### EXTENDED ABSTRACT

Blurry backgrounds are now ubiquitous in visual ads and in the design of apps and websites. Various online businesses adopted blurry backgrounds in their commercial webpage with blurry backgrounds perceived as cool and stunning (Kamps 2013). The question we ask is: is the use of blurriness simply a matter of aesthetic considerations or is it possible that the use of blurred backgrounds can impact consumer decisions, for example when choosing a hotel to stay at or purchasing a lottery ticket?

Aerial perspective theory hypothesizes that spatially distant objects appear blurrier than do spatially nearer objects (Palmer and Brooks 2008). Further, construal level theory (CLT; Trope and Liberman 2010) suggests that greater spatial distance activates a high-level construal (Liberman and Förster 2009), which in turn increases risk-taking by promoting sensitivity to payoff (Sagrignano et al. 2002). By connecting these two distinct literatures, our work leads to a novel prediction: the use of blurry backgrounds could activate a high-level construal, which in turn could facilitate consumers' risk-taking.

We report six experiments that collectively explore our theorizing. We first ran two pilot studies to examine the aerial perspective theory empirically. In Pilot Study 1a (N=570), we manipulated four levels of blurriness (from 0% to 3%) of the two photos showing horizontally juxtaposed objects (i.e., trees or houses). Participants assigned to a 2 (photo type: houses vs. trees) x 4 (blurriness: 0% vs. 1% vs. 2% vs. 3%) between-subjects design saw one of eight photos and estimated how far the objects were located. The results showed that participants' perceived distance of the objects increased linearly in proportion to the level of blurriness. Pilot Study 1b (N=215) adopted a 3 (photo type: houses vs. trees vs. buildings) x 3 (blurriness: 0% vs. 5% vs. 10%) mixed-design with photo type as a within-subjects factor, where only backgrounds (not target objects) were blurred and a categorization task (Wakslak et al. 2006) was included to assess participants' construal level. This study found that participants' perceived distance increased linearly in proportion to the level of blurriness, while their levels of construal linearly decreased. Bootstrapping results (5000 resamples) yielded a significant indirect effect of blurry backgrounds on construal through perceived distance.

In Study 1 (N=118), we adopted the website format from a real website titled Mystery Hotel (wotif.com), on which consumers book a hotel without knowing the hotel name and thereby take risks. We replaced the website's original background with two different pretested backgrounds (i.e., abstract pattern and hotel lobby) and manipulated blurriness (0% vs. 10%) for each of them. 118 MTurkers assigned to one of the four (blurriness: blurry vs. sharp) x (image type: abstract pattern vs. hotel lobby) between-subjects conditions viewed the website image and answered the two-item ( $\alpha = .97$ ) purchase intention questions for hotel booking. An ANOVA revealed only a significant main effect for blurriness, showing that exposure to blurry backgrounds increased consumers' purchase intention. A post-hoc study (N=97) confirmed that the Mystery Hotel website was significantly riskier but not more curiosity-evoking, compared to the version where hotel names were revealed. Since the pretested images were rated as equally familiar, the results also rule out the processing fluency account whereby fluency affects risk perception through perceived familiarity (e.g., Song and Schwartz 2009).

Study 2 (N=124) employed the same procedure and measures as those used in Study 1, but the study used only the abstract pattern background and adopted a categorization task after the purchase intention questions. Replicating Study 1, blurry backgrounds increased consumers' purchase intention to make a hotel booking. Blurry backgrounds also elevated participants' levels of construal. Lastly, bootstrapping results (5000 resamples) yielded a 95% CI excluding zero, suggesting that construal level mediated the effect.

In Study 3 (N=111), we aimed to replicate the effects in the online lottery domain while ruling out two alternative hypotheses: 1) ambiguity tolerance and 2) mood effects. By combining another pretested background (i.e., abstract pattern) with an online Powerball website format, and manipulating blurriness, we created a pair of fictitious Powerball website images. Participants randomly assigned to one of the two conditions (blurriness: blurry vs. sharp) saw the fictitious website and answered the two-item ( $\alpha = .89$ ) purchase intention questions. Participants then completed a 20-item ambiguity tolerance scale (AT-20), rated their feelings using six mood items, and answered a question about their lottery purchase frequency. An ANCOVA with lottery purchase frequency as a covariate showed that blurry backgrounds increased participants' purchase intention. We also found no significant differences in participants' AT-20 scores and mood scores across conditions.

In Study 4 (N=303), we investigated whether emphasizing riskiness of the target option would attenuate the effect. MTurkers assigned to a 2 (blurriness: blurry vs. sharp) x 3 (headline: payoff salient vs. probability salient vs. control) between-subjects design were presented with a real lottery task, shown with a blurry or sharp background. The main body text noted that participants had a 25% chance of winning an extra \$2, in addition to the \$0.5 recruitment fees. Headline sentences above this main text were manipulated such that either payoff (extra \$2) or probability (a 25% chance) was emphasized. In the control condition, no such emphasis was placed. Participants revealed their intention to play the lottery ("Yes" vs. "No") and completed a response category width task (Krüger et al. 2014) for construal level assessment, whereby a wider category estimation indicates a higher construal level. Blurry backgrounds increased participants' lottery participation rates in the control and payoff salient conditions, but not in the probability salient condition. Blurry backgrounds also induced wider category estimates in the control and payoff salient conditions, whereas the effect was not significant in the probability salient condition. Bootstrapping analyses (5000 resamples) also validated a moderated mediation model, showing that the mediating role of construal level was only valid in the control and payoff salient conditions.

Together, these results suggest that exposure to blurry backgrounds activates a high-level construal which in turn promotes consumers' risk-taking. Additionally, the results indicate that highlighting the riskiness of the target option may attenuate effects.

# When products become autonomous: Drawbacks of a perceived lack of control and how to resolve it

Moritz Joerling, RWTH Aachen University, Germany  
Robert Böhm, RWTH Aachen University, Germany

## EXTENDED ABSTRACT

### INTRODUCTION

Autonomous products are on the rise. Partly or fully autonomous products fulfill tasks and make decisions in more and more domains, where the consumer has previously executed actions manually. It is projected that 32.4 million units of autonomous products only for domestic tasks will be sold by 2020, representing a market value of \$11.3 billion and a growth rate of 30-35% per year (*Executive Summary World Robotics 2017*).

Therefore, the investigation of consumer perceptions of autonomous products is a research topic of growing importance (Schweitzer and van den Hende 2016). On the one hand, consumers might be attracted by an increased convenience and by the option to use the time saved to engage in different activities. On the other hand, they might reject autonomous products due to perceived disempowerment and lack of control (Schweitzer and van den Hende 2016) or higher perceived complexity and risk (Rijsdijk and Hultink 2003). The perception of having control appears to be particularly relevant in this regard, since being in control positively contributes to humans' positive emotions and well-being (e.g., Langer 1975), whereas a lack of control induces negative feelings such as stress or even depression (Peterson and Stunkard 1992).

Beyond (lack of) control, we propose "responsibility" for the outcome as an additional important factor for the perception of autonomous products. To understand post-consumption evaluations and reactions, the attribution of responsibility is particularly important (Weiner 2000). It has been shown that the valence of outcome has an important impact on the perception of responsibility (Bradley 1978; Kelley 1967; Miller and Ross 1975). Therefore, we differentiate between positive and negative outcomes obtained by an autonomous product. The relevance to investigate responsibility in case of negative outcomes obtained by an autonomous product is obvious. For example, in the context of healthcare, where autonomous products are already in place: Who feels responsible when a surgery-supporting robot or a robot to support care services coincidentally harms a person? It is important to note that legal and perceived responsibility can fall apart. Such incongruity can cause cognitive dissonance and a decrease of subjective well-being (Festinger 1957), which, in turn, might affect product adoption and customer experience (Anderson et al. 2013).

Beside negative outcomes, we also consider positive outcomes as an important factor for the product experience. Responsibility for positive outcomes raises satisfaction (Tsiros, Mittal, and Ross 2004), commitment (Van Dyne and Pierce 2004), awareness, accomplishment, and self-worth (Wolf and McQuitty 2011).

The present contribution provides the first comprehensive investigation of responsibility for outcomes obtained by autonomous products, including its psychological processes and potential interventions to increase perceived outcome responsibility. As such, we link the literature on behavioral and decisional control (e.g., Averill 1973; Inesi et al. 2011) as well as the literature on responsibility perception, i.e. self-serving bias (Bradley 1978; Kelley 1967; Miller and Ross 1975) to the increasingly important research field of consumer

perceptions of autonomous products (Rijsdijk and Hultink 2003, 2009).

### THEORETICAL BACKGROUND AND RESEARCH HYPOTHESES

#### *Perceived behavioral control*

Ajzen (1991) defines perceived behavioral control as "the individual's perception of the extent to which performance of the behavior is easy or difficult." To prevent misunderstanding of the term it is suggested to read "perceived behavioral control" as "perceived control over performance of a behavior" (Ajzen 2002). In context of autonomous products, the user is replaced as a physically active decision-maker by automated systems (Wolf 2015) and products operate without interference of the user (Rijsdijk and Hultink 2009), what leads to the following hypothesis:

*Hypothesis 1: Perceived behavioral control over products decreases with an increasing degree of product autonomy.*

#### *Responsibility*

Responsibility is the „extent to which decision makers feel a sense of ownership of the outcome and so may credit themselves for good and blame themselves for bad outcomes.“ (Botti and McGill 2006). Research of perceived responsibility shows that with increasing engagement of persons in the decision process, the emotional evaluation of the output increases as well (Botti and Lyengar 2004). DeCharms (1968) suggests that control is an important factor for the evaluation of the output, since individuals value output more positively when they perceive the behavior stems from their own choice. Output will be devaluated, in contrast, when individuals perceive their choice is restricted by environmental circumstances (see also Festinger 1957). Since the decision is an important source for control (Inesi et al. 2011) and autonomous products replace humans as physical decision-makers (Wolf 2015), we hypothesize:

*Hypothesis 2: The perceived responsibility for outcomes decreases with increasing lack of perceived behavioral control over the product.*

#### *Self-serving bias*

In the context of attribution theory, extensive research exists about the influence of the outcome domain, i.e., positive vs. negative outcomes, on the corresponding attribution (e.g., Miller and Ross 1975; Ross 1977). The research of attribution theory also detected some attributional biases, among others self-serving bias. The self-serving bias suggests that people tend to attribute negative outcomes to external circumstances and positive outcomes to themselves, as a mechanism of self-protection (Miller and Ross 1975). Following this theory, one would expect that people attribute negative outcomes of autonomous products to the product, whereas positive outcomes should be attributed to themselves (Moon 2003). Therefore, we hypothesize:

*Hypothesis 3: Positive outcomes obtained by autonomous products are more likely attributed internally, whereas negative outcomes are more likely attributed externally, i.e., to the autonomous product.*

Taken together, we expect to find a moderated mediation effect.

## EMPIRICAL STUDIES

### Study 1

*Purpose* of study 1 was to investigate whether the degree of product autonomy influences the outcome responsibility. Therefore, we conducted an online experiment with a 3 (product category: car vs. heater vs. lawn mower)  $\times$  2 (degree of autonomy: manual level vs. full autonomy)  $\times$  2 (outcome domain: negative vs. positive) between-subjects design.

*Method.* We gathered  $N = 321$  participants via Prolific. Participants have been randomly assigned to one of three product categories (car, heater, or lawn mower) as well as to one of the product autonomy conditions (manual level vs. full autonomy). After reading the product descriptions, participants answered questions about the perceived autonomy (Rijsdijk and Hultink 2003) and perceived behavioral control of the specific product (Collier and Sherrell 2010). Afterwards, participants have been randomly assigned to a positive or negative outcome description and answered three questions about the outcome responsibility (Botti and McGill 2006).

*Findings.* We conducted a moderated mediation analysis as suggested by Preacher, Rucker, and Hayes (2007). We indeed confirm a significant mediation of perceived behavioral control for the relation between product autonomy and outcome responsibility for positive outcomes ( $B = -.70$ ;  $SE = .17$ ; 95% CI [-1.04, -.38]; based on 10,000 bootstrap-iterations). In the negative outcome domain, however, the mediation effect of perceived behavioral control disappears ( $B = -.28$ ;  $SE = .1717$ ; 95% CI [-.6293, .0458]).

### Study 2

*Purpose.* Opposite to our expectations, we find in study 1, that the mediation of perceived behavioral control for the relation between product autonomy and perceived responsibility, only applied to positive (i.e., successful) outcomes but not to negative ones (i.e., failures). Therefore, we aimed in our second study to identify the process that causes the high responsibility for negative outcomes obtained by autonomous products.

In our first study, the products were described as if the participant would own them. Although this had no particular reason with regard to the experimental manipulations, it may have affected participants' responses. Therefore, we propose and test the effect of perceived ownership on the perception of responsibility of negative outcomes obtained by manual or autonomous products.

Ownership can be differentiated in legal and psychological ownership (Pierce, Kostova, and Dirks 2001). Psychological ownership describes the feelings of ownership people develop towards objects (Pierce, Kostova, and Dirks 2003). It can be defined as "the state in which individuals feel as though the target of ownership or a piece of that target is 'theirs'" (Pierce et al. 2003, 86). Beyond that, psychological ownership can appear in the absence of legal ownership (Furby 1978).

The feeling of ownership is associated with different behaviors and effects, like citizenship or experienced responsibility (Pierce et al. 2003). Already children learn from their parents to take care of their own things, what may explain the importance of responsibility for owned things (Furby 1978). Moreover, feelings of responsibility

include positive behaviors as caring for the owned product and protecting it (Pierce et al. 2003). Therefore, the feeling of owning an autonomous product may increase the perception of responsibility for the outcomes obtained by this product. Accordingly, we hypothesize:

*Hypothesis 4: Responsibility for negative outcomes obtained by autonomous products increases when individuals perceive ownership of the product, whereas responsibility for negative outcomes obtained by manual products is independent of perceived ownership.*

*Method.* We test our hypothesis in an online experiment. We used the manual vs. autonomous car vignette of study 1 but additionally varied whether the car was described as being owned by the participant vs. provided by a company (and used by the participant). Hence, we applied a 2 (degree of autonomy: manual vs. full autonomy)  $\times$  2 (ownership: owned vs. non-owned) between-subjects design. Note that we only used the scenario with a negative outcome because the perception of negative outcomes was of particular interest in the current study. We gathered  $N = 236$  participants via Prolific Academic. As in Study 1, participants were randomly assigned to one of the vignettes. After reading the product description, they answered questions on the perceived autonomy, perceived behavioral control, and perceived ownership. Then the negative outcome was described and participants stated their perceived outcome responsibility.

*Findings.* As expected, we find a significant interaction effect between perceived behavioral control and ownership condition on outcome responsibility ( $B = -0.42$ ,  $SE = .10$ ,  $p < .001$ ;  $f = 0.07$ ). A lack of control decreases the responsibility for a negative outcome only when this outcome is obtained by a non-owned product ( $B = 0.43$ ,  $SE = .07$ ,  $p < .001$ ) but not by an owned product ( $B = 0.01$ ,  $SE = .07$ ,  $p = .874$ ). Additionally, perceived behavioral control mediated the effect of autonomy degree (manual vs. autonomous product) on perceived responsibility only in case of non-owned products (Index of moderated mediation = 1.33;  $SE = .33$ ; 95% CI [0.66, 2.01]). This indicates that a lack of control accounts for reduced responsibility for a negative outcome only when the participant perceives no ownership of the product (indirect effect:  $B = -1.22$ ;  $SE = .32$ ; 95% CI [-1.85, -0.57]). For a negative outcome obtained by an owned product, participants feel responsibility irrespective of perceived control over the product (indirect effect:  $B = 0.11$ ;  $SE = .33$ ; 95% CI [-0.52, 0.77]).

### Study 3

*Purpose* was to test an intervention that could increase consumers' responsibility for positive outcomes obtained by autonomous products. We tested whether the mere option to potentially interrupt product autonomy might increase consumers' perceived controllability and, in turn, outcome responsibility, particularly for positive outcomes. We used two product stimuli (car vs. heater), which both described a fully autonomous product. In one condition, participants were told they would have the possibility to interrupt the product autonomy, whereas in the other condition they had no such option. Afterwards, participants learned of a positive or negative outcome obtained by the product. Hence, we applied a 2 (possibility to interrupt product autonomy: uninterruptible vs. interruptible)  $\times$  2 (outcome domain: positive vs. negative)  $\times$  2 (product category: car vs. heater) between-subjects design. In line with our reasoning regarding the effect of the intervention, we hypothesized a moderation effect:

*Hypothesis 5: Responsibility for positive outcomes obtained by autonomous products increases when individ-*

uals have the possibility to interrupt the product, whereas responsibility for negative outcomes is independent of the possibility to interrupt the product autonomy.

**Method.** We gathered  $N = 223$  participants online via Prolific Academic. As in the previous studies, we assessed perceived behavioral control following the product description and assessed perceived outcome responsibility following the outcome description.

The procedure of the experiment was identical to Study 1 and 2, hence, participants were randomly assigned to one of the vignettes. To further stimulate a realistic feeling for the described product, we showed pictures of the described products in addition to the product description.

**Findings.** Participants indeed perceived higher behavioral control over autonomous products with the possibility of interruption ( $M_{interruptible} = 4.11$ ,  $SD = 1.51$  vs.  $M_{uninterruptible} = 2.64$ ,  $SD = 1.53$ ; OLS regression:  $B = -1.47$ ,  $SE = .20$ ,  $p < .001$ ;  $f = 0.19$ ). Moreover, a moderated mediation analysis provides support for the expected causal pattern (Index of moderated mediation =  $-0.43$ ;  $SE = .19$ ; 95% CI  $[-0.85, -0.09]$ ). Perceived behavioral control mediated the effect of uninterruptible vs. interruptible autonomous products on the perceived responsibility for positive outcomes ( $B = -0.45$ ;  $SE = .14$ ; 95% CI  $[-0.76, -0.20]$ ). In the negative outcome domain, as expected, the mediation effect failed to reach significance ( $B = -0.18$ ;  $SE = .14$ ; 95% CI  $[-0.29, 0.26]$ ).

## GENERAL DISCUSSION

Autonomous products are becoming increasingly popular. Our findings contribute to this developing research field. In three experimental studies, we have shown that perceived control over a product is an important element for the evaluation of outcomes obtained by this product. That is, when consumers perceive a lack of control over the product, this may decrease their perceived outcome responsibility. Interestingly, we find and replicate that this effect is restricted to positive outcomes, whereas participants feel generally more responsible for negative outcomes, irrespective of whether these were obtained by manual or by autonomous products. We are able to show the boundary conditions of this effect: In Study 2, we demonstrate that the high perceived responsibility for negative outcomes is due to the perception of ownership over the product (and decreases when ownership is absent). In relation to an increasing amount of alternative consumption forms like access-based consumption or product sharing, this represents an important finding. Since companies like UBER already test autonomous cars in field ("Self-Driving Cars | Explore Pittsburgh | Uber" n.d.), it is a realistic scenario, that customers will access and share autonomous products in the future. The missing responsibility for negative outcomes might represent an important factor for customers to demand such services.

The decreased responsibility for positive outcomes due to lower behavioral control over autonomous products is also of relevant interest. Since responsibility for outcomes may increase satisfaction (Tsiros et al. 2004), commitment (Van Dyne and Pierce 2004), awareness, accomplishment, and self-worth (Wolf and McQuitty 2011), marketers need solutions to overcome the lack of responsibility. We propose one simple solution: Increasing consumers' perception to have the possibility of interrupting the product autonomy at any time increases perceived controllability and, in turn, perceived responsibility for positive outcomes. This effect is interesting because in our experimental setting consumers did actually not interfere, and the outcome was still obtained solely by the autonomous product. This intervention may be of interest for developers and designers

of autonomous products because it could increase consumers' post-purchase satisfaction.

# Shared Values, Trust, and Consumers' Deference to Experts

Samuel G. B. Johnson, University of Bath, UK

Max Rodrigues, DePaul University, USA

David Tuckett, University College London, USA

## EXTENDED ABSTRACT

Consumers develop expertise in some areas (Alba and Hutchinson 1987), but are necessarily ignorant in others and must defer to experts. Deference creates a trust problem because others often have their own agenda (Sperber et al. 2010), particularly in economic contexts where money is on the line, as well as a problem of consensus because experts frequently disagree. Although advice-taking and attitude change have been carefully studied in other contexts (Bonaccio and Dalal 2006; Fleming and Petty 2000), little work has examined a potentially key determinant of consumers' deference to expert advice: The alignment between the consumer's and expert's cultural-ideological values.

Although values influence risk assessments in domains such as climate change (Kahan et al. 2010), little is known about how experts' values influence deference in less political contexts, such as consumer choices. We hypothesized that consumers would use shared values as a cue to the broader quality of the expert's judgment (and perhaps their trustworthiness as well). Further, we hypothesized that this effect would be exacerbated among consumers who subscribe to objectivist theories of moral truth (Goodwin and Darley 2008), since this view would imply that ideologically aligned experts have superior access to fundamental truths.

**Study 1** examined whether shared values play a role in consumer advice-taking in a hedonic domain—book recommendations. Participants ( $N=198$ , 38 excluded) were introduced to two book critics—one whose biography, publications, and facial features suggested more hierarchical values (e.g., deference to authority), and one who was presented as favoring egalitarian values (e.g., political equality). After answering multiple-choice questions about each advisor's biography, participants evaluated 14 books—2 for which the advisors agreed, and 12 for which they disagreed (half recommended by each advisor, counterbalanced), with their comments adapted from real reviews at [lithub.com](http://lithub.com). For each book, participants reported their likelihood of reading the book (0–100 scale) and checked a box to receive more information about the book at the study's end (a link to the book's Amazon page). Finally, participants completed value scales used in previous work (Kahan et al., 2010).

Difference scores for product evaluations between the products recommended by the egalitarian advisor and the hierarchical advisor were strongly predicted by egalitarianism ( $b=8.97$ ,  $p<.001$ ) but had no relationship with communitarianism. This shows not only that cultural values not only predict which experts consumers defer to, but that these effects are specific to the particular dimension of experts' and consumers' worldview under consideration (we manipulated experts' egalitarianism but not communitarianism). These expressed purchase intentions also manifested in information-seeking behavior, when participants were given the opportunity to access links to the books' Amazon pages. A mediation analysis uncovered a significant indirect effect of egalitarianism on clicks via purchase intention ratings (95%CI: .010 to .035).

Moreover, a replication study with undergraduate participants and consequential choices (a chance to win the chosen book in a lottery) uncovered a similar pattern of results, with choices deferential to the egalitarian rather than hierarchist critic predicted by egalitarianism ( $b=0.47$ ,  $p=.043$ ) but not communitarianism ( $b=0.08$ ,  $p=.71$ ).

**Study 2** extended the findings to more utilitarian products (e.g., blenders, printers, dehumidifiers). Participants were introduced to the same advisors, whose biographies were altered so that they were product reviewers. Participants evaluated 10 products, for which the advisors disagreed about 8 (counterbalanced), with their comments based on real Amazon reviews. Participants reported the probability that they would consider purchasing each product, and checked a box to receive more information. As in Study 1, egalitarianism was a strong predictor of purchase intention patterns ( $b=7.11$ ,  $p<.001$ ), while communitarianism was not ( $b=-0.53$ ,  $p=.75$ ). The indirect mediation path for clicks (Egalitarianism->Purchase Intentions->Clicks) was marginally significant (95%CI: -.001 to .013). Finding similar patterns of value-based deference for utilitarian products such as blenders undercuts the possibility that the effects of Study 1 were driven by social signaling (i.e., reading books to affiliate with one's cultural group).

**Study 3** tested the mechanisms. We hypothesized that perceived judgment would play a crucial mediating role, while also measuring the role of trust. We also measured similarity to test whether judgment has an effect over-and-above brute similarity (which has been found to be a significant predictor of attitude change; Burger et al. 2004; see also Fleming and Petty 2000). As in Studies 1 and 2, differences in purchase intention were predicted by egalitarianism ( $b=3.79$ ,  $p=.019$ ) but not communitarianism ( $b=0.68$ ,  $p=.67$ ). In a parallel mediation analysis, judgment (indirect effect 95%CI: 0.02 to 3.70) and similarity (95%CI: 0.86 to 4.39) together fully mediated the effect of shared values on purchase intentions, with no further effect of trust (95%CI: -1.80 to 1.38).

An analogous study using utilitarian products and WTP as the dependent measure uncovered similar patterns of mediation, with judgment playing the dominant role.

**Study 4** tested whether the mediating effect of perceived judgment quality was itself moderated by participants' beliefs about the objectivity of moral truth (e.g., "There are no clearly true or false answers to [moral] questions" [reverse-coded]). Analogous to previous studies, deference as measured by purchase intentions were affected by egalitarianism ( $b=0.68$ ,  $p<.001$ ) but not communitarianism ( $b=-0.03$ ,  $p=.82$ ). Participants in this study also made consequential choices, which were likewise affected similarly ( $z=2.49$ ,  $p=.013$  and  $z=0.15$ ,  $p=.88$ , respectively). A moderated mediation analysis revealed that egalitarianism predicted differences in perceived judgment ( $b=1.05$ ,  $p<.001$ ), but moreso among participants high in moral objectivism ( $b=0.26$ ,  $p=.018$ ). This led to a stronger indirect effect (egalitarianism->judgment->deference) for participants high rather than low on objectivism ( $b=0.93$  vs.  $b=0.56$ ) and a significant index of moderated mediation (95% CI: 0.00 to 0.36).

**Implications.** These studies show that the match between consumers' and experts' values is a major determinant of deference, leading consumers to favor some products over equivalent others, with this effect generalizing across hedonic and utilitarian products. This is important both to practitioners and to consumer advocates. While these effects can present opportunities for marketers to better target advertisements, they also expose consumers to the risk of persuasion attempts coupled with insincere value claims, which may circumvent consumers' vigilance.

# The Best of Both Worlds: Androgyny in Consumer Choice

Niusha Jones, University of North Texas, USA

Blair Kidwell, University of North Texas, USA

## EXTENDED ABSTRACT

The marketplace is awash with masculine or feminine brands and products designed to appeal specifically to men or women (Grohmann 2009; Yan 2016). Are such binary appeals truly effective, or might some consumers prefer brands or products that feature a blend of masculine and feminine associations?

We define an *androgynous choice* as a choice in which brand and product design dimensions are associated with masculinity and femininity. For example, Apple MacBook is an androgynous choice because the brand is masculine (a high tech brand represented by Steve Jobs- a male spokesperson) (Grohmann 2009) and the product has a feminine design (light color, thin, and slick notebook) (Lieven et al. 2015). Drawing upon the link between masculinity and femininity with agency and communion (Bakan 1966; Wiggins 1991) and simultaneous pursuance of different motives on dimensions of a single choice (Chan, Berger, and Van Boven 2012), we propose that consumers can simultaneously pursue both agentic and communal motives through acquiring androgynous choices. Furthermore, to maximize their goal attainments, people tend to prefer “multifinal” choices that satisfy multiple purposes simultaneously rather than choices associated with single purposes (Kopetz et al. 2008). Thus, we propose that androgynous choices satisfy both agency and communion and are thus multifinal and preferred over either masculine or feminine choices.

In study 1, we coordinated with a local bakery to conduct a field experiment to monitor customers’ choices of androgynous, masculine, and feminine choices. Multiple brand names were tested, and a fictional masculine (i.e., Brown Bear) and a fictional feminine brand (i.e., Sunny Bunny) were chosen. The bakery made same size cookies in the feminine (i.e., round) and masculine (i.e., rectangular) shapes. The match between the feminine brand with masculine shaped cookie produced an androgynous choice (Sunny Bunny brand/rectangular cookies), and the match between feminine brand and feminine shaped cookie produced a feminine choice (Sunny Bunny brand/round cookies). The match between masculine brand with feminine shaped cookie produced an androgynous choice (Brown Bear/round cookies), and the match between masculine brand and masculine shaped cookie produced a masculine choice (Brown Bear/rectangular cookies). Over the course of study, bakery staff put the cookies on the countertop on similar plates; brand names were printed on cards and set next to the plates in card holders. One hundred and twenty-nine customers’ choices were recorded through a hidden camera. Consumers preferred an androgynous choice (Sunny Bunny brand/rectangular cookies) over a polarized feminine (Sunny Bunny brand/round cookies) ( $N_{\text{Androgynous}} = 45$  vs.  $N_{\text{Polarized}} = 22$ ,  $\chi^2(1) = 7.89$ ,  $p < 0.01$ ). Further, consumers chose an androgynous choice (Brown Bear/round cookies) over a polarized masculine (Brown Bear/rectangular cookies), ( $N_{\text{Androgynous}} = 51$  vs.  $N_{\text{Polarized}} = 11$ ,  $\chi^2(1) = 25.80$ ,  $p < 0.01$ ). Study 1 provided preliminary support for the hypothesis that an androgynous choice will have a greater influence on consumer preferences than will single-gender choices.

In study 2, we examine whether simultaneous pursuance of agency and communion underlies consumers’ preferences for androgynous choices. A total of 211 participants viewed an advertisement for an Apple MacBook, expressed their willingness to purchase, and responded to measures of agentic and communal motives on the CSIV scale (Locke et al. 2012). Finally, participants evaluated

the product in terms of masculinity and femininity and responded to demographics. Participants perceived the Apple MacBook as an androgynous product ( $M_{\text{masculinity}} = 5.43$ ,  $M_{\text{femininity}} = 5.38$ ). The results of the analysis (Process model 1, Hayes 2017) showed that the interactive effect of agency and communion was a significant predictor of consumers’ willingness to purchase the androgynous product ( $b = .15$ ,  $p = .03$ ). To explore the significant interaction, we used the Johnson-Neyman technique (Spiller et al. 2013). The effect of agentic motives on boosting willingness to purchase an androgynous product was significant when the communion motive was higher than 6.38 ( $p = .05$ ). The outcome of this experiment provides support for our hypothesis that simultaneous pursuance of agentic and communal motives drives preferences for androgynous choices.

In study 3, we use a moderation-of-process design (Spencer, Zanna, and Fong 2005) to provide further evidence for the proposed mechanisms. We selected five choices associated with masculinity, five associated with femininity, and five associated with androgyny. Two hundred and fifty-three students were randomly assigned to one of the 4 (prime: control, agency, communion, and agency-communion)  $\times$  3 (gender associations of choice: masculine, feminine, androgynous) conditions in a mixed model with product associations serving as a within-subject factor. To invoke agency and communion, we used recall tasks (McAdams 2001). Then, respondents indicated their willingness to pay for each product (Rucker and Galinsky 2008). A mixed model ANOVA revealed a significant interaction between gender association of choice and prime conditions ( $F(3, 249) = 3.37$ ,  $p = .02$ ). Consumers indicated higher willingness to pay for masculine choices when they were primed with agentic motives ( $M_{\text{agency}} = 5.03$ ,  $M_{\text{Control}} = 4.29$ ,  $p = .03$ ). Participants showed a higher willingness to pay for androgynous choices when they were primed with agentic-communal motives ( $M_{\text{Agency and Communion}} = 6.22$ ,  $M_{\text{Control}} = 5.56$ ,  $p = .04$ ). Participants indicated higher willingness to pay for feminine choices when they were primed with communal motives contrasted with the control condition ( $M_{\text{Communion}} = 5.16$ ,  $M_{\text{Control}} = 4.28$ ,  $p = .01$ ).

Research in marketing has predominantly followed a bipolar perspective towards masculinity and femininity by studying polarized masculine or feminine choices (e.g., Debevec and Iyer 1986; Grohmann 2009). There are three main goals in the present research. First, while prior work has focused on consumers’ responses to binary masculine and feminine choices, we examine consumers’ responses to the co-occurrence of masculinity and femininity within a single choice. Second, in this work, we attempt to reconcile two diverging streams of literature that focus solely on brand or product gender associations by studying consumers’ responses to varying gender associations across brand and product dimensions. Third, while prior research has focused on identity-congruency as the main driver of consumers’ preferences for masculine and feminine choices, we focus on agency and communion as motives that explain chronic and situational preferences for such choices.

# The Mystique of Masculine and Feminine Choices: How Aversive Feelings Underlie Preferences

Niusha Jones, University of North Texas, USA

Blair Kidwell, University of North Texas, USA

## EXTENDED ABSTRACT

Research suggests that consumers seek masculine or feminine choices to reinforce their gender identities (Debevec and Iyer 1986; Grohmann 2009). But, is the entire allure of a masculine or a feminine choice captured in securing one's sense of manhood or womanhood? If not, what other purposes might these choices serve?

Drawing on the symbolic links between agency with masculinity and communion with femininity (Bakan 1966) and research on symbolic compensatory consumption (Rucker and Galinsky 2013; Wicklund and Gollwitzer 1981), we propose that consumers consider masculine and feminine choices as sources of agency and communion, and thereby use masculine choices to alleviate low-agentic feelings (e.g., feeling incompetent, powerless, or incapable) and feminine choices to allay low-communal feelings (e.g., feeling excluded, disconnected, or isolated). Further, we suggest that these boosts in preferences for masculine and feminine choices are due to the perceptions that acquiring these choices would provide consumers with increased senses of agency and communion.

In study 1, we used an Implicit Association Test (Nosek, Greenwald, and Banaji 2005) to explore implicit cognitive associations between agentic attributes and masculine choices, communal attributes and feminine choices. Based on a pretest eight masculine and eight feminine products were chosen. Further, eight agentic and communal attributes were chosen (Fiske et al. 2002; Spence et al. 1979). One hundred ninety-four students participated in the IAT test. For each participant, the strength of the association between concepts (D-Score) was calculated. The mean IAT D-score was .50, which is significantly different from 0;  $t(185) = 15.91, p < .001, d = 1.16$ . The positive D-score shows that participants were faster in categorizing stimuli in the compatible rather than incompatible trials suggesting that consumers implicitly associate masculine choices with agency while they associate feminine choices with communion. This study provides preliminary evidence for our theorizing that consumers associate masculine choices with agency and feminine choices with communion and lays the groundwork for our proposed compensatory functions.

In study 2, we aimed to provide evidence for the effect of low-agency on preferences for masculine choices and the underlying mechanism. One hundred thirty students were randomly placed in low-agency (Horowitz et al. 2001) and control conditions. Participants viewed advertisements for a Taichi retreat, they expressed their willingness to participate in the retreat and indicated to what extent they thought that participation in the retreat would provide them with a sense of agency. An ANOVA analysis showed that there was a main effect of low-agency condition on increasing consumers' preferences to participate in a Taichi retreat ( $M_{\text{Low-agency}} = 5.82, M_{\text{Control}} = 4.49, F(1, 128) = 9.22, p < .01$ ). There was a significant effect of the manipulations on the perceptions of agency provided by the masculine choice ( $M_{\text{Low-agency}} = 6.37, M_{\text{Control}} = 5.45, F(1, 128) = 8.15, p < .01$ ). The results of the mediation analysis (Hayes 2017) suggested that participants' higher willingness to participate the Taichi retreats was due to the perceptions that these retreats would provide them with a sense of agency ( $\beta = .82, SE = .29$ ).

In study 3, we aimed to provide evidence for the effect of low-communion on driving preferences for feminine choices and the underlying mechanism. One hundred thirty-seven students were

randomly placed in a low-communion condition via a recall task (Horowitz et al. 2001) or a control condition (Horowitz et al. 2001). Participants viewed advertisements for a Yoga retreat, they expressed their willingness to participate in the retreat and indicated to what extent they thought that participation in the retreat would provide them with a sense of communion. An ANOVA analysis showed that there was a main effect of the low-communion condition on boosting the desire to participate in a yoga retreat ( $M_{\text{Low-communion}} = 6.17, M_{\text{Control}} = 4.85, F(1, 135) = 9.31, p < .01$ ). There was a significant effect of the manipulations on the perceptions of communion provided by the feminine choice ( $M_{\text{Low-communion}} = 5.78, M_{\text{Control}} = 4.93, F(1, 135) = 8.36, p < .01$ ). The mediation analysis (Hayes 2017) showed that participants' higher willingness to participate in the yoga retreat was due to the perceptions that the retreat would provide them with an increased sense of communion ( $\beta = .69, SE = .26$ ).

The present work proposes a novel compensatory function for symbolically gendered choices and recognizes that consumers' preferences for these choices may be prompted by specific aversive feelings. The results revealed that consumers hold implicit cognitive associations that link masculine choices to agentic attributes and feminine choices to communal attributes (study 1), masculine and feminine choices may be acquired in a self-completory manner to cope with aversive feelings of low-agency and low-communion, and the perceptions that obtaining these choices would provide consumers with enhanced senses of agency and communion underlie these boosts in preferences (studies 2 and 3). Given that daily life is infused with events and interactions that can trigger low-agentic or low-communal feelings and be detrimental to psychological and physiological health (Smith and Jordan, 2015), this research contributes to the understanding of consumers' choices and their impact on consumers' well-being. Prior research shows that consumers can compensate for low-agentic feelings through acquiring products that symbolize power, status, intelligence, or conspicuous consumption (Mandel et al. 2017), while they can compensate for low-communion through pursuing anthropomorphic choices, risk-taking, and spending on others (Mandel et al. 2017). While these forms of compensation play an important role in reducing the distress caused by experiencing low-agency and low-communion, they may also harm consumers' financial welfare through spending on products that may have no functional value other than symbolic, overspending on others, or taking on unnecessary risks (Rucker and Galinsky 2008). In this work, we focused on how consumers can employ their daily functional choices (e.g., activities and food choices) to alleviate low-agentic and low-communal feelings. Given the pervasiveness and ease of identifying masculine and feminine themes in colors and shapes of products, brands, and food options, this work holds important implications for devising solutions for enhancing consumers' well-being.

# Effortful but Valuable: How Perceptions of Effort Affect Charitable Gift Choice and Valuations of Charity

Haesung Annie Jung, The University of Texas at Austin, USA  
Marlone D. Henderson, The University of Texas at Austin, USA

## EXTENDED ABSTRACT

### INTRODUCTION

There has been a recent trend in charitable giving, in which increasing number of donors are requesting that their donations be used for a specific initiative, instead of being directed to a charity's general, unrestricted fund. Although consumers' decision to make a restricted or unrestricted charitable donation directly affects how charities function and operate, no research has yet examined what affects consumers' donation choice and why. We propose that although targeting a donation to a specific initiative enhances preference matching, consumers concurrently perceive the process of choosing among several charitable initiatives as being difficult. Thus, we predicted that the extent to which consumers are focused on the procedural difficulty of an action should affect the likelihood of them making a restricted or unrestricted donation. Specifically, when consumers increase their focus on action feasibility, they're more likely to delegate their gift choice to charity, thereby make unrestricted donations. Such tendency should be considerably reduced as consumers increase their focus on action desirability. Furthermore, based on previous work that people often derive value from investing effort (Loewenstein, 1999), we anticipated that consumers who make restricted charitable donations, thus have exerted more cognitive effort to identify a particular designation of their contributions, would attach a greater value to the charity post-giving, than consumers who make unrestricted charitable donations.

### THEORETICAL BACKGROUND

Restricted charitable donations enable consumers to aid a particular initiative that he or she considers most worthy of supporting thus is often referred to as *donor-centered funds*, as opposed to *general* or *unrestricted funds*. Prior work has shown that consumers respond positively to the opportunity to earmark their donations (Helms, Scott, & Thornton, 2012), although there exists a substantial variability in whether consumers choose to do so (Helms, Scott, & Thornton, 2013; Eckel, Herberich, & Meer, 2017). Among several reasons why consumers may choose to make unrestricted donations despite the ability to target a specific initiative, we focus on decision difficulty. Specifically, previous research has shown that when a decision involves alternatives that preclude any from being easily verified as being superior or inferior, it creates a feeling of uncertainty (Scholnick & Wing, 1988) which often lead consumers not to exercise a choice (Tversky & Shafir, 1992) or to delegate the decision to parties that they perceive impartial (Botti & McGill, 2006). Charitable initiatives are essentially different ways that consumers can aid needy others. Therefore, we argue that an objectively superior or inferior alternative is difficult to identify, as there are no objective criteria for judging a better or worse way of helping. In many cases, valuations are not read off a predetermined list but instead are constructed on the spot (Lichtenstein & Slovic, 2006). Thus, we argue that choosing one initiative among multiple requires donors to invest some amount of cognitive effort in order to identify an initiative that most closely fits their interests and ideals. Simply put, we propose that making a restricted donation is perceived as more cognitively difficult and thus requires more effort than making an unrestricted charitable donation.

If indeed the decision difficulty associated with identifying a desired initiative to help is what deters consumers from targeting a donation, the extent to which consumers focus on such difficulty should predict the likelihood of them making a restricted or unrestricted charitable donation. Specifically, the relative focus on action desirability versus feasibility often serves as a strategy in establishing preferences (Gollwitzer, 1990), such that when people increase their focus on action desirability, they tend to establish preferences based on maximizing the primary benefit gained from the action (Sagrignano, Trope, & Liberman, 2002), whereas when people increase their focus on action feasibility, they tend to establish preferences based on maximizing the ease or convenience in pursuing the action (Irmak, Wakslak, & Trope, 2013). Because actions that are easier to execute are higher in feasibility, we predicted that consumers with greater focus on action feasibility (vs. desirability) should exhibit more pronounced tendency to make unrestricted donations, while such tendency should be reduced as consumers increase their focus on action desirability.

We also explored the consequences of consumers' choice to make a restricted or unrestricted charitable donation. People often derive value from effort that they have invested in achieving a goal (Kaufman, 1999; Lane, 1992; Loewenstein, 1999), such that people who go through a greater amount of difficulty and thus exerted more effort to attain something tend to value it more highly than people who attain the same thing with a minimum of effort (Lewis, 1965). Similarly, we predicted that when consumers have made more cognitive effort to identify a specific program of the charity that most closely aligns with their interests, it is likely that consumers would endorse the charity more than consumers who delegated their donation choice to charity. In particular, as commitment is defined as 'an enduring desire to maintain a valued relationship (Moorman, Zaltman, & Deshpande, 1992)', we anticipated that consumers who made restricted charitable donations would exhibit greater charity commitment post-giving, than consumers who made unrestricted charitable donations. The following three studies tested our hypotheses.

### METHODS AND RESULTS

In study 1, we tested the idea that consumers perceive making a restricted charitable donation to be more difficult than making an unrestricted charitable donation. Participants (N = 201) read a brief description of needy children and a donation request. The appeal explained that if a donation is made, participants could choose to direct the donation to one of the following: child nutrition, education, emergency aid, humanitarian action, building new homes, and where it's most needed. The latter option represented the unrestricted gift option, which is the standard practice for charities to use such phrasing when signaling to donors that they are making an unrestricted donation to charity (e.g., see [worldvision.org](http://worldvision.org); [redcross.org](http://redcross.org)). Nevertheless, to confirm that individuals perceived this option as delegating the decision to charity, a pretest (n = 70) asked participants which of the above gift options (child nutrition, education, emergency aid, humanitarian action, building new homes, where it's most needed) granted the charity the most freedom in deciding how collected donations are distributed. The percentage of participants who chose one of the specific initiatives as the option that grants the charity the most freedom was contrasted with the percentage of participants who

chose “where it’s most needed” as the option that grants the charity the most freedom using a one-sample binomial test. As expected, “where it’s most needed” was dominantly chosen (75.7%,  $p = .000$ ).

We instructed participants to imagine that they had agreed to donate and indicate which of the options they wished to direct their donation to. If participants designated their donation to where it’s most needed, we coded their response as 1, indicating an unrestricted donation. If participants designated their donation to a particular charitable initiative, we coded their response as 2, indicating a restricted donation. Participants then rated the decision difficulty. The results showed that participants who made restricted donations reported experiencing greater decision difficulty ( $M = 2.42$ ,  $SD = 1.38$ ) compared to those who made unrestricted donations ( $M = 1.89$ ,  $SD = 1.22$ ,  $t(195) = 2.92$ ,  $p = .004$ ).

In Study 2, we tested whether consumer focus on action feasibility versus desirability predicts the likelihood of making a restricted or unrestricted donation to charity. We manipulated action focus via priming a why versus how mindset. Specifically, participants ( $N = 226$ ) described three goals that they wanted to accomplish, and those in the why mindset condition ( $n = 108$ ) elaborated on three reasons why they wanted to accomplish each goal, while those in the how mindset condition ( $n = 118$ ) elaborated on three ways that they could accomplish each goal (Henderson & Burgoon, 2014). Such priming procedure that induces people to focus on the outcome value versus step-by-step process has been shown to shift focus to action desirability versus feasibility as well as transfer to subsequent judgments (Freitas, Gollwitzer, & Trope, 2004).

Participants then read a brief description of needy children. We told participants that one way they could help was by obtaining donations from the researchers, who would provide funding when participants watched and evaluated some materials for a future psychology study. Participants read that if they earn donations from evaluating psychology materials, they could choose to direct the donations raised to one of several charitable initiatives or leave their donation unrestricted (the options provided were identical to Study 1). Participants indicated whether they would participate, and only the participants who agreed moved forward (67%,  $n = 152$ ).

Before participants designated their donation to one of the presented options, participants first rated the extent to which they were focused on desirable (choosing an option that best matches their interests/ideals) and feasible (choosing an option that is most simple/convenient) aspects of their donation choice. Participants then made their donation choice. As in previous study, if participants designated their donation to where it’s most needed, we coded their response as 1, indicating an unrestricted donation. If participants designated their donation to a particular charitable initiative, we coded their response as 2, indicating a restricted donation.

The results showed that our manipulation was successful, such that participants primed with a why mindset focused more on action desirability than those primed with a how mindset ( $M = 5.80$ ,  $SD = .85$  vs.  $M = 5.42$ ,  $SD = 1.12$ ,  $t(150) = 2.35$ ,  $p = .02$ ). In contrast, participants primed with a how mindset focused more on action feasibility than those primed with a why mindset ( $M = 4.07$ ,  $SD = 1.35$  vs.  $M = 3.48$ ,  $SD = 1.29$ ,  $t(150) = 2.75$ ,  $p = .007$ ). Furthermore, we found a significant main effect of mindset on donation choice ( $\beta = .94$ , S.E. = .34, Wald = 7.78,  $p = .005$ ), such that 55.1% of participants in how mindset condition made unrestricted donations, while only 32.4% of participants in why mindset condition chose to do so.

In study 3, we tested our last hypothesis that participants would attach a greater value to the charity thus exhibit greater charity commitment, when they chose to make a restricted donation as opposed to when they chose to make an unrestricted donation. Before the

main task began, we notified participants ( $N = 140$ ) that all participants would be entered into a lottery to win a bonus of \$25. We then presented participants with an appeal from a charity requesting help in raising donation for needy children. We further explained that if a donation is made, participants could designate their donation to one of several initiatives or leave their donation unrestricted. Participants indicated whether they would donate some portion of their prize money if they win the lottery, and only the participants who were willing to donate (59%,  $n = 83$ ) moved forward.

We manipulated participants’ donation choice via providing instructions pertaining to desirability or feasibility. Specifically, participants in restricted donation condition were instructed to choose an option that most closely fits their interests, while participants in unrestricted donation condition were instructed to choose an option that is most convenient. Participants then made their donation choice which we coded as 1 if they made an unrestricted donation, and 2 if they made a restricted donation. Participants then rated 11 items aimed to measure their commitment to the charity ( $\alpha = .88$ ). Example items included “I will likely to give again to this charity” and “I feel a sense of belonging to this charity.”

The results showed that the instructions given to participants to alter their donation choice was successful in affecting their actual choice ( $\beta = 1.06$ , S.E. = .46, Wald = 5.26,  $p = .02$ ). 53.7% of participants made unrestricted donations when provided with an instruction pertaining to feasibility, while only 28.6% participants provided with an instruction pertaining to desirability chose to do so. When entering the effect of instruction (desirability vs. feasibility), participants’ donation choice (restricted vs. unrestricted) as predictors of charity commitment, we found that there was only a significant main effect of donation choice. Specifically, participants who made restricted donations reported greater charity commitment than those who made unrestricted donations ( $M = 4.93$ ,  $SD = .82$  vs.  $M = 4.40$ ,  $SD = 1.05$ ,  $F(1,79) = 4.97$ ,  $p = .03$ ).

## DISCUSSION

Consumers’ decision to make a restricted or unrestricted charitable donation directly affects how charities distribute the received funds across various needs of the charity. Given the influential role of consumers’ donation choice on charity operations, understanding the psychological processes in which consumers make their donation choice is both theoretically and practically important. To that end, the present article is the first to examine how consumers respond to an opportunity to earmark their gifts for a specific purpose of a charity as well as examine when consumers are likely to give in a restricted or unrestricted manner. We also examine what implications consumers’ donation choice have for charities. Specifically, our findings suggest that charities can reap distinct benefits from receiving restricted or unrestricted donations, such that unrestricted donations provide immediate flexibility in utilizing the received funds while restricted donations increase consumers’ willingness to extend the relationship with charity. Thus, if the charity’s goal is to maximize fund flexibility, we propose that charities would benefit from inducing potential consumers to focus more on action feasibility. For example, when communicating to potential donors, charities could emphasize *how* they go about helping the needy rather than emphasizing *why* they do it. On the other hand, if the charity’s goal is to foster sustained donor engagement, we propose that charities would benefit from inducing potential consumers to focus more on action desirability. For example, charities could emphasize *why* donors should help, or what are the primary benefits or end values associated with their contributions. Nonetheless, the current research has limitations. Specifically, Study 3 measured participants’ commitment with the charity imme-

diately after participants have made their donation choice and it was self-reported. Thus, future research should explore whether consumers' donation choice has impact on charity commitment after a longer delay period, and whether the differences in the level of commitment is manifested at the behavioral level (e.g., actual likelihood of making another donation to charity).

# When Do People Learn *More* from Others' Prosocial Behavior?

## A Meta-Analysis of Prosocial Modeling Effect

### EXTENDED ABSTRACT

#### INTRODUCTION

Prosocial behavior is contagious, such that prior work has shown people (across all ages) rely on social examples – whether and what others contribute – as guides of their own prosocial decisions. Specifically, both children and adults are more likely to cooperate (Doescher & Sugawara, 1992; Braver & Barnett, 1976), donate or share resources (Poulos & Liebert, 1972; Wagner & Wheeler, 1969) and care for others (Gray & Pirot, 1984; Bryan & Test, 1967) when they learn that others have done the same.

The prototypical prosocial modeling situation involves a prosocial model and someone who observes the model's behavior (referred to as observer in this paper). Specifically, an observer is exposed to a prosocial model who helps someone in need. Then, the observer is given the opportunity to also help someone in need. The critical outcome of interest is whether the observer imitates the model's behavior.

Despite the widespread use of modeling in encouraging helping behavior, research has suggested that the effects of prosocial modeling events vary as a function of the social context in which they occur (Masor, Hornstein, & Tobin, 1972). Specifically, some findings suggest that prosocial modeling has negligible effect when helping is costly (Wagner & Wheeler, 1969), when the intensity of modeling behavior is low (Rosenbaum, 1956) and often doesn't generalize to other behaviors than those that are modeled (Braver & Barnett, 1976). Thus, our first goal of this meta-analysis was to examine the robustness of the prosocial modeling effect.

