$ ,  $p < .001$ ), and perceived human nature mediated the effect of country on perceived uncanniness ( $\beta = .15$ , 95% CI = .03-.32).

Taken together, these studies demonstrate that consumers prefer to interact with robots that have low versus high human-likeness, and that even perfectly human-like robots produce more negative reactions than humans. Businesses that sell and employ consumer robots – and consumers who buy and interact with them – may therefore be better off not to make robots with high human-likeness.

# The Speed of Life: The Effects of Real and Implied Speed on Consumer Behavior

Chair: Yael Shani-Feinstein, Ben-Gurion University, Israel

## **Paper #1: Slow and Steady Versus Fast and Furious: The Effect of Speed on Decision Making**

Ellie J. Kyung, Dartmouth College, USA  
Yael Shani-Feinstein, Ben-Gurion University, Israel  
Jacob Goldenberg, IDC Herzelia, Israel

## **Paper #2: The Inimical Lure of Intense Means**

Jordan Etkin, Duke University, USA  
Szu-chi Huang, Stanford University, USA

## **Paper #3: The Impact of Implicit Rate of Change on Arousal and Subjective Ratings**

James A. Mourey, DePaul University, USA  
Ryan S. Elder, Brigham Young University, USA

## **Paper #4: Time Flies...But Only When the Speed is “Just Right”: How Animation Speed Affects Perceived Waiting Time**

Yu Ding, Columbia University, USA  
Ellie J. Kyung, Dartmouth College, USA

### **SESSION OVERVIEW**

Moving through space and time, we experience life at a pace—whether fast or slow. We listen to songs with fast or slow tempo, we make progress towards a goal or towards a destination at a fast or slow rate. The effects of speed can be real (e.g. making decisions on a mobile device while commuting) or perceived (e.g. visually simulated or through framing.) While much research has focused on the effects of time or distance on decision-making, the effects of rate and speed have been largely overlooked. This session brings together research that answers the question of how real and perceived rate can affect consumer behavior in a range of contexts and discusses underlying psychological mechanisms.

In the first paper, Kyung, Shani-Feinstein and Goldenberg examine how people’s judgments are influenced when they feel they are on the move at a fast versus slow speed. Through eight studies involving actual movement (studies on moving trains) and sensory stimulation (studies with videos/simulated visual movement), they demonstrate that the sensation of movement at high (v. low) speed leads to processing at high (v. low) levels, with implications for preference, choice, and risk tolerance.

In the second paper, Etkin and Huang focus on the rate of goal progress. Across ten studies, they show how people are attracted to more intense means that enable a fast rate of progress towards the goal, but in turn, this preference can undermine successful goal attainment, as the intense means over longer goal durations are more difficult to sustain.

In the third paper, Mourey and Elder examine how implicitly implied rate, even non-consciously perceived, can influence perceptions and behavior. Through five studies, they demonstrate that increasing or decreasing size, color saturation, or panning of sound in a way that is consciously unnoticed, leads to an unconsciously perceived rate of change that increases arousal, and influences subsequent subjective evaluations of products presented in advertisements.

In the fourth paper, Ding and Kyung examine how the speed of moving animations influence perceived waiting time and task engagement. Through seven studies, they show that relative to fast animation speeds, moderate animation speeds during waiting time result in faster subjective time perception, greater engagement, and greater task motivation, even when people’s estimates of objective time passing in seconds are relatively accurate.

Together, these four papers examine how rate can affect consumer decision making, whether the rate is actually experienced (paper #1), unconsciously and consciously implied (papers #2 and #3) or simulated (papers #1 and #4). The effects are examined in the domains of product choice, preference, and evaluation in addition to self-regulation and motivation, and draw from a rich breadth of literature. This session will be of interest to researchers in time perception, psychological distance, self-regulation, and decisions through technology-mediated interfaces.

## **Slow and Steady Versus Fast and Furious: The Effect of Speed on Decision Making**

### **EXTENDED ABSTRACT**

Quick as lightening. Slow as a turtle. Faster than a speeding bullet. Creeping like a snail. Our literature and language are filled with analogies about the velocity at which we move. Indeed, we are constantly in motion—in cars, trains, buses, escalators—at different speeds, and mobile technology increasingly allows us to engage in activities while on the move.

How does this pace, the velocity at which we feel we move, influence our decision making? Put differently, what is the effect on thinking when we feel we are actually moving fast versus moving slow? We examine this question through a series of eight studies, where participants experience different levels of speed through (i) actual movement on trains at different speeds, (ii) visually moving starfields simulating movement through a spaceship, and (iii) videos depicting scenery changes out of moving vehicle windows.

Previous literature in visual perception suggests that increasing speed reduces the number of objects that are individually tracked in our visual field (Alvarez and Franconeri 2007) and that as the speed of an object sufficiently increases, it is no longer seen as an object moving across the visual field, but as a single, visually integrated “motion streak” (Geisler 1999). Similarly, a light that is turned on and off at a rapid rate is no longer seen as having distinct light and dark phases, but perceived as a continuous “Gestalt flicker” (Van De Grind, Grüsser, and Lunkenheimer 1973). Thus, we hypothesize that when people feel they are moving at a faster (v. slower) speed, they tend to adopt a bigger picture, abstract, more gist-like view absent details (Reyna 2008; Reyna and Brainerd 1995; Trope and Liberman 2010) because they are accustomed to being unable to process details at higher speeds. Conversely, moving at slower speeds allows people to adopt a more detailed, verbatim-like view of situations.

We posit that people are accustomed to adopting a higher-level perspective at faster speeds because processing details is physically infeasible, and that this change in perspective influences judgments in predictable ways. For example, previous research has demonstrated that adopting a higher-level (v. lower level) perspective increases preference for options with desirable versus feasible features (Dhar and Kim 2007; Goodman and Malkoc 2012; Liberman and Trope 1998; Zhao, Hoeffler, and Zauberger 2007) construal level theory has broadened the notion of temporal distance to psychological distance and examined the wide ranging implications of this construct on evaluation and behavior. This commentary seeks to take a step back to admire the “forest” that has been created and suggest additional extensions and implications along the different stages of consumer decision making: goal pursuit, evaluation by way of consideration-set formation and receptivity, and finally choice influenced by

context, comparability of options, and post-choice happiness and regret. In the field of social psychology, dual processing theories have emerged as some of the most influential models in understanding and explaining the shift in people's evaluation of objects and social situations. Many dual processing theories distinguish differences in processing along an intuitive, affective versus a deliberative, analytical dimension and hence the type of information that is emphasized (e.g., Kahneman & Frederick, 2002; Petty & Cacioppo, 1986 or increases focus on outcomes relative to odds for probability-based (Todorov, Goren, and Trope 2007).

Through eight studies, we demonstrate that the perceived speed at which people feel they move—whether through actual movement or sensory simulation—affects decision making in systematic ways. Affect, other dimensions of psychological distance, and approach aversion (Hsee et al. 2014) are ruled out as alternative explanations.

Study 1 ( $n = 159$ ) provides initial evidence that speed influences processing by demonstrating that people prefer higher-level, abstract representations when moving faster (v. slower). Speed was primed using a moving starfield on a black background with text superimposed on an opaque background. Using the Vallacher and Wegner (1989) Behavioral Identification Form, those primed with the fast (v. slow) starfield preferred actions described at a higher-level ( $M_{fast} = 14.06$  v.  $M_{slow} = 12.51$ ,  $p < .05$ ).

The next three studies demonstrate the effect of speed on product preferences and choice. In study 2 ( $n = 172$ ) using the same manipulation, participants in the fast (v. slow) condition preferred a desk with more desirable (v. more feasible) attributes ( $M_{fast} = 4.81$  v.  $M_{slow} = 3.58$ ,  $p < .01$ ). Affect and perceived time are ruled out as alternative explanations.

Study 3a ( $n = 95$ ) was conducted with participants on an actual moving train, who were asked to make a choice between one of two breakfast menus: one with many entrées (a more desirable option) or one with fewer entrées (a more feasible option, Goodman and Malkoc 2012). Results from a logistic regression demonstrated a significant effect of velocity ( $\beta = .011$ ,  $p < .05$ ), such that higher speed travelers preferred the larger choice set. Study 3b ( $n = 146$ ) replicated these same effects in the lab, priming speed through videos simulating train ride experiences (preference for longer, more desirable menu choices  $M_{fast} = 79\%$  v.  $M_{slow} = 60\%$ ,  $p = .01$ ), and showed that the underlying mechanism depends on the desirability versus feasibility of options.

The next two studies extended the effects of speed into the domains of consumer intertemporal preferences and risk. Study 4 ( $n = 60$ ) demonstrated that even when controlling for objective time (e.g. participants were told they could receive one chocolate now v. two chocolates in 15-20 min), participants moving on trains at faster velocity were more likely to wait for the larger reward ( $\beta = .014$ ,  $p = .05$ ). Using an Eckel and Grossman (2002) paradigm, study 5 ( $n = 111$ ) showed that participants primed with fast (v. slow) speed through a train scene video, were more likely to select the riskiest, most desirable (Liu 2008) gamble with the highest expected utility ( $M_{fast} = 36\%$  v.  $M_{slow} = 18\%$ ,  $p = .01$ ).

Studies 7 and 8 demonstrate that these effects are moderated by focusing on time (preference for desirable v. more feasible attributes, using the starfield paradigm) and distance (using the Vallacher and Wegner (1989) Behavioral Identification Form on a moving train), and whether speed is something that is experienced versus used for inference making.

Together, these studies demonstrate the effects of speed (using three different paradigms) on a variety of decision making contexts with implications for theory and practice, underscoring the need for further research on its effects given the plethora of technological ad-

vances that make decision-making on the move an everyday occurrence.

## The Inimical Lure of Intense Means

### EXTENDED ABSTRACT

One of the first challenges people face after adopting a goal is deciding how to pursue it. If a person wants to lose weight, s/he must decide whether to burn more calories by joining an intensive bootcamp class or by taking long walks. Choosing effective means plays a crucial role in consumers' ability to successfully achieve their goals.

Importantly, the means people choose also determine their rate of goal progress, i.e., how quickly consumers advance towards their goal. Within a given unit of time, means can accomplish more or less goal progress. For example, burning 500 calories per day through intense exercise would help people lose more weight daily than would burning 100 calories per day through a milder activity. Means that accomplish more in a given amount of time thus enable a faster rate of progress (Carver, Lawrence, and Scheier 1996; Carver and Scheier 1998; Huang and Zhang 2011).

Compared to means that achieve a slower rate of progress (i.e., "mild means"), using means that allow a faster rate (i.e., "intense means") is intuitively appealing. Intense means can enable consumers to accomplish more in a given period (e.g., lose more weight in a month) or achieve a specific desired outcome faster (e.g., lose 10 pounds in less time). When choosing their means, we thus suggest that people will prefer intense means over mild ones.

Importantly, we further propose that this preference can have negative consequences, undermining successful goal attainment. Because intense means accomplish more per unit of time, they are more difficult to sustain. Burning 500 calories per day through an intense workout, for instance, is much more challenging to sustain than burning just 100 calories per day by walking more. We find that people do not adequately factor sustainability into their decision and therefore prefer intense means regardless of the duration of goal pursuit. While using intense means can indeed improve outcomes for short-term goals (e.g., exercising for a week), it backfires and hurts performance for longer-term goals (e.g., exercising for a month), reducing the likelihood of success. This strong, yet detrimental, preference for intense means persists even among consumers who self-select into using intense means, when given information about the low base rate likelihood of success, and after previously failing with intense means themselves.

Ten studies demonstrate the proposed preference for intense means (studies 1, 2a-e) and its detrimental effects (studies 3-5). In study 1, we launched four advertisements on Facebook for a weight-loss program, varying the intensity of the means (intense vs. mild; burning 500 vs. 100 calories per day) and the duration of the program (short vs. long; one week vs. one month). The ads received a total of 35,414 hits, with the intense means ad receiving significantly more in both the short (week-long) duration conditions (Wald's  $\chi^2(1, N = 18,000) = 41.58$ ,  $p < .001$ ) and the long (month-long) duration conditions (Wald's  $\chi^2(1, N = 17,414) = 16.38$ ,  $p < .001$ ). Regardless of how long they would be pursuing the goal, consumers preferred intense means.

Studies 2a replicated this preference for intense means in the lab. Participants were randomly assigned to solve a series of subtraction problems for a total of five minutes (short duration) or 15 minutes (long duration), with bonus pay upon successful completion. Participants could choose to solve either two problems per minute (mild means) or six problems per minute (intense means). In both

the short (89.9%) and long (92.8%) duration conditions, the majority preferred the intense means. Further, participants went on to use their chosen means; whereas the intense means marginally improved performance in the short duration condition ( $F(1, 191) = 2.92, p = .089$ ), it led to worse performance in the long duration condition ( $F(1, 191) = 4.05, p = .046$ ). Study 2b gave participants a choice between using the intense means for a short duration versus the mild means for a long duration, which both required participants to complete a total of 30 subtraction problems. The majority (73.5%) again preferred the intense means/short duration combination. Study 2c replicated this effect after first providing real information about intense means' low base rate likelihood of success; Study 2d replicated this preference even when participants had personally failed at using the intense means; Study 2e replicated this preference even when participants knew they could not leave the lab early by making faster progress.

Study 3 then directly examined the consequences of using intense means (without choice). Participants were randomly assigned to one of the four conditions tested above, solving either two problems per minute (mild) or six problems per minute (intense) for a total of five minutes (short duration) or 15 minutes (long duration), with bonus pay upon successful completion. We found that in the 5-minute task, participants earned more from using the intense (vs. mild) means ( $F(1, 167) = 3.74, p = .055$ ), but in the 15-minute task, participants earned *less* from using the intense (vs. mild) means ( $F(1, 167) = 6.06, p = .015$ ). Whereas intense means can improve outcomes for goals of short duration, for longer duration goals, they reduce performance. Moreover, comparing the 5-minute/intense means with the 15-minute/mild means condition, which both required participants to complete a total of 30 subtraction problems, revealed a higher average bonus payment in the long/mild (vs. short/intense) means condition ( $t(167) = 2.22, p = .028$ ).

Studies 4 and 5 further replicated these effects with different behaviors (transcribing passages of text and doing pushups in a field-based workout program).

The findings provide an answer to the question of why people often fail to achieve long-term goals: they choose the wrong (intense) means. To improve consumer welfare, people should be encouraged to adopt means they can in fact sustain.

### The Impact of Implicit Rate of Change on Arousal and Subjective Ratings

#### EXTENDED ABSTRACT

As demands on consumers' attention increase, the likelihood that a consumer consciously attends to any one individual advertisement decreases. While prior research has looked at priming effects and other forms of implicit influence, very little research has explored the effects of an implicit experience of "change" (Simons and Rensink 2005; Rensink 2004) and even fewer projects have considered consequences within a consumer context (Shapiro and Nielsen 2013).

The purpose of our research is to explore implicit experiences of change across different sensory modalities to identify *when* and *how* these experiences affect consumer behavior. We propose two contributions: first, implicit rate of change yields heightened arousal without conscious awareness of the source of this feeling; and second, this arousal is misattributed to dynamically-constructed choices.

Implicit perception refers to the process in which individuals engage in perception without consciously being aware they are doing so (Simons et al., 2006). Examples include "change blindness," in which visual changes take place in one's context without the individual consciously attending to or noticing the change. Perhaps

the most famous example of change blindness is the gorilla video in which participants fail to notice a person in a gorilla costume interrupting a game of catch (Simons and Chabris 1999).

Although individuals may not report consciously noticing a change, some research has shown that participants are capable of reporting a *feeling* of change even if unaware of the source of those feelings (Rensink 2004). That individuals may *feel* change without awareness of its source leads to our proposal that this "feeling of change" might affect perceived arousal with possible downstream consequences via misattribution (Loersch and Payne 2011).

These implicit perceptions of change and subsequent conscious feelings of arousal may also tie into the vast literature on constructed preference—the idea that consumers create their preferences on the spot is based on often irrelevant, misattributed contextual factors (Reber, Schwarz, and Winkielman 2004; Schwarz 2004; Schwarz and Clore 1996). Indeed, individuals experiencing implicit perceptions of change may misattribute the subsequent arousal to unrelated tasks, such as rating tasks or choices. Furthermore, following dynamic constructivist theory, we propose that this misattributed influence should hold only for subjective ratings (for which no set answers exist), and not for objective ratings (for which there are definitive answers; Lichtenstein and Slovic 2006).

We propose that an individual experiencing an implicit perception of change will experience arousal due to this change. Without a source to attribute the arousal, individuals may then to attribute that arousal to a subjective rating or choice. The individual will not report consciously noticing the stimulus that changed but may report a conscious feeling of arousal. The effect of the changing stimulus on bolstered subjective ratings will be mediated by this measured state of arousal.

Five studies show support for this proposed effect. Using both changing visual and aural cues, results suggest that individuals misattribute arousal from implicit perceptions of change to subsequent subjective ratings.

The purpose of Study 1 was to demonstrate initial support for the hypothesized effect. Participants were randomly assigned to one of three conditions—a control condition or one of two implicit change conditions (increasing or decreasing)—in which the size of a Starbucks cup changed in size 10% (or did not change) with each subsequent screen of an online survey. Following the task, participants completed a series of subjective (e.g., "How much do you like Starbucks?") and objective questions (e.g., "At what temperature is Starbucks' hot chocolate served?") pertaining to Starbucks. As predicted, participants in the change conditions had significantly stronger ratings for the same subjective questions compared to participants in the control condition. No difference emerged for objective questions. No participant reported noticing the changing cup size.

The purpose of study 2 was to demonstrate the same effect using a different sense modality in a different consumer context. Participants were randomly assigned to one of three conditions—no panning, pan left, pan right—in which sound moved (or did not) during a commercial for a popular medicine. Participants in the change conditions reported that the ad was more effective and that they would be more likely to use the medicine than participants in the control condition. No participant reported noticing the changing sound.

In Study 3, participants were randomly assigned to view a Nike print advertisement that either changed in color saturation (increase or decrease) or did not. Results replicated the prior findings: participants in the varying color saturation conditions had significantly higher preference ratings for a series of random consumer products than participants in the control condition. No participant reported noticing the changing saturation.

In study 4, participants were randomly assigned to view a Sea-World television commercial that increased, decreased, or did not change in color saturation. As predicted, participants in the changing saturation conditions reported stronger ratings for subjective questions (but not objective questions) relative to control participants. No participant reported noticing the changing saturation.

Study 5 replicated the first study with a measure of arousal to support mediation. As predicted, participants in the changing Starbucks cup conditions reported greater state-level arousal, which, in turn, mediated the stronger ratings for subjective (but not objective) questions. Again, no participant reported noticing any change.

In a series of five studies, we demonstrated that subtle experiences of change—size, color saturation, audio movement—leads to an unconsciously perceived rate of change that systematically affect subjective ratings in a variety of consumer contexts. Stimuli included common marketing media (e.g., print ads, television commercials), demonstrating the robustness of the effects. In doing so, we linked two disparate literatures—the implicit perception literature and the constructed preference literature—to reveal important, predictable consequences for modern consumers faced with greater demands on their conscious attention. Beyond the practical implications for marketers faced with increasing challenges in capturing consumer attention, additional consideration should be given to helping consumers be more aware of the role that implicit perception plays in their decision-making processes, particularly when determining dynamically constructed preferences.

### Time Flies...But Only When the Speed is “Just Right”: How Animation Speed Affects Perceived Waiting Time

#### EXTENDED ABSTRACT

Waiting online is torture. Consumers are impatient: Web users abandon pages after even a mere two seconds of waiting time for information retrieval (Nah 2004). Yet given the limitations of technology, waiting is sometimes a necessary evil when consumers interact with technology interfaces. A critical question for managers is how to reduce the perception of waiting time that critically impacts how consumers evaluate their experience (Gorn et al. 2004, Sackett et al. 2010).

One way to try and reduce perceived waiting time is to introduce animation to decrease perceived waiting time. Research in interface design suggests that processing bars with accelerating speeds, relative to those with constant or decelerating speed, result in the shortest perceived waiting time (Harrison, Yeo, and Hudson 2010; Matthews 2011). Similarly, research in time perception suggests that time is perceived as passing more quickly if more versus fewer visual changes occur during a particular duration (Ahn and Soman 2009; Hansen and Trope 2012; Allman et al. 2014). Both streams of research suggest that increasingly faster animation speeds should result in shorter perceived waiting time. However, we suggest that faster is not always better, and that animation speed can make time fly—but only when the speed is “just right.”

Drawing from work in sensation seeking theory and visual perception, we suggest that the optimal speed that minimizes perceived waiting time that is not necessarily the fastest one. Increasing arousal level can increase consumers’ time perception (Schwarz, Winkler, and Sedlmeier 2013; Zukerman 2014), thus animation that moves too quickly could increase arousal level to the point of increasing time perception. Relatedly, when visual stimuli increases speed until a point where it becomes too fast to process, it is seen as a “motion streak” rather than an individualized set of movements (Geisler 1999), thus limiting the benefits of constantly increasing animation

speed. Seven experiments demonstrate that relative to fast animation speeds, moderate animation speeds during waiting time result in faster subjective time perception, greater engagement, and greater task motivation, even when people’s estimates of objective time passing in seconds are relatively accurate.

In Experiment 1a ( $n=615$ ), US mTurk participants were directed to wait on a webpage (for 17 seconds, unbeknownst to participants) in the middle of the survey with either a picture of a static wheel, a slow-circling wheel (500ms per movement) or fast-circling wheel (100ms per movement). Immediately afterwards, they were asked to rate their subjective waiting time on a slider from 0 (very short) to 100 (very long) and their level of engagement. The fast-circling wheel resulted in shorter perceived wait times (35.4) relative to the static wheel (43.5,  $p = .001$ ), but the slow-circling wheel resulted in an even shorter perceived wait times (30.6) relative to the fast-circling wheel ( $p = .04$ ). Experiments 1b-1e replicated these effects for multiple time durations (7s, 13s, 15s, 17s), different animation pictures (wheel rotating and snail moving), different scales to measure time perception (7-point and 100-point), and different participants (Mturk adults and university students). Furthermore, three replications found that animation speed had no effect on objective waiting time estimated in seconds, but significantly affected perceptions of subjective waiting time.

Experiment 2 ( $n=423$ ) tested whether the effects of animation speed extend beyond time perception to task motivation. U.S. mTurk participants were asked to solve 10 arithmetic problems (e.g.  $17*5=?$ ) and under each problem participants saw a static snail picture, a slow-moving snail (400ms per movement) or a fast-moving snail (100ms per movement), and the page advanced automatically after 40 seconds. If participants perceived that time was moving faster when seeing the slow versus fast moving snail, then they should be motivated to move more quickly to solve more problems in the slow-moving snail condition. While participants in the static (3.45) and fast-moving (3.51) conditions solved the same number of problems ( $p = .78$ ), those in the slow-moving condition (4.06) solved more problems than those in both the static ( $p = .008$ ) and fast-moving ( $p = .013$ ) conditions. The total number of problems answered followed a similar pattern of results. These results suggest that the slow-moving animation increased people’s speed in working through the math problem, consistent with perceiving that time was moving faster in the slow-moving animation condition. Thus animation speed can benefit task speed without sacrificing accuracy, suggesting a novel intervention to the traditional speed-accuracy trade-off which can increase performance (Wickelgren 1977; Förster, Higgins, and Bianco 2003).

In Experiment 3, we explicitly test the hypothesis that there is an optimal animation speed that is “just right” by testing seven different speeds (static, 50ms, 100ms, 300ms, 500ms, 700ms, 900ms), following the same procedure as Experiment 1a. As shown below, there is a significant quadratic effect of animation speed on subjective time perception ( $b = 0.61$ , Robust SE = 0.29,  $t = 2.10$ ,  $p = .036$ ), although animation speed had no linear nor quadratic effect on objective time estimates ( $ps > .2$ ). Thus as animation speeds slowly increase, subjective time perception decreases, but past changes of 300ms per movement, increasing speeds no longer benefit subjective time perception.

Together, these studies demonstrate that animation speeds can materially influence people’s subjective time estimates, even while their objective time estimates remain constant. Relative to static or fast-moving animation speeds, more moderate animation speeds (300-500 ms per movement) result in the lowest perceptions of subjective waiting time, resulting in higher levels of engagement (Ex-

periment 1a) and motivation (Experiment 2). Experiment 3 provide direct evidence for the u-shaped relationship between animation speed and subjective waiting time. Future research can investigate factors that influence optimal speed and the types of customer experiences that are improved by reducing perceived waiting time in online and mobile contexts.

## SESSION OVERVIEW

### Objective of the Session

Consumers constantly face decisions on allocating their limited resources including time and financial assets between themselves and others. This session brings together four papers that uncover new antecedents for consumers' voluntary resource allocation decisions in prosocial contexts (papers 1-3) and demonstrate the positive effect of social motivation on the efficiency of resource allocation in a commercial context (paper 4).

### How the Papers Fit Together

Extending prior research showing that donors want to see a specific, tangible impact from their donations, **paper 1** (Lewis & Small) investigates how information framing might influence the efficiency of resource allocation. For instance, when the information is framed in terms of the "cost per unit of impact" (e.g., \$2 per meal), consumers perversely donate less when the marginal dollar buys more impact. Framing this information in terms of the "units of impact per dollar amount" (e.g., 5 meals per \$10) reduces the inefficiency in the allocation of financial resources.

Relatedly, **paper 2** (Goswami & Urminsky) tests the effect of framing match-incentives to donate as social collaboration vs. as separate behavior on donations. Challenging the implications of the standard impure altruism model, they find that framing a matching donation as the match donor adding to one's donation (as opposed to the match donor donating a matching amount on their own) surprisingly reduces funds raised.

**Paper 3** (Dong & Tsai) identifies another social antecedent for consumers' resource allocation decisions. That is, the activation of the sharing economy *concept* triggers an interdependent self-view and thus increases consumers' subsequent willingness to transfer

their resources to others (e.g., volunteering time and donating money to real charity organizations; spending more on prosocial consumption).

While the first three papers examine resource allocation in various prosocial contexts, **paper 4** (Chung et al.) expands the investigation to a commercial context and shows that social motivations increase the efficiency of allocating real-estate resources on Airbnb.com. Specifically, the authors identify three main motivations ("to-earn-cash", "to-meet-people", "to-share-beauty") that drive consumers' hosting behavior by analyzing textual responses from Airbnb hosts. Moreover, the latter two (social) motivations are shown to lead to greater retention likelihood, compared to the first (financial) motivation.

Overall, while the first two papers show how marketing communications (cognitive frame in paper 1 and social frame in paper 2) may be utilized to increase the efficiency of resource allocation, the last two papers explore a new territory in consumer psychology research, namely the psychological motivations afforded by the salience of the sharing economy.

### Why the Topic is Important

Taken together, the present findings advance and challenge several key assumptions about resource allocation and altruism such as the standard impure altruism model. They spark a lively discussion on the ubiquitous yet unexplored cognitive (papers 1 & 2) and social antecedents (papers 3 & 4) of consumer resource allocation. The primary audience for this session will be basic and applied researchers interested in resource allocation, altruism, financial decision making, and pro-social behaviors. (488 words)

### Ineffective Altruism: Giving Less When Donations Do More

#### EXTENDED ABSTRACT

When people decide how much of their resources to allocate to charity, they have the potential to make a substantial impact. Yet, donors do not always maximize this potential. Effective altruism necessitates allocating more resources to charities when the marginal dollar donated has the biggest impact (Singer 2015). Organizations like GiveWell facilitate effective altruism by providing donors with information about the cost-effectiveness of their donations, including estimates of cost per mosquito net, cost per life saved, and much more. Although providing cost-effectiveness information should help donors allocate resources efficiently, our research finds that it can sometimes backfire, depending on how the information is framed. When the information is framed in terms of the "cost per unit of impact" (e.g. \$2 per meal), they perversely donate less when the marginal dollar buys more impact. Framing this information in terms of the "units of impact per dollar amount" (e.g. 5 meals per \$10) mitigates this inefficiency.

Past research finds that donors want to see a specific, tangible impact from their donations (Cryder, Loewenstein, and Scheines 2013). We build on that notion and argue that donors calibrate their donation amount to achieve a unit of tangible impact. This behavior is analogous to cabbies who calibrate the number of hours they drive in order to achieve their daily income target (Camerer et al. 1997).

For example, when allocating donations to mosquito nets, donors give more when it is more expensive to provide one net – just as New York cabbies drive more on days when it is less profitable to drive. For example, when the cost of providing a mosquito net via Against Malaria is \$2.00, a person will be inclined to donate \$2.00. If instead the cost of a mosquito net is \$1.00, then the same person will be inclined to donate \$1.00. Thus, when the marginal dollar has more impact (when the net is cheaper), a person will donate less. Framing information in terms of cost per net facilitates this behavior by highlighting the cost of a net. In contrast, framing information in terms of nets per dollar amount, e.g. 5 nets per \$10, mitigates the effect by obscuring the cost of a net.

We demonstrate this result in Study 1, in which 587 online participants made real donations to a foodbank. Participant made two donation decisions, each with a \$0.30 endowment. Participants could keep whatever of their endowment they chose not to donate. We manipulated the cost effectiveness of the donation within subjects, so that one decision was assigned to the cheap condition (\$0.05 per meal), the other to the expensive condition (\$0.10 per meal). We (truthfully) explained to participants that the cost of a meal varied because we subsidized each decision by a different amount. Between subjects, we randomly assigned each participant to either a cost per meal condition (e.g. “Facing Hunger Foodbank can provide a meal for every 10 cents donated”) or a meals per dollar condition (e.g. “Facing Hunger Foodbank can provide 10 meals per dollar donated.”). To ensure that participants understood that they did not have to donate in increments of \$0.05 or \$0.10, we told them “Facing Hunger Foodbank can use any donation amount. Every cent helps.” Our results revealed greater donations when meals were more expensive, but only when information was framed in terms of cost per meal ( $p = .019$ ; pre-registered analysis).

We replicated this result in Study 2, in which 969 participants made 4 real donation decisions, each with some chance of being implemented. For each decision, they were given an endowment and could donate any amount of it to a specific type of aid (\$0.30 for meals, \$0.90 for rehydration therapy, \$1.20 for deworming medication, and \$1.80 for measles vaccines). We randomly assigned each of these donation decisions to one condition in a 2 (cost effectiveness: cheap versus expensive) by 2 (framing: cost per unit versus units per dollar) design. As in Study 1, we used subsidies to make the cost of a unit of impact “cheap” (equal to  $\frac{1}{3}$  of the participants’ endowments) or “expensive” ( $\frac{1}{2}$  of participants’ endowments). In the cost per unit condition, we framed the information in terms of cost per unit of impact (e.g. “On average, every 10 cents you donate covers the cost of one meal.”). In the units per dollar condition, we framed the information in terms of the units of impact per dollar (e.g. “On average, every dollar you donate covers the cost of 10 meals”). As an additional step to ensure that the donation information could not be construed as a suggested donation, we had participants choose their donation by moving a slider on a scale where the only points labelled were the end points: 0 and the full budget. The slider was always initially set at the full budget, as a decoy suggested donation. Nonetheless, our results revealed greater donations when a unit of impact was more expensive, but only when information was framed in terms of cost per unit of impact,  $p = .003$ ; pre-registered analysis).

In sum, when donors know the cost required to fund a unit of impact, they donate inefficiently—giving less when aid is more cost-effective. This effect is mitigated when equivalent cost information is framed in terms of the units of impact per dollar amount. The results shed light on the importance of framing cost information to encourage more efficient resource allocation.

## How Framing Donor Match as Collaboration Impacts Donation: The Importance of In-Context Field Experiments In Fundraising

### EXTENDED ABSTRACT

A matching solicitation can be thought of as a conditional leadership gift that uses a commitment to match others’ contributions at a given rate (commonly, 1:1 or a standard match), sometimes limited to the maximum amount the leader is willing to give. Often considered as the “staple of fund-raising” (Leonhardt 2008), matching solicitations have attracted the interest of fundraising practitioners and academics alike. Specifically, there is interest in designing matching solicitations that might yield better performance than a standard match (Karlan and List 2007).

In this research, we explore two different matching interventions to motivate prior donors. First, we frame who will get the credit for matched donation funds that accrue to the organization. Specifically, potential prior donors were informed that a supporter had offered a matching grant such that for every dollar donated, the organization will receive two dollars on *behalf of the donor*. We call this the giving-credit intervention. This was compared to a standard matching solicitation where the organization will receive two dollars – a dollar from the potential donor and a dollar from the supporter.

Second, we set a cutoff below which donated funds are not matched. Specifically, potential prior donors were informed that for every dollar they *add* to their last contribution, the organization will receive two dollars – a dollar from the potential donor and a dollar from the supporter. We call this the incremental-matching intervention. This was compared to a combined giving-credit *plus* incremental-matching intervention where the donor was acknowledged for the total money that accrued to the organization on account of a donation and incremental-matching.

For each of the two comparisons, the standard theoretical models of impure altruism (Andreoni, 1990) that assume additively separable but heterogeneous utilities from private consumption, from pure altruism, and from warm glow predict at least a weakly positive improvement in fundraising performance from the credit-framing intervention. This is due to an increase in warm glow feelings from a given donation amount, *via*.

In addition, we collected predictions from people with experience and expertise in fundraising. The beliefs of the experts should reflect the model implications if the model describes reality and the experts are well-calibrated. Expert beliefs could diverge from the model predictions, either because the experts have imperfectly learned the implications of a relatively accurate model, or because they have learned about donor’s actual behaviors that diverge from the model implications. We recruited fundraising managers of non-profit organizations (N=105) via an online panel, for a brief survey. On average, participants had 10.2 years in fundraising related work experience, and 66% reported having experience working in fundraising campaigns that specifically used matching contributions. Each participant read about all the solicitations and then evaluated them pair-wise in terms of participation rate and average donation amount (non-zero donation amounts).

Experts were unequivocal about the benefits of giving-credit intervention in a matching solicitation. Seventy percent of the experts thought the framing would yield higher participation while only 14% thought participation would be lower ( $p < .001$ ) compared to standard matching. Likewise, experts thought that adding giving-credit to the incremental match would generate higher participation than an incremental mechanism alone (53%), rather than lower participation (19%;  $p < .001$ ). Expert’s opinion was similarly positive for the effect

of the giving-credit intervention on average contribution amounts. Therefore, there was a broad consensus between the expert opinions and the model predictions.

Next, we tried to assess the ground truth by running a field test. We partnered with a small non-profit in Chicago to conduct a natural field experiment (Harrison and List 2004) where the decision makers did not know that they were part of a study. The company sent 1480 mailers to prior donors who were primarily small-amount contributors (median last contribution: \$45).

The overall contribution rate was 5.6%. However, there was no evidence that the giving-credit match improved donation rates. Instead, surprisingly, the results strongly pointed in the opposite direction. Contrary to both the predictions of the impure altruism model and the expert practitioners, when the solicitation was framed to give donors credit for the matching funds, the participation rate was significantly *lower* than the regular framing, under the standard match (4.1% vs. 8.1%;  $\chi^2(1)=4.06, p=.043$ ). Likewise, incremental matching with the giving-credit intervention directionally reduced, rather than increased, participation compared to the incremental matching offer with the regular framing (3.9% vs. 6.6%,  $\chi^2(1)=2.08, p=.148$ ). Overall, comparing both the matching conditions with giving-credit framing to the combined matching conditions with regular framing, the former significantly reduced participation (4.0% vs. 7.4%;  $\chi^2(1)=6.21, p=.013$ ). The detrimental effect of the giving-credit did not vary depending on the matching method (standard vs. incremental;  $\beta=0.149, z=0.281, p=.778$ ).

In a similar fashion, giving-credit significantly reduced average contributions relative to regular framing, for the standard 1:1 match offer ( $t(36)=2.43, p=.020$ ). Giving-credit did not yield significantly higher donations than regular framing under incremental matching and the effect of framing did not significantly differ by matching method ( $\beta=0.642, t=1.52, p=.134$ ).

As a consequence of these two effects, giving-credit raised significantly less money than regular framing under standard matching ( $t(610)=2.13, p=.033$ ) and directionally less under incremental matching ( $t(553)=1.41, p=.160$ ). Overall, combining both the matching conditions, giving-credit significantly reduced the money raised per mailing compared to the regular framing ( $t(1165)=2.56, p=.010$ ). Money raised did not significantly differ between standard and incremental matching ( $t(1165)=0.831, p=.41$ ).

Our results indicate the limitations of both theoretical models and well as expert judgments in evaluating the effectiveness of novel matching interventions in particular, and fundraising in general. The predictions from these sources of guidance strongly suggested that the giving-credit intervention will be at least as good as the standard match. The ground truth was the opposite. In our future studies, we will attempt to understand the psychological mechanism behind the observed behavior, and the implications for the theoretical model of altruistic behavior.

### The Psychology of the Sharing Economy: How the Sharing Economy Concept Promotes Consumer Altruistic Behaviors

#### EXTENDED ABSTRACT

The sharing economy has transformed many consumers' lifestyle over the last few years. The total revenue for the sharing economy sector is estimated to grow from US\$13 billion in 2013 to US\$335 billion by 2025 (Kindergan 2015). How might the salient characteristics of the new lifestyle facilitated by the sharing economy, that is, the emphasis on peer-to-peer sharing of idle resources, influence consumer psychology? Although there have been

discussions about the impact of the sharing economy on business and policy, there has not been systematic research on how changes in lifestyle enabled by the sharing economy might influence consumer decision making. In the present research, we find that the salience of the sharing economy *concept* can make consumers behave altruistically in subsequently unrelated contexts.

We trace this effect to a more accessible interdependent self-view activated by the concept of the sharing economy. Previous research has shown that one can think of the self independently or as members of a group (Gardner, Gabriel, and Lee 1999). The relative accessibility of one or the other self-view can be influenced not only by relatively stable factors such as one's cultural background, but can also be manipulated so that even those with generally interdependent (vs. independent) self-view can be induced to take the opposite perspective (Gardner et al. 1999; Oyserman and Lee 2008). We posit that the salience of the sharing economy concept may impact consumers' judgment, in particular, by cueing a more salient interdependent self-view. This is because the sharing economy model builds on the peer-to-peer sharing of idle resources. In order to enjoy the benefits afforded by the sharing economy business model, consumers need to work together and jointly participate in the transaction. This form of transaction might remind people that they have to rely on a peer consumer in order to achieve their goals and that they are part of a greater social group, thus increasing the value they place on interpersonal connectedness and group cohesion, which are precisely what interdependent self-views entail.

Moreover, prior research suggests a positive relationship between an interdependent self-view and altruistic behavior (Oyserman, Sakamoto, and Lauffer 1998; Swaminathan et al. 2007), as an interdependent self-view emphasizes on behaviors that maintain or enhance relationship with others. Drawing on these findings, we hypothesize that the salience of the sharing economy concept may increase consumers' subsequent altruistic tendency, driven by the heightened accessibility of an interdependent self view. In the current research, we focus on two types of altruistic behaviors, namely pro-social and pro-environmental behaviors (Griskevicius, Tybur, and Van den Bergh 2010).

In Study 1a, we intended to test the basic hypothesis in a field setting. Participants were approached on campus and were invited to participate in a short survey for a student club. They were instructed that the club was hoping to find potential corporate sponsors and wanted to get their opinions. Under this guise, participants in the salience of sharing economy concept condition were asked to evaluate logos of three sharing economy brands. Those in the control condition were asked to view logos of three typical brands (comparable in industries) in the market place. Afterwards, all participants were asked to indicate their willingness to help the student club (e.g., amount of money intended to donate, amount of time willing to volunteer). The results revealed that participants exposed to logos of sharing economy (vs. control) brands expressed a greater tendency to donate money and volunteer their time. Study 1b replicated these findings through collaborating with another real charity organization.

In Study 2, we replicated this effect in an online setting with a different manipulation of the salience of sharing economy and a different measure of altruistic behavior (i.e., pro-environmental behavior). It followed a 3(sharing economy vs. control 1 vs. control 2) between-subjects design. First, participants were asked to recall a past experience participating in either sharing economy or commercial exchange (control 1) as a user. We also included a third baseline condition (control 2) in which the recall task was omitted. Afterwards, participants were asked to indicate their choice between a green and non-green option for three different product categories. The results

showed that the salience of sharing economy concept increases consumers' subsequent preference for green products, and this pattern of results persisted across three different product categories.