Our second goal was to examine the conditions that have previously been demonstrated to moderate the modeling effect. Specifically, literature on identity congruence has shown that identity impacts the effectiveness of social information (Smith, Bruner, & White, 1956) such that the more similar the individual is to the source of the social information, the stronger its impact is likely to be. Indeed, social identities may be diagnostic of the decisions or judgments at hand, and thus other consumers' behavior can become more relevant to a judgment (Feldman & Lynch, 1988) when aspects of these consumers are similar to the target consumer's identity (Reed, 2004). Such findings would suggest that prosocial modeling effect should be greater when the model and the observer share similar characteristics. Nevertheless, some findings suggest the opposite, such that witnessing acts of moral excellence elicits a state of moral elevation (Haidt, 2000). Thus, exceptional moral characters, rather than models that resemble one's next door neighbors, are more effective in increasing helping behaviors (Freeman, Aquino, & McFerran, 2009). Given such mixed findings, we utilize a meta-analytic approach to examine the role of similarity between the model and observer in the effect of prosocial modeling.

Finally, we tested for additional moderators of modeling effects, including characteristics of model (gender, single vs. multiple), characteristics of observer (gender, age, students or non-students), proximity of the model and observer (presence of verbal interaction, acquaintance), characteristics of modeling behavior (e.g., donation

vs. caring) and characteristics of outcome behavior (e.g., outcome behavior measured in public vs. private). In so doing, we aimed to provide an extensive review of when prosocial modeling effect is likely to be increased or decreased.

#### METHODS AND RESULTS

*Sample of Studies:* For an initial over-inclusive list of studies, we searched PsycINFO, PsycARTICLES, EBESCO, Social Sciences Citation Index, Web of Science, Dissertations Online, ERIC, and Google Scholar for articles that contained either of the following items: prosocial, altruis\*, help\*, shar\*, donat\*, volunteer\*, cooperat\*, giv\*, charit\*, genero\*, moral\*, model\*, imitate\*, bystander, learn\*, observ\*, mimicry, media, song, lyrics, game, advertis\*, television and film. We also searched for references of all relevant articles and posted a call for papers on several listserves in psychology and education. This process allowed us to start with as comprehensive a list as possible. From this list, we retained all studies that had (a) at least one group exposed to prosocial modeling; (b) a clear control group with which modeling groups could be compared; (c) random assignment to these groups and (d) behavioral observations of outcome variable (as opposed to prosocial emotions or intentions). These criteria produced a list of 42 articles that contained 120 eligible studies (4 unpublished). The dataset embraced a total of 9,325 participants.

*Variables retrieved from each study:* Our focal moderator was the similarity between the model and the observer. First, we coded for gender match or mismatch between the model and observer and the age differences (younger, same age, older) between the model and observer. We also coded for a number of other potential moderators. Specifically, we coded for gender of the model and whether the model was single individual or multiple individuals. We coded for gender and age of the observer, as well as whether the observer was a student or not. We additionally coded for variables that may induce interpersonal proximity between the model and the observer. In particular, we coded for whether the model was an acquaintance or non-acquaintance to the observer and whether there was a verbal interaction between the model and observer. In terms of the behavior-relevant characteristics, we coded the type (formal or informal) and medium (direct or indirect) of modeling behavior. We defined formal helping as behaviors that are proximal to characteristics of charitable giving, which often involves a transfer of material resources to others in need (e.g., donating money or tokens). Other behaviors that involve emotional or physical support were categorized as informal helping, which include cooperation and picking up dropped pencils. In regard to the medium, we categorized modeling medium as direct, when the observer was exposed to prosocial model(s) in person. We categorized modeling medium as indirect, when the observer was exposed to prosocial model(s) via a reading a written material, listening to a verbal description, or watching a film. Lastly, we coded information regarding the measured outcome behavior. Specifically, we coded the type of outcome behavior (formal or informal) and whether the behavior was measured in private or public. We categorized outcome behavior as private, when there were no others

present during measurement of outcome behavior. In contrast, we categorized outcome behavior as public, when there was at least one other present during measurement of outcome behavior. Lastly, we coded for whether the type of modeling behavior match or mismatch with the outcome behavior. For example, if modeled and outcome behavior were both formal giving (e.g., donation), such combination was categorized as 'match'. If modeled behavior was formal giving while the outcome behavior was informal giving, such combination was categorized as 'mismatch'.

*Effect sizes and analysis strategy:* All effects sizes were calculated as the standardized differences in dependent measures between prosocial modeling and control groups. Effect sizes were calculated directly from the means, standard deviations, and sample sizes for the experimental and control groups wherever possible. When not, effect sizes were computed from F ratios, t-test, or chi-square test. All effect sizes were converted to Hedge's  $g$ , a standardized effect size that corrects for a slight positive bias in Cohen's  $d$  that is present in all small samples (Hedges, 1981). R's *robumeta* package (Fisher, Tipton, & Zhipeng, 2017) was used to calculate average effect sizes. This analysis allowed for the clustered data (i.e., effect sizes nested within samples) by correcting standard errors to take into account the correlations between effect sizes from the same sample. Given the diversity of study characteristics in the dataset, some variation in the true effect was expected across these studies. Thus, a random-effects model was used to calculate pooled effect sizes. A Cochran's test revealed the studies to be significantly heterogeneous,  $Q$  ( $df = 41$ ) = 158.26,  $p < .0001$ , supporting this choice. Random-effects models tend to be less vulnerable to Type 1 error than fixed-effects models and are thus widely recommended (Cumming, 2014).

*Results:* Across 42 studies, the average effect size of the difference between prosocial modeling and control groups on helping behavior was  $g = 0.76$ , 95% CI = [0.56, 0.96], indicating a large effect of prosocial modeling on observers' helping behavior. Next, we examined the possibility of the publication bias. In so doing, we examined the distribution of studies in a funnel plot (plotted according to their sample size and standard error) using Duval and Tweedie's (2000) trim and fill approach. The funnel plot of the effect size distribution was significantly asymmetric,  $z = 3.30$ ,  $p < .001$ , and the trim and fill method was used to correct for this asymmetry by estimating missing studies, yielding an estimated effect size of  $g = .33$ ,  $p < .001$ , 95% CI = [0.14, 0.53]. The adjusted effect is smaller than the non-adjusted effect, suggesting the presence of underreporting of null findings. A significant effect nevertheless emerged across the studies. On the basis of this estimate, the results should not be discounted as artifacts of publication bias.

*Similarity between model and observer:* We examined the moderating role of similarity between the model and observer in the effect of prosocial modeling. First, we examined the role of gender match or mismatch between the model and observer. The mean effect size when there was a gender match between the model and observer was  $g = .87$ , 95% CI [0.43, 1.31]. The mean effect size when there was a gender mismatch between the model and observer was slightly larger ( $g = 1.16$ , 95% CI [0.43, 1.88]), although the difference was not statistically significant ( $p = .40$ ). Next, we examined the role of age differences between the model and the observer. As there were no cases in our dataset in which the age of the model was younger than the observer, we were only able to compare the effect sizes when the model's age was relatively similar to the observer or relatively older. The mean effect size when the model's age was relatively similar to the observer was  $g = .59$ , 95% CI [0.40, 0.79] while when the model was relatively older, the mean effect size was  $g =$

1.00, 95% CI [0.59, 1.40]. This difference was marginally significant ( $t(24.1) = 1.95$ ,  $p = .06$ ).

*Other potential moderators:* To explore other potentially relevant variables, we first examined characteristics of the model. Whether the model was a single individual ( $g = 0.73$ , 95% CI [0.51, 0.94]) or multiple individuals ( $g = .87$ , 95% CI [0.43, 1.31]) did not influence the modeling effect ( $t(16.3) = .68$ ,  $p = .51$ ). There were also no statistically significant differences in the effect sizes when the models were males only ( $g = .68$ , 95% CI [0.29, 1.06]), females only ( $g = .81$ , 95% CI [0.21, 1.41]) or mixed ( $g = 1.00$ , 95% CI [0.68, 1.32]). However, we found that the composition of observer gender matters. Specifically, the effect size was significantly larger when the observer was composed of only females ( $g = 1.17$ , 95% CI [0.69, 1.64]), compared to when the observer was composed of males-only or mixture of males and females ( $g = .70$ , 95% CI [0.49, 0.92]),  $t(9.12) = 2.38$ ,  $p = .04$ . Furthermore, when the observer was composed of the same gender, the effect size was larger ( $g = 1.04$ , 95% CI [0.57, 1.50]) than when the observer was composed of mixture of males and females ( $g = .58$ , 95% CI [0.42, 0.74]). This difference was statistically significant ( $t(22.5) = 2.07$ ,  $p = .05$ ). Neither characteristics of the observer (age, students or non-students) nor the proximity between the model and the observer (verbal interaction between the model and observer, acquaintance between the model and observer) influenced the prosocial modeling effect.

Of note, the type of modeling and outcome behavior had significant influence on prosocial modeling effect. When the modeling behavior was formal, the mean effect size was  $g = .94$ , 95% CI [0.61, 1.27]. When the modeling behavior was informal, the mean effect size was  $g = .51$ , 95% CI [0.30, 0.71] and the difference was statistically significant ( $t(29.8) = -2.40$ ,  $p = .02$ ). Similarly, when the outcome behavior was formal, the mean effect size was  $g = .87$ , 95% CI [0.58, 1.15] while the mean effect size was  $g = .56$ , 95% CI [0.32, 0.79] when informal. The difference was marginally significant ( $t(23.4) = -1.77$ ,  $p = .09$ ). Whether modeling was communicated in a direct ( $g = .88$ , 95% CI [0.54, 1.21]) or in an indirect ( $g = .61$ , 95% CI [0.43, 0.79]) manner did not significantly influence the modeling effect ( $p = .14$ ). Lastly, whether the outcome behavior was measured in private ( $g = .76$ , 95% CI [0.53, 0.99]) or in public ( $g = .78$ , 95% CI [0.38, 1.18]) did not significantly influence the modeling effect ( $p = .90$ ).

Finally, we examined whether the matching information of modeled and outcome behavior influences the modeling effect. When the type of modeling behavior was identical to the outcome behavior (e.g., both behaviors were formal or informal), the mean effect size was  $g = .90$ , 95% CI [0.61, 1.17] while when the type of modeling behavior mismatched the outcome behavior (e.g., modeled behavior was formal while outcome behavior was informal), the mean effect size was smaller ( $g = .54$ , 95% CI [0.35, 0.73]). This difference was statistically significant ( $t(18.64) = 2.27$ ,  $p = .03$ ).

## DISCUSSION

Across 42 studies ( $n = 9,325$ ), effect-size analyses revealed that prosocial modeling produced a reliable, large-sized effect ( $g = .76$ ). The literature was also found to be robust to selective reporting of significant findings (i.e., the file-drawer effect). Such findings suggest that prosocial modeling is an effective tool to increase helping behaviors.

We found no evidence that the more similarities exist between the model and observer, the more impactful effect the modeling should produce. Specifically, modeling effect was similar regardless of whether there exists gender match or mismatch between the model and observer. In fact, modeling effects were larger when the model was older (as opposed to similar age) than the observer.

Among additional variables that we explored, we found evidence that modeling effects are larger for female observers than males or mixed (males and females) observers. We also found that modeling effects are larger when the modeled behavior is of similar type to outcome behavior (e.g., modeling and outcome behavior are both formal or informal helping). Interestingly, although not tested in previous prosocial modeling research, we found evidence that modeling behaviors that are formal (i.e. donating) produce greater effect than modeling behaviors that are informal (i.e. caring). The aim of the present research was to test the robustness of the prosocial modeling effect as well as explore moderators. Indeed, practitioners in charitable organizations, educational institutions and business firms commonly use prosocial models to stimulate charitable giving, cooperation, citizenship behavior and green consumption. Thus, our aim was also to provide a practical guide regarding when modeling effects are likely to be maximized or minimized in inducing helping behaviors. We look forward to future research that delves more deeply into the mechanisms for why certain moderators in our investigation produced more or less effect of prosocial models.

## Parallel Practices of Visual Domination and Subversion

Veronika Kadomskaia, Monash University, Australia

### EXTENDED ABSTRACT

Volunteer tourism is seen as a form of good will tourism (Sin 2009), appealing to those who want to make a difference whilst travelling. Despite growing scrutiny over this utopian framing of volunteer tourism (Palacios 2010; Raymond and Hall 2008), there is limited exploration of this travel phenomenon (Alexander 2012; Nadeau and Lord 2017).

Consequently, we know little about the broader sociocultural conditions which shape the ways in which this consumption practice is performed. As Urry (2002) exhorts, it is important to consider tourism in relation to wider economic, social, and cultural processes. This is also in line with a growing academic argument that discourses of ethical consumption, while advocating individual responsible consumption, depoliticize and deflects responsibility away from governments and large corporations (Carrington, Zwick, and Neville 2016), and that 'ethical' consumption practices should be explored as a structural rather than individual phenomenon. What is also less understood is how these sociocultural discourses are played out visually. This is surprising given a rich literature stream in marketing about the performative power of images, and the rise of social media. With the advent of various social media platforms, visual consumption has become a paramount means of apprehending the world and presenting one's identity (Schroeder 2005), where the communicative power of photography generates and maintains these discourses in a ubiquitous and seemingly natural way (Schroeder and Borgerson 2005). To address these theoretical asymmetries we ask: what are the broader sociocultural discourses which frame volunteer tourism, and how do they shape visual representational practices in a volunteer tourism marketplace?

This paper draws on postcolonial theory (Brace-Govan and de Burgh-Woodman 2008), which allows scholars to critically evaluate issues of cultural Othering, racism and exploitation when representing and marketing the 'third world' (Ashcroft, Griffiths and Tiffin 1995), and has become an important tool for researchers critiquing the role of the West in dictating the development agendas of third world nations (Udombana 2000). The promise of 'civilizing' the 'primitive' underpins the imbalance of power in the binaries of colonizer/colonized, West/East, Global North/Global South (Bhabha 1990; Said 1993; Spivak 1987) and perpetuates a global divide that continues to exist today. These binaries of 'us and them' underpin the exchange of aid in volunteer tourism, highlighted through the primarily North to South flow of volunteer tourists (Palacios 2010). Despite the idealized promise of intercultural encounters to break down boundaries between self and Other in this context, the encounters are inflected by histories of colonialism which continue to structure relationships between the Global North and South (Bhabha 1990; Said 1993; Spivak 1987).

Our exploration is grounded in a critical visual analysis of purposively selected consumer-generated visual representations of volunteer tourism experiences on Instagram. A hashtag search of #volunteertourism, #voluntourism, and #volunteerabroad results in over 30,000 images, and 9 consumer-generated images displaying volunteer-host interaction were selected for close analysis. The coding process included first cycle and second cycle coding methods, following Saldaña's (2016) and Rose's (2001) recommendations for visual analysis. Grouping first cycle codes into emerging themes formed each of four sociocultural discourses around volunteer tour-

ism, and the final stage of analysis was to critically analyse these themes within a satirical, consumer-generated Instagram site, 'Barbie Saviour'.

Whilst our findings reveal that a 'postcolonial gaze' dominates consumer-generated visual representations of volunteer tourism, parallel practices of visual subversion were also identified, casting doubt upon the postcolonial gaze. Volunteer tourists' Instagram images expressed the discourse of 'making a difference' through consumer hashtags such as "giving back", but such idealism was counteracted with hashtags emphasizing the travel component of experiences. The discourse of helplessness was also visualized through a display of colonial patterns of travel and an absence of adult aid recipients. Next, the discourse of sentimentality was identified through visual displays of love and happiness in images, as well as through consumer hashtags, included the harmful stereotype of poor but happy. Finally, we identified signs of power discrepancies in these images, visualized through differences in wealth and modernity between volunteer tourists' and the children pictured in their photographs, as well as through the dominant positioning of volunteer tourists' as rescuers in these images.

Parallel practices of visual subversion were also identified. The satirical Instagram account, Barbie Savior, reflects the growing use of parody as a consumer tactic for marketplace resistance (Mikkonen and Bajde 2013). Images frequently depict Barbie as a rescuer and highlight disparities in wealth between Barbie and the locals in her images. Furthermore, Barbie being labelled as "20 years young" and "not qualified" in the bio section of the Instagram account specifically opposes the naive belief in volunteer tourism, in that the mostly young, inexperienced and unskilled volunteer tourists can make significant changes to poverty simply due to being Western (McGehee 2012; Nutt 2011). In short, the returned volunteer tourists behind Barbie Savior utilize humorous tactics to problematize volunteer tourism and dismantle the postcolonial gaze that shapes the marketplace.

This study demonstrates the usefulness of a postcolonial perspective in enabling marketing scholars to confront structural biases which shape the representational contours of 'ethical' markets, thereby advancing the argument that postcolonial theories can re-frame marketing phenomena in productive ways (Brace-Govan and de Burgh-Woodman 2008; Tadajewski and Brownlie 2008). Our sample of consumer images embody the article's themes and are representative of our ideas concerning how the postcolonial gaze constrains these marketplace actors' ability to perform volunteer tourism practices ethically. Thus, we follow the interpretivist approach of examining a limited range of materials in order to make broader points about representation and identity in visual materials (Gombrich 1999; Buchanan-Oliver, Cruz, and Schroeder 2010). Our study delivers a critique of the broader sociocultural factors that underpin volunteer tourism, thus extending ethical consumption research beyond the terms of consumer identity projects and offering insights into the intertwined and not-so-visible linkages between marketplace actors, practices, and ideologies. This study highlights the need for consumers to obtain preparatory education about the political, social, economic and cultural histories of the places they visit, to enable these cross-cultural engagements to explore systems of poverty and inequality more sustainably.

# Corporate Social Responsibility and Dishonest Consumer Behavior

In-Hye Kang, University of Maryland, USA  
Amna Kirmani, University of Maryland, USA

## EXTENDED ABSTRACT

Increasingly, organizations are proclaiming their values by taking stands on controversial social issues. These actions often take the form of corporate social responsibility (CSR). However, little research investigates polarizing CSR issues. Although CSR can influence purchase behavior toward the organization (e.g., boycotting), we propose a novel way in which consumers may respond to polarizing CSR: dishonest consumer behavior, i.e., the extent to which consumers lie and cheat the organization for financial rewards. Dishonest consumer behaviors are highly costly for organizations. For example, return fraud and abuse were expected to cost retailers about \$22.8 billion in 2017 (Total Retail 2018). Thus, investigating factors that impact dishonest behavior is important from a theoretical and practical perspective.

We propose that the effect of CSR on dishonest behavior depends on the consumer's cause-related identity, which refers to the degree of fit between the CSR cause and the consumer's self-concept (Sen and Bhattacharya 2001; Winterich and Barone 2011). Although prior work on CSR considers the effects of cause-related identity, it does not examine incongruent or oppositional identity. In contrast, we view cause-related identity as a continuum from congruent to neutral to incongruent, where incongruent cause-related identity is conceptualized as one that is the opposite of the consumer's self-concept (Reed et al. 2012).

We propose that the moderating role of cause-related identity is mediated by anticipatory self-threat. Anticipatory self-threat refers to the expectation that the individual's positive self-view cannot be maintained after he or she acts in a certain way (White et al. 2012). When a CSR cause is congruent with the consumer's self-concept, dishonest behavior would hurt their self-view because their dishonest behavior does not reflect who they are, both by the fact of acting unethical and because it means they do not support the cause. To reduce this anticipatory self-threat, they would be less likely to act dishonestly toward an organization engaged in CSR than one not engaged in CSR. In contrast, when the CSR is incongruent, CSR will backfire. Although dishonest behavior would still hurt their moral self-view as in the case of our baseline, i.e., no-CSR, it would also boost their overall self-view by affirming their cause-related identity. Thus, CSR (vs. no-CSR) would reduce the anticipatory self-threat, increasing dishonest behavior.

Moreover, we expect an asymmetric effect of CSR under incongruent and congruent identity. Because of consumers' motivation for self-verification (Swann et al. 1989), consumers will consider the information that an organization supports the identity-congruent [identity-incongruent] CSR cause as positive [negative]. Consumers react more strongly to negative than to positive information (Baumeister et al. 2001). Thus, we expect that CSR will have a greater impact on dishonest behavior under incongruent (vs. congruent) cause-related identity condition.

Using actual dishonest behavior, study 1 tested these predictions using a 2 (CSR: present, absent) by (cause-related identity: military veteran support, measured continuously) between-subjects design. All participants read the description of a company, and those in the CSR present condition read about its CSR in the domain of military veteran support. Participants could cheat the company by over-reporting their performance for monetary rewards. After completing filler tasks, participants indicated military veteran support

identity (Bolton and Reed 2004) along with other identities such as political ideology. The interaction between CSR and cause-related identity was significant. CSR (vs. no-CSR) significantly decreased [increased] cheating for participants with the congruent [incongruent] military veteran support identity. Consistent with the proposed asymmetric effect, the coefficient for CSR was larger in the absolute size for participants with the incongruent (vs. congruent) identity.

Study 2 tested mediation via anticipatory self-threat (H2) using 2 (CSR: present, absent) by 3 (cause-related identity: LGBT support congruent, neutral, incongruent - measured) between-subjects design. We first measured cause-related identity using a categorical measure to separate neutral and incongruent identity more clearly. Then, participants read the description about a clothing retailer where CSR was manipulated. We measured their intention to return the used shirt and anticipatory self-threat. For the intention, the interaction between CSR and cause-related identity was significant. The effect size of CSR was bigger in the incongruent (vs. congruent) condition. Anticipatory self-threat was a significant mediator.

Given that incongruent CSR leads to dishonest behavior, how can we attenuate this effect? Building on the anticipatory self-threat mechanism, we propose that making moral values situationally salient will attenuate the effect. When moral values are salient, anticipatory self-threat will be heightened from considering acting dishonestly itself (Mazar et al. 2008). Thus, we expect that when moral values are salient, anticipatory self-threat will be elevated regardless of an organization's CSR and the consumer's cause-related identity, attenuating the backfiring effect of CSR.

Study 3 tested the moderating role of salience of moral values using a 2 (cause-related identity: refugee support congruent, incongruent - measured) x 3 (salient value: competence, honesty, care) between-subjects design. Since our focus was on testing whether salient moral values attenuated the effect of incongruent identity on dishonest behavior, we included only the CSR present condition. After we measured refugee support identity, we manipulated salient values using a writing task. Next, participants read the description about a theme park's CSR activity in the domain of refugee support and indicated their intention to lie about their child's age to get a discount on the ticket and anticipatory self-threat. For the intention, the interaction between cause-related identity and salient value was significant. As predicted, in the competence salience condition, participants with incongruent (vs. congruent) identity showed significantly higher intention for acting dishonestly. In the honesty and care salience conditions, the intention was not different between incongruent and congruent conditions, suggesting that the backfiring effect of CSR under the incongruent condition was attenuated. In study 2 and 3, we also ruled out alternative explanations of liking for and perceived morality of the organization and expected harm to the organization.

Overall, we demonstrate the effects of polarizing CSR on dishonest behavior and show a condition under which CSR backfires. We also demonstrate that the effect is driven by egoistic motives (e.g., to avoid feeling bad about themselves) rather than altruistic motives (e.g., expected harm to the organization).

# Boomerang Effect: How Sustainable Disposal Options Spur Green Consumers to Overconsume

Sommer Kapitan, Auckland University of Technology, New Zealand  
Saerom Lee, University of Texas at San Antonio, USA  
Eunjoo Han, Auckland University of Technology, New Zealand

## EXTENDED ABSTRACT

One co-author's mother cheerily donates her clothing to a local charity and revels in her quarterly yard sales. She reports her deep affinity for the environment and avoidance of waste, akin to the set of consumers whose values center on environmental responsibility, reduction of waste and consideration of planetary resources (Haws, Winterich, and Naylor 2014). After donating her clothes to a local charity or hosting her yard sales, however, she usually comes home with armloads of new purchases. Does a sustainable disposal option, such as donating or selling, lead consumers to buy more new items? Disposal and dispossession practices are among the most understudied fields in marketing and consumer behavior (MacInnis and Folkes 2010). The present research investigates the effect of disposal on subsequent consumption decisions and contributes to the literature on disposal and sustainable consumption. Specifically, we explore how disposal justifies consumption of new items for consumers whose values center on environmental responsibility (hereafter, "green consumers").

Our goal is to determine when and why the attitudes-behavior gap in sustainable consumption might ironically widen for green consumers (Haws et al. 2014). In particular, we focus our lens on disposal and dispossession practices such as donation and selling of used goods to understand the downstream impacts of this particular set of sustainable behavior, which delays the arrival of the product to the dump or rubbish bin (Phipps et al. 2013). We propose that green consumers who are the most focused on avoiding waste in their consumption (Haws et al. 2014) will be licensed by disposal and dispossession options that are perceived as producing the least amount of waste on the environment.

Virtuous behaviors from charitable giving and volunteering to recycling and healthy food choices can license consumers to choose a more self-indulgent or immoral subsequent behavior (e.g., Khan and Dhar 2006; Ross and Kapitan, 2018). For example, individuals are less likely to engage in moral actions after they recall past moral (vs. immoral) behavior (Jordan, Mullen, and Murnighan 2011). The mere presence of a healthy option leads to an indulgent food choice by vicariously fulfilling a healthy eating goal (Wilcox et al. 2009). Similarly, individuals are found to use more resources (e.g., paper) when the option to recycle is available (Catlin and Wang 2013). Importantly, research suggests that licensing effects can be stronger for individuals whose values can be fulfilled by the previous virtuous behavior (Kivetz and Zheng 2006; Wilcox et al. 2009).

Building on this literature, we propose that sustainable disposal options such as selling or donating will encourage consumers to purchase new items more. Notably, this effect will be more likely to occur for green consumers who hold stronger pro-environmental values against incurring waste and ensuring goods live on (Haws et al. 2014; Luchs et al. 2011). That is, we argue that sustainable disposal will ironically lead green consumers to consume more goods, which may eventually produce more waste for society. This is mainly because sustainable disposal can fulfill green consumers' values or goals associated with their pro-environmental identity as it is expected to reduce waste for society. As such, green consumers will be more likely to perceive sustainable disposal as prosocial and virtuous behavior reducing waste for society. This, in turn, will lead green consumers

to be licensed to purchase new items without concerns about potential negative environmental impacts of their consumption following disposal via donating or selling of used items. Four studies provide converging evidence for these predictions.

## Study 1

Study 1 aimed to provide initial evidence that sustainable disposal may drive enhanced future consumption for green consumers. To this end, we recruited a sample of clothing donors, asked them to first recall their experiences donating clothing, and asked them to report how likely they would be to purchase new clothing.

### *Method and Procedure*

One hundred and two participants (59.8% female) recruited from Amazon's MTurk participated in this study in return for monetary rewards. Participants were first instructed to recall and describe a recent clothing donation experience. Participants were then asked to consider a shopping scenario, in which they found a t-shirt that was appealing to them (See Appendix A). After reading the scenario, participants reported their purchase intention (two items; e.g., "How likely would you be to purchase the t-shirt?";  $\alpha = .93$ ). In addition, participants completed a scale measuring green consumption values (six items;  $\alpha = .95$ ; Haws et al. 2014; e.g., "It is important to me that the products I use do not harm the environment.") Finally, participants completed other background measures.

### *Results and Discussion*

A regression analysis using green values (mean-centered) as the independent variable and purchase intention as the dependent variable revealed a significant effect of green values on purchase intention ( $\beta = .20$ ,  $t(96) = 1.95$ ,  $p = .05$ ). This finding suggests that participants who had stronger green values were more likely to purchase a new shirt on a shopping trip after recalling recent donation behavior. In the next study, we further examine the proposed effect by manipulating green values.

## Study 2

The purpose of Study 2 was to enhance the internal validity of the proposed effect by manipulating green consumption values. We also extended the type of sustainable disposal options (e.g., donating and selling).

### *Method and Procedure*

One hundred and ninety-two undergraduate students (53.6% female) participated in the study with a 2 (consumption values: green vs. control) X 2 (disposal type: donate vs. sell) between-subjects design. First, participants completed an essay task making salient their green consumption values (vs. an essay task on a neutral topic (i.e., typical day)). Next, participants considered a scenario in which they found an appealing t-shirt at the mall a few days after they had sold (vs. donated) their clothing (Appendix B). After that, participants reported purchase intention as in study 1 ( $\alpha = .89$ ). Participants also completed a manipulation check for green consumption values ( $\alpha = .98$ ) and other background measures.

### Results and Discussion

An ANOVA on green values revealed our manipulation was successful ( $M = 5.46$  vs.  $M = 3.65$ ;  $F(1, 190) = 76.92, p < .001$ ).

An ANOVA using consumption values and disposal type as independent variables and purchase intention as the dependent variable showed a main effect of consumption values on purchase intention ( $F(1, 188) = 3.95, p < .05$ ). Participants whose green values were salient ( $M = 5.27$ ) were more willing to purchase the new shirt compared to those in the control condition ( $M = 4.78$ ). The effect of disposal type ( $F(1, 188) = .09, p = .76$ ) and the interaction were NS ( $F(1, 188) = .01, p = .91$ ).

Study 2 demonstrated that consumers whose green values are salient are more likely to purchase new clothing after sustainable disposal activities—i.e., donating and selling of used items. Making green values temporarily salient can alter the way that disposal influences consumption for consumers who may not be intrinsically green as well. Also, the effect emerged across both donation and selling conditions, indicating that either form of sustainable disposal leads to a licensing effect for green consumers. In the next study, we seek to determine the underlying mechanism for this effect.

### Study 3

In study 3, we sought to explore the proposed underlying mechanism of this effect via waste perceptions. To this end, we also explored a theoretically relevant boundary condition of the effect—i.e., an unsustainable disposal option (i.e., trashing) which does not reduce waste perceptions (Spencer, Zanna, and Fong 2005). If the positive effect of green values on subsequent consumption following a sustainable disposal is driven by reduced perceptions of waste, the observed effect should disappear when disposal increases waste perceptions (e.g., trashing used items).

#### Method and Procedure

Seventy five undergraduates (36% female) participated in a study with a two-group (disposal type: donate vs. trash) between-subjects design, with green consumption values measured continuously. Participants read a disposal and shopping scenario similar to study 2. The scenario varied only in disposal options (donate vs. trash) (see Appendix C.). After that, participants indicated purchase intention ( $\alpha = .92$ ). Next, participants indicated waste perceptions on two items (“Purchasing this shirt is a waste for society,” “Purchasing this shirt is a waste for society?”;  $\alpha = .70$ ). Participants also completed a scale of green consumption values as in study 1 ( $\alpha = .95$ ) and other background measures.

#### Results and Discussion

As expected, regression analysis revealed a significant interaction between disposal and consumption values ( $\beta = -.73, t(71) = 3.01, p < .01$ ). In the donation condition, participants with stronger green consumption values were more likely to purchase the new shirt ( $\beta = .34, t(35) = 2.22, p < .05$ ). In the trash condition, we found an opposite effect: those characterized by stronger green values were less likely to purchase the new shirt ( $\beta = -.39, t(36) = 2.07, p < .05$ ).

Bootstrapping analysis for moderated mediation (Hayes 2012; Process Model 8; N of bootstrap = 5,000) revealed a significant index of moderated mediation (95% CI =  $-.872$  to  $-.046$ ). Specifically, the indirect effect of green consumption values on purchase intention via waste perceptions was significant in the donation condition (95% CI =  $-.780, -.062$ ). In contrast, the indirect effect was NS in the trash condition ( $-.162, .221$ ). These results supported our prediction that waste perceptions underlie the positive effect of green values on purchase intention following a sustainable disposal behavior (i.e., donating).

Study 3 provided evidence for the mediating role of waste perceptions in the effect of green values on purchase of new items following sustainable disposal. In the next study, we explore a boundary condition for the observed effect.

### Study 4

The objective of study 4 was to explore a theoretically and practically relevant moderator of the effect of green values on overconsumption following sustainable disposal. In doing so, we sought to provide additional support for the underlying mechanism through waste perceptions. According to our theorizing, green consumers should be less inclined to purchase a new item following donation when donating is described as practically ineffective in reducing waste for society. For example, when a charitable organization cannot use all of the donated clothing, donated items can be sent to landfills (Matteis and Agro 2018), increasing waste for society. Thus, we manipulated need for donation in order to mitigate the positive effect of green values on consumption following donation.

#### Method and Procedure

One hundred and ninety-one undergraduates (52.9% female) participated in a study with a two-group (need for donation: high vs. low) between-subjects design, with green consumption values measured continuously. Participants first read and evaluated a news article. Depending on condition, the article described that charitable organizations either need more donations of clothing or have no need for clothing donations (Appendix D). Next, participants considered a clothing donation and consumption scenario (same as Study 2). After reading the scenario, participants indicated purchase intention for a new shirt ( $\alpha = .94$ ), waste perceptions ( $\alpha = .86$ ) and green consumption values ( $\alpha = .93$ ).

#### Results and Discussion

As expected, regression analysis on purchase intention revealed a significant interaction between need for donation and green values ( $\beta = .33, t(187) = 2.06, p < .05$ ). In the high need for donation condition, participants with stronger green consumption values reported higher purchase intention ( $\beta = .31, t(95) = 2.79, p < .01$ ). In the low need for donation condition, the effect of green values on purchase intention disappeared ( $\beta = -.02, t(92) = .16, p = .87$ ).

Bootstrapping analysis for mediated moderation (Hayes 2012; Process Model 8) revealed that waste perceptions underlie this effect (95% CI =  $.070$  to  $.443$ ). The indirect effect of green values on purchase intention via waste perceptions was significant in the high donation need condition ( $.025, .309$ ). In contrast, the indirect effect was NS in the low need condition ( $-.195, .013$ ).

Consistent with our theorizing, consumers with green values were not likely to purchase more clothing following disposal via donation when they learned that clothing donations were not needed and would not be helpful in reducing waste. Not only do the findings offer a way to help green consumers avoid the observed licensing effect, but this also provides confirming evidence for the mediating role of waste perceptions in the proposed relationship.

#### Conclusion

Four studies provide converging evidence that sustainable disposal options, which are thought to reduce waste associated with disposal, can ironically lead green consumers to consume more new items, which can create more waste for society in the end. This boomerang effect of sustainable disposal on new consumption for green consumers is mainly due to the perception that donating or selling unwanted items reduces waste and environmental harm for society, a key consideration for green consumers whose consumption values center on environmental responsibility. Furthermore, this research

demonstrates theoretically relevant boundary conditions and moderators of the effect – i.e., unsustainable disposal option and lack of actual need for donation by a charitable organization. These findings contribute to the literature on disposition, licensing effect, and sustainable consumption.

# Assemblages of Denim: Transforming from a Mundane to a Remarkable Consumption Object

## EXTENDED ABSTRACT

### INTRODUCTION

In the contemporary consumer culture, consumer items and their meanings are resources which consumers use to form their identities, establish communities, reproduce cultural values through rituals or resist to dominant ideologies (Muniz and O'Guinn 2001, Rook 1985, Thompson 2004). However some consumer items or practices are inconspicuous, invisible, are away from the consciousness of people. They are part of the habitual side of the daily life such as food (Couplan 2005), cars (Dant 2004) or denim (Miller and Woodward 2012). Although a consumer object is often categorized as either a mundane or a remarkable item, recent research has been looking at the fluid nature of consumer objects. For example, Hagberg (2016) studied the historical transformation of shopping bags as mundane objects through time by entering into different consumption practices. Sofonova and Valcheva (2012) identified mechanisms of historical transformation of bottled water from a mundane to a remarkable consumer object. In this study, we aim to extend Miller and Woodward's (2012) study on denim by explaining how denim transforms and retransforms from the ordinary to the remarkable status in everyday life consumption. In this study, our problematic is to understand this continuous transformation of the nature of a consumer item from mundane to remarkable. In a grocery store or at the train station, a denim trouser becomes this blindingly obvious, ordinary thing, but at other instances, it becomes edgy, stylish, formal, or very authentic. Even the same trouser as an object can shift between these categories.

Assemblage theory allows us to understand this fluid and emergent nature of consumer object categories (mundane or remarkable). Becoming a mundane or remarkable denim trouser necessitates a disassembling of the elements of the object (fabric, color, style) and the consumer (gender, age, occupation, bodily parts like long legs) and then these elements form assemblages with other elements like time, place, other clothing items, community, and consumption situations (like rituals). When we analyze these parts and their exteriority relationship with each other, we found that there are two main assemblages occur which defines either the ordinary or the mundane. That is, this study delineates the process of how ordinary and remarkable as categories of consumption objects form.

We conducted this study in Eskişehir, Turkey. Eskişehir is a city located in the northwest of Turkey with approximately a population of 800000 and two universities. From the 2000s onwards, the city witnessed an urban regeneration process, aiming to transform the small rural town to a modern European city (Babadoğan 2005). Today new recreation sites, shopping malls, and commercialized street life of Eskişehir made global consumer culture available to young university students who have recently moved from different parts of Turkey. In addition to spending their time on the campuses, they socialize and enjoy their leisure times in cafes, restaurants, and theme parks. They are exposed to fashion items, novelties, and local as well as global brands in the shopping malls of the city. Jean consumption in this dynamic context allows us to see multiple ways and situations of jean consumption where ordinary and remarkable jean categories emerge.

### METHOD

This study is based on the data gathered from in-depth interviews, focus groups, and participatory observations. Data collection began with participant observations in university canteens and shopping malls in Eskişehir. At the same time, we conducted six in-depth interviews with university students, ages from 17 to 24. Then, we conducted three focus group interviews with female university students since they appropriated denim in a wide array of situations. After the transcription of the data (30 pages of field notes, 65 pages of interview transcript and 40 pages of focus group transcripts – all single space) we conducted inductive coding. We developed preliminary themes and decided to expand our research by theoretical sampling (Creswell, 2006). By applying snowball sampling procedures, we reached six more informants including both men and women; working, housewife and unemployed; married, divorced and single. Ages of latest informants are range from 29 to 32. Interviews lasted 60 to 80 minutes and were recorded and transcribed (single space 120 pages). In-depth interviews generated information on informants' decisions on their clothing purchase, denim choice and consumption situations. Then to understand the subjective meaning of denim, we asked for their experiences on wearing denim. We look for dramatic changes, high emotional situations in which jeans or denim has a place. Afterward, we wanted to learn where they prefer to wear jeans. By doing this, we would be able to see whether denim is a part of daily life or more special for the informant. After this primary analysis, we recognized the ordinary and remarkable categories emerge from the data. To understand how these categories form, we decided to extend the data collection and analyze the data from an assemblage theory perspective.

In the data, there are highly recognizable territorialization, deterritorialization, and reterritorialization processes and, material and expressive components in denim consumption experiences of informants (Deleuze and Guattari, 1987; DeLanda, 2009). In the analysis we adopted the following stages of analysis of the assemblages: 1) describing the alloy of heterogeneous bodies of human and non-human elements, 2) description of material, expressive and imaginative qualities of these bodies, 3) depiction of territorialization and deterritorialization processes as a result of the interactions of these heterogeneous parts, 4) defining the agencies of the human and non-human elements in these territorialization and deterritorialization processes. After introducing the context of blue jean consumption in Turkey, we provide the findings of the study.

### CONTEXT

Clothing has always been a symbolic and political issue in Turkey. Sumptuary laws and clothing legislations had long been part of the Turkish history. While the Turkish Republic was forming, new dress codes were issued in order to harmonize people's clothes with the modern Western world by leaving aside the traditional and religious clothing aside and to establish social unity and solidarity by eliminating the differences between different groups and identities such as urbanite, peasantry, bureaucracy, religious ranks, Muslim, and the non-Muslim population (Doğaner, 2009: 33). While some people agreed on these regulations and accepted them, others resisted passively by not being so visible in the public sphere. Turkey later

on faced with a head-scarf ban in universities from the early 1970s to late 2000s. This clothing issue was a perfect example to see the tension between secular and Islamic publics of the country since it is a highly controversial and symbolic issue in Turkey. Not only head-scarf but the veil was a tool of stigmatization in society because Turkish secularists used it to strengthen their hegemonic political conception of the Turkish Republic (Gürbüz, 2009). However, later on, it becomes more of a fashion concept (Sandıkcı ve Ger, 2010). Throughout its history, like head-scarf, denim possessed symbolic and political meanings as well.

Turkish consumers met denim during the late 1950s, after getting closer to the West and America as a result of Marshall Aid (Çalışlar and Güler 2003). Consequences of the intense admiration of the American way of life are the popularity of smuggled American products sold illegally in the big cities like İstanbul, Ankara, and İzmir. During the sixties, while European fashion favored functional and simple styles and cheap fabrics which are accessible to everyone, equality, and suitability to contemporary urban lifestyle, denim became an essential fabric for the fashion designers. Its repercussions were seen in Turkey. As well as ordering jeans to tailors, fashion-conscious women started sewing their jeans at home in this closed market economy. In the meantime, another critical wave of interactions was through hippies who were passing by Istanbul on their way to Katmandu. Second-hand jeans of the broke hippies sold and became popular among the youth who have associated themselves with this global counterculture (Çalışlar and Güler 2003). The seventies and early 80s, there was a political turmoil in the country, although at the beginning leftist student groups rejected blue jeans as an American icon but later appropriated as the working class clothing by making changes like cutting of the brand names or wearing them with green parkas and army boots. Rightist students rejected wearing blue jeans and preferred a conservative style like suits or cord trousers (Kasapoğlu Akyol 2010).

In the 1980s, after the Turkish government adopted neo-liberal economics and markets are opened, foreign blue jean brands such as Levi's and Wrangler. Reputable global brands like Levi's became the symbol of prestige among upper middle-class consumers. During the 80s and 90s, immigration from the rural parts of the country to the big cities created a tension in the cities. Jeans became the symbol of the western modern city life differentiating the university students of peasantry backgrounds from the urbanites. In 1990s blue jean became the symbol of youth, comfort, and freedom as well. By the 2000s, blue jeans were spread to the society; jeans find its place in the lives of young-old, rich-poor, rural-urban, conservative-liberal, religious-secular.

People wear jeans with several meanings whereas their choice may be seen in distinct occasions like job, education, spare time or even some ceremonies. Today especially among the middle-class youth who are exposed to the global fashion discourses, wearing practice is considered more like combining jeans with other clothing items and accessories. Some prefer jeans because of its comfort, its role in creating equality among different factions of the society and others prefers it to form authentic identities. In this study, we are interested in this fluid role of denim in the lives of the consumers, how it is shifting its role from a mundane to a remarkable consumption object.

## FINDINGS

Our findings reveal that denim trousers are objects becoming blindingly obvious in some instances and can be remarkable items for consumers in shaping their identities at other times. Utilizing assemblage theory perspective, we conceptualize continuous trans-

formation of denim from ordinary to remarkable item for young Turkish consumers.

The informants interpret denim as an ordinary item by using the terms: comfortable to wear, easy to use, a durable fabric, can be worn anywhere, prefer to wear denim to the situations where I do not need to think about my dressing, denim is suitable for shopping, picnic (informal environments), week-ends, or at the café, no need to spent effort or to think about what to wear, wear and go out, wrapped in the wardrobe (no need for ironing and hanging), it can be bought from cheap or expensive shops, for anyone, does not represent richness or poorness, and does not emphasize a gender position (makes a women unseen because it gives a masculine look rather than emphasizes the femininity), or a life saver.

*"You can buy a pair of jeans from the bazaar. If you have Money, you can buy from an expensive shop. It is something everyone can wear... All are same, the same blue color" (Arzu, F, 30)*

*"I do not have ironing problem. I wake up in the morning and wear the pair of jeans I wrapped up" (Caner, M, 30)*

*"If I do not want to spend effort, I wear jeans" (Jale, F, 32)*

*"When we are at a picnic! Grass, kids, people wearing jeans. It is normal...or we are in a cafe at Bağlar, everybody wearing jeans, youth... normal" (Rabia, F, 29).*

*Interviewer: ...OK! We have heard about your clothing style. What is the place of blue jeans in your clothing style?*

*Informant #4: Indispensible (Loughing)*

*Informant #1: Ordinary...*

*Interviewer: Can you open it more?*

*Informant #4: In everyday life, we keep wearing, using jeans.*

*Informant #5: For me, it is the most functional (Focus Group #1)*

Unlike the mundane denim, stylish and authentic denim, which is special to the consumer and often used for its symbolic meaning in the identity creation process is also identified. A body of ideal shape (defined by the global fashion discourse), denim (befitting, ripped, stonewashed), complementary parts (high-heels, jacket, silk blouse), and places (formal, informal, work, leisure) assembles the denim. Stylish ones are described by these terms: style (tight, skinny, ripped etc.), material characteristics of denim (e.g. pockets, colors of threads, or tones of blue different than the denim blue, such as ice blue), branded denim delivering fit between body and cut, ideal bodily aesthetics of long legs and skinny body necessary for a befitting stylish jean, harmony with other clothing items and accessories, fit between the situation, the jean and the other items worn (restaurant, at night, silk blouse), fashionable jeans, western and American myth of blue jean, low rise, and feminine jeans (transforms men to an "emo" person, feminizing, making him distinct), designer jeans, ornamented jeans with crystals or embroidery. Here are some scripts mentioning these elements of stylish jeans:

*What we called jeans was blue, even a single tone of blue. Now there is ice blue, light blue, dark blue, black... the threads of the pockets or the threads on the sides... was like yellow threads on the blue denim. Now their colors are the same. When the colors are the same, you can wear them to formal places... My black jeans... I have a black leather jacket... I wear my black jeans with this jacket. It gives a rock style... I associate this color with rock" (Arzu, F, 30)*

*It is about the ratio of the height to width ration [of the human body].(Zeynep, F, 30)*

*“For example, if I am coming to the school, I wear an appropriate shoe, such as a high heel which makes it close to a classic style. Japanned leather [shoes]can be suitable. Everything does not fit with jeans but I try to make them match. On top, I will wear a shirt but a sporty shirt...” (Arzu, F, 30)*

*According to me, jeans fit better to the people who are tall and with long legs. (Arzu, F, 30)*

*Sempre [a restaurant]is an expensive and a cool place. They [customers of Sempre]pranked themselves out when coming. It is not like coming to a wedding ceremony but they have a different style. You may feel yourself awkward [as not belonging to a group with a jean]. (Jale, F, 32,)*

The network of human and non-human components of the denim assemblage with their expressive and material qualities shape denim as mundane or remarkable. The material and expressive qualities of the place (e.g. a fancy restaurant with its brand image and atmospherics), other clothing items (e.g. a black shirt with gold details), accessories (e.g. a necklace), fashion discourses (e.g. being stylish and aesthetic or body type), brands, and other people in the context (e.g. friends, relatives, colleagues) are bodies of heterogeneity. The components and the rules of interaction among components can differ according to what appropriateness refer to in a specific situation (e.g. aesthetics, comfort, or functionality). Also, the same denim trouser can be part of different assemblages. It can fit a fancy restaurant as well as a student canteen. There are situations where denim cannot form an assemblage such as formal situations. For example, an assemblage containing a professor in the university context is seen as inappropriate, because university represents the workplace (a formal place) for a professor.

Mundane denim is an assemblage of human and non-human actors such as the denim itself, the situation which denim is worn, the persons' body and the bodily experiences like fitting on the body, feeling comfortable. In the assemblage of mundane denim, an essential element is the denim fabric itself; it should be a coarse cotton fabric in denim blue color. This material element has a role in the territorialization of the ordinary denim in the society. However while this material element of the assemblage transforms to a different fabric which is flexible, in a different color or thinner, then the mundane denim deterritorializes and transforms into stylish denim which is more authentic and remarkable.

However, the material element of the denim fabric now transforms into a more expressive element. For example, the flexible fabric may mean trendy and befitting. While the expressive role of the fabric becomes influential, the stylish denim territorializes. Depending on the changes in the heterogeneous bodies in the assemblages and the influence of their material and expressive characters, denim jeans continuously reproduced as mundane or stylish in the society. Between mundane and stylish denim, black denim possesses a different position. Black jeans are not mundane jeans; they deterritorialize what a mundane jean is as a result of color, the material quality of the denim. Black jean is specific; it is preferred when going out at nights or combined with black jackets to get a rock star image. As can be seen, the rock start cool identity created with black jeans reveal that

black jeans can be a component in the stylish denim assemblage and has a role in the territorialization of the stylish denim.

Denim has the capacity to code/decode both material and expressive roles in both different assemblages. For ordinary denim assemblage, mundanity, comfort, usefulness, casual wear, sneakers, and functionality are leading parts. The materiality of denim is becoming more significant than its expressive meaning. When it is ordinary, denim is a problem solver and unnoticed clothing object. Those types of denim are not spectacular. They are clothes that anyone can wear anywhere.

Remarkable denim assemblage is the opposite of ordinary denim. For remarkable denim assemblage, high-heels, advertising discourse, fashion discourse, top clothing, and ideal beauty are the prominent parts. Consumer use denim when they want to be seen or realized. When it is remarkable denim, its expressive roles become more important than its materiality. It can be black, stretchy or skinny, but most importantly it needs to be remarkable. Besides, denim's relation with other parts of the assemblage is more powerful than mundane denim. It needs to match with high-heels or jacket inevitably. So consumer's capacity to create denim assemblage is more vital at remarkable denim assemblage.

Sociohistorical background of the Turkish context highlights that western and American life are admired and used as status markers (Üstüner and Holt 2010). Denim like its European counterparts do not only operate as a mundane object but at the same time it becomes a stylish one used in defining the identities through conforming the global fashion discourse's understanding of aesthetics. Therefore, denim representing western fashion utilized as a symbolic resource in establishing a modern western identity and transforms to the remarkable denim.

## DISCUSSION

This study contributes to the consumer research literature demonstrating that the dualities of mundane-remarkable, invisible-conscious, ordinary-extraordinary are oversimplifications. Denim consumption was presented as a mundane consumption item (Miller and Woodward 2012). However adopting the assemblage theory perspective, we demonstrate that consumer items can transform from mundane to remarkable, as a result of the territorialization and deterritorialization processes of the denim. We bring an alternative understanding of the notion of “liquid” consumption (Bardhi and Eckhardt 2017) by demonstrating the continuous transforming nature of the denim, the consumer object. Unlike Hagberg (2016) and Sofonova and Valcheva (2012) studying the transformation of consumer objects historically, our study shows the fluid nature of consumption objects at a single period. Miller and Woodward (2012) emphasize denim as a mundane object in the British context.

# The Impact of Product Type on Disposal Intentions

Mustafa Karataş, Koç University, Turkey  
Rabia Bayer, Koç University, Turkey  
Zeynep Gurhan-Canlı, Koç University, Turkey

## EXTENDED ABSTRACT

Despite early suggestions that product characteristics might play a significant role at the stage of disposition (Jacoby, Berning, and Dietvorst 1977), extant research focused largely on the impact of product characteristics on consumers' choice and consumption, leaving the impact of product characteristics on disposition largely uninvestigated. Although empirical studies recently started to study the impact of several product characteristics such as form distortion and size on recycling intentions (Trudel and Argo 2013), the research is yet to identify the role of other product characteristics on disposition intentions. In the current research, we investigate how hedonism/utilitarianism dimension of a product impacts recycling versus trashing intentions.