In Study 3, we followed a one-factor, four level (exposure to logos of: sharing economy brands vs. typical brands/control vs. pro-social brands vs. high-tech brands) between-subjects design. First, participants were asked to evaluate three brand logos depending on their condition. Then participants were asked to complete two sets of questions capturing their preference for green products, a procedure adopted from Haws, Winterich, and Naylor (2014). The results revealed that the effect is unique to sharing economy brands and cannot be generalized to any high-tech brands or prosocial (charity) brands. Moreover, the effect arises from the heightened accessibility of interdependent thoughts.

Finally, in Study 4, we adopted a 2(self-view: interdependent vs. independent)  $\times$  2(salience: sharing economy vs. control) between-subjects design. We first primed participants with either a salient interdependent or independent self-view using a word jumble task (Spassova and Lee 2013). We then activated the salience of the sharing economy using the same brand logo evaluation task. Lastly, participants were asked to indicate whether they would be willing to help out a graduate student using a real behavioral measure adopted from Zhong and Liljenquist (2006). Consistent with our previous studies, when primed with salient interdependent self-views, participants in the sharing economy (vs. control) condition expressed a greater willingness to help out the graduate student. However, this effect disappeared among participants who were primed with salient independent self-views.

Taken together, our findings contribute to the limited literature on the study of the psychological consequences of incidental exposure to sharing economy—a fast-growing business model that is transforming consumer lifestyle and behaviors—in the marketing literature. These results also extend the current literature on altruism by identifying a novel antecedent that could enhance consumers' subsequent altruistic behaviors.

### **Mining Consumer Minds: How Airbnb Hosts' Motivations Affect Their Retention and Pricing Decision**

#### **EXTENDED ABSTRACT**

Consumers are no longer mere buyers of products from a firm. Consumers who are motivated to share their possessions can now profitably do so by using platforms and marketplaces that facilitate sharing. Many consumers nowadays participate in the sharing economy as micro-entrepreneurs for multiple reasons – to seek extra income, to resist and reject conspicuous consumption, to meet others, and to foster a collaborative community (Ozanne and Ballantine 2010). This so-called sharing economy is expanding globally, with some estimating it at a value of 15 billion in 2013 to 335 billion dollars in 2025 (PWC 2015).

Despite all the growth, however, the sharing economy is not exempt from challenges. As the number of sharing economy platforms increases, a central question surrounding the sharing economy concerns how to motivate customers to participate in the sharing economy. Firms struggle to find ways to identify and motivate individual consumers to become micro-entrepreneurs, and to keep them engaged on the platform. Given the small service fee that firms receive from each transaction, scaling up operations is critical, and firms rely heavily on acquisition and retention of these micro-entrepreneurs. A critical question in this context therefore concerns how to best motivate customers to share their possessions, so as to maximize their

likelihood of engaging with the sharing platform and staying on it in the long-term.

This research aims to highlight the role of consumers as micro-entrepreneurs and examine the motivations' role in determining firm-level outcomes. To do so, we provide a practical way for firms to extract latent consumer motivations from textual data and showcase the downstream consequences of these motivations on customer engagement and retention, as well as pricing decisions. The insights are revealed by employing multi-method including text-mining, regression analysis, latent-attribution model as well as lab experiments.

We first uncover motivations from 25,290 lay hosts who responded to the survey question, "why did you start hosting?". The open-ended survey question is analyzed using two text-mining analyses – the supervised multi-label classification and the Poisson Factorization. Employing both text-mining methodologies revealed that Airbnb hosts are mainly driven by three motivations that may operate singly or jointly: 1) the motivation to earn cash, 2) the motivation to share the beauty of their property, and 3) the motivation to meet people. While the monetary motivation is commonly thought of as the main driver to participate in the sharing economy, we find that nearly 42% of hosts are driven by non-monetary motivations.

Based on the identified motivations at an individual-level, we examine the downstream consequences of these motivations by analyzing 593,503 reservation details. In contrast to the common intuition that the motivation to earn cash leads to greater host engagement, we find that the motivation to share the beauty of their home or to meet others leads to greater engagement. This was revealed in hosts' tendency to use more words and more photos to advertise their homes, and they opened more nights to receive booking. Moreover, a buy-till-you-die latent attrition model analysis (BG/BB model; Schmittlein, Morrison and Colombo, 1987) revealed that having these two motivations ('share beauty', 'meet people') leads to less churning likelihood (i.e., coefficients: -.163, -.142 respectively), while the cash motivation leads to greater churning likelihood (i.e., coefficient: .259).

Building on the retention findings, we then project the financial profit of motivation group. When we refer to the engagement and retention results, these makes us predict that the two motivation groups ('share beauty', 'meet people') would generate higher CLV than the cash-motivation group. However, our analysis suggests that it is only the host who are motivated to share beauty that generate high revenue (\$14,750 in a 36-month period after joining Airbnb), while the motivation to meet people led to much lower CLV (\$12,880). Cash motivation led to CLV a size of \$13,770, which was in between these two groups.

These puzzling CLV finding (meeting people < cash < sharing beauty) is the result of the different pricing strategy employed by each host. Note that hosts can flexibly choose how much to charge per night. We found that the average price is the highest among hosts motivated to share beauty ( $M_{\text{sharing beauty}} = \$198.39$ ) and the lowest among those motivated to meet people ( $M_{\text{meet people}} = \$128.34$ ). The price of those who were motivated to earn cash lay in the middle ( $M_{\text{cash}} = \$183.78$ ). While these findings are intriguing, the observed pricing pattern may also be explained by other factors such as the accommodation size, amenities, and location, such that hosts who live in luxurious properties are likely to not only report that they want to share the beauty of their homes, but also charge higher price because of their "objectively" superior property. We therefore control for this property traits using 60 other variables (e.g., kitchen, laundry, doorman, max capacity) and still find the consistent pattern of results. To further check the robustness of our findings, we conducted 2 controlled lab experiments where we show the exact same

home pictures and amenity description to all participants. Then we manipulate and elicit one of the three motivations (Experiment 1) or measure individual differences in motivations (Experiment 2). Then we ask all participants how much they would charge per night. The same pricing result emerges in both experiments. We believe that the motivation to meet people drives the price down because lower price attracts more guests, and the motivation to share beauty drives the price up due to the subjective valuation (endowment) of their homes.

Our research makes several contributions, first by being one of the first papers to explore the downstream consequences of different motivations extracted from textual data for customer behaviors such as engagement, retention and pricing decisions. Second, we contribute to the sharing economy literature by using rich secondary datasets from Airbnb and by focusing on host behavior (as supposed to guest behavior), thereby revealing consumers' new role as micro entrepreneurs. Third, from a methodological point of view, we use state-of-the-art machine learning and natural language processing (NLP) approaches to extract motivations from textual responses.

## Paper #4: People Overpredict the Benefit of Using Expensive Items and Appearing Rich in Friend-Making

Xilin Li, University of Chicago, USA  
Christopher K. Hsee, University of Chicago, USA

### SESSION OVERVIEW

People often make inferences about others' attitudes and preferences. Previous research has explored how people make such inferences based on our beliefs about others and salient social cues. The goal of this session is to highlight recent advances in our understanding of people's beliefs about others and under which conditions their social judgments and predictions err. Four papers feature a set of empirical regularities that consistently show that people often hold inaccurate beliefs about others' values, preferences, motives, and attitudes.

Jung, Moon, and Nelson report that people are often biased about others' preferences of both positive and negative goods. In particular, they find that people think that others have more intense consumption experiences regardless of the valence of those experiences. In turn, people's biases about others' preferences can produce paradoxical beliefs about others' valuation: People believe both that others who enjoy a good the same amount would pay more for it, but also that others who would pay the same amount for a good would enjoy it more.

Reit and Critcher provide evidence that when predicting whether others will choose A over B, people can be led astray by a prevalence heuristic—their intuitive sense of the commonness of A compared to B. The prevalence heuristic can give rise to a forecasting bias whereby people overestimate others' interest in choosing commonplace but bland items over rarer but exciting ones. The authors further outline when and why we are more likely to rely upon the prevalence heuristic and provide evidence that use of the heuristic can extend to costly decisions such as pricing.

Barasz, Kim, and Evangelidis study how people make inferences about why others make the choices they do. They propose that such inferences are often formed as a function of what is chosen. Specifically, when observers encounter someone else's choice, they use the chosen option's attribute values to infer the importance of that attribute in the decision-maker's choice. Consequently, when a chosen option has an attribute whose value is extreme, observers infer—sometimes incorrectly—that this attribute disproportionately motivated the decision-maker's choice.

Li and Hsee demonstrate that people predict that others are more willing to befriend them if they use expensive items and appear rich, but in reality others are more willing to befriend those who do not. This self-other discrepancy occurs because people misconstrue others' purpose of friend-making. In particular, people overestimate the extent to which choosers care about the utilitarian aspect in friend making (i.e., how useful the friend is if one is in need) relative to the hedonic aspect (i.e., how comfortable one would feel around the friend).

Together, these papers offer new insights into people's beliefs about others. Given the theoretical contributions and practical applications of the four papers, we expect this session to appeal to a broad audience in the fields of consumer behavior, judgment and decision-making, and social cognitive psychology.

## Self-Other Biases in the Perception of Values and Preferences

### EXTENDED ABSTRACT

People frequently consider others' preferences and values in making decisions. When deciding to purchase a good, people think about whether others would buy it and, if so, how much others would pay for it. When recommending a product, they consider whether others would enjoy it as much as they would. How do people perceive others' values and preferences? Frederick (2012) showed that people tend to think that others pay more for goods than they do. Although he considered a number of psychological accounts for the effect, none of them satisfyingly explained this overestimation bias. Extending this work, we examined that this overestimation more broadly generalized to others' preferences: people also think that others enjoy goods more than they do. Across field and lab experiments, we sought to identify the determinants of these biases in people's perception of others' values and preferences.

To establish people's overestimation bias in others' preference, in Study 1, we conducted a field study at a movie theater in California. Moviegoers ( $N=238$  groups) paid what they wanted and were told that 20% of their payments would go to a charity. Each group indicated: (a) how much they or another customer would enjoy the movie on a 7-point scale (1: not at all, 7: very much), (b) how much they would pay, and (c) how much they thought others would pay. Moviegoers thought that others would pay more ( $M = \$7.02$ ,  $SD = 2.54$ ) than they paid ( $M = \$6.03$ ,  $SD = 3.00$ ), and also that others would enjoy a movie more ( $M = 6.48$ ,  $SD = .87$ ) than they would ( $M = 6.07$ ,  $SD = 1.15$ ).

The results in Study 1 could have been driven by a selection of moviegoers who chose to watch a movie at this theater. Previous research has shown that a number of social forces influence payments under the voluntary payment contexts (e.g., Gneezy et al. 2010, 2012; Jung et al. 2014, 2016, 2017). In Study 2 ( $N = 374$ ), we test whether the observed overestimation bias persists in a lab setting in a non-voluntary payment pricing context. We replicated the overestimation of both payment and enjoyment for a wide range of goods that varied on three relevant dimensions: utilitarian or hedonic, relatively cheap or expensive, and relatively certain or uncertain market price.

Products are typically considered neutral (e.g., a tube of toothpaste) or positive (e.g., a trip to Paris). Consumers may overestimate others' enjoyment because they believe that others are more posi-

tive about their consumption experiences of the typical goods. Alternatively, the bias might also persist in the negative domain, which would mean that people tend to think that others dislike negative experiences more than they would. In Study 3 (N=441) examined whether this effect extended to the negative domain (e.g., “shaving head completely”). People believed that others would pay more to avoid negative experiences and that others would also dislike those experiences more than they would. These results suggest that people think that others have more *intense* consumption of a variety of goods, whether good or bad.

An alternative explanation for the overestimation bias could be that when estimating others' preferences, people might be thinking of someone whose preference is not so average. Instead, they might be thinking of someone whose preference for a target object or experience is exceptional. When assessing their own social lives, people think that their social life is worse than others because they compare themselves to a biased sample of those who have exceptionally rich social lives such as the most social friend they know (Davidai and Deri 2017). Similarly, when estimating others' preferences for a bottle of wine, people might be thinking of someone who enjoys drinking wine more than the average person. Such a biased pool of others might be more accessible because it is easier to observe others buying and liking than others not buying and not liking (Tversky and Kahneman 1973). Therefore, people might be thinking that the average other buys products more and also likes products more than they do. Such an explanation would provide a simple explanation for why people overestimate others' WTP for goods as well as their utilities from those goods.

Study 4 (N=1320) examined whether the biases come from the inaccurate perceptions of an average person. Participants (N=1320) estimated an identically-paying other's enjoyment or an identically-enjoying other's payment for a number of products. The logic is that people may think that others value and enjoy a good more than they do, but what cannot be true is that the perceived other simultaneously value a good more and less than they do. In other words, people cannot assume the perceived other as both enjoying a product less and more for the price they pay. However, this exact paradox emerges. Participants estimated that an identically-paying other would enjoy these goods more than they would, simultaneously believing that an identically-enjoying other would pay more for these goods. Therefore, depending on how one asks, people believe that other people derive more utilities for every dollar spent, while simultaneously thinking that other people derive less utilities from every dollar spent. The paradoxical results suggest that people do not simply think of an inaccurate average person in estimating the utilities and values of others, they also distort the scale of evaluation. In Studies 5a, 5b, 6a, and 6b we show that the similar paradoxes do not appear in people's quantity/numeric estimation about others in non-value/preference domains (e.g., height and weight, kindness and donation). Finally, Study 7 shows that the biases and the paradox extends to estimation of others' willingness-to-wait, suggesting that the phenomenon is broader in the domain of value and preferences.

This research shows that people are biased about others' preferences of both positive and negative goods, suggesting that people think that others have more intense consumption experiences whether it is good or bad. Furthermore, their biases ultimately lead to paradoxical interpretations that are entirely inconsistent with how we theorize about value and utility.

## The Prevalence Fallacy: Confusing Commonplace Choices for Preferred Choices

### EXTENDED ABSTRACT

People are often tasked with predicting others' choices. A dinner host must decide how many servings of vanilla ice cream vs. tiramisu to have on hand. A bed and breakfast owner must decide how much orange juice vs. mango juice to stock. A shoe salesman must decide how many of the new shoes in black or blue to carry.

We argue that when forecasting choice, people naturally call to mind a social heuristic. A hallmark of a heuristic is it involves attribute substitution—reliance on an imperfectly valid but readily accessible cue when making difficult, potentially intractable judgments (Kahneman, 2003; Kahneman & Frederick, 2002). We propose that in predicting whether others are likely to choose A or B (e.g., vanilla ice cream or tiramisu), people can be led astray by the attribute *prevalence*—their intuitive sense of the commonness of A compared to B.

When people buy or use an item, then this does lead an item to become more prevalent. The greater prevalence of vanilla ice cream over tiramisu does indeed reflect that the plain frozen treat has been *chosen to be eaten* more often than the Italian delicacy. But this does not imply that people are likely to choose vanilla ice cream *over* tiramisu when given the choice between the two. After all, vanilla ice cream is not merely a more common dessert choice, it is (for a variety of reasons) more commonly offered as an option to begin with.

We present six studies that, in combination, test whether and when people commit this prevalence fallacy. Study 1 documents the forecasting bias: Across eleven choice pairs, participants overestimated other participants' interest in choosing commonplace but bland items (e.g., pizza) over rarer but more exciting ones (e.g., Thai food). Study 2 replicates these findings in an incentive-compatible context in which we went to great lengths to assure participants the experimenter was blind to their actual choices. This study also directly tied participants' perceived prevalence of each item to their forecasts of choice.

Our next studies examined when and why prevalence is relied upon. Study 3 found people leaned on perceived prevalence over and above many other cues when forecasting others' choice (e.g., projection, the price of each option, how others were thought to like each option.) But upon more careful consideration, participants avoided the prevalence fallacy and relied on more normatively defensible input. Study 4 outsourced stimulus selection of the choice pairs to pretest participants; this allowed us to establish the generality of the prevalence fallacy without the unintentional distortion of experimenter bias. Study 5 sought evidence that people lean on prevalence (“what has been chosen”) because it is deceptively similar to the forecast of interest (“what will be chosen”). By this logic, prevalence may be used as a cue to estimating choice in particular, but less so (or maybe not at all) when considering other symptoms of preferences (e.g., what people like, what they would be most pleased to receive, etc.) To this end, Study 5 demonstrated that perceived prevalence is spontaneously used as a guide when forecasting others' choices, but not when forecasting what others would be pleased to receive.

Lastly, Study 6 illustrated a literally costly consequence of the heuristic. A two-part marketplace simulation study found amateur sellers' reliance on prevalence prompted them to systematically misprice goods. For example, participants considered selling Budweiser (i.e., relatively common item) and Japanese imported beer (i.e., relatively rare item) to online customers. For each item, participants could either raise, lower, or leave untouched a price that pretesting had identified as profit-maximizing. Consistent with the

prevalence fallacy, participants were more likely to suboptimally *raise* the price of the Budweiser (48.38%) than Japanese imported beer (20.13%), and more likely to suboptimally *lower* the price of the Japanese imported beer (48.32%) than the Budweiser (14.57%). Additional analyses tied these strategic pricing errors—which were observed across eleven sales pairs—to the prevalence fallacy (i.e., a tendency to overestimate the relative choice popularity of commonplace items). In short, strategic pricing errors can be tied directly to the prevalence fallacy.

Empirically, the focus of this paper is to provide evidence for a novel social heuristic. But we also have a broader methodological goal: to offer a thoughtful discussion of how to best provide evidence that a heuristic exists. To that end, we identify and outline two distinct empirical approaches to testing for the existence of a heuristic, what we call the *systematic bias* approach and the *cue-correlation* approach. When using the *systematic bias* approach, researchers identify contexts in which a heuristic should distort judgments in a particular direction and determine whether that occurs. For example, the prevalence heuristic should lead people to overestimate the extent to which others will choose commonplace but bland options (e.g., vanilla ice cream) over rare but enticing options (e.g., tiramisu). One shortcoming of this approach is the mere observation of systematic bias means the evidence is equally consistent with any other heuristic that might make the same prediction. The *cue-correlation* approach addresses this shortcoming by providing more direct evidence of the heuristic in use. Specifically, this approach ties variation in the heuristic attribute (e.g., prevalence) to variation in the judgment (e.g., forecasts of choice), thereby providing firmer support for reliance on a heuristic (Critcher & Rosenzweig, 2014; Kahneman & Tversky, 1973). The outlining of the two distinct heuristic-testing approaches should make the paper meaningful not merely in explaining the prevalence fallacy, but in offering a template that future heuristics and biases researchers may use.

## I Know Why You Voted for Trump: (Over)inferring Motives Based on Choice

### EXTENDED ABSTRACT

People often speculate about why others make the choices they do. This paper investigates how such inferences are formed as a function of what is chosen. Specifically, when observers encounter someone else's choice (e.g., of political candidate), they use the chosen option's attribute values (e.g., a candidate's specific stance on a policy issue) to infer the importance of that attribute (e.g., the policy issue) in the decision-maker's choice. Consequently, when a chosen option has an attribute whose value is extreme (e.g., an extreme policy stance), observers infer—sometimes incorrectly—that this attribute disproportionately motivated the decision-maker's choice. Seven studies demonstrate how observers use an attribute's value to infer its weight—the value-weight heuristic—and identify the role of perceived diagnosticity: more extreme attribute values give observers the subjective sense that they know more about a decision-maker's preferences, and in turn, increase the attribute's perceived importance. The paper explores how this heuristic can produce erroneous inferences and influence broader beliefs about decision-makers.

Studies 1 and 2 examined inferences—how observers use attribute value to predict attribute weight (i.e., the value-weight heuristic). Participants encountered an option that someone else had chosen; in one condition (“control”), the chosen option had only non-extreme value attributes (S1: city with average weather; S2: politician with moderate policy stance), while in a second condition

(“extreme”), the chosen option had a single extreme attribute value (S1: city with better-than-average weather; S2: politician with extreme policy stance). In both studies, observers in the extreme conditions inferred that the attribute (i.e., weather, policy issue) had been relatively more important than participants in the control conditions (S1:  $p < .001$ ,  $d = 1.08$ ; S2:  $p < .001$ ,  $d = .93$ ). We also replicated S2 and tested perceived diagnosticity (e.g., the subjective feeling of knowing someone else's preferences) as a mediator (e.g., I could confidently guess why the person made this choice or I have a good sense for what the person liked most about this choice). We found a significant indirect effect: extremity increased perceived diagnosticity, and in turn, the perceived importance of the attribute.

Studies 3-7 examined over-inferences—how observers overuse available information and make systematic mispredictions. In S3, participants observed a decision-maker's choice of city; we varied the diagnosticity of available information across four conditions. In one condition (“trade-off”)—the most diagnostic—a decision-maker had supposedly chosen City B, with better-than-average weather, over City A, with better-than-average job prospects (the cities were equivalent on other dimensions), such that actual diagnostic information was conveyed: an observed relative preference for weather over jobs. Using this as a benchmark, we compared two other conditions where less (or non-) diagnostic information was conveyed: one condition (“dominating”) in which the same City B was objectively better than the forgone City A (i.e., no trade-off had been made), and one condition (“extreme only”) in which only the chosen City B was displayed (i.e., no information provided about forgone City A). We also tested a baseline condition (“non-extreme only”), in which City B was average on all dimensions was chosen. Replicating S1 and S2, participants in the three extreme conditions (i.e., trade-off, dominating, and extreme only) inferred that weather was more important than participants in the non-extreme condition (all  $p$ 's  $< .001$ , all  $d$ 's  $\geq .94$ ). However, demonstrating the robustness of the heuristic—and observers' relative insensitivity to varying levels of available information—estimates in the three extreme conditions did not differ significantly (all  $p$ 's  $> .40$ ). In other words, people seemed to act as if they had actual, diagnostic information—even when they did not. We replicated these findings using an incentive compatible design; even with actual money on the line, participants in the extreme conditions were more likely to make an inference (versus not)—and infer that the attribute with the extreme value had been most important.

Studies 4 and 5 directly tested prediction errors by assigning participants to either be a decision-maker or an observer. As decision-makers, participants chose an option with an extreme attribute value—a city with extreme weather (S4) or a light bulb with extreme eco-friendliness (S5). As observers, participants simply encountered the other person's choice. In both studies, observers inferred that the attribute with the extreme value must be most important to the decision-maker—even though decision-makers reported otherwise; this resulted in a significant prediction error (S4:  $p = .001$ ,  $d = .51$ ; S5:  $p < .001$ , Cramer's  $V = .34$ ). It also led observers to (mistakenly) believe that decision-makers would continue prioritizing the extreme attribute in future city choices (S4:  $p = .002$ , Cramer's  $V = .23$ ) and purchase decisions (S5:  $p = .001$ , Cramer's  $V = .25$ ).

Study 6 attempted to debias observers. Using the same light bulb paradigm as S5, participants took both a decision-maker and observer role. However, we counterbalanced the order of the study: half of participants first chose for themselves and then observed someone else's choice (“decision-maker first”), while the other half first observed someone else's choice and then chose for themselves (“observer first”). We speculated that once participants had reflected on their own decisions (“decision-maker first”)—and realized that

the choice of an extreme attribute value could be incidental (rather than central) to a decision—they would be less likely to make the error for other people. Indeed, this is what we found: although the prediction error was not fully eliminated, it was significantly reduced (interaction:  $p=.003$ ).

Why does this matter? We suggest that these inferences affect broader interpersonal inference-making. For this, we surveyed self-reported Clinton and Trump voters five days post-Election. In line with our other results, Clinton voters perceived immigration policy—which a pretest revealed was a “high value” attribute of Trump’s campaign—to have been more important in Trump voters’ decisions than Trump voters reported that it had been ( $p<.001$ ,  $d=.73$ ), which was correlated with broader unfavorable impressions of Trump voters. These results provide consequential, real-world evidence for the value-weight heuristic in action.

Our work contributes to research on prediction errors and social inferences by demonstrating a novel heuristic: that observers use attribute information to infer motives for choice—the value-weight heuristic—even when such a heuristic may err.

### People Overpredict the Benefit of Using Expensive Items and Appearing Rich in Friend-Making

#### EXTENDED ABSTRACT

People are social animals and want to be popular. A common method people adopt to make themselves popular is to use expensive items and give others the impression that they are rich. While appearing rich has its benefits, we expect a self-other discrepancy about perceived wealth in friend-making: people (candidates in friend-making) overpredict the extent to which others (choosers in friend-making) would befriend them if they use expensive items (defined here as items considerably more expensive than what most others in the situation use) and appear financially superior. We posit that this self-other discrepancy occurs because candidates overestimate the extent to which choosers care about the utilitarian aspect in friend making (i.e., how useful the friend is if one is in need) relative to the hedonic aspect (i.e., how comfortable one would feel around the friend).

We have four completed studies. Study 1 demonstrated the proposed self-other discrepancy. We assigned 164 employees from a company to a candidate condition and a chooser condition. We asked those in the candidate condition to predict whether someone they met at a party was more willing to befriend them if they drove a non-expensive car or an expensive car, and asked those in the chooser condition whether they were more willing to befriend someone they met at a party if the person drove a non-expensive car or an expensive car. We observed the proposed self-other discrepancy: Most candidates (62.4%,  $\chi^2(1)=5.19$ ,  $p=.023$ , compared with 50%) expected others to be more willing to befriend them if they drove the expensive car, but most choosers (62.0%,  $\chi^2(1)=4.57$ ,  $p=.033$ , compared with 50%) were more willing to befriend those who drove the non-expensive car.

Study 2—a lab study—replicated the self-other discrepancy involving real choices rather than hypothetical predictions. We assigned 208 students who were interested in an advertised “friend-making study” (which was a pretext) to either a candidate condition or a chooser condition, and had them go through a “screening process” (which was the real experiment). We told participants in the candidate condition that for friend-making purposes, we needed to take a photo of them, and they could choose to have their photo taken either at a desk with expensive items on it (and hence appear rich) or at a desk with non-expensive items on it (and hence not ap-

pear rich). We told participants in the chooser condition that if they were selected to the “friend-making study,” they would be paired with one of two potential friends, showed the photo profiles of the two persons, who were similar, except that one was seated at the expensive-item desk and the other at the non-expensive-item desk, and let the participants choose one as their friend. We again observed the self-other discrepancy: Most candidates (79.6%,  $\chi^2(1)=36.13$ ,  $p<.001$ , compared with 50%) chose to have their photos taken at the expensive-item desk, but most choosers (59.0%,  $\chi^2(1)=3.44$ ,  $p=.064$ , compared with 50%) chose to be paired with the person sitting at the non-expensive-item desk.

Study 3—a field study—focused only on choosers, and demonstrated that their preference for befriending those using non-expensive items is not due to social desirability or experimental demand, and is observable even in naturally-occurring settings. We conducted the study at an informal social gathering. Two similar-looking female volunteers, one wearing an expensive outfit and appearing rich, and the other wearing a non-expensive outfit and not appearing rich, approached people at the event, and asked if they would join a party she and her friends would host. Replicating the chooser result of the other studies, more people approached by the non-rich volunteer signed up for the party than did people approached by the rich volunteer (24.0% versus 7.8%,  $\chi^2(1, N=152)=7.51$ ,  $p=.007$ ).

Study 4 further replicated the self-other discrepancy by using a chiefly private-consumption item (apartment), and explored the discrepancy’s underlying mechanism by manipulating the purpose of friend-making. We assigned 584 US MTurkers to six conditions, which constituted a 2 (role: candidate vs. chooser)  $\times$  3 (purpose: unspecified vs. utilitarian vs. hedonic) between-participants design. In the unspecified-purpose condition, we did not mention any purpose of making friends; in the utilitarian-purpose condition, we said the purpose was to find friends who were potentially useful; in the hedonic-purpose condition, we said the purpose was to find friends who would be comfortable to be around. We then asked participants in the candidate condition to predict whether someone they met at the party was more willing to befriend them if they rented an expensive apartment or a non-expensive apartment, and asked participants in the chooser condition whether they were more willing to befriend someone they met at the party if the person rented an expensive apartment or a non-expensive apartment. In the unspecified-purpose condition, we replicated the self-other discrepancy: most candidates (64.6%,  $\chi^2(1)=8.17$ ,  $p=.004$ , compared with 50%) expected the chooser to be more willing to befriend them if they rented the expensive apartment, but most choosers had the opposite preference (67.0%,  $\chi^2(1)=11.56$ ,  $p=.001$ , compared with 50%). The discrepancy mitigated in the two specified-purpose conditions. In the utilitarian-purpose condition, most candidates (87.8%,  $\chi^2(1)=55.88$ ,  $p<.001$ , compared with 50%) expected the chooser to be more willing to befriend them if they rented the expensive apartment, and most choosers (78.4%,  $\chi^2(1)=31.19$ ,  $p<.001$ , compared with 50%) indeed had such a preference. In the hedonic-purpose condition, most candidates (76.3%,  $\chi^2(1)=26.81$ ,  $p<.001$ , compared with 50%) expected the chooser to be more willing to befriend them if they rented the non-expensive apartment, and most choosers (76.0%,  $\chi^2(1)=26.04$ ,  $p<.001$ , compared with 50%) also had such a preference.

In sum, the present research reveals a self-other discrepancy in which people overestimate the friend-making benefit of appearing rich, and explores its underlying mechanism. Theoretically, this research enriches the extant literature on self-other discrepancy and perspective taking research. Practically, it helps people form more realistic beliefs about the influence of perceived wealth on social attractiveness and sheds light on how to increase social popularity.

### SESSION OVERVIEW

The past decade has witnessed the explosion of ‘Big Data’, and with it, many novel opportunities to study and model human cognition and behavior. Large-scale datasets of human activity “mined” from the Internet, in particular, have proven to be extremely useful for studying various aspects of human cognition. The papers in this session demonstrate that this approach can also be useful for studying consumer behavior. Specifically, they showcase various ways in which Big Data, combined with novel computational methods, can be used to derive insights about various aspects of consumer cognition and behavior.

The first paper in this session, by Lu, Bradlow, and Hutchinson, develops and tests a model of goal progress that captures consumption decisions related to online content, with parameters that can be mapped to specific theories from consumer psychology. They apply this model to large dataset of Coursera.com learners, and find that their consumption patterns are consistent with theories of goal gradient and resource slack. Moreover, they show that the model allows them to predict changes in consumption behavior when content release shifts from weekly installments (drip-release) to on-demand (all-at-once).

The next three papers utilize large scale text corpora drawn from the Internet, combined with machine learning and natural language processing techniques, to model and predict various aspects of consumer cognition and decision making.

First, Bhatia demonstrates that this approach can be used to predict the items that come to consumers’ minds when they need to construct choice sets from memory. Moreover, he shows the approach can be applied to a number of specific consumption domains (e.g., food shopping, gift-giving, etc.), and that it successfully predicts the responses of participants across six preregistered experiments.

Next, Zhang, Nrusimha, and Hsu demonstrate that this approach can be used to predict the likelihood that consumers will recall specific brands (e.g., Coke) within a product category (e.g., soft drink). They verify the accuracy of this approach by comparing its predictions to the responses of a large sample of participants.

Finally, Bhatia and Olivola demonstrate that this approach can be used to predict how entire product categories and individual brands are perceived along various trait dimensions by consumers. Specifically, they show that, across a wide range of product categories

(e.g., beauty products, cars, etc.), across specific brands within each category (e.g., for cars: Mazda, Hyundai, etc.), and across evaluative trait dimensions (e.g., competence, excitement, etc.), their model of brand trait perceptions is consistently well correlated with the judgments of participants in studies of brand perceptions.

In sum, the papers presented in this session showcase highly novel approaches to studying various aspects of consumer cognition and behavior. In particular, marketing researchers and practitioners can use the growing availability of ‘Big Data’, in combination with recently developed computational methods, to greatly advance consumer research. This session will appeal to marketing researchers interested in learning about cutting-edge approaches to studying consumer behavior.

## Testing Theories of Goal Progress Within Online Learning

### EXTENDED ABSTRACT

Online education has experienced rapid growth and change within the last decade. Firms like Coursera and edX offer both free and monetized content, and partner with universities to offer specializations and degrees. The setting of online education has unique features such as scheduled content and learning assessments that make it an appropriate testing ground for theories of how consumers progress towards goals.

We examine the behavior of 508 individuals engaged in two courses offered by Wharton Online through Coursera in 2015: Introduction to Marketing (“Marketing”) and Introduction to Operations Management (“Operations”), each consisting of four weeks of lecture videos and quizzes. We selected for individuals who had paid for both course certificates when the two courses were offered during the same four weeks. We build a model that captures decisions about whether to consume Marketing or Operations, whether the content is a lecture or a quiz, and when to take breaks of different lengths. On average, we observe 75.4 (SD = 45.2) of these decisions per person. The parameters of our model can be mapped to specific theories from consumer psychology, which provides an underlying behavioral interpretation for the patterns we find in the data.

The key feature of our model is the “Goal Progress” construct that we embed into the utility specifications of choosing Marketing and Operations, with each individual’s goal assumed to be to visit all available lectures and quizzes within a given course. For example, let  $G_M[j]$  represent “progress” or the percentage of available content in Marketing visited by choice  $j$ . The Goal Progress construct for Marketing is given by the expression  $\beta_{1M}G_M[j] + \beta_{2M}G_M[j]^2$ . Note that  $G_M[j]$  varies as individuals progress towards their goal by visiting more content, as well as when more content is released each week, which resets the goal by increasing the total amount of available content.

Because the Goal Progress construct has both linear and quadratic components, utility can flexibly vary with progress in different ways. Individuals may experience fatigue or satiation and exhibit decreasing utility (Inman 2001; Nelson and Meyvis 2008). In contrast, goal gradient theory (Kivetz, Urminsky, and Zheng 2006) predicts an acceleration of effort as individuals approach completion of their goal. The stuck-in-the-middle effect expands upon this by suggesting that individuals may also be motivated to move away from the starting line, resulting in a dip in utility near the middle (Bonezzi, Brendl,

and De Angelis 2011). Finally, individuals may exhibit a peak early on with a decline towards the end because they overestimated their future slack for time resources (Zauberman and Lynch 2005).

To estimate the parameters of our model (e.g.,  $\beta_{IM}$  and  $\beta_{2M}$ ), we use a hierarchical Bayes procedure, which allows us to account for unobserved heterogeneity across individuals (Gelman et al. 2014). We obtain a set of parameters for each individual that comes from a multivariate normal distribution for the population. Thus, for both Marketing and Operations, we can use the estimated parameters from the Goal Progress construct to classify each individual as a specific type of learner for each course. In Marketing, the linear and quadratic coefficients have population means of  $\beta_{IM} = 0.67$  (CI = [0.57, 0.78]) and  $\beta_{2M} = -0.36$  (CI = [-0.60, -0.09]), respectively, which corresponds to a small goal gradient effect. In contrast, for Operations, the linear and quadratic coefficients have population means of  $\beta_{IO} = 0.49$  (CI = [0.33, 0.72]) and  $\beta_{2O} = -4.09$  (CI = [-4.48, -3.69]), respectively, which corresponds to a strong resource slack effect. Compared to Marketing, the Operations content was more technical and built up across weeks, which may have resulted in attrition as learners found the material increasing in difficulty.

Since media firms are increasingly making content available “on-demand” (i.e., available all at once instead of in weekly installments), we use the parameter estimates of our model to conduct a counterfactual simulation where all course content was available starting on the first day. Our model predicts a sharp shift in activity towards the first weeks of the course, since individuals now have one overarching goal to complete all of the content, rather than waiting for the goal to be reset each week. To empirically verify our predictions, we took advantage of a policy change where the Coursera platform transitioned the courses from weekly to on-demand release in 2016. Using a new dataset from after this policy change, consisting of 1,907 individuals who matched the criteria of our original sample, we find that our predictions are consistent with observed changes in learner behavior.

## Semantic Processes in Memory-Based Consumer Decision Making

### EXTENDED ABSTRACT

Many common decisions do not involve fixed, exogenous sets of choice items. Rather, consumers must construct the choice sets by themselves, typically through the use of memory processes (see Alba and Hutchinson 1987; Lynch and Srull 1982). The key role of memory in generating choice sets in consumer decision-making raises a number of important questions at the intersection of memory and consumer research. From a theoretical perspective: What are the mechanisms that determine the items that are retrieved by consumers when exogenous choice sets are not provided? How do these mechanisms relate to core memory processes known to play a role in non-preferential choice tasks, and do these memory processes facilitate or hinder efficient memory retrieval for consumer decision-making? Practically, can the mechanisms at play in memory-based decision-making be tested? The set of retrieved choice items in everyday consumer decisions is completely unconstrained—any choice item can come to mind, and the items that do come to mind often lack a clear category structure. So how can the relationship between the various retrieved items, and between these items and other relevant variables (such as choice context), be quantified?

I attempt to address these questions using existing insights on human memory combined with novel techniques from machine learning and data science. The task of retrieving feasible sets of choice items from memory has similarities to well-studied cognitive

tasks, such as free-recall and free-association. Thus it is likely that both the mechanisms that guide retrieval in these tasks, as well as the effects generated by these mechanisms, carry over to the domain of consumer decision-making. For example, as with free-recall and free-association, the generation of memory-based choice sets may involve associative activation processes. This would cause memory-based choice sets to display semantic clustering, with retrieved items increasing the retrieval probability of other semantically related items (Bousfield and Sedgewick 1944; Gruenewald and Lockhead 1980; Romney et al. 1993). For this reason, we would also expect retrieved items to depend on contextual cues, such as choice context, with items semantically related to these cues being more likely to be retrieved (Hare et al. 2009; Moss et al. 1995; Nelson et al. 2004).

Moreover, it may also be possible to apply novel methodological tools used to study memory processes in free-recall and free-association tasks to the domain of consumer choice. For example, recent work has shown that new techniques from machine learning and data science, such as semantic space models, are able to quantify the semantic similarity between items, and between items and contextual cues (Hills et al. 2012; Howard and Kahana 2002; see also Bhatia 2017). These models possess representations for a very large set of objects and concepts, implying that they can also be used to measure the semantic relationships at play when consumers must generate choice sets from memory.

I tested the applicability of semantic space models for studying semantic clustering effects and context effects in memory-based consumer choice in six preregistered experiments. In Experiments 1A-1C participants were shown a description of a consumer choice setting and asked to list any 20 items that came to their mind as they considered making their decisions. Specifically, the settings were: food choice (Experiment 1A), vacation choice (Experiment 1B), and purchasing a gift for someone else (Experiment 1C). After these items were listed, participants were taken to a second screen on which they rated each of their 20 items in terms of desirability, on a scale from -3 to +3.

I use word2vec, a well-known semantic space model, to quantify the semantic distance between each pair of listed choice items for each participant (Mikolov et al. 2013). I subsequently analyzed semantic clustering using the path analysis method proposed by Romney et al. (1993). This method involves measuring the total semantic distance (in word2vec space) between each pair of adjacently listed items in a participant’s list, and comparing this distance to a random path on the same list. Using this method I found that listed paths were significantly shorter than random paths effects in all three settings, demonstrating strong semantic clustering. Listed paths were also shorter than the hypothetical paths that would have been generated had items been listed in order of desirability. This indicates that semantic clustering leads to some degree of suboptimality in memory retrieval, with undesirable items being retrieved significantly earlier than had decision makers been able to retrieve items strictly in order of desirability.

In Experiments 2A-2C, I examined the influence of consumer choice context on the retrieval of items. These experiments considered the same choice domains as Experiments 1A-1C but varied the contextual cues given to participants: Breakfast vs. dinner for Experiment 2A, wine tasting vs. camping trip for Experiment 2B, and baby shower vs. Valentine’s day gift for Experiment 2C. Each participant was only shown one context and asked to list any 20 items that came to mind. I again used word2vec to quantify semantic distance between pairs of listed items, and found robust semantic clustering effects (replicating Experiments 1A-1C). I also used this method to calculate semantic similarity to the consumer choice context, and

found that participants were much more likely to list items that were semantically related to the context in consideration. The effect of consumer context was most pronounced for items listed earlier.