Based on past research suggesting that hedonic products evokes a sense of guilt (Strahilevitz and Myers 1998), we predict that hedonic products are more likely to be recycled than trashed. This prediction relies on the assertion that recycling is a compensatory behavior consumers actively engage in when they experience guilt related to a consumption act such as buying products with excessive packaging (Dahl, Honea, and Manchanda 2003).

The disposition decision for utilitarian products, however, is likely to be different from decisions about hedonic products. Disposition of utilitarian products is generally not based on psychological obsolescence, which refers to replacing a product for symbolic reasons such as the product being unfashionable or less attractive (Cooper 2004). Rather, they are disposed due to physical obsolescence. In other words, consumers dispose of utilitarian products when they are no longer physically capable of conferring the practical utility they are used for due to raw material degradation. Consequently, consumers are likely to perceive little value from recycling utilitarian products—which are perceived to be depreciated—at the stage of disposition, leading to higher trashing intentions.

We tested our predictions in four experiments. In study 1, three research assistants observed student customers' disposition behavior (of plain coffees and coffees with cream topping) at the cafeteria of a college during a period of ten days. A pretest among a sample from the same university showed that plain coffee is perceived as more utilitarian than hedonic, whereas a coffee with cream topping is perceived as more hedonic. 127 observations was noted. Among 59 plain coffee cups, 34 cups (57.6%) were trashed whereas 25 cups (42.4%) were recycled. Conversely, among 68 cups of drinks with cream topping, more cups were recycled (49 cups; 72.1%) than trashed (19 cups; 27.9%). A binary logistic regression revealed that this effect was significant ( $\chi^2(1)=11.05, p<.001$ ).

In study 2, MTurk participants ( $N=104$ ) indicated either a hedonic or a utilitarian possession. Next, they stated their intentions to either recycle or trash this product when they decide to no longer use it on a 101-point scale. We obtained a significant interaction ( $F(1, 100)=9.95, p<.01$ ). In the utilitarian condition, participants indicated a significantly higher intention to trash ( $M_{trash}=45.8; M_{recycle}=25.5; F(1, 100)=4.69, p<.05$ ). In the hedonic product condition, this pattern reversed ( $M_{recycle}=44.6, M_{trash}=22.6; F(1, 99)=5.26, p<.03$ ).

Study 3 ( $N=200$ ) had a 2 (consumption goal: utilitarian vs. hedonic goal) x 2 (disposal type: trashing vs. recycling) x 2 (guilt: low vs. high), between-subjects design. In the hedonic (vs. utilitarian) condition, participants were asked to imagine that they had a kindle

for reading lowbrow (vs. highbrow) books. Following past research showing that price deals reduce guilt associated with consumption (Choi et al. 2014), we used price promotion as the guilt-reducing cue. In the high-guilt (vs. low-guilt) condition, participants were told that they bought the kindle at the original market price (vs. at a price discount of 50%). Finally, participants indicated on a 101-point scale their intention to either recycle or to trash when they no longer use the kindle. We found a significant interaction of product type and disposal type ( $F(1,192)=19.45, p<.001$ ). Consumers reported a significantly higher intention to recycle the hedonic kindle ( $M_{recycle}=50.0, M_{trash}=30.6; F(1, 192)=8.83, p<.004$ ). Conversely, when consumers considered the kindle for using for utilitarian purposes, their trashing intentions were higher ( $M_{recycle}=23.5, M_{trash}=45.6; F(1, 192)=10.66, p=.001$ ). Moreover, when no guilt-reduction cue was provided, participants in the hedonic condition reported significantly higher intentions to recycle ( $M=62.0$ ) than to trash ( $M=28.7; F(1,192)=11.88, p<.001$ ). However, this effect disappeared when participants were asked to think that they purchased the kindle at a discounted price ( $M_{recycle}=39.4, M_{trash}=32.6; F(1,192)=.52, p>.45$ ). On the other hand, providing the guilt reduction cue did not change the pattern of findings in the utilitarian condition. Participants' intentions to trash a kindle for utilitarian purposes was higher than recycling in both high guilt ( $M_{trash}=47.2, M_{recycle}=24.8; F(1,192)=5.48, p=.02$ ) and low guilt ( $M_{trash}=44.1, M_{recycle}=22.2; F(1,192)=5.19, p<.025$ ) conditions.

We tested the process prediction for utilitarian products in Study 4 ( $N=240$ ), which employed a 2 (product usage goal: hedonic vs. utilitarian) x 2 (disposal: recycling vs. trashing) x 2 (product condition information: absent vs. worn out), between-subjects design.

Participants were first asked to think about a shirt they use either for utilitarian or hedonic purposes. Next, participants were asked to further imagine that they decided to no longer use his product. In one condition, they were informed that they decided to longer use the shirt because it was worn out. They finally indicated their intention to recycle or trash the shirt on a 101-point scale. The results replicated our basic prediction ( $F(1, 232)=60.39, p<.001$ ). In the utilitarian condition, trashing intentions ( $M=66.4$ ) were significantly higher than recycling intentions ( $M=33.3; F(1,232)=33.73, p<.001$ ). This pattern reversed in the hedonic condition ( $M_{recycle}=63.8, M_{trashing}=33.1; F(1,232)=26.91, p<.001$ ). The worn-out condition of the shirt did not influence the disposal intentions for the hedonic product ( $M_{worn-out-recycle}=62.6, M_{worn-out-trash}=39.7; F(1,232)=7.46, p<.01; M_{not-worn-out-recycle}=65.1, M_{not-worn-out-trash}=27.1; F(1,232)=21.37, p<.001$ ). The physical condition of the shirt, however, exerted a significant influence on consumers' disposal intentions for the utilitarian shirt. When no information regarding the shirt's physical condition was provided, trashing intentions ( $M=58.4$ ) were significantly higher than recycling intentions ( $M=40.3; F(1,232)=5.06, p=.025$ ). When participants were told that they were disposing the product because it wore out, the significance of the difference between trashing ( $M=74.9$ ) and recycling ( $M=25.8$ ) intentions improved ( $F(1,232)=34.89, p<.001$ ).

The current research advances extant knowledge on consumer disposal behavior by investigating the impact of product type—as it relates to hedonic and utilitarian perceptions—on disposal decisions. Recently, a research stream developed by Trudel and colleagues (Trudel and Argo 2013; Trudel, Argo, and Meng 2016) found that several product characteristics such as form and size distortion, and

identity expressiveness influence whether consumers would recycle or merely bin the product. We contribute to this research stream by showing that a significant product-related variable—whether the product is perceived as hedonic or utilitarian—which has been long shown to influence consumer behavior at choice and post-choice stages influences consumer decisions also at the stage of disposition. We replicated the proposed effect across three types of products—paper cups, electronics, and garment—which play a significant role in waste generation (EPA 2012). Our findings provide significant implications for public policy makers, who put significant efforts to increase these figures.

# Increasing Consumption of Larger Product Sizes through Symbolic Congruity: Size Label Color and Product Temperature

Seth Ketron, East Carolina University, USA  
Nancy Spears, University of North Texas, USA

## EXTENDED ABSTRACT

In product packaging, size labels provide semantic information indicating the relative magnitude of a product, and color influences consumer perceptions in both physical and physiological ways (i.e., Aydinoglu and Krishna 2011; Creusen and Schoormans 2005; Hagtvedt and Brasel 2017; Krishna et al. 2017; Labrecque et al. 2013; Prelec et al. 1997; Spence 2011). Among these associations lies temperature: red associates with aggression and warmth, while blue tends to represent calmness and cold (Bagchi and Cheema 2013; Bellizzi and Hite 1992; Chebat and Morrin 2007; Labrecque et al. 2013; Mahnke 1996; Mehta and Zhu 2009; Mehta et al. 2017; Szocs and Biswas 2014).

Importantly, color, size labeling, and temperature can all accelerate (or decelerate) arousal, which can increase (decrease) consumption accordingly. The common view of color is that warm colors – especially red – are more arousing, while cool colors (i.e., blue) are more relaxing (Bellizzi and Hite 1992; Crowley 1993; Gorn et al. 2004; Kaltcheva and Weitz 2006). Temperature itself can affect arousal, with warmer temperatures generally suppressing arousal (Cheema and Patrick 2012; Halali et al. 2017; Tham and Willem 2010). Further, larger product sizes lead to generally higher rates of arousal and consumption than smaller sizes (i.e., Scott et al. 2008; Aydinoglu and Krishna 2011; van Ittersum and Wansink 2012; van Kleef et al. 2014; Karemeas et al. 2015; Ilyuk and Block 2016; Roose et al. 2017).

Research has appeared to neglect the potential effects of combining color and temperature cues in congruent ways (i.e., red with hot products and blue with cold products). We argue that such combinations could lead to boosted arousal and higher perceived value of larger sizes. Although prior scholars have shown that red tends to be more arousing than blue (i.e. Bellizzi and Hite 1992), we argue that congruity between color as a symbol of temperature and the temperature of a product itself can also be stimulating, which can make blue more arousing when paired with cold products and red less arousing when paired with hot products. As such, because red is typically associated with warmth and blue with coolness, blue size labeling for warm products and red size labeling for cool products create sensory mismatches that may dampen arousal toward the given product. Further, we propose that environmental temperature may moderate this influence due to its own effects on arousal (Cheema and Patrick 2012; Halali et al. 2017; Tham and Willem 2010). Four studies test these predictions.

Study 1 established the initial effect of size labeling and product temperature on arousal. This 2 X 2 between-subjects study utilized images of bottled water labeled either small or large in either red or blue. Label color and labeled size interacted to predict arousal, which was higher for the large size than for the small size in the blue condition but not in the red condition.

Studies 2a and 2b extend study 1 by testing both arousal and a key consumer outcome variable (WTP) within the same studies. In study 2a (2 X 2 between-subjects design), we test our predictions using a cold product context (milk) with similar size and label conditions. For the blue label, WTP was significantly higher for the large size than for the small size, but there was no significant difference for the red label. Further, arousal mediated for blue but not for red

Study 2b replicated study 2a using a hot product (coffee). As expected, WTP was not significantly different across size conditions for the blue condition but was significantly higher for the large size than for the small size in the red condition. Once again, arousal was a significant mediator, but only for the red label.

Study 3 was a controlled laboratory experiment involving either a cool room or a warm room, either hot or cold products, and either red or blue size labeling (2 X 2 X 2 between-subjects design), with selected size (definitely the small – 1 to definitely the large – 7) as the DV (unlike prior studies, subjects saw both small and large as available options in this study). The three-way interaction of room temperature, product temperature, and size label color was significant. For the cool room condition, the interaction of product temperature and size label color was significant: for the hot product condition, subjects exhibited a stronger preference for the larger size when the sizes were printed in blue as opposed to red, while the difference was equally strong and not significant for the cold product. Meanwhile, for the warm room condition, this interaction was not significant. Further, arousal mediated the three-way interaction and selected size.

Taken together, the four studies above show that congruity between size label color and

product temperature drives up arousal, increasing the desire and perceived value of the larger size. Further, air temperature moderates these effects, suggesting that a cooler air temperature can override incongruities when at least two of the three temperature-related factors align (color temperature, product temperature, and air temperature) and that warmer air temperatures reduce the effects on arousal. These studies change our understanding of the arousing properties of color: red may not always be more arousing than blue when the temperature-related symbolic properties of color are taken into account. Beyond academia, these findings are important to firms that sell beverages of certain temperatures, especially when different sizes are involved, and shows that aligning packaging elements such as size labels with product and air temperatures can boost consumer responses and perceived value in larger available sizes.

The above studies are limited in a few ways. First, consumers did not actually handle hot or cold products; we plan to address this limitation through a field study in which subjects will handle products that are either hot or cold. Second, the effects are limited to beverages; while beverages are a major component of the market, additional product contexts would provide broader generalizability for the theory. Third, we test only two variables (selected size and WTP) in the above findings, so subsequent studies will include additional variables to broaden the scope of consumer responses.

# Enhancing Perceptions toward In-Home Artificial Intelligence Devices through Trust: Anthropomorphism and Non-Branded Device Messages

Seth Ketron, East Carolina University, USA  
Brian Taillon, East Carolina University, USA  
Christine Kowalczyk, East Carolina University, USA

## EXTENDED ABSTRACT

In a world of connected devices and technology, consumers are opening their homes to artificial intelligence (AI) devices, such as Google Home, Amazon Echo and HomePod. These devices are changing the way consumers interact with brands/products, companies, information, and each other. A source of entertainment, information, home control, and personal reminders, in-home AI devices offer convenience and personalized content on-demand through voice-control. With more machines exhibiting human intelligence (Siau and Yang 2017) and the integration of AI in these devices, the topic has remained under-researched. Thus, this exploratory research seeks to better understand how owners and non-owners feel about in-home AI devices and what barriers, like trust, may be preventing some from adopting this product.

Study 1 was a qualitative pretest with a mixed sample of 114 students and MTurk panelists (male = 41; mean age = 33) was conducted. The pretest goal was to determine barriers to adoption among non-owners (N = 58) and to ascertain owners' (N = 56) interaction with their devices. More specifically, owners were asked to elaborate on the uses with their devices, while non-owners were asked why they do not own a device and what would motivate a purchase. After data collection concluded, participants' comments were reviewed for references to trust by owners and non-owners.

Trust was a commonly cited concern among non-owners. While several participants mentioned concerns with high prices or lack of perceived benefits/value, many participants were worried about unauthorized listening or tapping of personal data. Also, non-owners indicated that they would more likely adopt a device with greater assurances of privacy and information protection, indicating that trust inhibits adoption. Meanwhile, device owners cited a variety of uses and engagements with their in-home AI devices, and a few cited trust-related concerns. A comment theme for owners was the humanlike aspect of their device, indicating conversational uses and considering their devices to be household members. Consumers may develop an affinity for their devices through their anthropomorphic characteristics. Anthropomorphism may be a way of increasing trust toward in-home AI devices. To explore this concept, Study 2 tested the influence of anthropomorphism on consumer trust toward AI devices.

Based on the findings of study 1, study 2 examined the influence of anthropomorphism, or the attribution of human characteristics to inanimate objects, as a way of boosting trust (Aggarwal and McGill 2007/2012; Epley et al. 2007; Kim and Kramer 2015; Maeng and Aggarwal 2014; Toure-Tillery and McGill 2015; Triantos et al. 2016; Waytz et al. 2014). 101 MTurk panelists (male = 45; mean age = 36) participated in a 2 (anthropomorphic cue: absent versus present) between-subjects experiment that included an image of a common in-home AI device with an icon of a female personal assistant in gray (anthropomorphic condition) or no icon at all (control condition). Purchase intentions were significantly higher for the anthropomorphic device, and current owners indicated higher purchase intentions toward the device than non-owners. However, the interaction was not significant. Further, mediation analysis revealed that the anthropomorphic device led to higher warmth, which led to higher trust; consequently, trust led to higher purchase

intentions. Although purchase intentions did not exhibit a significant interaction, the question remained if anthropomorphism boosts trust among owners and non-owners. Therefore, the analysis of the independent variables on trust was repeated. Trust was significantly higher for the anthropomorphic condition and for current owners. Additionally, a marginally significant interaction emerged, such that among non-owners, the anthropomorphic condition led to significantly higher trust than the control condition, whereas owners exhibited a non-significant difference.

Study 3 next examined how branded directions in AI information affected trust of in-home AI devices and willingness to adhere to those directions as well as rely on the device for future assistance. Each subject participated in a 2-level (instructions: non-branded versus branded) between-subjects design. Subjects were instructed to imagine that they were consulting an in-home AI device for directions to remove a stain from a garment and read a list of instructions that included either Tide (branded instructions) or no brand name (unbranded instructions). The main effects of ownership on adherence to directions and future reliance on the device were not significant. Meanwhile, the main effects of branding on both adherence to directions and future reliance were both significant. Further, a marginally significant interaction emerged for adherence to directions, with non-owners indicating similar willingness to follow the instructions between the non-branded and branded conditions. However, owners were significantly more willing to follow the directions in the non-branded condition than in branded condition. Meanwhile, the interaction of ownership and branding on future reliance was not significant. Serial mediation with the branding manipulation as the sole initial predictor was significant and full, such that the branded condition led to significantly higher perception of the device as a marketing agent, which subsequently reduced trust and in turn led to lower adherence to directions and future reliance.

This research provides the first examination of how owners and non-owners of in-home AI devices feel about the device and how barriers to adoption can be reduced through anthropomorphism and unbranded instructions related to general product usage. Study 1 identified trust as a barrier to adoption among non-owners and a main concern among owners. Study 2 considered the humanlike characteristics of the device and confirmed that an anthropomorphic cue boosts trust among owners and non-owners. Study 3 found that in-home AI devices using branded content are considered marketing agents and are therefore less trusted, leading to lowered adherence to instructions and future reliance on the device. In sum, these findings provide valuable insight on the adoption and use of these devices. While a few limitations exist (experimental design, sample size, brand usage), the area of AI research offers extensive opportunities to better understand consumer behavior toward in-home AI devices.

# Deprivation of Control and the Phonetic Appeal of Brand Names

Jamel Khenfer, Zayed University, United Arab Emirates  
Caroline Cuny, Grenoble Ecole de Management, France

## EXTENDED ABSTRACT

People must often respond to control threats of different nature in their daily lives: mundane (e.g., stockout) or tragic (e.g., natural disaster), negative (e.g., flight delay) or positive (e.g., early delivery). Research documents a wide range of responses that people can implement to compensate for low control states, from overestimating one's ability to control random events (Langer 1975) to seeking structure (Cutright 2012). In this research, we uncover a compensatory strategy to restore control that involves the phonetic appeal of certain brand names.

Specifically, we investigate consumers' attraction for brand names containing plosive consonants (i.e., "b", "d", "g", "k", "p", and "t") in the context of perceived control loss. Past research suggests that executing articulatory movements in the mouth to produce sounds can bear sensory information (Strack, Martin, & Stepper, 1988; Topolinski et al., 2015; 2017). Here, we propose that plosives entail a physical action that reflects one's readiness for action because of the abrupt popping sound made by a stoppage of air in the mouth followed by a sudden explosive release. Based on past research suggesting that individuals exert greater effort immediately following a loss of control as a way of regaining control (Greenaway et al., 2015a), we hypothesize that perceived control loss increases the appeal of plosive-based brand names because plosives elicit the feeling of doing something.

In a pilot study ( $N=130$ ), we sought to provide evidence for the assumption that brand names containing plosive (*versus* fricative) consonants are more likely to elicit a disposition to act. Using a computerized lexical decision task, we observed that when participants were exposed to plosive-based prime words, they were faster to recognize the word "action" and "effort" as real words ( $M=635.21.25$ ,  $SD=124.67$ ) than when they were exposed to fricative-based prime words ( $M=650.24$ ,  $SD=123.48$ ;  $F(1, 129)=2.93$ ,  $p=.089$ ). We further found that participants were slower to recognize the words "calmness" and "passivity" as real words following prime words containing plosives ( $M=693.68$ ,  $SD=161.40$ ) compared to fricatives ( $M=654.42$ ,  $SD=117.63$ ;  $F(1, 129)=13.99$ ,  $p<.001$ ). We found no effects with fillers words.

In Study 1 ( $N=123$ ), we tested our hypothesis that people prefer brand names containing plosives to the ones containing fricatives when their sense of control is threatened. We observed a main effect of condition where perceived control loss resulted in the choice of more brand names containing plosives (vs. fricatives),  $b=.18$ ,  $SE=.09$ ,  $Z=4.51$ ,  $p=.034$  ( $M_B=50.8\%$ ,  $M_{CD}=55.4\%$ ).

In Study 2 ( $N=105$ ), we sought to provide evidence of mechanism by restoring control following the control threat by having participants make (or not) a personal choice to boost personal control. Furthermore, we sought to rule out an alternative explanation based on the possibility that plosives are overrepresented among top brand names and thus could drive preferences based on a sense of familiarity. Accordingly, Study 2 measured brand liking for alveolar

plosives ("d", "t") because their overrepresentation does not exceed the overrepresentation of alveolar fricatives (e.g., "s"). As expected, we found a significant simple effect of perceived control loss when control was not restored,  $b=2.80$ ,  $SE=1.35$ ,  $t(101)=2.08$ ,  $p=.040$  (*Estimated value*  $_{high\ control}=10.83$ ,  $SE=.96$ ; *Estimated value*  $_{low\ control}=13.63$ ,  $SE=.96$ ). This effect, however, became non-significant when participants' sense of control was restored,  $b=2.29$ ,  $SE=1.39$ ,  $t(101)=1.65$ ,  $p=.103$  (*Estimated value*  $_{high\ control}=11.19$ ,  $SE=.99$ ; *Estimated value*  $_{low\ control}=13.48$ ,  $SE=.97$ ).

In Study 3 ( $N=244$ ), we sought to replicate the findings of Study 2 and identify an important boundary condition—i.e., the presence of a context-relevant interventionist external agent—that would illustrate when plosives are likely to lose their appeal in contexts of reduced control. As such, Study 3 placed the locus of control restoration on the service provider who either intervened or not in the context of a cancelled flight. We found a significant simple effect of perceived control loss when the service provider did not intervene to restore control ( $b=.76$ ,  $SE=.36$ ,  $Z=2.06$ ,  $p=.039$ ;  $M_{High\ control}=40.3\%$ ;  $M_{Low\ control}=59.0\%$ ). However, this effect became nonsignificant when the service provider intervened to restore control,  $b=-.10$ ,  $SE=.36$ ,  $Z=-.28$ ,  $p=.779$  ( $M_{High\ control}=47.5\%$ ;  $M_{Low\ control}=45.0\%$ ).

In conclusion, when making decisions regarding brand names, managers need to consider the sensory information that consumers may extract from them, and specifically the use of plosives to anticipate low control states. By uncovering a novel response to control threat, our findings contribute to the recent infusion of compensatory control research to understanding consumer behavior.

# Disgusting? No, Just Different! Understanding Consumer Skepticism Towards Sustainable Food Innovations

Jan Andre Koch, University of Groningen, The Netherlands

Jan Willem Bolderdijk, University of Groningen, The Netherlands

Koert van Ittersum, University of Groningen, The Netherlands

## EXTENDED ABSTRACT

Though desperately needed, consumers reject sustainable consumption alternatives which deviate far from the norm. Labgrown meat and insectbased meat substitutes, for instance, could revolutionize the food industry, but consumers are disgusted by both, arguing they are unnatural and carriers of disease respectively (Verbeke et al., 2015; Vanhonacker et al. 2013). Mapping perfectly onto textbook definitions of disgust elicitors like impurity and pathogens, consumer arguments have been embraced as the obvious cause of these innovations' failure—with limited success.

We argue that addressing these consumer rationales has shown limited success as sustainable consumption alternatives are not rejected based on their inherent features. Instead, we find that consumers reject foods that are not normal to them *because* they are not normal to them and only post hoc rationalize their rejection.

In the socialization process, norms—culture's guidelines of what is normal and approved of—get internalized and are complied with as a goal in itself (Gintis, 2003). Important norms are more likely to be internalized (Villatoro et al. 2015) accordingly, internalized norms can be seen society's important values. Any behaviors that oppose these will elicit moral disgust (Cottrell & Neuberg, 2005). While it is tempting to view disgust as an inherent feature accompanying specific products, we find that this is not the ultimate cause. The same product can be considered delicious or appalling, depending on one's internalized norms. In other words, we argue sustainable consumption alternatives elicit disgust not because they are feared to be impure or unhealthy, but rather because they are considered abnormal.

To establish the relationship between normalness and disgust, 43 attendees of a health event were sequentially presented with two novel foods, either camel milk and horse meat or dried grasshoppers and seaweed. Treating observations as independent in spite of the within-subjects design, we could stack them. We find that consumption correlates negatively with both perceived abnormalness ( $r(83)=-.50, p<.001$ ) and perceived disgust ( $r(83)=-.40, p<.001$ ). Abnormalness and disgust correlate positively ( $r(83)=.69, p<.001$ ).

We hypothesized that the awareness of engaging in normviolating behavior is sufficient to elicit disgust. Accordingly, in study 2, we presented a cupcake to 137 participants, half of which were informed about its insectbased, normviolating colorant before assessing it. We find significant differences in the disgust expected during its consumption between aware ( $M=.19, SD=1.08$ ) and unaware participants ( $M=-.20, SD=.88$ );  $t(131.683)=2.29, p<.05$ ). Seeing that participants experiencing disgust were unlikely to eat the cupcake ( $r(137)=-.23, p<.05$ ), we conclude that disgust is elicited by normdeviating foods and will consequently lead to rejection.

Study 3 tested the links between internalized norms, disgust, and rejection. 145 participants saw a picture of one of two ambiguously looking food items: (1) a hamburger described as either made of lab-meat (normviolating) or an unfamiliar breed of cattle (normcongruent), (2) a fried isopod described as either an insect (normviolating) or a kind of shrimp (normcongruent). The relationship between the foods (norm-violating vs. normcongruent) and their rejection was tested with perceived normviolation and disgust as serial mediators using Hayes' (2013, model 6) PROCESS macro with

10,000 bootstrapped samples at a 95% confidence interval, showing a significant indirect effect of the food on rejection with the two mediators norm-violation and moral disgust (.29, 95% CI .11, .56). The total indirect effect was also significant (1.19, 95% CI .44, 1.93). A food perceived as a normviolation will elicit moral disgust which will then lead to rejection.

Presenting participants ( $N=222$ ) with two unfamiliar food items, anteggs and crabeggs, study 4 replicated study 3 and supported its results while excluding any potential confounding effects of familiarity with the food item. Serial mediation was tested using model 6 in the PROCESS macro (Hayes, 2013) with 10,000 bootstrapped samples at a 95% confidence interval. We confirmed a significant indirect effect of the food on rejection through the two mediators of normviolation and moral disgust (.37, 95% CI .20, .63) and a significant total indirect effect (1.26, 95% CI .65, 1.92). Even unfamiliar foods that are not subject to a norm, but are derivatives of a food item, are regulated through norms.

Studies five and six tested the final hypothesis that consumers' rationales are constructed post hoc, to support rejection. A pre-study asked participants ( $N=205$ ) whether they would consume cow's, camel's or dog's milk and to list both reasons supporting and arguments that could change their decision. We used milk as all its inherent features are comparable, but for cultural reasons cow's milk is seen as normal and healthy, camel's milk as somewhat abnormal (seen in study 1) and dog's milk as outrageous (Curtis, 2016). This study's main goal was to find the arguments participants justify their rejection with to use in study 5, a quasi-replication of Haidt's (2001) rationalization study. Study 5 asked participants ( $N=67$ ) to taste milk either described as dog's milk (actually goat's milk) or camel's milk (actual camel's milk). Afterwards a personal interview asked each participant to explain their decision with the interviewer being trained to challenge participants' arguments. While coding and analyzing has not yet concluded, during the interviews we found that participants who rejected, often used easily refutable arguments but would not change their minds, even after their arguments collapsed, hinting at those arguments being post hoc rationalizations. More detailed results will be shared during the conference.

Study six primed participants ( $N=128$ ) with either a disgusting or neutral video-clip and warned them about the clip's potential effects on subsequent studies. In an alleged unrelated subsequent study participants were presented with milk (camel's or Jersey milk) to taste voluntarily and one random rationalization out of a set of eight (based on the pre-study). Preliminary analyses confirm that participants in the disgust condition agreed more with a random confabulated argument ( $M=3.34, SD=1.37$ ) than participants in the neutral condition ( $M=2.80, SD=1.22$ ;  $t(126)=2.38, p<.05$ ). This indicates that circumstantial disgust leads consumers to look for arguments supporting their aversive feeling, even when the disgust elicitor is explicitly highlighted.

Concluding we can say that in the case of sustainable consumption alternatives, disgust is elicited through perceived abnormalness and ultimately wrongly attributed to the foods' features.

# Social Sharing of Negative Emotions in Virtual Travel Communities

Clara Koetz, Rennes School of Business, France  
Anke Piepenbrink, Rennes School of Business, France

## EXTENDED ABSTRACT

Virtual communities offer a social environment in which several emotional processes take place. After a collective emotional event, such as a terrorist attack, these communities can provide individuals a space for social contact and emotional support and an opportunity to reduce the negative emotions arising from these situations (Rimé, 2009). The novelty and importance of this type of event coupled with the broad media coverage elicit strong negative emotions, such as sadness and fear, and stimulate people to engage in social sharing (Luminet et al., 2004). Socializing negative emotions help individuals to obtain cognitive clarity, and to regulate their emotions by venting, obtaining emotional and social support, and being in touch with others (Duprez et al., 2015). Also, people may feel stimulated to express their sympathy, and share feelings of sorrow or concern for those involved in the event (Eisenberg & Miller, 1987). The objective of this article is to analyze the social sharing of negative emotions triggered by a terrorist attack in a virtual travel community. Specifically, we examine the cases of anger, sadness, and fear. We also analyze sympathetic feelings expressed in these contexts.

We conducted a multi-method study in two steps. Firstly, we collected all threads and their replies in the TripAdvisor Paris Forum from 01/01/2014 to 31/12/2017 (1,072,499 posts, including 101,393 opening posts and replies), comprising the URL, name of posting person, date and time, index of reply, content, number of previous posts on TripAdvisor, and location. Emotions were extracted with the R package *syuzhet* (Jockers, 2015) using a large dictionary for word-emotions associations developed via crowdsourcing on Amazon's Mechanical Turk. For the quantitative data analysis, we compared the threads and their replies seven days before and after the Paris terrorist attack on several characteristics by performing t-tests of the mean or the proportion. We also compared sympathy scores of the period after the attack across various groups of threads. Secondly, we conducted a qualitative analysis of the 20 largest threads created within seven days in the Paris Forum after the Paris terrorist attack and the thread that was created after the Nice terrorist attack on July 14, 2015 in the same forum.

The results of the quantitative analysis demonstrated that the terrorist attack affected the number of replies, time dynamics, and the emotional content of the posts. The number of replies increased from 8.39 (mean before the attack,  $M_{BA}$ ) to 13.23 (mean after the attack,  $M_{AA}$ ,  $p = 0.008$ ) per thread. Three categories were examined in relation to time dynamics: (a) duration, which refers to the time difference between the opening post and the last post in the same thread without a significant difference between before and after the attack; (b) timing, which refers to the average time between the first post and replies ( $M_{BA} = 53.68$ ,  $M_{AA} = 3.36$ ,  $p = 0.000$ ); and (c) timing within period, which refers to the average time between the first post and replies within the period of seven days before and after the attack ( $M_{BA} = 0.70$ ,  $M_{AA} = 0.58$ ,  $p = 0.001$ ). The negative emotional content of the posts increased after the terrorist attack; specifically, we identified that anger ( $M_{BA} = 0.54$ ,  $M_{AA} = 0.91$ ,  $p = 0.000$ ), sadness ( $M_{BA} = 0.91$ ,  $M_{AA} = 1.23$ ,  $p = 0.000$ ), and fear ( $M_{BA} = 0.79$ ,  $M_{AA} = 1.37$ ,  $p = 0.000$ ) were stronger after the attack compared to before the attack. This was not the case for disgust, which showed to be the same before and after the attack ( $M_{BA} = 0.48$ ,  $M_{AA} = 0.49$ ,  $p = 0.423$ ). We also examined the difference of articulated sympathy in the posts' contents before and after the terrorist attack. For that, we developed a dictionary with 75 terms identifying

the expression of sympathetic concerns based on the first thread created in the Paris Forum after the attack (Paris Update). The analysis of all threads in the Paris Forum demonstrated an increase in sympathy after the terrorist attack ( $M_{BA} = 0.18$ ,  $M_{AA} = 0.75$ ,  $p = 0.000$ ). When conducting the analysis based only on the threads that had at least one sympathy word (sympathy > 0), this difference was also significant ( $M_{BA} = 1.95$ ,  $M_{AA} = 3.80$ ,  $p = 0.000$ ).

Three main categories emerged from the qualitative analysis. Firstly, individuals used this forum to exchange information about the attack, such as places affected and number of victims, and its possible impact on touristic products. Despite this informational content, the exchanges were permeated by a strong, predominantly negative emotional content. Secondly, individuals used the forum to share previous experiences in similar situations, such as other terrorist attacks, and to recount problematic moments during trips. The experiences narrated expressed positive emotions, such as love, or negative emotions, such as sadness and anger. In general, participants agreed that continuing a trip to Paris is a way to demonstrate courage and resistance against terrorism, and this message provided support and comfort for those who were anxious or hesitant about traveling. Thirdly, the forum was also a space where people shared their emotions about the attack, the victims, and the city. Our analysis also shows the important process of emotional sharing based on sympathetic feelings.

Our results demonstrate changes after a terrorist attack in the characteristics of posts, such as number of replies, time dynamics, and emotional content, and in posters' profiles in a virtual travel community. These results were triangulated with a qualitative analysis of the larger threads created after the attack, showing that these effects correspond to mechanisms of sharing information, experiences, opinions, and emotions elicited by the attack. In general, the exchanges seem to have a positive effect on participants: on one side, they gave them the opportunity to vent the negative emotions elicited by the attack; on the other side, they offered them a space where emotional support and sympathetic concerns could be shared. New studies must be conducted to analyze if the participation on virtual travel communities can minimize the negative impact of these events on individuals' perceptions of touristic products.

# Just Let the “New me” do it: How Anticipated Temporal Landmarks Cause Procrastination

Minjung Koo, Sungkyunkwan University, South Korea  
Ke Michael Mai, National University of Singapore, Singapore  
Hengchen Dai, University of California, Los Angeles, USA  
Camilla Eunyoung Song, University of Florida, USA

## EXTENDED ABSTRACT

Moments that elicit feelings of a “fresh start” have been shown to spur goal initiation. However, successful goal pursuit requires not only goal initiation but also persistent effort investment to an existing goal. While prior work has focused on the motivating effects of temporal landmarks as a type of fresh start on the initiation of a goal, the current research draws attention to a dark side of temporal landmarks by examining the effect of anticipated temporal landmarks on motivation to persist in an *ongoing* goal. We find that when an upcoming temporal landmark becomes salient, individuals perceive their current and future selves as two separate agents, delegate responsibility to their future self (i.e., “intrapersonal loafing”), and thus exert less effort to pursue their ongoing goals. For example, for people who have been pursuing a dieting goal, a focus on the upcoming New Year will ironically lead them to feel less motivated to continue on their diet, because they expect their new, future self can pick up the slack.

In Study 1, we tested our predictions using Google search field data (“Google Trends”). The frequency of searches for the term “calorie” was used as a proxy measure of motivation to pursue a diet goal ( $N = 4,565$ ). We compared the frequency of the search during the period right before temporal landmark (i.e., when a temporal landmark is more salient and thus more anticipated), to the average search volume. As predicted, the search volume for the term “calorie” was lower during the period right before the temporal landmarks, compared to the average search volume during other periods (all  $ps < .012$ ).

In Study 2, we tested our hypotheses in a more controlled setting, in which we manipulated the salience of a temporal landmark by framing one’s upcoming life event as a new beginning or not (Dai, Milkman and Riis 2015). Participants who had a current weight loss goal ( $N = 182$ ) read a scenario about an expected job position change in 3 days, which was framed either as a first-time event (anticipating-temporal-landmark condition) or as a regular and repetitive event (control condition). Participants indicated their motivation to pursue their weight-loss goal “today”. As predicted, participants in the anticipating-temporal-landmark condition were less motivated to pursue the goal “today” ( $M = 4.31, SD = 1.54$ ) than the control condition ( $M = 4.81, SD = 1.48; t(180) = -2.24, p = 0.03$ ).

In Study 3, we aimed to test the first logical step in our theorizing (i.e., perceiving the current and future selves as separated) by directly manipulating whether participants anticipated a distinct future self while working on a current goal and examining whether such an anticipation would impair their motivation. Participants ( $N = 62$ ) solved math problems in seven rounds that included the base line period (rounds 1-2), anticipation period (rounds 3-5), and the post period (rounds 6-7). All participants chose a character to represent themselves in the task, and completed the first two rounds (base line). Half of participants learned that they would work with a new character starting in the 6<sup>th</sup> round, and the other half did not receive this information. We analyzed participants’ effort investment (the number of solved problems per round) in the anticipation period. Regardless of the manipulation, participants solved more problems as they progressed, reflecting a learning effect. However, this increase was smaller when anticipating the identity change ( $M = 3.79, SD = 7.46$ )

than the control condition ( $M = 7.93, SD = 7.35; t(60) = -2.20, p = .032$ ), suggesting a lowered motivation for the task.

In Study 4, we aimed to test the other half of our theory by examining whether the demotivating effect is mediated by one’s responsibility shift to the future self. Participants ( $N = 320$ ) who had a work-out goal imagined that their birthday was coming in 3 days. We framed this birthday as a birthday that coincided with the beginning of a cycle or as one of many regular birthdays (Dai et al. 2015). Participants reported their motivation to work out “today” and responded to two goal-responsibility shift questions (e.g., “I felt that I can easily make up for the skip later”). As predicted, those in the anticipating-temporal-landmark condition reported lower motivation ( $M = 3.48, SD = 1.84$ ) than those in the control condition ( $M = 4.16, SD = 1.97; t(318) = -3.15, p = .002$ ). This effect was mediated by increased tendency to shift the responsibility to the future self ( $a \times b = -.25, 95\% CI = -.50, -.04$ ).

In Study 5, we explored whether the effect of anticipated temporal landmarks can be mitigated if participants are reminded of the contributions they have been making to the goal. The procedure was similar to Study 4, except for the addition of the reminder manipulation. Participants wrote down specific activities that they had done for the work-out goal either at the beginning of the study (reminder condition) or at the end of the study (no reminder condition). Two-way ANOVA yielded a predicted significant interaction ( $F(1, 430) = 4.05, p = .045$ ). No reminder conditions replicated the previous findings ( $M_{anticipating-temporal-landmark} = 6.68, SD = 2.06$  vs.  $M_{control} = 5.88, SD = 2.38; F(1, 430) = 6.47, p = .01$ ). However, when there was a reminder, motivation did not differ between the two conditions ( $M_{anticipating-temporal-landmark} = 5.91, SD = 2.46$  vs.  $M_{control} = 6.01, SD = 2.37, p = .77$ ).

In sum, the current research documents a detrimental effect of anticipating temporal landmarks on one’s motivation to pursue an ongoing goal. Given that previous research has focused on positive effects of temporal landmarks on motivation (Dai, Milkman and Riis 2014; Peetz and Wilson 2013), we advance the field’s understanding of how motivation dynamically changes before or after temporal landmarks. In addition, we identify a novel mechanism of intrapersonal loafing such that loafing occurs not only with other individuals, but also with other temporal selves within an individual.

# Can't Take the Heat? Randomized Field Experiments in Household Electricity Consumption

Jesse Burkhardt, Colorado State University, USA

Praveen K. Kopalle, Dartmouth College, USA

Kenneth Gillingham, Yale University, USA

## EXTENDED ABSTRACT

In residential electricity consumption, informational interventions such as in-home displays and social-comparisons have been shown to increase the salience of price changes (Jessoe, 2014 #3) (Jessoe and Rapson 2014) and impact an electricity system: the times when demand is at its highest and conservation is needed most (Joskow and Wolfram 2012).

This paper examines the relative effectiveness of passive and active information interventions on appliance-level, household electricity consumption in two randomized field experiments over a two year period (2013-14). The first field experiment focuses on critical peak pricing (CPP) on summer days during peak evening hours where the price is higher and the second on off-peak, lower price nights. The contribution of our research is three fold. First, we examine the long-term effectiveness of passive and active information interventions on household energy consumption during critical peak pricing days. The passive informational interventions include (i) providing access to an online personal account to track electricity consumption in real time or (ii) sending a simple text message stating "A Pecan Street Project critical peak pricing event is taking place tomorrow 4PM to 7PM". The active interventions include sending the passive text message plus (iii) an action such as "pre-cool your home" or "reduce your air conditioning usage" or "do not use your clothes dryer", or (iv) "Your experimental electric rate will be \$0.64 per kilowatt hour from 4 p.m. - 7 p.m."

Second, studying the differential impact of price increase during peak demand versus price decrease during off-peak demand on consumer price elasticity for electricity consumption. Finally, identifying the breakdown of consumers' price elasticity at the appliance level.

Three hundred households from a neighborhood in Austin, Texas were recruited to participate in the field experiment. All participants in the four treatment groups were told that during the months of June through October, there would be critical peak load pricing on certain days from 4PM to 7 PM. All participants continued to receive and pay their Austin Energy electric bills, which reflected the normal Austin Energy electric rates (\$0.4654/kWh). To provide a monetary incentive for customers to participate in the four treatments, Pecan Street, an organization focused on advancing research and innovation in energy conservation, established a credit account for each participant that reflected a participant's response in terms of energy saving. The amount of credit in participants' accounts was adjusted every month at the time they received their electric bill. The adjustment reflected the difference between what participants actually paid Austin Energy and what they would have paid if the experimental rates were in effect. If the bill using the experimental rate was lower (higher) than participants' Austin Energy bill, the difference was deposited (deducted) in their credit account. At the end of the experiment, payments were issued to participants equal to the amount of the final credit in their account. If there was a negative credit in a participant's account, the participant paid nothing. The control group was not told about critical peak load pricing nor charged a higher electric rate during critical peak load periods or received any text messages.

A peak load price is a feature which applies only during certain designated days of the summer months (June, July, August, and Sep-

tember). That is, a summer peak price of \$0.64 per kWh was applied to participants' energy consumption during the weekday afternoon hours of 4-7 P.M., but only on days designated as "Critical Peak" days.

A total of 24 treatment days were conducted during the months of June through October in 2013 and 2014. The minute and appliance level (bedroom, air conditioner etc.) electricity consumption from each of the 300 households provided us with 360 million observations, including the pre-treatment period, i.e., March-June 2013.

The economics of information (Stigler 1961) would suggest that theoretically, all four treatment conditions may be effective in reducing energy consumption relative to the control. Interestingly, we find that only the pricing treatment had a significant impact on reducing electricity consumption. Accordingly, we estimate a price elasticity of residential energy consumption of -0.17 during critical peak pricing and that turning down air conditioning comprises the bulk of the response (63%), followed by living room activities (10%).

In a second field experiment, we test whether the critical peak pricing effect is symmetric, i.e., whether households increase their consumption of electricity by the same amount if the price is lowered during off-peak periods. West Texas has a lot of wind power and low wholesale prices on off-peak nights. We conducted an additional treatment for the 62 households in the pricing trial during the five windiest months: March, April, May, November, and December. The treatment occurred during 10PM to 6AM in 2013 and 2014. The treatment rate was 2.65 cents/kWh. The households received text messages 24 hours before the first day of the month.

Upon controlling for all other factors, the triple diff-in-diff results suggest that the impact of a price decrease during off-peak has statistically significantly increased the electricity consumption ( $b=.004$  (clustered s.e.=.0008),  $p < .01$ ,  $R^2=.19$ ,  $n=90,000,000$ ) during the off-peak periods, implying an elasticity of -0.43, more elastic than that during critical peak pricing.

Our results have important welfare and policy implications. The consumer welfare gain from reduced critical peak consumption over 27 critical peak days applied to the Energy Reliability Council of Texas (ERCOT) region is about \$39.1 million. Similarly, reducing price during off-peak periods increases consumer welfare by about \$100 million due to load shifting. Further, our results point to the appliance usage most amenable to energy conservation during critical peak time. In contrast to previous results from crisis periods, such as the California electricity crisis (Reiss and White 2005) and the time shortly after the Fukushima disaster, there is little evidence in our study of a consumer response to pure informational appeals (Ito, Ida, and Tanaka 2018).

# Why is 1 out of 20 Riskier than 5%? Effect of Representing Unlikely Events as Frequency versus Percentage on Risk Perceptions

Nevena T. Koukova, Lehigh University, USA

Joydeep Srivastava, Temple University, USA

## EXTENDED ABSTRACT

Consider two individuals contemplating the purchase of a new laptop computer. Both are interested in the same specific brand and model. While one individual comes across a product review stating that 5% of the brand's laptops are expected to require repairs, the other individual reads a review reporting that 1 out of 20 of the brand's laptops is expected to require repairs. Although the likelihood of failure is relatively low and objectively equivalent, the numeric representation of the probability information in the two reviews differs such that the expected performance information is provided in terms of percentage (5%) and frequency (1 out of 20) formats, respectively. Will the perceived risk associated with purchasing the laptop differ across the two individuals? Will one of them be more likely to buy the laptop? If so, which of the two individuals, and why? What if the performance information is described positively such as functioning satisfactorily rather than negatively such as requiring repairs? Surprisingly, despite the relatively large literature examining the influence of probability format (e.g., Kirkpatrick and Epstein 1992; Slovic, Monahan and MacGregor 2000), as well as the framing of attributes and outcomes (Tversky and Kahneman 1981; Levin, Schneider and Gaeth 1998), the answers to these questions are not clear. Further, since different theoretical perspectives lead to competing predictions, the current research seeks to examine how the numeric representation of a relatively low probability in terms of a frequency versus percentage affects risk perceptions, and provide insights into the underlying reasons for the effects.

Our results suggest that risk perceptions are higher and purchase intentions are lower when a probability in the negative frame is represented as a frequency (1 out of 20) than as an equivalent percentage (5%; study 1). Moreover, a consistent finding in the context of relatively low probabilities (studies 2a and 2b) is that probability frame moderates the effects of probability format on risk perceptions such that while risk perceptions are higher in the frequency (vs. percentage) format in the negative frame (1 out of 20 vs. 5%), there is no difference in the positive frame (19 out of 20 vs. 95%). Study 3a attests to the robustness and generalizability of the findings by showing a similar pattern for a less extreme probability level (2 out of 20 vs. 10% and 18 out of 20 vs. 90%) and to a frequency that is not represented as "1 out of" some number. Further, although probability frame does not affect risk perceptions in the percentage format when the probability is extreme (5% is not different than 95%), the effect of frame emerges when the probability is not as extreme (10% > 90% as well as 20% > 80%). Thus, framing does not affect evaluations when the probability level represented as a percentage is at the extreme but has an effect at less extreme levels. In contrast, frame affects risk perceptions when the relatively extreme probability is represented as a frequency (1 out of 20 > 19 out of 20).

We also identify a boundary condition such that at a moderate probability level, risk perceptions do not vary across the frequency and percentage formats even in the negative frame (4 out of 20 vs. 20%). Further, probability frame has a similar effect wherein risk perceptions are higher in the negative (vs. positive) frame for both frequency and percentage formats. Taken together, the pattern of findings across the studies suggest that the effects of probability format on risk perceptions are likely to manifest when the numerators

are relatively small, thus facilitating individuals to imagine or identify themselves with the situation.

We further provide insights into the underlying mechanism. Our finding that risk perceptions are higher when a probability in the negative frame is represented as a frequency (1 out of 20) than a percentage (5%) is in contrast with the idea that a specific probability of occurrence will be perceived as less likely and thus less risky when it is denoted by a ratio of 1 out of some number (Denes-Raj and Epstein 1994). Importantly, we generalize the finding to a frequency that is not represented as "1 out of" some large number (i.e., 2 out of 20 vs. 10%).

Instead, we find that probability information described as a frequency evokes greater negative affect than an equivalent percentage. Based on the premise that a probability described as a frequency is more concrete than an equivalent percentage because it is easier to process, understand, and is more aligned to how statistical information is experienced (Denes-Raj and Epstein 1994; Gigerenzer and Hoffrage 1995), we argue that the extent to which individuals can imagine themselves or identify with the situation is likely to be higher with frequency than percentage format. A frequency format is thus likely to evoke greater negative affect thereby increasing risk perceptions relative to an equivalent percentage, particularly when the probability is framed negatively. Study 3a specifically shows that a frequency (vs. percentage) format facilitates the extent to which individuals imagine themselves in the situation when the probability is in the negative frame. We highlight the underlying process by demonstrating that the extent to which individuals can imagine (or identify) themselves in the situation mediates the effect of probability format and frame on risk perceptions.

Finally, study 4 explicitly tests the extent to which individuals' construal level in terms of high-level, abstract and low-level, concrete processing moderates the effects of probability format. Matching the probability format with construal level (i.e., pairing frequency with low-level construal and percentage with high-level construal) has a significant effect on extent of imagining, negative affect, and risk perceptions, but these effects attenuate when there is a mismatch (i.e., pairing frequency with high-level construal and percentage with low-level construal). Thus, it provides compelling evidence for the underlying reasoning for our findings.

In sum, this research addresses the questions raised in the introductory illustration and contributes to the literatures on probability judgments, affective decision making, and risk perceptions. We propose a conceptual framework that explains the differential effects of probability format, based on how format information is processed, and suggest moderators for the effects.

# Narrative Transportation and Cognitive Responses: The Other Side of the Story

Rebecca J. Krause, Northwestern University, USA

Derek D. Rucker, Northwestern University, USA

## EXTENDED ABSTRACT

Narrative transportation is the sensation of being physically relocated (“transported”) into a story (Green and Brock 2000). Narrative transportation is posited to robustly and positively affect persuasion (Escalas, Moore, and Britton 2004; Hamby, Brinberg, and Daniloski 2017; Moyer-Gusé 2008). A key explanation for the effectiveness of narrative persuasion is that narrative transportation reduces counterarguing (Escalas 2007; Green and Brock 2000; van Laer et al. 2014) where people become absorbed in a story (Green and Brock 2000). Because narratives engross the consumer in the story, the transported consumer engages in less counterarguing of the advertised product, which increases persuasion. The implication for marketers is clear: “stories are orders of magnitude more powerful than sets of facts, no matter how those facts are packaged,” (Aaker 2018, 6).

The current work explores two critical questions on this topic. First, do stories always beat facts? Second, can story-based advertisements be improved by incorporating compelling facts, or will facts detract from story enjoyment?

On the first question, although we accept that narrative transportation can reduce counterarguing, we suggest this is an incomplete story of how narrative transportation operates. Specifically, cognitive-response models suggest that greater attention to messages need not inherently produce greater counterarguing. Rather, when message arguments are strong, greater attention to message content can cause bolstering, or the generation of positive message-related thoughts (Greenwald 1968; Petty and Cacioppo 1986). If narrative transportation disrupts cognitive processing, it should be capable of either aiding or inhibiting persuasion. Specifically, narrative transportation should hinder persuasion when it disrupts consumers’ ability to bolster strong message arguments.

On the second question, this paper explores how to best blend facts with narratives. Prior narrative research suggests that one should hide message arguments within narratives to maximize persuasion because it is believed that arguments fundamentally disrupt transportation (Slater and Rouner 2002; Wang and Calder 2006, 2009). In contrast, we suggest that facts relevant to the story’s plot do not necessarily represent an interruption. A narrative’s persuasive power comes from its ability to selectively direct attention (Green and Brock 2000). We suggest that marketers might use this power to draw attention towards message arguments, rather than away from them. Thus, rather than hiding message arguments throughout a narrative, marketers may produce greater persuasion by emphasizing arguments. One way to do this is to consolidate arguments, or group arguments in the story in a bullet-pointed list or other prominent manner such that they are noticeable, rather than disbursing arguments, or hiding them throughout the story (Reynolds 1992; Almer, Hopper, and Kaplan 2003) researchers must ensure sufficient attention to experimental materials to provide usable data. The current study suggests an experimental design feature to encourage participants to thoroughly process information contained in experimental materials. Based on Reynolds’ (1992). If stories can draw attention toward arguments and still remain transporting, consolidating (strong) arguments will lead to greater persuasion than disbursing them.