Overall, these experiments demonstrate that semantic processes play a key role in the formation of memory-based consumer choice sets, by generating both semantic clustering and context dependence. The experiments also show how decisions involving everyday consumer purchases can be studied with the use of semantic space models. These models make it possible to obtain representations for a very large set of words and concepts. These representations, in turn, provide measures of semantic similarity for nearly any pair of choice items, and between choice items and a wide range of choice contexts, allowing quantitative analyses of item retrieval in unconstrained memory-based consumer decision settings.

### Predicting Consumer Brand Recall and Choice Using Large-Scale Text Corpora

#### EXTENDED ABSTRACT

Consumer memory processes have long been recognized as playing an important role in mediating the effect of marketing actions on consumer behavior (Hoyer and Brown 1990; Lynch 1991; Nedungadi 1990; Posavac, Sanbonmatsu, and Fazio 1997). Brand managers often strive to foster brand awareness, increase brand accessibility, and create favorable brand images. Consumer memory has become an integral component of consumer-based brand equity (Christodoulides and de Chernatony 2010), as well as related metrics such as brand salience, brand awareness, and top-of-mind widely used by marketers (Farris 2010).

Despite its importance and significant advances in the theoretical and empirical understanding of the relationship between consumer memory and choice behavior, measures of consumer memory have remained dependent on survey-based self-report methods. This reliance on verbal self-reports places inherent limitations on the ability of researchers and practitioners to scale across product categories and markets, or to integrate with the large amounts of purchase data that are routinely available within firms.

This paper proposes to take a step toward addressing these challenges by leveraging advances in machine learning (ML) and natural language processing (NLP) to draw inferences about core aspects of consumer memory from large text corpora. Specifically, we show that it is possible to develop predictive models of consumer brand recall using a type of models from NLP. A well-established theoretical framework for semantic memory is that concepts (e.g. categories, brands, products) are organized as nodes in an associative network, where the links between any two nodes represent their associations (Collins and Quillian 1969). When one concept (e.g. a category) is processed, the activation will be spread to other concepts (e.g. brands within this category) to the extent that they are closely related to the previous concept (Collins and Loftus 1975). The stronger the association, the higher the probability of the successful retrieval of the latter concepts (Anderson 1983). Recent advances in NLP have made it possible to uncover such semantic relations and associations between words from large text corpora quantitatively, using so called word embeddings models (Mikolov, Sutskever, Chen, Corrado, and Dean 2013). Such models represent words and phrases ('tokens') as vectors in high dimensional spaces in a way that the spatial distances between the vectors reflect the semantic relatedness between the tokens. This "word to vector" (or *word2vec*) approach has been shown to improve the performance of machine learning models in applications such as translation and conversation beyond simple co-occurrence statistics. Successful applications of word embeddings

also include using the uncovered associations to understand more complicated phenomena, such as stereotypes (Caliskan, Bryson, and Narayanan 2017) and cognitive biases (Bhatia 2017). For example, male words are found to be more associated than female words with mathematics than with arts (Caliskan et al. 2017).

To demonstrate our approach, we examined the extent to which word embeddings trained on large text corpora can be used to make predictions about average brand recall success (e.g., "Coke") for specific product categories (e.g., "Soft drink"). In three batches of aided recall experiments on Amazon Mechanical Turk (N = 120/batch), we asked participants to type down all brands that came to mind when prompted with a category cue. We included a diverse range of product categories, including both consumer packaged goods (batteries, beer, bottled water, breakfast cereals, chewing gum, fast food, Greek yogurt, orange juice, potato chips, and soft drink), as well as durables (headphones, luxury cars, and laptop computers), and services (auto insurance, gas stations, and hotels). The choice of categories was primarily based on extant literature on brand memory and focused on categories for which memory factors play a crucial role in purchase decisions (Dickson and Sawyer 1986; Lynch 1991). We also avoided categories where most brand names are polysemous, such as airlines and banks (e.g., United, Delta, Chase, Fidelity).

We define the total rate of recall for a certain brand in a given category to be the percentage of participants whose list of brands when prompted with the category included that brand. We used the standard *Google News word2vec* Vectors (3 million English word tokens) trained on the Google News corpus (3 billion running words) (Mikolov et al. 2013). The association between any two such vectors is defined as the cosine distance between them, following practices in existing studies (Bhatia 2017; Mikolov et al. 2013).

We show that mean recall rates are significantly associated with similarity as assessed using cosine distance between brand and category, consistent with the hypothesis that word embeddings capture association strengths. Furthermore, two consistent trends emerged across categories. First, the brands with the highest rate of recall almost always have very high similarities with the categories they belong to in word embeddings. Second, the brands that have low cosine similarities tend to have low recall rate. Interestingly, word embeddings cosine similarity seems to track brand recall in a nonlinear manner, resembling a power function. Few brand names are highly recalled without high cosine similarity to the categories, almost all of them being brands which produce products spanning multiple categories (for example, "Samsung" has relatively low similarity to "television" despite a high recall rate).

By showing a relationship between category-brand associations predicted by word embeddings and empirical recall data, we demonstrate the great potential of applying this novel tool to better understand and quantify brand memory. Using large-scale real-world text corpora, word embeddings provide a high-quality abstraction of the informational environment that the general population is exposed to, from which quantitative inference could be drawn. The availability of off-the-shelf word embeddings models like *word2vec* also makes it a highly accessible and flexible tool for marketers. Further work is needed to improve its performance for multi-category brands, better address individual differences in brand recall, and to link brand memory predictions to purchase behavior.

### Data-Driven Computational Brand Perception

#### EXTENDED ABSTRACT

A key determinant of a brand's value (and equity) is, of course, how it is *perceived* by consumers --i.e., how it is represented in their

minds. There are numerous pathways through which brand perceptions (and mental representations) influence brand value (Keller 2003, Schmitt 2012). At the most basic, and obvious, level, brands are valued to the extent that they are seen as having desirable characteristics, such as being associated with trustworthy, reliable, and competent firms and products (Keller 2003). These positive associations, in turn, contribute to a brand's intangible qualities, increasing purchase likelihood and customer loyalty (Keller and Lehman 2006). Moreover, companies themselves have corporate brands that reflect how they are perceived by consumers (e.g., Aaker et al. 2010, Bhattacharjee et al. 2017, see also Keller and Lehman 2006). Therefore, an important goal for both firms and marketing researchers, is to be able to measure how individual brands, and product categories, are perceived by consumers (e.g., Aaker 1997).

Although brand perception has long been, and continues to be, a core topic in marketing, the methods for studying it have largely remained the same: to gauge how brands are evaluated on specific dimensions of interest (e.g., masculinity, sophistication, etc.), researchers typically collect responses from human participants (e.g., numerical ratings), then average these to estimate aggregate brand perceptions. This general approach can be costly (both in terms of money and time spent), slow (if one needs to estimate perceptions for a very large set of brands and/or evaluation dimensions), and often relies on relatively small samples of human judges (who are rarely representative of the broader population) to draw inferences about market-level brand perceptions.

We introduce a novel approach to predicting and mapping brand trait perceptions using 'Big Data' mined from the Internet combined with machine learning techniques. Recent developments in computational linguistics have made it possible to uncover human-like associations between a very large range of objects and concepts, including popular brands and various traits. We show such techniques allow us to predict how entire product categories and individual brands are perceived by consumers along various trait dimensions by consumers.

We used a prominent prebuilt set of vector representations in order to predict brand-trait associations. The representations we used were generated by the Word2Vec model, trained using the continuous bag-of-words and skip-gram techniques on a corpus of Google News articles with over 100 billion words tokens. These representations have a vocabulary of 300 million words and phrases, with each word or phrase being defined on 300 dimensions. We computed the association between each brand and trait in our dataset, as assessed by the cosine similarity between their corresponding vector representations.

We find that, across a wide range of product categories (e.g., beauty products, cars, etc.), specific brands within each category (e.g., for cars: Mazda, Hyundai, etc.), and evaluative trait dimensions (e.g., competence, excitement, etc.), our model of brand trait perceptions is consistently well correlated with the judgments of participants in previous studies of brand perceptions.

In sum, we propose a totally different approach to estimating the way brands are represented in the minds of consumers. In particular, marketing researchers and practitioners can use the contents of the Internet, in combination with computational methods, to measure and map the representations of brands in the collective consumer mind. This computational, big-data approach presents many advantages, such as allowing researchers to rapidly collect data on a huge range of products across a large set of evaluation dimensions.

### **SESSION OVERVIEW**

How do consumers share their consumption experiences with others? A key finding in prior work on shared consumption is that consuming the same content with another person provides social benefits such as feelings of connectedness, subsequently amplifying enjoyment of the shared experience (Raghunathan and Corfman 2006; Ramanathan and McGill 2007). Similarly, desire for social connectedness leads consumers to make choices congruent with the accompanying individual's preferences (Dzhogleva and Lambertson 2014; Lowe and Haws 2014). While both forms of shared consumption are important, shared consumption can also occur in various other forms. In this special session, we present four papers that broaden the scope of shared consumption and expand its implications.

The first paper, by *McFerran and Argo*, demonstrates that when two people engage in an experience together, one person might have enabled access to the experience for the other person. VIPs attending an event as part of preferential treatment can grant access to the same experience to a guest. In such a situation, a VIP (vs. guest) has strong (vs. weak) personal associations with the experience. Five studies show that guests can be more helpful to a firm than the VIPs themselves, as they feel more status during the experience and are more likely to spread WOM.

The second and third papers investigate how simultaneity of experience impacts consumer perceptions. *Shaddy, Tu, and Fishbach* show that the sense of sharing an experience with another person can be fostered when similar events happen close in time, even if the events themselves are somewhat different. Across five studies, consumers prefer these two events to occur to them and another person on the same day, rather than on different days, particularly when the events are small in magnitude, positive in valence, and they like the other person. This effect is driven by consumers' desire for social connection. The third paper, by *Duani, Barasch, and Ward*, investigates consumer preference for different formats of content on social media, such as live streamed versus prerecorded. Five studies show that consumers prefer and enjoy live streamed (vs. prerecorded) con-

tent more, because they think that many others would also be watching the same content, increasing perceived social connectedness.

Finally, *Kim and Ratner* investigate the public (vs. private) nature of shared consumption. Across five studies, they demonstrate that anticipating another person will view what one has consumed, either because the other person is physically present for the consumption experience or the person will learn about the experience via social media, increases consumers' choice of hedonic (vs. utilitarian) options. This effect is driven by consumers' desires to send positive signals, such as that they are having a good time and are fun people.

This session enhances our understanding of how consumers share consumption with others by demonstrating novel approaches of defining shared consumption. Furthermore, this session also provides interesting marketing implications, such as whether firms should prioritize guests of VIPs and how social media impacts what people choose to consume and how they feel about their shared experiences.

### **"Felt Status, Social Contagion, and Consumer Word-of-Mouth in Preferential Treatment Contexts"**

#### **EXTENDED ABSTRACT**

In the US there are approximately 1.8 billion loyalty program memberships (i.e., approximately 12 for every household in the country; Kumar 2008), which are often designed to provide preferential treatment and status to loyal customers (Drèze and Nunes 2009; Sheth and Parvatiyar 1995). These loyalty programs cost American companies in total over \$1.2 billion annually (Wagner, Hennig-Thurau, and Rudolph 2009).

While previous research has examined the implications of consumers receiving versus not receiving preferential treatment (i.e. VIPs vs. non-VIPs), to date research has not examined the impact of such rewards on a third group of consumers: those consumers who receive status benefits because of their personal association with a "true" VIP. Guests of VIPs are important to consider because when companies design preferential treatment programs they often intentionally offer benefits to status holders that extend to members of the VIP's social network. To illustrate, typical VIP passes to clubs, concerts, and sporting events, as well as various customer appreciation events, routinely entitle the bearer to bring a guest, whom receives many (or all) of the same perks (e.g., dedicated check-in lanes, lounge access, room upgrades, priority boarding) as the VIP receives. What value do guests derive from these offerings, and is there sufficient value added for firms? To our knowledge, we provide the first inquiry into these questions.

Our research has two central purposes. First, we provide the first investigation into the implications of guests receiving the preferential treatment earned by a VIP. We argue that status is contagious from person to person and that as such not only do VIPs feel an increase in status when receiving preferential treatment, but so do their guests – an effect we refer to as "status by association" (SBA). Support for why status may rub off on those around them comes from research on emotional contagion (Hatfield et al. 1994; Neumann and Strack 2000; Ramanathan and McGill 2007), spontaneous trait transference (Argo and Main 2008; Winter and Uleman 1984;) and contagion effects (Argo et al. 2006; 2008). In fact, drawing from

work on satiation, we predict and find that feelings of status stemming from receiving preferential treatment is often lower for VIPs as compared to their guests. Second, we demonstrate that there are positive implications of guests receiving preferential treatment for the firm. In particular, we find that when guests feel status because of receiving preferential treatment they have a heightened desire to tell others about the experience by engaging in positive word-of-mouth (WOM).

In Study 1, we demonstrated the tendency for status by association to occur. This study used a one-factor between-subjects design. Participants read a scenario indicating that they are planning on attending a nightclub (a context that frequently has benefits of status (e.g., VIP sections, free beverages, special entrances)). In the scenario, participants read that upon arrival they notice that there is a long line at the nightclub. In the self condition, participants read that they have a VIP card that allows them to jump the line. In the friend condition participants read that their friend has a VIP card that allows both of them to skip the line up. In the same benefit control condition, the participant knows someone who is already at the front of the line so the participant will get in right away and will not have to wait (i.e., no status but still get to cut the line). In the no benefit control condition, participants arrived before the line forms, so access is gained into the club without waiting (i.e., no status but no special and/or negative treatment). Results demonstrated that individuals feel more status in both the self and friend conditions (which do not differ from one another) as compared to the two control conditions; the same pattern held for intentions to share WOM, and felt status mediated this effect.

A second lab study using the same nightclub scenario and a satiation paradigm in a 3(self, other, no benefit, between subjects) x 3 (frequency of experience, within subjects) showed that (1) feelings of status decline within person over time, (2) felt status and WOM are no different for the self and other conditions at all three points in time (replicating the previous study), (3) felt status satiates faster in the two preferential treatment (vs. no benefit) conditions, and (4) the decline in felt status over time again predicts reduced WOM. These results suggest that a VIP who has experienced repeated preferential treatment should be expected to feel less status and be less likely to share WOM than a guest for whom the experience is more novel, and experienced satiation drives this effect.

Study 3 was a field study involving both the owner/main decision makers and guests in real luxury suites at a professional football game. Respondents self-identified as either owners or guests of the suite in a survey. Results revealed that guests feel more status than owners (regardless of whether they were actual friends or merely friends of friends), and this mediated higher WOM intentions. These effects were negatively related to the number of games people have watched from the suite (i.e., more games, lower felt status and WOM intentions), again suggesting (via cross sectional data) that status decays over time and that WOM is harder to cultivate among long-standing status holders as a result.

Study 4 used Twitter data from an entire football team's season, matched with ticketing information from the team. Results showed that game-day tweets that came from sections of preferential treatment, without exception, came from those who were not registered as the ticketholders of the seat/luxury suites. In other words, WOM came from guests, not from VIPs themselves.

In Study 5, we asked a sample of marketing managers (n=250) to predict our central effect. Marketers (inaccurately) reported VIPs as contributing a greater degree of WOM than guests.

Collectively, our results show that frequent status holders may require more and more perks to feel the same felt status over time

as a person who only experiences VIP treatment on a single (or few occasions), and that a path to cultivating increased WOM for a firm's preferential treatment is to encourage VIPs to bring guests. Allowing VIPs to bring guests may be more beneficial than firms might think.

### **“The Preference for Simultaneity: When Different Events Happen to Different People at the Same Time”**

#### **EXTENDED ABSTRACT**

In this research, we explore the preference for simultaneity, which we define as the preference for events that happen to the self and to close others to occur at the same time. We propose that people prefer simultaneity because it facilitates social connection (Baumeister and Leary 1995). To that end, we further predict that the preference for simultaneity is both moderated and mediated by the desire to connect with others.

This account is consistent with research documenting the various positive effects of sharing experiences with others. We build on this work to suggest that simultaneity yields many of the same benefits, even when different events happen to different people in different places (unlike in shared experience paradigms, where the same event happens to different people in the same place). Simultaneity itself creates value.

But, of course, there are limits. The magnitude of these events represents an important boundary condition. Some events are simply too emotionally overwhelming to benefit from simultaneity. They exhaust the joint emotional resources of the self and other (Linville and Fischer 1991). Consequently, we predict that the preference for simultaneity systematically decreases as the magnitude of events increases. Moreover, due to loss aversion, this preference should disappear at lower magnitudes for negative events than for equivalent positive events.

Critically, this proposed preference for integration of events that happen to the self and to close others stands in contrast to the documented preference for segregation of events that happen to just the self. The hedonic editing hypothesis, in particular, suggests that people should segregate gains and integrate losses (Thaler 1985). But people actually tend to prefer segregating both (Thaler and Johnson 1990). Thus, our theory argues that shifting from intrapersonal to interpersonal preferences for event timing yields the exact opposite pattern.

In Study 1, we recruited 50 pairs of friends sitting together in an on-campus dining hall. We asked each pair of participants to schedule delivery of a pair of prizes (i.e., one prize for each participant). These prizes could be delivered to each person on the same day, requiring four total weeks of waiting. Or they could be delivered on different days, requiring three total weeks of waiting. We randomly selected one pair of participants to actually receive their prizes, based on this choice. Choices reflected a preference for simultaneity (“same day” choice share: 67%;  $\chi^2(1) = 21.78, p < .001$ ).

In Study 2, we sampled a wider range of experiences. These events spanned four categories (e.g., small positive, large positive, small negative, large negative) and three domains (e.g., academic, social, financial). For each combination of valence, magnitude, and domain, we asked participants to imagine that one event happened to them (e.g., finding a \$5 bill) and a different event (with the same combination of valence and magnitude) happened to a close other (e.g., receiving a \$5 refund). We then measured whether participants preferred these events to occur on the same or different days. Participants exhibited a preference for simultaneity for small positive events (80%;  $\chi^2(1) = 86.65, p < .001$ ), large positive events (75%;  $\chi^2(1) = 62.50, p < .001$ ) and small negative events (75%;  $\chi^2(1) =$

60.50,  $p < .001$ ). This preference did not extend to large negative events (50%;  $\chi^2(1) = .02$ ,  $p = .899$ ), consistent with our proposed boundary condition.

However, the events tested in Study 2 were not all objectively equivalent in magnitude. Therefore, Study 3 employed a 2 (valence: gains vs. losses; between-subjects)  $\times$  6 (amount: \$10 vs. \$100 vs. \$1,000 vs. \$10,000 vs. \$100,000 vs. \$1,000,000; within-subjects) mixed design. Participants imagined that they and a friend each gained or lost each of six amounts in their separate investment accounts. They then decided if they preferred these gains or losses to occur on the same or different days. Participants exhibited an overall preference for simultaneity (66%;  $\chi^2(1) = 60.17$ ,  $p < .001$ ), which decreased as magnitude increased ( $z = -7.62$ ,  $p < .001$ ) and was further qualified by an interaction ( $z = 2.70$ ,  $p = .004$ ), confirming the preference disappeared at lower magnitudes for negative events than for equivalent positive events.

Study 4 tested whether the preference for simultaneity is moderated by desire to connect. Study 4 employed a 2 (liking condition: like vs. dislike; between-subjects)  $\times$  6 (event: within-subjects) mixed design, in which participants considered whether they would prefer simultaneity for events that occurred to both the self and a person whom they either liked or disliked. We sampled a variety of everyday events. Participants in the like condition exhibited a preference for simultaneity (68%), while participants in the dislike condition did not (26%;  $z = 7.65$ ,  $p < .001$ ).

Finally, Study 5 tested whether the preference for simultaneity is mediated by the desire to connect, which we manipulated by identifying a counterpart with either the same or opposite political beliefs as participants. We then asked them to decide whether they preferred either a positive event (e.g., getting upgraded to first class) or a negative event (e.g., missing a flight) to occur on the same or different days as this counterpart. We also asked participants to indicate how much they desired social connection with this person. Participants desired both simultaneity and social connection more in the same condition ( $M_{\text{simultaneity}} = 4.69$ ,  $SD_{\text{simultaneity}} = 1.38$ ;  $M_{\text{connect}} = 5.13$ ,  $SD_{\text{connect}} = 1.43$ ) than in the opposite condition ( $M_{\text{simultaneity}} = 3.71$ ,  $SD_{\text{simultaneity}} = 1.56$ ,  $F(1, 202) = 22.95$ ,  $p < .001$ ;  $M_{\text{connect}} = 2.31$ ,  $SD_{\text{connect}} = 1.42$ ,  $F(1, 202) = 202.93$ ,  $p < .001$ ). Moreover, the desire to connect fully mediated the effect (indirect effect = 1.00,  $SE = .23$ , 95% C.I. = [.572, 1.482]).

Our work suggests marketers are potentially missing opportunities to capitalize on the preference for simultaneity (e.g., retailers shipping packages to multiple recipients often prioritize immediate rather than coordinated delivery). And people already exhibit this preference in the marketplace. Moviegoers flock to midnight movie premieres, protestors coordinate nationwide rallies, and sports fans eagerly refresh Twitter streams during games. Our research suggests one important reason why: Simultaneity facilitates social connection.

### **“Brought To You Live”: On The Consumption Experience of Live Social Media Streams**

#### **EXTENDED ABSTRACT**

Previously reserved for only large and commercial media outlets, social media platforms like YouTube and Facebook have now made live streaming widely accessible to the general public: 63% of millennials have watched live content and already 42% have created it (eMarketer). Previous research on live television has shown that people expect to enjoy live over delayed content because of indeterminacy, or the fact that events unfold in ways that are not determined *ex ante* (Vosgerau, Wertenbroch, and Carmon 2006). In this prior re-

search, broadcast format did not interact with the hypothetical presence of others, suggesting that preferences for live content were not driven by expectations of a shared social experience.

Our research builds on this prior work by (i) moving beyond expectations (to actual experiences), and (ii) examining the effects of peer-to-peer live streaming (rather than live broadcast television) on consumers' enjoyment and viewing decisions. Live streaming by individual consumers differs from live television in several key ways. Most relevant to our research, live streaming is a more intimate form of communication typically involving non-professional broadcasters and a more salient audience, or online community, who is also watching. As such, we argue that feelings of social connection and co-experience (e.g., Raghunathan and Corfman 2006; Shiteynberg et al. 2014) could serve to make content more enjoyable when it is streamed live vs. prerecorded.

Using a unique interface that we developed, we show that people enjoy the same exact experience more when they believe it is live than when they believe it is prerecorded. This effect is driven by the social connection that live viewing facilitates, and operates above and beyond the effect of indeterminacy.

In Study 1, participants ( $N=401$ ) were informed that they would watch a short video (e.g., aerobics lesson, musical concert) being broadcasted by an individual, and learned that the content was either streaming live or prerecorded (manipulated between-subjects). As in previous research, participants in the live condition expected to enjoy the video more than those in the prerecorded condition ( $M_{\text{live}}=3.96$ ,  $M_{\text{pre}}=3.50$ ;  $F(1,400)=7.09$ ,  $p=.008$ ). However, unlike in previous work, participants also anticipated greater social connection from the live viewing ( $M_{\text{live}}=3.93$ ,  $M_{\text{pre}}=3.23$ ;  $F(1,400)=20.89$ ,  $p<.001$ ), and this expectation of a shared, social experience fully mediated the effect of live streaming on predicted enjoyment (95% CI [.25, .68]).

In Study 2 ( $N = 209$ ), an additional condition that was told that the live video was streaming with a delay (and thus that the process and outcome were pre-determined) expected to enjoy the experience as much as the live condition, suggesting that indeterminacy is unlikely to be the only factor driving the preference for live content.

Study 3 ( $N = 608$ ) replicated these findings with real viewing experiences. All participants selected which of 6 types of content (e.g., puppies playing, painting lesson) being broadcasted by an individual online they would like to watch. Half the participants were told the video was streaming live, while half were told that the video had been prerecorded. Participants in the two conditions watched the exact same video (except for a small “live” banner at the bottom of the video in that condition). As predicted, we found a main effect of live streaming on enjoyment ( $F(1,607)=11.35$ ,  $p=0.03$ ): participants who thought they were watching the video live enjoyed it more ( $M=4.76$ ) than those who thought they were watching a prerecorded video ( $M=4.49$ ). They also felt a stronger sense of social connection ( $M_{\text{live}}=3.49$ ,  $M_{\text{pre}}=3.13$ ;  $F(1,607)=7.832$ ,  $p=0.005$ ) and reported greater willingness to attend a similar event in the future ( $M_{\text{live}}=5.10$ ,  $M_{\text{pre}}=4.74$ ,  $F(1,607)=5.33$ ,  $p=0.021$ ). We again found that social connection fully mediated the effect of live streaming on enjoyment (95% CI [.05, .27]).

Study 4 ( $N=138$ ) replicated the previous results while introducing a new direct behavioral measure. Participants chose their preferred content and were randomly assigned to watch it either “live” or “prerecorded.” Participants in the live condition again enjoyed their viewing experience more than those in the prerecorded condition ( $M_{\text{live}}=4.72$ ,  $M_{\text{pre}}=3.98$ ;  $F(1,137)=6.32$ ,  $p=0.01$ ) and felt directionally more socially connected ( $M_{\text{live}}=3.23$ ,  $M_{\text{pre}}=2.87$ ;  $F(1,137)=1.73$ ,  $p=0.19$ ). In addition, people who watched the experience live were significantly more likely to choose to continue

watching the same type of content for the next two minutes (24%) than those who watched the experience prerecorded (7%;  $\chi^2=7.575$ ,  $p=0.006$ ).

Finally, Study 5 ( $N = 620$ ) directly tested the social connection mechanism by manipulating social presence directly. In a 2(live, pre-recorded)  $\times$  2(solo, social) between- subjects-design, participants chose a username and which content to view, and were informed that the video was streaming live or recently recorded, as in the previous studies. Participants in the social condition were told that they would watch the video with 4 other people, and saw these people's avatars (along with their own) in a virtual viewing room. Participants in the solo condition were told that they were watching the video by themselves. We predicted that if enjoyment of live streaming is driven by the social nature of the experience, then the effect of live vs. prerecorded content would diminish when viewers already felt like part of a group.

As expected, participants in the social condition felt more socially connected than those in the solo condition ( $M_{\text{social}}=3.26$ ,  $M_{\text{solo}}=2.45$ ,  $F(1,616)=41.76$ ,  $p<.001$ ). However, this effect was qualified by a significant interaction ( $F(1,616)=4.90$ ,  $p=.02$ ); participants who watched the video solo felt more connected when the video was live than when it was prerecorded ( $M_{\text{live}}=2.63$ ,  $M_{\text{pre}}=2.29$ ;  $F(1,616)=4.112$ ,  $p=0.043$ ), but this was not the case for participants watching in a group ( $M_{\text{live}}=3.16$ ,  $M_{\text{pre}}=3.36$ ;  $F(1,616)=1.29$ ,  $p=0.26$ ). Similar results emerged for enjoyment: participants who watched the video solo enjoyed it more when it was live ( $M_{\text{live}}=4.75$ ) than when it was prerecorded ( $M_{\text{pre}}=4.37$ ;  $F(1,616)=4.71$ ,  $p=0.03$ ), but this was not the case for participants watching in a group ( $M_{\text{live}}=4.65$ ,  $M_{\text{pre}}=4.52$ ,  $F(1,616)=0.49$ ,  $p=0.48$ ).

In sum, we find that above and beyond indeterminacy, greater enjoyment from live streaming (vs. prerecorded) content is driven by social connection and a sense of shared experience. Given the increasing popularity of social streaming platforms and advertising through micro-influencers on social media, our findings have important implications for consumers and marketers alike.

### Signaling Fun: Anticipated Sharing Leads to Hedonic Choice Short Abstract

#### EXTENDED ABSTRACT

Prior research demonstrates that the presence of others impacts consumers' choices to assimilate an accompanying other's preferences, choices, and attitudes, resulting in congruency (Dzhogleva and Lambertson 2014; Lowe and Haws 2014; Mead et al. 2010; Ramanathan and McGill 2006). However, prior work is relatively scant on how the presence of others might systematically shift the direction of consumers' choices, controlling for the other person's preferences. Specifically, we investigate how anticipating that others will observe one's choices (i.e., anticipated sharing) impacts hedonic choice.

We propose that when making a public (vs. private) decision, consumers' choice for hedonic (vs. utilitarian) options increases, as a result of signaling efforts. When consumers are physically accompanied by a friend, they anticipate their consumption choices to be observed by the friend. In such public decisions, consumers employ hedonic choices to communicate positive information about themselves, such as they are having a good time and a fun-loving person. Moreover, with the recent advances in social media and smartphones, consumers can easily choose to make consumption decisions public by sharing it on social media, even if they are physically alone. We demonstrate that anticipating one's choice to become visible to social media friends (i.e., public decision) increases he-

donic choice, consistent with the effects of sharing through physical accompaniment. In addition, while hedonic choices have signaling values, choosing hedonic options often come at a personal cost (e.g., less preferred options). Thus, when the consumer is less motivated to signal positive impressions, such as when the target audience is a stranger or someone the consumer does not wish to pursue a relationship with, the effects are mitigated.

Study 1 tested the main hypothesis that in the presence of a friend, consumers make hedonic (vs. utilitarian) choices. In a 3-cell (condition: Alone vs. Friend-Public vs. Friend-Private) design, participants ( $N=233$ ) chose to redeem either a mint chocolate cookie (i.e., hedonic) or a granola bar (i.e., utilitarian). In a lab setting, participants either made the choice alone or in the presence of a partner with whom they had just completed a relationship induction task. Participants in the "Friend-Public" (vs. "Friend-Private") condition were told that they would receive their chosen snack in a transparent plastic (vs. brown paper) bag. Despite a pretest confirming that students personally prefer granola bars, 63% of students in the "Friend-Public" condition chose the cookie, while only 47.2% in "Alone" condition chose the cookie ( $p = .052$ ). "Friend-Private" condition fell in the middle. Follow-up analysis revealed that many in the "Friend-Private" condition voluntarily disclosed their snack choices to their friend, contaminating the manipulation, but suggesting the strength of consumers' signaling motives.

Study 2 again employed real choice as the main dependent measure, but instead of making a trade-off between hedonic versus utilitarian options, participants ( $N=172$ ) were faced with the choice of either redeeming or foregoing a free mint fudge cookie (i.e., hedonic choice). A 3-cell (condition: Alone vs. Friend vs. Stranger) design was used to test if closeness between the consumer and the other person moderates the effects. Participants in the "Friend" condition went through a relationship induction task with the person next to them, whereas the "Stranger" condition participants did not. Participants in the "Friend" condition chose to redeem a cookie significantly more than those in the "Alone" condition ( $p = .049$ ). Hedonic choice in the "Stranger" condition was marginally lower than in the "Friend" condition ( $p = .067$ ), and did not differ from the "Alone" condition ( $NS$ ). Furthermore, we find consistent patterns for how much of the cookie participants actually consumed.

In Study 3, we tested the prediction that the presence of an accompanying friend and virtual friends on social media both lead to hedonic choice. Participants were asked to imagine going shopping either alone ("Alone" and "Social Media" conditions) or with a friend ("Accompanied" condition) and whether they would choose to order ice cream during the shopping outing. Prior to considering the shopping scenario, participants in the "Social Media" condition recalled their most recent post on social media. Results ( $N=268$ , mTurk workers) confirmed that both the "Accompanied" condition and "Social Media" condition significantly increase the likelihood of ordering ice-cream, compared to the "Alone" condition ( $p = .050$  and  $p = .043$ , respectively). This effect was mediated by their signaling motives (i.e., desire to signal to others that they were having a good time; 95% CI: [.0310, .2512]).

Study 4 employed a more direct manipulation of anticipation of sharing one's choices on social media. In a 2-cell (condition: Control vs. Social Media) design, participants ( $N=391$ , mTurk workers) were presented with four retailers (i.e., two hedonic and two utilitarian) and asked to imagine choosing a retailer to receive a \$10 gift card from. Those in the "Social Media" condition were further asked to imagine uploading a photo of what they would buy with the gift card on a social media account of their choice. Choice results supported that anticipating one's choices becoming public to friends (on social

media) significantly increases hedonic (vs. utilitarian) choices ( $p = .030$ ). This pattern was again mediated by signaling motives (95% CI: [.0754, .3872]).

Study 5 directly manipulated consumers' signaling motives by asking participants ( $N=209$ , undergraduate students) to imagine that they were either on a "Good date," "Bad date" or a date without further information ("Control" condition). Participants were asked to indicate whether they would choose to walk with their date back to the car following a scenic route or a less scenic route (both taking the same amount of time to walk). As expected, participants in the "Good date" condition chose the more hedonic road significantly more than those in the "Bad date" condition ( $p = .024$ ), while the "Control" condition fell in the middle.

Taken together, our results show that anticipated sharing leads consumers to choose hedonic (vs. utilitarian) options, due to signaling motives. We further demonstrate that such effects of public decision expand beyond physical accompaniment. As consumers can easily make consumption decisions public via social media sharing, our results have important implications for consumer welfare and shared consumption.

## **Paper #4: Portals of Transformation In Consumer Experiences**

Linda L Price, University of Oregon, USA

Basil Arnould Price, York University, UK

### **SESSION OVERVIEW**

Self-transformation and life transitions constitute an important area of consumer research. Recently scholars have argued for a need to re-examine the nature of self-transformation and transitions in late modernity (Bardhi and Eckhardt 2017; Price et al 2017) as well as the theoretical lenses applied (Mimoun and Bardhi 2017; Sherry 2005). This session aims to examine several understudied aspects of self-transformations and life transitions, including the experience of multiple and purposeful self-transformations (first paper), the experience of liminality by relational partners (second paper) and the role of community and social media in transformation (third paper), as well as the dark side of transformations (all papers). Further, the session introducing new theoretical perspectives to examine self-transformation, such as that of portal theory anchored in literary fantasy and mythology (Campbell 2010; Mendlesohn 2008) (fourth paper). The session also extends the research on another important concept in this domain, consumer liminality through a) the notion of permanent liminality, b) relational liminality, and c) the portal. All papers articulate the role of brands, objects, consumption practices, and social networks in self-transformation and deploy a variety of interpretivist methodologies. The session examines consumer self-transformation in contemporary consumer society in three different cultural contexts: US, Brazil and France.

The session is comprised of four papers. The first paper examines the experience of being in permanently liminal among precarious professionals in Paris. Drawing on in-depth interviews and participant observations, the study examines the strategic pursued of flexibility as a new form of capital in global cities via variety seeking consumption and perpetual transitions. The second paper, examines how mothers of teenage daughters experience the liminal transition to adulthood in affluent Brazilian and American middle class families. They show that relational partners also go through a liminal transition where they institutionalize consumption rituals and communities to manage it. The third paper examines the transformation of consumer collectors as they are incessantly working to update their collections. Collectors change themselves and their collections to constantly provide novel content to their social media followers, and to make themselves more attractive to the brand as worthy influ-

encers. This study examines the dark side of ‘trying to keep up’ the influencer position online among collectors of the plastic shoe brand Melissa. The fourth paper introduces a new theoretical approach to examine self-transformation, portal theory that illuminates the practices involves around transformation as well as highlights the dark side of such transitions. It highlights the properties and requirements of portals and the consequences of passage between the ordinary and the magical realm to delve into consumer experiences of liminality and transformation in liquid modernity.

The authors examine the experience of transformation and transition documenting the fractures that returning through the portal causes and practices players enact to cope with these fractures. We anticipate broad interest in the session from scholars interested in consumer journeys of transformation, identity transitions, liminality, variety seeking, collections, motherhood, family identity, rituals, literary fantasy, and life transitions.

### **Permanent Liminality in Flexible Consumer Lifestyles**

#### **EXTENDED ABSTRACT**

Scholars argue that consumers must and are embracing adaptability and change to manage the demands of liquid modernity (Bardhi and Eckhardt 2017), where social structures are increasingly unstable and continuously evolving (Bauman 2000, 2007). Flexibility and adaptability have been important currencies historically and have mainly been included in a cosmopolitan travel ideology (cf., Thompson and Tambyah 1999). However, in liquid modernity, flexibility has become a currency and skill in all aspects of life (Bardhi, Eckhardt, and Arnould 2012; Weinberger, Zavisca, and Silva 2017). This has resulted in the emergence of the flexible consumer lifestyle, which we define as purposefully embracing instability, change, and adaptability in every aspect of life through professional precariousness (Gill and Pratt 2008). When following the flexible consumer lifestyle, work and life blur. Work becomes the space of self-development, social connection, and consumption. The flexible consumer lifestyle is also associated with a very reflexive project of the self and prioritizes variety, unpredictability, and change in consumption.

Consumers adopting a flexible lifestyle may occupy a space of permanent liminality, which refers to a social space “when a temporary suspension of the normal, everyday, taken-for-granted state of affairs becomes permanent” (Szokolczai 2009, 233). Indeed, flexible workers, who experience professional precariousness (Gill and Pratt 2008), are presented as permanently liminal as they dwell on the interstices between organizations and are undergoing many, frequent life transitions of various degrees and lengths (e.g., Garsten 1999; Ybema, Beech, and Ellis 2011). Permanent liminality is traditionally considered as a negative, macro-level perspective to characterize contemporary society (Szokolczai 2000; Thomassen 2014). Nonetheless, organization scholars apply it at the individual-level to characterize flexible work as a space of permanent liminality. In this context, permanent liminality is conceived as positive, and even empowering, under proper conditions (e.g., Czarniawska and Mazza 2003; Sturdy, Schwarz, and Spicer 2006; Ybema, et al. 2011). Because permanent liminality questions a fundamental assumption of liminality, that of its temporariness, whether and how occupying such social space is sustainable calls for further illumination.

We use a qualitative approach, combining in-depth interviews with 16 flexible consumers—characterized by both professional precariousness (i.e., contingent, casual, informal, and contractual work) and contingent accommodation conditions (e.g., flat-sharing, short- and medium-term renting, co-living, etc.)—, projective techniques, and participant observation in collaborative workplaces. We explore whether the flexible consumer lifestyle can generate a social space of permanent liminality, how to characterize the experience of consumers pursuing such lifestyle, and how this experience is managed in the marketplace. Our sample includes an equal number of male and female independent workers, aged 28 to 44, earning yearly between €10,000 and €48,000, and residing in Paris, a global city.

First, we unpack consumers' performance of the aspiration to flexibility. Our informants use extreme variety seeking and consumption routines' disruption as a key to enter an out-of-ordinary reality. They actively unsettle the everyday (e.g., breakfast routines, commute, daily cosmetic rituals, etc.) and work-related projects. They also proactively pursue the (re)discovery of novel food, music, and challenging experiences. Furthermore, our informants continuously attempt to demonstrate their lack of attachment to solid objects and brands. In doing so, they endeavor to weaken their connection to social structure and to facilitate their many micro-level moves, for example as they constantly change working and living spaces. Through these intensifying consumption performances, consumers move in and out of the everyday structure and develop resilient optimism and holistic thinking. These two skills are necessary to be comfortable in, and benefit from, the uncertainties, risks, and surprises of a flexible lifestyle.

Aspiring to flexibility requires a constant change and renewal of behavior, a detachment from material anchors and from status/role symbols, and the freedom to act outside of mainstream rules. This is reflected in permanent liminality, a constant cycle of transitioning within which one remains relieved from everyday life and ordinary social constraints. Flexible consumers strive to be enduringly liminal and use intensifying consumption performances to separate from their anchors in the structure (i.e., appearances, roles, and statuses). However, permanent liminality seems to be unsustainable over time as consumers are faced with external and internal forces pulling them toward the structure.

Under these pressures, our informants frequently transgress the performance template of permanent liminality, which entails constant in-betweenness, out-of-the-ordinariness, and transitioning. They are drawn into the structure as they enact transgressive consumption performances. First, they delineate breathing spaces, like transforming a closet into a private nest, to rest and recharge. Second, they restore boundaries by deploying objects and activities symbolizing belonging to specified categories, like a start-upper attempting to have her right to off-time acknowledged by purchasing a desk marking her workspace in her living-room. Finally, they fasten anchors, consisting of emotionally-charged places and objects, which can be reused or revisited to find one's way back to the structure. For instance, a mid-thirties freelancer keeps her bulky first adult bed as a transitional object, despite several international moves.

With this study, we contribute to consumer research on liminality by further theorizing permanent liminality at the individual-level. We depart from prior literature, primarily in organization studies, and support that permanent liminality cannot be sustained, even in liquid modernity. We advance that permanent liminality is unsustainable because individuals need a release from the pressures of its overwhelming pursuit. To preserve their wellbeing, flexible consumers transgress permanent liminality's required performances. Narrative strategies are deployed to cope with, and minimize, these trans-

gressions. Nonetheless, we evidence how permanent liminality as an aspirational lifestyle is bolstered by a marketplace ideology of flexibility and governs consumption practices.

## **Liminal Motherhood: Relational Partners Experience of Liminality**

### **EXTENDED ABSTRACT**

Liminality has been increasingly used in consumer research area to investigate the role of consumption in identity project formation, during periods of transition between two recognized sociocultural spaces. Schouten (1991) pioneered the theory's application in consumer research, studying American women who had cosmetic plastic surgery. Recently, Cody (2012) studied how Irish tweens girls, those aged eight to twelve years old, mediate identity transition through consumption. Drenten (2013) explored symbolic consumption of American adolescent girls going through coming of age process. Also, Cappellini and Ai-wan Yen (2016) investigated Taiwanese women living in the UK, highlighting how collective consumption practices may exacerbate negative feelings of ambiguity, perpetuating liminality. Nevertheless, the effects of socio-structural liminality, the social and structural invisibility experienced by those going through a recognized life transition (Turner, 1974), on those individuals emotionally involved in this change process were not studied. We fill this gap by researching mothers of tweens girls, and proposing that liminality may be comprehended as a physical and emotional state experienced by both the individual who goes through the socio-structural change and those emotionally involved in the process.

For over two years, we conducted a phenomenological research and hermeneutical data analysis (Thompson, 1997). Twenty non-structured in-depth interviews were conducted with mothers of tween girls, ten in Brazil and ten in the USA. Also, three Brazilian mothers participated in a second interview with the support of images. Besides, observation, mostly participatory, was conducted and registered in a field diary. Furthermore, one of the researchers, the mother of a tween, recorded her impressions in a second introspective diary. Both diaries contributed to achieving reflexivity within the study, broadening the scope of the phenomenon and complementing other studies (Wallendorf & Brucks 1993).

Guilt, self-charging, and concern with errors and hits are evident in the mothers' narratives. These feelings may occur in other phases of motherhood but in this transition, they are more pronounced, especially in the case of mothers who pursue a professional career. Contrary to previous historical periods, the maternal value is characterized as natural and social, establishing a pattern of conduct for women, imposing motherhood as an obligation, and constituting the myth of the maternal instinct (Badinter, 1985). This mother role model challenges those women who feel they do not play it to their fullest or feel pressured by conflicting social expectations of contemporaneity (Badinter, 1985; Thompson, 1996). Thompson (1996) highlights the challenges of working mothers who see themselves as jugglers trying to balance the various demands of their lives; consequently, they want products and services that facilitate balancing their life projects. However, as the market does not recognize tweens as a concrete space, the conflicts of this motherhood phase also do not exist; therefore, these mothers lack market support resources.

We identify two aspects of the way mothers experience their daughters liminal transition. First, they experience feelings of uncertainty and even self-loss, when not perceiving themselves as a mother of a child anymore. Second, they agonize over experiencing their daughters' growing pains, or transitional suffering; mothers

concern about girls' sense of belonging, finding their social group, or *communitas* (Turner, 1974). This is most evident in the narrative of mothers whose daughters experienced some problem of adjustment in the group, or difficulty in coping with body changes. That is, mothers suffer from both their mother-role transition and the difficulty that daughters experience during the transition from childhood to adolescence.

Considering that other people may be part of the individuals' extended self (Belk, 1988), mothers' identity, or how they see themselves, is intimately related to their daughters' identities. Thus, daughters are not part of the mothers' extended self only as an object to entertain them, or a means to achieve an ideal aspirational self (Kimura & Sakashita, 2013), but rather as a significant part of who they truly are. And this transition, characterized by the distancing of the mother, can be very painful, since it's as if mothers were losing a piece of their self.

Consumption that could play a role in facilitating the transition from childhood to adolescence has a limited role, due to the lack of market's options. Thus, not only are girls in a liminal space, but also their mothers, who do not have support mechanisms to cope with these changes. Therefore, perhaps to mitigate this sense of uncertainty, or to fill the void of rites of passage in contemporaneity, mothers create their own rituals of initiation (Van Gennep, 1978). So, consumer rituals fill the gap of the old rites of passage, representing mothers' individual mechanisms to re-establish the social order of their family unit, during the transition. Rituals represent a mechanism to reinforce the shared identity of the mother-daughter family group (Epp & Price, 2008).

Though data collected in both countries reinforced each other, narratives of US resident mothers also introduced evidence of a previously unexplored phenomenon. A liminal identity trace results from the intense mobility of individuals between countries and the actual American society configuration, an apparent melting pot of diverse cultures, which not necessarily completely merged (Jacoby, 2004). To mediate the tension of balancing values of distinct cultural heritages, while maintaining a sense of their cultural roots, mothers, though recognizing the girls' American reality, weave a particular narrative of proper conduct, education, and consumption patterns toward girls. Mothers produce a bricolage, building their social identity from the different cultural resources available to them, appropriating the symbols that suit them, often recreating them (Russell & Tyler, 2005).

Finally, just like girls do, mothers also seek the help of their *communitas*, other mothers facing the same dilemmas. Moreover, technology features as a tool enabling the interaction and full participation within the *communitas*. Also, amplifying this circle of relationship through social networks; though often weakening the institutional central role formerly exercised by the school.

We contribute to broadening the understanding of liminality as a threaded phenomenon, experienced simultaneously and differently by emotionally intertwined individuals. An experience mediated by symbolic consumption, even though market, generally, disregards it.

### **Walking the Thin Edge: The Dark Side of Brand Communities and Collecting**

#### **EXTENDED ABSTRACT**

Fans are often avid collectors (Fiske, 1992). Moved by passion and enthusiasm, they actively, selectively, and passionately collect objects (Belk, Wallendorf, Sherry, and Holbrook, 1991) that materialize their affection, such as for fictional characters, celebrities, movies and television shows, sporting activities, players, and teams.

Consumers can also become devoted to products and brands (e.g., Nutella and Apple), collecting merchandise and paraphernalia. An important aspect of fandom is social interaction (Schau, Muñiz & Arnold 2009; Oliver 1999). As such, online platforms play a pivotal role in supporting and disseminating information amongst fans within online communities where collections and collectable objects are hot topics.

Our review of the existing consumer behavior literature shows that although a general theory of collecting have been developed in the field (Belk 1982, 1994, 1995a, 1995b, 2014; Belk, Wallendorf, Sherry, Holbrook and Roberts, 1988; Belk et al. 1991), there are surprisingly few subsequent studies that have explored consumer collecting of products or brands (Baker and Gentry, 1996; Hughes and Hogg, 2006; Long and Schiffman, 1997; Martin and Baker, 1996; Slater, 2000, 2001). A recent interdisciplinary stream of research has shown that digital technologies have transformed the curatorial practices of collectors in extreme ways; often facilitating, but also complicating the acquisition, curation, and exhibition of collectable objects (Watkins, Sellen, and Lindley, 2015). For example, Scaraboto, Ferreira and Chung (2016) found that as collectors and their audiences jointly interpret and shape the meaning of collections online, conflicts can arise particularly due to consumers' high levels of involvement and emotional attachment to the brand and products.

Personal collections also serve to shape the self-definitions of collectors (Belk et al., 1988). For example, clothes, shoes, and accessories offer material support to consumers' identity narratives (Ahuvia, 2005; Belk 1988; Thompson and Haytko, 1997). Recent studies show that online communities promote deeper engagement with products and brands; therefore, encouraging collective self-transformations (Scaraboto and Fischer, 2012; Ferreira and Scaraboto, 2016). As branded clothes, shoes, and accessories are typically seasonal products that are issued iteratively, they invite "consumers to pay renewed attention when a next installment of the brand is released" (Parmentier and Fischer 2014, 1228). Hence, they work as "serial brands", leading "consumers to expect that there will be something new to pay attention to" (Parmentier and Fischer 2014, 1228). This encourages endless interactions among serial brands' collectors within online communities, with each new installment and every product release.

The longer term consequences of such endless pursuit of collectable objects and efforts to sustain their collective sense of identity remains under researched. Furthermore, there are also recent calls for research to explore the "fine line" that exists when consumers become "fanatical" about a product or brand; where they experience both positive and negative outcomes as a result of their "extraordinary pursuit of a consumption object" (Chung, et al, 2018, 17). Chung et al. (2018, 21) also suggest investigating the structures and dynamics of fanaticism that is driven and perpetuated by collectives. This study addresses this by focusing on a community centered around the plastic shoe brand, *Melissa*. Based on netnographic and ethnographic data collected over four years, we examine the thin edge (or the fine line) walked by *Melissa* fans and collectors (self-labelled '*Melisseiras*'), several of which have become brand influencers on social media.

While consumers can experience rewarding benefits of being *Melisseiras* (e.g., the 'feel good' factor associated with having many followers), they can also easily fall into a trap when their fascination over the plastic shoes lead them to deepen their engagement with the brand and brand community. *Melisseiras* who wish to maintain her status as collector and influencer need to continue adding items to their collections; updating their knowledge of *Melissa*, and produc-

ing brand-related content to share on social media platforms; all of which demands much effort that can become burdensome.

As a serial brand (Parmentier and Fischer, 2014), Melissa re-signifies the completeness of collections and the required knowledge of its items when introducing new collections and product extensions (e.g. bags), which could be as often as every two months. Consumers' collection and knowledge therefore become outdated quickly, and they may experience challenges trying to catch up and/or reinventing themselves in order to remain relevant to their followers, and develop/preserve their relationship with the brand.

While many Melisseiras' posts capture fantasy-like Melissa collections, Melissa-themed birthday parties, wedding proposals at Melissa retail stores, and visits to Disneyland in Melissa shoes and accessories, which may be the envy of many girls, a Melisseira cannot stop buying, collecting, or wearing her Melissa shoes. For many Melisseiras who are of working-class background, Melissa shoes can be considered expensive; they must make significant sacrifices in order to keep adding items to their collections, store the items, and produce content that is visually attractive and suggestive of an inspirational lifestyle. A Melisseira therefore walks along a thin edge in terms of balancing both positive and negative outcomes associated with their intense pursuit of Melissa shoes (and maintenance of their Melisseira/influencer status).

Our findings suggest that brands can allure consumers to keep on consuming by acknowledging them as collectors and granting them status as influencers. Melisseiras invest heavily to attract the brand's attention, and when they finally receive it, many continue developing their collection and their influence to preserve the relationship with the brand. Our findings also highlight the ambivalent role of social media and acquired audiences (McQuarrie, Miller and Phillips, 2012) – while Melisseiras can achieve "Instafame" (Marwick, 2015) via social media; they also expose themselves to audience members that have the ability to cast (sometimes negative and hurtful) judgment on them and/or their posts.

Our study of consumers as collectors from a dynamic and integrative perspective, exposes the dark side to brand community and collecting; providing fresh insights that contribute to our understanding of collectors and their pathways towards becoming (or ceasing to be) devoted collectors. This could in turn help brands develop tools to better relate to its most loyal consumers.

## Portals of Transformation In Consumer Experiences

### EXTENDED ABSTRACT

We examine portals drawing on theory from literary fantasy and mythology to motivate new understandings of contemporary consumer behavior. Although passages between worlds are a ubiquitous part of the postmodern consumer experience (Thomassen 2014), their characteristics have escaped much formal theoretical attention in consumer research. With few exceptions, portals, if discussed at all, are examined as interfaces between corporeal and online environments, with an emphasis on making them seamless and user friendly. Accessing a space beyond the everyday has captured the imagination for centuries. Fascination with alternative worlds and universes continues to present day—and customer experience places—real or virtual—offer a new frontier for innovative companies (Gilmore and Pine 2002). Marketing examples abound that use porters and portals to convey consumers' transportation into a magical realm. For example Disney uses fantasy portals in parks to allow time to transition from the real (unhappy) world to a magical one, and in a recent advertising campaign Toyota reimagines fairytales with the new C-HR crossover playing the role of porter between

the ordinary world and a magical realm. Portals in cathedrals, retail servicescapes, and virtual environments signal a change of roles and rules not dissimilar from passages represented in literary fiction such as Narnia's wardrobe, station 9 ½ in Harry Potter and the forest in numerous fairytales. Nevertheless, the use and limitations of the portal device as an allurement into a magical consumer realm has received little systematic attention. In particular, the consumer experience rarely addresses what must be given up. In order to access these experiences, the consumer pays a price. Drawing on literary theory, we posit that different configurations of portal experiences have critical implications for consumers' transformation experiences.

Our paper outlines the properties and requirements of portals drawing on literary fantasy and mythology. We focus on a close examination of how portals are integrated into contemporary consumer culture with the purpose of uncovering new insights into consumer transformation. A passage is "at its heart" "a displacement, a process of transformation undertaken, but not yet finished," (Thomassen 2014, 13). The portal is conventionally understood as a door or gateway between worlds, but scholars argue it is far more. As evident in many folk tales, the portal signifies a nexus point of magical agency where one world engages another and myriad power associations, imbalances, and liminality negotiate and interplay (Campbell 2010). Understanding portals consists of unpacking two parts: first, the means of accessing it—the portal key; and second, the physical, emotional and often transmutating experience that demarcates the two separate realms—the ordinary world and the "other" magical realm. An expansive definition of a portal key includes any person, place or thing that can act as an agent for the consumer to travel between worlds—literally or symbolically carving out a space through which the protagonist enters the other world (Campbell 2010). The portal key may be an object such as a product or brand that inspires transformation, or creation of a portal so that the consumer can access an alternative reality that holds the promise of a more meaningful rich life (Mendlesohn 2008). Consumers themselves can be their own portal key into an alternative realm—their own porters and guides. In consumer culture the individual draws on market resources to engage the transformation, although as Baudrillard argues rather than enveloping the imaginary, as the product of synthesis, it may spiral into simulacrum (1994).

The experience on the other side of the portal, while it may hold the promise of a better world or a higher plane of consciousness, is still liminal and exacts a price from its protagonist. Transmutation is a consequence of movement through the portal, both in passage into the magical realm and, when possible, passage back. Transmutation is the voluntary or involuntary rejection of bodily safety, sanctity and health in order to ascend (descend) to a "greater" stage of experience. Questing this "greater" stage of experience, consumers may be swept up into magical realms that hold them in their grip and exact a formidable price. Gambling, video gaming, virtual reality, wilderness adventures and numerous other consumer passages between realms might be better understood using portal theory. Many fairytales represent the way in which portals exact a price. For example, in the Hans Christian Anderson story, the Little Mermaid first ascends from the ocean to the mortal realm through transmutation of her tail and voice and then gives up her physical body and moves upward to become a daughter of the air. We illustrate how the transmutation device as a means to access the portal is relevant to consumer experience in a postmodern world. It is through transmutation that the consumers' imagined fairy realm on the other side of the portal reveals itself to be unsatisfactory. Tolkien defines the fairy world as the perilous realm, not only because of the monsters that dwell therein, but also because of the fairy world's seductive

and ultimately destructive power (1947). We illustrate how a deeper understanding of portals, including the physical and psychological anxiety or pain of passage that is intensified by prolonged exposure to the fairy realm has rich implications for consumers' contemporary experiences of longing, liminality and transmutation in their consumer journeys.

### SESSION OVERVIEW

Experiential consumption has become an integral part of the market economy (Pine and Gilmore 2011), with consumers spending an increasing percentage of their incomes on restaurants, travel, and leisure (Quittner 2016). Extensive research has shown that this shift may be beneficial to consumers, as experiences bring people greater happiness and well-being than material goods (e.g., Dunn, Gilbert, and Wilson 2011; Gilovich and Kumar 2015; Nicolao, Irwin, and Goodman 2009; Van Boven and Gilovich 2003). However, not all experiences are created equal. Only recently has some work started to explore how consumers may evaluate their experiences more or less favorably depending on certain behaviors and mental processes that occur before, during, and after the experience (e.g., Barasch, Zauberaman, and Diehl 2018; Tully and Meyvis 2016; Yang, Gu, and Galak 2017).

In the current session, we contribute to this growing stream of research by uncovering new perceptual, cognitive, and affective factors that can enhance, or sometimes diminish, the very same experience. In particular, we examine: *How do memories, perceptions, and expectations shape evaluations of consumption experiences in a positive (vs. negative) direction?*

**Ibrahim, Häubl, and Waisman** examine how the act of rating consumption experiences influences consumers' retrospective evaluation of those experiences. They find that rating a consumption experience, compared to not rating it, leads to polarization of evaluations (i.e., positive experiences become more positive, negative experiences become more negative). Four longitudinal studies support a memory account of this polarizing effect.

**Tully, Cheema, Amir, and Proserpio** investigate the impact of eliciting different reference points on evaluations of experiences. Through a variety of lab experiments, extensive field studies, and

analysis of online reviews, they demonstrate how making expectations salient reduces consumers' likelihood of recommending experiences by shifting their focus to external, less emotional components of the experience.

**Munz and Barasch** examine consumers' preference for uncertainty resolution in experiences and its impact on subsequent appraisal of those experiences. Across four studies using real games, they observe that consumers prefer to resolve their uncertainty later (vs. earlier) in the experience when the outcome of experience is negative (vs. positive). But interestingly, after having the experience they prefer to resolve their uncertainty earlier, regardless of the outcome.

Finally, **Oh, Goodman, and Choi** study the bi-directional relationship between happiness and experiential purchases. Across four studies, they demonstrate that happy people tend to think more abstractly (vs. concretely) and as a consequence, view their purchases as more experiential and less material. They discuss the implications of experiential framing of purchases as a way to enhance consumers' subjective well-being over time.

Together, these papers highlight the diverse factors that can shape consumers' enjoyment of these experiences. Given the widespread interest and applicability of experiential consumption, we expect this session to have wide appeal and attract researchers interested in experiential versus material consumption, word-of-mouth, judgment and decision making, memory, and happiness/well-being. All four papers use a diverse set of approaches in studying this topic, which we believe will generate a lively and fruitful discussion.

## **Good Gets Better, Bad Gets Worse: The Polarizing Effect of Rating a Consumption Experience**

### EXTENDED ABSTRACT

Whether having just checked out of a hotel, left a restaurant, or made an online purchase, it is increasingly common for consumers to immediately rate their consumption experiences. With the growing popularity of net-promotor scores (Reichheld 2003), firms use this feedback to monitor quality, identify loyal customers, and display ratings on social media. As useful as this feedback is to firms, we know little about how giving this feedback impacts consumers.

We propose that responding to these surveys (i.e., act of rating) provides consumers with additional information about their consumption experiences. Just like the consumption experience itself, the rating experience is stored in memory and can influence future cognitions and behaviors. Prior literature suggests the affective dimensions of a consumption experience strongly influence consumers' evaluations (Mano and Oliver 1993). But over time, memory for an experience can be distorted (Cowley 2007; Murphy and Balzer 1986). In this paper, we specifically investigate how memory for rating a consumption experience interacts with memory for the focal experience to influence consumers' subsequent evaluation of that experience.

We consider two competing theoretical frameworks to derive predictions about how the act of immediately rating a consumption experience changes retrospective evaluation.

Exemplar models of memory (e.g., Hintzman 1984) suggest that rating an experience will always influence subsequent evaluation of

that experience to some degree. According to exemplar models, each experience is stored as a memory trace. Each trace contributes to a retrieved memory in proportion to its activation by a cue (i.e., being asked “How much did you enjoy the experience?”). As the interference from other memory traces increases, the retrieved memory is influenced less by the affective dimensions of the memory trace for the focal experience. Therefore, *ceteris paribus*, the greater the time intervening between experience and evaluation, the lower the affective intensity of the evaluation. But, when one of the interfering traces is itself an evaluation of the experience (the earlier rating) it adds to the affective intensity of the retrieved memory, attenuating the overall loss of intensity.

In contrast, the accessibility-diagnostics framework (Feldman and Lynch 1988) suggests that consumers’ evaluation of an experience is influenced by an earlier rating only when memory for that rating is the most accessible diagnostic memory. It is an all-or-nothing account that has been adopted to explain mere measurement effects (e.g., Chandon, Morwitz, and Reinartz 2004; Morwitz, Johnson, and Schmittlein 1993) and memory distortion in consumption experiences (Cowley 2007).

When little time intervenes between experience and retrospective evaluation, these frameworks suggest different processes leading to negligible effects. The accessibility-diagnostics framework (Feldman and Lynch 1988) suggests both immediate and retrospective evaluations are based on memory for the focal experience and thus, memory for rating will not influence retrospective evaluation. The exemplar memory account suggests memory for rating will compensate for some loss of affective intensity, leading to slightly greater affective intensity in retrospective evaluation compared to when a rating has not been previously solicited.

However, with more intervening time, both frameworks predict the effect of rating an experience (vs. not rating it) is to polarize retrospective evaluation. A positive (negative) consumption experience should be evaluated more positively (negatively) when it has been previously rated. Critically, these two theoretical perspectives suggest widely different causes and magnitudes for this polarization.

The accessibility-diagnostics framework (Feldman and Lynch 1988) suggests the retrospective evaluation will be based on the more accessible memory for the earlier rating. Immediate rating and subsequent evaluation should be consistent, so no loss in affective intensity is expected. Contrarily, an exemplar memory account suggests the influence of memory for rating only partly attenuates a drop in affective intensity over time. The longer the interval, the greater the drop in intensity, and the more evident the influence of the earlier rating in attenuating this effect.

We test these competing theoretical accounts in four longitudinal studies ( $N=1995$ ). Our findings support the exemplar memory account. We observe a polarizing effect of rating a consumption experience that increases in magnitude over time. In study 1, participants in a 2(Experience: positive vs. negative)  $\times$  3(Time 1 Rating: emoticon scale vs. slider scale vs. no-rating control) design used a 100-point slider scale to rate their enjoyment of a video seven days after watching it. Participants in the rating conditions also rated their enjoyment immediately after watching the video. Comparison of immediate ratings in the slider scale condition ( $M_{Time1-positive}=83.61$ ,  $M_{Time1-negative}=33.04$ ) to the ratings seven days later in the no-rating control condition ( $M_{Time2-positive}=69.12$ ,  $M_{Time2-negative}=52.61$ ) confirmed substantial reduction of affective intensity over time.

Contrary to the accessibility-diagnostics account, when participants rated the video immediately, their later enjoyment ratings also reflected less enjoyment. But, consistent with the exemplar memory account, a significant two-way interaction indicated polar-

ization compared to the no-rating control condition ( $p=.011$ ). Participants who previously rated the positively valenced video reported directionally greater enjoyment ( $M_{rating-positive}=71.64$ ) than those who had not previously rated it ( $M_{control-positive}=69.12$ ,  $p=.21$ ). The opposite occurred when participants watched the negatively valenced video: Participants who had previously rated the video reported enjoying the video significantly less ( $M_{rating-negative}=46.41$ ) than those in the control condition ( $M_{control-negative}=52.61$ ,  $p=.026$ ).

We also investigated the polarizing effect of rating the positively valenced video over seven-day (study 2a), three-day (2b), and one-day (2c) intervals. Consistent with the exemplar memory account, after seven days participants reported having enjoyed the video more if they had also rated it immediately ( $M_{rating}=78.83$ ) as compared to control ( $M_{control}=71.97$ ,  $p=.015$ ). The same pattern of means emerged after three days, but with only a marginally significant difference ( $p=.092$ ). After one day we found no difference across conditions ( $p=.646$ ).

Our findings demonstrate that, consistent with an exemplar memory account, rating a consumption experience changes consumers’ retrospective evaluation of that experience by attenuating the loss of affective intensity. The result is a polarization effect that improves retrospective evaluation of positive consumption experiences while making negative experiences feel even more negative. Because consumers are inundated with opportunities to rate their consumption experiences, these findings have important implications for when marketers can benefit from soliciting immediate feedback from consumers.

### My Experience or My Expectations: The Effect of Expectations as Reference Points on Willingness to Recommend Experiential Purchases

#### EXTENDED ABSTRACT

Consumers’ willingness to recommend their purchases is critical for businesses, with word-of-mouth being consistently rated as the most credible and trustworthy form of marketing (e.g., Nielsen 2015). However, research that speaks to the reason consumers decide to engage in word-of-mouth is still relatively nascent. In this work, we add to word-of-mouth literature by investigating whether the reference points against which experiential purchases are compared systematically influence willingness to recommend experiences.

We find that when consumers use expectations as reference points, it reduces their likelihood of recommending experiential purchases to others. Moreover, we demonstrate how and why this effect occurs. An experiential purchase consists of what is offered to a consumer (e.g., a movie, theater seats) and what is experienced by the consumer (e.g., enjoyment, comfort). When evaluating an experiential purchase, we suggest that people typically introspect and consider what they experienced (e.g., their emotional reactions). However, making expectations salient shifts their focus to the more external components of the offering. For instance, in the case of going to the movies, rather than considering one’s enjoyment, expectations shift focus towards external factors such as the plot quality, which is less emotional in nature. As existing research shows that word-of-mouth is greater when content is emotional (Berger 2014), this shift in focus results in a decreased willingness to recommend experiences.

In study 1, customers at a pub were asked to fill out a short customer survey as they paid for their meal. The survey varied whether customers considered their expectations or their experience at the restaurant prior to indicating their likelihood of recommending the restaurant to others. Participants in the expectations condition were

less likely to recommend the restaurant than were participants in the control condition,  $F(1, 246) = 4.03, p = .046$ .

In study 2, we replicated this effect with willingness to recommend college courses. In this study, we compared the effect of expectations to another plausibly high reference point: people's goals. Participants either reflected on their goals or expectations for the first college course they had taken before indicating their likelihood of recommending the course to a friend. Replicating study 1, participants considering their expectations were less likely to recommend the course compared to participants considering their goals,  $F(1, 375) = 7.84, p = .005$ .

In study 3, we compared the effect of evoking expectations to both goals and a control condition in another restaurant field study. Some participants wrote about either their goals or expectations for their restaurant visit while participants in a control condition did not complete any writing task. All participants then indicated their likelihood of recommending the restaurant. Expectations lowered evaluations relative to the goals and control conditions,  $F(1, 197) = 4.89, p = .028$ , whereas there were no differences between those in the goals condition and those in the control condition,  $F < 1$ . Open-ended responses regarding people's goals and expectations were coded for whether they pertained to the person's experience (e.g., "have fun" coded as yes vs. "good food" coded as no). Supporting our process explanation, expectations were less likely to involve personal experiences and emotional reactions, and this explained the lower evaluations by those in the expectations condition.

Study 4 provided greater evidence for the proposed process by asking lab participants to draw their expectations, goals, or experience for a recent restaurant visit. Replicating studies 1-3, participants in the expectations condition were less likely to recommend the restaurant compared to those in the goals and control conditions,  $F(1, 386) = 6.01, p = .015$ , whereas there was no difference between the latter two,  $F < 1$ . To examine whether participants in the expectations condition were less likely to think about their own experience, participants' drawings were coded as to whether the drawing included a person (e.g., themselves). Indeed, people were included significantly less often in the drawings created by participants in the expectations condition than participants in the goals and control conditions,  $\beta = -0.54, SE = 0.11, \text{Wald } \chi^2 = 23.59, p < .001$ , whereas there were no differences in drawing of goal and control participants,  $\beta = -0.16, SE = 0.13, \text{Wald } \chi^2 = 1.52, NS$ . Further, differences in the inclusion of a person in the drawing mediated the effect of condition on likelihood of recommending the restaurant.

In study 5, we further examine the process by manipulating the purchase type (material good vs. experience) orthogonally to manipulating the salience of expectations. If this is about shifting focus away from one's experience, this effect should depend on the extent one is focused on the subjective experience to begin with, and be more pronounced for experiences than for material goods. Indeed, there was a significant interaction,  $F(1, 380) = 11.71, p = .001$ . Whereas expectations decreased willingness to recommend experiences,  $F(1, 380) = 4.22, p = .041$ , they actually increased willingness to recommend material goods,  $F(1, 380) = 7.81, p = .005$ .

Next, we examined real online reviews. Analysis of 1,931,556 hotel reviews from TripAdvisor demonstrates that when review content references expectations, the star-rating associated with the hotel is, on average, 0.2 stars lower,  $p < .001$ . Using LIWC's affective language score as a proxy for reflecting on one's personal experience and emotional responses, we find that a reduction in affective language helps explain the lower evaluations by those referencing expectations. These results are robust to different specifications including hotel-year-month of stay fixed effects and user fixed effects.

Finally, in a dataset including 39,672 hotels from Expedia.com, we demonstrate that the proportion of users referencing expectations in their reviews reliably predicts a decrease in the percentage of consumers who recommend the hotel at an aggregate level,  $p < .001$ .

In summary, across a variety of contexts, we find that expectations reduce willingness to recommend experiences, and this reduction is explained by shifting focus away from one's subjective experience and emotional reactions. Consequently, firms may receive more word-of-mouth recommendations if they focus consumers' attention on their experiences rather than their expectations.

## Losing Fast or Slow? Preferences for Uncertainty Resolution

### EXTENDED ABSTRACT

Is losing like a Band-Aid—better resolved quickly? Or does holding onto hope for a positive outcome improve even an otherwise negative experience? In other words, if you knew for sure that you would lose, would you prefer to know earlier (perhaps to get the bad news over with), or would you prefer to learn later in the contest (perhaps taking some consolation in fighting until the end)?

On the one hand, knowing that losing is inevitable may be like a looming electric shock. To avoid *dreading* such a shock, consumers often pay to accelerate experiencing it, preferring to get it over quickly (Berns et al. 2006; Loewenstein 1987). Losing late in a game may also seem to consumers like a near-win. Such near-wins seem to amplify negative emotions such as unhappiness when earning a silver medal (Medvec, Madey, and Gilovich 1995) and regret when missing a train (Gilbert et al. 2004; Kahneman and Tversky 1982). Consumers may therefore avoid these feelings by choosing earlier resolution.

On the other hand, discounted utility models (Frederick, Loewenstein, and O'Donoghue 2002) presume that future events are discounted. If future bad news is downplayed or discounted, these models would predict that consumers today would choose to delay losing as long as possible. In addition, consumers may simply dislike giving up the chance to continue playing. They generally prefer keep their options open (Shin and Ariely 2004), avoid risking sudden death in games (Walker et al. 2018), and overweight scenarios that keep hope alive (Rottenstreich and Hsee 2001).

Given the plausibility of both hypotheses, we tested them by asking consumers for their preferences in the context of games. Across four studies, we observed that consumers preferred to lose more slowly (later in the game) when presented a choice between fast and slow (studies 1 and 2) and when compared to winning (all studies). We also replicated the pattern in a naturalistic setting involving March Madness basketball (study 4). Finally, we showed that playing the game led to changes in preferences to favor earlier resolution, regardless of the outcome (studies 3 and 4), a pattern not well-predicted by existing theory.

Study 1 demonstrated the main effect. Participants ( $N=144$ ) were given a choice between two losing best-of-seven sequences of coin flips. One involved being certain of losing earlier (L L L L W W W) and the other later (L W L L W W L). They could also indicate no preference. We also asked about their preference for winning earlier or later (counterbalanced). When facing certain loss, participants chose the latter sequence most frequently (62.5% later, 18.8% earlier, 18.8% indifferent), significantly more often than 50% of the time,  $\chi^2(1, N=144) = 10.03, p = .002$ . They were indifferent when asked about winning (45.1% later, 48.6% earlier, 6.3% indifferent).

Study 2 ( $N=236$ ) replicated study 1 with two key differences: preferences for winning and losing were incentive compatible (one

person was selected to see either their preferred win or loss scenario played out for a \$50 Amazon giftcard), and half the participants were randomly assigned to a condition where the game ended immediately when the winner was decided (if the best-of-seven game was decided on the fourth round, no other rounds followed). There was no difference when the game ended in this way, so we collapsed the data. When facing certain loss, participants chose the latter sequence most frequently (64.4% later, 18.2% earlier, 17.4% indifferent), significantly more often than 50% of the time,  $\chi^2(1, N=236) = 19.59, p < .001$ . They were indifferent when asked about winning (40.7% later, 47.5% earlier, 11.9% indifferent).

Study 3 explored whether preferring to lose later is an affective forecasting error. We examined how much enjoyment participants ( $N=276$ ) actually felt when experiencing the sequences from study 1. We measured enjoyment after each round and overall at the end. Consistent with participants' preferences in studies 1 and 2, losing on the seventh round was more enjoyable than losing on the fourth round based on the sum of all rounds,  $F(1, 272) = 18.1, p < .001$ , and overall enjoyment at the end,  $F(1, 272) = 14.7, p < .001$ . We also asked whether they would want to change to the other sequence if they were to play the game again. Those who lost on the seventh round preferred to switch to the lose-after-four sequence 78.5% of the time, while those who lost on the fourth round preferred to switch to the lose-after-seven sequence only 27.8% of the time,  $\chi^2(1, N=137) = 35.15, p < .001$ . A similar pattern emerged for winning (55.2% chose to win earlier, while only 16.7% chose to win later,  $\chi^2(1, N=139) = 22.60, p < .001$ ). Experiencing the game seemed to lead to preferences for earlier uncertainty resolution next time.

Study 4 replicated the effect in a field setting ( $N=217$ ). We conducted a longitudinal study prior to and immediately following the first basketball game of March Madness. At time 1, we asked participants what time in the game (0 - 40 minutes) they would want to *know for sure* that their favorite team would win or lose (counterbalanced). The results replicate the basic effect. Participants wanted to know for sure about losing significantly later in the game ( $M = 28.9, SD = 11.6$ ) than winning ( $M = 25.8, SD = 9.9$ ), matched  $t(216) = 3.09, p = .001$ . We also replicated study 3 when examining changes in uncertainty resolution timing preferences. At time 2 (after the game), participants preferred earlier certainty compared to time 1,  $F(1, 216) = 4.02, p = .046$ , regardless of being asked about winning or losing. These results hold when controlling for the outcome of the game.

We have shown that consumers prefer to lose games slowly, at least prior to experiencing them. Our work has interesting implications for consumers across a variety of domains that involve uncertainty resolution, such as sports games, election and health outcomes, and awaiting results from performance evaluations and job opportunities.

## Reversing the Experiential Advantage: Happiness Leads People to Perceive Purchases as More Experiential than Material

### EXTENDED ABSTRACT

Consumers derive more personal satisfaction and happiness when they consume experiences instead of material goods (Gilovich, Kumar, and Jampol 2015; Van Boven and Gilovich 2003), suggesting that consumers should be spending more of their discretionary income on experiences instead of material goods to increase happiness (Dunn, Gilbert, and Wilson 2011; Dunn and Norton 2013). In this research, we investigate whether part of this puzzle may be backwards: Could happy consumers view their purchases as more

experiential and less material? If so, can encouraging consumers to view their purchases as more experiential increase their happiness?

Related research hints at the possibility that happy people may view their purchases more experientially. First, happy people tend to construe the world more abstractly (Updegraff and Suh 2007) and a positive mood evokes an abstract construal (Labroo and Patrick 2009). If we assume that experiences are construed more abstractly, and given that happy people tend to think more abstractly, then we would expect that happy participants will perceive their purchases as more experiential than material compared to those less happy. Further, to test this abstract mindset mechanism, we test whether the effect of happiness on experiential perceptions is stronger when consumers are in an abstract mindset compared to a concrete mindset.

Studies 1 and 2 test our main hypothesis with chronic happiness, examining whether consumers high on subjective well-being (SWB) perceive purchases as more experiential (vs. material) than those low on SWB. Study 1 examined consumers' own purchases using the experience sampling (Csikszentmihalyi and Larson 1987). We measured SWB by creating an index based on satisfaction with life and PANAS and messaging participants five times a day by a smartphone notification for 7 days. Participants also identified their most important purchase for the day and rated how experiential or material they perceived their purchase (sliding scale 0 = *definitely material* to 100 = *definitely experiential*). An HLM model (controlling for age, gender, income, and the purchase category), found a positive relationship between SWB and experiential-material perceptions ( $\gamma = 0.23, t(206) = 1.99, p = .048$ ). In other words, the happier the respondent was, the more experiential he or she perceived their purchases.

Study 2 examined purchases made by others. Participants rated 37 different purchase items [varying from more tangible (e.g., wallet), less tangible (e.g., a movie ticket), and were ambiguous (e.g., television)] in terms of the extent to which each purchase was experiential or material on a 9-point scale (1 = *definitely material*, 5 = *equally material and experiential*, 9 = *definitely experiential*; counterbalanced). Consistent with study 1, there was a positive relationship between SWB and material-experiential rating ( $r = .24, p = .001$ ). In other words, the happier participants were, the more experiential they thought a purchase was in general.

Study 3 provides causal evidence by manipulating positive (happy), negative (sad), and neutral (control) affect. Participants first wrote about three recent events (either happy, sad, or neutral, depending on condition) in their life in a very detailed manner (Schwarz and Clore 1983). Then participants rated 14 purchases as more experiential or more material. As expected, happy participants perceived purchases as more experiential ( $M = 4.87$ ) compared to those in the sad condition ( $M = 4.56; t(356) = 2.31, p = .022$ ), and compared to the control condition ( $M = 4.58; t(356) = 2.15, p = .032$ ). No difference was found between the control and sad condition ( $p = .87$ ).

Study 4 tested our mechanism by inducing an abstract construal in a 2(emotion: happy vs. control) x 2(mindset: abstract vs. concrete) between subjects design. In the first part, 287 participants listed three ways of spending with the goal of advancing their happiness and enjoyment in life (\$10-\$1,000). In the second part, participants wrote about either a happy event or an event from yesterday (depending on condition). The abstract condition focused on the 'why' aspect of the event, whereas those in the concrete condition focused on the 'how' aspect (Vallacher and Wegner 1987). Results showed the predicted emotion by mindset interaction ( $F(1,283) = 5.67, p = .018$ ). In the abstract condition, happy participants rated their purchase more experientially ( $M = 5.89$ ) than control ( $M = 4.91; t(283) = 3.02, p = .003$ ). In the concrete condition, there was no difference

in experiential perception between the happy ( $M = 4.95$ ) and control condition ( $M = 5.05$ ;  $t(283) = 0.31, p = .75$ ).

Finally, study 5 tests the implications of our findings by examining whether consumers may increase their happiness by focusing on the experiential nature of their purchases. We conducted a 1-week intervention study where 131 participants first provided their baseline psychological state (i.e., life satisfaction, affect balance, happiness, and financial well-being) and demographics. In the *experiential framing* condition, we asked participants to consider all their purchases as experiential when both anticipating and making each purchase. In the *purchase-planning* condition, we asked participants to foster a habit of planning their consumption by thinking about when, where, and how much they spent before and during every purchase. In the *control* condition, participants simply reported all purchases they made at the end of each day. At the end of the intervention, participants completed the same well-being measures. Only participants framed their purchases as experiential reported significantly increased levels of life satisfaction, affect balance, happiness, and financial well-being over time ( $p$ 's  $< .05$ ). No differences between pre- and post-measures were found in the purchase-planning group and the control group.

In sum, these results suggest that happy consumers view their purchases as more experiential than their less happy counterparts. This bi-directional relationship between happiness and experiential framing implies that consumers can strategically use such malleability of purchase perception to increase their financial well-being and happiness by changing their way towards everyday purchases. Study 5 provides such evidence. The research provides an additional explanation for the experiential advantage and throws into question whether experiences lead to more happiness compared to material purchases or whether happiness leads to experiential framing (or both).

### SESSION OVERVIEW

The current session discusses cognitive mechanisms that can drive consumers to prefer larger, later outcomes (i.e., two marshmallows tomorrow) to smaller, sooner outcomes (i.e., one marshmallow now). A myopic focus on smaller, sooner outcomes can negatively impact consumers' financial wellbeing. For example, this myopic focus can lead to suboptimal choices for home mortgage down payments (Atlas, Johnson, and Payne 2017), low credit scores (Meier and Sprenger 2012), and insufficient retirement savings (Hershfield et al. 2011). In the current session, we examine cognitive mechanisms and interventions that can lead to increased preferences for larger, later outcomes.