*Experiment 1.* The study design was 2 (narrative vs. facts alone) x 2 (strong vs. weak arguments), between subjects. Participants (N = 397) read either a list of facts about a fictitious cell phone, or those

same facts embedded within a narrative about mountain climbers. The cell phone facts presented were pretested to be weak or strong. Participants indicated their attitude toward the cell phone on a 9-point semantic differential scale. When arguments were weak, narratives led to greater persuasion than facts alone ( $M_{\text{narrative}} = 6.83$ ,  $M_{\text{facts-only}} = 4.04$ ,  $p < .001$ ), but when arguments were strong, narratives led to less persuasion than facts alone ( $M_{\text{narrative}} = 6.82$ ,  $M_{\text{facts-only}} = 7.53$ ,  $p = .0093$ ). Put differently, strong facts presented by themselves were more persuasive than narratives with the same facts. This represents a rare reversal of the positive relationship between transportation and persuasion.

*Experiment 2.* We sought evidence for cognitive elaboration as a mediating process via measurement of participants’ message-relevant thoughts. The design was the same as Experiment 1. Participants (N = 389) saw the same cell phone facts and/or story as used in Experiment 1. Then, participants indicated on a two item scale their use intent for the fictitious cell phone. They also listed the thoughts they experienced while reading the advertisement. The use intent results mirrored Experiment 1’s attitude results for both weak arguments ( $M_{\text{narrative}} = 5.75$ ,  $M_{\text{facts-only}} = 3.04$ ,  $p < .001$ ), and strong arguments ( $M_{\text{narrative}} = 6.62$ ,  $M_{\text{facts-only}} = 7.32$ ,  $p = .020$ ). A moderated mediation analysis (Preacher, Rucker, and Hayes 2007; Hayes 2013) with narrative condition as the independent variable, argument quality as the moderating variable, use intent as the dependent variable, and an index of message-related thought favorability (Wegener, Petty, and Smith 1995) as the mediating variable was significant: the 95% bias corrected confidence interval (CI) did not contain 0 (index = -0.46, SE = 0.08; 95% CI [-0.65, -0.32]).

*Experiment 3.* Experiment 3 had a 3 (Narrative-Disbursed, Narrative-Consolidated, Facts only) x 2 (Strong vs. Weak arguments), between subject design. Participants (N = 600) saw a list of facts about a fictitious medication, a story with those same facts disbursed throughout, or a story with those same facts consolidated in one attention-grabbing location. For strong arguments (when consumers were likely to bolster), the story with consolidated arguments was more persuasive than the story with disbursed arguments ( $M_{\text{consolidated\_strong}} = 7.60$ ,  $M_{\text{disbursed\_strong}} = 6.79$ ,  $p = .005$ ). For weak arguments (when consumers were likely to counterargue), the story with disbursed arguments was more persuasive than the story with consolidated arguments ( $M_{\text{consolidated\_weak}} = 5.38$ ,  $M_{\text{disbursed\_weak}} = 6.07$ ,  $p = .015$ ).

Narrative transportation is an important means of persuasion. However, extant literature contains little theory regarding when transportation’s effect on persuasion can backfire, which suggests stories always trump facts. Across three experiments we demonstrate that though narratives increase persuasion when arguments are weak, when arguments are strong narratives decrease persuasion compared to facts (experiments 1 and 2) due to the disruption of bolstering (experiment 2). This implies, and we demonstrate, that when strong arguments are present, facts should be consolidated within stories (experiment 3). This work may also offer insights for marketing practitioners. Our findings suggest marketers may need to be more strategic about the use of stories in advertising than prior research suggests. We provide guidance on when narratives may actually be ineffectual in advertising, and also provide new insight on the best ways to incorporate facts into advertising narratives.

# Cueing Backwards: Attention Processes In Multi-Attribute Choices

Antonia Krefeld-Schwalb, University of Geneva, Switzerland

Agnes Scholz, University of Zurich, Switzerland

Ursa Bernadic, University of Geneva, Switzerland

Benjamin Scheibehenne, University of Geneva, Switzerland

## EXTENDED ABSTRACT

Marketeers are naturally interested in biasing purchase decision in their favor. This can either be achieved bottom-up, biasing the choice between different alternatives, or top-down, influencing the decision-making process, e.g. which decision strategy is applied. The following series of experiments explores one backward cueing method that aims at directing attention to memorized information to influence the choice and the decision strategy applied.

Decision making in multi-attribute choices is flexible, adaptive and varies between individuals. For example, one key feature that allows to discriminate between different decision-making processes is whether compensatory or non-compensatory strategies are applied (Gigerenzer & Todd, 1999). Compensatory means that less valid cues can overwrite cues of higher validity, contrarily non-compensatory means that more valid cues cannot be overwritten by less valid cues. Several factors in the environment have been proposed to influence the decision making process (Bröder & Schiffer, 2003; Rieskamp & Otto, 2011) namely Structural Modeling (SM. Even without feedback and training, the environment, such as the distribution of the validity of the information influences which strategy is applied (Krefeld-Schwalb, Donkin, Newell, & Scheibehenne, 2018; Mata, Schooler, & Rieskamp, 2011) ISBN : "9780199894727", ISSN : "0882-7974", PMID : "18179298", abstract : "Are older adults' decision abilities fundamentally compromised by age-related cognitive decline? Or can they adaptively select decision strategies? One study (N = 163. Recently it was suggested that one of the driving forces behind the adaptation of decision making are attentional processes. Spatial cueing single attributes in a multi-attribute choice task, increased the influence of these attributes on the choice (Platzer, Bröder, & Heck, 2014). Cueing spatial locations of a previously presented information increases visual attention to this position and the likelihood that this information is retrieved from memory (Souza & Oberauer, 2016), even for verbal material (Krefeld-Schwalb, 2018) and if the cue does not contain retrieval-relevant information (Scholz, Klichowicz, & Krems, 2018). But not only memory retrieval may be biased toward cued options, but also choices and the applied decision-strategies are influenced by the cued information (Platzer et al., 2014; Renkewitz & Jahn, 2012). Beyond influencing the weight of single attributes, Platzer and colleagues (2014) suggested that cueing influences directly the decision strategy applied. Their results show that cueing valid information supports the use of non-compensatory strategies, whilst cueing less valid information increases the motivation to search for more information in memory, and thus the use of compensatory decision strategies.

We will report three experimental studies investigating the mechanisms underlying the influence of the cueing effect. In the first experiment we investigated the size of the cueing effect. In the second experiment we analysed the interaction of the cueing effect with different decision-making environments, defined by the distribution of the cue validities. Finally, experiment 3 was further designed to exclude alternative explanations of the cueing effect.

In the first experiment participants had to choose one out of two movies (alternatives) they think would be more successful at the box offices based on the recommendations (cue values) of 6 movie critics (cues). Those critics had varying probability of having recommended

the more successful movie in the past (validities). This information was presented in an information board, with columns representing the two movies and the rows representing the cues. Asterisks illustrated recommendations, and hyphens illustrated no recommendations of the movies. One critic could recommend both, one, or none of the movies. The critics' probabilities to predict the more successful movie, thus the cue validities were depicted in percentages on the left side of the respective row [65%,63%,63%,62%,60%,58%]. In cued trials, after the complete information had disappeared, the frame of one of the rows was emphasized. Consequently, participants were asked to make their choice in the following choice task, on the memorized information.

We replicated the cueing effect on the choice, and on the decision strategies applied in this experiment. Controlling for the correspondence of the cue and the strategies we showed that cueing increased the use of compensatory decision strategies. In experiment 2 we investigated the cueing effect in a slightly adapted preferential choice task and whether it interacts with the decision environment, defined by the distribution of the cue validities (Krefeld-Schwalb et al., in press; Mata, Schooler, & Rieskamp, 2011) ISBN : "9780199894727", ISSN : "0882-7974", PMID : "18179298", abstract : "Are older adults' decision abilities fundamentally compromised by age-related cognitive decline? Or can they adaptively select decision strategies? One study (N = 163. The distributions were either uniform [65%,63%,63%,62%,60%,58%], j-shaped [90%,69%,68%,66%,63%,60%] or linear [90%,83%,76%,69%,62%,55%], manipulated block wise within subjects. Although, decision making differed between the environments in experiment 2, with increased use of non-compensatory decision strategies in the j-shaped conditions, the cueing effect was replicated in all conditions and did not differ between them. Finally, a third experiment was designed to exclude alternative explanations of the cueing effect. In particular we ascertained that the participants were aware that the cue does not provide any additional information on the choice. In two of three conditions, manipulated within subjects, participants were either instructed that the cue might help them to memorize the previously presented information (condition 1) or distract them from this information (condition 2), while condition 3 was conducted without cueing.

The cueing effect on the choice was replicated again, but only in condition 1 ("memory" instructions). Beyond that decision making was influenced as in the previous experiments in both cueing conditions.

To conclude, our series of experiments provides strong support for the effectiveness of cueing in multi-attribute choices. In particular, drawing attention to the spatial position of an attribute after its presentation in a multi-attribute choice task led to an increased influence of this attribute on the choice. Furthermore, cueing increased the probability that individuals applied a compensatory decision strategy. Particularly, cueing increased the probability that all previously presented information was recalled and integrated in the choice, whilst the cued information still received a higher weight on the choice.

Thus, we suggest that backward cueing is an effective means to influence decision making in the consumer context and beyond.

# Taking a Leaf out of my Review: The Asymmetrical Link between Linguistic Similarity and Attitude Certainty for Writers and Readers of Product Reviews

Ann Kronrod, University of Massachusetts Lowell, USA

Yakov Bart, Northeastern University, USA

## EXTENDED ABSTRACT

Firms and research have recognized the importance of investigating what makes WOM persuasive (e.g., Homburg, Ehm, and Artz 2015; Rosario et al. 2016). In particular, several studies have suggested that people who express certainty in their opinions are more persuasive (Karmarkar and Tormala 2010; Petty, Briñol and Tormala 2002; Tormala 2016). A common interpretation of these findings is that firms would benefit from reviews by consumers who are certain in their opinions. However, we question this intuition through identifying novel links between attitude certainty and linguistic components of reviews – specifically, linguistic similarity of product reviews to each other.

Literature on the links between repetition, similarity, validation and certainty suggests that information repetition and consistency makes people more certain about it (e.g. Dechêne, et al. 2010; Kendal, Giraldeau, and Laland 2009; Koriat 2011, 2012; Skurnik et al. 2005), and that opinions that are held by more people are perceived as more valid (e.g. Cialdini 2009; Nakahashi, Wakano, and Henrich 2012; Petrocelli et al. 2007; Zou et al. 2009).

Research on linguistic similarity shows that mimicking the other parties' language or adjusting one's linguistic style to another person's increases liking and trust (Moore and McFerran 2017) and the likelihood to reach an agreement (Huffaker, Swaab, and Diermeier 2011; Ludwig et al. 2013; Su, Mariadoss and Reynolds 2015; Sagi and Diermeier 2017; Swaab, Maddux, and Sinaceur 2011)..

Building on these literatures we suggest that:

*Hypothesis 1* when consumers read product reviews that are linguistically similar to each other, their attitudes about the product become more certain. This increase in attitude certainty is mediated by an enhanced perception of validity.

Further, as uncertainty increases the need for validation (e.g. Tormala and Rucker 2007):

*Hypothesis 2* we expect similar reviews to influence uncertain consumers more than certain ones.

But does attitude certainty have a positive effect on review writers' linguistic similarity as well? Following the same logic of connecting need for validation, attitude certainty and linguistic similarity, we arrive to an insight that stands in contrast with our prediction in H1 and H2: writers of product reviews who are certain in their attitudes, experience lower need for validation and therefore *do not* write reviews that are similar to other reviews. Uncertain review writers, however, have higher need for validation and therefore they are more likely to consult with other reviews when writing their own. Consequently we predict that:

*Hypothesis 3* reviews of uncertain writers would be more linguistically similar to other reviews, whereas reviews of certain authors would be less similar to other reviews.

## Method

We investigate the link between certainty and linguistic similarity in reviews in six studies. Study 1 tests the link for readers (H1) and study 2 does so for writers (H3). In **Study 1** participants read five hotel reviews that were similar or different from each other and expressed their attitude certainty about the hotel. We found that, supporting our prediction, product attitudes were more positive and attitude certainty was higher after reading similar reviews than different ones. Mediation analysis suggested that attitude certainty mediated the effect of review similarity on product attitudes. In **Study 2** we manipulated participant's attitude certainty about a short video that they watched, then showed all participants a "previously written review" of the video, and then they wrote a review of their own. Using automatic text analysis we found significantly higher linguistic similarity of the reviews to the example review in the uncertain condition. **Study 3** tests H2 by manipulating readers' certainty about a camera before reading a set of similar/different reviews. We find that for uncertain readers similar reviews increase attitude certainty, but for certain readers the effect of linguistic similarity on attitude certainty is attenuated. **Study 4** replicates our Study 2 results for writers, and rules out an alternative explanation that uncertain consumers write reviews that are similar to other reviews because they seek validation of their opinion and not because they are unsure as to what to write. In **Study 5**, we replicate Study 1 with a set of negative hotel reviews, in order to eliminate an alternative explanation that similarity simply elevates positive attitudes (the similarity effect). Finally, **Study 6** manipulates need for validation and shows that it mediates the effect of language similarity on certainty in readers. We found that for people with low need for validation similar reviews did not have a significantly different effect on attitudes than different reviews. However, when participants felt high need for validation, reading similar reviews had significantly higher effect on attitudes, compared with reading different reviews.

## Discussion

We identify an ironically asymmetrical link between attitude certainty and linguistic similarity: while linguistic similarity in product reviews increases attitude certainty of readers of the reviews, those similar reviews are more likely to have been the output of uncertain review writers. This work informs literature on attitude certainty offering linguistic similarity as a source of validation. Importantly, we simultaneously investigate readers and writers of reviews.

From a managerial perspective, our findings reveal novel insights related to how managers may alter their approach to collecting user-generated content (from writers) to achieve optimal impact on consumers of that content (readers), given these uncovered opposite connections between attitudinal certainty and linguistic similarity for writers and readers. Further, the current work examines similarity of consumer-generated information about products. But what if *any* similarity of *any* text from *any* source has a analogous effect, simply as a consequence of repetition of information? If so, then similarity of marketer-originated texts, such as advertising, should have a similar impact on attitude certainty.

Finally, as linguistic similarity has been introduced in literature as an implicit measure of trust (e.g. Mohammadhassanzadeh and Shahriari 2013; Moore and McFerran 2017; Scissors et al. 2010), the

current work is closely related to the ACR 2018 conference theme, as it belongs to the general investigation of the link between language and trust.

Although it is our faith that this paper is not similar to other papers, we hope that nevertheless, our readers will be certain in their positive attitudes about it!

# How Mortality Salience Shapes Consumers' Responses to Brands

Polina Landgraf, IE Business School, Spain

Antonios Stamatogiannakis, IE Business School, Spain

Haiyang Yang, Johns Hopkins Carey Business School, USA

## EXTENDED ABSTRACT

Consumers are frequently exposed to death-related information (e.g., news about terrorist attacks, natural disasters), which may make their mortality salient (MS; Greenberg et al. 1990). Yet, the understanding of how MS influences everyday consumption is still limited (Huang et al. 2018). Adding to this literature, we propose that MS can systematically impact consumers' brand preference. Specifically, we argue that (a) MS sensitizes consumers to the perceived perpetuity of brands, and (b) exciting (vs. other) brands tend to be perceived as less perpetual. As a result, MS dampens consumers' preference for brands with an exciting but not with other personalities.

Consumers can "manage" their fear of death by symbolically achieving perpetual existence (Lifton 1973). The onset of MS thus can drive consumers to focus on the means to attain perpetuity (Mikulincer and Florian 2000). Building on this, we propose that MS can increase the weight of perpetuity-related aspects in consumer preference.

We study this proposition in the context of branding. Brands may possess different personalities (Aaker 1997). We argue that different personalities are associated with the notion of perpetuity to varying degrees. Specifically, many of the traits comprising an exciting brand personality (e.g., young, contemporary) are fleeting in nature. Exciting states also tend to be short-lasting (Eysenck 2016). Thus, brands with an exciting (vs. other) personality tend to be perceived as having relatively lower levels of perpetuity. Because MS makes consumers become more sensitive to perceived perpetuity, we propose that exciting (vs. other) brands tend to be preferred less under MS.

Six studies provide support for our propositions. A pilot study showed that exciting (vs. other) brands are perceived as relatively less perpetual. Specifically, participants evaluated the perpetuity of the 42 brand traits comprising the five brand personalities (Aaker 1997). Supporting our proposition, traits associated with an exciting personality were rated as significantly less perpetual than those associated with sincere, competent, sophisticated, and rugged personalities.

Study 1 demonstrated the effect of MS on brand preference. Participants were randomly assigned to a 2 (MS vs. control)  $\times$  2 (exciting vs. control brand) between-participants experiment. Participants were first primed with MS (vs. not) using an established procedure (Ferraro et al. 2005). They then evaluated an exciting (vs. control - sincere) brand (Aaker 1997). A significant two-way interaction supported our predictions. In the MS, compared to the control condition, the exciting brand had significantly lower evaluations; the control brand had equal evaluations across both MS and control conditions.

Study 2 tested the mediating role of perceived perpetuity. Participants were randomly assigned to a 2 (MS vs. control)  $\times$  2 (exciting vs. control brand) between-participants experiment. The MS manipulation was identical to that in Study 1. We used a different brand and dependent variable (purchase intention), and measured brand's perceived perpetuity. We found a significant two-way interaction on purchase intention. In the MS, compared to the control condition, the exciting brand elicited significantly lower purchase intention; the opposite was true for the control brand.

A moderated mediation analysis showed that, as predicted, the MS  $\times$  brand personality interaction on perceived perpetuity was

significant. The perceived perpetuity had a significant effect on purchase intention. The moderated mediation index excluded zero. The indirect effect of MS on purchase intention through perceived perpetuity was significant for the exciting, but not for the control brand.

Study 3 directly manipulated the perceived perpetuity of exciting brands. Participants were assigned to a 2 (MS vs. control)  $\times$  2 (perpetual exciting vs. non-perpetual exciting brand) between-participants experiment. The MS manipulation was identical to that in Study 1. Participants evaluated pretested descriptions of a perpetual vs. non-perpetual exciting brand. We found a significant two-way interaction on brand evaluation. Supporting our propositions, the non-perpetual exciting brand was evaluated significantly lower in the MS compared to the control condition, while evaluations of the perpetual exciting brand did not differ significantly.

A moderated mediation analysis revealed that, as expected, the MS  $\times$  brand's perpetuity interaction on perceived perpetuity was significant. The perceived perpetuity had a significant effect on brand evaluation. The moderated mediation index excluded zero. In line with predictions, the indirect effect of MS on brand evaluation through perceived perpetuity was significant for the non-perpetual exciting, but not for the perpetual exciting brand.

Studies 4a-4b explored the real-life implications of MS on the brand equity of hundreds of brands following two death-reminding tragedies: 9/11 and Hurricane Katrina. We used a large-scale longitudinal dataset collected quarterly by a leading consulting firm (Mizik and Jacobson 2008) to conduct an analysis within a difference-in-differences framework. Brand equity was the dependent variable, and ratings for exciting brand personality and a dummy variable for MS (0 = Quarters before, and 1 = Quarters after 9/11 and Hurricane Katrina, respectively for each study) was the independent variable.

Study 4a showed a significant exciting personality  $\times$  MS interaction on brand equity. The positive impact of exciting personality on brand equity significantly decreased after 9/11. A spotlight analysis showed that equity of very exciting brands significantly decreased following 9/11, while brands low in excitement were not significantly affected. Study 4b revealed a similar significant exciting personality  $\times$  MS interaction. Again, the positive effect of exciting personality on brand equity significantly decreased after Hurricane Katrina. A spotlight analysis showed that equity of very exciting brands significantly decreased after Hurricane Katrina, while brands which were low in excitement were not significantly affected. Similar decreases were not observed for any other brand personality in neither of the Studies 4a-4b.

In summary, four experiments and two field-based investigations offered converging support that MS can dampen consumers' preference for exciting brands because they are perceived to be less perpetual. This effect does not manifest with other brand personalities. This research adds to literature on MS by showing that MS sensitizes people to brand aspects related to perpetuity, which in turn influences consumers' preference. We also contribute to the branding literature by demonstrating that MS can systematically influence consumers' preference for brands with different personalities.

# Two-by-Two: Categorical Thinking About Continuous Bivariate Data

Bart de Langhe, ESADE, Spain

Philip M. Fernbach, University of Colorado at Boulder, USA

Julie Schiro, University College Dublin, Ireland

## EXTENDED ABSTRACT

Most variables that companies care about are continuous in nature, but they are often analyzed categorically. For instance, consider Rogers' (1962) innovation adoption curve, one of the most celebrated ideas in marketing. Though there are no natural boundaries on the continuum of innovativeness, customers are classified into five categories (innovators, early adopters, early majority, late majority, and laggards) based on arbitrary cutoffs, in this case defined by the mean and standard deviation (e.g., the cutoff for innovators is two standard deviations above the mean). Similarly, many companies ask customers to indicate their recommendation likelihood on a 0-10 scale, where 0 means "not at all likely" and 10 means "extremely likely." Instead of analyzing the data continuously, customers are grouped into three categories—detractors (scoring between 0 and 6), passives (scoring 7 or 8), and promoters (scoring 9 or 10). The percentage of detractors is then subtracted from the percentage of promoters to compute a Net Promoter Score.

We propose that the ubiquity of such analyses is not just statistical convention, but rather reflects a natural tendency of the mind. Just like our perceptual system automatically divides the continuous spectrum of wavelengths into distinct colors, or separates continuous differences in voice onset time into discrete phonemes, decision-makers tend to simplify and structure continuous data by discretizing it, a strategy we call "categorical thinking." Categorical thinking can be advantageous in that it facilitates communication. But categorical thinking can also harm judgment quality. One downside has been well-noted: Categorical treatment of continuous variables ignores meaningful variation, leading to flawed inferences.

This paper highlights an additional problem with categorical thinking. When people think about data categorically, they do not weigh all observations equally, which is a prerequisite for interpreting the data correctly. They focus disproportionately on observations where both X and Y are high, akin to what happens when people interpret the relationship between dichotomous variables. When people evaluate dichotomous variables, a highly robust finding is that people's judgments demonstrate "cell weight inequality": some observations have more influence on judgments of contingency than others. Specifically, the joint presence of variables (i.e., the A-cell) has the largest impact and the joint absence of variables (i.e., the D-cell) has the smallest impact.

Dichotomous data is different from continuous data, which may invite very different cognitive processes, and researchers have explicitly cautioned against extrapolating from one literature to the other (Broniarczyk and Alba 1994). Nevertheless, given people's penchant for categorical thinking, we hypothesize that it is common for decision-makers to intuitively analyze continuous bivariate data by treating it more like a contingency table, where they first group observations into categories, and then compare frequencies. Thus, we predict an analogue of A-cell bias for continuous data.

We show that categorical thinking occurs naturally, though it can be amplified or attenuated depending on how the data are pre-

sented. Categorical thinking leads to an overweighting of observations where both variables are high (i.e., the A-cell). We also demonstrate several ways in which categorical thinking makes people susceptible to misinterpreting the data. For instance, data transformations that do not change the correlation, but do change frequencies in different cells, can dramatically alter perceptions of relationship strength. Reverse-coding of variables can have a similar effect.

In Study 1, we demonstrate an analogue of the A-cell bias for continuous marketing data that is presented in various formats (sequential presentation, tabular presentation, and scatterplots). In Study 2, we show that people's mental representation of the A-cell is malleable and dependent on data coding. People weight observations with high numeric values more, regardless of their objective meaning, and thus they interpret identical data differently when variables are reverse-coded. Studies 3 and 4 provide process evidence that categorical thinking leads to the A-cell bias. In Study 3, we show that the A-cell bias can be amplified by adding dividing lines to scatterplots. People's verbalizations of their thought process mediate the effect of this manipulation on the A-cell bias. In Study 4, we show that the A-cell bias can be attenuated by interventions that discourage categorical thinking such as adding a regression line to data, asking people to draw their own regression line, or including an ellipse around the data cloud.

Companies' decision-making apparatus is increasingly organized around data analysis and visualization. Procter & Gamble's managers now meet in "business spheres" that immerse their teams in data. Tableau, a leading data visualization software company, envisions future business meetings where managers work together with their teams, creating visuals on the fly, as they try to understand their data. As this approach becomes more common, it will be critical for companies to understand the biases inherent in intuitive data analysis.

As we have shown, one important source of bias comes from thinking about continuous data categorically, and failing to weight all observations equally. This tendency makes people highly susceptible to data interpretation errors. We demonstrated that judgments and decisions can change dramatically based on the position of a few data points. Similarly, people reason very differently about identical data when variables are reverse-coded. And merely overlaying dividing lines on a scatterplot substantially changes how it is interpreted. The implication is that seemingly innocuous and arbitrary data analysis decisions can lead to very different judgments.

# Both Good from Afar...and Far from Good? Mental Representation Changes Consumer Preference for Products from a Brand with a Reputation for Innovativeness

Jeff Larson, Brigham Young University, USA  
Kelly Goldsmith, Vanderbilt University, USA  
BJ Allen, University of Arkansas, USA

## EXTENDED ABSTRACT

There is widespread agreement that firms and brands benefit from fostering a reputation for innovativeness. For example, past research has documented a variety of ways in which a reputation for innovativeness improves firm performance, including improved stock returns (Mizik and Jacobson 2008), increased customer loyalty (Henard and Dacin 2010), and increased customer satisfaction (Kunz, Schmitt, and Meyer 2011), among other benefits (Barone and Jewell 2013; Stock and Zacharias 2013; Zandan 1992).

However, it is also common for consumers to have apprehensions about innovativeness. For example, consumers are more likely to associate innovative products with expectations for product malfunctions as compared to their less innovative counterparts (Ali 2000; Marks 2012; Schneider and Hall 2010). Therefore, consumers may simultaneously maintain both positive and negative associations with innovation. On one hand, innovation has the potential to introduce desirable and novel products and product features to the market (Henard and Dacin 2010; Kunz, Schmitt, and Meyer 2011). On the other hand, these novel products and product features may be less likely to function in accord with expectations, as compared to more established offerings (Ali 2000; Hirunyawipada and Paswan 2006; Kiely 1997; Pavlou 2003; Ram and Sheth 1989).

Building on the understanding that a reputation for innovativeness is accompanied by associations related to both desirability (e.g., exciting new features) and feasibility (e.g., functional risk, the possibility of product malfunction), we contend that the effect of a brand reputation for innovativeness on consumers' interest in products from that brand will vary based on whether the behavioral context directs consumers' attention to either desirability-related or feasibility-related product associations.

Research in this area of Construal Level Theory (Trope and Liberman 2003, 2010) has repeatedly shown that abstract representations shift attention to products' desirability-related attributes, whereas concrete representations shift attention more toward feasibility-related concerns (e.g., Dhar and Kim 2007; Trope and Liberman 2003, 2010). On this basis, we predict that when the behavioral context favors a reliance on abstract representations, a brand reputation for innovativeness will have a positive effect on product preference, because consumers will be more likely to associate products from that brand with the desirability-related aspects of innovativeness (e.g., exciting new features). In contrast, when the behavioral context favors a reliance on concrete representations, a brand reputation for innovativeness will have a negative effect on product preference, because consumers will be more likely to associate products from that brand with the feasibility-related aspects of innovativeness (e.g., functional risk).

In our experiments, we primarily vary mental representation through the elicitation task. Specifically, participants in our experiments make either isolated evaluations of the products or they make choices between them. This method for manipulating mental representation was chosen for two primary reasons. First, recent research by Meyvis, Goldsmith, and Dhar (2012) demonstrates that the task of evaluating products in isolation (vs. making choices among the same products) prompts the adoption of more abstract (vs. concrete) representations. Second, we chose this manipulation of mental representation

in order to ground our inquiry in relevant marketplace phenomena.

Formally, we offer the following predictions:

*Hypothesis 1* Consumers' preference for products from a brand with a reputation for innovativeness (vs. other reputations) will be higher among those asked to evaluate such products in isolation (vs. in a choice task).

*Hypothesis 2* The positive effect of a brand reputation for innovativeness (vs. other reputations) on preference in evaluation is mediated by a shift in expectations for desirability-related attributes (i.e., novelty and value).

*Hypothesis 3* The negative effect of a brand reputation for innovativeness (vs. other reputations) on preference in choice is mediated by a shift in expectations for feasibility-related concerns (i.e., quality concerns).

We test these hypotheses in four experiments. Experiment 1 used a 2 (brand reputation: innovativeness vs. consistency) by 2 (response mode: choice vs. evaluation) design. Participants began the experiment by reading about two different blender manufacturers who had recently introduced blenders under their own brand name. One brand was focused on innovation, the other on consistency. Participants then saw blenders from each of these brands and either (1) chose their preferred blender or (2) evaluated their purchase likelihood for each blender. Participants in the choice condition preferred blenders from the company focused on consistency; Participants in the evaluation condition evaluated blenders better when they came from the company focused on innovation.

In experiment 2, participants saw a blender from a company focused on innovation or focused on consistency. They evaluated the blender on purchase likelihood, perceived quality, and novel features. Participants in the innovation condition rated the blender higher on both purchase likelihood and novel features, but not higher on perceived quality. Consistent with our hypothesis, there was a significant indirect effect of a reputation for innovativeness on purchase likelihood through novel features, but not through perceived quality. Under an abstract mental construal, a reputation for innovativeness increases purchase interest because it increases the perception that the product is likely to have novel features.

In experiment 3, participants made multiple choices between two blenders—one from a company focused on innovation and the other from a company focused on consistency. Replicating the results of experiment 1, participants preferred the blenders from the company focused on consistency. We found a significant indirect effect of a reputation for innovativeness on choice through both perceived quality and novel features. Under a concrete mental construal, a reputation for innovativeness increases perceptions of the product's novel

features but also decreases perceptions of the product's quality. The net effect is a decrease in purchase interest.

In experiment 4, we manipulated both brand reputation and construal level. Consistent with our conceptual account, a brand reputation for innovativeness decreased quality perceptions (relative to a brand reputation for quality) under a concrete mental construal. However, under an abstract mental construal, a brand reputation for innovativeness had no effect on perceived quality.

# Millionaires on Instagram: Millennials' Display of Experiential Luxury and Personal Branding Strategies on Visual Social Media

Marina Leban, ESCP Europe, France

Benjamin Voyer, ESCP Europe, UK

## EXTENDED ABSTRACT

Modern luxury research draws upon the concept of conspicuous consumption, the act of publicly displaying luxury goods as a means of showing-off one's wealth (Veblen, 1899). Millennials are considered to be the next generation of luxury consumers. With the rise of social media, it is predicted there will be over 3 billion users by 2021 (Statista, 2017). However, little is known as to how millennial consumers behave on visual social media and what they display in their accounts.

The concept of personal branding states that individuals are able to create their own brand by being their own marketer (Peters, 1997). Thus doing, they are reinventing themselves into someone they would like to publicly display, while being in total control of their branded self (Kaputa, 2005). This concept has not been looked at in the context of micro-celebrities – individuals who acquire popularity on social media through followers (Marwick, 2015). Instagram being a highly visual social media platform creates an environment that is fit for setting the scene by displaying wealth. This study explores millennials' display of experiential luxury through personal branding strategies on visual social media, looking at the case of 'Millionaires' of Instagram.

We collected data through an anonymously curated platform on Instagram called "Rich Kids of Instagram" (see Marwick, 2015). The final sample included a total of 27 users. We carried out a visual content analysis and a netnography. The content analysis included 493 Instagram posts. The netnography immersion lasted 6 months and was conducted on 810 Instagram posts.

In terms of results, we first conducted a descriptive content analysis and found that the Instagram pictures were of individualistic and unaltered nature. Instagram pictures usually portrayed only one person and were usually unfiltered, authentic pictures. Furthermore, findings showed an absence of the display of brand prominent luxury products in the posts, and the text associated did not mention brand names. These results seem to contradict previous research, suggesting that the wealthier you are, the more you are prone to signal your status by displaying brand prominent goods (Han et al., 2010). Interestingly, the preferred setting in the posts takes place in a public space rather than a private space. A majority of posts were geo-tagged. Geo-tags were typically precise, indicating exact names of the restaurant, hotel or other locations. This corroborates previous research on impression management (Goffman, 1959), showing that individuals carefully stage their everyday life in a front stage (the public space) and curate their posts in a back-stage (the private space) (Zhao et al., 2013).

The netnography findings confirmed the preferred experiential nature of posts location. Subjects posted text on specific experiences such as going on holiday, night-outs, weekend escapes and birthdays. Text was used merely to reinstate and reinforce the importance of their experience such as "#VacationMode". Moreover, followers probed account users by either enquiring on the geographical location related to the post or simply requesting more Instagram posts. Thus the content and location appeared highly appreciated and demanded by followers.

In sum, findings revealed two main aspects of the personal branding strategies adopted by wealthy micro-celebrities. First, the restrained use and lack of display of conspicuous luxury branded products. Second, an emphasis on experiential luxury through the

use of geo-tags. These findings carry theoretical implications. Contrary to more 'traditional' luxury consumption theories (Veblen 1899), findings showed that wealthy millennials put an emphasis on more unconventional and immaterial - rather than material - aspects of their luxury consumption. The experiential nature of luxury consumption was exemplified by the almost systematic use of geo-tags. Followers seemed to be especially motivated by this aspect of the luxury consumption experience, which can be seen as a truer, more authentic, form of consumption experience.

This study also contributes to the understanding of how millennials conceive luxury consumption in a broader sense. The co-construction of meaning allowed by textual and visual social media can contribute to re-creating and co-constructing the meaning of luxury. Visual social media such as Instagram allow consumers to create and express experiential luxury by bridging liquid and solid consumption. Personal branding pioneers, such as millionaire millennials known as 'rich kids' micro-celebrities on Instagram, use tactics to distinguish themselves and attract followers. Experiential luxury, rather than luxury products (Hemetsberger, von Wallpach, and Bauer 2012), appears to be the main focus of luxury consumption for this new generation of luxury consumers.

# Analyzing the Perception of Experiential Luxury Consumption of Millennials on Instagram: A New Methodological Approach

Marina Leban, ESCP Europe, France

Matthias Plennert, Friedrich-Alexander-University of Erlangen-Nürnberg, Germany

## EXTENDED ABSTRACT

Luxury consumption has been extensively researched, primarily looking at the consumption of material goods, but has neglected experiential luxury consumption. In fact, millennials, the new upcoming luxury consumers, seem to be more interested in the latter. Instagram, a visual social media platform, is used by millennials - 18 to 30 year olds - more so than other generations (Pew Research Center 2016). Instagram allows users to record their everyday lives through posting pictures containing features such as geolocation tags (Manikonda, Hu, and Kambhampati 2014)(Manikonda, Hu, & Kambhampati, 2014). Yet there is a gap in the literature in understanding how and to what end millennials use these features. Recently a new subgroup of wealthy millennials, called Rich Kids of Instagram (RKOI for short) emerged on the platform. RKOI are millennials, micro-celebrity pioneers (Senft 2008), heavy luxury consumers influencers that are extensively followed on Instagram. In this study, we explore (1) how these rich millennials signal their experiential luxury consumption through geo-tags on Instagram, and (2) how this type of unconventional luxury consumption is perceived by these rich millennial followers.

The research design aims at examining the perception of experiential luxury consumption of RKOI by Instagram users. Thus we focus on following attributes: (1) the perception-intensity of RKOI posts by Instagram users, measured in the number of likes and comments (in the following referred to as "social response"), (2) the location of the RKOI posts and their social response in geographic coordinates (latitude and longitude) and (3) the visual post content, categorized in distinctive settings by a qualitative content analysis (Bock 2011). The data collection is based in a data mining process, with which we crawl and extract information from the HTML structure of each RKOI post – such as number of likes and comments, hashtags, descriptions or location via coordinates. Our sample of RKOI posts consists of 700 geotagged RKOI posts by 21 European citizen users on 407 unique locations.

This study shows that rich micro-celebrities, called Rich Kids of Instagram, signal experiential luxury on visual social media, through the use of geo-tags.

Although most research has looked at tactics used by micro-celebrities and celebrities in building their brand image online (Marwick 2015; Rokka and Canniford 2016), consumer research has not been able to measure yet the social impact it has to micro-celebrities/celebrities' followers. Results have shown that followers seem to have potential interest in experiential luxury lifestyle. Moreover, this research is a step forward in confirming that millennials are not interested in consuming traditional luxury goods or services (Han et al. 2010). Followers seem to be interested in viewing content that exhibits traveling lifestyle in famous and traditional luxury capitals (Kim et al 2014).

This paper carries important methodological and managerial contributions. First, to the best of our knowledge, this is the first study that shows a multi-disciplinary methodological approach that

bridges geography with marketing. This innovative research design of examining a sample with geographical and visual attributes, and the social response numbers with geographical, statistical and qualitative methods enables new insights into the perception of social media content. Second, the research contributes to understanding how millennials engage with experiential luxury (through geo-tags) on Instagram.

In terms of managerial contributions, market researchers in city branding (Demirbag Kaplan et al. 2010) could use such data to determine millennials tourism trends and to better target that particular consumer segment accordingly.

Finally, since this methodological approach is not limited to the case example of RKOI, it is applicable to other social media research contexts. Conditions for this method to work are (1) to use data coming from a social media platform with geo-tags implemented, (2) and for geo-tags to be widely used by social media users. Future researchers could apply and analyze data with this method on other Instagram users such as social media influencers or scrutinize the spatial characteristics of posts within a specific area in detail (e.g. looking at all posts that were geo-tagged in Florence).

# “Million Dollar Smile?” How Smile Intensity, Relationship Norm and Consumer Self-Construal Influence Ad Effectiveness

Hsiao-Ching Lee, National Kaohsiung University of Science and Technology, Taiwan

## EXTENDED ABSTRACT

Marketers widely use the image of a smile to create a positive impression among consumers. The well-known interpersonal benefits of a smile could lead one to believe that a smile always conveys positive information and receives positive social feedback. On the contrary, Wang et al. (2016) cautioned that bigger and broader smiles sometimes generate undesirable consequences, and a slight smile is perceived more favorably when people associate it with the trait of competence. Our study contributes to the evolving research stream regarding smile intensity by examining how consumer evaluations of service advertisements are affected by the way the model smiles in the ad. Drawing from the social-functional perspective, we explore the differences—and the reasons for those differences—in consumers’ responses to two types of smiles (broad and slight), and identify boundary conditions associated with the roles of relationship norm and consumer self-construal.

Relationship norms affect compliance, and influence the decoding of the inferences consumers make regarding a consumption context (Scott, Mende, and Bolton 2013; Wan, Hu, and Wyer 2011). Two types of relationship norms have been distinguished: communal and exchange relationships (Clark and Mills 1993). The communal norm leads to an emphasis on warmth, as opposed to competence, whereas the exchange norm leads to a greater emphasis on competence than on warmth (Scott et al. 2013). A person showing a broad smile tends to evoke a perception of warmth while a person showing a slight smile is likely to be perceived as competent (Wang et al. 2016). Thus, we expect an interactive effect between relationship norm and the model’s smile intensity.

Two distinct types of self-construal (i.e., independent and interdependent) distinguish how the self is viewed in relation to others (Singelis 1994). People with an independent self-construal (“independents”) see themselves as autonomous and unique, whereas those with an interdependent self-construal (“interdependents”) see themselves as relational and interconnected with others (Markus and Kitayama 1991; Triandis 1993). People prefer advertisements that express values congruent with their self-construal (Van Baaren and Ruivenkamp 2007).

Since communal relationships raise expectations of kindness and concern for general welfare (Clark and Mills 1979), the communal norm leads to an emphasis on warmth as opposed to competence (Scott et al. 2013). Consumers whose norm is the communal relationship are thus expected to appreciate the warmth associated with the brand. In contrast to a slight smile, a model’s broad smile will enhance these inferences of warmth. Therefore, we expect that interdependents find a model’s broad smile to be more persuasive than a slight smile, and this effect will be stronger in the context of a communal relationship than in an exchange relationship.

The effect of a slight smile is expected to be stronger in an exchange relationship than in a communal relationship. An exchange relationship implies “quid pro quo” and an expectation of prompt repayment for received benefits (Clark and Mills 1979). In the context of the consumer-firm relationship, consumers are concerned with how much they receive in exchange for how much they give. This

concern motivates consumers to focus on the level to which their own self-interest is dependent on the competence of the brand. A model showing a slight smile is perceived as more powerful, competitive or competent than the same model showing a broad smile. Thus, the slight smile can enhance a brand’s image as one of competence, and is aligned with the independents’ expectations regarding an ideal brand under the exchange norm. Therefore, a model with a slight smile is expected to increase the favorability of evaluations of the brand.

We design two experiments. In Study 1, a 2 (smile intensity: broad vs. slight) x 2 (relationship norm: communal vs. exchange) x 2 (consumer self-construal: interdependent vs. independent) between-subjects design, in which self-construal was measured. The ad of travel agency was chosen as target product. Attitude toward the brand as the dependent variable. Study 2 employs a 2 (smile intensity: broad vs. slight) x 2 (relationship norm: communal vs. exchange) x 2 (consumer self-construal: interdependent vs. independent) between-subjects design, in which relationship norm was assessed via a measure of communal and exchange orientation. Purchase intentions for the gym service served as the dependent variable. In addition, we conducted moderated mediation analysis to examine whether processing fluency served as the underlying mechanism. There was no overlap of participants across the two studies. Through various manipulations and priming of the independent variables, both of two studies obtained the consistent results and suggest that for interdependents, a model’s broad smile was more persuasive than a slight smile, and the effect was stronger in the communal relationship than in the exchange relationship. In contrast, we found independents to perceive a slight smile as more persuasive than a broad smile, and the effect was stronger in the exchange relationship than in the communal relationship. Further, we did find a significant indirect effect of smile intensity, relationship norm, and consumer self-construal interaction through the processing fluency.

This research contributes to the literature regarding the effects of smile intensity on advertising persuasion. Previous research has shown that this effect is bounded by consumer-related factors (Wang et al. 2016). Our study shows that relationship norm and consumer self-construal can provide self-schemata and influence how consumers perceive a model’s broad and slight smile differently. The current work offers rich managerial implications. Marketing managers who wish to maximize the advertising value of the model’s smile must take into consideration the relationship norm that is most easily invoked by the brand and/or product being promoted. Marketers may treat self-construal as an interesting communication challenge in which consumers can be induced to think collectively or individually. Although relationship norm and self-construal, as studied here, may not be the only two ingredients missing from the extant advertising literature, they explain the situational effectiveness of a model’s smile and offer important insights into how these two variables impact the selection and usage of a model. Marketers who pay attention to such concerns are likely to stand a better chance of winning consumer hearts.

# Thanks for Nothing: Expressing Gratitude Invites Exploitation by Competitors

Kelly Kiyoon Lee, Georgetown University, USA

Jeremy A. Yip, Georgetown University, USA

Cindy Chan, University of Toronto, Canada

Alison Wood Brooks, Harvard University, USA

## EXTENDED ABSTRACT

Economic exchanges such as negotiations, ultimatum games, and deception games are characterized as mixed-motive interactions in which individuals must decide when to focus on their self-interested outcomes and when to focus on joint outcomes with their counterparts (Dana, Cain, and Dawes 2006; Gino and Moore 2008). Social norms of competition are salient in these economic exchanges, and people are often motivated to claim value for themselves (Larrick and Wu 2007; Loschelder et al. 2016).

Individuals typically act in accordance with their own interests because they obtain personal material gains or emotional benefits (Barasch et al. 2014; Zlatev and Miller 2016). A number of interpersonal factors has been shown to influence self-interested decisions, including trust (Lount et al. 2008), identity (Bryan et al. 2013), and - most relevant to the current work - emotion (Gino and Pierce 2009).

Considerable research has focused on the benefits of gratitude. For example, feeling gratitude has been linked with prosocial behavior (McCullough et al. 2001), trust (Dunn and Schweitzer 2005), and personal responsibility (Chow and Lowery 2010). Interestingly, no prior work has investigated the potential negative consequences of gratitude. This is a surprising omission because gratitude is commonly expressed in social interactions, and selfish preferences and behavior frequently occur in economic exchanges.

We explore whether expressions of gratitude trigger self-interested behavior. In social exchanges, individuals pay attention to social signals that communicate their counterparts' motives to cooperate or compete (Adams et al. 2015; Galinsky and Schweitzer 2015). One important social signal is emotional expression. Emotional expressions provide insight into the cognitive appraisals and motives that commonly accompany the emotional experience (Ames and Johar 2009; Barasch et al. 2016). We extend the emotions-as-social-information model (Van Kleef 2009; Van Kleef, Homan, and Cheshin 2012) and identify a strategic inference that individuals frequently make about their opponents based on their expressions of gratitude. Prior research has found that in cooperative relationships, people make inferences about the communal strength of the relationship when they interact with a partner who expresses gratitude (Lambert et al. 2010). Based on gratitude expressions, individuals infer that their partner is more caring about the welfare of others.

We advance scientific understanding of the inferences made about gratitude expressions by investigating whether individuals view grateful counterparts as particularly forgiving. Forgiveness is defined as the prosocial willingness to cancel a debt or accept a transgression in order to restore a relationship (Adams and Inesi 2016; Finkel et al. 2002; McCullough 2008). Building on existing research, we adopt an interpersonal conceptualization of forgiveness (Bies et al. 2016; McCullough et al. 1997). When people express forgiveness, they communicate a willingness to move past conflict, accept an imbalance in resources, and repair the relationship (Exline et al. 2004). However, recent research has revealed that in the absence of wrongdoing, individuals can respond negatively to expressed forgiveness (Adams et al. 2015).

We postulate that individuals are particularly likely to infer that their grateful counterparts have a tendency to forgive selfish behavior. That is, we establish a link between expressions of gratitude and

inferences about the willingness to forgive. We expect that strategic inferences of forgiveness can explain the effect of gratitude expressions on self-interested behavior.

In Study 1, we randomly assigned participants to either a Gratitude Expression or Neutral Expression condition. We manipulated expressions of gratitude by having confederates describe themselves as a grateful person or an unemotional person. We measured self-interested decision-making by having participants make offers in an ultimatum game. Next, participants completed a measure of the inferred forgiveness of their counterpart and a manipulation check. Participants in the Gratitude Expression condition rated their counterpart as expressing higher levels of gratitude than did participants in the Neutral Expression condition (Our emotional expression manipulation was successful in all of our studies). Importantly, participants in the Gratitude Expression condition made more selfish offers than participants in the Neutral Expression condition. We show that inferred forgiveness mediates the effect of gratitude expressions on selfish offers.

In Study 2, we contrasted the effect of gratitude with the effect of another positive-valence emotion, excitement. We show that participants who perceived gratitude were more likely to make selfish decisions in the ultimatum game compared to those who perceived excitement or neutral emotion.

In Study 3, we contrast the effect of gratitude in competitive interactions with cooperative interactions. We reconcile our findings with prior research demonstrating that gratitude expressions motivate prosocial behavior in cooperative interactions (McCullough et al. 2001). To explore whether the type of interaction moderates the relationship between gratitude and selfish behavior, we employed a 2 (Setting: Competition vs. Cooperation) x 2 (Emotional Expression: Gratitude vs. Neutral) between-subjects design. We manipulated expressions of gratitude by having confederates describe themselves as a grateful person or a neutral person. We used a modified version of Prisoners' Dilemma Game (Lieberman, Samuels, and Ross 2004) to manipulate the type of interaction. In the Competition condition, the game was framed as the Wall Street Game and their partner was identified as an opponent. In the Cooperation condition, the game was framed as the Community Game and their partner was identified as a teammate. As predicted, expressed gratitude increases selfish behavior in competitive settings, whereas it decreases selfish behavior in cooperative settings.

In Study 4, we extend the effect of expressing gratitude on selfish behavior to a distinct but related behavioral domain: deception (Yip and Schweitzer 2016). We show that perceivers of gratitude expressions were more likely to exploit opportunities to cheat than were perceivers of neutral expressions.

Across four studies, using different emotional expression manipulations and different measures of self-interest, we obtain a consistent pattern of results: expressing gratitude invites self-interested, exploitative behavior from perceivers.

Our work challenges the prevailing assumption that gratitude promotes prosociality. People may become accustomed to the benefits of gratitude in cooperative situations and carry their habits of saying "thank you" and expressing gratitude into competitive situations, thereby unknowingly harming their own economic outcomes. Our findings reveal a dark side of gratitude.

# Doing Worse by Doing Good: How Corporate Social Responsibility Makes Products Less Dangerous

Linda Lemarié, University of Neuchâtel, Switzerland

Florent Girardin, Ecole Hôtelière de Lausanne (EHL), Switzerland

## EXTENDED ABSTRACT

In recent years, much research has focused on the impact of CSR on business activity, showing that by investing in CSR companies can “do well by doing good” (Chernev & Blair, 2015; Du, Bhatlacharya, & Sen, 2007; Orlitzky, Schmidt, & Rynes, 2003). Chernev and Blair (2015), for instance, have demonstrated that CSR activities can create a “halo effect” inducing consumers to evaluate more positively the performance of products of companies involved in prosocial actions. In the specific case of controversial companies, i.e. companies producing products that could be dangerous for health, environment or the society, the literature also seems to convey a rather positive view of CSR investments (Cai, Jo, & Pan, 2012; Yoon, Gürhan-Canli, & Schwarz, 2006). However, this literature has mainly focused on the positive effect of CSR on the image or financial performance of companies without paying much attention to the potentially harmful effects on consumers. In this research, we question whether products that are explicitly presented as hazardous to health or the environment can be perceived as less dangerous because of the company’s involvement in charitable actions.

If we refer to the vast majority of research conducted in the field of impression formation (e.g. Baumeister, 2001; Skowronski & Carlston, 1989), the natural answer to this question seems rather to be no. Indeed, it has been repeatedly shown that the negative characteristics of a person or an object exert a stronger influence on its overall evaluation than his or its positive characteristics (Baumeister, 2001). However, the literature also points out that to form their impression people rely on the available informational cues that are the less ambiguous (e.g. Wyer, 1973). Based on this premise, we hypothesize that the dangerous nature of a product sold by a company can be difficult to assess and therefore perceived as relatively ambiguous by the target contrary to the prosocial actions undertaken by the organization. In sum, we expect consumers to infer that a product sold by a socially engaged company cannot really be dangerous.

The goal of study 1 was to test whether the addition of a charity logo to a product can lessen the impact of a warning informing about the hazard posed by the product. We recruited 195 MTurk participants to evaluate a new fictitious brand of deodorant. We used a two - 1 (warning sign) X 2 (logo of a charitable organization: present versus absent) - plus control group (no warning sign and no charitable logo) experimental design. After the product presentation, participants completed a short survey regarding their attitude toward the brand (Yoon et al., 2006) and the perceived danger associated with the product.

Results show that brand attitude was significantly lower in the warning only condition ( $M=3.627$ ,  $SD=1.73$ ) than in the control condition ( $M=4.65$ ,  $SD=1.31$ ,  $p < .01$ ) and the warning plus charity logo condition ( $M=4.44$ ,  $SD=1.15$ ,  $p < .01$ ). Control and warning plus charity logo condition did not differ ( $p > .10$ ).

Regarding the perceived danger, participants in the warning only condition rated the product as significantly more dangerous for health and the environment ( $M_{\text{health}} = 2.97$ ,  $SD = 1.22$  and  $M_{\text{environment}} = 3.05$ ,  $SD = 1.12$ ) than in the warning plus charity logo condition ( $M_{\text{health}} = 2.41$ ,  $SD = 1.05$  and  $M_{\text{environment}} = 2.72$ ,  $SD = 1.13$ ,  $p < .05$ ) and in the control condition ( $M_{\text{health}} = 2.21$ ,  $SD = 1.19$  and  $M_{\text{environment}} = 2.51$ ,  $SD = 1.12$ ,  $p < .05$ ). Control and warning plus charitable logo condi-

tions did not differ in terms of perceived danger of the product ( $p > .10$ ).

These results support our hypothesis. The presence of a charity logo on a product tempers the presence of a warning sign on consumers’ attitude toward the brand and perception of danger associated with the product. These findings suggest that, in presence of a charity logo, consumers may infer that the product is not really dangerous and be less affected by the presence of a warning sign in their evaluation.

The aim of study 2 was to replicate study 1 taking into consideration a crucial potential moderator: the salience of the benefits that the company derives from these CSR activities. Indeed, it has been shown that a CSR activity perceived as primarily serving the interests of a company may be ineffective or even counterproductive (Chernev and Blair, 2015; Wagner, Lutz, & Weitz, 2009; Yoon et al., 2006).

One hundred forty-eight MTurk participants were randomly assigned to three different conditions: Control (no CSR), “Self-interested CSR” and “Neutral motives CSR”. To vary the manipulation, we used a text presenting products sold by a fictitious brand of soft drinks named Galaxis. To make clear that the company sells dangerous products, we mentioned that “the overall risks of obesity and diabetes related to the consumption of its products are the highest in the whole industry”.

After reading the text, participants rated their attitude toward Galaxis and the perceived danger associated with products sold by Galaxis.

Confirming our assumption, results show that participants evaluated the brand significantly better when CSR activities were mentioned ( $M = 4.64$ ,  $SD = 1.20$ ) than when they were not ( $M = 3.89$ ,  $SD = 1.33$ ,  $p < .01$ ) but this effect was non-significant when brand self-interests were salient ( $M = 4.09$ ,  $SD = 1.47$ , NS). Finally, participants evaluated Galaxis’ soft drinks as significantly less dangerous in the “Neutral motives CSR” condition ( $M = 4.34$ ,  $SD = 1.93$ ) than in the control condition ( $M = 5.12$ ,  $SD = 1.58$ ,  $p > .05$ ) and in the “Self-interested CSR” condition ( $M = 5.08$ ,  $SD = 1.59$ ,  $p > .05$ ). There was no difference between the “Self-interested CSR” condition and the control condition (NS).

These findings have implications for understanding when and why CSR activities of controversial companies can reduce the perceived dangerousness of their products. We show that when CSR does not seem to be dictated by personal interests, the charitable activities of controversial companies can create a benevolent halo that leads consumers to classify products as less dangerous and reduces the effectiveness of hazard warnings. Further research is still needed to understand whether these effects can be generalized to all types of product-related hazards.

# Anchors as Midpoints: It's Not the Size of the Adjustment That Counts, It's The Direction

Joshua Lewis, University of Pennsylvania, USA  
Joseph Simmons, University of Pennsylvania, USA

## EXTENDED ABSTRACT

People's estimates of unknown quantities are tethered to values they have previously considered, a phenomenon known as anchoring (Tversky & Kahneman, 1974). Previous research has attributed anchoring effects to a process of *insufficient* adjustment from anchors (e.g. Epley & Gilovich, 2006; Tversky & Kahneman). In this report, we propose an alternative explanation for anchoring effects, "anchors as midpoints", which instead focuses on the *direction* of adjustment. Specifically, people treat anchors as if they were a mental midpoint of the number line. Consequently, compared to what their unanchored estimates would suggest, people are more likely make estimates that are higher than high anchors, and lower than low anchors.

In our paper, we test this prediction, as well as three other predictions: First, the original prediction will be most evident when people's intuitions about the magnitude of the stimulus match the magnitude of the anchor. Second, anchoring effects will be stronger when people can adjust from an anchor in either direction, compared to when an arbitrary direction of adjustment is imposed. Finally, people will be less likely to adjust from arbitrary anchors in the direction of the correct answer than unanchored estimates would suggest.

In Study 1, 341 laboratory participants made 20 estimates about the percentage of American adults who met various criteria e.g. "What percentage of American adults eat meat?" We randomly assigned each of participants' estimates to one of three conditions: *high anchor* vs. *low anchor* vs. *control*. We pretested the high (low) anchors to approximate the 85<sup>th</sup> (15<sup>th</sup>) percentile of unanchored estimates for the specific question (Jacowitz & Kahneman, 1995). Consistent with the theory of anchors as midpoints, we found that participants estimated higher (lower) values than the high (low) anchor more frequently in the *high anchor* (*low anchor*) condition than in the *control* condition ( $ps < .001$ ). Moreover, we also found that our effect for high (low) anchors was greater for questions with intuitively high (low) answers ( $ps < .001$ ).

A potential alternative explanation for our findings in Study 1 is that participants thought that the anchors were informative. To rule out this possibility, we ran Study 2 with 472 online participants using transparently random anchors, generated with the last two digits of the first ten numbers in participants' contact list. Each of the 10 resulting numbers corresponded to one of the 10 estimation questions. For example, if the resulting number was below 24.5 (above 74.5), the anchor for the corresponding estimation question would be 24.5 (74.5). If the number was between 24.5 and 74.5, participants would make the corresponding estimate without considering an anchor. We designed questions about the percentage of participants in the survey who would prefer one option over another. We expected participants to have the intuition that a certain option would be generally preferred (e.g. chocolate over apples). Therefore, for each question, we randomized whether the participant estimated the percentage of survey respondents preferring the popular option over the unpopular option (*intuitively high* condition), or vice versa (*intuitively low* condition). Consistent with our theory, we found that people were more likely to estimate a value higher (lower) than 74.5 (24.5) in the *high anchor* (*low anchor*) condition compared to the *control* condition ( $ps < .001$ ), particularly for intuitively high (low) quantities ( $ps < .001$ ).

In Study 3, we recruited 778 online participants to estimate on how many of the next 100 days each of 10 cities would be hotter than Kansas City, MO, after considering anchors. We wanted to rule out the possibility of obtaining this finding because participants believed the restrictions on the direction of adjustment to be informative. The goal of this study was to test another prediction of our theory of anchors as midpoints; that anchoring effects are stronger when people can adjust from the anchor in either direction than when they are compelled to adjust away from the extremes. We manipulated both the anchor and the direction of adjustment using the first 10 numbers in participants' contact lists, to ensure that our manipulations were understood as uninformative. For example, if the number comprising the last two digits of one of these numbers was below 24.5 (74.5), participants could adjust in either direction from an anchor of 24.5 (74.5). If the number was between 24.5 and 49.5 (49.5 and 74.5), we compelled participants to estimate a value higher (lower) than the anchor of 24.5 (74.5). We truncated our dependent variable to enforce the same restriction on estimates in all conditions in our analyses, so that we treated estimates higher than 74.5 as equal to 74, and estimates lower than 24.5 as equal to 25. Even with this truncated dependent variable, and with the transparently uninformative manipulation, anchoring effects were stronger for participants who could adjust from the anchor in either direction than for participants who were compelled to adjust away from the extremes ( $p < .001$ ).

An important prediction of our theory is that people are more likely to adjust from anchors *away from the correct answer* than their unanchored estimated would suggest. To test this hypothesis, we recruited 1,994 online participants to answer estimation questions with an objectively correct answer. Specifically, participants estimated the percentage of pixels in an image that were either yellow or black. The percentage of black pixels in each of these images ranged from 2.5% to 97.5% in intervals of 5%. Within subjects, and across estimates, we randomly assigned 50% of estimation questions to a *control* condition and 50% to an *anchor* condition. We randomly assigned *all* estimates an anchor from the same distribution as the correct answers to the estimation questions. However, in the *control* condition, participants never actually saw these anchors. Consistent with our theory, we found that participants were *less* likely to adjust in the correct direction, and *more* likely to adjust towards extremes, from real anchors than from control anchors that they never considered ( $ps < .001$ ).

In summary, our studies confirm a series of novel predictions made by the theory of anchors as midpoints, which are not predicted by other theories of anchoring.

# Consumer Responses to Premium Framing: Better to Offer the Target Product as a Free Gift?

Maggie Wenjing Liu, Tsinghua University, China

Lu Yang, Tsinghua University, China

Yuhuang Zheng, Tsinghua University, China

## EXTENDED ABSTRACT

Premium promotion, which is widely adopted by retailers, involves offering a free product or service to consumers if they purchase certain products and services (D'Astous and Jacob 2002). Previous studies examining consumer response to premium promotions mainly focused on objective factors such as premium attractiveness (Buil, de Chernatony, and Montaner 2013) and premium fitness (D'Astous and Landreville 2003) rather than framing of the premium. Past research has found that subtle variations in price framing may influence consumers' evaluation despite identical discount levels (Raghubir 2006). However, the presence of such an effect in premium framing (i.e., framing the target product vs. non-target product as a free gift) remains unknown.

On the other hand, in this digital age, e-commerce websites and search engines can easily identify consumers' target products by tracking their search history and it is possible for online stores to offer product packages with target products listed as free gifts. For instance, in Alibaba's Tmall, a Chinese e-commerce giant, consumers searching for earphones can find earphones either as a standalone product or as a premium (e.g., as a free gift when buying a shampoo). The current research explored how the different premium framings influence consumer response and its underlying mechanism.

Literature suggests that when pursuing a goal, individuals focus more on goal-related information (Huffman and Houston 1993). Therefore, we propose that consumers with a purchase goal are more sensitive to the information related to their target product, such as its price information. Based on Thaler (1985), a free gift can provide consumers with transaction utility through a deal. Moreover, consumers often overreact to zero price (Shampanier, Mazar, and Ariely 2007) due to positive affects. Thus, when consumers' target product is free, they can obtain large transaction utility through the deal and the zero price. Together, it is likely for consumers to perceive greater transaction utility when their target product (vs. non-target product) is framed as free. Additionally, transaction utility is consistently shown to enhance evaluation and purchase intention (Vaidyanathan et al. 2000). Formally, we propose that:

*Hypothesis 1* Consumers' evaluation and purchase intention of premium promotion is higher when their target product is free than when non-target product is free.

*Hypothesis 2* This effect is mediated by perceived transaction utility.

Furthermore, Chen (2009) found that people with interdependent (independent) self-construal rely on their external (internal) reference price and are more (less) sensitive to situational price information. As premium framing is one type of external price information, consumers with interdependent self-construal should be more likely to perceive an increase in transaction utility from premium framing. In contrast, consumers with independent self-construal will likely exert no different responses to specific premium framing. Formally,

*Hypothesis 3* The effect of premium framing is stronger for consumers with interdependent self-construal, but disappears for those with independent self-construal.

To test these hypotheses, we conducted three studies.

Study 1 test the main effect (H1) and had a 2 (target product: flash drive vs. earphone)  $\times$  2 (premium framing: flash drive free vs. earphone free) between-subjects design. Results revealed that consumers evaluate the premium promotion as more attractive under the target free condition than under the non-target free condition (5.99 vs. 5.01;  $t(158)=-2.69$ ,  $p=.008$ ), supporting H1.

Study 2 replicated the findings of study 1 with services (hair treatment), tested the mediator role of transaction utility and compared consumer response to premium framing with other promotion types. The experiment employed a one-factor (promotion type: target free premium vs. non-target free premium vs. bundle pricing vs. half price) between-subjects design. The last two groups are control conditions. The results revealed that participants in the target free condition (3.93) are more likely to purchase the service than those in the non-target free (2.95;  $p=.013$ ), bundle pricing (3.14;  $p=.045$ ), and half price (2.86;  $p=.008$ ) conditions. Similar effect on affective evaluation ( $F(1, 136)=5.12$ ,  $p=.002$ ) were observed. Bootstrapping analysis showed that transaction utility mediates our main effect (95% CI: .20, 1.56), supporting H2. Moreover, a posttest following study 2 which changed the "free" to "20% off" found both the main effect on purchase intention ( $p=.41$ ) and affective evaluation ( $p=.83$ ) dismissed. Together, study 2 not only replicated the documented effect but also showed that compared with other often-used promotions, consumers respond to target free promotion more positively.

Study 3 aimed to explore the moderating role of self-construal. Participants were randomly assigned to one of the 2 (self-construal: independent vs. interdependent)  $\times$  2 (premium framing: target free vs. non-target free) between-subject conditions. We manipulated self-construal by asking participants to read a story and count the pronouns (e.g., I vs. we) in it (Brewer and Gardner 1996). The results showed a significant two-way interaction ( $F(1, 204)=3.91$ ,  $p=.049$ ), under the interdependent condition, target product free (vs. non-target free) led to more positive evaluation (6.39 vs. 5.85;  $F(1, 204)=6.69$ ,  $p=.010$ ). However, under independent condition, there was no difference between target free and non-target free framing (6.12 vs. 6.17;  $F(1, 204)=.06$ ,  $p=.82$ ). Namely, this effect dismissed when consumers were primed with independent self-construal.

We examined how premium framing influences consumer response even when the net price savings remained the same. Three studies provided convergent evidence for the premium framing effect. Specifically, consumer evaluation and purchase intention of promotion is higher when their target product (vs. the non-target product) is free (Studies 1–2), owing to differential perceptions of transaction utility (Study 2). Moreover, self-construal moderates the premium framing effect (Study 3).

This research enriched the understanding of the factors influencing consumer response to premium promotions and demonstrated that different premium framing can also influence consumer response, even when the price savings are objectively identical.

Second, we contribute to the bundle price framing literature by exploring the framing effect in premium promotions instead of the discount. Finally, we advance knowledge regarding self-construal on consumers' price perceptions. Our findings also have several managerial implications for retailers to improve their promotions effectiveness through a subtle change in premium framing. For example, e-commerce websites can display a deal where consumer's target product listed as a gift.

# Rituals Enhance Self-Brand Connection: The Role of Time Perception

Maggie Wenjing Liu, Tsinghua University, China

Xian Wang, Tsinghua University, China

Qichao Zhu, Tsinghua University, China

## EXTENDED ABSTRACT

“Twist, Lick, Dunk!” Although Oreo has never explicitly recognized these three special actions as a brand ritual, it does educate consumers to perform a series of fixed and sequential behaviors to consume the cookie in an inadvertent manner (Rook 1985). This paper aims to reveal the effect of this kind of a brand ritual. Since a brand ritual relies on shared meaningful activities for consumers within their own spaces, we contend that the nature of a brand ritual is individual-based. This paper adopts the notion of an individual-based ritual as a ritualistic behavior with a symbolic meaning, occurring in a fixed and episodic sequence (Vohs, Wang, Gino, and Norton 2013).

Three studies demonstrate that a brand ritual makes consumers feel time expands, i.e., feeling they have abundant time at hand, further reinforcing their connection with the brand. Self-brand connection represents the extent of how a consumer incorporates a brand into “self” (Escalas and Bettman 2003). The causal impact has been hinted in anthropology. Performing a ritual may lead consumers to be more emotional and inclined toward incorporating a brand into the “self” concept (Di and Hassenkamp 2008). Besides, a brand ritual may influence consumers’ time perception, which is linked with feelings and behaviors (Graham 1981; Rudd, Vohs, and Aaker 2012). Since a ritual is often linked with special occasions that make people feel, memorize, and immerse themselves into the special moment, consumers experiencing a brand ritual may also feel and involve themselves with the brand. Thus, we anticipate that a brand ritual expands time perception, thereby triggering a connection with the brand.

Study 1 aims to test the main effect. We introduced a fictional coffee brand “Vindu” to the participants, who were randomly assigned to the ritual or control group. The ritual group was instructed to carefully read the following: “the special requirement for Vindu is that you must perform three sequential actions before tasting each sip of coffee: closing eyes for five seconds, taking deep breaths, and stirring the coffee for a moment. Now imagine that you would be tasting three sips of Vindu coffee. Before having each sip, you perform these three actions in sequence.” In contrast, the control group was also asked to imagine performing these three actions three times but in a random manner. The participants then took the self-brand connection test (Escalas and Bettman 2003). To confirm the effectiveness of the manipulation, we asked them to rate the extent to which they feel the three actions were like a ritual or a random series of actions (Vohs et. al 2013). The ritual group presented a significantly higher level of self-brand connection than the control group.

Study 2 intends test whether there is a difference in the effect between a ritual with meaning and a ritual without meaning and to explain the mechanism. Participants were randomly assigned to three groups: the ritual group (ritual with symbolic meaning), the routine group (ritual without symbolic meaning), and the control group (no ritual). Each participant was offered two Gullon biscuits. Participants from the routine group were told that Gullon introduced a new way of eating, comprising three actions: first, break the biscuit in half; then, close the eyes and take a deep breath; last, eat the right half, and then the left. The ritual group also performed these three actions. However, in step 2, when closing their eyes, they murmured “life is half living and half reliving.” Participants from the control group

were told to eat the way they like. Then, they took the self-brand connection test. We measured time perception by asking questions such as: “how slowly do you feel the time passes when eating biscuits?” For the main effect, the routine and ritual groups were not different from each other in brand connection, and both had a significantly higher level of self-brand connection than the control group. This shows that whether a brand ritual carried a symbolic meaning did not influence the self-brand connection. After controlling for the illusion of control and other relevant variables, the perception of time was shown to mediate effect of ritual on brand connection.

We conducted Study 3, a qualitative study to investigate how consumers cope with a real brand ritual. We selected FP, a service offering monthly subscription of flowers, as our case because it educates consumers to carry out a series of sequential actions, such as trimming roots at a 45-degree angle. Monthly subscription of flowers is a new consumption mode as flowers are generally termed as festival goods rather than daily goods. If customers accept FP flowers as part of their daily lives, we can consider it as evidence that they have built a close connection with FP. We conducted exhaustive interviews with FP customers and found three themes that mold the FP consumption process: object-oriented, behavior-oriented, and ritualized-meaning. Based on the practice theory (Arsel and Bean 2013), the three themes construct a ritualization process of the “O-D-M” (object-doing-meaning) mode. Studies 2 and 3 verified time perception as a mechanism. The difference is that the lab experiment did not reveal a significantly different effect between rituals with and without meaning, while the qualitative study recognized the effect of a ritual’s meaning. This is because a brand ritual’s symbolic meaning is constructed by doings. Customers in study 3 perform an FP ritual every day, and thus they gradually share a meaning and connection with the brand.

From a theoretical perspective, our work is one of the first attempts to explore the ritual effect in the brand area. It also elaborates the relationship between a ritual’s doing and meaning from the perspective of time perception. The managerial implications are important for branding, advertising, and consumer relationship. In a real market, companies can try to create a brand ritual as an effective strategy.

# The Impact of Childhood Exposure to Interparental Conflict on Consumer Response to Online Reviews

Mengmeng Liu, Chinese University of Hong Kong, China  
Maureen Morrin, Temple University, USA  
Boyou Grace Chae, Temple University, USA

## EXTENDED ABSTRACT

Online reviews often exhibit less consensus, wherein reviewers disagree on aspects of product performance. Research on the effect of review consensus exhibits mixed results (e.g., Zhu and Zhang 2010). In the current research, we focus on an important but previously unexamined moderating variable: the level of exposure to interparental conflict (IPC) during one's childhood.

Interparental conflict (IPC) refers to the extent to which a person *observed* his or her *caregivers* engaging in destructive conflict during childhood. It is typically measured via self-reports regarding the frequency and intensity of having observed parental arguing, as well as the extent to which such disputes were not constructively resolved (Grych, Seid, and Fincham 1992). Our research shows that adults who witnessed high levels of IPC as children evaluate products with low (versus high) levels of review consensus less favourably. We further show the underlying mechanism.

Across three studies, we demonstrate that high IPC individuals devalue a product with lack of review consensus and that pessimistic expectations underlie the effect.

In study 1, we manipulate review consensus by varying the extent to which product attributes are consistently evaluated positively (or negatively) by reviewers. MTurk participants were randomly assigned to a low or high review consensus condition. Self-report IPC was administered either at the beginning or at the end of the questionnaire (randomly determined), to check for order effects (there were none). Floodlight analysis (Spiller et al., 2013) shows that high IPC individuals evaluated the luggage less favorably in the low (vs. high) consensus condition. Review consensus had the opposite effect on low IPC individuals.

In study 2, we tested the proposed underlying mechanism that devaluation of product with lack of review consensus is due to pessimistic expectations. For generalizability of the effect, we use star ratings to manipulate review consensus. MTurk participants were randomly assigned to a low or high review consensus condition, and IPC was measured toward the end of the study. Floodlight analysis shows high IPC individuals evaluated the hotel less favorably in the low (vs. high) consensus condition. Lower IPC individuals exhibited no effect of reviewer consensus. We next tested the proposed underlying process (PROCESS macro, Model 15, Hayes, 2013): IPC → negative product review expectations → lower product evaluations when review consensus was low. Our results show that high IPC individuals did indeed have lower expectations about the reviews, that lower expectations reduced product evaluations. More importantly, review consensus moderated this effect, such that low consensus reduced product evaluations when review expectations were low. The indirect effect was significant.

In study 3 we directly manipulated the positivity of expectations to provide additional process evidence. We expected that enhancing expectations would offset the chronically pessimistic expectations of high IPC individuals. Mturk participants were randomly assigned to one condition in a 2 (review expectation: positive = high rank vs. neutral = no rank) x 2 (review consensus: high vs. low) full facto-

rial design. As results indicated, the interaction of expectations and review consensus was significant for high IPC individuals but not for low IPC individuals. Floodlight analysis shows high IPC individuals evaluated the hotel less favorably in the high (vs. low) consensus condition when positive expectations were created as predicted. Individuals scoring lower on IPC exhibited no interactive effect of expectation and reviewer consensus.

We document unique and long-lasting effects of childhood experience on adults' consumption. We found that individuals who report having been exposed to high levels of interparental conflict (IPC) while growing up rate products exhibiting less (versus more) review consensus less favorably. We further show this result is driven by negative review expectations, which is likely reflective of high IPC individuals' chronically higher pessimism levels. Enhancing the expectations of high IPC individuals reversed the effect. Our results are robust to family structure (i.e., parental divorce), suggesting that family communication processes may explain behaviors beyond those captured by earlier work on family structure.

This research has important theoretical contributions. By documenting the unique and long-lasting effects of destructive family communication processes in childhood on consumers' expectations and behavior, it contributes to consumer developmental psychology. Extant research on consumer developmental psychology has mainly focused on the impact of family structure (e.g. parental divorce, Rindfleisch, Burroughs, and Denton 1997), with little systematic investigation on the impact of family communication processes. It also contributes to the work on review consensus. We not only identify a novel moderator of the effect of review consensus but also illustrate the underlying process based on review expectations. The effects of IPC on consumption offer multiple avenues of exploration.

# Remind Me of What I Have: Thinking about a Favorite Possession Mitigates the Negative Impact of Inequality on Subjective Well-being

(Joyce) Jingshi Liu, Hong Kong University of Science and Technology, China

Amy Dalton, Hong Kong University of Science and Technology, China

Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China

## EXTENDED ABSTRACT

Income inequality negatively impacts people's subjective well-being, social relationships, and health (e.g. Alesina et al. 2004; Oishi et al. 2011; Oshio and Kobayashi 2010). Different mechanisms underlie these negative effects, for example, inequality lowers trust and perceived fairness of a society, which in turn reduce happiness (Oishi et al. 2011). Many governments redistribute income with the attempts to reduce inequality (Alesina et al. 2004). While these efforts are crucial for societies, they often require changes in public policies and economic structures that are beyond individuals' reach, and their effects take time to unfold. Thus, it is important to seek out strategies that individuals can adopt to protect themselves from the impact of income inequality. To this end, we examine how *reminding* people about their possessions may play a role. The key insight of our findings is that reminding people of a single best possession, rather than a larger number of possessions, that they own can mitigate the negative impact of income inequality on subjective well-being.

Income inequality has been shown to increase conspicuous consumption because people want to reduce the gap between what they have and what others have (Christen and Morgan 2005; Jaikumar and Sarin 2015; cf. Ordabayeva and Chandon 2010). However, how these *acquired* consumptions in turn influence well-being at a given level of income inequality is unclear. On one hand, research generally finds that material possessions, compared to other resources such as time (Mogilner 2010) or experiences (Gilovich et al. 2015), have a relatively weak impact on subjective well-being and happiness. On the other hand, material possessions have also been shown to successfully compensate people from threats and aversions (Gao et al. 2009; Reimann et al. 2017). Thus, we explore *when* material possessions can be used to mitigate the negative impact of income inequality on subjective well-being.

Importantly, rather than examining acquisition of material goods, we examine the mindsets consumers can adopt when thinking about possessions they already acquired. This approach is important because while it can be costly to acquire new possessions and potentially lead to overspending (Christen and Morgan 2005), it is much easier for consumers to change the way they think about acquired possessions. In particular, we examine two mindsets. Consumers may focus on the quantity of their possessions and thereby think about *all the things* they own; alternatively, they may focus on the quality of their possessions and thereby think about the *best or favorite thing* they own. These two mindsets may have differential influence on the extent to which income inequality impacts subjective well-being.

To elaborate, economic theory posits that the products a consumer purchases reflect the maximum utility within her budget constraints (Samuelson 1938). In many product categories, such as clothing, accessories, books, consumers often own a large number of items. Thus, reminding them of all their possessions may make salient the abundance of resources, and hence buffer them from the negative impact of inequality. On the other hand, consumers' favorite possessions are often associated with personal memories and social relationships (Kleine and Baker 2004; Price et al. 2000; Wallendorf and Arnould 1988). Thus, a favorite possession is unique to the consumer and incomparable with other people's possessions. Thus,

reminding consumers of a favorite possession may reduce their attention to the comparison and potential gap between what they own and what others own. This may in turn reduce the negative impact of inequality due to social comparison. Therefore, it is plausible that either approach can be effective.

In three studies, we test the *interactive* effects of income inequality and consumers' focus on possessions (i.e. all possessions or a favorite possession) on subjective well-being. Participants in the first two studies come from the same country (United States), thus, rather than using a regional-level income inequality measure (e.g. GINI coefficient), we focus on consumers' *perceived* income inequality. Indeed, perceived inequality may not confirm with actual inequality. Thus, in the first study, we also validate whether perceived income inequality negatively impacts subjective well-being.

## Study 1: Do Reminders of Material Possessions Help?

The objective of this study is twofold. First, we test whether perceived income inequality indeed negatively impacts people's subjective well-being. Second, we test whether reminding people of their possessions, with a focus on either all possessions or a favorite possession, can mitigate this negative impact.

### Method

Participants ( $N=367$ ) completed a 3 (writing task: all possessions, favorite possession, control) by perceived inequality (continuous) study. Because it is infeasible to ask participants to recall all the possessions they own, in this and all other studies, we asked participants in the all-possession condition to write about all the possessions they purchased within a time period and a product category. Specifically, those in the all-possession [favorite-possession] condition wrote about all the shirts [the favorite shirt] they purchased in the past five months, whereas those in the control condition wrote about their morning routines. Afterward, participants reported their subjective well-being (Diener et al. 1985,  $\alpha > .80$  in all studies). Then, they completed a series of filler questions, and reported perceived inequality on a one-item scale ("To what extent do you agree or disagree with the following statement: income inequality exists in my country", 1 = "strongly disagree", 7 = "strongly agree").

### Results

Perceived inequality did not differ across writing task conditions ( $F(2,364) < 1$ , all  $ps > .6$ ). Thus, we regressed subjective well-being on the dummy coded all-possession and favorite-possession conditions (keeping control as the omitted variable), perceived inequality (standardized), all X inequality interaction, and favorite X inequality interaction. Results yielded a negative main effect of perceived inequality ( $\beta = -.31$ ,  $p = .01$ ), qualified by a favorite X inequality interaction ( $\beta = .34$ ,  $p < .07$ ), and no other significant effect. We analyzed the slope of perceived inequality in each condition. Results showed that perceived inequality had a significant negative impact on subjective well-being in the control condition ( $\beta = -.31$ ,  $p = .01$ ), consistent with the findings from prior research using national- or state-level income inequality (Alesina et al. 2004; Oishi et al. 2011). The slope of perceived inequality was also negative, but became less significant, in the all-possession condition ( $\beta = -.19$ ,  $p = .19$ ). More importantly, the slope became non-significant and positive in direc-

tion in the favorite-possession condition ( $\beta=.03, p>.8$ ), suggesting the negative impact of perceived income inequality was mitigated.

### Discussion

Results of this study provide preliminary evidence that reminding people of a favorite possession, relative to all possessions, is an effective way to mitigate the negative impact of income inequality on subjective well-being. Nonetheless, because the negative slope in the all-possession condition is only near-significant, it is unclear to what extent reminding people of all possessions may also reduce the negative impact. One possible reason for the lack of effect in the all-possession condition may be that the product category in this study (shirts) is too narrow. Thus, recalling all the shirts one has purchased in the past 5 months does not really make salient the amount of material possessions and resources one has. To address this issue and to better understand the effects of the two mindsets, we replicate the all-possession and favorite-possession conditions using a broader product category in the next study.

### Study 2: The Effect of Recalling a Favorite vs. All Possession(s)

The objective of this study is to obtain further evidence that recalling a favorite, versus all possession(s), can mitigate the negative impact of income inequality on subjective well-being. To ensure that the weak effect of recalling all possessions in the previous study is not due to the narrow product category, we use a more inclusive category, clothing items, in this study.

### Methods

Participants ( $N=182$ ) completed a 2 (writing task: all possessions, favorite possession) by perceived inequality (continuous) study. Those in the all-possession [favorite-possession] condition wrote about all the clothing items [the favorite clothing item] they purchased in the past five months. They then reported subjective well-being, completed a series of filler questions, and reported perceived inequality, using the same scales as in study 1.

### Results

Perceived income inequality did not differ across writing task conditions ( $F(1,180)<1, p>.6$ ). We regressed subjective well-being on writing task, perceived inequality (standardized), and their interaction. Results yielded a significant writing task main effect ( $\beta=.25, p=.03$ , favorite possession = 1, all possessions = -1), qualified by a writing task by inequality interaction ( $\beta=.25, p=.03$ ), and no other significant effect. Slope analyses showed that income inequality had a significant negative effect on subjective well-being in the all-possession condition ( $\beta=-.33, p=.04$ ). Thus, even with a broader product category, reminding consumers of the many possessions they own did not mitigate the negative impact of income inequality. In contrast, the slope of income inequality became non-significant and positive in direction in the favorite-possession condition ( $\beta=.16, p>.3$ ). This result replicated the effect of recalling a favorite possession observed in the previous study.

### Discussion

Taken together, studies 1 and 2 suggest that reminding people of a single favorite possession (vs. many possessions) is an effective way to mitigate the negative impact of income inequality on subjective well-being. This strategy is important given that income inequality is rising in many countries (Atkinson et al. 2011). Thus, an important next step for our research is to test the generalizability of our proposed strategy in a larger sample across countries. To this end, in the next study, we replicate our effects using a sample of consumers across eight different countries.

### Study 3: Cross-country Generalizability of Our

#### Approach

Different countries vary in their national levels of subjective well-being, income inequality, as well as materialistic values (Ger and Belk 1996). These variations raise the possibility that the observed effects of reminding people of their material possessions may not hold in a broader population. To test the robustness and generalizability of our effects, we conducted a cross-country study in eight different countries, including China, India, Pakistan, U.K., Spain, Russia, Mexico, and Chile. The selected countries vary in their geographic locations, GDPs, languages, population sizes, and national income inequality levels (measured by the GINI coefficients). We balanced the sample size in each country.

#### Method

Participants in the eight selected countries participated in an online study using the Qualtrics survey platform. The study had the same basic design as study 2 – a 2 (writing task: all possessions, favorite possession) by income inequality design. Due to language difference across countries, the survey questionnaire was translated to the main language spoken in each country by a professional translation team. Moreover, because consumers in different countries might have different shopping habits, we further broadened the criteria of possessions in the writing task. Specifically, participants in the all-possession [favorite-possession] condition wrote about all the clothing items [the favorite clothing item] they purchased in the *past one year*. Afterward, participants reported subjective well-being, completed a series of filler questions and demographic information, as in previous studies. Finally, to be consistent with the previous studies, we measured individual-level perceived income inequality using the same scale. We included only participants at the age ranged from 18 to 70 (98% of the total sample) in our analyses, resulting a sample from 1169 qualified participants from eight different countries.

#### Results

*Individual Level Analyses.* Participants in different countries varied in their baseline-level perceived income inequality ( $F(7,1161)=118.88, p<.001$ ) and subjective well-being ( $F(7,1161)=40.47, p<.001$ ). Thus, we controlled for dummy coded country variables as covariates (Mexico was the omitted country). We first tested the effect of the writing task manipulation on perceived income inequality, and the result showed null effect ( $p>.3$ ). Thus, we regressed subjective well-being on writing task (favorite-possession = 1, all-possession = -1), perceived inequality (standardized) and their interaction, controlling for country dummy variables. Results of the analyses yielded a marginal interaction effect of writing task and perceived inequality ( $\beta=.06, p=.09$ ), and no other significant effect. Slope analyses showed that perceived inequality negatively impacted subjective well-being in the all-possession condition ( $\beta=-.12, p=.05$ ). However, this effect became non-significant and positive in direction in the favorite-possession condition ( $\beta=.01, p=.9$ ). Thus, results from a sample of consumers across eight different countries replicated the effects observed in the previous studies, using participants from the United States. Reminding consumers of a favorite possession (vs. all possessions) effectively reduces the negative impact of income inequality on subjective well-being.

*National Level Analyses.* Insofar we have only tested our effects with perceived income inequality. In this study, we are also interested in testing whether our proposed strategy helps reduce the negative impact of *actual* income inequality on subjective well-being. To do so, we relied on the GINI coefficient as an indicator of the actual income inequality of a country. However, because the years and methods used to calculate the GINI coefficients varied by countries

(Oishi et al. 2011), we did not treat the GINI coefficients as a continuous variable. Instead, we categorized the eight countries in our sample into two inequality levels – high versus low – based on their GINI coefficients (high inequality countries: Russia, China, Chile, Mexico; low inequality countries: Pakistan, U.K., India, Spain).

We first tested whether participants in the high (vs. low) inequality countries varied in their subjective well-being. Indeed, those in high inequality countries ( $M=4.60$ ) had lower subjective well-being than those in low inequality countries ( $M=4.87$ ,  $p=.001$ ). Next, we conducted an ANOVA on subjective well-being using inequality level (low=-1, high=1) and writing task (all possessions=-1, favorite possession=1) as factors. Because different countries have different baseline happiness, we also controlled for country-level happiness as a covariate (adopted from the World Happiness Report 2017; results did not change without the covariate). Results yielded a significant interaction ( $F(1,1164)=4.35$ ,  $p=.04$ ). Simple effect analyses showed that participants who lived in one of the high versus low inequality countries reported lower subjective well-being if they were in the all-possessions writing task condition ( $M_{\text{high}}=4.55$ ,  $M_{\text{low}}=4.95$ ,  $p<.001$ ). However, the difference in subjective well-being became non-significant if they were in the favorite-possession condition ( $M_{\text{high}}=4.67$ ,  $M_{\text{low}}=4.73$ ,  $p>.5$ ). Thus, the difference in subjective well-being between participants in high- and low-inequality countries was mitigated after participants recalled their favorite possessions. Taken together, we observed consistent effects of our approach (i.e. reminding consumers of their favorite possessions) on the impact of both perceived (individual-level) and actual (country-level) income inequality.

## Conclusion

Our research makes several contributions. First, while prior research finds a relatively weak effect of material purchases on consumers' well-being (Gilovich et al. 2015; Mogilner 2010), we show that the way in which consumers *think about* their material possessions can influence their subjective well-being, by mitigating the negative impact of external factors, such as income inequality. Second, we identify a simple and mundane strategy that people can adopt to reduce the negative effect of income inequality. Rather than keeping up with the Jones (through conspicuous consumption), which may lead to a vicious cycle of overconsumption and debts (Christen and Morgan 2005), consumers can simply focus on the best thing they have. Third, we show generalizability of our proposed strategy using a cross-country sample from eight different countries. Prompting consumers to think about a favorite possession (vs. all possessions) mitigates the negative impact of both perceived and national-level income inequality on subjective well-being. Thus, our findings contribute to improving consumers' well-being and understanding the relationship between possessions, inequality, and well-being.

# Doing Worse but Feeling Better: Consequences of Collective Choice

Nuno Jose Lopes, University of Navarra, Spain  
Elena Reutskaja, IESE Business School, Spain

## EXTENDED ABSTRACT

### Conceptualization

Consumer decisions are often made together with other people (Davis 1976). Nonetheless, marketing scholars typically investigate consumers as independent individuals who chose alone, leaving joint decisions under-researched (Bagozzi 2012). However, choosing with others differs substantially from choosing alone. This article compares the implications on decision outcome and emotions felt when either an individual or a group of two people chose from a set with many alternatives.

Group decision is not the averaging of its members (Zajonc Wolosin, and Wolosin 1972). When several people choose together, they frequently have different tastes and goals, which can lead them to disagreement. Despite this latent conflict, groups are typically still able to reach a decision agreement. This is possible because collective consumer decision is fundamentally cooperative in nature (Fisher, Grégoire, and Murray 2011), which implies that conflicting preferences are overcome through self-sacrifice and mutual concessions (Corfman and Lehman 1987). Therefore, knowing the consequences of cooperation and self-sacrifice on the value of the alternative selected constitutes one of the contributions of the current article.

Iyengar, Wells, and Schwartz (2006) demonstrated that individuals who do better in taxing decisions can actually feel worse. However, it is unclear whether these effects are also extended to collective choice. On one hand, research on individual decision-making suggests that engaging in a difficult selection can lead to the experience of negative emotions (Bettman, Luce, and Payne 1998). Given that group decision might imply contradictory preferences which can degenerate into affective conflict (Amason 1996), groups might experience even stronger negative emotions than individuals. Nevertheless, groups' cooperative mindset and the fact that human beings have a tendency to enjoy sharing an activity with others (Baumeister and Leary 1995; Raghunathan and Corfman 2006) could elicit positive emotions in dyadic decision. Which of these drivers has a stronger influence on dyadic emotions experienced during choice is still unknown in the consumer literature and is the other goal of the current article.

### Method

Study 1 aimed to compare the subjective value of the alternative selected by individuals and dyads, and assess the magnitude of sacrifice in collective decisions. Participants were randomly assigned to the individual or collective condition, between-subjects. They were 60 individuals (63% women) and 41 dyads (61% women; dyad members did not know each other). Every choice set had 30 alternatives of the same category (poster, chocolate, ice cream, and desk lamp; random assignment and order). Procedure: first, each participant alone had to evaluate every alternative in the choice set (-5 = "I don't like it at all" to +5 = "I like it very much"). Afterwards, participants ticked which alternatives they would consider from the choice set, followed by the selection of the favorite alternative. Finally, a short questionnaire was filled. This procedure was done three times. In the collective condition, both the consideration and the selection stages were done by dyad members together.

The goal of Study 2 was to compare the valence of the dominant emotion experienced by individuals and dyads while making a

taxing decision such as choosing from a large choice set. It had the participation of 42 individuals (36% women) and 44 dyads (dyad members knew each other; 51% women), between-subjects. Movies was the only category. Procedure: each participant alone started by evaluating every alternative on the same scale as study 1. Then, to set participants' emotions to neutrality they watched a 4-minutes documentary. Afterwards, from a choice set with 30 movies participants had to select their favorite to watch briefly in the end. This was done either individually or in dyads. Then, a short questionnaire was filled. The selection and questionnaire tasks were repeated six times. Finally, one of the movies selected as favorite was watched for 5-minutes.

Along study 2, the emotions of each participant were recorded every 35 milliseconds with an automated facial recognition software. This allowed to know the intensity (0 = minimum to 100 = maximum) of each of the six basic emotions: enjoyment, sadness, anger, disgust, fear, and surprise (Ekman 1992). This information was then aggregated in two-seconds' intervals and the emotion with the highest average intensity along the interval was considered the dominant one. Then, the dominant valence was coded as positive if the strongest emotion was enjoyment, or negative if it was anger, sadness, disgust, or fear. Surprise was out of analysis as the literature still debates its valence.

### Major Findings

Study 1 showed that dyads selected an item with an inferior value in comparison to individuals ( $M_{\text{dyad}} = 3.51$ ,  $SD_{\text{dyad}} = 1.26$ ;  $M_{\text{ind.}} = 4.50$ ,  $SD_{\text{ind.}} = 0.84$ ;  $\chi^2(1) = 63.85$ ,  $p < .0001$ ). This difference was the consequence of dyad members giving up her top-rated alternative, which implied an average sacrifice of 1.10 value points ( $SD_{\text{dyad}} = 1.01$ ). Nonetheless, dyads were not less satisfied with the option selected comparatively to individuals ( $M_{\text{dyad}} = 7.78$ ,  $SD_{\text{dyad}} = 1.76$ ;  $M_{\text{ind.}} = 7.97$ ,  $SD_{\text{ind.}} = 1.80$ ;  $\chi^2(1) = 0.27$ ,  $p = .602$ ). Moreover, 69% of the dyads behaved very cooperatively as in at least 2/3 of their selections (a) both dyad members conceded the same or (b) they engaged in sequential reciprocity ("You win now, I win next").

Besides replicating study 1 findings, study 2 revealed that whereas individuals' selection process was dominated by negative emotions (73% of the two-seconds intervals), dyadic selection, on the contrary, was dominated by positive emotion (45% of the intervals). Proportion tests confirmed the differences between individuals and dyads both for the negative ( $z = 44.85$ ,  $p < .0001$ ) and the positive ( $z = -34.22$ ,  $p < .0001$ ) dominant emotions. Moreover, study 2 showed that while choosing, dyad members experienced a level of enjoyment almost five times stronger than that of individuals ( $M_{\text{dyad members}} = 26.13$ ,  $SD_{\text{dyad members}} = 15.44$ ;  $M_{\text{ind.}} = 5.67$ ,  $SD_{\text{ind.}} = 8.34$ ;  $\chi^2(1) = 46.61$ ,  $p < .0001$ ). Level of dyad familiarity had no effect.

This article demonstrated that although dyads *do worse* in terms of selection outcome, they do not report a lower level of satisfaction. Furthermore, collective consumers *feel better* as they enjoy the selection process much more.

# Brand Movement

Gregorio Fuschillo, Kedge Business School, France

Jon Bertilsson, Lund University, Sweden

Andrea Lucarelli, Lund University, Sweden

## EXTENDED ABSTRACT

For three decades, consumer research has paid a great deal of attention to the role of brands in fostering social formations such as subcultures, communities, and publics. Some of these formations manipulate elements of consumer culture for the sake of ideological and cultural changes. In this regard, consumers organize themselves in movements, namely anti-brand movements, which overtly criticize brands. Following these streams of research, this article introduces the notion of *brand movement* to conceptualize current phenomena whereby consumers-citizens turn to brands to produce a political change in society. In turn, brands have the power to channel, mobilize, and empower these consumers-citizens to gain more political legitimation and success in social territory. We define brand movement as a *brand-related platform that propels the evolution and dissemination of political views, ideas, and actions*.

Consumer-related social formations are a key phenomenon of current consumer societies (Jenkins, 2006; Kozinets, and Handelman, 2004). Studies in consumer culture show the way in which consumption nourishes subcultures, communities, tribes, collaborative networks, collectives, movements, activism, and publics of consumers (Arvidsson and Caliandro, 2016; Cova et al., 2007; Kozinets, 2001; Scaraboto and Fischer, 2013; Schouten and McAlexander, 1995; Thompson et al., 2006; Weijo et al., 2018). Brands are at the core of these sociocultural phenomena (Luedicke et al., 2010; Muniz and O'Guinn, 2001; Schau et al., 2009). More specifically, the strong connection of consumers to their brands leads to the rise of social groups of devotees turning the brand into a cult object (Belk and Tumbat, 2005; Muniz and Schau, 2005). However, consumers can also unite against a brand when they despise it (Izberk-Bilgin, 2012; Kozinets, and Handelman, 2004). While most of the research in consumer culture has focused especially on those brand-related social formations emerging in opposition to the society as a whole, as an alternative to it, or both (Kozinets, 2001; Muniz and O'Guinn, 2001; Schouten and McAlexander, 1995), we still know little about those brand-related social movements that gain momentum in their interaction with the current society.

In their pioneering study on brand-related social movements, Kozinets and Handelman (2004) provide evidence of alternative social formations in consumer societies, specifically that they more politically active than communal formations as tribes and publics (Arvidsson and Caliandro, 2016; Cova et al., 2007). However, their analysis focuses especially on anti-brand movements, telling little about those emerging around consumers' strong connection brands. As noted in social movement theory, social movements arise especially from shared common beliefs, but also from non-traditional political actions aimed at redressing the power gap between underdog individuals and powerful elites (Melucci, 1989). In cultural studies, these beliefs mostly manifest themselves in the form of a textual brand – e.g. celebrities – that consumers use to resist dominant ideologies, develop a sense of belonging among them, and gain social territory (Fiske, 1989; Jenkins, 1992; Kozinets, 2001). Drawing from this broader theoretical framework, this study aims at investigating the role that textual brands play in political social movements in today's consumer societies.

The present study explores Beppe Grillo's movement, which became later known by its current name of the Five Star Movement.

Beppe Grillo is a textual brand as he is an Italian celebrity – a humorist – with his community of fans gathered around his blog – *beppegrillo.it*. Founded officially in 2009, with the help of web strategist Gianroberto Casaleggio, around Beppe Grillo and his followers' proposals to adopt social networks (i.e. Meetup) to communicate and coordinate local meetings, Five Star Movement is today the biggest political party in Italy (election 2018), with mayors of the party in large cities such as Rome and Turin. We collected data through the netnographic method (Kozinets, 2002) by analyzing online discourses - TV shows, journal articles, press reviews, social networks, and consumer generated content. The amount of data totaled 148 hours of video and about 200 pages of visual and textual data.

Based on Melucci's theory of new social movements, we identify four main markers that constitute the empirical grounding for brand movement. These are “*challenging administrative logic on symbolic grounds*”, “*acting political, changing the social*”, “*functioning as daily socio-technical networking*” and “*consciousness of living in a global (consumer) society*”.

The conceptualization of brand movement offers an understanding of empirical phenomena under analysis in which brands allow citizens-consumer to participate in political processes; this is in order to gain more space and power in the society, instead of contrasting/resisting market logic or using/engaging with the market in order to gain socio-political power. In doing so, the article sheds new light on the entanglement between brands and consumer activism (Kozinets 2002; Kozinets & Handelman 2004). In fact, rather than emphasizing the role of consumer activism in resisting the market and/or its global brands (Kozinets & Handelman 2004; Thompson and Arsel, 2004; Thompson et al., 2006; Weijo et al., 2018), this study illustrates that brand-related activism may be used to attain real, substantial political and democratic ends. All in all, via brand movement, rather than providing consumers with support for social belonging (Muñiz & O'Guinn 2001; Schouten & McAlexander 1995), or a means of self-promotion (Arvidsson & Caliandro 2016), brands may offer consumers the power to achieve actual political goals. This is because brand movements are able to connect with, tap into, soak up and integrate values and ideologies from different worlds of worth into a novel-pragmatic configuration of political ideas in order to challenge the existing political landscape.

# Cultivating a Network of Trust: Exploring the Trust Building Agency of Objects in Home Sharing

Marian Makkar, Auckland University of Technology, New Zealand

Drew Frankin, Auckland University of Technology, New Zealand

## EXTENDED ABSTRACT

With trust so central to the function and success of home sharing, this research proposes that trust is best established through interplay of trust entities. However, apart from literature detailing trust in platform security (Lu, Wang, and Hayes, 2012), in the seller (Ert, Fleischer, and Magen, 2016), or in reviews (Filieri, 2016), little is understood about how trust is built in home sharing. In order to offer a more refined understanding of trust, we explore the sources of rational, affective and contextual trust and suggest the value in tracing objects as a key property of trust building in home sharing. We review this emergence through the lens of consumer culture perspectives (Arnould and Thompson, 2005) embedded in organizational trust literature (Korsgaard, Brower, and Lester, 2015) to assist in providing a vocabulary that can serve as an organizing framework. To understand how trust is built in home sharing networks (Airbnb), this study adopts interpretivist research practices. This approach enables an in-depth understanding of participants' Airbnb experiences (shared with hosts or full unit rentals) specifically relating to trust in engaging in the network. This study is based on a three-year multi-sited ethnography of Airbnb consumption experiences that includes netnographic data (Kozinets, 2010) of Airbnb online communities in New Zealand, interviews with guests and hosts and field observation.

Previous research suggests that attributions of trust are influenced by rational, affective and contextual factors (Korsgaard et al., 2015). Johnson and Grayson (2005) propose rational trust as the confidence or willingness to rely on a service producer who is competent and reliable. Rational trust has also been posed to include evaluations of satisfaction (Baxter, 2012; Ganesan, 1994), communication (Doney, Barry, and Abratt, 2007), integrity (Mayer, Davis, and Schoorman, 1995), value co-creation (Franklin and Marshall, 2016) and transparency (Eggert and Helm, 2003). Affective trust represents the non-calculative, emotional, or empathetic, element of trust within a relationship. This kind of relationship has been described as the mood felt by the parties and the strong mutual feeling, or shared values, upon which their relationship is based (Sekhon, Roy, Shergill, and Pritchard, 2013). This functions as a projection of the image that the other party will exercise benevolence toward the other if presented with an opportunity to do so (Sirdeshmukh, Singh, and Sabol, 2002). Lewicki and Bunker (1996) describe contextual trust as manifesting within relationships that are embedded in a broader context, such as organizational membership or shared community, as the actors share certain characteristics, thus signaling trust.

This study predicts that building trust in home sharing may involve processes of pre-objectification of material objects (the home) through interactions with the digital platforms (home photos, reviews and profile photos) (Ferreira and Scaraboto, 2016), thus enhancing other sources of trust.

By considering the agency of objects in building trust in home sharing (Latour, 2004), we offer a broader view of seven well-established dimensions of dyadic trust in the existing trust literature. These dimensions include competence, communication, transparency, value co-creation, shared values, integrity and benevolence.

Airbnb guests initially consider attributions of competence in their Airbnb hosts through their digital profiles prior to making contact. These include star ratings, reviews and badges such as Superhost titles. Attributions of competence continue during communica-

tion between host and guest, but are also engendered in the materials of the home such as mattress and duvet quality:

They can see our reviews. They can see what the people in Bordeaux and Saint Sebastien said about us as guests whether we're good, clean. They can say no to us if they didn't want to have us. Without positive reviews I don't think they can trust us. (Karen, guest).