Paper #1 investigated the role of considering opportunity costs when making intertemporal choices. The authors examined psychological processes underlying the Asymmetric Subjective Opportunity Cost (ASOC) effect, whereby opportunity cost reminders increase the preference for the larger, later option, but not the smaller, sooner option. They found that highlighting opportunity costs serves as an implicit nudge, selectively increasing the preference for the larger, later option.

Paper #2 tested whether attaching a small donation option (as little as \$1) can lead people to choose a larger, later option. Previous literature suggests that when people make a decision that involves others, they focus on positive and prominent attributes. Building on this prediction, the authors found that attaching a charitable contribution increases the preference for a larger, later option by placing more emphasis on the consequential magnitude dimension.

Paper #3 tested the role of response mode in intertemporal outcome evaluations. The authors found that a choice task can increase the preference for larger, later options whereas a matching task can decrease the preference for larger, later options, especially when an individual experiences a loss of control.

Lastly, Paper #4 investigated intertemporal tradeoffs in college choices. The authors showed that college choices focusing on financial information (attending costs and expected salary after graduation) induce intertemporal tradeoffs between low-cost & low-return colleges and high-cost & high-return colleges. However, the authors

found that student loans that were supposed to increase forward-looking college choices (i.e., larger, later options) have only limited effectiveness in shifting college choices.

## The Asymmetric Effect of Highlighting Intertemporal Opportunity Costs

### EXTENDED ABSTRACT

Recent work (Read, Olivola, and Hardisty 2017) demonstrated that time discounting is driven by an asymmetric attention to the opportunity costs of choosing smaller, sooner (SS) vs. larger, later (LL) rewards. Specifically, highlighting the opportunity costs of choosing SS-rewards moves people toward more patient choices, whereas similarly highlighting the opportunity costs of choosing LL-rewards has no effect on patience – a phenomenon labeled the Asymmetric Subjective Opportunity Cost (ASOC) effect. For example, taking the 'standard' way of presenting an intertemporal choice ("Do you prefer \$100 today OR \$150 in one year?") and adding a subtle 'nudge' that highlights the opportunity cost of choosing the SS-option ("...\$100 today **and \$0 in one year** OR...") increases the likelihood that consumers choose the LL-option. By contrast, using the very same kind of nudge to highlight the LL opportunity cost ("...OR **\$0 today and \$150 in one year ...**") has no effect on choices. Finally, adding both nudges ("...\$100 today **and \$0 in one year** OR **\$0 today and \$150 in one year ...**") is equivalent to only adding the former ('SS-zero') nudge. This pattern of results suggests that *consumers naturally consider the opportunity cost of delaying gratification (i.e., no reward now), but are less likely to spontaneously consider the opportunity cost of choosing the immediate reward (i.e., no reward later)*. The ASOC effect helps explain why consumers tend to be impatient (e.g., Olivola and Wang 2016) and neglect their 'future selves' (e.g., Pronin, Olivola, and Kennedy 2008). It also helps explain previous findings in the literature (e.g., Loewenstein and Prelec 1991, 1993; Magen, Dweck, and Gross 2008; Wu and He 2012).

Here, we seek to characterize the nature of, and investigate the psychological processes underlying, the ASOC effect.

Study 1 ( $N=235$ ) examined two questions: whether the ASOC effect impacts future decisions and whether consumers anticipate the ASOC effect. Participants completed two separate blocks of intertemporal choices, separated by a filler task. In the first block, they were randomly assigned to one of the four 'core' framing conditions: the 'standard' format (no opportunity cost highlighted: "...\$54 today OR \$80 in 30 days..."), the LL-zero format (LL opportunity cost highlighted: "...\$54 today OR \$0 today and \$80 in 30 days..."), the SS-zero format (SS opportunity cost highlighted: "...\$54 today and \$0 in 30 days OR \$80 in 30 days..."), and the 'explicit zero' format (both opportunity costs highlighted: "...\$54 today and \$0 in 30 days OR \$0 today and \$80 in 30 days..."). Then, after completing the first block and the filler task, all participants were presented with the same set of choices in standard format. We replicated the ASOC effect in the first block, finding a positive effect of SS-zero on patience ( $F(1,231)=25.97, p<.0001, \eta^2=.10$ ), but no effect of LL-zero nor an interaction ( $F_s<.2$ ). More interestingly, the SS-zero manipulation in the first block also increased patience in the second ('nudge-free') block ( $F(1,231)=7.98, p=.005, \eta^2=.03$ ).

The second part of Study 1 examined intuitions concerning the effect(s) of making the opportunity cost(s) explicit. First, participants were presented with a single intertemporal choice in the standard format. After making their decision, they were presented with the same choice in one of the three alternative frames (explicit zero, SS-zero, or LL-zero), and asked whether this alternative frame would make people more, less, or equally likely to prefer the LL-option. Only 28% predicted that adding the SS-zero would increase patience (16% predicted it would *decrease* patience), while nearly the same proportion (26%) predicted LL-zero would have the opposite effect (22% predicted it would *increase* patience). In sum, the ASOC effect is strong enough to carry over into future decisions, yet too subtle for most consumers to anticipate its impact.

Study 2 ( $N=415$ ) replicated the dual-block design of Study 1, but with different sets of choices in each block. We replicated the SS-zero effect in both the first block ( $F(1,407)=21.00, p<.0001, =.05$ ) and second block ( $F(1,407)=8.50, p=.004, =.02$ ), and found no effects of LL-zero nor interactions in either block ( $F_s<1$ ). This shows that the ASOC effect can even influence a different set of future choices.

Study 3 ( $N=190$ ) used a thought-listing procedure to examine whether our opportunity cost manipulations would alter the explicit contents of consumers' thoughts during decisions (as categorized by independent coders, blind to the experimental design and hypotheses). We replicated our previous intertemporal choice results but found no significant differences between conditions in the content, order, or number of thoughts listed --in fact, any mentions of receiving "\$0"/"nothing" were extremely rare (only 1% of all thoughts listed across all conditions), suggesting that the ASOC effect operates at an implicit level.

Study 4 ( $N=227$ ) measured choice times to investigate whether the SS-zero increases patience by slowing decisions and promoting additional (implicit) consideration of the (otherwise neglected) SS opportunity cost. We again replicated the choice results. More interestingly, we found a similar pattern with response times: the SS-zero increased the time spent deciding ( $F(1,223)=15.4, p<.001, =.06$ ), whereas there was no effect of LL-zero nor an interaction ( $ps>.12$ ). This suggests that highlighting the opportunity cost of choosing SS prompts additional (implicit) processing by participants, leading to more patient choices, while highlighting the opportunity cost of choosing LL does not influence decision processing or choices.

Study 5 ( $N=381$ ) showed the ASOC effect replicates under both low and high cognitive load, further suggesting it is an implicit ('System 1') phenomenon that occurs regardless of whether consumers can allocate all (previous studies), most (low-load condition), or only some (high-load condition) of their cognitive resources to the decision.

Taken together, these five studies reveal novel insights regarding the ASOC effect. On the one hand, the effect is potent enough to influence future decisions and choice times; on the other hand, the effect seems to be largely implicit, as consumers do not anticipate it, it doesn't alter accessible thoughts, and it is immune to cognitive load. Finally, we showed that the effect seems to operate by slowing down the decision making process and getting consumers to (implicitly) consider the opportunity costs of being impatient.

## Decreasing Impatience with Bundled Donations

### EXTENDED ABSTRACT

People frequently make decisions that involve balancing tradeoffs across time, including situations as wide ranging as selecting expedited shipping options, making financial investments, or simply

choosing what to eat. Formal theories aim to describe and predict this behavior in general by applying discounted utility models of intertemporal choice. Building on traditional psychophysics findings, all discounted utility models adopt the position that time is processed in a similar manner as other psychophysical stimuli (such as brightness, loudness, etc.), suggesting that any future outcome will be discounted at a common rate, regardless of the item. The current work instead focuses on the context-related differences in the psychology of discounting and proposes that good-specific differences in time discounting exist, are predictable, and can be leveraged to encourage more forward-looking behavior.

In particular, this work examines differences in discounting when outcomes involve charitable contributions rather than purely pecuniary benefits. Research suggests that when people make decisions that impact others, they tend to rely more on positive attributes (Beisswanger et al. 2003; Polman 2012) and prioritize more prominent attributes (Kray 2000; Kray and Gonzalez 1999; Tversky, Sattath, and Slovic 1988). Thus, when making intertemporal tradeoffs that impact others, people may place more emphasis on the typically more consequential magnitude dimension rather than the time dimension. Furthermore, if charitable contributions do in fact increase the prominence of the magnitude dimension, bundling donations into one's personal intertemporal tradeoffs may shift preferences toward larger, later options. Many common decisions naturally contain other-regarding elements: shipping has an environmental impact, financial investments may support social causes, and food is associated with many ethical concerns. The experiments presented below abstract away from the social issues linked to the choice options themselves and identify a robust and general phenomenon in which the simple inclusion of a bundled charitable contribution in intertemporal tradeoffs nudges preferences toward larger, later options.

Experiments 1a-c first document within-individual differences in discounting that exist between monetary outcomes and charitable donations. In Experiment 1a, participants made 90 total intertemporal tradeoff decisions involving larger, later (LL) and smaller, sooner (SS) options in three sets: involving money only, contributions to a charity rated as close, and contributions to a charity rated as distant to the participant. Decisions were incentive compatible and task order, choice order, and choice option order were fully randomized. Exponential discounting parameters were estimated by maximum likelihood, and revealed that participants applied a significantly higher discount rate on their own personal future monetary outcomes compared to donations of equivalent value; no difference was observed between close and distant charities. In Experiment 1b, participants made choices involving subjective present value equilibrated choice options constructed through a matching task. Decisions made at this equivalence point favored LL options significantly more frequently when choices involved a charitable donation but not when they involved money only. In Experiment 1c, participants made a decision between SS and LL options constructed such that the SS option should be favored given preferences the participant shared earlier. Participants displayed significantly more preference reversals favoring the LL option when choices involved donations rather than money only. Together these data indicate that individual participants do not apply a single discount rate across items; they consistently displayed greater patience when choice options involved donations rather than money only. Further, the data are consistent with the notion that donations increase magnitude prominence and cannot be fully explained by psychological distance or an egocentric empathy gap.

Leveraging these findings, Experiments 2-5 examine how bundling donations in intertemporal tradeoffs facilitate more forward-

looking decisions. In Experiment 2, participants made a decision involving a bonus they would receive after having participated in a lab session. They were randomized into either a money-only or a bundled-donation condition. Holding total monetary payouts constant, in the money-only condition participants chose between either \$4.35 today and \$6.09 in 60 days; in the bundled-donation condition they chose between \$3.35 today with a \$1 donation made to the National Park Foundation, or \$5.09 in 60 days with a \$1 donation made to the National Park Foundation. Participants chose the LL option significantly more often when donations were bundled into the tradeoff. Experiment 3a examined this in a within-participant design involving 24 decisions at different values and time delays. To address concerns of differential valuation of choice options between tasks, Experiment 3b involved value-matched donations to ensure choice options were equally attractive in the money-only and bundled-donation tasks. Experiment 3c also held base values (rather than total monetary values) fixed across tasks. Experiment 3d examined decisions at higher magnitudes where base values were increased fivefold but donations remained fixed at \$1. Across all of these experiments, participants favored LL options significantly more frequently when donations were bundled with intertemporal tradeoffs. Experiment 4 then measured changes in attribute importance and observed that the magnitude attribute was more prominent in the bundled-donation task relative to the money-only task. This change in magnitude prominence mediated the effect of donation bundling on the choice of LL options. Experiment 5 subsequently moderated the effect by highlighting urgency associated with a charitable cause. Relative to when they the charitable cause was described in general terms, when the cause was described as providing urgent aid to victims of Hurricane Maria, participants selected LL options less frequently in intertemporal tradeoffs that were bundled with the small, \$1 donations.

In sum, these findings indicate that individuals adopt different discounting processes when thinking about money and charitable causes, in particular by increasing reliance upon the magnitude dimension. As a result, the inclusion of small donations added to both choice options in intertemporal tradeoffs can increase magnitude prominence and drive more forward-looking decisions even when the large majority of payoffs as a percentage are delivered to the self rather than others. These results have important implications for how managers may wish to frame decisions in the marketplace and also raise fundamental questions around how researchers should model time preferences.

### **The Effect of Psychological Control on Temporal Discounting: Conceptual and Methodological Implications**

#### **EXTENDED ABSTRACT**

People often exhibit a tendency to overvalue the present and undervalue the future, known as temporal discounting (Samuelson 1937). Researchers used several elicitation methods to examine temporal discounting. In the matching method, participants are provided with an outcome at time 1 and asked how much money at time 2 would make them indifferent between receiving the outcome at the two points in time. In the choice method, participants make choices between smaller sooner and larger later amounts (Ahlbrecht and Weber 1997). Using methods interchangeably is sensible if distinct methods are all inherently sensitive to the same psychological process.

We propose that psychological control has the potential to inform our understanding of both consumers' propensity to engage in

temporal discounting and when different elicitation methods lead to divergent results. When experiencing a loss of control, individuals engage in actions to restore their sense of control (Whitson and Galinsky 2008). We suggest that one means to restore control is to obtain valued objects immediately as opposed to after a delay. The immediate obtainment of an object can satisfy an individual's need for control because it signals to an individual that she is able to obtain desired outcomes in her environment. In contrast, the delayed obtainment of an object may do little to address an individual's need for control because desired outcomes are not, in fact, obtained. As a consequence, individuals experiencing a loss of control may overvalue the obtainment of items in the present and undervalue the obtainment of the same item in the future—that is, they will engage in greater temporal discounting.

We propose that, while similar in many ways, the matching and choice elicitation methods have an important methodological difference that could prove extremely consequential. Specifically, the choice method inherently gives participants control because it allows them to decide whether or not they want to incur a delay; choice is an established psychological salve for a loss of control (Inesi et al. 2011). If individuals' sense of control is restored by the act of making a choice, we would expect a loss of control to have little, if any, effect on temporal discounting. In contrast, the matching method does not give participants choice, instead asking them for their willingness to accept. As such, if our hypothesis about the link between a loss of control and temporal discounting holds, only the matching method might be suited to observe the effects of a loss of psychological control.

In Experiments 1A and 1B, we directly test (1) the relationship between psychological control and temporal discounting and (2) whether this relationship is contingent on the elicitation method employed. In Experiment 1A, to instill a loss of control we used an established recall paradigm (Whitson and Galinsky 2008). Participants in the low control condition were asked to write about a past incident where they felt a loss of control. Participants in the baseline condition were asked to write about their experiences yesterday. Next, we measured participants' propensity to engage in temporal discounting with either a matching or a choice task. In the matching task, participants were asked to provide a dollar amount that would make them indifferent between receiving \$100 now versus in a month (“\$100 now = \$ \_\_\_\_\_ in a month”). In the choice task, participants completed a series of eight binary choices, choosing between receiving \$100 now or varying amounts money (\$200, \$205, \$210, \$215, \$220, \$225, \$230, and \$235) in a month (Hardisty and Weber 2009). Our analysis revealed the predicted two-way interaction emerged between the treatment and elicitation method. While participants' temporal discounting in the matching task was sensitive to a loss of control, this was not the case in the choice task (see Table 1). In Experiment 1B, we replicated our findings using a different manipulation of a loss of control: participant in the loss-of-control condition experienced a technical problem they could not control while watching a video, whereas participants in the baseline condition did not experience this problem.

While informative, one concern can be raised about Experiments 1A and 1B: different results across elicitation methods might be driven by the limited variance in responses for the choice task. Experiments 2A and 2B sought to replicate previous findings while allowing for greater variance in the choice task. Both experiments were similar in their procedure, but employed different manipulations of control (the recall task in 2A and the video task in 2B). Participants in both experiments completed one of the three tasks: a matching task, a choice task with a low variance, or a choice

task with a high variance. As before, temporal discounting elicited through matching tasks revealed a significant effect of the control treatment. In contrast, temporal discounting measured via choice tasks show no differences of the control treatment in both the low-variance and the high-variance conditions.

In Experiments 3 and 4, instead of examining the carryover effect of psychological control induced in a prior task, we investigate whether relatively small alterations that are meant to change the level of control *within* the same elicitation methods influence the extent of temporal discounting. Experiment 3 framed the elicitation methods as tasks that limit the way participants can respond and thus lower their control while Experiment 4 framed the elicitation methods as tasks that give participants a sense of control. Across both experiments, we find that even manipulating a sense of control *within* the task is sufficient to affect temporal discounting for matching, but not for choice tasks.

Across six experiments, we find that when experiencing a loss of control, participants exhibit more temporal discounting. Importantly, this observation is critically moderated by the elicitation method used. A loss of control increases temporal discounting with the matching method, but not with the choice method because the choice elicitation method naturally gives participants control. As a consequence, the current work not only reveals a novel driver of temporal discounting, but suggests that it cannot be taken for granted that findings obtained with one elicitation method will generalize to another.

### Temporal Discounting Induces a Myopic Focus on the Costs of Higher Education

#### EXTENDED ABSTRACT

The second quarter of 2010 was an alarming moment for American consumers; for the first time in history, the size of student debts surpassed credit card loans, and became the second largest consumer debt in the United States (Haughwout et al. 2015). Now, 70 percent of students borrow student loans for their college education. The loan repayments after graduation could influence their future spending and wealth. The government, and nonprofit and for-profit agencies have started to provide college financial information for concerned students and parents (e.g., College Scorecard from the Department of Education, College ROI from Payscale). However, potential influences of college financial information on the college choice have not been studied extensively (Urminsky and Zauberman 2015). Our research explores how education consumers respond to the availability of this information, focusing on the effects of making proximal costs and future returns available and salient.

We propose that framing higher education as a financial investment leads to substantial tuition myopia, leading many students to overweight the costs of colleges relative to their long-term financial returns. We find that temporal discounting (Samuelson 1937; Koopmans 1960; Frederick et al. 2002), a tendency to devalue an outcome as it moves further away from the present, underlies the tuition myopia phenomenon. Using quantitative analysis and behavioral experiments, we demonstrated that financially impatient consumers prefer low-cost and low-return colleges and financially patient consumers prefer high-cost and high-return colleges in both hypothetical and real college choices.

To begin, we analyzed 498 colleges from the College Scorecard database that provide bachelor degree education, have an enrollment of over 5,000 students, and are currently operating. These 498 colleges generated 123,753 college choice pairs ( $= {}_{498}C_2$ ). This analysis demonstrated that there are two different types of college choices.

The first category is a choice between a Low-Cost and High-Return college (LCHR college, hereafter) and a High-Cost and Low-Return college (HCLR college, hereafter). Temporal discounting is not a critical factor for the LCHR vs. HCLR choice pairs because LCHR colleges provide greater financial benefits with lower costs than HCLR colleges. There is no economically rational reason to choose the HCLR colleges over the LCHR colleges, *ceteris paribus*. The second category is a choice between a High-Cost & High-Return college (HCHR college, hereafter) and a Low-Cost & Low-Return college (LCLR college, hereafter). These HCHR vs. LCLR choice pairs entail an intertemporal tradeoff, a resource allocation between present and future; larger investment now leads to greater return in the future (HCHR colleges) whereas smaller investment now leads to smaller return in the future (LCLR colleges). Thus, financially impatient consumers may prefer LCLR colleges because they focus on proximal outcomes (that is, school years with negative incomes) and LCLR colleges demand lower costs than HCHR colleges.

We tested this prediction using four behavioral experiments. In Study 1, we tested our main hypothesis by examining whether participants' discount rates are related to education attainments and real college choices - the kind of college they attended. We measured individual discount rates, education attainments, and asked them to name their alma mater if they attended a college. We categorized attended colleges using the college group ranking based on Carnegie Classification as a means by which to categorize chosen colleges as LCLR or HCHR colleges. The results demonstrated a relationship between individual discount rates and participants' choice of higher education ( $\beta = -.19$ ,  $t(458) = -4.07$ ,  $p < .001$ ). Respondents who showed high discount rates attended LCLR colleges, whereas respondents who showed low discount rates attended HCHR colleges. Study 2 replicated the findings in Study 1 in using hypothetical college choices. Drawing from the original total set of pairs of LCLR and HCHR colleges we sampled from College Scorecard, we randomly presented 12 pairs of LCLR and HCHR colleges with college financial information and measured the individual discount rates. We found strong evidence that respondents made intertemporal tradeoffs when making college choices ( $F(2,182) = 192.0$ ,  $p < .001$ ,  $\eta_p^2 = .68$ ) and also find a significant correlation between individual discount rates and the preference for LCLR colleges ( $r = .35$ ,  $p < .001$ ).

Study 3 and Study 4 tested whether the favorable student loans can remove the intertemporal tradeoffs demonstrated in Study 1 and Study 2. In the United States, backed by the Higher Education Act of 1965, the government offers several subsidized loan programs (e.g., Stafford loans, Perkins loans) that cover tuition and other attendance costs. These student loans alter the cost and benefit characteristics of the college education. College tuitions are no longer "immediate" costs under the student loans. Student loans stretch out the cost of higher education over many years after graduation, reducing the burden of immediate payments during the college education. Thus, these student loans remove intertemporal tradeoffs and make HCHR colleges a dominant option. HCHR colleges provide relatively larger net income during and after the loan repayment period than LCLR colleges.

However, we found that respondents still made intertemporal tradeoffs when making college choices even with the student loan options. In Study 3, we offered a favorable student loan options alongside the college financial information (3.76% APR with 30-year repayment plan). However, this additional information did not remove intertemporal tradeoffs from the college choice ( $F(2,344) = 211.82$ ,  $p < .001$ ,  $\eta_p^2 = .55$ ). We found similar results in Study 4. Instead of providing the loan information as we did in Study 3, we presented the student loan repayment information, which can high-

light the financial benefits of choosing HCHR colleges. This alternative cost information did in-fact increase the preference for HCHR colleges ( $F(1,172) = 6.57, p = .011, \eta_p^2 = .04$ ). However, this was not enough to remove intertemporal tradeoffs from the college choice ( $F(2,344) = 211.82, p < .001, \eta_p^2 = .55$ ).

To sum up, the current study provide insights regarding how education consumers would respond to college financial information when making college choices. The current study suggests that presenting college financial information leads to tuition myopia; people prefer less expensive colleges even when long-term financial returns are smaller than expensive colleges.

### **SESSION OVERVIEW**

In his pioneering article on rituals and consumer behavior, Dennis Rook defines rituals as expressive, symbolic, and repeated behaviors that are “performed with formality, seriousness and inner intensity” (1985, 252). Marketing scholars have studied the importance of rituals for consumers and marketers to individual consumers, consumer communities, consumer-marketer interactions, and culture. Rituals transfer meaning to consumption goods (Belk, Wallendorf, and Sherry 1989; McCracken 1986), enhance consumption experiences (Epp and Price 2008), and shape and influence the identities of consumers (Schouten 1991). Marketers successfully rely upon rituals to establish the iconicity and authenticity of brands by incorporating these enactments in marketer-consumer exchanges (Arnould and Price 1993), commercial spaces (O’Guinn and Belk 1989), marketing messages (Otnes, Ilhan, and Kulkarni 2012), and consumer socialization practices (Arsel and Bean 2012).

Although rituals remain a popular topic in consumer research, three broad areas noticeably warrant further investigation. First, scholars need to acquire a better understanding of the roles various market actors (e.g. marketers, consumers, service providers) play in perpetuating and valorizing consumer rituals in non-US contexts. Second, research on the “dark side” of rituals (e.g., the negative experiences and detriments consumers may experience by engaging in them) is limited, despite the consumer-welfare implications of such inquiry. Third, as Belk (2013) observes, extant research on rituals neglects exploring the intersection of the digital space and rapid technological changes with consumer rituals.

In this special session, we highlight these gaps by reviewing extant ritual scholarship, addressing these gaps through illustrative research, and pointing towards avenues for future research on contemporary consumer rituals. The authors of Paper #1 review thirty years of research on consumer rituals to examine the roles of rituals with regard to consumer identities, objects, experiences, relation-

ships, cultural institutions, and market interactions. In doing so, they also identify important areas for future research. In Paper #2, the authors examine moralized rituals of market actors who offer microloans to consumers in a poverty setting. Paper #3 investigates how stakeholders stigmatized a coming-of-age cultural ritual in Norway, denoting it as “dark-side” ritual activity and highlighting its consumer-welfare consequences. Finally, in Paper #4, the authors study how family identity is shaped by a digital platform, through the influence of digital forces on family rituals.

This session appeals to the need for making ritual scholarship consonant with consumer experiences and consumption practices in the contemporary market landscape. The papers included uncover potential areas for future research, focusing on how rituals influence consumer behavior in today’s globalized and digitized marketplace. Interested audiences should include the broad spectrum of scholars interested in ritual behavior, CCT research, and consumer welfare.

## **Ritual Scholarship in Marketing: Past, Present and Future**

### **EXTENDED ABSTRACT**

Since Rook (1985) first described important linkages between rituals and consumer behavior, scholars have examined consumer rituals from the perspectives of the individual consumer, marketers, marketing exchanges, and cultural institutions. New modes of communication and expression (e.g., digital media), and globalization calls for a thorough understanding of the consumption-related ritual topics, and what areas they should explore in the future. In this paper, we systematically review articles in the top marketing and consumer behavior journals to provide an overview of the current composition of ritual scholarship, and of prospective areas for future research. In so doing, we hope to categorize ritual scholarship into broad conceptual domains and evaluate our current understanding of rituals in each, identify gaps in our understanding based on the changing market environment, and suggest areas of inquiry to address these gaps.

We examined articles in the top twelve marketing journals identified in the SCImago Journal Rank of all marketing journals, each with an impact factor of at least 2.5. We searched for articles pertaining to consumption rituals in the twelve journals by consulting the three business databases included in the EBSCO database. Of these journals, five included pertinent articles: *Journal of Marketing*, *Journal of Consumer Research*, *Journal of the Academy of Marketing Science*, *Journal of Consumer Psychology*, and the *Journal of Retailing*. We determined that the authors’ foci led to an emergent partition of the literature into five domains (albeit with a few overlaps). The research team engaged in close reads and iterative discussion of articles, identifying various themes and research extensions within each domain. The themes are: foundational, macro-level, meso-level, marketplace-level, and micro-level.

### **Foundational**

This domain includes conceptual articles that define and describe the construct of consumption rituals, and theoretical papers that explore how rituals influence consumer behavior. The field continues to develop theoretically around the initial definition and conceptual exploration of consumption rituals that Rook (1985) offers. Research examines how rituals transfer meaning to objects through

exchange, possession, grooming, and divestment (McCracken 1986). During the process of meaning transfer, rituals may result in commodities becoming decommoditized (Belk, Wallendorf and Sherry 1989), which may apply to both material and digital possessions of consumers (Belk 2010; 2013).

### Micro-level

We delineate micro-level ritualistic consumption as involving individuals, dyads, or families. A dominant theme in these articles is people's reliance on rituals to help them socialize others' consumption practices, particularly through family rituals (Epp, Schau and Price 2014). Micro-level studies reveal ritual socialization practices may be highly gendered (Wallendorf and Arnould 1991), and that brands can be powerful forces of socialization (Diamond et al. 2009). The micro-domain also examines interconnections between rituals and identity (Bradford 2015; Schouten 1991).

### Meso-level

Meso-level articles focus on how rituals influence sociologically-similar groups of people who interact within or outside of market-mediated contexts (Kates 2004). We find that rituals at the meso-level primarily serve four emergent functions: socialization, belongingness, identity maintenance, and resistance. Within meso-contexts, rituals indoctrinate consumers into a collective, helping them socialize with other consumers in communal settings (Wooten 2006). Within groups such as brand communities, rituals may also help consumers deepen their connections and social relations to other consumers (Schouten and McAlexander 1995). Meso-level research also highlights how ritual artifacts assist consumers to form or sustain their identities (Mehta and Belk 1991); Ritson and Elliott 1999), and sometimes also transform identities within groups (Belk 1992).

### Marketplace-level

This domain pertains to the marketers' use of rituals. By far, the most pervasive way they do so is to help them iconize a marketplace. Ritualization is also one of the key socialization practices marketers leverage for their consumers (Arsel and Bean 2012). Other marketplace-level articles explore how practitioners use rituals to enhance aspects of the buyers/seller or customer/provider relationship (Sherry 1990), especially customer relationships and customer perceptions of the buying experience (Arnould and Price 1993). Research highlights the importance of language in marketers' rituals, and how marketers rely on performative, symbolic, and shared aspects of language to achieve customer-related goals (Otnes, Ilhan, and Kulkarni 2012; Sherry and Camargo 1987).

### Macro-level

Articles that we classify in the macro domain locate rituals within cultural phenomena. The entry of market forces in socio-economic spaces can spur new rituals, or reformulate the meaning of existing ones (Callon 2016; Vikas, Varman, and Belk 2015). Consumers use rituals as mechanisms to negotiate and interact with their cultural environments (Sherry 2000) and as sources of identity-related meanings (Arnould 1989; Fernandez and Lastovicka 2011).

We find extant articles typically do not focus on ritual aspects or elements that make them more or less efficacious. Specifically, future research could explore how rituals connect to a broader range of theoretical constructs (e.g., discourses, practices, and sentiments). In addition, research could ask: What roles do various actors (e.g., marketers, consumers, service providers) enact in perpetuating and valorizing rituals? How do the elements of ritual practices relate to

the individual and/or collective emotions of consumers? We also find inadequate investigation of the beneficial or detrimental outcomes of engaging in consumption rituals. Ritual scholarship also needs to capture the impact of current and disruptive dynamics in consumer culture (e.g., marketplace globalization; dominance of digital consumer culture). Finally, we identify the importance of ritual(s) scholarship in unexplored regions (e.g. non-US countries), economies (e.g. B-O-P; emerging) and cultural categories.

## The Ritualistic Dimension of Microlending

### EXTENDED ABSTRACT

The rise of microcredit as a popular tool for fighting poverty (Mader 2015), begs the question of how debt came to be seen as cure for poverty. The question becomes all the more pertinent with the recent popularization of online microlending, or the provision of interest-free credit to low-income borrowers through online platforms such as Kiva.org (Bajde 2013, Schwittay 2014). Every day, millions of lenders around the world devote their time, money and energy to low-income borrowers with the hope of helping them escape poverty. Despite the growing skepticism among development experts regarding the capacity of microlending to actually alleviate poverty and extensive media coverage on the damaging effects of microdebt (Banerjee and Jackson 2017), online microlending continues to thrive (Schwittay 2014).

Our study addresses this puzzle by investigating the role of ritual in the moralized market of online microcredit. We draw upon a four-year multi-method investigation of the online microcredit market, assembled by microlending platforms and microfinance institutions to attract interest-free capital from potential lenders. We show how this moralized market facilitates rituals of generativity (Magatti 2017), through which lenders adopt the role of socially-generative actors who generously help the poor and generatively tackle the problem of poverty. Through these rituals microcredit is dramatized as a potent and virtuous solution to social problems (i.e., poverty), and lenders are enthused and energized to act as generative and responsible moral actors by investing their money, time, and energy in microloans.

To holistically investigate the moralized market of microcredit, we followed the action of diverse market actors (Martin and Schouten 2014) via participant observation and interviews with lenders, borrowers, and microcredit professionals (n=27 interviews), and conducted a systematic analysis of microlending websites, promotional material, and media. During data analysis, we moved iteratively between data and theory, and between emerging analytical themes and relevant theoretical frames (Thompson and Troester 2002).

Our study unpacks microlending as a ritual of generativity (Magatti and Giaccardi 2014; Magatti 2017), assembled by microlending platforms to enable lenders to emotionally connect with the poor and empower them to escape poverty. Kiva.org, the world's leading microlending platform, states that microloans "celebrate and support people looking to create a better future for themselves, their families and their communities," giving them the "power to create opportunity for themselves" and "realize their potential." Due to high repayment rates, lenders can recuperate their money and perpetually reinvest it, further magnifying the horizon of opportunity (Varul 2009) for development through financial empowerment.

The rituals of microlending (i.e., selecting the borrower, making the loan, receiving updates, reinvesting repayments) dramatize credit as a potent engine of growth and prosperity for both borrowers and their communities. Microloans obtain a romantic aura of potentiality, typically absent from in other poverty-alleviation rituals (e.g.,

charitable giving). As stated by the lenders interviewed, every loan repayment update proves the loan has helped the borrower to improve his/her life. Some lenders, and even the institutions promoting microlending, do recognize that the power of credit is not infinite. Nevertheless, romantic renditions of microcredit as a magical cure for poverty continue to overshadow the realities of life in poverty and the complexities of development (Bateman 2010; Giesler and Veresiu 2014; Banerjee and Jackson 2017).

Further, the ritual of microlending transforms what is essentially a contractual relationship between the lender and the borrower into a relationship of solidarity and care. As Kiva's 'Product Philosophy' states bluntly: "Lending is connecting." Informant-lenders readily embrace this ethos. They convey how the stories and pictures of borrowers published on the platforms enable them to recognize the qualities and challenges they share with borrowers, despite their vastly different life circumstances. This enables lenders to emotionally connect with the poor and experience a sense of solidarity (i.e., shared commonality and a willingness to help others). Periodic loan updates and repayments temporally extend the ritual, enabling the lenders to experience the loan process as a prolonged interaction with the borrowers (Flannery 2007).

However, our data also shows the described rituals of generativity can be very one-sided. The borrowers interviewed know nothing of the lenders and their noble intentions. Rather, borrowers experience the loans as a commercial exchange with the local microfinance institutions, which actually charge interest rates to cover their expenses. They do not fully understand why their pictures and stories are recorded and shared online. Market-mediated rituals of microlending thus may induce solidarity, responsibility and generativity, but they also mask enduring imbalances of power (Rajak 2011).

The popularity of microlending can at least in part be accounted for by its ritualistic qualities. Online platforms assemble and coordinate flows of stories, images, data, and money to facilitate what we call rituals of generativity. Through these rituals, market resources like credit are dramatized as virtuous engines of social progress, empowerment and solidarity, providing consumers with opportunities to act as generative and responsible moral actors. Further research on moralized rituals is needed to explain the performative dynamics of consumer responsabilization (Giesler and Veresiu 2014) and neo-liberal moral governance (Shamir 2008; Rajak 2011).

## Stigmatization of a Cultural Ritual

### EXTENDED ABSTRACT

Cultural rituals are defined as "aesthetic, performative, and symbolic public events occurring on a grand scale that are broadly accessible to consumers" (Otnes, 2018, 489). When creating and sustaining these rituals, stakeholders from various institutions exert different roles in the ritual (e.g., service delivery, legislative permissions, media coverage, social control). This paper explores how such stakeholders stigmatize enactment of a controversial Norwegian ritual. We demonstrate that when concern emerges over the "dark side" of this cultural ritual, stakeholders engage in prolonged, pervasive stigmatization to enact change in ritual participation. We address this question: How do stakeholders in a cultural ritual stigmatize and shape the actions of ritual participants?

Our enabling theory is the "stigma turbine," a framework that "locates...stigma within the broader sociocultural context and illuminates its relationship to forces that exacerbate or blunt stigma" (Mirabito et al., 2016, p. 170). As sources of stigmatization / destigmatization, powerful historical, institutional, and commercial "winds" exert pressure on the turbine. Winds increase or decrease

the stigma, influencing directionality of the turbine toward stigmatization, destigmatization or stagnation (due to conflicting winds). We focus on how the cultural winds specifically influence the "societal" blade of the turbine, representing the meso-level of culture.

The "Russfeiring" or "Russe" is an annual national coming-of-age ritual celebration for Norwegian high school seniors in their final semester. Over the past thirty years, it has evolved into a large-scale, nationally coordinated event comprised of multiple sub-rituals. The most significant artifact (Rook 1985) is the "Russ-bus," a core element enabling participants to "roll to" other Russ events. It serves as a concealed party space away from authorities, schools, and parents. This lack of transparency contributes to conflicts with these stakeholders. Teams of 15 to 25 (mostly male) students invest substantial time, money (from 20,000 to 60,000 USD – focus group interview, 2018; Stavanger Aftenblad, 2017) and effort securing commercial sponsors for their buses, which feature custom logos, branded imagery, theme songs, special apparel, and social-media sites. A well-organized commercial ecosystem of suppliers, service providers, and contractors supports the Russ-bus industry. The bus is increasingly regarded as a disruptive social element, facilitating wild partying, excessive drinking/drug abuse, littering, noise, and irresponsibility. Parents and teachers worry about accidents, deviance, and academic consequences. The police monitor disruptions of public places and traffic violations. These concerns have been ineffectual in shaping norms pertaining to the Russ-bus – until recently.

In 2017, propelled by (among other activities) a stigmatizing media storm (Boydston et al. 2014), "Casanova2017," a Russ-bus team consisting of 25 males, became the national "poster-child" of criticism aimed at the Russ-buses. Its theme song, which the team bought from professional "Russ" song-writers, provided the media with the triggering wind it needed to initiate the stigma turbine. The media featured its song lyrics in headlines, triggering shock in the marketplace, as the lyrics suggested sex with a thirteen-year old girl. The release triggered public debate about the entire Russ-celebration. Casanova2017 faced public outrage, sponsorship withdrawal, condemnation by experts on rape and sexual misconduct, threats to personal safety, and an outcry among female students.

We draw upon four types of qualitative data: interviews, text from social media/the Internet, and written and broadcast news accounts. We created a database of media coverage, comprised of news articles in traditional and social media, recordings of available television and YouTube interviews, and meetings with educators, public authorities (e.g. local police, the Norwegian Public Roads Administration, a collaborating NGO), stakeholders, parents, and students. We analyzed 111 pages of interview transcripts, 321 pages of text in printed media, two documentaries, 228 YouTube videos, several hours of news broadcast, and chronological posts on Instagram and Facebook for themes pertaining to stigmatization activities and consequences. In January 2018, we conducted a focus-group with four members of Casanova2017.

We find stakeholders engage in the following stigmatizing actions: shunning, chastising, scapegoating, and responsabilizing (and/or denormalizing) (Bell et al. 2010), which we define, describe and differentiate in our analysis. The transcript indicates Casanova2017 members are cognizant of these practices: "When you get there and have published such a song – you have nothing to say...In that situation, we felt really small actually" (Focus group interview, January 2018).

Furthermore, these actions wielded both immediate consequences for Casanova2017, and longer-term consequences for Russe celebrations across the nation. Stakeholders involved in the Russ-bus ecosystem supported various agendas and contributed to both ritual

stigmatization and destigmatization. Media and school authorities represented the key stigmatizing forces. Local authorities, as neutral actors, focused on the actual (but relatively small) damage from the Russe celebration, instead of the morality aspects. Commercial actors for the Russ-bus (i.e., apparel suppliers, interior designers and music vendors) played contradicting roles, supporting/maintaining Russ-buses, but also exploiting the existing rebellion underlying the Russe foolishness in their commercial interest. As young consumers, Casanova2017 team members tried to resist these stigmatizing forces, but report feeling powerless and neglected, as stigmatized groups often do (Adkins & Ozanne 2005; Bell et al. 2010; Crockett et al. 2017).

Casanova2017 participants found public apologies and moderating their ritual practices were their only means to moderate the stigma that the winds generated. Commercial endorsers deemed the team untouchable. The stigma of sexual deviance transferred to many Russ-buses, associating them with violence and rape. In addition, the founder/leader of an NGO against sexual violence spoke at the high school of Casanova2017's team leader. The national celebration also saw longer-term consequences. For instance, the "russeknuter" (badges Russ participants earn when completing a task or dare during the festivities) now exclude sexual activities. Nationwide, female Russe participants are more aware of the increasing sexualization of Russ rituals, and now publicly criticize this development (Aftenposten 2018).

### Exploring the Intersection of Digital Virtual Consumption and Family Rituals

#### EXTENDED ABSTRACT

Ritual experiences contain four "tangible" elements: ritual artifacts; a ritual script; ritual performance role(s); and, a ritual audience (Rook, 1985). In light of a changing consumer culture that is increasingly digitized, how are rituals performed within and shaped by digital platforms and spaces? Belk (2013) specifically calls for research into how the digital world shapes rituals such as gift-giving and collecting. Scant existing research explores how digital spaces shape rituals. One exception is Epp, Price, and Schau (2014) who examine how technologies influence family practices, including rituals, during family physical separations (e.g., due to military service). However, their focus is on how technologies enable the reassembling of family consumption practices. Drenten and Zayer (2018), in their study of digital virtual consumption, highlight the need for future research with regard to how the changing digital landscape impacts rituals. In this vein, we broadly ask, how are consumer rituals shaped by digital virtual consumption?

We detail our findings based on in-depth interviews with fourteen users (ages 21 to 45) of Pinterest, a digital platform that allows users to collect, share, and organize "pins" (images and videos found online). The site claims usage among a third of American online users (Greenwood, Perrin, and Duggan 2016) and boasts 150 million active online users worldwide (Omnicores Agency Report 2017). We follow the conceptualization of Pinterest as a site for digital virtual consumption (see Drenten and Zayer 2018). In total, 506 pages of double-spaced text were analyzed.

We find digital virtual consumption (DVC) enables consumers to perform a wide range of rituals, from personal and small group rituals to rites of passage and aesthetic rituals. In particular, we leverage Molesworth and Denegri-Knott's theoretical work (2013, 223). They identify DVC as a space through which consumers "acquire and test out practices and subject positions, not always possible through either material real or the imagination on its own, but always

linked to both." We focus our analysis on how DVC enables family rituals in particular. We identify four ways DVC supports and enables family rituals: 1) they provide virtual ritual artifacts 2) they aid in locating ritual scripts 3) they build capacities in ritual performance and 4) they extend the reach of ritual audiences. This process, in turn, enables families to create and maintain their identity. Our findings illuminate the changing nature of family rituals in light of digital advances. We also reveal opportunities for marketers to become embedded in these rituals, and to aid in the betterment of consumers' lives through the solidification of family identities. For example, we find DVC serves to foster positive family rituals (e.g., family meal times; nightly parent-child bedtime rituals).

To demonstrate the four ways that Pinterest as a site for DVC supports family rituals, we offer these examples from our data. First, DVC provides virtual artifacts to support family rituals. Tom uses Pinterest to support bedtime rituals with his kids by maintaining a Pinterest board featuring French bulldog images. Tom says he and his kids share the dream of getting a French bulldog. For now, however, they use digital images to support their evening rituals.

*... yeah, I like to share [the pictures] with the kids too. At night, we like to look at French bulldog movies and pictures on here, and they are always like, 'Aww, let's get one like that!' It is just cool. We all snuggle together in bed. They will come in and be there, so we are physically close which is kind of cool. Instead of all of us on three devices, we are all on one device...just dreaming about having this dog is kind of fun too. (Tom)*

Thus, digital images act as virtual artifacts to support Tom's quality time spent with his children in the evening. DVC acts as an impetus to bring his family closer together—physically and emotionally.

Second, DVC aids in locating scripts for performing family rituals. Our data show various ways consumers turn to Pinterest for direction on how to execute family rituals. Rebecca, who is newly engaged, pins recipes to follow for her future family meals, in anticipation of creating new mealtime rituals with her fiancé: *"now I'm not just like cooking for myself, so I feel like I need to like cook a real meal rather than just make myself like half a sandwich"*. Third, DVC builds capacities in ritual performance. Consumers turn to Pinterest to support executing their ritual performances in the "real world." For instance, Kelsey pins Christmas list ideas to a Pinterest board shared with her parents, who can then click the links to shop for her. This type of capacity-building pinning practice is evident across the data to support a variety of family rituals (e.g., holiday traditions, family vacations, birthday-party planning). Fourth, DVC has the potential to extend the reach of ritual audiences by making family rituals viewable beyond the family unit. Thus, what once may have been a privately shared family ritual is instead emplaced in a public forum that is shared with friends and strangers via social media. For example, Emma's family has strict dietary guidelines due to their oldest son's peanut allergy, which shapes their family mealtime rituals. Emma shares peanut-related recipes and content, knowing her followers will see it: *"so people can see how my life can be affected by [my son's peanut allergy]."*

Emma uses DVC to educate others about the nuances in her family's mealtime rituals. Notably, some consumers utilize privacy settings on digital platforms to limit who can view their activities. In sum, our data suggest digital virtual consumption supports and facilitates family rituals. This process, in turn, enables the creation and maintenance of family identities.

### **SESSION OVERVIEW**

Much research in consumer behavior has embraced the idea that identity drives choice. Consumers like and choose products associated with the social categories that they belong to (Escalas and Bettman 2003; Reed 2004), and use brands and product choices to build and express their identities (Belk 1988; Berger and Heath 2007). In contrast to theoretical perspectives on the self-concept that construe it as dynamic and multi-faceted (Chen, Urminsky, and Bartels 2016; Markus and Wurf 1987), much work on how identity influences consumption has examined a single, stable identity's (i.e., a social category's) influence on choice. While recent calls have been made to examine identity-based consumption from a perspective more in line with a dynamic, multifaceted view of the self-concept (Reed and Forehand 2016), explorations of how multiple parts of or changes to the self-concept influence choice are relatively rare. Further, even though theoretical approaches to the self-concept include aspects of the self that are not social categories (e.g., Chen et al. 2016; Linville 1987; Strohminger and Nichols 2014; 2015), most work on identity-based consumption has focused on social categories as the driver of choice.

This session addresses the need to understand identity-based consumption with a more complex approach to the self-concept. These papers examine open questions in the identity-based consumption literature that cannot be addressed by considering identities in isolation and treating the self-concept as static. How do beliefs about the interactions and relationships between various parts of the self-concept influence identity-based choices? How do beliefs about how the self will change over time relate to future well-being? And, how do individual-level aspects of the self influence decisions?

Taken together these papers seek to answer the question of how the complex and dynamic self-concept influences choice. The first two papers in the session examine how the various identities, roles, and personal characteristics that make up the self-concept influence the use of mentally accounted funds and likelihood of displaying

identity-consistent behaviors. The third paper examines how beliefs about the dynamic nature of the self-concept—beliefs about how one might change over time—are related to future life satisfaction. The second and fourth papers examine how aspects of the self-concept beyond social categories, individual-level traits like goals and desires, and the need for self-efficacy, drive consumption decisions.

By embracing the perspective that identity-based consumption is influenced by a complex and dynamic self-concept, these papers provide valuable insights into how consumers' beliefs about the self drive their choices and outcomes. The research in this session also expands the study of identity-based consumption into new areas; it examines not only preferences for products and behaviors associated with the social groups that consumers belong to, but also use of budgeted funds, life satisfaction, and preferences for brand logos. Further, this session raises important questions regarding the relationship between identity-based choice and satisfaction, and category-level and individual-level aspects of the self. Overall, these papers provide both a more sophisticated view of how consumers think about the self and broaden the scope of identity-based consumption research.

## **Don't Forget the Accountant: Role-Integration Increases the Fungibility of Mentally Accounted Resources**

### **EXTENDED ABSTRACT**

Inherent in any instance of mental accounting (Thaler 1985, 1999) is the accountant: the individual who is labeling and tracking personal expenses. While this seems obvious when explicitly stated, most mental accounting research largely takes the accountant for granted and, instead, focuses on how manipulating specific components of the mental accounting process (e.g., the relevant or active mental account, the potential expense being considered, or the source of the funds in the account) can influence consumers' spending or consumption decisions.

In contrast, the current research focuses on the accountant and builds on two empirically established premises: (i) many mental accounts are constructed around goals (Brendl et al. 1998) and (ii) integrated roles (i.e., roles that are overlapping and influenced by each other), versus segmented roles (i.e., roles that are separate and uninfluenced by each other), have a higher degree of hedonic spillover. In combination, these two premises lead to the prediction that life roles being more integrated (vs. segmented) will result in greater fungibility of resources allocated to mental accounts corresponding with those roles. Thus, individuals with integrated life roles will be more likely to use funds allocated to a specific role-aligned account in pursuit of goals associated with a distinct, yet integrated life role. This prediction is supported across six studies.

In study 1, participants (N = 100) were given descriptions of two common life roles: the (i) work-life role and (ii) home-life role. Participants then indicated the extent to which they integrated/segmented their work and home roles using a slightly modified version of the Work-Family Role Integration-Blurring Scale (Ilies et al. 2009). Lastly, participants were asked to imagine that they maintained a home-expense and work-expense budget (similar to Cheema and Soman 2006) and were asked the extent to which spending money from one account on expenses related to the other account would feel "right," "good," and "easy to justify" (which were combined into a single measure of resource fungibility). A linear regression

revealed that the work-home role-integration measures significantly predicted the perceived fungibility of funds between participants' work-expense and home-expense budgets ( $\beta = .283, t = 3.10, p < .003$ ), as predicted.

Study 2, examining the mentally-budgeted resource of time, asked participants ( $N = 194$ ) to explicitly categorize themselves as having either integrated or segmented work-life and home-life roles. They were then asked to imagine that they were supposed to attend a family barbecue (in other words, they had budgeted time for their home role), but had decided to go to work to help with an emergency project. It was found that those with integrated (vs. segmented) roles (i) found it easier to justify this decision ( $p < .03$ ), (ii) would experience less regret about this decision ( $p < .001$ ), and (iii) would consider this decision "right" and be more likely to make the "same" decision (items combined;  $p < .031$ ). Thus, integrated participants treated their home-budgeted time as being more fungible.

Study 3 ( $N = 100$ ) replicated the main results of study 2 using the same decision context (the choice to leave the family barbecue), but did so by manipulating participants' perceptions that their work-life and home-life roles were integrated. This was done by having participants explain ways in which they either (i) allowed these two roles to overlap with each other or (ii) kept these roles separate and distinct.

While studies 1-3 all examined first-person effects, they were limited in the breadth of life roles that could be examined—those studies needed to rely on roles that most, if not all, participants would have. Study 4 turned to a third-person design to generalize the results to a broader set of life roles. First, participants' ( $N = 160$ ) personal perceived life-role integration/segmentation (using work-life and home-life roles as examples) were manipulated as in study 3. Then participants were told of another person, Sally, that was a student athlete. They learned that Sally, like themselves (per the role-integration manipulation) either integrated or segmented her student and athlete life roles. They were then told that she had allocated time for one role or the other (studying or practice), but that she had received a request to use that time for the other role (by a team captain or study group, respectively). As expected, participants indicated that Sally was more likely to change plans (i.e., treat her budgeted time as being more fungible) when she was integrated versus segmented ( $p < .04$ ).

Studies 5 and 6 replicated the basic effect using third-person scenarios examining purchase decisions. In short, study 5 found that participants ( $N = 165$ ) believed another person's likelihood of purchasing a summer dress (an expense more linked with one's home-life versus work-life) was unaffected by role integration when that person had a budget surplus in her role-aligned, "home clothing" budget (and, concurrently, a depleted "work clothing" budget). However, when this other person's "home clothing" budget was depleted but her "work clothing" budget had a surplus (which would force her to purchase the dress from the "wrong" account), participants believed that she would be less likely to purchase the dress if her roles were segmented versus integrated ( $p < .001$ ).

Similarly, study 6 ( $N = 172$ ) found that the source of funds (which has been shown to influence spending decisions in previous research: Reinholtz et al. 2015) impacted the expected likelihood of another person making a purchase only when that person maintained segmented (vs. integrated) roles ( $p < .001$ ). This is consistent with the previous findings since role integration makes mentally-accounted funds more fungible and, thus, less constrained in use by their source.

In sum, six studies using both first-person and third-person tasks find reliable and robust evidence that mentally-accounted for

resources (be it money or time) are treated as being more fungible when (i) the focal mental accounts correspond with salient or active life roles and (ii) the individual integrates (vs. segments) those roles. Thus, this research expands our understanding of both the boundaries of mental accounting and the consequences roles have on consumption decisions.

## Placing Identity into the Self-Concept: The Role of Causal Beliefs in Identity-Based Consumption

### EXTENDED ABSTRACT

It is well established that consumers' identities, the social categories they belong to, are a key driver of choice. Much of this research focuses on situational factors, particularly salience of an identity, to explain differences in consumers' likelihood of acting in identity-consistent ways (Forehand et al. 2002; Reed and Forehand 2016). However, within the same situation, consumers who consider themselves members of a given social category vary in their likelihood of engaging in identity-consistent behaviors. Thus, explaining these differences requires a focus on consumer's internal beliefs about these identities.

A recent theoretical account of self-concept representation (Chen et al. 2016) suggests that subjective beliefs about the causal relationships between aspects of the self-concept (including social categories but also individual-level characteristics like personality traits, morals, etc.) are a critical part of the self-concept. More specifically, Chen et al. (2016) found that people who see an aspect of their self-concept as more *causally central* (linked to many other features of the self-concept) perceive it as more defining of who they are as individuals than those who see the same aspect as more *causally peripheral*. Thus, our prediction is that consumers who believe that an aspect of their self-concept (e.g., being a football fan) is more causally central are more likely to behave in ways that are consistent (e.g., pay more to see their team play) with that aspect than those who believe that the same aspect is more peripheral.

In Studies 1A and 1B, we examined whether the causal centrality of being a fan of a football team related to an identity-consistent behavior, willingness to pay for tickets to see the team play. The studies were conducted with football fans at a time when the identity of being a football fan was very salient, during the 2016 (Study 1A) and 2017 (Study 1B) Super Bowls. So, differences in willingness to pay cannot be attributed to differences in salience of the football fan identity. In Study 1A ( $N = 253$ ), to measure causal centrality, we had participants report which other important aspects of their self-concepts caused them to be football fans (e.g., a participant might report that she was a football fan because of some of her important childhood memories) or were caused by them being football fans (e.g., a participant might report that some of his close friendships were a result of his football fandom). As predicted, participants who perceived fandom as causally central (involved in more causal relationships) reported greater willingness to pay ( $\beta = 57.74, p < .01$ ). The effect of causal centrality on willingness to pay persisted when controlling for income ( $\beta = 57.64, p < .01$ ).

In Study 1B ( $N = 242$ ), we replicated the effect found in Study 1A ( $\beta = 33.74, p = .027$ ) and examined the relationship between identity importance and causal centrality. We found that importance of being a football fan mediated the effect of causal centrality on willingness to pay ( $\beta = 11.34, 95\%$  Bootstrapped CI = [4.76 20.87]), suggesting that causal centrality contributes to identity importance and causal centrality may drive behavior via importance. This result is consistent with theoretical accounts that suggest that important aspects of the self-concept influence behavior more (Markus and Wurf

1987) and provides a novel psychological explanation for what it means for an aspect to be important to the self-concept.

In Studies 2A and 2B, we expanded our exploration into an aspect of the self-concept that is not a social category, the desire to buy environmentally-friendly products. We measured the causality centrality of the desire and had participants complete a series of hypothetical purchase decisions in which they chose between two versions of a product: an expensive environmentally-friendly version and a cheap conventional version. Replicating the results of Studies 1A and 1B, we found that people who perceived their desire to buy environmentally-friendly products as more causally central chose more environmentally-friendly products ( $\beta = .127, p < .01$ ).

In Study 2B ( $N = 300$ ), we examined the relationship between salience, the focus of much research on identity-based consumption, and causal centrality. In a  $2 \times 2$  design, participants were randomly assigned to a salience manipulation (a writing task about what being frugal or environmentally friendly meant to them) and we measured the causal centrality of their goal to be environmentally friendly. We found a main effect of causal centrality (replicating the results of Study 2A,  $t(298) = 2.66, p < .01$ ) and of salience such that people who wrote about environmental friendliness selected more environmentally-friendly products ( $t(298) = 2.43, p = .016$ ). There was no significant interaction ( $F_{(1,290)} = .18, p > .05$ ) suggesting that causal centrality and salience independently influence choice.

Finally, in Study 3 ( $N = 243$ ), we examined political identity (being a Democrat or Republican) during a time when it was very salient, the 2016 Presidential election. A logistic regression predicting whether participants voted for their party's candidate based on causal centrality of political party (the number of causal links political party had to other features) revealed that, as predicted, people who believed that their political party was more causally central were more likely to vote with their party than those who saw political party as more causally peripheral ( $\beta = .099$ , Wald  $\chi^2(1) = 8.67, p < .01$ ). Further, the relationship between causal centrality and voting held even controlling for satisfaction with the party's candidate and ideology (liberal vs conservative) ( $\beta = 1.54$ , Wald  $\chi^2(1) = 6.99, p < .01$ ), suggesting that causal centrality predicts identity-consistent behavior above and beyond simple preference (satisfaction and ideology).

In five studies we find evidence that consumers who perceive an aspect of their self-concept as more causally central are more likely to engage in identity-consistent behaviors. Further, we find evidence that causal centrality predicts these behaviors above and beyond simple measures of preference and the salience of an identity. Thus, the research provides a more nuanced understanding of identity-based consumption and highlights the need to understand how consumers think about their identities in the context of the broader self-concept.

## Examining the Link between Predicted Identity Change and Future Well-Being

### EXTENDED ABSTRACT

The relationships that people have with their future selves can be important predictors of the decisions they make in intertemporal contexts, where decisions have consequences at multiple points in time (Hershfield and Bartels 2018). Greater continuity with one's future self, for example, has been associated with lower discount rates (e.g., Bartels and Rips 2010), greater accrual of financial assets (Ersner-Hershfield et al. 2009), more ethical decision-making (Hershfield, Cohen, and Thompson 2012) and that the consideration of future consequences mediates the extent to which people regard inappropriate negotiation strategies as unethical (Study 2, and better health (Rutchick et al. 2018).

Crucially, this growing body of work has examined the link between future self-continuity and outcomes in a *cross-sectional* context: feelings about the future self, in other words, are always linked to current outcomes. In theory, if feeling more connected to one's future self results in decisions that are more patient in nature (e.g., choosing to save now rather than spend), then feeling connected to one's future self should also result in more positive outcomes at distant points in time. However, an alternative possibility may exist: disconnection from the future self could shield individuals from continually denying themselves pleasures in the present, allowing them to experience sustained satisfaction over time (Keinan and Kivetz 2008). Whichever the case, research has yet to examine whether heightened future self-continuity actually affects the well-being that the future self experiences.

The current research is the first to check in with the future self. Using a 10-year longitudinal dataset of thousands of Americans, we estimate how thoughts about one's future self in an initial survey correspond with life satisfaction 10 years later.

## Method

### Participants

We use 10-year panel dataset from the first two waves of the National Survey of Midlife Development in the United States (MIDUS). 4,963 respondents were surveyed in both the first wave (MIDUS I, 1994-1995; MIDUS I age range 20-75,  $M_{\text{age}} = 46.5$  years; 53.3% Female) and the second wave (MIDUS II, 2004-2006).

### Questions and Measures

Our main independent variable is a bottom-up measure of predicted identity change constructed from questions in MIDUS I regarding present and predicted traits. The 1995 survey asks "How calm and even-tempered are you now?" (*MIDUS I present trait*) and "How calm and even-tempered do you think you will be 10 years from now?" (*MIDUS I predicted trait*). The survey includes similar questions for caring, wise, willingness to learn, and energetic. Using methodology from Quoidbach, Gilbert, and Wilson (2013), we calculate the absolute predicted change for the five traits:

$$\text{predicted change in [trait]} = | \text{MIDUS I predicted [trait]} - \text{MIDUS I present [trait]} |.$$

Next, we take the sum of the absolute predicted changes of the five traits to get our primary independent variable, *Predicted Identity Change*.

The dependent variable, life satisfaction, is a combined 5-item response (where individuals rate on a 0-10 scale their life overall, work, health, relationship with spouse or partner, and relationship with children).

## Results

As our main analytical strategy, we regress life satisfaction in MIDUS II on predicted identity change from MIDUS I (with controls including age, gender, income, and education). For a conservative estimate, we further include life satisfaction from MIDUS I as a control. After controlling for the concurrent relationship between identity predictions and wellbeing, greater predicted identity change significantly predicts less life satisfaction ten years later ( $\beta = -0.07, t = -4.39, p < 0.001$ ; See table 1). Note, the standardized coefficient is interpreted such that a 1 SD increase in predicted identity change in 1995 is associated with a .07 SD decrease in life satisfaction in 2005. The general result implies that after controlling for wellbeing in 1995, those that predict greater identity change experience less life satisfaction ten years after the original prediction.

These results holds after a number of robustness checks—using various controls, including alternate dependent variables, and running the analyses on predicted changes for each trait separately. Furthermore, we decompose the effect into predictions of trait improvement and predictions of trait decline, and show that predicted ID change in *either direction* is associated with less future life satisfaction.

We acknowledge that we measure predicted identity change differently than the previous research on psychological connectedness (Hershfield and Bartels 2018). However, a post-test validation study (N = 300) indicates that the bottom-up measure of predicted identity change is similar to the top-down, global assessment of future self similarity commonly used in previous research. Namely, bottom-up predicted identity change significantly correlates with a common top-down measure from the literature ( $r = .39, p < 0.001$ ), has moderately high test-retest reliability, as shown over a two-week period of time (N = 237;  $r = 0.64, p < 0.001$ ), and shows strong convergent validity in that it correlates with various outcome measures at similar magnitudes compared to the top-down measure.

## Conclusion

The research to date on the future self examines how measuring and manipulating predicted identity change corresponds with *current* outcomes. That said, the intertemporal decisions that are affected by impoverished relationships with the future self, such as inflated discount rates, lower asset accrual, and worse ethicality, should most profoundly negatively affect *future* wellbeing. We present the first project that demonstrates how greater predicted identity change corresponds with less subjective wellbeing ten years after the original prediction.

## When Prominent Logos Make You Feel Competent

### EXTENDED ABSTRACT

People want to feel good about their abilities, especially when they engage in performance-related activities that require skill (Alicke and Sedikides 2009, Leary 2007). We posit that when consumers engage in performance-related activities, brand logos displayed prominently (vs. subtly) on products help consumers feel more efficacious.

To conceptualize our research, we build on recent work examining whether, when, and why consumers prefer products prominent versus subtle logos (e.g., Han et al. 2010, Berger and Ward 2010). In contrast to that work's examination of this issue through the lens of social signaling, we study consumers' preferences for prominent versus subtle logos through an alternative theoretical lens of self-efficacy, which can enrich our understanding of logo preferences and yield novel predictions.

Self-efficacy refers to people's beliefs about their capabilities or competence to perform a specific task (Bandura 1994). Feeling good about one's ability to perform tasks is a fundamental psychological need (Alicke and Sedikides 2009). We posit that consumers prefer products with prominent (vs. subtle) logos as a strategy to enhance their feelings of efficacy. We argue that our proposed effect should materialize in product categories that have a performance-related component and thus involve consumer activities that require a certain level of skill and ability. Examples of such consumer activities include playing an instrument, doing sports, cooking, or home improvement.

We tested our proposed effect, the underlying process, and boundary conditions in nine studies that used diverse product categories, contexts, and samples.

In a pilot study, we examined the relationship between the size of brand logos and price in performance-related product categories. In contrast to the previously observed negative price-logo size relationship for non-performance products (i.e., that more expensive products have less prominent logos; e.g., Han et al. 2010), we observed a significant *positive* price-logo size relationship for performance products (i.e., that more expensive products have *more* prominent logos).

In Study 1A (N = 240), we tested whether consumers have a stronger preference for products with prominent (vs. subtle) logos for performance- versus non-performance products. Participants were randomly assigned to one of three product categories (gloves, backpacks, T-shirts) and one of two performance conditions (performance vs. non-performance). Participants were either told that the product was intended for a performance situation (e.g., gloves were intended for skiing) or a non-performance situation (e.g., gloves were intended for going out in winter). After choosing a brand for the product, participants customized their product by drawing the brand logo on a plain picture of the product. Participants drew (and hence preferred) bigger logos in the performance (vs. the non-performance) condition (effect of performance:  $F_{(1, 205)} = 9.45, p < .05$ ; other effects *NS*). In Study 1B, we replicated these results using choices between products with prominent logos versus no logo as the dependent variable ( $F_{(1, 1120)} = 24.44, p < .001$ ).

In Studies 2A and 2B (N = 529), we tested whether self-efficacy mediates this effect. Participants were assigned to a performance-versus a non-performance context and were asked to choose between a product with a prominent versus a subtle logo. Preferences for the product with a prominent (vs. subtle) logo were stronger in a performance context than in a non-performance context ( $\beta = 0.62, p < .05$  for choice in Study 2A;  $F_{(1, 242)} = 25.15, p < .001$  for preference in Study 2B). This effect was mediated by feelings of efficacy ( $CI_{95\%}$  [0.03, 0.65] in Study 2A;  $CI_{95\%}$  [-0.68, -0.26] in Study 2B). In Study 2C, we examined preferences for prominent (vs. subtle) logos in a private versus public performance-related setting, and we found that people preferred a prominent logo in both private and public settings (effect of public vs. private setting:  $F_{(1, 201)} = 1.64, p > .05$ ), showing that social signaling (present only in public settings) does not prevail over self-efficacy motives in driving the effect (present in both public and private settings).

In Study 3 (N = 322), we examined the first boundary condition of the effect – whether the brand is specialized in the activity versus not (i.e., a generic brand that also produces products for other activities). Since a generic brand is not specifically focused on performance in the focal activity, its logo should not promote an efficacious self-view in the activity. Accordingly, preferences for prominent logos for performance products were reduced when the focal brand was generic rather than specialized ( $F_{(1, 318)} = 7.47, p < .05$ ).

In Study 4 (N = 243), we tested whether the preference for a prominent (vs. subtle) logo for performance products is reduced when consumers are not motivated to improve in the given activity. If consumers are not motivated to improve their skills, they are also not motivated to feel efficacious; therefore, they should not look for products to enhance their feelings of efficacy. As predicted, we found that preferences for prominent logos for performance products were reduced when participants were not motivated to improve their skill in the activity vs. when they were motivated ( $F_{(1, 160)} = 9.29, p < .01$ ).

Finally in Study 5 (N = 147), we tested whether the preference for a prominent (vs. subtle) logo for performance products is reduced when the product is used for an activity that is easy, and hence requires little skill and involves low desire to feel efficacious (vs. difficult, and hence involves a lot of skill and high desire to feel effica-

cious). Our effect held when the activity was difficult ( $F_{(1,97)} = 8.69$ ,  $p < .01$ ), but not when the activity was easy ( $F < 1$ , NS).

In sum, this research broadens the existing knowledge connecting brand logo prominence to consumers' product preferences. Our research contributes to the literature on self-efficacy by proposing a new antecedent of self-efficacy, consumption choices. Moreover, the conceptual distinction between performance- and non-performance related products may improve the understanding of specific consumer phenomena (such as product preference for prominent logos). Apart from its theoretical value, this distinction is also relevant from a substantive perspective as performance products account for a large share of the consumer goods market.

### SESSION OVERVIEW

Despite the extensive research regarding framing effects on choice and perceived experience, we know very little about the role of task and option frames in the online environment. The proposed session examines this topic from a variety of angles. The unique characteristics of online shopping experiences (e.g., virtual shopping cart, multi-stage checkout process, side-by-side product comparison) present new opportunities for marketers to frame decisions in ways to increase customer engagement and revenues. These issues also raise important questions regarding the psychological processes triggered by alternative frames. The papers included in proposed session identify four specific ways in which framing matters in the online environment, including an examination of the psychological processes underlying such effects.

The first two papers examine how choice processes are represented when online consumers construct their consideration sets from a wide array of products. In particular, Perfecto and Nelson study how matching the valence of the frame (choose vs. reject) and the valence of the product attributes (positive vs. negative) can improve overall consumer experience. To that end, they find across four studies that consumers who derive their consideration set through matched valence—choosing from desirable products or rejecting from undesirable ones—feel more satisfied with their decision and enjoy the final product more than those who make “mismatched” decisions.

In the second paper, Park and Simonson examine alternative frames of rejection during consideration set formation. Throughout three studies in web-based store environments using virtual shopping carts, the authors vary the decision to pass on a product as either an active rejection (e.g., “reject this item”) or a passive rejection (e.g., “look at other items”) and find that active (vs. passive) rejection leads to a larger shopping cart and reduces cart abandonment.

The next two papers identify when and the extent to which dynamic option framing could be most effective in the online context. Specifically, Duke and Amir argue that compared to a two-stage format (e.g., “whether” → “how many” to buy), asking simultaneously “whether” and “how many” to buy in a quantity-integrated format

(e.g., not buy, buy 1, buy 2, buy 3) can significantly increase purchase likelihood. In a series of 22 studies, the authors find support for the effect across a number of online products and purchase contexts.

In the fourth paper, Stich, Spann, and Häubl identify another common option representation format for online products—opaque products. The authors suggest that through initially masking some attributes of a product from consumers and revealing only once a purchase has been completed, marketers may (1) offer an “easy way out” when choice among fully specified products is difficult, (2) enable consumers to explore products they would not otherwise be aware of, and (3) add an element of fun and excitement to the purchase decision.

Taken together, these papers identify distinct web-based features that give birth to novel frames and product representations. We expect the session to have broad appeal, given that these findings provide important implications for consumer behavior theory development and practical applications in the digital age.

## **Improving Customer Satisfaction Online through Valence Matching**

### EXTENDED ABSTRACT

Consumers are frequently stuck with decisions they would rather not make, between outcomes they would rather not obtain. For example, everyone would like to fly first-class but budgets restrict most to choosing seats in coach. Work on lose-lose decisions has shown that decision makers feel worse about their decisions than if someone else had made it for them (Botti and Iyengar 2004)—the opposite of the prevailing wisdom that people enjoy being able to decide for themselves (Langer 1975) or decide from positive options (Perfecto et al. 2017).

However, research on congruence in construal level theory (Liberman and Trope 2008) and regulatory fit (Higgins 2000) suggest that there is hope for decision makers faced with only bad options: matching the valence of the frame to fit with the valence of the options. Taking these literatures together, in an earlier project, we found that reframing the same lose-lose decision to be negative (e.g., “Reject the option you don’t want”) can leave participants feeling nearly as good about their lose-lose decisions as they did about win-win decisions (Perfecto et al. 2017).

Nevertheless, these studies used very abstract stimuli (e.g., rating liking of pairs of words) in artificial settings. As consumer researchers, we should be interested not just in reliable effects, but also in their applicability to consumers’ interaction with the marketplace (Inman et al. 2018). To that end, the present paper takes Perfecto et al.’s (2017) idea of attribute matching to more realistic consumer contexts and, importantly, to investigating actual consumption. Across four studies, we find that participants who make decisions matched on valence—choosing from positive options or rejecting from negative ones—feel more satisfied with their decision and enjoy the outcome more than participants who make “mismatched” decisions.

Study 1 (N = 406) demonstrates this basic effect with consumer goods. Consumer goods are an interesting case for valence matching since, by virtue of having a nonzero price, they do have some positive value. However, some goods are certainly more highly valued than others. With that in mind, participants were shown a pair of desirable goods—two new iPhones—and a pair of less desirable goods—two

flip phones—and were asked to make a selection. Furthermore, because online shopping sites (including Apple) frequently allow customers to compare a small number of items side-by-side, participants were told that they had put both options in their cart in order to better compare them. Finally, to make their selection, half of participants were asked to select the phone they would prefer to keep in their cart to buy; the other half were asked to select the phone they would prefer to delete from their cart before completing their purchase. After each decision, participants reported how certain they were that they selected the better phone and how satisfied they felt with their decision. Supporting previous research, when the valence of the options matched the valence of the frame (i.e., keeping iPhones and deleting flip phones), certainty and satisfaction were significantly higher than in mismatched conditions ( $t$ 's > 3.98,  $p$ 's < .005).

Study 2 ( $N = 512$ ) applies this effect to a more realistic scenario. Although companies frequently allow visitors to their websites to whittle down their offerings to a smaller set (the last step of which featured in the previous study), rarely are so few options offered to begin with. To that end, Study 2 was nearly identical to Study 1, except participants first saw several options: eight iPhones or eight flip phones. For each set, participants were asked to select two phones for closer consideration: half of participants were asked to select the two phones they wanted to keep under consideration, half selected the six phones they wanted to remove from consideration. Then, the study proceeded as in Study 1. Despite the preceding decisions, participants who made matched final decisions reported greater certainty and satisfaction than participants who made mismatched decisions ( $t$ 's > 3.01,  $p$ 's < .02).

The goal of Study 3 ( $N = 242$ ) was to investigate the downstream consequences of this increased satisfaction from matching. Participants evaluated 3 pairs of short videos, pretested to be entertaining or boring. On each trial, participants were asked to select by choosing or rejecting. After making their selection, participants reported how easy the decision felt to make in addition to their satisfaction. Then, after watching each video, participants rated it on four dimensions: liking, engagement, humor, and likelihood of sharing with friends, creating composite measure of enjoyment. In line with the previous studies, participants rated videos selected from a matched decision as marginally more enjoyable than participants who rated the same videos from a mismatched decisions ( $t$ 's > 1.96,  $p$ 's < .072).

Studies 4a and 4b extend this finding to intertemporal discounting, specifically selecting a plan for retirement. Since matched decisions feel easier to make (Study 3) and are made faster (Perfecto et al. 2017; Liberman and Trope 2008), consistent with System 1 thinking, perhaps participants will also be less patient, given matched decisions. Study 4a ( $N = 502$ ) looks first at abstract discounting decisions (i.e., smaller sooner vs. larger later amounts). Participants made choices or rejections across 12 trials, including both pure gains and losses. Participants' responses from matched decisions were less patient than those from mismatched decisions ( $t$ 's > 3.23,  $p$ 's < .003). In Study 4b ( $N = 608$ ), participants were shown 4 pairs of retirement plans, highlighting either gains (a secure future) or losses (paycheck deductions) involved, and asked either to choose or reject. Participants making matched decisions were more likely to select plans with lower deductions ( $t$ 's > 2.14,  $p$ 's < .031).

Together, these four studies show that by matching the valence of a decisions frame with that of its options, one can facilitate consumer decision making. When a company is selling less-than-desirable goods, they can frame the purchase decision as a rejection of alternatives and improve the customer's satisfaction and even enjoyment of the product. Employers, too, can improve their employees'

wellbeing by framing their retirement options in a matched manner, to nudge them towards greater patience.

## Shades of Rejections: The Effect of Rejection Frames on Commitment to Choice

### EXTENDED ABSTRACT

In the age of Amazon.com and online shopping, consumers today face an ever increasing number of options in the online market. As a result, customers often need to pass on more products than they choose to buy. Despite the prevalence of rejection of alternatives in the marketplace, the traditional focus of consumer research has been on understanding how decision makers navigate and *choose* among a set of alternatives (Tversky and Kahneman 1981; Bettman, Luce, and Payne 1998; Dhar and Simonson 2003). In fact, relatively little attention has been paid to the psychology of passing on (vs. choosing) an alternative and the different ways of framing the rejection.

In this research, we propose that the framing of decisions to *not* include an item to a consumer's consideration set can influence the experiential aspect of how the consumer constructs her consideration set, which in turn affects her commitment to the constructed set. Specifically, we test this idea in the online context, where the experience of adding items to the consumer's cart impacts the way the consumer ultimately evaluates the items in her cart and makes a purchase from the cart. Throughout four studies, we allow participants to browse through consumer products and add items to their shopping cart for reconsideration. When asking participants whether they would like to add the product to their cart, we vary the framing of decisions to pass on the product as either an active rejection (e.g., "reject this item") or a passive rejection (e.g., "look at other items") and examine its downstream psychological and behavioral consequences.

Study 1 ( $N = 604$ ) asked participants to imagine shopping for a microwave oven at an online store. Participants evaluated nine microwaves, one at a time, and decided between two buttons whether to add each microwave to their cart for reconsideration. The button to add was "add to shopping cart", whereas the decision to *not* add varied across three conditions ("reject this item", "look at other items", no button (control)). Participants then proceeded to their cart, where they found the items they had added earlier and were asked to buy one of them or the no-choice option. We found that when the option to not add an item was framed as "reject", individuals added more items to their cart compared to those in the "look at others" and the control condition  $M_{reject} = 3.57$  vs.  $M_{look\ at\ others} = 3.13$ ,  $M_{control} = 3.14$ ;  $F(2, 601) = 3.67$ ,  $p = .026$ ). Furthermore, individuals in the "reject" group were more likely to purchase a microwave oven from their cart (92.8% purchase likelihood) than those in the "look at others" (88%) and the control (86.7%);  $\chi^2(1) = 4.28$ ,  $p = .039$ . We also found longer decision time for the two rejection conditions compared to control  $M_{reject} = 5.37$  vs.  $M_{look\ at\ others} = 5.56$ ,  $M_{control} = 1.88$ ;  $F(2, 601) = 14.64$ ,  $p < .001$ ), indicating that the two rejection modes did not differ in their processing ease or deliberation.

Study 2 ( $N = 387$ ) investigated whether rejection elicits a greater sense of decision. Using a similar design, participants reviewed nine microwaves and were instructed that they could reconsider their previous options by clicking on them again. Consistent with our prior finding, the "reject" group added more items to their cart ( $t(385) = 2.102$ ,  $p = .036$ ) and were more likely to purchase from their cart compared to the "look at others" condition ( $\chi^2(1) = 4.06$ ,  $p = .044$ ). More importantly, individuals who passed on items via "reject" (vs. "look at others") were less likely to revisit and reconsider the items they had previously rejected ( $t(385) = 2.3$ ,  $p = .022$ ).

Study 3 ( $N = 219$ ) tested the underlying mechanism by asking participants to provide a reason for their choice. We found in a 2 (reason vs. no reason)  $\times$  2 (rejection frame: “reject this item” vs. “look at other items”) between-subjects design that when individuals had to provide reason for their choice, the cart size difference between the two rejection frames was no longer significant ( $M_{reject\ without\ reason} = 3.98$  vs.  $M_{look\ at\ others\ without\ reason} = 3.07$ ,  $p = .02$ ;  $M_{reject\ with\ reason} = 2.18$  vs.  $M_{look\ at\ others\ with\ reason} = 2.3$ ,  $n.s.$ ). This is because the threshold for adding to the cart has become higher when reasons for/against are articulated, and their willingness to add is not diminished by the reluctance to reject. We also observed that reason based choice moderates the framing effect on purchase likelihood.

Study 4 ( $N = 366$ ) further tested the mechanism and directly manipulated the selection threshold. Through a 2 (cart threshold: high vs. low)  $\times$  2 (rejection frame: “reject this item” vs. “look at other items”) between-subjects design, we found that the two rejection frames differed in their cart size when given a high threshold (“add up to 3 items”), but not when items could be added relatively freely (“add at least 8 items”);  $M_{high\ threshold-reject} = 2.54$  vs.  $M_{high\ threshold-look\ at\ others} = 2.32$ ,  $p = .085$ ;  $M_{low\ threshold-reject} = 10.44$  vs.  $M_{low\ threshold-look\ at\ others\ with\ reason} = 10.63$ ,  $n.s.$  The cart threshold also moderated the effect of rejection framing on the commitment likelihood.

In four studies, we demonstrate that framing of rejection can influence consumers’ consideration set size and their subsequent commitment to purchase from the set. Overall, this research has not only theoretical implications for understanding different rejection motivations but also practical implications for marketers to reduce shopping cart abandonment and recapture online consumers’ commitment.

### The Quantity Integration Effect: Integrating Purchase and Quantity Decisions Increases Sales by Providing Closure

#### EXTENDED ABSTRACT

Consumers have countless opportunities to purchase products in multiple quantities. For example, when shopping online, a customer may encounter a pop-up asking, “Would you like to add any cookies to your order?” with options, “No” or “Add to cart.” She would respond by choosing whether or not to buy, and could later adjust the quantity. Alternatively, this appeal could be quantity-integrated, requiring her to simultaneously indicate whether and how many to buy, with options such as: “No thanks,” “Add 1 cookie to cart,” “Add 2 cookies to cart,” and “Add 3 cookies to cart.” Although these two selling formats provide consumers with the same ultimate choice (whether and how many cookies to buy), we find that quantity-integrated formats significantly increase purchase likelihood.