Communication and transparency are important dimensions of trust building in services and are enacted by agents, or boundary spanners, during the service encounter (Anderson and Narus, 1990). Yet in home sharing, these activities are manifest even before an agreement to stay, or encounter, takes place.

To co-create is to jointly-configure a customer solution and is more than simply transactional in nature. This activity results in a more customized solution and, by extension, trusting disposition between parties. Co-created value in home sharing is realized through homely practices such as having dinner with the host:

The key to her home rather than a hotel was important. You go in and you use the key to open YOUR apartment and this is where YOU'RE living. You go in and you feel like you can do the groceries." (Karen, guest).

Shared values also contribute to trust building in home sharing. By unraveling the Airbnb network, it became apparent that shared values are realized through familiarity with the sharing economy world. Shared values may even be encoded in the home appliances or design that creates closeness with the other:

I don't need to meet the host but like to feel welcome and really it's the little extras that count... I love quirky decor and don't want to stay in someplace that lacks a soul (guest, online).

Integrity and benevolence are other dimensions of trust that are delivered through practices of unspoken rules of hospitality, respect of home and house rules and the needs of the other. Homely material objects, such as family photos on the wall, can also signify decency, sincerity and the familial care and protection by the other. Benevolence, or acts of service outside of profit motive, are discovered through the act of gift-giving and the meanings of the gifts (Sherry Jr, 1983) that adhere to hospitality culture:

"I've got two necklaces from Chinese guests and one gave me a little book and one gave us a little sculpture, like a little carving, so just really little things but it's a nice gesture." (Angie, host).

Within an increasingly networked and fluid society, where actors fluctuate between physical to digital platforms and devices, this research demonstrates that objects feature as a key agent of trust building in home sharing.

# “Yes, I Can” or “No, I Can’t” – Effect of Extraneous Affirmation- and Negation-Evoking Contexts on Brand Recall Memory: The Role of Semantic Activations

Sudipta Mandal, Indian Institute of Management, Ahmedabad, India  
Arvind Sahay, Indian Institute of Management, Ahmedabad, India  
Sanjeev Tripathi, Indian Institute of Management, Indore, India

## EXTENDED ABSTRACT

In the real world, consumers often draw up a shopping list by recalling brand names. Lynch Jr and Srull (1982) classified such choice options as “memory-based”. If consumers cannot recall a brand, they are less likely to consider it, and therefore, purchase it. Consequently, factors that affect memory-based choices are important practically and theoretically. Our research focuses on how (i.e., the phenomenon) and why (i.e., the psychological mechanism) the recall of brands could be impacted by extraneous brand placement contexts that evoke a negation versus an affirmation (such as a “NO” versus a “YES”).

Our research is the first to show that an entirely unrelated negation (vs. affirmation) in a brand’s placement context leads to impaired brand recall memory. The principal contribution of our work is the investigation of the underlying mechanism. We demonstrate that negations spontaneously generate negation-related semantic associations, which through a spreading activation mechanism (Collins and Loftus 1975) influences brand recall memory. Specifically, we show that the nature of these negation-related semantically activated concepts, decreases consumers’ “general judgments of importance” toward discrete consumer issues, which in turn impairs brand recall memory.

Extant research has shown that negation is associated with cognitive inhibition, and latencies (Carpenter and Just 1975; Giora et al. 2007; Kaup and Zwaan 2003). A negation operator prevents the activation of the core concept or schema being negated (MacDonald and Just 1989).

Research has also shown the importance of context factors in brand placement effects (Newell, Salmon, and Chang 2006; Van Reijmersdal, Smit, and Neijens 2010). For example, there is an evidence of a spill-over effect induced by the context towards conventional advertising, as reflected through consumers’ emotions (e.g., involvement, liking, feelings) (Pavelchak, Antil, and Munch 1988; Moorman, Neijens, and Smit 2005).

We hypothesize that concepts that are coexistent with an extraneous negation are susceptible to spill-over inhibitory effects of negation. Thus,

*Hypothesis 1* Mere association of any brand-related information, with an extraneous context or episode that elicits a negated response, impairs the recall of that brand as compared to an extraneous context or episode that elicits an affirmative response.

Often “motivation” determines how people react to their environment when processing information, and formulating attitudinal/behavioural responses (Darke, Chattopadhyay, and Ashworth 2006), we hypothesize that when consumers are motivated to remember, the effect in H1 should disappear. Thus,

*Hypothesis 2* When consumers are motivated to remember, the brand recall should be almost similar under both extraneous negation and affirmation contexts.

Furthermore, evidence of brain mechanisms linking language and action, is indicative of “embodied cognition” (Niedenthal 2007). One facet of embodiment is the fact that motor actions impact sub-

jective feelings (Adelmann and Zajonc 1989; Semin and Smith 2002). Thus,

*Hypothesis 3* Mere association of any brand-related information, with an extraneous horizontal shaking of the head (embodied “No”) should impair the recall memory of that brand as compared to an extraneous vertical nodding of the head (embodied “Yes”).

Fundamentally, it is possible that the experience from a source concept increases the accessibility in memory of specific semantic concepts that such experiences exemplify. These concepts may then spread over to others, based on associative network models (“spreading semantic activation”, Collins and Loftus 1975). Consequently, we hypothesize that, negation, results in spreading of concepts semantically related to negation. Such concepts trigger exclusion of the negated and its associated entities from an individual’s immediate purview of consideration. Spreading semantic activation coupled with the aforementioned act of exclusion, reduces the importance of not only the negated entity and anything associated with it, but also induces generally lower judgments of importance in an individual’s mind. Being cognitive misers, humans disregard the unimportant, and forget under negation. Thus,

*Hypothesis 4* The accessibility of negation-related semantic concepts should mediate the effect of negation on the judgment of importance.

*Hypothesis 5* Higher judgments of importance lead to higher brand recall memory compared to lower judgments of importance.

We conducted five laboratory experiments to validate our hypotheses, all of which were supported. Experiment 1 shows that an extraneous negation (vis-à-vis an extraneous affirmation) elicited by a brand’s placement context impairs subsequent brand recall memory (H1). Experiment 2 shows that consumers’ motivation to remember moderates the effect observed in H1 (H2). Experiment 3 provides convergent evidence from an embodied cognition perspective (H3). Experiment 4 shows that accessibility of negation-related semantic concepts mediate the effects of explicit negation on the judgment of importance (H4). Finally, Experiment 5 shows that higher judgments of importance lead to higher brand recall compared to lower judgments of importance (H5).

The principal theoretical contribution of our work is in investigating the underlying mechanism leading to extraneous negation-induced forgetting. Moreover, it is possibly the first research that demonstrates, both semantically and through embodiment, that an extraneous affirmation/negation can impact memory. A fundamental practical implication for brand managers is to decide what type of programs/context they would like to use to advertise/promote their brands. Managers need to appreciate that negation-inducing contexts could potentially adversely impact the brand recall of their brands and consequently their revenues.

# Linguistic Antecedents of Anthropomorphism

N. Alican Mecit, HEC Paris, France

Tina M. Lowrey, HEC Paris, France

L. J. Shrum, HEC Paris, France

## EXTENDED ABSTRACT

In consumer research, humanlike form has been regarded as the prerequisite for anthropomorphism (Hur, Koo, and Hofmann, 2015; Kim, Peng Chen, and Zhang, 2016). Given that activation of knowledge structures about humans and nonhumans and their application to a nonhuman target determines the extent to which humanlike qualities are attributed to the target (Epley, Waytz, and Cacioppo 2007), we argue that humanlike form is not essential for consumers to anthropomorphize nonhuman agents, because even in the absence of humanlike characteristics, people may continue to anthropomorphize, as some languages make their speakers focus on the similarities, rather than the differences, between humans and nonhumans. Recent empirical evidence also shows that whether the language of a given country has gendered pronouns or not is a strong predictor of gender equality in that country (Prewitt-Freilino, Caswell, and Laakso 2012). In English, not only are there different pronouns for male (he) and female (she), but English also separates humans (he and she) from non-humans (it).

Although most languages distinguish grammatically between humans and nonhumans, some languages (e.g., French, Turkish), do not make these distinctions. Given that language shapes thought (Whorf 1952), we propose that (1) native speakers of these languages are more likely to attribute human qualities to nonhuman agents (i.e., anthropomorphize) than those whose native language separates humans from nonhumans, and that (2) native speakers of languages lacking differential treatment implicitly consider linguistic cues as characteristics of the anthropomorphized entity.

To test our hypotheses, we first conducted a pilot study with participants ( $n = 41$ ) whose native language was either English or Turkish. We administered the individual differences in anthropomorphism questionnaire (Waytz, Cacioppo, and Epley 2010) in English in both conditions. Consistent with our expectation, native Turkish speakers anthropomorphized more than did native English speakers.

In study 1 ( $n = 225$ ), to address concerns that answering questions in a second language may affect responses (e.g., anxiety, MacIntyre and Gardner 1994), we administered the same anthropomorphism scale to either native French-speaking participants or native English-speaking participants, and also manipulated whether native French-speaking participants answered in French or English. Data from 17 participants who failed an attention check were excluded from analyses. As expected, native French speakers scored higher on the anthropomorphism scale than did English speakers independent of the language of administration. French participants who answered the survey in English did not differ from French participants who answered the survey in French.

In study 2 we addressed issues of causality by manipulating the pronoun categories of native English speakers on MTurk ( $n = 120$ ) through a learning task (Roberson, et al. 2005). Data from 13 participants who failed to follow the instructions were excluded from analyses. In the learning task, participants rewrote 60 sentences by replacing the underlined noun with a pronoun. In the control group, participants replaced the nouns with regular pronouns (he/she/it), but in the treatment we asked participants not to use "it." Instead, like French, we asked them to use either "he" or "she," depending on the arbitrary gender indicated in parentheses next to the underlined noun. Participants then completed the anthropomorphism scale. As

expected, participants in the treatment group who used pronouns like a native French speaker anthropomorphized more than did the control group who used all English third-person singular pronouns (he/she/it).

In study 3, we tested whether native speakers of languages that do not distinguish grammatically between humans and nonhumans implicitly consider linguistic cues such as the grammatical gender as characteristics of the anthropomorphized entity. In French, each noun has a specific article that indicates the grammatical gender of the noun: le (masculine) and la (feminine). To test our hypothesis, we identified a nonhuman noun (cache), which can take either the feminine or the masculine article. We manipulated the name of a fashion brand in an ad as "le cache" or "la cache," and measured brand attitudes of 242 French speakers. The expected gender  $\times$  gendered pronoun was significant. Male participants in the masculine grammatical gender condition evaluated the brand more favorably compared to male participants in the feminine grammatical gender condition. Similarly, female participants in the feminine grammatical gender condition evaluated the brand more favourably compared to female participants in the masculine grammatical gender condition, although the difference was not significant.

These results show that French speakers imbue nonhumans with human characteristics even in the absence of anthropomorphizing visual cues. When reasoning about nonhumans, in this case the brand "le/la cache," native French speakers activate knowledge about humans and apply it to nonhumans, which results in an interplay that is similar to what one can observe between humans.

Overall, we show that humanlike form is not essential for consumers to anthropomorphize nonhuman agents. Native speakers of languages that do not separate humans from nonhumans are more likely to anthropomorphize than those whose native language treats humans and nonhumans differently. We further show that native speakers of languages lacking differential treatment implicitly consider linguistic cues, such as the grammatical gender, as characteristics of the anthropomorphized entity and behave accordingly.

## EXTENDED ABSTRACT

A creative process is “*the sequence of thoughts and actions that lead to a novel, adaptive production*” (Lubart 2001, 295). Narratives of the creative process can enhance the perceived quality of a product and stimulate inferences on the creator’s ability to produce additional high-quality ideas and outputs (Baas et al. 2015; Mourgues et al. 2016), improve empathy between creators and their audiences (Davis 1983; Friestad and Wright 1994), and increase *process transparency* (Buell and Norton 2011; Buell, Kim and Tsay 2017). These narratives can emphasize either the experience of *insight* (Schooler, Fallshore, and Fiore 1995) – the sudden, dream-like, spontaneous and illuminating experience facilitating the emergence of new ideas – or the application of *effort* (Lucas and Nordgren 2015) – the methodical, planned, and rational stage in which ideas are organized and transformed into a new product.

People hold beliefs on how creative products are generated (e.g., Sternberg 1985; Runco and Bahleda 1986; O’Connor, Nemeth and Akutsu 2013), and these beliefs can influence product evaluations due to reliance on stereotypical knowledge and heuristics (Sternberg 1985; Levy, Stroessner, and Dweck 1998). We maintain that an insight-based narrative of the creative process (Rothenberg 1970; Kasof 1995) has greater fit with artistic domains, whereas an effort-based narrative of the creative process has greater fit with scientific domains (Lucas and Nordgren 2015). Because lay beliefs influence evaluations of creative products (Baas et al. 2015; Sternberg 1985), we expect artistic products to receive better evaluations when their creative process is described through insight-based narratives rather than effort-based narratives and that the opposite pattern holds for scientific products.

We also expect experts to be more analytical in processing information and less sensitive to heuristics, to own to a higher extent the meta-cognitive skills necessary to evaluate others’ level of ability (Kruger and Dunning 1999), and to be more receptive towards effort-based narratives of the creative process (Ericsson, Krampe, and Tesch-Romer 1993; Ericsson, Prietula, and Cokely 2007), thus to respond relatively more favorably to information on central and concrete – rather than ephemeral and transient – factors characterizing the creative process. Six studies support the proposed conceptual framework and the existence of optimal narratives for the promotion of artistic and scientific products to different audiences.

Study 1 verified the existence of associations between an insight-based creative process and artistic domains, and between an effort-based creative process and scientific domains. Participants read the descriptions of twelve new successful artistic works and scientific works and rated the extents to which they were the outcome of insight and effort. Each art work received higher insight ratings than effort ratings, and each science work received higher effort ratings than insight ratings. Furthermore, all art works received higher insight ratings than all science works, and all scientific works received higher effort ratings than all art works.

Studies 2A and 2B investigated whether describing a creative process using insight- vs. effort-based narratives affects evaluations of new products in artistic and scientific domains, respectively. Participants in Study 2A read an interview in which a band described the creative process leading to their last song either as insight-based or effort-based. Afterwards, they listened to a 45-second excerpt of the

song. Participants evaluated the song more favorably and were willing to pay more, when it was presented through insight-based (vs. effort-based) narratives. In study 2B we measured intentions to fund a Kickstarter project based on scientific research that was presented through insight- vs. effort-based narratives of the creative process. When it was presented through effort-based narrative, the project was considered (marginally) more likely to reach the fund-raising goal and participants allocated more funds to it than when it was presented through an insight-based narrative.

Studies 3A and 3B replicated studies 2A and 2B but also tested the proposed fit mechanism, as well as the role of expertise, in the artistic and scientific domain, respectively. Participants in Study 3A evaluated the song from Study 2A more favorably and were willing to pay more for it when they read it was the outcome of insight than effort. The perceived fit between the creative process narrative and the image of the creator mediated both effects. In addition, an insight-based creative process produced more favorable evaluations of an artistic product, but this effect was attenuated as recipients’ expertise increased. Participants in Study 3B evaluated the project from Study 2B as (marginally) more likely to reach the fund-raising goal and assigned more funds to it when it was described as effort-based than as insight-based. Also in this case, the perceived fit between the type of creative process and the work mediated both effects. In line with our prediction, expertise did not interact with the type of narrative of the creative process, as both experts and non-experts prefer effort-based narratives. However, the perceived fit between the nature of the creative process and the image of the creator only mediated the effect when participants’ expertise was low to average.

In Study 4, participants read descriptions of a new product presented as either artistic or scientific, and as the outcome of either an insight- or an effort-based creative process. When the product was described as artistic, participants evaluated it more favorably and were willing to pay more for it, if they read it was the outcome of insight rather than of effort. When the product was presented as scientific product, the opposite pattern was observed.

This research clarifies that beliefs on the nature of the creative process depend on the domain of the creative output, and that the most effective communication strategy regarding the creative process leading to a product depends critically on both the nature (scientific or artistic) of the product, and the level of expertise of the audience targeted.

# Believing in and Reacting to Rumors: The Role of Congruity and Nature of Existing Predisposition

Satadruta Mookherjee, Binghamton University State University of New York, USA  
Subimal Chatterjee, Binghamton University State University of New York, USA

## EXTENDED ABSTRACT

### Introduction

The prevalence of rumors is a common phenomenon in today's world and spreading rapidly as more and more consumers adapt to the digital world of the internet and social media. Our research investigates conditions under which consumers treat rumors (unverified information) identical to facts (the same, but verified, information). We investigate to what extent congruent/incongruent information (rumors/facts) about liked/disliked entities (both people and products) affect consumers' belief in that information and the resulting attitude change towards the focal entity.

### Theory

Research suggests that two things happen (almost automatically) when we expose a consumer to a piece of information (fact or rumor) about a focal entity. First, she automatically compares it to her baseline or prior knowledge (Higgins et al. 1977), and this process determines the compatibility or congruity of the information with what she knows and believes (e.g., to what extent the rumor fits with her pre-disposition towards a focal entity; McGuire, 1972). Second, she either accepts the information (fact or rumor) as true or rejects it as false (Allport and Lepkin 1945), and is more likely to act upon it only if she believes the information to be true (Rosnow, Yost, and Esposito 1986).

According to cognitive consistency theories, congruent information about a focal entity elicits positive feelings (Festinger, 1957) and consumers will believe such information automatically (without verification). This line of reasoning suggests that consumers will not distinguish between fact and rumor for congruent information. However, and on the contrary, Borgstede et al. argue that consumers analyze congruent information about a focal entity systematically before acting on it. This is because consumers do not wish to get their hopes up about the focal entity too much (e.g., following a positive rumor about a liked brand/person) only to see it dashed later on (rumor turns out to be false).

Incongruent information about a focal entity, on the other hand, creates surprise by evoking unexpected cognitive challenge (Alden et al. 2000) and motivates the consumer to analyze and resolve the discrepancy (Schutzwohl and Borgstedt 2005). If the information is just a rumor (e.g., negative rumors about a liked entity), then consumers should have less reasons to be tense or worried, and the desire to lessen the tensions associated with incongruity should motivate consumers to distinguish between rumor and fact and act accordingly.

Below, we report a study testing how exposure to congruent/incongruent information about liked/disliked entities may lead consumers to treat rumors as equivalent to fact (e.g. believe the rumor just as much as they believe the fact).

### Participants, Stimuli and Measures

We asked 825 M-Turk workers to think about a fast food restaurant/actor that they liked/disliked very much and indicate how much they liked/disliked the entity (9-point scale, capturing valence and magnitude of predisposition). Next, they read a positive/negative piece of news about the focal entity. The positive (negative) news

about the restaurant/actor described the restaurant using healthy (fatty) ingredients in their food/the actor receiving a prestigious, humanitarian award (arrested for disorderly conduct). We measured how good (bad) they thought the positive (negative) news to be (9-point scale capturing valence and magnitude of information). Finally, the participants in the rumor (fact) condition read that the news was a rumor, unverified by major media outlets (fact, verified by the major news outlets). Thereafter, we measured to what extent participants believe the news (9-point scale), and how their attitude towards the focal restaurant/actor (composite of affect, cognition, and behavior) has changed as a result (9-point scale, with 5.0 or mid-point indicating no change).

### Analysis and Results

We created a congruity variable (congruent/incongruent information) where the congruent (incongruent) conditions matched positive news with a liked (disliked) entity and negative information with a disliked (liked) entity. We ran two ANOVAs, the first for belief and the second for attitude change. The predictors were information exposure (fact/rumor), congruency (congruent/incongruent), and predisposition towards the focal entity (like/dislike). We controlled for (1) magnitude effects (for predisposition and information), (2) the focal entity (person/product and (3) the participant's gender, age, tolerance for inconsistency, and gullibility.

Our first ANOVA found that consumers believe (1) less in rumor than fact ( $M$ 's of 5.44 and 6.35), and (2) less in incongruent than congruent information ( $M$ 's of 5.21 and 6.57). However, a significant information by congruency interaction shows that consumers discriminate between rumor and fact somewhat less for incongruent information ( $M$ 's of 4.89 and 5.52) than congruent information ( $M$ 's of 5.98 and 7.14). The results indicate that consumers do not accept congruent information blindly (just because they fit with what they expect). They appear to carefully process the information to separate fact from rumor, and, in fact, do so more carefully relative to incongruent information.

In our second ANOVA, once we controlled for belief, we found attitude change towards the entity to be similar across rumor and fact ( $M$ 's of 5.24 and 5.41), but more positive following exposure to congruent than incongruent information ( $M$ 's of 5.52 and 5.13). We also found a three-way interaction between the type of information, congruency, and predisposition. The results indicate that, in the case of incongruent information, rumor/fact leads to identical attitude change irrespective of how consumers feel about the entity ( $M$ 's of 5.24 and 5.00 for liked entities and  $M$ 's of 4.94 and 5.35 for disliked entities). However, in the case of congruent information, attitude change for a liked entity is less positive following rumor than fact ( $M$ 's of 6.49 and 7.25) but identical for a disliked entity ( $M$ 's of 4.03 and 3.98).

From a managerial perspective, the key lesson here is to identify when consumers treat a rumor as a fact (e.g., when are they more susceptible to deceptions from the competition). The fact that attitude change following incongruent information about a liked entity is identical for rumor and fact should alert managers to the necessity of inoculating their own consumers against negative competitive messages. On the contrary, given that attitude change following congruent information for a disliked entity is sensitive to the fact/rumor distinction suggests that the company has to be sure about the facts before maligning a competitor's brand to its own audience.

# Priming & Privacy: How Subtle Trust Cues Online Affect Consumer Disclosure and Purchase Intentions

James A. Mourey, DePaul University, USA  
Ari Ezra Waldman, New York Law School, USA

## EXTENDED ABSTRACT

Consumers are quick to say that maintaining privacy in an increasingly digital world is more and more difficult (Pilot). Yet recent research (Mourey) suggests that consumers are more sensitive to subtle cues when they experience a choice as “feeling difficult.” The purpose of the current project is to explore whether the increased feelings of difficulty in maintaining privacy online counterintuitively makes consumers *more* likely to disclose personal information when exposed to subtle cues that prime “trust.” Five studies show that individuals are more likely to disclose highly personal information based on subtle cues of trust including verbal trust primes (Study 1), social network size (Study 2), friends’ online engagement (Study 3), and the verbal and visual fluency of a website’s privacy policy (Study 4), all without their conscious awareness.

## Literature Review

A growing body of research has shown that privacy disclosure decisions are strongly influenced by contextual factors. Consider, for example, observing others sharing private information makes individuals more likely to share, an online “herding effect” (Acquisti et al., 2012; John et al., 2011). These prior projects found that individuals engage in comparative behavior based on the signals of others and suggests that such signals—e.g., social network size, the engagement of others online—implicitly influence behavior.

However, recent research also suggests that the influence of subtle cues (a.k.a. primes) is rarely as straightforward as once thought. Indeed, the same studies involving subtle cues and priming (Schnall, Benton, and Harvey, 2008) have been replicated (Arbesfeld et al., 2014), not replicated, or replicated with results in the *opposite* direction (Johnson et al., 2014). To address these inconsistencies, recent research (Mourey, forthcoming) proposed a two-part model to explain both *when* primes are likely to exert a stronger influence and in *which direction* those primes are likely to influence behavior. First, he proposes that individuals are more likely to employ contextual cues when tasks “feel difficult.” Second, when difficulty is interpreted to mean a task is “impossible” and individuals “give up” mentally (i.e., not waste cognitive effort on an impossible task), a prime exerts a prime-consistent effect. Alternatively, when difficulty is interpreted to mean a task is “important,” individuals process more deliberately and, in doing so, exhibit prime-reactance (Ferguson and Bargh, 2004).

For the current project, participants should be *more* sensitive to trust/distrust primes when engaging in a difficult task online (e.g., maintaining privacy, assessing an unknown company), and the direction of that influence depends on what they interpret that difficulty to mean.

## Pilot

The purpose of the pilot was to show that participants do, in fact, experience difficulty with respect to maintaining privacy in online contexts. Participants ( $N = 107$ ) found maintaining privacy difficult online in general ( $M = 4.31$ ,  $SD = 1.60$ ;  $t(106) = 1.99$ ,  $p < .05$ ), on social networks ( $M = 4.41$ ,  $SD = 1.70$ ;  $t(106) = 2.50$ ,  $p < .01$ ), and in the real world ( $M = 4.42$ ,  $SD = 1.55$ ;  $t(106) = 2.81$ ,  $p < .01$ ), and that maintaining privacy was becoming *more* difficult ( $M = 5.56$ ,  $SD = 1.18$ ;  $t(106) = 13.74$ ,  $p < .001$ ). This first study provided support for

the studies that each rely on maintaining privacy in online contexts as a difficult scenario.

## Study 1

Study 1 relies on verbal priming to cue trust, distrust, or nothing (control). Participants ( $N = 122$ ) completed word descrambling tasks containing trust cue words, distrust cue words, or neutral words. Participants then drafted a post for their preferred social network and asked to indicate which information from a list of twenty personal they would be willing to disclose. Participants also indicated how much they trusted the site and completed the 12-question Interpretation of Difficulty (IoD) scale regarding their perceptions of difficulty doing the task. Results revealed that trust primes led to more trust and distrust primes to more distrust for people who interpreted difficulty to mean “impossible,” (the opposite was true for participants who interpreted difficulty to mean “important”). Thus, we obtain initial support for our hypothesis.

## Study 2

Study 2 relies on social network size and prior theorizing on “herding effects” in which social network size is a cue of trust (larger = more trust). The study design was the same as Study 1 with the verbal primes replaced by participants’ attention being drawn to the size of their social network. Results revealed that participants ( $N = 203$ ) were willing to disclose more private information the larger their network if difficulty was interpreted as impossible, with trust mediating the effect.

## Study 3

Study 3 also looked at a practical application of this subtle cue online influence by using a feature common to most social networks: number of likes on an item. Greater engagement from friends has been shown to cue more engagement from individuals. Here, the priming stimuli was an ad liked by 24 (or 2) friends, and the dependent measure of interest was how likely participants indicated they were to try the made-up restaurant featured in the ad. Trust was also measured. Results showed that participants ( $N = 197$ ) randomly assigned to the “many friends” ad condition were more likely to try the restaurant if they interpreted the difficulty of the task as “impossible.” Effects, again, were mediated via trust, as friend engagement influenced trust, which, in turn, influenced willingness to try an unknown restaurant.

## Study 4

The final study used privacy policy as the contextual stimulus, varying both the perceptual fluency (figure/ground contrast) and the verbal fluency (complexity of language). Participants ( $N = 214$ ) first reviewed the privacy policy, then indicated the same disclosure decisions as done in the prior studies, as well as measures of difficulty and trust. Results showed that easy-to-read (difficult-to-read) privacy policies increased (diminished) trust which, in turn, increased (decreased) disclosure of private information.

## General Discussion

Five studies support that 1) consumers find maintaining privacy increasingly difficult, and 2) in these difficult situations, subtle cues

of trust/distrust exert greater influence on disclosing personal information. Counterintuitively, increasing difficulty maintaining privacy online makes people more sensitive to cues that encourage more disclosure.

# A Salience Theory of Three Exposure Effects

Kellen Mrkva, Columbia Business School, USA

Leaf Van Boven, University of Colorado Boulder, USA

## EXTENDED ABSTRACT

We propose and support a salience theory of exposure effects which posits that repeated exposure influences evaluations by increasing salience, the relative quality of standing out in relation to other stimuli in the environment. Across four experiments, we demonstrate that exposure effects previously attributed to absolute (mere) exposure are actually explained by heightened relative salience. Additionally, we demonstrate that exposure, in addition to increasing liking (Zajonc 1968), increases affective intensity and makes evaluations more extreme.

In Experiments 1-2, we replicated the procedure used in most mere exposure research. In Experiment 1, 116 American adults who were recruited from Amazon Mechanical Turk participated in exchange for \$1.25. Sixteen dropped out of the study prior to completing the key measures (resulting  $N = 100$ , 50 female,  $M_{\text{age}} = 36.39$ ). Participants viewed eight stimuli, presented in a slideshow with exposure manipulated: Two stimuli were presented 9 times, two were presented 3 times, two were presented 1 time, and two were not presented (1.0 second per presentation). Following the slideshow, liking was measured as in previous research: "How much do you like each image" (-3 = *dislike*, 0 = *neutral*, 3 = *like*), and we assessed affect intensity (1 = *not at all intense*; 9 = *extremely intense*). We also measured self-reported salience, fluency, and apprehension to test our hypothesis that salience accounts for the exposure effect, whereas fluency and apprehension account for less if any of the exposure effect. Prevailing theories of mere exposure posit that increased fluency (Bornstein and D'Agostino 1994; Reber, Winkielman, and Schwarz 1998) or reduced apprehension (Harrison 1977; Zajonc 1968) account for the exposure effect. Because salience increases evaluative extremity (Downing, Judd, and Brauer, 1992; Sadler and Tesser 1973), we also hypothesized that exposure would increase extremity (measured as distance from the neutral midpoint of the liking scale; Downing et al., 1992). This procedure was repeated for three stimulus sets commonly-used in mere exposure experiments (Chinese characters, paintings, and Turkish words).

We used linear mixed effects models to test each prediction. Each model treated Participant and Stimulus as random effects to properly model variance associated with participants and stimuli (Judd, Westfall, and Kenny 2012).

As predicted, exposure increased salience,  $t(83.60) = 7.14$ ,  $b = 0.76$ ,  $p < .001$ . Exposure also increased liking,  $t(70.08) = 6.50$ ,  $b = 0.26$ ,  $p < .001$ , replicating previous research (Zajonc 1968). Additionally, exposure made evaluations more extreme,  $t(24.85) = 3.42$ ,  $b = 0.09$ ,  $p = .002$ . Exposure also increased affective intensity,  $t(34.54) = 4.48$ ,  $b = 0.39$ ,  $p < .001$ .

We also conducted multiple mediation analyses (Preacher and Hayes 2008) to test the hypothesis that salience accounted for the effects of exposure on liking, evaluative extremity, and affective intensity. These analyses revealed that there was an indirect effect of relative exposure on liking through salience as a mediator ( $ab = 0.10$ , 95% CI [0.08, 0.13]). Mediation analyses were also consistent with our hypotheses that salience accounted for the effects of exposure on evaluative extremity and affective intensity. Fluency and apprehension accounted for smaller proportions of each effect (if any), contrary to prevailing theories that these variables account for exposure effects.

Experiment 2 was a replication of Experiment 1. American adults who were recruited from Amazon Mechanical Turk ( $N = 109$ ) participated online in exchange for \$1.00. Four participants dropped out of the study prior to viewing all three slideshows and were thus removed prior to analyses (resulting  $N = 105$ ; 54 female,  $M_{\text{age}} = 34.12$ ). Repeated exposure again increased salience,  $t(30.45) = 5.64$ ,  $b = 0.44$ ,  $p < .001$ , affective intensity,  $t(32.10) = 4.88$ ,  $b = 0.20$ ,  $p < .001$ , and evaluative extremity,  $t(34.40) = 2.09$ ,  $b = 0.03$ ,  $p = .044$ . Unlike in Experiment 1, repeated exposure did not appreciably increase liking,  $t(37.10) = 1.19$ ,  $b = 0.03$ ,  $p = .243$ . A multiple mediation model suggested that the effects of repeated exposure on evaluative extremity and affective intensity were partially accounted for by salience, whereas fluency and apprehension did not account for these effects.

In Experiment 3, we directly manipulated salience to complete a causal chain in which exposure increases salience (Experiments 1-2) and salience increases evaluative extremity and affective intensity (Experiment 3). Undergraduates ( $N = 71$ , 45 female,  $M_{\text{age}} = 19.34$ ) participated for course credit. We directly manipulated salience by presenting 12 stimuli on a screen simultaneously, with 1 oriented differently from the others (1 horizontal and 11 diagonal or 1 diagonal and 11 horizontal). This manipulates salience while equating exposure duration and inherent differences between horizontally-oriented and diagonally-oriented stimuli. Salience increased evaluative extremity,  $t(43.84) = 4.70$ ,  $b = 0.43$ ,  $p < .001$  and affective intensity,  $t(40.08) = 4.73$ ,  $b = 0.91$ ,  $p < .001$ , supporting our proposed causal chain.

Because salience is a relative quality of standing out in relation to other objects, we hypothesized in Experiment 4 that relative exposure influences evaluations more than absolute exposure. Participants ( $N = 400$  from Mechanical Turk) were assigned to either the within-subjects condition (similar to Experiments 1-2) or one of three between-subjects conditions in which they viewed stimuli presented at one level of exposure (i.e., 9 times, 3 times, or 1 time). This was designed to isolate exposure from relative salience; we hypothesized that exposure would increase liking and extremity when confounded with relative salience (i.e., within-subjects condition) but not when exposure was isolated from salience (i.e., between-subjects conditions). As predicted, relative exposure increased liking and evaluative extremity. In contrast, absolute exposure (between-subjects) did not. A difference-in-differences analysis revealed that the relative exposure effect was significantly larger than the absolute exposure effect.

These results cohere with previous findings that relative comparisons are more impactful than absolute states (e.g., Shafir, Diamond, and Tversky 1997). They also build on the emerging evidence that salience may account for several judgment and decision making phenomena (Bordalo, Gennaioli, and Shleifer 2012; Mrkva and Van Boven 2017; Yechiam and Hochman 2013). The findings have important theoretical implications as well, suggesting that effects previously attributed to absolute (mere) exposure and fluency are actually explained by heightened relative salience.

# Non-Normative Influence of Self-Decided Prices on Product-Related Inferences

Sudipta Mukherjee, Virginia Tech, USA

Mario Pandelaere, Virginia Tech, USA

## EXTENDED ABSTRACT

### Introduction and Theoretical Background

Price is a key factor in consumer decision making (Adaval and Monroe, 2002; De Langhe et al., 2014). From a purely economic perspective, consumers should be willing to buy a product if the value that they expect from the product is higher than the product price – implying that consumers should determine the value of a product independent of the price. However, ample research shows that consumers often use the marketer-provided prices to make product inferences (Zeithaml, 1988; Parasuraman et al., 1988; Brucks et al., 2000). This is rational assuming that marketers decide product-prices based on the market dynamics of supply and demand, which would lead a product price to be closely aligned to its inherent value (i.e. quality and usefulness).

While, inferring product value from marketer-provided prices may be rational, this is not the case when consumers themselves generate or decide on product prices as in pay-as-you-wish/pay-what-you-want pricing schemes (Kim et al., 2009), auctions (Greenleaf, 2004) and price negotiations (Srivastava et al., 2000). Normatively, product value should influence self-decided prices rather than the reverse. Still, we argue that consumers may infer value from the price they decide to pay; this may lead to biased inferences when self-decided prices are affected by irrelevant contextual factors. We argue that due to sheer habit of inferring value from marketer-provided prices (Plassmann et al., 2007, 2008; Rao and Monroe, 1989; Scitovszky, 1944), consumers will over apply the price-quality heuristic in the case of self-decided prices too. That is, higher the self-decided price, the more favorable would be the inferred product value.

### Study 1

Study 1 tests the idea that an undue influence on self-decided prices affects subsequent judgments of product usefulness. To influence self-generated prices, we had participants indicate for a range of prices if they would consider buying a product at that price. Prices were presented from low to high or from high to low; based on the phenomenon of anchoring (Kamins, Dreze, and Folkes, 2004; Ariely and Simonson, 2003), we expected a higher willingness-to-pay in the latter condition, causing higher judgments of product usefulness.

### Design and Procedure

This study implemented a dichotomous-choice willingness-to-pay procedure in which respondents (111 undergraduate students, 67% female,  $M_{age} = 20.74$ ) were provided with multiple prices for the same product (Bluetooth speaker) and were asked to indicate whether they would be willing to buy the product at each of the presented prices. The prices (ranging from \$10 to \$100) were either systematically increasing (ascending price order condition) or decreasing (descending price order condition). The final (vs. first) price that respondents were willing to buy the product at was calculated as their willingness-to-pay price in the ascending (vs. descending) price order condition. The willingness-to-pay price is conceptually identical to the self-decided price (Kim, Natter, and Spann 2009). Having obtained the self-decided price, the experimental procedure next required respondents to indicate how useful they thought the product would be.

### Results

Excluding 10 participants who exhibited response reversal/response inconsistency (willingness to buy the product at a higher price but not at a lower price), a one-way ANOVA showed that self-decided prices were lower (vs. higher) in the case of ascending (vs. descending) price presentation order ( $M_{ascending} = \$19.26$ ,  $SD = 14.39$ ;  $M_{descending} = \$35$ ,  $SD = 25.85$ ;  $F(1, 100) = 14.86$ ;  $p < 0.0001$ ;  $d = 0.75$ ). More importantly, as hypothesized, a one-way ANOVA results reveal that the ascending (vs. descending) price presentation resulted in less favorable perceived product usefulness ( $M_{ascending} = 3.54$ ,  $SD = 1.65$ ;  $M_{descending} = 4.18$ ,  $SD = 1.65$ ;  $F(1, 110) = 4.24$ ;  $p = 0.042$ ;  $d = 0.38$ ). Further, it was found that the effect of price presentation order on product-related inference (perceived usefulness) was mediated through self-decided prices (10000 sample 95% C.I.: (-0.27, -0.07)). Interestingly, the inverse direction of the indirect effect, the normatively expected influence of product-related inferences on self-provided prices, was not significant (10000 bootstrap 95% CI (-1.86, 0.43)).

### Study 2

This study tested the robustness of the results obtained in the previous study and showed that the underlying effect was caused not by difference in the starting prices between ascending and descending price order conditions, but rather by differences in self-decided prices.

### Design and Procedure

Using 170 (49% female;  $M_{age} = 20.91$ ) undergraduate students, this study utilized a 2 (Price presentation order: ascending vs. descending) x 2 (Price steps: \$10 vs. \$20) between-subject factorial design. This study differed from the previous study in three ways. First, prices ranged from \$100 to \$200. Second, price step was also manipulated by varying the prices in the self-decided price elicitation procedure either in steps of \$10 (\$10 price step condition) or \$20 (\$20 price step condition). We anticipated that because the number of different prices being presented is larger (vs. smaller) in the price step \$10 (10 different prices) (vs. price step \$20 (5 different prices)), the self-decided prices will differ more between ascending and descending price presentation orders more when the price step is \$10 as compared to when the price step is \$20. Further, as the starting price was the same for both price step \$10 and price step \$20, any systematic differences between the effect of price presentation order on product-related inferences for price step \$10 vs. price step \$20 conditions would indicate that the underlying effect of price presentation order on product-related inferences is due to self-decided prices and not due to the starting price itself. Third, the product-related inferences was operationalized through measuring anticipated product satisfaction.

### Results

For self-decided prices, we found a significant interaction between price presentation order and price step ( $F(1, 156) = 4.55$ ,  $p = 0.034$ ) such that ascending (vs. descending) price presentation order resulted in lower self-decided prices only when price step is \$10 ( $M_{ascending} = \$43.9$ ,  $SD = 63.75$ ;  $M_{descending} = \$94.15$ ,  $SD = 80.65$ ;  $F(1, 156) = 10.57$ ;  $p = 0.001$ ;  $d = 0.69$ ), and not when price step is \$20 ( $M_{ascending} = \$50.24$ ,  $SD = 61.34$ ;  $M_{descending} = \$53.24$ ,  $SD = 72.73$ ;  $F(1, 156) = 0.036$ ;  $p > 0.5$ ).

We also found a significant interaction between price presentation order and price step for anticipated product satisfaction ( $F(1, 156) = 4.19, p = 0.042$ ), such that while ascending (vs. descending) price presentation order resulted in lower anticipated product satisfaction only in the price step \$10 condition ( $M_{ascending} = 3.87, SD = 1.11; M_{descending} = 4.42, SD = 1.01; F(1, 156) = 3.4; p = 0.067; d = 0.52$ ), and not in the price step \$20 condition ( $M_{ascending} = 4.01, SD = 1.69; M_{descending} = 3.7, SD = 1.45; F(1, 156) = 1.1; p = 0.3$ ).

Finally, we ran a moderated mediation model (Preacher and Hayes (2008) PROCESS model 7) to test whether price step moderates the indirect effect of price presentation order on anticipated product satisfaction through self-decided prices. A 95% C.I. (-0.53, -0.02) for a 10000 bootstrap sample indeed reveals that the index for moderated mediation (Index = -0.25, SE (boot) = 0.13) does not contain 0. While the 95% C.I. for a 10000 bootstrap sample for the indirect effect of price presentation order on anticipated product satisfaction did not contain 0 for the \$10 price step (-0.47, -0.10), it did contain 0 for the \$20 price step (-0.18, 0.15). This suggests price steps indeed does moderate the mediating influence of self-decided prices on the relationship between price presentation order and anticipated product satisfaction. More importantly, it provides further evidence that people infer product value from self-decided prices.

### Study 3

Study 3 aims to replicate the previous findings using a different paradigm to influence self-decided prices. In addition, the present study attempts to rule out cognitive dissonance (Festinger, 1962; Elliot and Devine, 1994) and self-perception (Bem, 1972; Calder and Staw, 1975) as rival explanations.

#### Design and Procedure

MTurk panel members ( $N = 318$ ; 55% female;  $M_{age} = 36.14$ ) were randomly assigned to one cell of a 2 (bid amount: low vs. high) x 2 (perspective: self vs. other) between-subject factorial design. This study utilized an interactive gameplay scenario to influence prices. Respondents were either required to take part in an online interactive simulated game titled "Wheel of Fortune". Respondents were asked to imagine that they were taking part in the last stage of a multistage game during which, at each stage, they were required to bid a certain amount of money in order to win a product. Respondents were required to bid the amount before knowing what product they could win – thus ensuring that the bid amount was completely unconnected to the inherent product characteristics. Upon putting in their bid amounts, respondents were informed about the product that they had won (the same product, sunglasses, for all respondents), and were asked to indicate the expected product quality.

In order to manipulate the bid amount, respondents were told that they either had \$20 left or \$100 left to bid for the last round, and that this amount could not be converted into cash or credit and would go to waste unless used for bidding on the product. Other than manipulating the bid amount, this was also useful in ruling out the potential alternative explanation of cognitive dissonance (arising from potentially indicating a low expected quality after having bid a high amount), by providing respondents a clear justification of their bid amount. Further, gameplay perspective (self vs. other) was manipulated: Half of the participants had to imagine playing themselves, whereas the other half had to imagine watching someone else participating. If similar results are obtained when participants imagine observing others as when they imagine playing themselves, these effects cannot be attributed to self-perception processes (nor cognitive dissonance). They would nevertheless support the idea that people infer product value, even when prices are clearly not reflective of the value the market assigns to the product.

### Results

As expected, the amount bid in the low bid amount condition was lower than that in the high bid amount condition ( $M_{bid\ amount\ low} = \$18.25, SD = 4.19; M_{bid\ amount\ high} = \$88.56, SD = 22.6; F(1, 316) = 1495.92, p < 0.0001, d = 4.33$ ). A general linear model, which included the main effects of bid amount (low vs. high), perspective (self vs. other), and their interaction, revealed that while the main effect of bid amount on expected product quality was significant ( $M_{bid\ amount\ low} = 4.53, SD = 1.44; M_{bid\ amount\ high} = 4.87, SD = 1.34; F(1, 314) = 4.82, p = 0.029, d = 0.24$ ), the main effect of perspective (self vs. other) ( $p = 0.2$ ) and the interaction between bid amount and perspective ( $p = 0.33$ ) was not significant.

### Study 4

#### Design and Procedure

Undergraduate students ( $N = 119; M_{age} = 20.87$ , 53% female) were randomly assigned to one cell of a 2 (bid amount: low vs. high) between-subject design. We used the game show paradigm as in study 3. In addition, this study also included a price-quality schema measure to test if the effect is stronger for those with stronger price-quality schema; this would indicate that the over-application of a price-quality heuristic explains the observed effect.

### Results

As expected, the amount bid in the low bid amount condition was lower than that in the high bid amount condition ( $M_{bid\ amount\ low} = \$17.55, SD = 5.16; M_{bid\ amount\ high} = \$89.05, SD = 21.62; F(1, 117) = 620.51, p < 0.0001, d = 4.55$ ). More importantly, the expected product quality was higher in the high bid amount condition as compared to the low bid amount condition ( $M_{bid\ amount\ low} = 3.41, SD = 1.61; M_{bid\ amount\ high} = 4.06, SD = 1.55; F(1, 117) = 5.06, p = 0.026, d = 0.41$ ). Further, there was a significant interaction ( $F(1, 115) = 17.32, p = 0.0001$ ) between experimental condition and price-quality schema in predicting expected product-quality, such that while the effect was significant for those with strong price-quality schema ( $p < 0.0001$ ) but not for those with weak price-quality schema ( $p = 0.22$ ).

### Study 5

#### Design and Procedure

Undergraduate students ( $N = 239; M_{age} = 38.13$ , 64% female) were randomly assigned to one cell of a 2 (amount left: \$20 vs. \$100) x 2 (reminder about random nature of bid amount: present vs. absent) between-subjects design. We used the same paradigm as in Study 3 and 4. In addition to manipulating bid amount, we also manipulated whether participants were reminded that the bid amount was just the outcome of a random process, that is, just the amount they happened to have left on the last round of gameplay. Half of the respondents were asked to indicate if the amount was indeed random, whereas the other half did not get that cue. We expected that the over-application of a price-quality heuristic is a mindless process. If so, any cue that makes people more mindful about the nature of the self-decided price should attenuate or even eliminate the effect of bid amount of perceived product value. Finally, we also measured individual differences in price-quality beliefs to replicate the moderation of the previous study.

### Results

As before, bid amount was significantly higher in the \$100 left condition as compared to the \$20 left condition ( $M_{bid\ amount\ low} = \$17.98, SD = 4.03; M_{bid\ amount\ high} = \$82.68, SD = 27.48; F(1, 237) = 640.58, p < 0.0001, d = 3.29$ ). More importantly, a general linear model analysis, with bid amount and reminder intervention as the

fixed factors showed a significant interaction ( $F(1, 235) = 9.44, p = 0.002$ ) between bid amount (low vs. high) and reminder intervention (present vs. absent) on expected quality. The expected product quality was significantly higher in the high bid amount condition as compared to the low bid amount condition ( $M_{bid\ amount\ low} = 3.95, SD = 1.46; M_{bid\ amount\ high} = 5, SD = 1.21; F(1, 235) = 17.16, p < 0.0001, d = 0.78$ ) when reminder intervention was absent, but not when the reminder intervention was present ( $F(1, 235) = 0.033, p > 0.5$ ). Further, showing the robustness of the finding from the previous study, there was a significant interaction ( $F(1, 114) = 7.63, p = 0.0067$ ) in the expected direction between price quality schema and bid amount in the conditions without reminder intervention.

### General Discussion, Theoretical Contributions, and Managerial Implications

The present research provides evidence for the non-normative influence of self-decided prices on product-related inferences, and contributes to marketing literature in several important ways. First, it contributes to the existing price-quality relationship literature by showing that consumers infer product value not only from marketer-provided prices but also from self-decided prices. Second, it contributes to the existing literature on price presentation order by showing that ascending and descending price presentation orders can differ in terms of their downstream influence on product-related inferences. Given that price presentation order is an important commonplace contextual factor that is relevant to a variety of marketer-customer interactions, such as auctions, negotiations, salesperson-customer interactions, amongst others, the findings from this research thus provide both substantial theoretical and substantive contributions.

# The “Upper Limit Framing” Effect: Upper Limit Framing of a Cost Estimate Influences Consumption Choices

Sudipta Mukherjee, Virginia Tech, USA  
Frank May, Virginia Tech, USA

## EXTENDED ABSTRACT

### Introduction and Theoretical Background

Consumers often make consumption choices on the basis of estimates, rather than actual temporal or monetary costs. Frequently, marketers interchangeably use “less than” vs. “not more than” frame to present consumers with an estimated upper limit of the underlying cost. For example, an Uber driver may tell you that he will arrive in “less than 20 minutes,” or “not more than 20 minutes.” Although these frames are equivalent and interchangeably used, we show that these frames result in differential consumption choices – what we term the *upper limit framing* effect. We show that less than (vs. not more than) framing of the upper limit of a temporal or monetary cost estimate can result in different consumer expectations regarding the underlying cost involved, and systematically influence subsequent consumption choices.

We draw our hypotheses from research on negation theory. Negation theory literature suggests that verbal inferences that involve negations are more effortful to process than equivalent affirmations (Dale and Duran, 2011; Nordemeyer and Frank, 2014; Khemlani, Orenes, and Johnson-Laird, 2012; 2014), although under certain circumstances they can be equally fluent to process (Johnson-Laird, 1970; Clark, 1974). In turn, the less fluent processing associated with negations leads individuals to neglect the negation. For example, someone deemed “innocent” will appear more free of guilt than someone deemed “not guilty.” Indeed, for cost estimates involving small amounts, our findings are consistent with this model: framing the upper limit as “less than” leads to contracted cost perceptions (vs. “not more than” framing).

Interestingly, we are the first to our knowledge to find conditions under which a negation frame is actually more fluent than an affirmation frame—when negation frames involve large cost estimates. Extant research has shown that large numbers require abstract construal to process (Hansen, Kutzner, and Wanke, 2012; Stanescu-Cosson et al., 2000; Dehaene, et al., 2003), which matches with the abstract nature of negation framed assertions (Gilead, Liberman, and Maril, 2012). Consequently, the abstract mindset required to process large numbers matches the abstract nature of negations, leading to more fluent processing (Lee and Aaker, 2004; Labroo, Dhar, and Schwarz, 2007). Thus, for cost estimates involving large amounts, the well-established effect of negations being more difficult to process should reverse due to a greater match between the mindset primed by large amounts and negation-framed assertions. Consequently, for large estimates, framing the estimate as *not more than* results in contracted cost perceptions (vs. *less than* framing).

### Methods and Results

Study 1 utilized a single factor (upper limit framing: less than vs. not more than) between-subjects experimental design. Specifically, respondents were presented with a real choice context – choosing to take part in a survey about the business school. Respondents in the *less than* (vs. *not more than*) condition were told that the survey will take less than (vs. not more than) 10 minutes. It was found that respondents in the *less than* condition were significantly more likely to choose to take part in the survey (vs. those in the *not more than* condition).

Studies 2 and 3 utilized single factor (upper limit framing: less than vs. not more than) experimental designs involving hypothetical

choice scenarios (study 2: restaurant wait time; study 3: Uber wait time). In both studies, respondents were asked to imagine that they had to wait for a period of time, and were presented with wait time estimates either using *less than* or *not more than* framing. The wait time estimates provided in study 2 (study 3) were: less than 30 minutes and not more than 30 minutes (less than 20 minutes and not more than 19 minutes). The wait times in study 3 were chosen to rule out the alternative explanation for the upper limit framing effect – potential non-equivalence of the two frames. Results from both studies showed that *less than* (vs. *not more than*) framing resulted in lower perceived wait time and higher likelihood to wait. Further, perceived wait time mediated the influence of upper limit frame on likelihood to wait.