Twenty-two hypothetical and consequential experiments with over 13,000 observations find evidence of this “quantity integration effect.” Overall, they find a 40% increase in average likelihood of purchase, and an increase in overall sales volume of 29%. The effect persists across myriad product offers and purchase contexts (e.g., buying for oneself vs. others), although an important moderator exists: the attractiveness of the product ( $\beta = -.19$ ,  $t = -3.02$ ,  $p = .005$ ). The effect is largest among product offers that are the least naturally attractive. Thus, a managerial strategy of changing a two-stage appeal to a quantity-integrated appeal appears most effective for the product offers that need it most.

We rule out several explanations for this effect. First, two-stage formats tend to initially offer only two options (e.g., “buy” vs. “don’t buy”), while quantity-integrated formats tend to offer one non-pur-

chasing option (e.g., “don’t buy”) and multiple purchasing options (e.g., “buy 1,” “buy 2,” “buy 3”). Thus, purchasing takes up a greater share of the options in a quantity-integrated decision, which may lead individuals to choose it more (Fox, Ratner, and Lieb 2005). Yet, we find a significant quantity integration effect even when the maximum purchase quantity is only one. In Study 1, participants ( $N = 600$ ) imagined ordering a pizza online and encountering a pop-up advertising a sale on Coke. They could purchase a maximum of 1, 3, or 5 Coke bottles (between-subjects). Two-stage participants answered, “Would you like to add any 2 liter bottles of Coke to your order?” with either “yes” or “no.” Quantity-integrated participants answered, “How many 2 Liter bottles of Coke would you like to add to your order?” with options “0” and “1” (when the maximum quantity was 1, and “2” and “3” as additional options when the maximum quantity was 3; etc.). Significantly more quantity-integrated (57%) than two-stage (40%) participants purchased soda ( $\chi^2(1) = 22.94$ ,  $p < .001$ ). Importantly, this effect was significant at all maximum quantity values ( $p$ 's  $< .05$ ), including one, where there were two choice options in both formats.

Further, the effect arises even when the phrasing of the questions is identical in both formats. In Study 2 ( $N = 201$ ), participants imagined encountering a chewing gum sale, where they could purchase up to five packs. All participants indicated what they “would do in this situation.” For two-stage participants, the options were: “Not buy any” and “Buy.” For quantity-integrated participants, the options were instead: “Not buy any,” “Buy 1 pack,” (...) “Buy 5 packs.” Still, significantly more quantity-integrated (67%) than two-stage (45%) participants purchased gum ( $\chi^2(1) = 9.37$ ,  $p = .002$ ).

Thus, differences in the number of choice options or phrasing of questions cannot explain the quantity integration effect. Instead, we propose it arises because of an asymmetry in the cognitive closure afforded by the two formats. Purchasing in a quantity-integrated format is more specific (e.g., “buy 1,” “purchase 3”) than it is in a two-stage format (e.g., “buy,” “add to cart”). Moreover, purchasing in a two-stage format is inherently less complete—it requires the subsequent selection of a quantity. Thus, making a purchase is necessarily less ambiguous, more structured, more precise, and more complete in a quantity-integrated format; these characteristics define “cognitive closure” (Webster and Kruglanski 1994). As consumers tend to seek closure in their choices, we propose the higher cognitive closure afforded by quantity-integrated (vs. two-stage) formats drives the effect.

Study 3a tests for differences in closure. Participants ( $N = 266$ ) imagined encountering a candle sale and chose whether to purchase in either a quantity-integrated or quantity-sequential format. Again, the quantity-integrated format yielded higher purchase rates (51% vs. 26%;  $p < .001$ ). After their initial decisions, participants respond to items measuring choice closure (Gu, Botti, and Faro 2013), such as, “To what extent do you feel you have reached closure about your choice?” Consistent with expectations, non-purchasers (for whom the purchasing process is completely finished) reported higher closure than purchasers ( $\beta = 1.07$ ,  $t(263) = 7.01$ ,  $p < .001$ ). More importantly, quantity-integrated participants reported higher closure ( $\beta = .41$ ,  $t(263) = 2.74$ ,  $p = .007$ ) than two-stage participants, supporting our framework.

To corroborate the role of cognitive closure, Study 3b participants ( $N = 603$ ) responded to the Study 2 scenario and completed the Need for Cognitive Closure scale (NFCC; Roets and Van Hiel 2011). Again, significantly more quantity-integrated (31%) than two-stage (22%) participants purchased ( $\chi^2(1) = 5.45$ ,  $p = .02$ ). Further, the selling format interacted with NFCC ( $\beta = -.29$ ,  $z = -2.17$ ,  $p = .03$ ). A floodlight analysis revealed that the quantity-integrated format

increased purchase among individuals moderate to high in NFCC (3.84 out of 6 and above; 60% of participants). However, individuals low in NFCC, who are influenced very little by the allure of closure, showed no quantity integration effect.

Broadly, individuals face many decisions that could be framed as two-stage or quantity-integrated decisions: whether and how much to invest in the stock market, whether and how much to exercise, whether and how much to volunteer, and more. In examining purchase decisions, we identify a critical difference in how individuals respond to these two choice processes, opening the door to further exploration of the power of integrating decisions to act and quantity decisions.

### Product Transparency in Online Selling Mechanisms: Consumer Preference for Opaque Products

#### EXTENDED ABSTRACT

Selling opaque products refers to a marketing practice where some attributes of an offered good or service are initially concealed from buyers and revealed only once a purchase has been completed (Fay 2008; Jerath et al. 2010). Opaque products represent inherently dynamic choice options because they involve the chance of getting any product from a set of known (or unknown) alternatives to be revealed after purchase. While the concept of opaque products is very general, most real-world implementations of it are currently in the domain of online shopping.

Since opaque products are not concrete but “virtual” products, they allow sellers to extend their product line without incurring the cost of developing new products or services (Fay and Xie 2008). This virtual nature also allows the seller to dynamically customize the product. Hotwire and Priceline were among the pioneers of this selling strategy. They offer, for instance, opaque hotel bookings, hiding the hotel’s name and exact location from their customers until after the transaction has been completed. However, opaque selling has become a widespread practice beyond the travel industry. Trading under various names (e.g., grab bag, lucky bag, or mystery bag), a number of major online retailers have started to sell opaque products. Amazon has recently begun to offer thematic surprise boxes, and at least 900 different sellers are listing opaque products on Alibaba Group’s Taobao.com platform (Chu and Manchanda 2016; Fay et al. 2015).

While prior research has thoroughly examined what motivates sellers to offer opaque products and the conditions that make this marketing practice effective (Rice et al. 2013), very little is known about consumers’ preference for such offers. Prior research on the phenomenon commonly assumed that consumers are rational and forward-looking, choosing the product that maximizes their expected utility. Consumer preference for an opaque product thus depends on consumers’ valuations of the non-opaque alternatives that compose it, as well as their expectations about the likelihood of each of the non-opaque alternatives turning out to be the opaque product. Consequently, consumers demand for opaque products is driven by price discounts that compensate for the uncertainty about the characteristics of the product at the time of purchase.

The central thesis of the present research is that, under some circumstances, consumers might have a preference for opaque (vs. fully specified) products even in the absence of a discount or other economic incentive. We propose three psychological mechanisms that are potential drivers of such a preference – choosing an opaque product may (1) offer an “easy way out” when choice among fully specified products is difficult, (2) enable consumers to explore prod-

ucts they would not otherwise be aware of, and (3) add an element of fun and excitement to the purchase decision.

We examine the proposed mechanisms in three online experiments. Study 1 investigates whether people choose opaque products even when non-opaque (i.e., fully specified) products are readily available, and whether they are more likely to do so the more difficult they perceive the choice to be. In this experiment, we test the hypothesis that greater choice difficulty, driven by the number of fully specified alternatives, promotes consumer choice of an opaque product. Study 2 examines the impact of choice difficulty on opaque product choice in a paradigm with real consequences. In this experiment, we manipulate choice difficulty via the composition (rather than the size) of the set of fully specified alternatives that are available. Study 3 investigates the role of consumers’ desire to explore, and of the fun and excitement that opaque products might add to the purchase decision, in motivating consumers to choose such products. In this experiment, we manipulate both the availability (yes vs. no) and the nature of the opaque product (included in the set of specific products vs. a different product).

Evidence from the three experiments demonstrates that consumers frequently choose opaque products even when fully specified alternatives are readily available, and it provides support for each of the three proposed mechanisms. In particular, we find that greater perceived choice difficulty promotes consumer choice of opaque products. The more difficult choices feel for consumers, the more likely they become to take the “easy way out” by choosing an opaque product. The choice difficulty that results in greater preference for opaque products can arise from both the size of the set of fully specified products that are available and the composition of that set (e.g., the presence or absence of a dominant alternative). In addition, we show that consumers’ desire to explore is a key driver of preference for opaque products. The concealment and eventual revelation of specific product information are essential features of an opaque product, implying that consumers can discover something new when choosing such a product. Moreover, our results show that the anticipated pleasure from experiencing surprise (and uncertainty resolution) also motivates consumers to choose opaque products. Consumers intentionally seek out the uncertainty involved in opaque products because this adds an element of excitement to the purchase decision.

### SESSION OVERVIEW

When a consumer contemplates a purchase, she must determine whether she currently has sufficient funds, and whether the purchase would leave her with enough funds for the future. Such decisions require judgments about both present and future financial resources.

A growing literature investigates perceptions of present and future financial flexibility. People generally believe they will have more time and money in the future (Zauberman and Lynch 2005). Perceptions of resource availability alter the strategies by which people plan, and whether they feel they must make sacrifices due to a paucity of resources (Fernbach, Kan and Lynch 2015). Perceptions of future resources are skewed by the future feeling closer, and more typical, than the past (Caruso and Van Boven 2013; Sussman and Alter 2012). The papers in this session build on prior research, investigating how perceptions of financial resources in the present and future influence spending and saving.

The first paper offers a novel influence on the pain of payment. The authors link pain of payment and financial slack, arguing that perceived decreases in financial slack are one possible antecedent to the pain of payment. They demonstrate an association between the extent to which a purchase reduces perceived slack, and the extent to which it is painful.

The second paper demonstrates that the effectiveness of budgeting is not uniform in time. When consumers create a budget, they experience some degree of pain due to a new financial commitment. However, over time they hedonically adapt, incorporating the new commitment into their status quo. As such, the effect of the budget dissipates. Four studies—including scenarios and real-world manipulations—provide evidence consistent with their hypotheses.

The third paper demonstrates a simple tool for de-biasing consumers' predictions about their future financial situations. Because people anticipate the future being more typical than the present, they have trouble imagining unplanned expenses arising in the future. The authors demonstrate with lab and field data that simply asking people to list reasons why future expenses may be *atypical* can mitigate or entirely eliminate this bias.

The fourth and final paper, demonstrates that approaching the end of a budgeting cycle can alter behavior. Analogous to a lab group attempting to spend money that will disappear at the end of a fiscal period, consumers become less thrifty and more risk-seeking towards the end of their budgeting periods.

Our session contains four papers that shed new light on how perceptions of financial resources in the present and future influence saving and spending. The papers offer lab and field / secondary evidence across multiple studies, and each aims to be published in a top tier marketing journal. We believe that the present session will have specific appeal to researchers studying consumer financial decision making. We also believe the session will generate interest more broadly, as the topics—spending, budgeting, saving, and accruing debt—are important consumer topics that manifest in many subfields of study.

### A Slack-Based Account of Pain of Payment

#### EXTENDED ABSTRACT

Pain of payment is the negative emotion a person may feel when making a purchase. We propose a novel influence on pain of payment that builds from prior work on financial slack (Zauberman and Lynch 2005) and mental accounting (Henderson and Peterson 1992; Thaler 1985, 1999).

Financial slack is “the perceived surplus (or deficit) of spare money an individual has at a given point in time” (Berman et al. 2016). People are averse to reductions in financial resources (Hobfoll et al. 2003), here operationalized as perceptions of financial slack. We propose that the more a purchase decreases one's slack, the more psychologically painful it will feel.

Consistent with past research, we suggest that slack judgments are formed in a manner consistent with mental accounting—people behave as if they (i) identify the mental accounts relevant to financial slack, (ii) judge each account's balance, and (iii) combine these judgments into an overall evaluation of financial slack. Critically, each mental account a consumer has may factor more or less into judgments of slack (Morewedge, Holtzman, and Epley 2007; Sussman and Shafir 2012). We predict that the more a mental account factors into judgments of slack, the more painful it will be to deplete.

We test this idea in study 1. We ask participants to rate nine financial profiles of other individuals. The profiles are comprised of four accounts (checking, savings, credit card debt, physical cash) that vary in value, allowing us to recover which accounts are most mentally related to slack for each individual. We then ask participants how painful it would be for them (the participants) to make purchases out of each of the four accounts. We find that the extent to which an account contributes to slack judgments predicts pain of payment out of that account ( $\beta = 1.90$ ,  $t(131.98) = 2.59$ ,  $p = .011$ ). Two replications (omitted for brevity) lend additional support, and suggest that the more frequently an account is used, the more it loads on judgments of slack, and the more painful it is to deplete.

Studies 2–4 seek to manipulate the extent to which a mental account factors into slack judgments, thereby manipulating pain of payment from them. In study 2, participants ( $n = 101$ ) imagined having \$1000 divided between either five different or two different mental accounts (between subjects). We reasoned that the more mental accounts present, the less any one would factor into judgments of slack (Anderson 1974; Kruglanski et al. 2002). As predicted, equat-

ing total amount of money one has, an equivalent transaction-reduced perceived slack more (7-pt scale;  $M = 3.10$  vs  $3.80$ ,  $t = 2.60$ ,  $p = .01$ ) and was more painful (7-pt scale;  $M = 3.21$  vs  $3.80$ ,  $t = 1.78$ ,  $p = .08$ ) when consumers had fewer total mental accounts.

Study 3 manipulates the extent to which a mental account contributes to slack using the phenomenon of *earmarking* (designating funds for a specific purchase). When funds are earmarked, they feel as though they have already been spent (Webb and Spiller 2014). Given that they feel spent, they should not contribute to one's sense of financial slack. By virtue of not contributing to slack, they should be less painful to spend. Participants ( $n = 299$ ) imagined spending money on either a book, a gift, or car repairs. As a manipulation of earmarking, they imagined either spending out of their checking account (non-earmarked), or a purchase-specific fund (e.g. a car-repair fund; earmarked). Across products, participants rated spending earmarked funds as less painful than spending non-earmarked funds ( $\beta_{\text{earmarking manipulation}} = -.80$ ,  $t(296.04) = -3.05$ ,  $p = .003$ ). This effect was mediated by perceived decreases in slack (95% BCCI [.04, .29]).

Study 4 manipulated the extent to which mental accounts were factored into slack by manipulating the fungibility of a mental account. We reasoned that more fungible resources (resources that have fewer limitations on where and how they can be spent; e.g. cash versus a gift card) should contribute to slack more. Participants ( $n = 200$ ) imagined that they had to purchase a textbook on Amazon.com, and were randomized into one of two scenarios: high fungibility (their purchase would be made with a regular gift card to Amazon) or low fungibility (their purchase would be made with a gift card to Amazon that could only be used to purchase books). As predicted, participants who paid with the more fungible asset felt that the purchase cut into their slack more (7-pt scale;  $M = 5.51$  vs  $3.43$ ,  $t = 9.00$ ,  $p < .001$ ), and found the purchase to be more painful (7-pt scale;  $M = 3.54$  vs  $2.97$ ,  $t = 2.11$ ,  $p = .036$ ).

Previous studies have shown that buy-now-pay-later purchases are less painful (Prelec and Loewenstein 1998). This is consistent with our theorizing so long as the consumer believes, as is typical, that she will have more slack in the future (Zauberman and Lynch 2005). However, we argue if the consumer believes she will have *less* slack in the future, the future payment would require more of the consumer's available slack and should be *more* painful.

Study 5 tests this prediction: 100 participants imagined an increasing or decreasing salary over the course of their career as a manipulation of slack. They then rated how painful two payment options for the same product would be: payment now versus payment in 20 years (in both cases the product would be owned immediately). We replicate previous findings when slack is increasing in the future: paying later is rated as less painful ( $t(100) = 3.71$ ,  $p < .01$ ). However, when slack is decreasing in the future, people rate the later payment as *more* painful ( $t(96) = 4.47$ ,  $p < .01$ ).

## How Temporal Separation in Budgeting Affects Spending Behavior

### EXTENDED ABSTRACT

A common strategy for controlling spending is to decide how much consumers want to spend before they begin shopping. Consumers often use mental accounts as budgets, allocating resources for specific expenses before they are incurred. Because mental budgets are set in advance of purchase opportunities, there is typically some amount of temporal separation between the moment that a budget is set and the moment that a purchase is made. Although it is relevant to real life budgeting experiences, little is known about how the temporal separation between budgeting and purchase influences

spending behavior. We suggest that consumers become increasingly likely to overspend the budgeted amount as temporal separation in budgeting increases.

One possible underlying reason for this effect is diminishing pain of paying towards the budgeted money. Prior research demonstrates that people gradually adapt to the hedonic cost, or pain, of a purchase over time (Gourville and Soman 1998). Consumers first open a mental account for a purchase, and as time passes since the payment was made, they slowly incorporate the payment into their status quo, reducing pain of paying (Soman 2001). While pain of paying is typically explored in the context of actually spending money (e.g., Shah et al. 2015, Soster et al. 2014), people may also experience similar feelings when they make the decision to spend money and budget for an upcoming purchase. Simply earmarking money for a specific purpose can result in the sense of spending (Webb and Spiller 2014), showing that budgeting money may produce a similar experience to spending money. We suggest that after people set a budget for a purchase, they begin to adapt to the cost of that decision. As this adaptation increases over time, the pain associated with the decision lessens, which in turn increases the willingness to spend money when actual purchase occurs.

In Study 1, participants ( $N=248$ ) were randomly assigned to imagine that they had budgeted \$200 for a tablet PC either one-day, one-week, one-month, or six-months ago. Next, they indicated how likely they would be to spend \$250, instead of their \$200 budget, for the tablet PC to purchase 1) a premium version and 2) a more appealing option as a measure for overspending ( $= .79$ ). As hypothesized, the likelihood of overspending significantly rises as the temporal separation increases ( $b=.22$ ,  $p=.02$ ).

Study 2 was a two-phase experiment where participants experienced *actual* time separation between budget setting (phase 1) and a subsequent choice decision (phase 2) for a class ring. Undergraduate students ( $N=89$ ), who were close to purchasing their rings, were randomly assigned to experience either an eight-week vs. one-week separation between phase 1 and 2. In phase one, participants set a ring budget based on actual prices and options. In phase two, they selected their ring from a set that included additional options at higher price. Overspending was calculated by subtracting the amount budgeted from the amount spent. Participants in the eight-week separation condition showed significantly greater likelihood to overspend ( $M=55.12$ ) than those in the one-week condition ( $M=2.83$ ;  $F(1,87)=3.76$ ,  $p=.05$ ). A post-experiment survey completed by recent ring purchasers ( $N=247$ ) showed that greater temporal separation significantly predicted overspending ( $b=6.10$ ,  $p=.03$ ), concluding that people are increasingly likely to overspend as temporal separation increases.

Study 3 investigated the proposed process. Because hedonic purchases generally induce greater pain of paying (Kivetz and Simonson 2002), we reasoned that the effect of temporal separation would be stronger for hedonic than utilitarian purchases. Participants ( $N=354$ ) imagined setting aside \$300 either two-months or one-week ago to purchase a tablet PC that provided either hedonic or utilitarian benefits. Overspending was measured by asking about willingness to buy a premium version of the tablet PC for \$330 on a seven-point scale (1=very unlikely, 7=very likely). We found a significant interaction between the temporal separation and the benefit type ( $F(1,350)=3.84$ ,  $p=.05$ ). For the hedonic-framed good, participants in the two-month condition showed greater likelihood to overspend ( $M=5.61$ ) than those in the one-week condition ( $M=5.10$ ;  $F(1,350)=4.83$ ,  $p=.03$ ). However, overspending did not differ across the time condition for the utilitarian-framed good ( $M_{\text{utilitarian}^* \text{distant}} = 5.46$ , vs.  $M_{\text{utilitarian}^* \text{near past}} = 5.59$ ;  $F < 1$ ).

Study 4 also investigated the process. When consumers experience temporal separation, they may reevaluate their budget as they search for and acquire more information about their potential purchase. If it is true that this effect is driven by pain produced at the time one budgets one's money, then prolonging the budgeting decision through increased deliberation should effectively reduce the temporal separation between the final budget and actual purchase, increasing pain and mitigating overspending. We employed a minimalistic experimental paradigm to explore this issue in the lab. Participants ( $N=211$ ) received a set number of credits to allocate to watching films. To manipulate temporal distance, participants set a budget for how many credits to spend on films they would watch following either a 5 or 20 minute wait period. To manipulate deliberation during the wait period, participants either engaged in an unrelated task, or were asked to repeatedly reconsider their options and adjust their film budget as necessary. Thus, the final budget decision in both 5-minute and 20-minute deliberation conditions were made at the same time; consequently, there should be no difference in overspending between these two groups. After the wait period elapsed, participants purchased films to watch using their credits. We calculated the difference between budget and purchase to measure overspending. A two-way ANOVA revealed a significant interaction ( $F(1,207)=3.94, p=.05$ ); non-deliberators were more likely to overspend when the film budget was set 20-minutes ago ( $M=3.40$ ) than 5-minutes ago ( $M=-3.58$ ). However, for deliberators, overspending was no longer different ( $M_{\text{deliberator} \times 20\text{-minutes}} = -3.52$  vs.  $M_{\text{deliberator} \times 5\text{-minutes}} = -3.24$ ). Furthermore, greater temporal separation raised overspending through lower pain of paying for non-deliberators ( $b=.63, 95\% \text{ CI: } [.01, 2.07]$ ), but not for deliberators ( $b=-.45, 95\% \text{ CI: } [-1.96, .12]$ ).

Together, our findings explore how temporal separation in budgeting affects spending behavior. We found that as the temporal separation between budget setting and actual purchase increases, people are increasingly likely to overspend their budget. The results provide preliminary evidence of an unintended side effect of greater temporal separation in budgeting.

## Causes and Consequences of the Expense Prediction Bias

### EXTENDED ABSTRACT

A number of important financial decisions that consumers face require them to accurately predict their future expenses. For example, a consumer's decision about how much money to save or borrow today hinges on knowing how much money they will spend in the future. However, past research suggests that consumers will tend to under-predict their future expenses (Ulkumen et al., 2008; Sussman and Alter, 2012), a phenomenon we label the expense prediction bias (EPB). The present research introduces a simple cognitive tool that markedly improves consumers' expense prediction accuracy. Underlining the importance of such a tool, we also provide evidence that EPB is associated with lower savings and higher debt.

To develop this tool we theorize that people mentally represent the future using prototypes, which we define broadly as cognitive "blueprints" based on the central or typical instances of a category. This proposition is consistent with research showing that the future is mentally represented in relatively more prototypical terms than the past (Kane, Van Boven, & McGraw, 2012). We further propose that prototypical prospection causes consumers to under-predict their future expenses because behavioural predictions are based on mental representations of the future (Buehler, Griffin, and Peetz, 2010), and prototypes lack contextual detail (Van Boven, Kane, and McGraw, 2009). Accordingly, we also propose that decreasing perceived typicality of future expenses will increase expense prediction accuracy.

Study 1 ( $n = 485$ , Mturk) tested the hypotheses that consumers believe their future expenses will be lower and more typical than their past expenses. Participants first reported and predicted their expenses for the past and the next week, then indicated how typical they perceived their expenses for each week to be. In support of our hypotheses, participants predicted their future expenses would be more typical than their past expenses, ( $M_{\text{nextweek}} = 5.03, M_{\text{pastweek}} = 4.71, p < .001$ ), and that their future expenses would be 10.80% lower than their past expenses ( $M_{\text{nextweek}} = \$161.43, M_{\text{pastweek}} = \$180.98, p < .001$ ).

Study 2 ( $n = 1048$ , nationally representative sample from T.E.S.S.) tested the hypothesis that experimentally decreasing perceived typicality of future expenses will increase consumers' expense predictions. Participants were randomly assigned to one of three conditions: control, typical, or atypical. In the control condition participants recalled and predicted their expenses for the past and next week as in study 1. Participants in the typical condition also recalled and predicted their expenses but were instructed to list three reasons why their expenses for next week would be similar to a typical week before making their prediction. We hypothesized that this would not significantly impact predictions (vs. control) because, if our theory is correct, predictions in the control condition should already be based on a prototypical mental representation of the future. The atypical condition tested our tool which instructed participants to list 3 reasons why their expenses for next week might be different from a typical week. We hypothesized that this would decrease perceived typicality of future expenses and therefore increase expense predictions. As expected, predicted expenses were significantly lower than recalled expenses in the control condition ( $t(415) = 2.76, p = .006$ ) and typical condition ( $t(331) = 2.07, p = .039$ ), but statistically equivalent in the atypical condition ( $t(299) = -1.49, p = .14$ ).

In study 3 ( $n = 302$ , Prolific Academic) participants were randomly assigned to predict their expenses for the coming week in one of the three conditions from study 2. Then, over the next seven days, they reported their expenses at the end of each day in an online financial diary. This allowed us to test the hypothesis that consumers under-predict their future expenses as compared to their actual expenses. Predicted expenses were significantly lower than actual expenses in all three conditions ( $ps < .001$ ), but the size of the bias was 30.7% lower in the atypical condition vs. control. A 3(condition: control vs. typical vs. atypical)  $\times$  2(expenses: predicted vs. actual) between-within ANOVA confirmed a condition by expenses interaction ( $F(2, 299) = 3.26, p = .040$ ), and planned contrasts further confirmed that expense predictions were significantly higher in the atypical condition ( $M_{\text{atypical}} = \$210.61$ ) than in the control ( $M_{\text{control}} = \$165.67, t(299) = 2.01, p = .046$ ) and typical conditions ( $M_{\text{typical}} = \$142.59, p = .001$ ). The data also revealed that higher EPB was associated with lower savings, ( $r(299) = -.14, p = .02$ ), more frequent credit card interest charges ( $r(216) = .16, p = .02$ ), lower credit scores ( $r(206) = -.13, p = .06$ ), and greater self-expressed need to repay debt ( $r(300) = .17, p < .01$ ).

In study 4 we conducted a five week field study with 187 clients of a midsized North American bank. On the Sunday preceding week 1 of the study participants predicted their expenses for the next week and next month. On the Sunday of each subsequent week participants reported their actual expenses for the target week from their online bank account, and predicted their expenses for the coming week. They also indicated how typical they perceived their expenses for the past and next week to be. For the last week of the study, half of our sample was randomly assigned to receive our "atypical" intervention. In each of the first four weeks of the study participants predicted that their expenses for the next week would be more typical

than they had been in the past week ( $ps \leq .005$ ), and correspondingly, expense predictions were significantly lower than actual expenses in each week ( $ps < .01$ ). Participants also under-predicted their expenses for the month ( $M_{diff} = \$416.77, p < .01$ ). In the last week of the study EPB was replicated in the control condition ( $M_{diff} = \$79.99, p = .002$ ) but completely neutralized by our intervention in the atypical condition ( $M_{prediction} = -\$6.65, p = .85$ ).

In sum, this research identifies a key driver and several consequential correlates of EPB. Importantly, it also provides a simple intervention that policymakers and FinTech companies can use to improve consumers' financial predictions, and in turn, their financial well-being.

### **The Last Hurrah Effect: End-of-Week and End-of-Month Time Periods Increase Financial Risk-Taking**

#### **EXTENDED ABSTRACT**

“TGIF: Thank Goodness it’s Friday.” It is a phrase that is ubiquitous in modern society and used to signify the positive feelings associated with the transition between the work-week ending and the weekend beginning. Modern society is filled with examples of various temporal landmarks, largely driven by social construction, that have subsequently created clear associations structuring individuals’ memories and experiences (Robinson 1986; Shum 1988), but also our current behavior as well. The end-of-the week, in particular, has had a pervasive impact on the way we dress, behave, and make decisions at work. For example, it is not unusual for individuals to dress a bit more casually or have that extra beer during a happy hour event. This feeling of slack has spilled over to work habits as well. A recent survey of HR professionals found that a majority of workers reportedly felt the least productive in the office on Fridays. This brings up a natural question: Could this end-of-the-week effect affect decision-making as well? More specifically, does the potential slack associated with the end of a period affect investors’ risk tolerance and risky decision-making?

Understanding when people are most prone or vulnerable to making budgeting errors and risky choices is important for many reasons. For many individuals, just a few poor investment decisions may be quite consequential for one’s likelihood to go into debt. Moreover, these small decision biases can have a major impact in terms of how markets are constructed and perform. DellaVigna and Pollet (2009) document significant under reaction to information in earnings announcements when the announcements came on Fridays—a time period when individuals, they argue, are more inattentive to the news relative to other days of the week. While a number of articles have identified calendar effects in financial domains, the literature has largely focused on how the end-of-week create led to abnormal trading volumes and returns as evidenced by delays in response or action. But what happens to individuals who are *actively* making investment choices? Could the end-of-week, or end-of-period effects, influence optimism and perceptions of slack that could subsequently increase the risk investors are willing to tolerate?

Using a unique panel dataset of peer-to-peer lending loans, combined with a lab experiment, we find that investors are significantly more likely to invest in riskier loans at the end of a work week or end of the month, subsequently yielding worse returns in comparison to non-end of week periods. We obtained data from Prosper.com, a platform that provides P2P lending service in America but allows both investors and borrowers to set their own interest rates. A borrower can post an auction style listing specifying the maximum interest rate (reserve interest rate) he is willing to accept and the

amount he requests. Borrowers who set their reserve interest rate high are more likely to default. On the other hand, lenders can expect higher lender rate (the interest rate a lender receives on a loan) when they invest in a loan with higher reserve interest rate. Lenders (investors) on this platform face the trade-off between high interest rate and high riskiness.

In particular, we collected all bidding data from Nov 09, 2005 to Oct 14, 2008. The data includes 5,829,817 different bids submitted by 54,821 lenders. We find that investors (i.e., lenders) are significantly more likely to invest in listings with higher reserve interest rates on Fridays (the end of week) ( $p < .001$ , robust to various individual-level such as experience and average interest rate of loans for the investor, as well as firm-level controls, such as availability of loans, proportion of risky to riskless loans). To rule out the possibility that Friday is intrinsically different from other weekdays, we also test Wednesdays and Thursdays that are ends of working periods. We find similar patterns in lenders bidding behavior. To address the concern that our findings are driven by holiday effect, we provide evidence that at the end of a month, lenders prefer high reserve interest rate listings as well. We also rule out the potential that ego depletion is driving our results by looking at end-of-day effects. When mental energy is low, self-control is likely to be impaired, potentially leading to less consideration of the costs or losses. However, we did not find a significant relationship between the time of day (measured as either the last two hours of the work day or last two hours of the day). Finally, we compare the payoff rates lenders receive on regular working days and end of period working days. We find lenders risk seeking bidding behavior on end of period working days results in lower payoff rate on average.

In order to get a better idea of the mechanism driving these effects, we ran a follow-up laboratory experiment where we investigated the proportion of risk individuals were willing to take as a function of whether the decision was in the middle (control group) or end of a cycle (end-of-period). More specifically, we asked individuals to complete a series of tasks, one of which was to allocate \$100,000 to either risky (stock) versus riskless (bond) asset. Individuals who had the risk decision at the end of the cycle were significantly more likely to put more money into stocks (vs. bonds) relative to those who made the allocation decision in the middle of the cycle ( $p = 0.014$ ). Both increased feelings of happiness and perception that there will be a fresh start partially mediate the relationship between the end-of-period effect and risky decision-making.

Across two empirical studies—panel data from real investment decisions and a laboratory experiment on asset allocation—we find evidence that individuals are prone to an end-of-week bias. Investors are more likely to select riskier loans due to feeling more positive and believing that the next period offers a fresh start, despite the fact that these loans and end of period working days result in lower payoff rate on average.

### **SESSION OVERVIEW**

Consumer financial decision-making is an important topic for the ACR community both from academic and public policy perspectives. Consumers' financial well-being is linked to overall well-being (Netemeyer et al. 2018) and positively affects a number of societal outcomes (Diener 2000). Numerous public opinion polls demonstrate that consumers feel uncertain or insecure in their ability to successfully manage their family's limited financial resources, plan for the future (retirement, college funds) and pay off debt (credit cards, loans; PWC 2016). The session looks at three critical financial management issues facing consumers: budgeting, savings and credit card debt repayment.

Significant research has examined how a lack of basic understanding of financial decisions negatively affects consumer decision making (Benartzi and Thaler 2001; Fernandez et al. 2014; Soll et al. 2013). Similarly, a large body of work in mental accounting examined how cognitive biases in categorization of funds into mental accounts leads to suboptimal financial choices (see Soman & Ahn 2011; Zhang & Sussman 2017 for review). Finally, more recent work has started to examine how consumers' subjective feelings about and while completing various financial tasks affect their financial decision-making (Park & Sela 2018). Complementing this line of work, the four papers in this session look at a novel factor affecting financial decisions - consumers' subjective feelings about three critical financial tasks.

The first two papers in the session focus on the domain of budgeting. First, Putnam-Farr & Ghosh explore consumers' differential feelings of control over their discretionary and non-discretionary spending and how these feelings affect consumers' ability to set and follow realistic budgets across different spending domains. Second, Huang & Ghosh examine budget tracking and adherence. They find that subjective feelings of progress in budgeting adversely affect consumer spending, increasing spending over the time of the budget.

Next, Morris, Huang & Bechler examine how perceived feeling of difficulty impact savings behavior. They find that increases in per-

ceived saving difficulty affect consumers' willingness to invest the money to get higher future returns. Finally, Mochon, Mazar & Ariely examine the domain of credit card debt payment. They find that while consumers are insensitive to the size of their debt, they are also insensitive to the frequency of making payments. They demonstrate that increasing payment frequency positively affects repayment rate and the likelihood of paying off credit cards.

Taken together the papers demonstrate that consumers' subjective feelings about their performance in three distinct financial decision-making domains have important consequences for their ability to successfully set and manage budgets, invest for the future and pay off debt. Importantly, all papers suggest simple interventions (for example, time-insensitive view of budgets and more frequent payment options for credit cards) that can improve consumers' financial management. We believe this session will be interesting to a broad ACR audience, including researchers in the area of financial decision making, affective influences on consumer behavior, and consumer welfare.

## **Turning “Expenses” to “Bills”: How Spending Categorization Impacts Budget Optimism and Likelihood of Success**

### **EXTENDED ABSTRACT**

According to the most recent Federal Reserve report, just under one-fourth of adults are not able to pay all of their current month's bills in full and forty-four percent of adults say they either could not cover an emergency expense costing \$400, or would cover it by selling something or borrowing money. (Board of Governors of the Federal Reserve System, 2017) While there is a case to be made that this problem is caused by broader issues of economic insecurity and income inequality, the issue can also be attributed to poor financial planning, specifically failure to set and adhere to budgets. Making and sticking to a budget is important. It allows for retirement savings, rainy day/emergency fund, and general financial preparedness. But despite the fact that 41% of Americans say they use a budget for planning (Jacobe, 2013), and many of them are using apps and bank software to track expenses, consumers often fail to budget in a way that promotes their long-term financial well-being. Popular press articles abound with reasons why people might fail, and most revolve around the fact that budgets are not set in a way that encourages people to adhere.

This focus on budget setting contrasts with the majority of prior academic work that instead examines adherence to pre-determined budgets (Baumeister, 2002; Heath & Soll, 1996; Peeters, Rijk, Soetens, Storms, & Hermans, 2018). In this work, we choose to focus on the very first step of budgeting process – setting budgets – in order to understand how the budget setting process impacts potential budget adherence. We propose that people set overly optimistic budget targets that fail to take into account the reality of how they spend *in certain categories* and therefore predispose them to failure and prevents from long-term engagement with budgeting efforts (Nelson, Malkoc, & Shiv, 2018; Soman & Cheema, 2004).

Most people underestimate future spending, and are even more likely to underestimate their spending when they estimate in the

context of goal setting (Peetz & Buehler, 2009), where aspirations often trump past experience. This may be in part because of overall consumer optimism (Tam & Dholakia, 2011) or because consumers view past spending behavior, which they often classify as non-recurring extraordinary expenses, as less diagnostic of future spending (Sussman & Alter, 2012). We examine this misestimation process in more detail, showing that people demonstrate optimism only in certain types of spending categories (defined by their combination of uncertainty and optimism), and that inaccuracies in prediction are driven mostly by these categories. We also provide suggestions for how to increase the accuracy of budget forecasting overall.

First, we demonstrate presence of this phenomenon in real-life budget planning. Using a large dataset from a popular budget tracking application, we demonstrate that while people are optimistic in general (budgeting less than they actually spend), they are almost twice as inaccurate in “expense” categories (e.g. clothing, restaurants, gifts), where they underestimate spending by an average of \$66 (s.e. 2.77) in the first month after setting a budget, compared to “bills” categories (e.g. cable, rent, insurance, loans), where they underestimate spending by only \$23 (s.e. 4.66, comparison controlling for individual level effects using random effects GLS regression). The same pattern is observed in months 2 and 3 after initial budget failure, suggesting that consumers are not updating their expectations to reflect actual spending. The “expense” category is one that is native to the tracking app, and describes all spending in areas that are not represented by monthly bills. In other words, it includes most spending that would be considered discretionary in nature.

In a subsequent series of lab experiments, we explore ways in which we can increase consumers’ accuracy in budgeting for these expense categories. Specifically, we demonstrate that we do not eliminate this category optimism by providing additional information about peer levels of spending (Study 1 and Study 2) or by asking consumers to first recall their own past spending (Study 2). In all cases, the projected spending in expense categories is significantly lower than in an equivalent group of bill categories (matched by actual spending from our field data).

We subsequently asked consumers (Studies 3&4) how they would respond to feedback about budget mispredictions. We found that people generally adjusted their future budget in the direction and magnitude of the actual amount spent last month for bills categories only. By contrast, for the expense categories, participants either kept their previous budget (no change to estimate) for large budget failures or decreased the budgeted amount to make up for last month’s overspending for smaller budget failures. Both of these reactions suggest that consumers are not using information from the budget failure to improve their budget estimates for discretionary expenses. We also find (Study 4) that consumers are more likely to attribute budget failure in expense than bills categories to themselves, yet they still do not sufficiently incorporate such failures into future budgets.

Finally, we demonstrate that the difference between one’s own past spending and one’s budget is attenuated when consumers are asked how much they are *likely* to spend, rather than how much they *should* spend (Study 5), suggesting that the optimism does not come from lack of awareness of past spending, but from overly aggressive spending targets in areas where people feel they ought to be spending less. We also find (Study 6) that the difference between bills and expenses is eliminated when participants are asked to project how their best friend would budget. The optimism thus appears to be personal in expectation. Both of these moderators open up interesting additional avenues for exploration. In follow up experiments, we attempt to improve budgeting by encouraging people to think of “expense”

categories as being more like bills, thus increasing focus on the accuracy of budgeting as opposed to minimizing spending.

### Time-insensitive Budget Tracking: Nudging Consumers to Spread out Spending over Time

#### EXTENDED ABSTRACT

Budgeting is considered a useful tool for consumer financial management (Heath & Soll, 1996; Thaler, 1999). It provides specific reference points and allows consumers to monitor spending relative to those reference points (Heath & Soll, 1996; Krishnamurthy & Prokocec, 2010). Despite the large body of work that examines biases in consumers’ tracking of prior spending (Soman, 2001; Sussman & Alter, 2012; Stille, Inman, & Wakefield, 2010; Cheema, & Soman, 2006), there is little work that examines different ways in which consumers can interpret accurate (unbiased) spending feedback. Yet, marketplace is abounded with bank software and financial applications that offer consumers accurate tracking of their expenses.