Study 4 tested the influence of upper limit framing on estimated monetary cost (getting a car repaired by a mechanic; less than \$475 vs. not more than \$475). It was found that *less than* (vs. *not more than*) framing resulted in lower perceived cost of repairs, which mediated the likelihood of getting the car repaired by the mechanic.

Studies 5 (house price: less than \$200,000 vs. not more than \$200,000) and 6 (plumbing repair cost: less than \$7,500 vs. not more than \$7,500) show that the upper limit framing effect reverses when the underlying cost is large—*not more than* framing results in lower perceived costs versus *less than* framing.

Finally, study 7 showed that there is a significant interaction between upper limit frame (less than vs. not more than) and estimate amount (car repair cost: \$250 vs. \$2500) in predicting perceived cost and likelihood to incur cost. Specifically, for the small estimated repair cost (\$250), the *less than* (vs. *not more than*) frame resulted in significantly lower perceived repair cost and higher likelihood to get the car repaired. However, the reverse was true for large estimated repair cost (\$2500). Furthermore, fluency of processing the cost estimate was higher (lower) for *less than* (vs. *not more than*) frame for small (large) amount, and mediated the interactive effect of frame and amount on cost perception.

### Contribution

This research makes a number of substantial contributions. First, we contribute to the negation literature by being the first to demonstrate situations in which negation frames are actually easier to process and have stronger meaning than affirmation frames (e.g., someone deemed “not guilty” can appear more free of guilt than someone deemed “innocent”). Additionally, we contribute to consumer research by showing how framing of cost estimates influence consumption choices and that equivalent frames for a cost estimate can result in distinct consumption choices. We also contribute to the literature on temporal and monetary costs by showing how *less than* versus *not more than* framings can influence cost expectations. Further, this research contributes to the semantic framing literature by finding a new semantic framing effect that involving negation based inference making.

Our research also presents substantial managerial implications. Given that marketers interchangeably use *less than* and *not more than* framing to express the upper limit of an estimate, we provide an important insight that the framing of the upper limit can influence perception of the underlying cost, and that this effect depends on the estimated amount.

# Approach and Loss Aversion: Consumer Responses to Approaching and Receding Stimuli in Advertising

Lana Mulier, Ghent University, Belgium  
Iris Vermeir, Ghent University, Belgium  
Hendrik Slabbinck, Ghent University, Belgium

## EXTENDED ABSTRACT

Consumers are increasingly confronted with dynamically moving stimuli in commercials, video games and virtual reality. Although the effect of physical (near vs. far) and psychological (concrete vs. abstract) *distance* of stimuli has been broadly investigated (Codispoti and De Cesarei 2007; De Cesarei and Codispoti 2006; Loftus and Harley 2005), much less is known about the effect of *movement* (approaching vs. receding) on advertising appeals and consumer decisions. Designing effective dynamic marketing campaigns requires better understanding of consumers' reactions to stimuli either moving away from or toward them. Building on the approach and loss aversion biases, we predict that people would show more negative (positive) emotions and attitudes on advertising effectiveness toward approaching (receding) stimuli.

People have an innate tendency of approach aversion, because approaching stimuli can be potentially more harmful and dangerous than receding stimuli. Approach aversion means that people feel more negatively toward a stimulus that is approaching rather than receding or static. This overgeneralized bias arises for a priori negative, nonnegative and ambivalent stimuli, and for stimuli moving in space, time, or probability (Davis et al. 2011; Hsee et al. 2014; Mühlberger et al. 2008). For instance, Hsee et al. (2014) reported more negative feelings toward neutral, negative and positive approaching stimuli than toward non-approaching stimuli. In line with these studies, we hypothesize that people will express more negative feelings toward approaching neutral stimuli versus non-approaching neutral stimuli (H1a).

However, it is still unclear whether there would be a parallel effect for *receding* stimuli, in the sense that these stimuli would evoke more positive feelings than approaching stimuli (Hsee et al. 2014). Specifically, loss aversion can manifest itself in people's reactions toward moving stimuli, because receding stimuli could induce a sense of loss. Loss aversion means that losses and disadvantages have greater impact on people's preferences than gains and advantages (Tversky and Kahneman 1991). Since people find it worse to lose something than to gain something, and thus attach more value to losses than gains, receding stimuli could evoke more positive feelings because the perceived value seems to increase (Hsee et al. 2014). As such, we predict that people will express more positive feelings toward receding neutral stimuli versus non-receding neutral stimuli (H1b).

Moreover, as emotions affect advertisements' evaluations (Poels & Dewitte, 2006), we hypothesize that people will evaluate an advertisement more negatively when the ad contains approaching neutral stimuli versus non-approaching neutral stimuli (H2a). Contrastingly, people will evaluate an advertisement more positively when the ad contains receding neutral stimuli versus non-receding neutral stimuli (H2b).

In Study 1, testing H1a-b, participants (MTurk;  $N = 242$ ,  $M_{\text{age}} = 37.45$ , 49% men) were randomly assigned to 1 of 5 conditions (approaching, receding, static-middle, static-near, or static-far stimuli) in a between-subjects design. Twelve neutral objects served as experimental stimuli, for which five videos were created. Stimulus movement was manipulated by a change in size. Participants indicated their feelings toward each object, on 9-point Self-Assessment

Manikin (SAM) scales measuring valence and arousal. Three control measures were randomly assessed: the Behavior Identification Form (BIF; Vallacher and Wegner 1989;  $\alpha = .90$ ), the Behavioral Inhibition and Behavioral Activation System Scales (BIS/BAS; Carver and White 1994;  $\alpha = .83$ ), and the Fight Flight Freeze Questionnaire (FFFQ; Maack et al. 2015;  $\alpha = .91$ ).

Multilevel analyses, controlling for the covariates, showed a (marginally) significant effect of condition on valence ( $F(4, 229) = 2.40$ ,  $p = .051$ ). Participants indicated more negative valence toward approaching neutral stimuli compared to static-middle neutral stimuli, partly confirming H1a. However, there was no significant effect of condition on arousal ( $F(4, 229) = .11$ ,  $p = .978$ ). H1b could not be confirmed, as receding neutral stimuli did not evoke significantly more positive feelings than non-receding neutral stimuli.

In Study 2, testing H1a-b and H2a-b, participants (MTurk;  $N = 123$ ,  $M_{\text{age}} = 38.24$ , 60% men) were randomly assigned to 1 of 5 conditions (similar to study 1) in a between-subjects design. One object from study 1 served as stimulus for a fictive advertisement on second-hand products. Stimulus movement was manipulated as in study 1. Attitude toward the ad (Aad), attitude toward the brand (Ab), and purchase intention (PI), were used as measures of advertising effectiveness. Participants indicated their feelings toward the product, on SAM scales measuring valence and arousal. Aad and Ab were measured on three-item, 7-point semantic differential scales (MacKenzie and Lutz 1989;  $\alpha_{\text{Aad}} = .97$ ,  $\alpha_{\text{Ab}} = .97$ ). PI was measured on a three-item, 7-point semantic differential scale (Pornpitakpan 2004;  $\alpha = .96$ ). Three control variables were randomly measured: the BIF ( $\alpha = .92$ ), the BIS/BAS scales ( $\alpha = .82$ ), and the GREEN scale, measuring environmentally friendly consumption values (Haws et al. 2014;  $\alpha = .95$ ).

ANCOVA analyses firstly showed a significant effect of condition on valence ( $F(4, 112) = 3.40$ ,  $p = .012$ ). Participants indicated more negative valence toward approaching neutral stimuli compared to non-approaching neutral stimuli, confirming H1a. Contrastingly, participants indicated more positive valence toward receding neutral stimuli than toward approaching neutral stimuli, partly confirming H1b. Secondly, condition could not significantly predict arousal ( $F(4, 112) = .64$ ,  $p = .633$ ). Thirdly, there were (marginally) significant effects of condition on Aad ( $F(4, 112) = 2.93$ ,  $p = .024$ ), Ab ( $F(4, 112) = 3.15$ ,  $p = .017$ ), and PI ( $F(4, 112) = 2.25$ ,  $p = .068$ ). Participants expressed more negative Aad, Ab, and PI toward approaching neutral stimuli than toward non-approaching stimuli, confirming H2a. In contrast, participants expressed more positive Aad, Ab, and PI toward receding neutral stimuli than toward approaching stimuli, partly confirming H2b.

This research revealed that consumers react more negatively to approaching stimuli, supporting approach aversion, and more positively to receding stimuli, providing preliminary evidence for loss aversion as underlying mechanism. Moreover, advertisements using approaching products decrease ad evaluations, while advertisements using receding products increase ad evaluations. This study is the first to demonstrate the importance of understanding how consumers react to approaching and receding stimuli in advertising. Using the right kind of movement can strengthen consumers' attitudes toward the products being advertised.

# More than Just a Number: The Negative Effect of 100% Claims

Nira Munichor, Bar-Ilan University, Israel  
Liat Levontin, Technion, Israel

## EXTENDED ABSTRACT

Many product labels include numerical claims. Consumers interpret these claims in different ways, beyond their numerical value. Non-round numbers, for example, are considered more informative and scientific than round numbers (Guang-Xie and Kronrod 2012). Correspondingly, evaluations of products associated with non-round numbers are based more on cognitions, whereas evaluations of products associated with round numbers lean more on feelings (Wadhwa and Zhang 2015). Round numbers, on the other hand, symbolize completion, and consumers are therefore more willing to accept offers with round prices (Yan and Pena-Marín 2017).

In the current research we focus on a common yet underexplored numerical claim, a 100% claim (e.g., “100% natural”). More than any other round number, 100% mathematically denotes completeness, and accordingly, in everyday language, the term “100%” stands for completeness, fullness or perfection (Lee 2014). Thus, it is not surprising that marketers intuitively believe that a 100% claim can make products more appealing, an intuition reflected in their extensive use of such claims. Indeed, Canadian consumers perceive a “100% Canadian milk” claim on milk and ice cream as an indication of product quality (Forbes-Brown et al. 2016).

We suggest that this intuition may backfire when the 100% claim is pseudo-informative, namely, does not convey meaningful information regarding the associated product—for example, a claim stating that a drink contains “100% juice”, which does not specify percentages of fruit content or other similar information. In these cases, consumers may rely less on the numerical information conveyed by the claim, and refer more to its symbolism. In addition, because the perfection symbolized by the term “100%” might be perceived as “cheap talk” that cannot actually be measured, consumer’s product evaluations decrease.

Four experiments show that participants evaluate products less favorably when those products carry a pseudo-informative 100% claim, as compared with a 99%, non-numerical, and even 101% claim (that serves as a symbol). We further show that the effect of a pseudo-informative 100% claim is triggered by perceptions of low measurability of the information embedded in the claim, suggesting an enhanced focus on 100% as a symbol.

Study 1 tested the effect of a pseudo-informative 100% claim on evaluations. Participants ( $n=99$ ) reviewed a picture of a beverage with a label that contained either a “100% juice” or a “99% juice” claim. They provided product evaluations by indicating on 7-point scales how appealing, tasty, healthy, fresh, natural, good versus bad, of high versus low quality, and close to perfection this product seemed to them (Cronbach’s  $\alpha=.89$ ). Participants also reported their perceptions of the product’s consumers: how successful, powerful, and high versus low in status they perceived them to be (Cronbach’s  $\alpha=.89$ ). As expected, when the label contained a 100% claim, product evaluations were lower ( $M=4.36$ ,  $SD=1.17$ ) than when the label contained a 99% claim ( $M=4.81$ ,  $SD=1.07$ ;  $F(1, 97)=3.86$ ,  $p=.05$ ), and perceptions of the product’s consumers were less favorable ( $M=3.76$ ,  $SD=1.16$  vs.  $M=4.19$ ,  $SD=.97$ ;  $F(1, 97)=3.93$ ,  $p=.05$ ). Thus, a product label containing a 100% claim can sometimes harm product evaluations.

Study 2 ( $n=153$ ) compared the effect of a 100% claim not only to that of a 99% claim, but also to that of a non-numeric claim. To make sure the (uninformative) numbers on the label triggers our ef-

fect, we used a foreign product—a Russian jam, such that participants could only understand the numbers, but not the text, written on the label. Put differently, the text on the label was exaggeratedly uninformative for participants. A MANOVA revealed significant differences in product evaluations ( $F(2, 150)=4.30$ ,  $p=.015$ ) and perceptions of the product’s consumers ( $F(2, 150)=4.77$ ,  $p=.01$ ). Product evaluations were lower with a 100% claim ( $M=3.42$ ,  $SD=1.16$ ) than with either a 99% claim ( $M=4.06$ ,  $SD=1.26$ ,  $p=.02$ ) or a non-numeric (non-understandable) claim ( $M=3.89$ ,  $SD=.97$ ,  $p=.11$ ). Perceptions of the jam’s consumers were also less favorable with a 100% claim ( $M=3.02$ ,  $SD=1.06$ ) than with either a 99% claim ( $M=3.51$ ,  $SD=1.16$ ,  $p=.06$ ) or a non-numeric claim ( $M=3.62$ ,  $SD=.93$ ,  $p=.01$ ).

If the effect of a pseudo-informative 100% claim is indeed triggered by decreased consideration of the numerical value of 100%, and enhanced consideration of its symbolism, then our effect should emerge also when a 100% claim is compared to other, superior, claims involving percentages that are symbolic rather than numerically informative. Thus, Study 3 used a 101%-satisfaction claim. Note that while 101% has no numerical logic, a 101%-satisfaction claim may imply extra effort to satisfy consumers, which consumers may find more convincing. Participants ( $n=81$ ) reviewed a hotel picture that contained either a 100% or 101% “satisfaction guarantee” claim. As expected, evaluations of the hotel were lower with a 100% claim ( $M=4.94$ ,  $SD=0.91$ ) than with a 101% claim ( $M=5.36$ ,  $SD=0.84$ ;  $F(1,79)=4.53$ ,  $p=.04$ ), and perceptions of the hotel’s consumers were less favorable ( $M=3.92$ ,  $SD=1.10$  vs.  $M=4.46$ ,  $SD=1.17$ ,  $F(1,79)=4.61$ ,  $p=.035$ ).

Study 4 aimed to provide more direct evidence for our hypothesis that consumers rely more heavily on the symbolism, rather than the numerical value, of a pseudo-informative 100% claim. Thus, Study 4 tested whether measurability perceptions mediate the claim effect on behavioral intentions (the mean of willingness to taste and willingness to buy the product, Cronbach’s  $\alpha=.75$ ). Participants ( $n=200$ ) reviewed a picture of ice-bars that included one of three uninformative claims: “Made with [100%/99%/no number mentioned] juice blend and other added ingredients.” The results of a mediation analysis (PROCESS Model 4, multicategorical, with 5000 resamples; Hayes 2013) show that both the 99% claim and the non-numeric claim were perceived as more measurable than the 100% claim ( $B=.63$ ,  $SE=.28$ ,  $p=.03$ , 95% CI [.07,1.18] and  $B=.63$ ,  $SE=.27$ ,  $p=.025$ , 95% CI [.08,1.18], respectively). Importantly, the relative indirect effects of the difference between the 100% claim and both the 99% claim and the non-numeric claim on behavioral intentions through measurability were significant ( $B=.13$ ,  $SE(boot)=.07$ , 95% CI [.02, .31] and  $B=.13$ ,  $SE(boot)=.07$ , 95% CI [.02,.30], respectively), suggesting that the negative effect of a 100% claim on willingness to adopt the product ensues from perceptions of lower measurability of that claim.

Our results suggest that using 100% claims for products may sometimes have unintuitive effects on consumers, which may yield negative effects.

# Spreading of Alternatives Without a Perception of Choice

Kurt P. Munz, New York University, USA  
Vicki G. Morwitz, New York University, USA

## EXTENDED ABSTRACT

Choosing a product changes a consumer's attitudes toward it. Brehm (1956) classically demonstrated this by asking consumers to first rate several products, and then choose between two they had rated about equally. He found that attitudes toward chosen products improved and rejected products declined upon subsequent measurement. He explained this "post-choice spreading of alternatives" (Brehm, 1956) by cognitive dissonance (Festinger, 1957). Specifically, the negative features of the chosen option became inconsistent with the knowledge of having chosen them. The resulting unpleasant feeling of dissonance motivated choosers to downplay the importance of those features, allowing them to be happier with their choice (Simon, Greenberg, & Brehm, 1995).

Researchers took Brehm's "free-choice paradigm" (1956) as evidence that choosing causally changes attitudes (Festinger, 1957, 1964). Recently however, Chen and Risen (2010) argued that the paradigm contains a methodological flaw. To demonstrate that choice causally affects attitudes, they argued that one would need to ensure the choice outcome could not be driven by existing preference (2010; Risen & Chen, 2010).

In response, several researchers demonstrated post-choice spreading while randomly assigning outcomes rather than allowing participants to make actual choices (Egan, Bloom, & Santos, 2010; Johansson, Hall, Tarning, Sikstrom, & Chater, 2014; Sharot, Velasquez, & Dolan, 2010). For example, Sharot et al. asked participants to make a choice based on information ostensibly presented subliminally. The "choice" outcome was actually randomly assigned. When participants believed they had made a choice, their attitudes toward chosen options improved, but when they believed a computer had chosen, there was no change in attitude (Sharot et al., 2010). The authors concluded that a "sense of agency" was critical to observing spreading. Similarly, following a procedure involving altering choices by sleight of hand, others have concluded that "it is not the choice per se that drives the preference change but rather the belief that a certain choice has been made" (Johansson et al., 2014, p. 288). These authors interpreted their results as consistent with self-perception theory (Bem, 1972), where people infer their own preferences from the choices they have made.

In contrast, we argue that neither choice nor the self-perception of having made a choice is required to observe spreading of alternatives. Instead, spreading occurs whenever a consumer *accepts an outcome*. Consumers normally accept the outcomes of their own choices, but they can also accept outcomes without believing they chose them personally. For example, when assigned to sell a product (study 1), people must accept that single course of action in order to act effectively (Harmon-Jones, Harmon-Jones, & Levy, 2015). Consumers may also accept outcomes when they use a decision process that does not allow agency over the final outcome (study 2) or when they accept an employer's prerogative to assign them a product for use in their work (study 3). We show that, consistent with the process presumed for post-choice spreading, consumers trivialize the importance of the negative features of the assigned outcomes (studies 2 and 3). These changes in importance mediate changes in attitude (study 3). Finally, individual levels of acceptance moderate the intensity of spreading (study 3).

*Study 1* demonstrated spreading (attitude improvement) favoring an assigned outcome. Participants ( $N=48$ ) were randomly

assigned to advocate for one brand versus a competitor in a role-playing "sales game." At time 1, we measured attitudes toward various retailer brands. At time 2 two weeks later, we randomly selected two brands each participant had rated equally, and then randomly assigned one as "assigned" and the other as "competitor." Participants believed they were to enter a chat room to attempt to convince another participant to shop at their assigned retail brand. They would be in competition against a third participant trying to sell the competitor brand. The chat room never occurred. Participants never actually advocated for their assigned brand, nor was any additional information provided about the brands. Immediately after assignment to condition, we re-measured attitudes toward the retailers. As predicted, we observed a significant interaction  $F(1,47)=5.7, p=.021$ . Attitudes toward assigned brands improved ( $M=2.3, SD=2.1$  from  $M=1.3, SD=2.5$ ),  $F(1,47)=6.7, p=.013$ , but attitudes toward competitors did not ( $M=1.1, SD=2.6$  from  $M=1.2, SD=2.5$ ),  $F<1$ .

*Study 2* demonstrated that outcome assignment led to changes in feature importance. Modeled after hotwire.com, participants ( $N=175$ ) in a longitudinal experiment booked a hypothetical hotel room through a web site where they chose only the neighborhood of the hotel; the web site assigned them a specific hotel in that neighborhood without further input. At time 1, we measured baseline hotel feature importance. At time 2 we manipulated whether an assigned hotel performed well on two secondary features: service and amenities. We expected that self-reports of the importance of the manipulated features should reflect the level assigned. As predicted, on a 100-point bipolar tradeoff scale we observed significant spreading in relative feature importance to match hotel assignments  $F(1,173)=7.97, p=.005$ . On independent 7-point scales, poorly performing features were trivialized  $F(1,173)=7.22, p=.008$ . Specifically, poorly performing attributes decreased in importance ( $p's<.05$ ) but well-performing attributes remained unchanged (*n.s.*).

*Study 3* showed moderated mediation. Two weeks after measuring baseline attitudes and feature importance, participants ( $N=410$ ) were told their employer had booked a hotel room for them for a business trip. Replicating study 1, attitudes spread to favor assigned hotels  $F(1,408)=17.67, p<.001$ . Replicating study 2, on a 100-point bipolar tradeoff scale we observed significant spreading in relative feature importance to match hotel assignments  $F(1,408)=23.80, p<.001$ . On independent 7-point scales poorly performing features were trivialized  $F(1,408)=52.61, p<.001$ , also replicating study 2. We additionally measured acceptance of the outcome by agreement with four measures. Acceptance moderated the amount of spreading in feature importance  $F(1,406)=14.11, p<.001$ , such that spreading was more pronounced as acceptance rose. Changes in importance mediated changes in attitude, a significant moderated mediation 95 CI: [-.60, -.14].

Across three studies, we found that spreading of alternatives does not require a self-perception of choice. Rather, spreading depends on accepting an outcome. Consistent with the logic of post-choice spreading, changes in feature importance mediated changes in attitude. Mere acceptance seems to yield the same attitude reappraisals currently attributed to choice.

# When Novices have more Influence than Experts: Empirical Evidence from Online Peer Reviews

Peter Nguyen, Ivey Business School, Canada  
Xin (Shane) Wang, Western University, Canada  
Xi Li, City University of Hong Kong, China  
June Cotte, Ivey Business School, Canada

## EXTENDED ABSTRACT

Over the past decade, online peer review platforms have played a major role in shaping consumer choice. Eliciting and displaying online reviews has become a priority for many firms as part of their marketing efforts to influence consumer decisions and stimulate firm sales. Just as firms have been interacting with expert professionals (Biswas, Biswas, and Das 2006; Wang 2005), firms are now also engaging with expert, or elite, *users* on peer review platforms (Chae et al. 2016; Stone 2014). Businesses invite expert users to try their products/services, with the objective of having expert users create and share high-quality reviews. Given the increasing engagement between businesses and elite users, we are interested in the relationship between user expertise and influence of user-generated reviews on consumers.

To get a more descriptive sense of how consumers are influenced by online peer review platforms, let's consider a situation where a consumer accesses a review website to make a choice on a service provider. Perhaps the consumer is at a conference in a new city, and decides to use a peer review website, such as tripadvisor.com, to find a restaurant for the evening. Consider the navigation process from accessing the user-generated review website to selecting a restaurant for the evening. She might begin by first narrowing down the options with a number of filters, including price range (cheap eats, mid-range, fine dining), meal type (breakfast, lunch, brunch, dinner), and regions in the city which are located nearby. Even after the initial filters, she is likely presented with tens, if not, hundreds of restaurants. In order to narrow the list of restaurants for her consideration set, she might use aggregate-level measures, such as the volume of reviews and the user rating average; considering only restaurants that have lots of reviews and are highly rated. Finally, from the handful of restaurants left in consideration, the consumer may read several reviews of each in order to help finalize a choice of restaurant for the evening.

This vignette highlights an important feature – a multi-stage filtering approach, from aggregate-level to individual – in the consumer decision-making journey (Boatwright and Nunes 2001). This filtering approach explains why, although there are hundreds of thousands, if not millions, of peer reviews on a review platform for restaurants within a given city, consumers do not read even a modest portion of them all. Aggregate level measures, such as the number of recent reviews and their average valence, affect the upstream ranking algorithm (Ghose, Ipeiritis, and Li 2012), which determines the rank of each service provider and the page on which they appear. Aggregate level measures are also used by consumers (Dai et al. 2017; Fisher, Newman, and Dhar 2018), which can narrow down their consideration set. Finally, a handful of reviews from each of the considered service providers are read to finalize consumer choice.

Extant research on the impact of online reviews has primarily only considered reviews at either the aggregate (Babić Rosario et al. 2016; Chevalier and Mayzlin 2006; Duan, Gu, and Whinston 2008) or the individual levels (Moore 2015; Mudambi and Schuff 2010; Packard and Berger 2017). In this research, we examine online peer reviews in terms of reviewer influence on consumers at the aggregate and the individual levels, and investigate the relationship between reviewer expertise and influence of reviews on consumers at

both levels. Is it simply the case that expert reviewers always have greater influence on consumers than their novice counterparts? If not, in what case might this not be true, or perhaps even reversed? Why?

## Hypotheses

Consistent with extant research on expertise (Alba and Hutchinson 1987), because of their abundant practice in generating prior reviews, expert reviewers are more skillful than their novice counterparts (Solomon 1990). Therefore, we expect that at the individual level of reviews, reviews by expert users will be more influential, as judged by readers, than reviews by novice users (H1).

However, at the aggregate level of reviews (volume and valence), we suspect the opposite to be true, where novice users have more influence than their expert counterparts. With regard to the volume measure, because of the Pareto distribution (Arnold 2015), where there are substantially more novice users than expert users, we predict that for any given service provider, under any (recent) time frame, there will be more reviews generated by novice users than by expert users. This would suggest that novice users are the main drivers of increasing the volume measure (H2).

In the case of the valence measure, because people tend to simplify complex information in a categorical/dichotomous manner (e.g., good versus bad; Billig and Tajfel 1973; Gutman 1982) and experiences tend to lead to a more nuanced perspective (Galinsky and Moskowitz 2000), we hypothesize that for any given experience, novice users assign more polarizing ratings (i.e., ratings that are more distant from the midpoint of the rating scale) than expert users (H4). As a result, we expect that novice users will have a greater tendency in shifting the existing average valence, especially when the average valence is close to the midpoint of the rating scale (H3).

- Hypothesis 1* At the individual level of reviews, reviews by expert (vs. novice) users are more influential on consumers.
- Hypothesis 2* Novice (vs. expert) users play a greater role in driving up the volume measure.
- Hypothesis 3* Novice (vs. expert) users play a greater role in shifting the valence measure up/down.
- Hypothesis 4* Novice (expert) users adopt a more polarizing (gradient) rating approach relative to their counterparts.
- Hypothesis 5* For service providers that generally provide moderately high [moderately low] quality service, novices assign significantly higher [lower] ratings than experts.

### Study 1: Qunar (Field Data)

The purpose of Study 1 is to test whether expert or novice reviewers are more influential on consumers at the individual and aggregate levels of online peer reviews. We scraped and analyzed over 130,000 reviews on 60 hotels, spanning 4 cities from Qunar.com, a major Chinese-based reputation platform.

Our main independent variable of interest is *user expertise*, which is defined as the number of reviews the user has generated on the platform prior to posting the current review. Our dependent variable of influence at the *individual* level is *review favorability*. Our dependent variables of influence at the aggregate levels are *review volume* and *rating-average distance*. We also assess differences in rating pattern with the *rating polarity* measure. For the operational definitions of the dependent variables.

To test the relationship between user expertise and the different dependent variables, we conducted an analysis of covariance (ANCOVA) for each. Across our tests, we include a number of control variables, including hotel identification, purpose of travel, and how long ago the review was posted from the date the review data was scraped.

We first find that, consistent with H1, users with more review-writing experience generate reviews that readers find more favorable ( $M_{Experts} = 0.40$  vs.  $M_{Novices} = 0.32$  average 'like' votes per review;  $F(1, 132\ 979) = 14.76, p < .001$ ). Next, we find that there is a significant negative relationship between user expertise and volume of reviews posted within the most recent six months ( $\beta = -846.7, t = -2.32, p < .05$ ). Results are robust for reviews posted within most recent one month, two months, and one year (all  $p$ 's  $< .05$ ). Novices do indeed drive the volume of reviews (H2). Consistent with H3, we find that users with less review-writing experience on average assign ratings that are further from the average, for hotels with moderate user rating averages ( $M_{Novices} = 0.88$  vs.  $M_{Experts} = 0.82$  units from existing average valence;  $F(1, 22\ 819) = 29.85, p < .001$ ). Finally, as per H4, we find that novice users assign more polarizing ratings than their expert counterparts ( $M_{Novices} = 1.64$  vs.  $M_{Experts} = 1.55$  average units from the midpoint of a five-point scale;  $F(1, 132\ 979) = 772.69, p < .001$ ).

### Conclusions

In Study 1, using Qunar hotel review data, we demonstrate that at the individual review level, expert (vs. novice) users have greater influence, as judged by reader assessment. However, at the aggregate level, we find that opposite effect, novice (vs. expert) users have greater influence, in terms of driving up the volume of reviews and shifting the average valence. We demonstrate that the shifting of the average valence can be explained by novice users' tendency to assign more polarizing ratings relative to their expert counterparts.

### Study 2: Priming Experienced Raters (Experiment)

The purpose of Study 2 to test the effects of user expertise on patterns of assigned star ratings in an experiment, by priming participants as either expert or novice raters. User expertise (expert vs. novice) was manipulated by having participants recall and evaluate memories of experiences either related or unrelated to the focal service, prior to assigning a rating to the focal experience. The design of the experiment is a 2 rating expertise (high vs. low) x 2 description valence (positive vs. negative) between-subjects design. The outcome measure in the experiment is the assigned star rating, along a 5-point scale from 1-*Terrible* to 5-*Excellent*.

Online participants ( $N = 190$ , %female = 56.3%,  $M_{Age} = 35.0$ ,  $SD_{Age} = 11.1$ ) on Amazon Mechanical Turk were randomly assigned to the beginner or veteran contributor level. Participants assigned to the expert (novice) condition were asked to think about restaurants

they have visited [electronic products they have purchased] over the past year (note that the dependent measure is specific to restaurants). Participants were then presented with a description of a moderately positive or moderately negative experience at a restaurant and then asked to assign a star rating for the experience.

A two-way analysis of variance revealed a significant interaction between contributor level and experience valence on assigned star rating ( $F(2, 187) = 5.68; p < .05$ ). For the moderately positive experience description, participants primed as expert raters assigned marginally lower ratings ( $M = 4.35, SD = 0.64$ ) than those primed as novice raters ( $M = 4.57, SD = 0.50; t(1, 94) = 1.89, p = .06$ ). For the moderately negative experience description, there was no significant difference in ratings between expert and novice raters ( $M_{Novice} = 1.61, SD = 0.57$  vs.  $M_{Expert} = 1.84, SD = 0.75; p = .13$ ). Most importantly, consistent with H4, we find that participants primed as expert raters assign ratings that were less polarizing ( $M = 1.29$  average units from the midpoint of a five-point scale,  $SD = 0.62$ ) than those primed as novice raters ( $M = 1.47, SD = 0.54, t = 2.12, p < .05$ ).

### Conclusion

Using an experiment, we showed that priming rating expertise, specifically, rating familiarity with a focal domain, reduces the extremity of ratings. This reflects the more gradient rating approach favored by users with high rating expertise in the earlier field data. The parallel findings between our field data in Study 1 and our experiment data in Study 2 allows us confidently draw the causal relationship between more extensive rating experiences and less polarizing ratings, as well as rule out unobserved reviewer characteristics as possible confounds of the effect.

### Study 3: TripAdvisor (Field Data)

The purpose of Study 3 is twofold. First, we test whether our findings from Study 1 from the Chinese-based platform Qunar.com replicate in a North American-based platform, TripAdvisor.com. Second, we test whether the more polarizing rating approach by novice users is systematic, such that for certain service providers, novice reviewers systematically assign higher and lower ratings than expert reviewers. We scraped and analyzed over 100,000 reviews on 60 hotels, spanning 6 cities, on tripadvisor.com, a major online North-American-based travel review platform. The same variables are collected as those in Study 1.

First, for replication of findings from Study 1. Second, we test whether, for certain service providers, novice reviewers systematically assign higher and lower ratings than expert reviewers. We find that for hotels that generally provide moderately high quality service (average valence of 4.4-4.6), novice users systematically assigned *higher* ratings ( $M = 4.53$ ) than expert users ( $M = 4.43; \beta = -0.056, t = -7.16, p < .001$ ), and therefore are systematically pushing up the average valence. However, for hotels that generally provide moderately low quality service (average valence of 3.5-3.7), novice users systematically assigned *lower* ratings ( $M = 3.27$ ) than expert users ( $M = 3.40; \beta = 0.060, t = 2.50, p = .01$ ), and therefore are systematically pulling down the average valence.

### Conclusions

In Study 3, using hotel review data from a North American-based review platform, TripAdvisor.com, we replicate the main results from Studies 1 and 2. More importantly, we show that the more polarizing rating approach by novice users is not random, but systematic, such that for service providers that generally provide moderately high [moderately low] quality service, novice users assign significantly higher [lower] ratings than expert users, and therefore,

are systematically pushing up [pulling down] the user rating averages.

### General Discussion

In our research, we examined the influence of expert and novice users on online peer review platforms at the individual and aggregate review levels. In Study 1 (Qunar), we show that at the individual review level, expert users have greater influence, as judged by readers' assessments.

However at the aggregate review level, novice users have greater influence, in terms of driving the volume of reviews and shifting the average valence. Further, we demonstrate that novice users' shifting of the average valence can in part be explained by their more polarizing rating approach relative to their expert counterparts. In Study 2, testing the idea that novice users adopt a more polarizing approach, we validate the causal relationship between lack of rating experience and rating polarity, and rule out unobserved reviewer characteristics as possible confounds. In Study 3 (TripAdvisor), we replicate the findings from Study 1. Also, we show that for moderately high [moderately low] service providers, novice users assign higher [lower] ratings than experts.

Although it is generally thought that experts play a more dominant role in shaping consumer opinion (Alba & Hutchinson 1987), the present research demonstrates this is not always the case. With the flourishing of user-generated content, consumers are less likely to access all the available content. Instead, they rely more and more on aggregate level measures that summarize the abundance of content to guide their consumption choice (Dai et al. 2017; Fisher et al. 2018). Our results show that novices have more impact at the aggregate level measures in terms of driving the volume of reviews and shifting the average valence. Our results suggest that firms should be cautious, and perhaps even hesitant, when focusing on having expert users generate reviews about their product/service. Further, firms that generally provide *moderately high* quality service may consider completely avoiding expert users, as experts assign significantly lower ratings than novices, and therefore, relative to their novices, are systematically pulling down the average valence.

To conclude, this research provides evidence, in the context of user-generated content platforms, for when and how novices have greater influence on consumers and the systematically different rating approaches adopted by expert and novice users. The findings from our study are important to service providers, particularly as consumers move away from traditional offline media and towards online digital media where user-generated content plays an increasingly larger role in shaping consumer choice.

# Does It Pay to Be Virtuous? Examining Whether and Why Firms Benefit From Their CSR Initiatives

Dionne Nickerson, Georgia Institute of Technology, USA

Michael Lowe, Georgia Institute of Technology, USA

Adithya Pattabhiramaiah, Georgia Institute of Technology, USA

## EXTENDED ABSTRACT

Formally defined as discretionary business practices and contributions of corporate resources intended to improve societal well-being (Korschun, Bhattacharya, and Swain 2014); corporate social responsibility (CSR) is increasingly present in consumer consciousness. In fact, we often see consumers seeking out and supporting brands that they perceive as contributing to the greater societal good, incentivizing brands to engage in CSR (Hughes 2016).

While CSR is increasingly important to brand strategy, specific guidance on the nature of activities that a brand should undertake, and a documentation of the ensuing returns, are lacking. Detecting potential differences in consumer response to CSR activities might have been challenging in prior research for three important reasons. First, prior work has typically not distinguished between particular types of CSR investment (Jayachandran, Kalaignanam, and Eilert 2013). Second, research has centered around financial performance measures such as firm market value and stock response - which are more separated from direct consumer involvement (Luo and Bhattacharya 2006; Mishra and Modi 2016). Third, other work has focused on documenting the influence of CSR campaigns by looking at measures of consumers' intentions and attitudes (Chernev and Blair 2015). To our knowledge, our paper forms the first attempt at leveraging field data to offer direct empirical support for the existence of benefits to firms from engaging in different types of CSR, because of direct consumer response.

We propose a new framework for managing CSR that is rooted in the perspective of consumer-brand relationships, by drawing on the concepts of forgiveness in relationships. We distinguish between three types of CSR engagement: correcting for the negative societal impact of a brand's business operations, compensating for the negative societal impact of a brand's business operations without making changes to operations, and cultivating consumer goodwill through prosocial acts unrelated to the negative societal impact of a brand's business operations. Conceptualizing CSR in this manner can be advantageous for brand managers, due to its direct focus on the influence of CSR on consumer actions. We argue that the three different types of CSR engagement can potentially engender different consumer attributions of sincerity in a brand's CSR efforts, and that these differences can be important for understanding any potentially heterogeneous impact that each type of engagement may have on brand sales.

We take a mixed methods approach to understand these relationships. We first leverage observational data to examine the existence of a causal impact of firms' CSR announcements on brand sales. We then examine the underlying psychological mechanisms that may be influencing changes in consumer purchase behavior in a controlled experimental setting.

To investigate the effect of CSR announcements on brand sales, we collect CSR press releases from prominent CPG (consumer packaged goods) brands as well as detailed brand sales data. Our analysis dataset contains 33 brands that announced CSR initiatives and 100 brands that did not, spanning 15 CPG product categories. We compare differences in brand sales before and after CSR announcements for brands that announced CSR initiatives ("treated" brands) and compare the analogous difference in brand sales for a closely comparable set of brands ("control" brands) within the focal brand's prod-

uct category that did not announce CSR initiatives. We thus use the synthetic control method to examine this effect (Abadie, Diamond, and Hainmueller 2010). The intuition behind this approach is that it creates a "synthetic control unit," computed as a weighted combination of all control units, to compare against the treated unit.

We find that, on average, corrective and compensating CSR actions are associated with a sales increase, whereas cultivating CSR actions are associated with a sales decrease. We show that this effect differs according to consumers' prior knowledge of the brand, measured as brand reputation. The results suggest that, for brands with lower reputations, corrective CSR leads to an overall increase in brand sales. The pattern of increases in brand sales is similar for lower reputation brands that undertake compensating CSR. In contrast, both higher and lower reputation brands experience sales decreases after engaging in cultivating CSR.

We explore the mechanism behind these sales effects in a controlled laboratory setting. An ANOVA ( $N=148$ ) examining the impact of the CSR on brand attitudes using brand reputation (higher vs. lower) and CSR type (corrective, compensating, or cultivating), shows that the significance of the impact of a CSR activity depends on the *a priori* reputation of the brand involved. Consistent with the model, the most positive consumer response was for "corrective" actions undertaken by a lower reputation brand, a response that was significantly higher than an identical corrective action undertaken by a higher reputation brand ( $M_{\text{lower/corrective}} = 1.52$ ,  $M_{\text{higher/corrective}} = .474$ ;  $F(1,142) = 14.53$ ,  $p < .001$ ). This was also true for compensating actions ( $M_{\text{lower/compensating}} = 1.30$ ,  $M_{\text{higher/compensating}} = .464$ ;  $F(1,142) = 8.63$ ,  $p = .004$ ). There was no such difference between lower and higher reputation brands for "cultivating" CSR actions ( $M_{\text{lower/cultivating}} = .827$ ,  $M_{\text{higher/cultivating}} = .617$ ;  $F(1,142) = .494$ ,  $p = .483$ ).

We used a bootstrap analysis to test for the mediating effect of consumers' perceptions of the sincerity of brands' CSR actions. An ANOVA with CSR type and brand reputation predicting perceived sincerity had a marginal interaction ( $F(2, 146) = 2.68$ ,  $p = .072$ ), and significant main effects of CSR type ( $F(1, 147) = 6.75$ ,  $p = .002$ ) and brand reputation ( $F(1, 147) = 50.37$ ,  $p < .0001$ ). Overall, perceived sincerity significantly mediated the moderated effect of CSR type on brand attitudes for both corrective-type actions (corrective:  $a_1 \times b_1 = -.1989$ , 95% C.I. =  $-.5322$  to  $-.0333$ ,  $p < .05$ ), and compensating CSR actions (compensating:  $a_2 \times b_1 = -.1988$ , 95% C.I. =  $-.5355$  to  $-.0183$ ,  $p < .05$ ). These results reveal that consumer perceptions of brand sincerity significantly mediate the relationship between CSR type and brand attitude.

These results show that the payoffs from CSR vary depending on the type of CSR engagement and that this effect can be materially significant. These findings contribute to the literature by investigating CSR as a multidimensional construct and by empirically demonstrating how firms' CSR initiatives affect consumer responsiveness.

# All We Need is Love: Examining Differences in Time and Money Donations between Dyads and Individuals

Hristina Nikolova, Boston College, USA

## EXTENDED ABSTRACT

Donations of both time and money are critical for societal well-being: in 2013, the dollar estimate of the annual volunteered time in the U.S. was \$167 billion and the total monetary donations were \$335 billion. Time and money donations have important benefits for consumers' personal well-being as well: consumers who donate monetary/time resources are happier, have higher life satisfaction, self-esteem, better physical and mental health (Thoits & Hewitt, 2001).

In the present research, we focus on the joint pro-social behavior of pairs of consumers (dyads) and compare it to that of individual consumers. Specifically, we examine whether there are differences between dyads and individuals in their donations of time and money – two fundamental resources in consumers' lives (Liu & Aaker, 2008).

We propose that while dyads and individuals will make similar monetary donations, dyads will donate less time than individuals. We base this prediction in the functionalist model of donations proposed by Clary and colleagues (1998, 1999), who argue that donating time serves six personal/social functions: *ego protection* (cope with life difficulties), *value expression* (express altruistic values), *career growth* (improve career prospects), *knowledge* (gain knowledge/skills), *self-enhancement* (enhance self-growth), and, most importantly, *social motives* (develop/strengthen social ties). To the extent that these needs are active and unmet, people will be more likely to donate time

On the other hand, donating money serves a more limited set of personal (not social) goals. Specifically, money donations have been most strongly linked to value expression, self-enhancement or identity-related motives (Aaker & Akutsu, 2009; Meier, 2007). Unlike donating time, donating money cannot serve any social functions such as building social ties.

Thus, we argue that time donation decisions are rooted in the degree to which social needs are salient at the time of the choice. Importantly, when individuals are making decisions in dyads, this joint decision context itself offers a proximal means of satisfying the social needs (Nikolova et al., 2018) that time donations may otherwise fulfill. In other words, in joint decision-making contexts dyads should be more likely to perceive that their needs for social connections are satisfied. As a result, the dyadic context temporarily lowers the importance of using the time donation decision to satisfy social needs. We predict that this should lead to lower time donations of dyads relative to individuals. However, the goals fulfilled by money donations, being less social, do not change when individuals decide alone or in dyads: individuals always desire to express their values and enhance the self, whether or not they are in a pair (Ariely et al., 2009). Thus, we do not anticipate any differences in the monetary donations of dyads and individuals. We test these predictions in four studies.

In Study 1, participants (n=248) were either paired to make joint decisions (n=98 pairs) or made the same decisions individually (n=52). Pairs/individuals imagined that they were shopping together/alone when they noticed a donation campaign for helping premature babies. They indicated the amount of money (\$)/time (hours) they were willing to donate to the campaign together/alone. Dyads (M=1.49 hours, SD=1.69) were willing to donate less time than individuals (M=2.65 hours, SD=2.58),  $F(1, 144)=10.66, p=.001, \eta_p^2=.07$ .

There was no difference in the monetary donations of dyads and individuals,  $p=.36$ .

Study 2 replicated these findings using real monetary and time donations. Participants (n=135) completed the study for \$6 and were assigned either to the individuals (n=55) or dyads condition (n=40 pairs). Participants read information about a charity called The World Needs More Love Letters ([www.moreloveletters.com](http://www.moreloveletters.com)). Participants were asked to write an encouragement letter to a couple Jon and Jasmine, who were both battling cancer. The number of words in the letters participants wrote represented the time donation measure. Finally, participants were given their compensation and a donation envelope in which they could donate some of it to Jon and Jasmin. Results showed that dyads (M=35.38, SD=29.76) wrote encouragement letters that contained less words than those of individuals (M=48.22, SD=51.67),  $F(1, 90)=6.82, p=.01, \eta_p^2=.03$ , controlling for amount of time spent on the task ( $b=.37, t(90)=12.76, p<.0001$ ). There was no difference in the monetary donations of dyads and individuals,  $p=.22$ .

In Study 3 (n=119), dyads (M=1.70 hours, SD=.96) were willing to donate less hours to help an organization called HopeLab with a fundraising event than individuals (M=2.43 hours, SD=1.85),  $F(1, 74)=4.90, p=.03, \eta_p^2=.06$ . There was no difference in the monetary donations of dyads and individuals,  $p=.42$ . Importantly, we find that dyads (M=4.27, SD=1.46) perceived lower happiness of giving time than individuals (M=4.76, SD=1.42),  $F(1, 117)=2.99, p=.09$ . This finding suggests that dyads might have a proximal satisfaction of their social needs (the other person), which reduces the value of outside opportunities for social utility.

In Study 4, we provide direct evidence of this mechanism using married couples. Participants (n=307) were recruited on MTurk and asked to indicate their relationship status. Participants who were single (n=131) represented the group of individuals and reported how many hours/what percent of income they donated each month. Participants who were married (n=176) represented the group of dyads; they reported the amount of time/money they donated jointly as a couple each month. All participants indicated the extent to which they felt that their needs for social connections were satisfied. To account for excess number of zeros on the time donation DV (78.4%), a Zero-Inflated Poisson regression was run: couples donated less time each month than single participants ( $b=-.28, \text{Wald } \chi^2(1)=10.79, p=.001$ ). There was no difference in the percent of income donated by couples and individuals,  $p=.87$ . Importantly, couples (M=4.81, SD=1.47) believed that their social connection needs were satisfied to a larger extent than single participants (M=4.27, SD=1.81),  $F(1, 287)=7.98, p=.005$ , and the satisfaction of social connection needs mediated the effect of decision-maker on time donation ( $b=.21, SE=.12, 95\%CI: .050, .555$ ).

Taken together, this research contributes to the pro-social behavior literature by being the first to compare the joint pro-social decisions of dyads and individuals, as well as offers important implications for organizations which rely heavily on volunteering couples (e.g., schools counting on parents' time donations).

# The Psychology of Fun: Inquiry into Consumers' Fun Experiences

Travis Tae Oh, Columbia University, USA  
Michel Tuan Pham, Columbia University, USA

## EXTENDED ABSTRACT

One prominent pleasure construct that plays a vital role in people's consumption is fun. The experience of "having fun" is ubiquitous among today's consumers, who spend considerable amounts of time and money on fun activities such as a week-long cruise. Moreover, firms frequently promote "fun" as an attractive promise in their advertising messages and strategically position themselves (e.g., Virgin Airlines) as fun brands.

Despite its growing presence as a unique concept in real-world circles, fun has yet to receive adequate academic attention as a psychological construct on its own right. Most of what is considered research on "fun," has utilized the word as a proxy of experiential utility (Babin et al., 1994) with little regard for its psychological contents (Alba & Williams, 2013; Pham 2013). Thus, the main goal of this paper is to propose a theoretical framework on the psychology of "having fun" in consumers' lives, and present fun as a unique construct, differentiated from related concepts such as happiness.

To reach this objective, we adopt a multi-method approach with an inductive focus, based on data consisting of 21 depth interviews, 335 narrative experiences, and 1,600 selfies.

## METHODOLOGY

To capture the full range of the phenomenon, we conducted three types of studies in different modalities (oral, written, and pictorial), broadening the scope of our understanding of fun in multiple contexts.

**Depth Interviews.** 21 interviews were conducted in the phenomenological tradition (Thompson et al. 1989). Participants ranged from ages 18 to 73, were balanced in gender, and came from diverse socioeconomic backgrounds (e.g., homeless to retired).

**Narrative Experiences.** We recruited participants from an online panel and randomly assigned them to three conditions: Fun, Happy, and Personally Interesting. After participants wrote about their respective experiences, they filled out various process measures that were expected to be more or less representative of fun.

**Prompted Selfies.** We partnered with a mobile market research company that specializes in collecting selfie data. Through its app, we recruited participants and randomly assigned them to one of four conditions (Fun, Happy, Proud, and Relaxed) to upload a selfie regarding that particular moment.

In the following sections, we present (1) a psychological framework of consumer fun, and (2) how fun is distinct from related positive constructs.

## EMERGING FRAMEWORK OF CONSUMER FUN

As shown in Figure 1, the cross-data analyses reveal six major psychological underpinnings of fun: (a) Novelty, (b) Spontaneity, (c) Connectedness, (d) Boundedness, (e) Engagement, (f) Liberation, and two affective layers (not shown in Figure): (g) Increasing Positive Arousal and (h) Decreasing Negative Arousal. In particular, among the six psychological concepts that contribute to fun, we find that "Liberation" is the most crucial element in defining the fun construct. This feeling of liberation is central to both the motivational and experiential aspects of fun- that is, consumers were unwilling to spend their resources on fun consumption if current circumstances were too restrictive (e.g., lack of money, exam week) or if the prod-

uct offerings or situational properties were unfavorable to "let loose" of oneself.

Given the importance of liberation as a major determinant in the fun construct and due to space limitations, we present a more detailed analysis only for this dimension below.

## Liberation

The concept of liberation can be found similarly in the Epicurean ideology of "ataraxia" which represents freedom from mental discomfort as the highest order of pleasure (O'Keefe 2010). While meaningful consumption (i.e. "eudaimonia") plays a significant role in people's lives, we argue that fun as a modern day epithet of *ataraxia* is also critical to understanding well-being in consumer psychology. In particular, we identify three sub-categories of liberation as (1) Freedom from worries, (2) Carefree mentality, and (3) Release from tension. For instance, a 27 year old teaching assistant narrates about her family trip on the Disney Cruise as, "Disney- I feel like it's not just for kids... but just to see adults sing Frozen songs, and just be... Carefree! Just to see people carefree, not caring what anybody thinks, singing all the songs, getting on all these rides, I find that fun."

## FUN AS A DISTINCT PLEASURE CONSTRUCT

We primarily focus on the differences between fun and happiness, as these two constructs are closely related, and have substantial implications to consumption experiences (e.g., Nicolao et al. 2009). The results below are primarily from the narrative experiences data and we leave out results from selfies due to space limitations.

## Results

Participants in the happy condition reported the highest level of meaningfulness ( $p < .01$ ). People in the fun condition reported that time progressed faster and was more fun than the happy condition (all  $ps < .05$ ). More importantly, participants in the fun condition reported significantly higher feelings of liberation ( $p < .001$ ) and connectedness ( $p = .08$ ) than the happy condition. LIWC analysis showed that between conditions, "friends" was higher in the fun condition ( $p = .06$ ) and "family" was higher in the happy condition ( $p < .01$ ).

## Discussion

We find evidence that consumers distinguish fun experiences as more fun, less meaningful, and progressing faster than happy experiences. These results suggest that consumers readily differentiate the two constructs. Interestingly, people felt happier with their family and more fun with their friends, implying that the content of connectedness matter, over and beyond social intimacy or belongingness.

## DISCUSSION

This research presents a novel framework of fun, as a unique construct. We also show that consumers readily distinguish fun as a unique construct, different from related concepts as happiness.

Based on these findings, we define fun as an affective pleasure construct identified by a strong sense of engaged liberation, which often arises from bounded, novel experiences that involve moments of spontaneity and connectedness with others.