Research has shown that feedback affects consumers behavior (Etkin, 2016; Fishbach & Finkelstein, 2012). While most research focuses on situations where consumers strive to achieve a desirable end state (i.e. an approach goal, Amir & Ariely, 2008; Cheema & Bagchi, 2011; Kivetz, Urminsky, & Zheng, 2006), we study feedback in a budgeting context, where both approach and avoidance goals are salient: consumers want to curb spending (i.e. focusing on the \$0 reference point), yet make desired purchases within the budget constraint (i.e. focusing on the budget reference point). Consider a consumer with a \$50 monthly coffee budget. Her budget tracking app shows that she has spent \$13 in the first week. The consumer can see her spending in a time-insensitive way (e.g. I am in safe range) or in a time-sensitive way (e.g. here is what I spent in one week). We test how these different interpretations of spending feedback affect consumers’ purchasing behavior over the budget period. We argue that time-sensitive focus would increase spending over time, as consumers move away from \$0 as a reference point and closer to the allocated budget. Yet, time-insensitive interpretation of spending feedback would lead to more consistent spending over time. Thus, we should expect both lower spending at the beginning of the budget period and higher spending at the end of the budget period for consumers with time-sensitive (vs. time-insensitive) focus.

We first tested manipulation of time-insensitive and time-sensitive focus in a pilot study. We expected that asking consumers’ about perceptions of overall budget progress versus budget success at a time would increase focus on the elapsed budget time. Participants imagined having a monthly \$200 budget for eating out. They were given feedback on their spending once every five days. The participants spending speed was kept at a pace to be equal to \$200 budget by the end of the budget period. As expected, while perceptions of budget progress increases over time ( $F(1,49)=16.33, p<.05$ ), perceptions of budget success were insensitive to elapsed budget time ( $F(1,49)=1.45, n.s.$ ).

In study 1, we tested if directing consumers’ attention to budget progress (time-sensitive) or success (time-insensitive) affects spending likelihood. Study 1 employed a 2(success vs. progress)\*5(feedback time) mixed design, using a scenario identical to pilot study, with progress and success measures manipulated between subjects. After receiving spending feedback, on day 5 and day 25, participants indicated their likelihood of eating out the next day. As predicted, focus on budget progress led to an increase in spending over budget time ( $M_{\text{progress}_t1}=2.98, M_{\text{progress}_t2}=4.00, p<.05$ ), while focus on budget success kept spending constant ( $M_{\text{success}_t1}=3.39, M_{\text{success}_t2}=3.25, n.s.$ ). Note that participants in success

condition spend more than participants in progress condition at the beginning of the budget period, suggesting that our effect is not driven by greater commitment to curbing consumption, because such commitment should decrease spending across time.

We replicated this effect in study 2 using a computer-simulated grocery shopping task where staying within the budget was rewarded. Study 2 used a 2(success vs. progress)\*2(unplanned purchase timing: at the beginning, at the end) between subject design. Participants were given a \$50 budget to complete a 15-item shopping list. Participants were given accurate feedback on their accumulated spending and were asked to indicate either their progress or success at managing their budget after they purchased the 5th and 10th items. Further, participants were shown chocolate bars that they can purchase after item 5 (vs. item 10, manipulated between subjects). They were told that the chocolate bars were not planned for in their budget, but that the purchase, if made, would add to their total spending (Stilley, Inman, & Wakefield, 2010a, 2010b). Consistent with Study 1, chocolate purchase intention increased when participants focused on budget progress ( $M_{\text{progress\_t1}}=2.51$ ,  $M_{\text{progress\_t2}}=3.71$ ,  $F(1,188)=8.31$ ,  $p<.05$ ), but not when they focused on budget success ( $M_{\text{success\_t1}}=3.29$ ,  $M_{\text{success\_t2}}=3.72$ ,  $F(1,188)=1.06$ , n.s.).

In Study 3, we test a simple, practically relevant way to make consumers less time-focused when interpreting spending feedback by giving them discrete yes/no feedback to indicate their budget standing. The study had a 3(success vs. discrete-feedback vs. control)\*2(feedback time) mixed design, with the first factor manipulated between conditions. We used a scenario similar to study 1. Participants reported their success or gave discrete answers (i.e. doing good vs bad) to indicate their budget status respectively in success and discrete-feedback conditions, while they didn't report anything in the control condition. Participants in the control condition increased their spending over time suggesting that time-sensitive focus is default in this setting (measured in dollars spent:  $M_{\text{progress\_t1}}=14.81$ ,  $M_{\text{progress\_t2}}=18.62$ ,  $F(1,51)=5.22$ ,  $p<.05$ ); while the spending remained constant in both success and discrete feedback conditions ( $M_{\text{success\_t1}}=13.89$ ,  $M_{\text{success\_t2}}=14.75$ ,  $F(1,54)=.84$ , n.s.;  $M_{\text{discrete\_t1}}=13.87$ ,  $M_{\text{discrete\_t2}}=14.56$ ,  $F(1,54)=.44$ , n.s.).

As tracking of real-time spending becomes a more common practice among consumers, understanding how consumers interpret unbiased spending feedback is important. Our studies add to the research on budgeting and financial well-being and have implications for helping consumers stay within their budgets.

### **Doing it the Hard Way: More Effortful Saving Leads to Less Investing**

#### **EXTENDED ABSTRACT**

The allure of having a leisurely, work-free retirement is becoming less of an American Dream and more of a proverbial American nightmare. To retire, consumers need to accumulate wealth—and today, most consumers have far too little. Recent surveys show 28% of Americans over the age of 55 have no monetary assets for retirement, and 60% have less than \$100,000.

For consumers to accumulate sufficient wealth for retirement, merely exerting effort to save money is not enough. They also need to invest. Indeed, the best instrument for growing one's long-term assets is to invest one's savings in the stock market over a long period of time and utilize the exponential growth of compound interest (Malkiel 1999). To illustrate, imagine two consumers who each save \$10,000 a year: Consumer A does not invest his savings while Consumer B invests all his savings per year in an S&P 500 index fund. If we conservatively assume an average annual return for the S&P 500

of 5% per year, in 40 years, Consumer A will have \$400,000 while Consumer B will have \$1.2 million.

There are numerous reasons why individuals don't invest, including the lack of financial literacy (Fernandes et al. 2014) and myopic loss aversion (Benartzi & Thaler 1995). Relatedly, there has been much research over the past several decades that seeks to understand the barriers consumers face when attempting to accumulate wealth, mostly focusing on changing the process through which one saves (Thaler & Benartzi 2004; Ulkumen & Cheema 2011; Tam & Dholakia 2014). In this research, we examine the interplay between these two financial behaviors—the effect of perceived effort in saving on one's likelihood to then invest this money to accumulate greater overall wealth.

Prior literature has shown that both reducing one's required effort to save (e.g., nudges, Thaler & Sunstein 2009) and increasing one's effort to save (e.g., through increased financial monitoring, Kan et al. 2015) can be beneficial for accumulating wealth. We hypothesize that, when it comes to investing one's savings, higher perceived effort in saving can backfire. This occurs because greater effort invested to obtain a good can lead to a greater attachment and value placed on it (Arkes et al. 1994; Cherry et al. 2002; Muehlbacher & Kirchler 2009; Norton et al. 2012), even if the "good" in this case is only a means to an end of accumulating greater wealth. Across seven studies using savings paradigms that involve accumulation, budgeting, and physical effort, we show that perceiving savings as being obtained in a more effortful way decreases willingness to invest this money, leading to lower accumulated financial assets. Importantly, reframing this effort as being exerted in order to invest, rather than as being exerted in order to save, can attenuate this effect.

In Study 1 we created lab-managed savings accounts for 251 individuals and had them transfer us \$70 in several increments over a two-week period using Venmo.com. Then, we asked them to rate how effortful they felt had been to accumulate their \$70 in savings, and gave them an opportunity to invest as much of their savings as they wanted into a 3-year period S&P 500 simulation task. For every 1-point increase in reported effort exerted in accumulating savings, individuals invested \$2.94 less in the simulation,  $t = -2.16$ ,  $p = .032$ , and received \$2.94 less in overall returns from their savings,  $t = -1.91$ ,  $p = .057$ .

Then, across five studies (Studies 2a-e) on mTurk with a total of 1,200 participants, we developed a saving and investing paradigm where participants exerted real effort (in the form of repeatedly pressing a button on a keyboard) to save money. Using a within-subjects design, participants performed the button pressing tasks for multiple repeated trials, mimicking a monthly saving cycle for multiple months. The trials required different amounts of effort to complete, and once participants received their savings that month, they decided how much of these savings they would like to invest (see, Gneezy & Potter 1997). Across the five studies we manipulated several variables, such as the expected value and riskiness of the investments as well as how these investments were presented. We found a consistent significant pattern in each study that the more times the button had been pressed in order to save, the less participants would allocate of their savings to the investments,  $ps < .001$ . Furthermore, in Study 2e, we asked participants to evaluate how valuable they felt their savings were on each trial and found a significant mediation from effort to investment through participants' perceived value of their savings, 95% CI: [-.005, -.001]; greater effort exerted in saving led to a greater attachment and value placed on the money saved, accounting for participants' reluctance to then invest.

Finally, in Study 3 ( $N = 401$ , mTurk) we found that the effect of effort on investment can be attenuated when effort exertion is

framed as for the accumulation of overall wealth rather than for the accumulation of savings. Using a similar paradigm as Studies 2a-c, we directly manipulated whether participants' effort was associated with accumulating savings or with having an opportunity to invest to increase overall wealth. We found a significant interaction between effort framing and effort exertion on the amount that participants invested,  $t = -2.00$ ,  $p < .05$ . We replicated the negative effect of effort exertion on investment when effort was framed as for the accumulation of savings,  $t = -3.33$ ,  $p < .001$ , such that every additional button press corresponded to a .01% decrease in investment; framing effort exertion as providing an opportunity to invest attenuated this negative effect,  $t = -.46$ ,  $p = .65$ .

Overall, these studies identified an important psychological barrier to one of the most instrumental financial tools for accumulating wealth—investing. While it is of paramount importance that individuals work hard to save, our findings suggest policymakers, banks, and marketers must attend to the potentially negative downstream consequences that can result from increasing consumers' awareness of the effort they exert when saving.

### Scope Insensitivity in Debt Repayment

#### EXTENDED ABSTRACT

Many consumers struggle with high levels of debt. For example, it is estimated that U.S. consumers hold \$995 Billion of revolving debt (Board of Governors of the Federal Reserve System 2017), and the average credit card debt for a balance carrying household is \$16,048 (Harrow 2017). Moreover, the amount of credit card debt continues to grow each year, as younger cohorts are borrowing more and repaying at lower rates than older generations (Jiang and Dunn 2013). As credit card debt grows, so do the burdens associated with it, such as fees, interest payments, delinquency and bankruptcy (Agarwal and Liu 2003; Stango and Zinman 2009).

In this project we examine whether scope insensitivity, the finding that people are often insensitive to the number or quantity of something they are paying for (e.g. Schkade and Payne 1994), can provide a partial explanation and solution for excessive credit card debt. Specifically, we argue that people are largely insensitive to the amount of debt they have when making credit card payments, which can lead them to fall further into debt. However, a different form of scope insensitivity can help them better manage their debt. To the extent that people are insensitive to the number of payments they make (Kahneman and Knetsch 1992), changing the frequency of payment within a billing cycle can help them pay off their debt more quickly.

In order to provide initial evidence for our claims, we analyzed a large data set of real credit card transactions. Specifically, we examined the payment frequency and amount for 160,218 credit card accounts over the course of one year. Importantly, this was a sample of people who were struggling with their credit card debt. Our analyses provided support for the potential dual role of scope insensitivity in credit card debt. First, people were largely insensitive to the amount of debt they had when deciding how much of it to pay off. Indeed, we found a weak relationship between magnitude of balance owed and amount paid ( $\beta = .09$ ,  $SE = .001$ ,  $p < .001$ ). That is, for every extra dollar that they owed, they increased their payment by only 9 cents. Additionally, we found that the majority of payments were round numbers. Indeed, 36% of all non-zero payments were multiples of 100 (and 51% were multiples of 50). This suggests that when deciding how much of their balance to pay, people seemed to be using simplifying heuristics that were largely insensitive to the scope of the problem they were facing (their balance), much as it

is common in the scope insensitivity literature (e.g. Schkade and Payne, 1994)

We also found an insensitivity to the number of payments in a billing cycle. When using a fixed effects regression model, we found that when people chose to make more frequent payments in a billing cycle, they paid off more of their credit card debt ( $\beta_{\text{payments}} = 351.1$ ,  $SE = .93$ ,  $p < .001$ ). That is, people paid \$351 more of their credit card debt for each additional payment within a billing cycle. This translated into paying off an additional 6 percentage points of their credit card debt for each additional payment in the billing cycle. While these results are correlational and open to multiple explanations, they provide initial evidence in the field consistent with the proposed dual role of scope insensitivity in credit card repayment. We next conducted a series of lab studies to test for its causal effect.

In the lab experiments, participants were given scenarios where they were presented with a credit card bill and asked to decide how much of it they would pay. In all of our studies we manipulated the size of the debt as well as the payment frequency—e.g. in some studies participants were told that they could make two payments during a billing cycle, and were asked to decide how much each payment would be. Across three studies, with slight variants on the same scenario, we found a pattern consistent with the field data. Participants were largely insensitive to the magnitude of the debt they were facing (the payments were not higher when the debt was larger). They were also somewhat insensitive to the number of payments made. When they had to make more payments within a billing cycle, they paid off a larger portion of their credit card debt (Table 1; Studies 1-3).

In study 4, we again manipulated the payment frequency and balance within a credit card repayment scenario. Additionally, we included a condition which allowed participants to choose their preferred payment frequency. This allowed us to test whether there would be demand for such an intervention, and whether the right set of people self-select into this payment condition. We found that about half of the participants chose a bi-weekly payment frequency over a monthly one. Moreover, participants in the choice condition behaved on average the same as those assigned to the bi-weekly condition, suggesting that the people who most benefit from the increased payment frequency were those who self-selected into this option. In this study we also found a main effect of balance, which was due to a ceiling effect in the low balance condition, which was lower than in the other studies. In sum, these results suggest that scope insensitivity may be both a source of the problem, and a potential solution for excessive credit card debt.

### **SESSION OVERVIEW**

Consumers often appear myopic in intertemporal choices between a smaller, sooner option and a larger, later option. Myopic choices relate to a wide range of consequential impatient behaviors, including health and financial decisions. This session features four papers that move beyond the traditional research paradigms and use novel, interdisciplinary approaches to understand myopic consumer choices. From comparative versus integrative search strategies (paper 1), to the neglect of duration ratio between present and future events (paper 2), to surgically-induced biological changes (paper 3), and anticipated interpersonal consequences (paper 4), each paper sheds light on a previously unidentified determinant underlying myopic choices.

Reeck, Lee and Johnson examine how the individual variation in information search strategies influences intertemporal choices. Using eye-tracking and neuroimaging data, they identify two distinct search strategies - comparative (i.e., alternative-based) and integrative (i.e., attribute-based), and find that consumers using comparative search are more patient and more sensitive to acceleration vs. delay framing than those using integrative search. Moreover, manipulating strategies can increase patience without the participant's knowledge.

Wei and Hsee find consumers often neglect the relative duration ratio between present and future events. Experiments demonstrate that the neglect of present-future duration ratio can give rise not only to myopic choices, when the ratio is low (i.e. when future events are longer than present events) but also to hyperopic choices, when the ratio is high (i.e., when future events are longer than present events).

When prompted to deliberate on the present-future duration ratio, consumers' choices become less myopic and less hyperopic

Viswanadham et al. investigate the effect of bariatric surgery, a drastic weight loss intervention, on the delay discounting for food and money. In two longitudinal studies, they find that obese patients exhibit more impatience for food rewards compared with lean individuals, and that one of the most successful current weight loss intervention - bariatric surgery - reduces impatience for food and thus attenuates this difference. Moreover, these effects were domain-specific and did not extend to money.

Yang and Urminsky find that intertemporal choices made for others are often more impatient than choices for oneself, contrary to predictions from prior theories that interpersonal choices would be the same or less impatient. Seven experiments suggest that the interpersonal feedback that consumers spontaneously anticipate from recipients reshapes the intertemporal tradeoff between immediacy and magnitude, and they identify how recipient specificity, feedback timing, and decision accountability each moderate the effect of interpersonal feedback.

In sum, myopic choices may be improved, these papers suggest, by subtly manipulating information acquisition (paper 1), highlighting the relative duration of present and future events (paper 2), weight loss interventions that impact the biological underpinnings of myopic behavior (paper 3), but not by delegating one's choices to others (paper 4). In sum, this special session provides new insights into consumer impulsivity and facilitates an interdisciplinary discussion on the topic.

## **Search Predicts and Changes Patience in Intertemporal Choice**

### **EXTENDED ABSTRACT**

Consumers often discount future rewards, making them less attractive than lower-value rewards delivered sooner (Laibson, 1997; Samuelson, 1937). When facing decisions involving outcomes over time, consumers use different psychological processes. Despite growing interest in heuristics in intertemporal choice (Ericson, White, Laibson, & Cohen, 2015; Read, Frederick, & Scholten, 2013), when heuristics are used and their impact on behavior remains unclear. Search strategies – how and in what order people acquire information – offer insight into the heuristics used in decision making. The present research examines individual differences in search strategies and how they influence patience in intertemporal choice. We identify two main types of search strategies and demonstrate that (1) search strategies influence patience, (2) that the effects of acceleration framing depend upon which strategy is used, and (3) subtly manipulating strategies increases patience.

In Study 1, participants (N=193) completed an intertemporal choice task in which decisions were framed as either choices to delay or accelerate consumption. In the delay condition, the smaller, sooner option was presented as the default, and participants had the option to switch to the larger, later option. In the acceleration condition, the larger, later option was presented as the default, and participants had the option to switch to the smaller, sooner option. We used MouseLabWeb (Willemsen & Johnson, 2011), a method similar to eye-tracking, to examine how participants acquired information during deliberation. Importantly, there were substantial differences in process across individuals, with individual differences explaining

six times more variation in search than variability across the options presented. Cluster analyses revealed two dominant strategies across individuals. Some people integrate both information about the timing and monetary value of an option, searching in an alternative-based manner. Other people instead search comparatively, evaluating how options differ on a key attribute (e.g., monetary amounts) and searching in an attribute-based manner. Importantly, differences in search also significantly predicted differences in choice. Comparative searchers were both more patient than Integrative searchers ( $\beta = -0.41$ , *s.e.* = 0.12,  $p = .001$ ) and exhibited a larger effect of acceleration framing ( $\beta = 0.08$ , *s.e.* = 0.03,  $p = .004$ ). Although Comparative searchers exhibited a significant effect of acceleration framing ( $\beta = 0.41$ , *s.e.* = 0.09,  $p < .001$ ), Integrative searchers did not ( $\beta = 0.07$ , *s.e.* = 0.08,  $p = .363$ ). These findings were replicated in a supplemental eye-tracking experiment, indicating that these results are not sensitive to the process tracing method employed. We also re-analyzed data from a previous experiment in which participants ( $N=20$ ) completed an intertemporal choice task while undergoing functional neuroimaging and eye-tracking. Comparative searchers exhibited greater differences in brain activation between delay and acceleration framing in lateral prefrontal cortex, ventromedial prefrontal cortex, and ventral striatum.

Study 1 established that individual differences in search strategies correlated with differences in patience and framing; Study 2, sought to establish a causal link between search strategy and behavior. Participants ( $N=207$ ) completed the intertemporal choice task in one of two conditions, presenting information in the display to encourage either comparative or integrative search. Consistent with Study 1, those in the Easy Comparative condition exhibited more patience than those in the Easy Integrative condition ( $\beta = -0.23$ , *s.e.* = 0.10,  $p = .027$ ). Additionally, those who used the Comparative search strategy exhibited a significant effect of acceleration framing ( $\beta = 0.65$ , *s.e.* = 0.12,  $p < .001$ ), while those who used the Integrative search strategy did not ( $\beta = 0.04$ , *s.e.* = 0.10,  $p = .702$ ). Further, these manipulations were not obvious to participants, and they did not believe that they affected their choices.

Study 3 explored the relationship between individual differences in search strategy and other individual differences that might influence patience in intertemporal choice. 200 participants completed the intertemporal choice task, with MouseLabWEB tracking information acquisition. After completing the task, participants then also completed measures of numeracy and financial literacy. Payne Index was computed as a continuous measure of search strategy, with higher scores associated with integrative search and lower scores associated with comparative search. Importantly, Payne Index exhibited a significant relationship with patient choice, ( $\beta = -0.05$ , *s.e.* = 0.02,  $p < .05$ ), with more comparative searching associated with greater likelihood of selecting the larger, later option, replicating the findings from Studies 1 and 2. When entered as separate predictors of patience in intertemporal choice, financial literacy exhibited a significant positive relationship with patient choice ( $\beta = 0.05$ , *s.e.* = 0.02,  $p = .033$ ), while numeracy exhibited a marginal relationship with patient choice ( $\beta = 0.04$ , *s.e.* = 0.02,  $p = .076$ ). Neither numeracy nor financial literacy predicted Payne Index ( $p$ 's  $< .1$ ), indicating there was not a significant relationship between these measures and search strategy. However, when Payne Index was included in the model as a predictor of intertemporal choice, neither numeracy nor financial literacy exhibited a significant relationship with choice any longer ( $p$ 's  $> .05$ ), while Payne Index still exhibited a significant relationship with patience ( $p < .05$ ). Thus, search strategy subsumes the variance explained by numeracy and financial literacy in predicting patient choice.

Taken together we show that 1) there are large and systematic individual differences in information acquisition, 2) these differences alter patience, and 3) manipulating information acquisition alters choices without the participant's knowledge. These results are important for both theory and practice. Cognitive models of intertemporal choice that do not take individual differences in information acquisition into account omit an important component of how choices are actually made. Analyses that do not investigate these effects may be averaging over two very different cognitive processes, and indeed different theoretical models may fit different subgroups better (Wulff & van den Bos, in press). Given the causal relationship between search strategies and time preferences, our results point to potential choice architecture interventions to increase patience.

### Situation Neglect Underlies Both Psychological Myopia and Psychological Hyperopia

#### EXTENDED ABSTRACT

Life consists of joy (e.g., play) and pain (e.g., work). How much time people spend on joy in the present often inversely determines how much time they spend on pain in the future. The more one works today (or when young), the more one can play tomorrow (or when older).

We study situations with the following structure: People go through two phases—the present and the future. In each phase, they spend their time either on joy (pleasant activities) or pain (unpleasant activities) or some combination of the two. In the present phase, people can choose how much time to spend on joy and how much time to spend on pain. In the future phase, people cannot choose; rather, how much time they will spend on joy versus pain will be inversely related to the time they spend on joy versus pain in the present.

We manipulate a key situational variable: the future-present relationship, which we operationally define as the ratio of the length of the present phase and the length of the future phase. If the future is longer (shorter) than the present, we say that the future is more (less) important than the present.

To maximize overall happiness in both the present and the future combined, people, when deciding how to allocate their present time between joy and pain, should be sensitive to the future-present relationship. The more (less) important the future is relative to the present, the more (less) time people should spend on pain rather than joy in the present. However, we propose that people are vulnerable to “situation neglect”: People are insufficiently sensitive to the future-present relationship. As a consequence, they make choices that do not maximize their overall happiness. Specifically, we propose:

- Hypothesis 1* When the future is more important than the present, people do not spend enough time on pain now and thereby appear myopic.
- Hypothesis 2* When the future is less important than the present, people do not spend enough time on joy now and thereby appear hyperopic.
- Hypothesis 3* Myopic and hyperopic choices yield less happiness than the choice that maximizes joy-to-pain ratio (i.e., “overall-ratio-maximizing strategy”).

*Hypothesis 4* Nudging people to deliberate on the hedonic consequences of their choices increases the joy-to-pain ratio in their choices as well as their overall happiness.

We present two experiments examining these hypotheses. In both experiments, participants were instructed to view flower pictures (joy) and cockroach pictures (pain) in two sequential phases. They learned the following two key features of the paradigm. First, participants could choose any combination of flower and cockroach pictures they wished to view, but only in Phase 1. In Phase 2, the proportion of flower versus cockroach pictures was inversely related to that in Phase 1. Second, participants needed to view different numbers of pictures in the two phases. When a participant needed to view more (fewer) pictures in Phase 2 than Phase 1, the choice in the present (Phase 1) commanded greater (less) importance for the future than for the present. We measured how many pictures of each type participants chose to view in Phase 1 and their overall happiness (i.e., mean value of sampled happiness after viewing each picture: 1=bad, 5=good).

Experiment 1 employed a 2 (future-present relationship: future-more-important vs. future-less-important) x 3 (strategy: free-choice vs. overall-ratio-maximizing vs. yoked) between-subjects design. In the free-choice condition, participants made their own choice in Phase 1. In the overall-ratio-maximizing condition, participants viewed the combination of pictures that maximized the overall flower-picture-to-cockroach-picture ratio without making any choices. In the yoked condition, each participant viewed the combination of pictures consistent with that chosen by the participant in the free-choice condition to whom s/he were yoked. In Phase 1 participants viewed 12 pictures. As hypothesized, when Phase 2 was long (i.e., 36 pictures), participants chose more flower pictures in Phase 1 than the overall-ratio-maximizing strategy ( $M=3.42$ ,  $t(49)=6.33$ ,  $p < .01$ ). When Phase 2 was short (i.e., 4 pictures), participants chose fewer flower pictures in Phase 1 than the overall-ratio-maximizing strategy ( $M=6.79$ ,  $t(42)=-8.52$ ,  $p < .01$ ). Regardless of the future-present relationship, participants in the overall-ratio-maximizing condition were happier than participants in both the free-choice condition (future-more-important:  $M_{\text{Free-Choice}}=3.32$  vs.  $M_{\text{Ratio-Maximizing}}=3.76$ ;  $t(272)=3.55$ ,  $p < .001$ ; future-less-important:  $M_{\text{Free-Choice}}=3.43$  vs.  $M_{\text{Ratio-Maximizing}}=3.82$ ;  $t(272)=3.62$ ,  $p < .001$ ) and the yoked condition (future-more-important:  $M_{\text{Yoked}}=3.40$ ;  $t(272)=3.89$ ,  $p < .001$ ; future-less-important:  $M_{\text{Yoked}}=3.28$ ,  $t(272)=4.04$ ,  $p < .001$ ). Results from Experiment 1 suggest that people are insufficiently sensitive to the future-present relationship and make choices that do not maximize their overall happiness.

Experiment 2 examined whether nudging people to deliberate before they make their choices would make them more sensitive to the future-present relationship and thereby improve their choices. Experiment 2 employed a 2 (future-present relationship: future-more-important vs. future-less-important) x 2 (deliberation: prompted vs. not prompted) between-subjects design. In the deliberation-prompted condition, prior to making any choices, participants were asked to pause and think carefully about the choice that would maximize their happiness. In all conditions, participants were free to choose how many cockroach and flower pictures to view in Phase 1. Replicating results in Experiment 1, participants' choices of flower pictures did not maximize the flower-picture-to-cockroach-picture ratio in the future-more-important condition ( $M=1.52$ ,  $t(62)=8.70$ ,  $p < .01$ ) and the future-less-important condition ( $M=8.10$ ,  $t(70)=-10.84$ ,  $p < .01$ ). Importantly, deliberating on the hedonic consequences of one's choice increased the flower-picture-to-cockroach-picture ratio

in both the future-more-important condition ( $M_{\text{NotPrompted}}=1.52$  vs.  $M_{\text{Prompted}}=0.96$ ;  $t(277)=-3.13$ ,  $p=.002$ ) and the future-less-important condition ( $M_{\text{NotPrompted}}=8.21$  vs.  $M_{\text{Prompted}}=9.66$ ;  $t(277)=2.38$ ,  $p=.019$ ). Consequently, deliberation increased their overall happiness in both the future-more-important condition ( $M_{\text{NotPrompted}}=2.69$  vs.  $M_{\text{Prompted}}=2.86$ ;  $t(277)=-2.18$ ,  $p=.030$ ) and the future-less-important condition ( $M_{\text{NotPrompted}}=2.76$  vs.  $M_{\text{Prompted}}=2.90$ ,  $t(277)=2.09$ ,  $p=.039$ ). Thus, myopia and hyperopia were both attenuated after participants were prompted to consider the hedonic consequences of their choices.

This research offers a new perspective on psychological myopia and hyperopia, that is, the situation neglect of the future-present relationship. People appear myopic when the future is more important than the present, and hyperopic when the future is less important than the present.

## The Effect of Bariatric Surgery on Delay Discounting for Food and Money: A Longitudinal Study

### EXTENDED ABSTRACT

Obesity has been recognized as a “global epidemic” (Caballero 2007), given its prevalence and its impact on the risk of cardiovascular disease, type-2 diabetes, and cancer. Countries are vastly heterogeneous in obesity rates; for instance, obesity concerns 38.2 percent of U.S. adults versus 15.2 percent of French adults, according to OECD. Yet obesity rates keep increasing in all developed countries, making it critical to understand the causes and the possible cures of obesity.

One of the most effective—and drastic—treatments against obesity is bariatric surgery, which consists in reducing the size of the stomach or re-routing the small intestine to a stomach pouch. Meta-analyses conclude that bariatric surgery promotes a sustainable reduction in weight, health risks, and mortality (Buchwald et al. 2004; Chang et al. 2014). Burgeoning research relying on before-after surgery studies also aim to better understand the psychological factors of obesity and the psychological impact of drastic weight loss (Hindle, Piedad Garcia, and Brennan 2017).

Impulsivity, measured by delay-discounting (DD, the preference for sooner smaller vs. larger later rewards) has been identified a potential psychological factor of obesity. Compared with lean subjects, overweight and moderately obese subjects exhibit greater DD (Fields, Sabet, and Reynolds 2013; Meule and Bleichert 2017). There are also correlations between DD and eating disorders such as anorexia or binge-eating (Davis et al. 2010; Decker, Figner, and Steinglass 2015). However, current literature provides little evidence of a causal effect of DD on weight gain (and no evidence of a causal effect of weight loss on DD). Also, DD has not been investigated in morbidly obese people, and it is unclear whether obesity-related impulsivity is specific to the food domain, or extends to other (e.g., monetary) domains.

In this research, we investigate the causal impact of drastic weight loss (via bariatric surgery) on DD. We also investigate DD in food and in monetary domains. We conducted two longitudinal studies with groups of French female morbidly obese patients from a hospital population qualifying for bariatric surgery, and groups of French female lean individuals with similar demographic characteristics.

In Study 1, the obese patients ( $N=74$ ,  $BMI\ 45.3\pm 0.65$ ) participated in a DD task before surgery, 3 months after surgery, and 12 months after. The lean individuals ( $N=40$ ,  $BMI\ 22\pm 0.40$ ) participated in the task twice with a 6-month interval. We used a simplified version of Li (2008)'s delay discounting procedure adapted for food and money. Participants made a series of binary choices between

four chocolates now and a larger number of chocolates one week later. The task was repeated with Euros.

Overall, obese patients exhibited greater DD for food (i.e. they asked for more chocolates in exchange of waiting one week) compared to lean individuals ( $\beta_{group} = 3.81$  ( $SE_{group} = 1.36$ ),  $Z_{group} = 2.88$ , [1.24, 6.57]). These differences were particularly pronounced at  $T_0$ , that is, when comparing pre-surgery obese patients and lean individuals ( $M_{obese, T_0} = 14$  ( $SE_{obese, T_0} = 0.94$ )  $>$   $M_{lean, T_0} = 10.2$  ( $SE_{lean, T_0} = 1.11$ );  $T_{group, T_0} = 2.60$ , [0.89, 6.70]) Delay discounting for food was attenuated post-surgery among obese patients but remained stable over time among lean subjects, as shown by the significant interaction effect between participant group and time ( $\beta_{group \times time} = 4.89$  ( $SE_{group \times time} = 1.85$ ),  $Z_{group \times time} = 2.64$ , [1.26, 8.52]). We found no difference between obese and lean subjects for monetary rewards, and no change post-surgery.

In Study 2, lean individuals (N=45, BMI 21.7±1.4) and obese patients (N=17, BMI 44±2.5) from the same hospital pool completed an incentive-compatible, delay-discounting task consisting of choosing between smaller-sooner and larger-later rewards for money and monetarily-equivalent chocolate rewards (Decker et al. 2015). Both groups repeated the task 6 months later, the obese patients after bariatric surgery.

We estimated discounting behavior with the “as soon as possible (ASAP)” DD model (Kable and Glimcher 2010) and compared differences in the discount parameter  $k$  between groups and across time. The ASAP model is a recent derivative of the standard hyperbolic discounting model (Green and Myerson 1996) from the neuroeconomics literature. As compared to the standard hyperbolic model, it can account for whether an individual is inconsistent when the sooner-smaller is available immediately versus not immediately (e.g. €10 now versus €15 in a week; €10 in one week versus €15 in two weeks).

We found again that obese patients exhibited greater impatience for food rewards than lean individuals ( $\beta_{group} = 0.065$  ( $SE_{group} = 0.019$ ),  $Z_{group} = 3.52$ , [0.029, 0.10]) and that this difference was most pronounced before surgery ( $k_{obese, T_0} = 0.0912$  ( $SE_{obese, T_0} = 0.023$ )  $>$   $k_{lean, T_0} = 0.0296$  ( $SE_{lean, T_0} = 0.007$ ),  $T_{T_0} = -2.48$ , [-0.114, -0.01]). While we did not find a significant interaction effect between participant group and time ( $\beta_{group \times time} = -0.029$  ( $SE_{group \times time} = 0.021$ ),  $Z_{group \times time} = -1.38$  [-0.070, 0.012]), a planned contrast for the difference in discounting before and after surgery showed that patients became less impatient after the surgery ( $M_{difference} = 0.041$ , ( $SE_{difference} = 0.018$ ),  $\chi^2 = 5.48$ , [0.0067, 0.076]). We found no such effects for money.

In conclusion, we provide novel evidence of differences in impatience for food between lean individuals and *morbidly* obese patients. We also show that bariatric surgery reduces such differences and that patients become less impatient post-surgery. Our results indicate that differences in DD are food-specific and do not extend to other rewards like money.

Interestingly, previous research has shown that lean and obese individuals show differences in the homeostatic control of food intake. For example, the functioning of hormones involved in signaling hunger and satiety (i.e., ghrelin and leptin) shows dysfunction in morbidly obese, which is restored after bariatric surgery (Poitou et al. 2005). This is why we also sampled different biomarkers of homeostatic control by collecting blood samples in both studies. We are currently exploring whether the differences in DD for food could be linked to differences in such biomarkers with the goal to provide a more holistic and biologically grounded model of differences in dietary decision making.

## Anticipated Interpersonal Feedback Reshapes Other-oriented Intertemporal Choices

### EXTENDED ABSTRACT

Consumers tend to appear myopic in their own intertemporal choices, favoring smaller sooner gratifications over larger later rewards that are more consistent with long-term wellbeing. However, many intertemporal decisions involve other people. How do these other-oriented decisions compare with otherwise identical self-oriented decisions?

We propose that other-oriented decisions may yield greater myopia (more choices of sooner-smaller options) than self-oriented decisions because the interpersonal feedback that consumers anticipate from their other-oriented decisions reshapes the tradeoff between immediacy and magnitude. In contrast, prior research has posited that other-oriented choices would be less impatient than self-oriented choices because the decision maker would be less tempted by the immediate gratification of the rewards (Hoch and Loewenstein 1991, Malkoc, Zauberman and Bettman 2010). This prediction has not been thoroughly tested, but is supported by some empirical results comparing decisions made for a nonspecific, abstract recipient with decisions made for the present self (Albrecht et al. 2010, McClure et al. 2004, Pronin, Olivola and Kennedy 2008).

Notably, the abstract other-oriented decisions previously studied lack the interpersonal consequences of typical other-oriented decisions, a critical factor in decision-making (Tetlock 1983). In an intertemporal choice involving other people, the anticipated consequences of feedback from the recipient often coincide with the timing of each option and covary with the magnitude of each choice option. Hence, besides the widely studied immediacy-magnitude tradeoff underlying the choice options per se (which underlies both self-oriented and other-oriented decisions), other-oriented decisions also involve a parallel immediacy-magnitude tradeoff in the anticipated feedback consequence associated with each option. In particular, discounting may be steeper for affect-rich stimuli (Tsukayama and Duckworth 2010) and interpersonal feedback can be more affect-rich than monetary outcomes. We thus theorize that anticipated interpersonal feedback renders other-oriented choices more impulsive than otherwise identical self-oriented decisions

In particular, we propose a decision model that incorporates both perspective-taking and anticipated interpersonal feedback and empirically test the four hypotheses derived from this model. Studies 1A-1C compared impatience in other-oriented decisions with self-oriented decisions, establishing a systematic difference. Studies 2-4 tested how recipient specificity, decision accountability, and feedback timing each moderate impatience in choices.

In Study 1A (N=157 MBA students), we examined intertemporal choices made for specific recipients with real consequences in 2 between-subjects conditions (choice for other vs. choice for self). Participants filled out a 5-min survey, and choose between two thank-you gifts for taking the survey, either to keep themselves or to give to a friend they had listed: a \$5 immediately redeemable gift card and a \$6 gift card redeemable in three weeks. More participants chose the \$5 gift card when the choice was for their friend to receive than when the choice was for themselves to keep (50.6% vs. 27.6%,  $\chi^2(1) = 8.59$ ,  $p = .003$ ,  $\eta_p^2 = .06$ ).

We replicated these results in another two scenarios with real recipients and real consequences. In Study 1B, with pairs of newly acquainted strangers making simultaneous choices (N = 88), participants were more likely to select an \$5 gift card when choosing for the other person (61.4%) than when choosing for themselves (34.1%;  $\chi^2(1) = 6.6$ ,  $p = .018$ ,  $\eta_p^2 = .08$ ). In Study 1C, with pairs of friends mak-

ing simultaneous choices ( $N = 116$ ), participants were more likely to choose an *SS* gift card when choosing for their friend (41.4%) than when choosing for themselves (19.0%,  $\chi^2(1) = 6.9$ ,  $p = .015$ ,  $\eta_p^2 = .06$ ). In sum, decision-makers made more impulsive choices when they chose for others than when they chose for themselves when these choices have real interpersonal consequences.

In Study 2, we aimed to reconcile the findings in the prior literature with those that we found in Study 1, by manipulating recipient specificity. We randomly assigned 552 Mturkers to 3 between-subjects conditions (choosing for-self, for-specific-other, for-nonspecific-other). Participants were asked to imagine a hypothetical scenario in which they chose between receiving a \$50 voucher and receiving a \$60 delayed voucher from an online store. Participants either chose for themselves, for a friend they had specified at the beginning of the study, or for an abstract and nonspecific customer of the store. Participants were more likely to choose the *SS* option when they were choosing for a specific other person (50.8%), than either for themselves (41.8%) or for the nonspecific other person (37.4%; contrast  $t(549) = 2.5$ ,  $p = .012$ ). In sum, people are more patient in intertemporal choices when choosing for specific others (but not general others) than for themselves.

In Study 3 ( $N = 275$ ), we further tested the role of decision accountability. Our decision model, which incorporates the role of interpersonal feedback on the decision, predicts that other-oriented intertemporal decisions would be less impulsive when decision-makers feel less accountable for the decision outcome, such as when their choice is merely a recommendation to the other person, who would then make a final decision. Consistent with this prediction, participants were more impulsive when making accountable decisions for a specific other person ( $t(224) = 4.41$ ,  $p < .001$ ) or decisions for themselves ( $t(160) = 3.63$ ,  $p = .001$ ).

In Study 4, we tested the impact of feedback timing on relative impatience in other-oriented choices. When interpersonal feedback is delayed for all decision outcomes, our model predicts that other-oriented decisions would be less impulsive. We randomly assigned 350 Mturkers to 2 (choice for a specific other vs. choice for self)  $\times$  2 (no-delay vs. delay in feedback) conditions. Choices in the sooner-feedback conditions replicated out prior finding that other-oriented decisions were more impulsive (61.9% vs. 30.9%,  $F(1,163) = 17.5$ ,  $p < .001$ ,  $\eta_p^2 = .10$ ). This self-other choice difference was attenuated in the delayed-feedback conditions (48.2% vs. 38.4%,  $F(1, 165) = 1.62$ ,  $p = .205$ ; 2-way interaction  $F(1, 328) = 3.96$ ,  $p = .047$ ).

These findings shed light on other-oriented decisions in a realistic consumer context and broaden the scope of research of intertemporal choices. Our results suggest that delegating decisions to others is not an effective strategy to reduce the choice of impulsive options, and may result in more myopic choices than choosing for oneself.