Our framework and investigation contributes to the growing literature on hedonic consumption by providing a content-rich insight into a highly relevant pleasure construct. Moreover, the multi-meth-

od approach expands the epistemological lens traditionally used in consumer research. Future studies could operationalize and manipulate the underlying mechanisms to further validate the framework, and distinguish from other related concepts as humor and play.

# Do Altruistic Individuals “Share” More Contents on Social Media?

Travis Tae Oh, Columbia University, USA

Keith Wilcox, Columbia University, USA

## EXTENDED ABSTRACT

The power of video contents to “go viral” has sparked much interest in managerial and academic circles. Despite the prevalence of the “Share” function in almost all online social network services and its important implications in viral marketing, the psychological processes and motivational factors underlying the behavior of “sharing” contents on social media have been understudied.

Word-of-mouth literature shows that altruism is a viable predictor of sharing information in consumer contexts (Sundaram et al. 1998), but it is unclear whether altruistic individuals would share more contents on social media. Purely altruistic acts typically incur a significant “cost” to the benefactor, but sharing on social media requires minimal costs while exposing the self to the scrutiny of many others. Thus, even if altruism increases sharing on social media as in other word-of-mouth contexts, the primary motive is more likely to be self-oriented (Berger 2014) than other-focused (Dichter 1966). Indeed, Baumeister (1982) theorizes that the self-presentational motive of gaining favorable evaluations from others often accounts for altruism and that heightening such concern will promote prosocial behaviors. Yet, this relationship has not been directly tested.

In this research, we examine the relationship between altruism and self-presentation motives in the context of sharing contents on social media. We propose that self-presentation concerns lead altruistic individuals to share more contents on social media, because they view sharing as a means to gain favorable evaluation from others. As suggested by Baumeister (1982), we expect that altruistic individuals will be motivated to gain favorable evaluations from others, and share contents to reap positive rewards of feeling good about the self.

Through a series of 4 studies, we provide novel evidence that indeed altruistic people are more likely to share contents on social media because of self-presentational concerns and rewards of positive feelings about the self. Interestingly, low altruistic individuals will also share more video contents when self-motivational cues are triggered, and this concern for others’ evaluations is dormant for such individuals in neutral states on social media. The findings contribute to our understanding of the relationship between self-oriented motives and altruism, and offer insight into the psychology of sharing video contents on social media, an important and pervasive phenomenon that underlies viral marketing.

## PILOT STUDY

In this study, we test whether individuals with high altruism are more likely to have (1) higher self-presentational concerns and (2) belief that others are judging them, especially in social media.

We recruit 233 people and measure the extent of self-presentational concerns when thinking about sharing video contents on Facebook. Additionally, participants imagine that they had just shared a video, and report their belief on others’ judging them on social media. Altruism was positively correlated with self-presentational concerns ( $p < .01$ ). When participants were grouped by levels of altruism, only the high altruistic individuals showed a significantly greater sensitivity to judgment by others on social media. Furthermore, self-presentational motives mediated the positive relationship between altruism and belief of others’ judgment when sharing on Facebook.

Thus, a stronger belief of others’ judgment on the self was present in high altruistic individuals, who in turn were more motivated

to present themselves favorably and accurately by “sharing” video contents on social media.

## STUDY 1

We investigate how altruism specifically relates to sharing on social media by measuring people’s actual behaviors on Facebook.

We recruited 267 online participants to login to their Facebook accounts and browse their “Activity Log” to report the number of activities (e.g., “Like”) conducted during the previous month. We also measured altruism (Philippe Rushton et al. 1981), self-monitoring (Snyder 1974), and cooperativeness (Cloninger et al. 1993). Only altruism positively predicted “sharing” on Facebook ( $p < .05$ ), while other traits showed negative or null effects.

The results of study 1 is particularly reliable given that we establish an effect by measuring actual past behaviors.

## STUDY 2 & 3

If self-presentational concerns motivate altruistic individuals to “Share,” we posit that triggering sensitivity to others’ judgments on the self should also increase likelihood of sharing on social media for non-altruistic individuals, and cancel out the positive correlation of altruism on sharing. In contrast, if self-presentational motives are the main mechanism, priming other-focused motives (i.e., for the enjoyment of others) should not moderate the positive relationship between altruism and sharing online. In the following studies, we test this hypothesis by directly manipulating the sensitivity to others’ judgment, and also measure positive feelings of the self (e.g., proud) as a mediator.

All participants engaged in a hypothetical task of watching a 15 second video (pretested for moderate likability) and were asked to imagine sharing the video on Facebook. We primed individuals to think about others’ passing judgment on them in one condition or to think about how others would enjoy the video (study 3), while no additional instructions were given in the control condition (study 2). In study 3, we measured positive feelings to test whether self-oriented rewards were mediating sharing contents on social media.

As expected, the main effect of altruism was positive and significant in all studies ( $p < .01$ ). More importantly, the interactions between altruism and the judgment manipulation were significant in both studies. The conditional effects of the judgment manipulation increased the likelihood of sharing for the low altruistic people, but had no effect in the high altruistic individuals. Furthermore, positive feelings showed mediated moderation patterns ( $p < .05$ ).

## CONCLUSION

Through a series of five studies, we present a robust finding that altruistic individuals are more likely to share contents on social media. We find support that self-presentational motivations – gaining a favorable evaluation from others – account for this peculiar relationship. Our evidence shows that altruistic individuals are more sensitive to others’ judgments on social media, and that positive self-oriented feelings mediate their intention to share contents online.

One limitation of the current research is that only one type of contents (video) is used, limiting the generalizability of the findings. Although we show a positive relationship between sharing and altruism with actual past Facebook activities data, future research should address this issue by testing additional types of contents.

# An Idea Opposed to Another Idea is Always the Same Idea: Reconsidering the Materialistic Aspects of Voluntary Simplicity

Mathieu Alemany-Oliver, Toulouse Business School, France  
Justyna Kramarczyk, Adam Mickiewicz University in Poznań, Poland

## EXTENDED ABSTRACT

In consumer research literature, voluntary simplicity is generally understood as a non-materialistic or an anti-materialistic lifestyle. Our study of Polish simplifiers stands in contrast to this view as it reveals the importance that possessions can have in the lives of our participants. The participants' relations to objects reveal a form of materialism that we describe as negative (vs. positive) and that emphasizes non-accumulation while leaving possessions a central place in the lives of consumers.

Voluntary simplicity can be defined as “the choice out of free will [...] to limit expenditures on consumer goods and services, and to cultivate non-materialistic sources of satisfaction and meaning” (Etzioni 1998, 620). It implies regaining control over one's own life and searching for meaning while avoiding mass consumption and accumulation (Elgin 1981; Zavestoski 2002). Voluntary simplicity is often associated with environmental values, ethical practices, material simplicity, distance from money, freedom, self-sufficiency, self-knowledge, and the spiritual world (Cherrier 2009; Cherrier and Murray 2007; Elgin and Mitchell 1977; Etzioni 1998; Gregg 1936; Huneke 2005; Leonard-Barton 1981; Moisander and Pesonen 2002; Shama 1981, 1985; Shaw and Newholm 2002). With such a conception of voluntary simplicity, it is not surprising to find close links between voluntary simplicity and materialism—or, specifically, its rejection—in academic works and other discourses on simplifiers (Etzioni 1998; Craig-Lees and Hill 2002; Nepomuceno and Laroche 2015, 2017). Unfortunately, this emphasis on a negative correlation between voluntary simplicity and materialism leads to a wrong assumption, namely that voluntary simplicity separates consumers from the material world. And yet, it would not be counterintuitive to think that the fewer possessions we have, the more we care about them and develop special relationships with them (Hill and Stamey 1990). Belk (1988) also points out that possessions are not mere objects but imbued with meanings that extend the self. Even the absence or refusal of objects can constitute a way of shaping the self (Lastovicka and Fernandez 2005; Hogg, Banister, and Stephenson 2009).

The results of a two-year ethnography of Polish simplifiers highlight materialistic aspects of voluntary simplicity that had not previously been underlined or had been emphasized very little. As in previous studies, we have observed that participants are motivated to live with fewer possessions without necessarily spending less (material simplicity), to take control of their lives (self-determination), and to better explore their inner lives (personal growth). It is interesting to note that the vast majority of participants pay little attention to ecological concerns or ethical principles, even though other studies have identified these concerns as motivating factors for simplifiers (Leonard-Barton 1981; Alexander and Ussher 2012; Shaw and Newholm 2002). One possible explanation for these differences may come from Poland's socialist past, which is more conducive to the development of a less ideological and mainly self-oriented version of voluntary simplicity. This would coincide with the results that Kala, Galčanová, and Pelikán (2017) obtained in the Czech Republic, another formerly socialist country. Last but not least, the results show how participants can attach great importance to their possessions and show relationships with objects that are very similar to those developed by materialistic consumers.

While voluntary simplicity is generally associated with a rejection of or indifference to materialism, the widely accepted definitions of materialism by Belk (1984), Richins and Dawson (1992), Richins and Rudmin (1994), and Shrum et al. (2013) confirm that our participants are materialistic and that there is, consequently, a form of voluntary simplicity that is materialistic. While the Polish simplifiers we observed and questioned proclaim themselves to be anti-materialists, they unknowingly reinforce the materialistic consumer culture by continuing to attach great importance to what they possess and reject. These results support Shaw and Newholm (2002) as well as Shaw and Moraes (2009), with the idea that voluntary simplicity occurs within, not outside, a consumerist market system. These results also reinforce the observations by Nepomuceno and Laroche (2015) that materialists themselves can sometimes resist consumption.

Finally, this research is an opportunity to rethink materialism. The results emphasize the critical role that possessions play in the lives of participants, but by their absence or scarcity and without the simplifiers intending to accumulate more. Therefore, we encourage researchers in our field to move away from the idea of a materialism that would only or mainly be reduced to the accumulation of goods. Instead, we propose to differentiate between positive materialism, which encourages accumulation, and negative materialism, which favors non-accumulation while leaving possessions a central place in the lives of consumers. We end this extended abstract by saying that negative materialism is potentially a durable solution and could respond to Scott, Martin and Schouten's (2014) call for new relationships with materiality.

# When Sharing Isn't Caring: The Influence of Seeking the Best on Sharing Favorable Word of Mouth about Unsatisfactory Purchases

Nicholas J. Olson, Texas A&M University, USA  
Rohini Ahluwalia, University of Minnesota, USA

## EXTENDED ABSTRACT

Past word of mouth (WOM) research typically finds that, if consumers share WOM with others, it tends to be consistent with actual perceptions (Berger 2014). Thus, a negative consumption experience, such as an unsatisfactory purchase, tends to elicit negative (vs. positive) WOM. In our work, we consider when the opposite may be true. Specifically, we examine the possibility that a goal of attaining the best, or maximizing, enhances consumers' tendency to share *favorable* WOM about unsatisfactory purchases.

Prior research demonstrates that when consumers have a goal of attaining the best, they are concerned with not only getting the best, but also being best relative to others (Weaver et al. 2015). When those seeking the best, or maximizers, make an unsatisfying purchase, it signals that they have failed to attain an objectively optimal outcome, which elicits strong negative feelings (e.g., regret; Schwartz et al. 2002). However, their objectively poor decision can still be relatively good if others make the same poor decision, which can be encouraged by speaking favorably about the bad purchase (Berger 2014). Extending this notion, we propose that maximizers (vs. non-maximizers) will be more likely to share favorable WOM about their unsatisfactory purchase, because they want others to make the same poor decision to enhance the relative standing of and subsequent feelings toward their own outcome.

We further posit that maximizers will only exhibit this behavior when sharing WOM with interpersonally close (vs. distant) others, as close others are a more consequential source of comparison (Festinger 1954), making their outcomes especially important in determining the relative standing of consumers' own choices. Finally, we consider the downstream consequences of maximizers' conduct, proposing that when they successfully persuade others to make their same poor purchase, they will feel better about their own purchase, but will also experience heightened feelings of guilt because of their deceptive behavior (Hoffman 1982). We tested and found support for our predictions in five studies.

In **study 1**, participants recalled a past unsatisfactory purchase, then listed either a close friend (close other) or acquaintance (distant other). All participants then reported their likelihood of recommending their purchase (sharing favorable WOM) to the other. They also indicated how much better they expected to feel about their own purchase if the other made the same purchase. Finally, after a filler task, participants reported chronic maximizing tendencies (Diab et al. 2008).

Supporting our predictions, maximizing had no effect on word of mouth in the distant other condition ( $\beta = .06, t = .53, p = \text{NS}$ ). However, in the close other condition, it enhanced the tendency to share favorable word of mouth about unsatisfying purchases ( $\beta = .34, t = 2.83, p < .01$ ). Moreover, this effect was mediated by maximizers' heightened expectations that they would feel better about their own purchase if close (but not if distant) others made the same purchase (95% CI = .0087 to .0649).

**Study 2** manipulated maximizing via an essay task, then asked participants to imagine three scenarios in which an unsatisfactory purchase was either completed or merely considered. After imagining each scenario, participants listed a close other and reported their likelihood of recommending and saying good things about their purchase (favorable WOM) to that other (7-pt scales). Consistent with

expectations, when the purchases were completed, participants in the maximizing condition were more likely to share favorable WOM ( $M = 4.36$ ) than those in the non-maximizing condition ( $M = 3.68; p < .05$ ). However, this effect was unexpectedly reversed when the purchases were merely considered, as participants in the maximizing condition were marginally *less* likely to share favorable WOM ( $M = 3.04$ ) than those in the non-maximizing condition ( $M = 3.71; p = .07$ ).

**Study 3** was similar to study 1, but after listing a close other and indicating their likelihood of saying good things and encouraging the other to make their same unsatisfying purchase (favorable WOM), they also reported their concern with enhancing the relative standing of their purchase, and how much better they expected to feel about their own purchase if the other made the same purchase. As predicted, maximizing promoted the tendency to share favorable WOM about unsatisfying purchases ( $\beta = .11, t = 1.94, p < .05$ ), and this effect was mediated by maximizers' heightened concern with enhanced relative standing, which led them to believe they would feel better about their purchase if a close other made the same purchase (indirect effect = .019, 95% CI = .0015 to .0436).

**Study 4** replicated past studies in an actual choice context, and considered the downstream consequences of maximizers' behavior. Participants (students) reported chronic maximizing tendencies, then completed a pen task in which they chose a pen from two options, learned their chosen pen was supposedly inferior (unsatisfying), and then anonymously shared WOM (how favorable their own pen was) with a purported fellow student, who would later choose from the same assortment, and whose choice would be revealed. Participants also indicated their expected decision regret if the fellow student chose the same pen. Supporting predictions, maximizing enhanced the tendency to share favorable WOM ( $\beta = .33, t = 2.52, p < .05$ ), because maximizers expected their decision regret would be reduced if the fellow student chose their pen (indirect effect = .095, 95% CI = .0026 to .2830). Following a 10-minute delay, participants learned the fellow student had supposedly chosen their pen, and they indicated their actual choice regret, as well as current feelings of guilt. While maximizers' choice regret was diminished following this information ( $\beta = -.36, t = -2.75, p < .01$ ), their guilt was enhanced ( $\beta = .28, t = 2.07, p < .05$ ).

**Study 5** was identical to study 4, except it manipulated whether the purported fellow student would choose between participants' pen and a superior or an inferior alternative. In the former condition, maximizing's positive effect on WOM was replicated ( $\beta = .37, t = 3.06, p < .01$ ), but in the latter condition, it was attenuated ( $\beta = .007, t = .05, p = \text{NS}$ ).

# How Awe Might Be Awesome: The Role of Awe in Consumers' Food Consumption and Perceptions of Misshapen Produce

Begum Kaplan-Oz, University of Massachusetts Amherst, USA  
Elizabeth G. Miller, University of Massachusetts Amherst, USA

## EXTENDED ABSTRACT

Consumers face numerous food choices that impact the well-being of themselves, the environment, and society. One such issue which is starting to receive greater attention is that of food waste. Nearly one-third of food produced is wasted globally in developed countries (Loebnitz et al 2015). Thus, understanding how consumer choices and perceptions contribute to food waste and identifying interventions that reduce waste have numerous benefits. In this research, we explore the role of awe in consumers' food consumption. Awe is a "moral, spiritual, and aesthetic" emotion (Keltner and Haidt 2003, p.297) that has been found to play a role in consumers' prosocial behavior (Piff et al 2015). Further, it has a number of features that suggest it may influence consumer food choices relevant to food waste.

Two factors that contribute to food waste are leftovers (Dewey 2017), particularly of vices which are more likely than virtues to be wasted (Kim and Kim 2016), and misshapen produce (Loebnitz et al 2015). In regards to leftovers, engaging in virtue food consumption is regarded as normal (Rook 1987) whereas engaging in vices elicits guilt (Ramanathan and Williams 2007). Recent research suggests that since consumers feel guiltier when they consume vices, they are more likely to leave leftover vices than leftover virtues (Kim and Kim 2016) which contributes to food waste. Related to misshapen produce, each year, 30-40% of produce is discarded, regardless of whether it is healthy to eat (USDA 2016). Thus, this situation also contributes to food waste (Loebnitz et al 2015).

In this research, we show that awe influences both consumers' consumption of virtuous foods and their perceptions of misshapen produce. Awe has been shown to shift one's focus from the self to others resulting in a diminished self (small self) and to make people feel more connected to nature and other people around them (Keltner and Haidt 2003; Shiota et al 2007). Accordingly, this feature might increase consumers' desire to be healthy and live longer by engaging in virtuous food consumption (H1). Additionally, feelings of small self have been shown to increase consumers' well-being and life satisfaction (Rudd et al. 2012; Piff et al. 2015). Thus, we propose that awe's influence on small self may increase consumers' desire for virtuous foods (H2). Further, feelings of awe can elicit perceptions of aesthetics and beauty (Keltner and Haidt 2003). Therefore, awe's ability to shift perceptions towards beauty and to enable a greater desire for nature (Piff et al 2015) could increase consumers' purchase intentions (H3a) and perceptions (organic/natural) towards misshapen produce (H3b). However, such effects may be affected by the importance consumers place on appearance. Previous research shows that perceptions of beauty impact consumers' behaviors (e.g. Eagly et al 1991; Lee et al 2015) which is referred as consumer vanity (Netemeyer et al 1995). Building on that, we define food vanity as the importance an individual attaches to the physical appearance of food. We propose that awe's effects on purchase intentions and perceptions of misshapen produce will be strongest for those who care about how their food looks (high level of food vanity; H4a-b).

Study 1 shows that awe increases participants' desires towards virtuous foods. Participants from Amazon Mechanical Turk (N=137) were randomly assigned to view an emotion-inducing video (awe, neutral). Results confirmed the effectiveness of the manipulation ( $M_{awe}=4.8$ ,  $M_{neutral}=3.69$ ,  $p<.002$ ). While the awe and neutral condi-

tions also differed with respect to happiness and peace ( $p's<.05$ ), these emotions did not predict the DVs when we included them as covariates in the main model ( $p>.4$ ). Participants indicated their likelihood of choosing virtuous and vice food options (a healthy (virtue-framed) chocolate, tasty (vice-framed) chocolate, and six snack options (3 virtues, 3 vices)). Consistent with H1, participants in the awe condition were marginally more likely than those in the neutral condition to prefer the virtue-framed chocolate ( $M_{awe}=4.91$ ,  $M_{neutral}=4.37$ ;  $F(1,136)=3.03$ ,  $p=.08$ ) and the virtue food options ( $M_{awe}=4.51$ ,  $M_{neutral}=4.25$ ;  $F(1,136)=2.92$ ,  $p=.09$ ). A bootstrap analysis revealed a significant mediation by small self (95% CI lower-bound=.11, Clupper-bound=.64), supporting H<sub>2</sub>.

Study 2 shows that awe increases participants' positive perceptions and purchase intentions towards misshapen produce. Participants (N=504 mTurkers) watched either an awe-eliciting or neutral video (Kaplan-Oz and Miller 2017). Results confirmed the effectiveness of the manipulation ( $M_{awe}=4.92$ ,  $M_{neutral}=3.53$ ,  $p<.001$ ). The awe and neutral conditions also differed with respect to happiness and peace ( $p's<.05$ ) but when we included them as covariates in the model, neither predicted the DVs ( $p>.5$ ). Participants rated their perceptions (organic/natural) and likelihood of purchase for three different foods (apple, carrot, eggplant; Loebnitz et al 2015) of varying abnormality. Finally, participants completed food vanity measures. A repeated measures analysis tested the impact of food shape abnormality, emotion and food vanity on buying intentions for the three food items and revealed a significant main effect for food abnormality ( $F(2, 492)=105.575$ ,  $p<0.001$ ). Participants were much less likely to purchase the extremely abnormal foods ( $M=2.95$ ) compared to normal ( $M=5.23$ ,  $p<.001$ ) and moderately abnormal foods ( $M=4.36$ ,  $p<.001$ ). The main effect for emotion was not significant ( $p > .4$ ), even though the means were in the expected direction ( $M_{awe}=4.21$ ;  $M_{neutral}=4.14$ ).

As expected, the results revealed a significant food vanity x abnormality interaction ( $F(2,492)=16.887$ ,  $p<.001$ ), with those high in food vanity less likely than those low in food vanity to purchase moderately ( $M_{high}=4.05$ ,  $M_{low}=4.67$ ) and extremely abnormal produce ( $M_{high}=2.09$ ,  $M_{low}=3.80$ ). However, as predicted in H4, this interaction was qualified by a marginally significant emotion x abnormality x food vanity interaction ( $F(2,492)=2.49$ ,  $p=.08$ ). The negative effects of food vanity on purchase intentions of misshapen produce were reversed for those in the awe condition for extremely abnormal produce ( $M_{awe-highV}=2.28$ ,  $M_{neutral-highV}=1.90$ ).

Similar results were obtained for perceptions of the food as organic/natural. Participants were less likely to perceive extremely abnormal produce as organic/natural ( $M=4.23$ ) compared to normal ( $M=5.23$ ,  $p<.001$ ) and moderately abnormal foods ( $M=5.07$ ,  $p<.001$ ;  $F(2,492)=23.708$ ,  $p<.001$ ). The main effect of emotion was not significant ( $p>.4$ ). There was a significant food vanity x abnormality interaction ( $F(2,492)=9.871$ ,  $p<.001$ ), with those high in food vanity less likely than those low in food vanity to purchase moderately ( $M_{high}=4.85$ ,  $M_{low}=5.31$ ) and extremely abnormal produce ( $M_{high}=3.64$ ,  $M_{low}=4.82$ ). However, the 3-way interaction with emotion failed to reach significance ( $p=.2$ ), although the means followed the same pattern as for purchase intentions.

Thus, across two studies, we find that awe influences consumers' food purchasing behavior and perceptions. Awe increased con-

sumers' preferences for virtue foods and increased their perceptions and likelihood of purchasing misshapen produce (for those high in food vanity). These findings have implications for alleviating food waste.

Food waste is a major concern of our society. While some research has explored the effect of negative emotions (e.g., shame, regret, guilt; Sirieix et al 2017) on consumers' attitudes and behaviors related to leftovers, the role of positive emotions (such as awe) has not been studied nor has the impact of emotion on perceptions of abnormally shaped food. Our research highlights the impact of awe as a potential intervention for reducing food waste caused by leftovers and misshapen produce. This research contributes to an increased understanding of the role of awe in consumer behavior. Additionally, this research contributes to consumers' food consumption literature by presenting the positive role of a unique emotion in increasing consumers' healthy food consumption which accordingly contributes to their wellbeing.

# With or Without You: How Second Person Pronouns Engage Listeners

Grant Packard, Wilfrid Laurier University, Canada  
Jonah Berger, University of Pennsylvania, USA

## EXTENDED ABSTRACT

What makes cultural products popular? Could products that literally speak to “you” be more engaging? Academics have long been interested in whether the use of second person pronouns (e.g., you, your, and yours) shapes audience involvement (Pennebaker 2011). While some have argued that this small category of words seems to enhance engagement (e.g., increasing likes of online posts, Cruz et al. 2017), other work has found little impact of second person pronouns on listeners (Packard et al. 2018).

We predict that “you” pronouns do enhance engagement with listeners. Importantly, however, rather than being narratively transported (Escalas 2007) as the driver of a story or by making them the focal subject or actor (e.g., “You’re driving down the street...”) as described in research on self-referencing (Burnkrant and Unnava 1995; Meyers-Levy and Peracchio 1996), we propose that “you” pronouns engage audiences by inducing a feeling of social attachment (Hazan and Shaver 1990). In short, “you” pronouns could work by evoking a “you” other than the listener: a person to whom the listener could imagine singing or speaking the words. We examine this proposition—that *other-referencing* underlies the positive impact of “you” pronouns—in three ways.

First, from a linguistic perspective, other-referencing “you” use should typically occur when this pronoun is presented as the object of a protagonist’s thoughts or actions (“I love *you*”) rather than as a self-referencing protagonist (“*You* love me”).

Second, if other-referencing drives the engagement benefit of “you” pronouns, this relationship will be mediated by second person pronouns’ ability to evoke an other to whom the listener is socially attached (Hazan and Shaver 1990).

Third, we expect that the effect of “you” use should be enhanced when second person pronoun references appear in a positively valenced manner. People are motivated to hold positive perceptions of the self, and these perceptions are maintained in part through the belief that others regard them in a positive light (Baumeister 1982, 1998; Leary 1996).

Three studies using field data and lab participants test these predictions.

Study 1 collected a dataset of 4,200 song rankings from the Billboard charts across 1,879 unique songs. We then captured each song’s lyrics and a variety of covariates (e.g., artist name, radio airplay). The lyrics were processed to identify all instances of second person pronouns. Independent judges coded whether each “you” appeared in an other-referencing or self-referencing role, as well as the valence of each “you” usage.

Results indicate that the more “you” pronouns that appear in a song, the more successful that song is (reverse-coded chart rank  $B = .19, t = 3.35, p < .001$ , model 1). This result was robust to a variety of controls (model 2).

Songs were more successful the more they mentioned “you” as the focus of someone’s attention (other-referencing;  $B = .1, t = 3.08, p = .002$ ). The number of “you” pronouns that invoked the audience as the actor themselves (self-referencing) or that were unassigned, however, had no effect ( $t_s < 1.48, p_s > .14$ ; models 3 and 4). Songs were also more successful if the “you” uses were judged to be more positive ( $B = .58, t = 2.73, p = .006$ ).

Study 2 asked 200 participants to report any song they had heard, and their attitude towards it. We then measured other-referenc-

ing (e.g., “Do the lyrics make you think about someone you know?”). Lastly, we collected measures for alternative explanations. We obtained the lyrics for each of the participant-reported songs to generate “you” pronoun statistics for each song. Independent judges coded each “you” use as more consistent with self- or other-referencing.

Regression analysis revealed that “you” pronouns increase song liking ( $B = .05, t = 2.56, p = .01$ ). This relationship was mediated by the song’s ability to evoke another person in the participant’s own life (indirect effect = .02, 95% CI [.008, .046]). Neither a perceived connection with the singer nor seeing into the singer’s personal life mediated the relationship, casting doubt on these alternatives.

Replicating the field data results, the impact of “you” pronouns was driven by the number of use cases judged to be other-referencing ( $B = .03, t = 2.50, p = .01$ ), but not by those judged as self-referencing ( $B = -.01, t = -1.02, p = .31$ ).

Study 3 sought to replicate the main effect of “you” pronouns by manipulating pronoun use in experimenter-controlled lyrics, and test for moderation of the effect by the extent to which the song’s content evokes a salient other.

Participants ( $N = 226$ ) who were currently involved in a romantic relationship were primed to think about their partner using a thought listing exercise, and then indicated their attitude towards this person. Participants were then presented with one of three versions of a positively valenced love song featuring one of either “you,” “s/he” or “it/that” pronouns (e.g. “Nothing can take [your, her (or his), its] place”).

Corroborating prior results, the version of the song with “you” pronouns was liked significantly more than the “s/he” version ( $B = .43, t = 3.40, p < .001$ ) and the “it/that” version ( $B = .31, t = 2.34, p = .02$ ). Consistent with the notion that the song was connecting them to others in their own life, the positive effect of “you” pronouns on attitudes towards the positive love song was stronger among people who had more positive attitudes towards their relationship partner (+1SD,  $B = -.53, t = -.377, p < .001$ ), but had a weaker effect among people who had less positive attitudes towards that partner (-1SD;  $B = .11, t = .56, p = .58$ ).

This research demonstrates that “you” pronouns have a significant impact on audience engagement. Textual analysis of thousands of songs and two lab studies suggest that second person pronouns engage the listener by evoking a personal other. This work deepens our understanding of when and why second person pronouns may succeed (or fail) in engaging the listener, offering new insights for both consumer and linguistic psychologists

# The Neutral Face of Blue: How Color Can Make Consumers Stay Sensitive

Sung-Hee W. Paik, University of Oregon, USA

Jiao Zhang, University of Oregon, USA

Aparna Sundar, University of Oregon, USA

## EXTENDED ABSTRACT

According to *The Largest U.S. Charities*, released by Forbes (Forbes 2017), more than half of the top 50 charities in the US use red, blue, or both in their logos. Despite this widespread use of red and blue, limited research has investigated the use of these colors in donation appeals. A logo's color, especially its hue, is known to influence marketing outcomes such as perceived benefits or brand personality (Bottomley and Doyle 2006; Labrecque and Milne 2012). The color of a logo may also be associated with meaningful concepts and even unrelated consumer inferences about the entity that the color represents (e.g. ethicality of a practice; Sundar and Kellaris 2017). Past research on color and donation appeals studied how background colors used in donation appeals influenced donation (Choi, Singh, and Rangan 2011; Mehta et al. 2011). However, the influence of logo color, and hues in particular, on prosocial intentions is less understood.

The current research investigates how the color of a charity logo influences consumers' sensitivity to the charitable cause and to donation. One aspect of this is sensitivity to the number of victims. As charitable causes often respond to natural disaster or disease and the number of donation recipients can be massive, examining sensitivity to victim numbers can be crucial. Another important criteria when interpreting the charitable cause is the social distance between donor and victims. Past research has shown that people indicate a greater willingness to help when the social distance between donor and victim is close (Loewenstein and Small 2007; Small and Simonsohn 2007). Given that many global charities ask donors to give to victims in other countries, the question of whether peripheral cues such as color can change the perception of victims is important.

Studies have shown that blue and red have distinct effects on psychological functioning and human behavior. Mehta and Zhu (2009) showed that red versus blue induces different types of motivation (i.e., avoidance vs. approach) in cognitive tasks. In the domain of advertising, Puzakova et al. (2016) showed that blue (vs. red) can broaden cognitive scope and make individuals more diagnostic in overall evaluation of information. Based on previous research on color, we examine whether the hue of a charity's logo influences potential donors' sensitivity to important objective dimensions of charitable causes (e.g., number of victims, social distance to victims). Specifically, we tested the prediction that, as blue can make donors more diagnostic about the objective information presented in an appeal, potential donors' willingness to donate will show greater sensitivity to the number of victims and the social distance to victims if the charity's logo color is blue rather than red.

In Study 1, we tested whether consumers' donation intention was more sensitive to the number of victims when a blue (vs. red) logo was presented. Participants (N=141) were recruited online to take part in a 2 (victim number: low vs. high) 2 (logo color: blue vs. red) between-subject experiment. Participants were asked to read the donation appeal of a fictitious charity supporting a rare disease and indicate their donation intention. Victim number (30 vs. 3000) and logo color (blue vs. red) were manipulated. A 2 2 ANOVA controlling for participants' gender, age, and income yielded a marginally significant interaction ( $F(1, 134) = 3.56, p = .06$ ). The results show that, when the blue logo was presented, participants indicated a significantly higher donation intention when the number of victims was

high versus low ( $F(1, 134) = 4.59, p < .05$ ). When the red logo was presented, the difference was not significant (*n.s.*).

In Study 2, we used a different charitable cause (child abuse) and added a black logo as a control. Participants were recruited online (N=263) to take part in a 2 (victim number: low vs. high) 3 (logo color: blue vs. red vs. black) between-subject experiment. A 2 3 ANOVA controlling for participants' demographics yielded a significant victim-number logo-color interaction ( $F(2, 254) = 3.60, p < .05$ ). As in Study 1, only when the blue logo was presented, donation intention was significantly higher when the number of victims was high vs. low ( $F(1, 254) = 7.60, p < .01$ ). The difference between victim-number conditions was not significant when a red or black logo was presented (*n.s.*).

In Study 3, we examined how logo color influences prospective donors' sensitivity to victims' social distance (e.g., nationality). We tested the prediction that consumers would donate more money to help socially close victims than to help socially distant victims if the logo of a charitable organization was blue vs. other colors. Participants (N=510) living in the US were randomly assigned to one of six conditions in a 3 (logo color: blue, red, green) 2 (victim nationality: US vs. Africa) between-subject experiment. They were told that children in the US (vs. Africa) were suffering from a rare disease and asked to indicate how much money on a sliding scale (\$0–\$30) they would be willing to donate to the charity. A 3 2 ANOVA yielded a significant logo-color victim-nationality two-way interaction ( $F(2, 504) = 3.30, p = .038$ ). Consistent with our prediction, when the blue logo was presented, participants donated significantly more money when the victims were in the US than when they were in Africa ( $F(1, 504) = 10.02, p = .002$ ). By contrast, when the red ( $F(1, 504) = .00, n.s.$ ) or green ( $F(1, 504) = .01, n.s.$ ) logo was presented, participants donated a similar amount of money, regardless of the victims' nationality.

Overall, our studies show that the hue used in a charity logo of a donation appeal influences consumers' sensitivity to victim numbers and to the social distance to victims, which in turn impacts consumers' donation. Considering the choice of hues in charity logos, our findings have practical implications. Furthermore, our studies contribute to the literature on color and donation by demonstrating that proper use of color can promote sensitivity to the charitable cause and can increase donation with regard to victim numbers and social distance.

# When Disadvantage is an Advantage: Benevolent Partiality in Consumer Donations

Gabriele Paolacci, Erasmus University Rotterdam, The Netherlands

Gizem Yalcin, Erasmus University Rotterdam, The Netherlands

## EXTENDED ABSTRACT

How should an altruistic consumer choose whom to help? The classical utilitarian answer, championed by the Effective Altruism movement, urges people to choose the charitable alternatives that produce the greatest welfare benefits (e.g., MacAskill 2015, Singer 2015), maximizing the *size* of the benefit and the *number* of recipients who benefit irrespective of their characteristics (Pellegrino 2017). The *size* criterion posits that one should give towards the causes that bring more benefit, which typically and aptly prescribes that, all else being equal, people should help the most disadvantaged. Because of the diminishing marginal returns of wealth, one should, for instance, donate \$100 to a poorer family rather than to a slightly less poor family, because \$100 produces a more sizable benefit for the former (MacAskill 2015, Singer 2015).

The effectiveness of donating to the disadvantaged, however, is contingent on donations directly alleviating the disadvantage; when economic disadvantage (or any other form of disadvantage) is unaffected by one's donation, it does not increase the size of the potential benefit and it is therefore irrelevant for one's donation decision. For instance, although economic disadvantage is more severe in Chad than in Nigeria, one should donate polio vaccines to hospitals in Nigeria (where polio has not been eradicated yet) rather than in Chad (where polio has been eradicated). When disadvantage is orthogonal to the cause, therefore, utilitarianism prescribes that donors should only attend to the *number* criterion: because "everybody to count for one, nobody for more than one" (Bentham 1789/1983), people should give towards the causes that allows benefiting more people as opposed to fewer.

In contrast to utilitarian prescriptions, we document a phenomenon that we call *benevolent partiality*. Across seven hypothetical donation studies, we find that many consumers weigh the well-being of members of disadvantaged groups more than what the disadvantage implies from a utilitarian standpoint, choosing to save the lives of members of more disadvantaged groups even if the same donation allows saving more lives.

In Study 1, participants decided whether to give \$10 towards shipping polio vaccines to a country or mosquito nets to another country—both being fictional third-world countries with a poor socioeconomic outlook. In a between-participants design, we manipulated orthogonally the relative number of beneficiaries across projects and the relative socioeconomic disadvantage of the two countries (e.g., average income, literacy rate). Participants responded much more strongly to the socioeconomic disadvantage in the recipients' country than to the number of people who would benefit from the donation.

In studies 2A-2B-2C, we provide individual-level evidence of benevolent partiality by eliciting participants' direct preferences for saving more people vs. saving people of more disadvantaged groups. Importantly, we took several precautions to make economic disadvantage irrelevant from a utilitarian standpoint: Donations impacted lives saved but not quality of life (i.e., donations do not alleviate disadvantage), and were described as the only means of help available to recipients (i.e., disadvantage cannot be used as a proxy for the inaccessibility of other solutions). We also repeatedly emphasized the restrictedness aspect of the donations, and analyzed our data with and without participants who failed to report in a comprehension check that money would be exclusively used to save lives. We found

that a sizable number of participants (about 40% in our studies) give money to the project in the most disadvantaged country rather than to the one allowing to save more lives (Study 2A), a result that cannot be explained by beliefs that either project will be underfunded (Study 2B), and that replicate when people can allocate their donation across projects (Study 2C).

Further studies addressed several predictors of benevolent partiality. In Study 3, we manipulated whether or not participants were asked to weigh the importance of the choice criteria prior to making a choice, mimicking a typically recommended step in prescriptive models of decision-making. We found that this intervention significantly reduced benevolent partiality, making participants more likely to choose the project saving more lives. In Study 4, we found that donors are particularly sensitive to disadvantage when this is caused by uncontrollable factors (e.g., natural soil type) compared to controllable factors (e.g., overharvesting). Finally, consistent with our moral framework, we found that benevolent partiality is less prevalent among people who have more permissive attitudes towards instrumental harm, a core dimension of utilitarian thinking which captures people's beliefs that sacrifices are acceptable if they produce a larger benefit (Kahane et al. 2017).

Altogether, our findings join recent research documenting how donation decisions are often sensitive to factors other than effectiveness (e.g., Berman et al. 2018; Cryder et al. 2017; Evangelidis and Van den Bergh 2013; Fetherstonhaugh et al. 1997; Small, Loewenstein, and Slovic 2007). Importantly, whereas this literature has typically documented instances of "heuristic ineffectiveness" that is often corrected when people jointly evaluate differently effective charitable options (e.g., Kogut and Ritov 2005), we documented benevolent partiality under the most conservative conditions—with donors evaluating options jointly and deliberately choosing to save fewer lives. Practically, this suggests that highlighting the socioeconomic disadvantage of donation recipients may increase prosocial behavior, even within the context of donations that address needs that are unaffected by disadvantage and do not affect disadvantage.

# How Passive Form Messages in CSR Advertisement Improve Consumer Reaction to the Campaign

Taehoon Park, University of South Carolina, USA  
Anastasiya Pocheptsova Ghosh, University of Arizona, USA  
Elise Chandon Ince, University of South Carolina, USA

## EXTENDED ABSTRACT

Corporate Social Responsibility (CSR) literature has documented that running a pro-social campaign provides indirect benefits to companies such as higher purchase likelihood and better perceived product performance (Sen and Bhattacharya 2001; Chernev and Blair 2015). However, these positive benefits are observed only when consumers believe that the company has sincere motive for engaging in pro-social campaign (Drumwright 1996; Ellen, Webb, and Mohr 2006).

One factor that affects perceptions of company's sincere motive for running CSR is company-cause congruence. Company-cause congruence refers to the extent to which the supporting company's core business is associated with the supported charity (Simmons and Becker-Olsen 2006). Some work in CSR and in sponsorship domains has shown that a high congruent campaign is more favored by consumers as it fulfills people's expectations (Pracejus and Olsen 2004; Rifon et al. 2004). By contrast, when there is a low company-cause congruence, consumers are more likely to elaborate on the campaign due to its unexpectedness and often end up with having more negative thoughts about it (Simmons and Becker-Olsen 2006; Koschate-Fischer, Huber, and Hoyer 2016).

Yet another line of research has suggested that high company-cause congruence can signal a greater self-benefit salience (Forehand and Grier 2003; Yoon, Gürhan-Canli, and Schwarz 2006). For example, Yoon et al. (2006) showed that consumers reported high self-benefit salience when a tobacco company was supporting cancer research than when it was supporting environmental charity. Similarly, Forehand and Grier (2003), find that consumers see higher self-benefit salience when a computer software company supports a fight against computer illiteracy versus general illiteracy among adults. When consumers infer that a company runs its campaign with an ulterior motive, their reaction to the company and CSR campaign is generally less favorable (Ellen et al. 2006). Therefore, when a high congruence campaign implies more of a self-centered benefit, positive effect of high congruence campaign will be attenuated.

Linguistics literature has documented that semantically same content can be perceived differently depending on whether it is described in an active or passive form (Turner and Rommetveit 1968; Johnson-Laird 1968; Tannenbaum and Williams 1968). For example, pro-social behavior of a company can be described either in an active form (e.g., Company A supports charity B) or a passive form message (Charity B is supported by company A). Tannenbaum and Williams (1968) documented that sentence form has a functional difference in focus, with active sentence having a more conceptual focus on the actor agent, whereas passive form places more attention on the acted-upon agent. For example, after reading active vs. passive form sentences, participants recalled actor agents more correctly for active sentences, whereas acted-upon agents were recalled better from the passive sentences (Turner and Rommetveit 1968). Difference in conceptual focus also impacts readers' attitudes toward the behavioral agent of an event. Using context of negative events, recent research has shown that people blame the behavioral agent more when the situation is described in active sentences compared to passive sentences (Fausey and Boroditsky 2010).

Extending the prior research on active and passive form sentences to the context of CSR advertising, we examine how consumers react to a pro-social campaign depending on the sentence form of advertising messages and congruence between CSR campaign and the company. Specifically, we argue that active sentence form in a CSR advertisement will focus consumers more on the agent (the company running CSR campaign) highlighting congruency between the company and the cause. By contrast, passive form sentences should de-emphasize the role of the agent (the company running CSR campaign) attenuating the impact that company-cause congruence has on CSR evaluation.

As a consequence, we expect that, when high congruence signals self-benefit, consumer reaction to such CSR campaign will be improved when messages in advertisement are written in passive (e.g., People in need are helped by Company A) as opposed to active (e.g., Company A helps people in need) form. This happens because, by shifting focus from the agent (company) to the acted-upon agent (CSR campaign), passive form CSR messages increase the company's perceived commitment to the campaign. However, since the relationship between congruence and self-benefit does not hold for low congruence, we should not observe these effects.

We test our propositions in four studies. Study 1a and 1b offer evidence of the impact of sentence form on company's evaluation through two different measures of consumer reaction. Study 2 focuses on the impact of sentence form on commitment to the campaign, while study 3 reports the complete path through a significant moderated mediation.

Study 1a employed a 2 (congruence: low vs. high) by 2 (sentence form: active vs. passive) between-subject design. Undergraduate participants ( $n = 173$ ) read about a description of petroleum company, whose core business is responsible for greenhouse effect. Next, participants were asked to examine the company's CSR campaign advertisement. For the high congruence condition, the campaign was about supporting a charity to conserve the natural environment. For the low congruence condition, the campaign was about supporting cancer research. In addition, we manipulated sentence form. For the high congruence condition, active form read "Exxon supports the World Wide Fund for Nature," while the passive form read "The World Wild Fund for Nature is supported by Exxon." For the low congruence condition, the active form read "Exxon supports the National Cancer Institute," while the passive form read "The National Cancer Institute is supported by Exxon." After reading one of four CSR advertisements depending on experimental condition, participants evaluated the company using two seven-point scales (1 = Very negative, 7 = Very positive; 1 = Very bad, 7 = Very good). The two items were averaged to form a composite index ( $r = .95$ ). An ANOVA revealed a significant interaction between congruence and sentence form on evaluation of the company ( $F(1, 169) = 5.19, p = .024$ ). As expected, for high congruence campaign, participants rated the company more favorably when the CSR advertisement used passive than active form messages ( $M = 4.37, SD = 3.73; F(1, 169) = 6.11, p = .014$ ). No difference was revealed for the low congruence condition ( $M = 4.03, SD = 4.23; F(1, 169) = .57, n.s.$ ).

A 2 (congruence: low vs. high) by 2 (sentence form: active vs. passive) between-subject study was conducted with online panel

participants ( $n = 171$ ). The target company was a car manufacturer, which was recently involved in a scandal about environmental pollution. Similar to study 1a, participants read about the target company, and then were exposed to either one of four CSR advertisements depending on experimental condition. The CSR campaign was either supporting natural environment protection (high congruence) or supporting art and culture education (low congruence). Sentence form was manipulated as in study 1a. For the high congruence condition, active form read “Volkswagen supports protection of the natural environment around the world,” while the passive form read “The natural environment protection around the world is supported by Volkswagen.” For the low congruence condition, the active form read “Volkswagen supports art and culture education,” while the passive form read “Art and culture education is supported by Volkswagen.” After reading the advertisement, participants reported intention to participate in CSR campaign on two seven-point scale items. One item was about intention to share the advertisement with their friends on social media (1 = Definitely not share the ad, 7 = Definitely share the ad), and the other one was to report their willingness to participate in the campaign by donating money (1 = Not at all, 7 = Very much). The two items were averaged to form a composite index ( $= .80$ ). Replicating the results of study 1a, an ANOVA revealed a significant interaction between congruence and sentence form on participation intentions index ( $F(1, 167) = 6.39, p = .012$ ). In the high congruence condition, participants expressed higher participation intention with the passive (vs. active) form message ( $= 3.31, = 2.39; F(1, 167) = 4.86, p = .029$ ). No difference was observed for the low congruence condition ( $= 2.41, = 2.98; F(1, 167) = 1.85, n.s.$ ).

First two studies demonstrated the predicted effect of sentence form on improving evaluation of CSR and the company running it, when the pro-social campaign is highly congruent with the company's core business. One potential limitation of previous studies is that the company was also involved in negative consequences related to its core business. To address this limitation, in study 2, participants were directly exposed to a CSR advertisement without reading company's information first to verify that the passive form effect still holds without any prior knowledge about the company.

Further, study 2 measured whether passive form sentence improves perceived company commitment for a high congruent CRS campaign. Given that the passive (vs. active) form shifts focus from the company to the CSR campaign, we expect that it will highlight how committed the company is to its CSR campaign. But this effect will only emerge when the campaign is highly congruent with the cause. This is because consumers attribute self-centric benefit to the company solely when level of company-cause congruence is high. No such attribution occurs when the congruency level is low.

Online panel participants ( $n = 162$ ) read a CSR advertisement of a chocolate company. The target campaign for high congruence condition was helping hungry people in need, whereas supporting building houses for homeless was the campaign in the low congruence condition. After reading the advertisement, participants reported the extent to which they agreed with a statement that the company is truly committed to its CSR campaign on a seven-point scale (1=Strongly disagree, 7=Strongly agree). An ANOVA revealed a significant congruence by sentence interaction on perceived commitment ( $F(1, 158) = 3.70, p = .056$ ). As expected, for the high congruence condition, participants in the passive form condition (vs. active) reported that the company was more committed to its campaign ( $= 4.90, = 4.22; F(1, 158) = 4.10, p = .045$ ), whereas no difference was observed for the low congruence condition ( $= 4.40, = 4.63; F(1, 158) = .49, n.s.$ ).

Study 3 directly manipulated consumer skepticism to examine the relationship between suspicion of self-centered benefit, commitment to CSR and company's evaluation. Prior work demonstrates that suspicion of an ulterior motive decreases evaluation of the agent (Campbell and Kirmani 2000). Holding the campaign constant, we manipulated the level of skepticism toward advertisement in general, and examined whether passive CSR messages improve consumer reaction through greater perceived commitment.

A 2 (skepticism: low vs. high) by 2 (sentence form: active vs. passive) between-subject design study was conducted with online panel participants ( $n = 136$ ). Skepticism toward advertisement was manipulated by asking participants to evaluate an irrelevant product advertisement before main stimuli. In the high skepticism condition, the target product was claimed to be better based on the company's own research, whereas the research was done by independent organization in the low skepticism condition. Next, all participants read the same CSR advertisement of a chocolate company that helps homeless people, as in study 2 low congruence condition. Then they rated perceived commitment of the company to CRS campaign with two items ( $= .89$ ). Finally, the participants evaluated the company with two items as in study 1a ( $= .94$ ). Replicating study 2 effect, an ANOVA revealed a significant interaction between skepticism and sentence form on perceived commitment ( $F(1, 132) = 3.94, p = .049$ ), such that the company seemed more committed with passive (vs. active) messages in high skepticism condition ( $= 4.84, = 4.19; F(1, 132) = 3.35, p = .07$ ), but not in low skepticism condition ( $= 4.46, = 4.80; F(1, 132) = .95, n.s.$ ). Replicating studies 1a and 1b effect, ANOVA showed a marginally significant interaction on company evaluation ( $F(1, 132) = 3.45, p = .066$ ), such that the company was favored more with passive (vs. active) messages in high skepticism condition ( $= 4.77, = 4.14; F(1, 132) = 2.89, p = .091$ ), but not in low skepticism condition ( $= 4.82, = 5.15; F(1, 132) = .85, n.s.$ ). A moderated mediation analysis (model 7, 5000 bootstraps) demonstrated that perceived commitment mediated the interaction effect on company evaluation only for the high skepticism condition (.422, 90% CI: .015, .855).

With four studies, we show that passive form messages in a CSR advertisement improve consumer reaction to the company and its CSR campaign when there is high congruence between the campaign and its core business. We argue that this happens because passive CSR messages reduce suspicion about self-centered benefits from the campaign by shifting focus from the agent (company) to the acted-upon agent (CSR campaign).

This research contributes to a CSR literature by extending prior findings about company-cause congruence. By showing how passive CSR messages improve high congruent campaign evaluation, we highlight a new way to enhance the success of high fit CSR campaign. We also demonstrate the positive effect of high congruence can be improved by signaling the company's commitment. In addition, our findings provide evidence that sentence form influences agent evaluation in the context of CSR campaigns. For managers, this research suggests an easy-to-implement tool that maximizes the positive effect of high fit CSR campaign. Compared to other factors such as length of campaign or donation amount, changing sentence structure is a cost efficient way for companies to improve evaluation and success of their CSR campaigns.

# To Touch or Not to Touch?: How Touch Influences Decision Confidence

Sang Kyu Park, University of Florida, USA

Yang Yang, University of Florida, USA

## EXTENDED ABSTRACT

An unfortunate reality of online shopping is that people do not have the opportunity to touch the actual products. When choosing between different options online, people often wish that they could touch the options in person and believe that doing so would result in an easier choice (Childers, Carr, Peck, and Carson 2001; Zhou, Dai, and Zhang 2007). In most cases, touching provides useful information by allowing people to examine the haptic characteristics of a target including texture and shape, which in turn widely affect attitudes and behaviors (see Krishna 2012 for a review). However, little is known for cases where touching does not provide any useful information. Do people still desire the opportunity to touch and expect touching to be helpful? For instance, do people naïvely believe that being able to touch a bottle of wine would help, even though touching the bottle itself offers no informative advantage? If so, does touching in those cases actually help?

## Theoretical Background

Building on the primordial nature of touch and the ubiquitous use of haptic information, we first posit that people rely heavily on touch. Touch is indeed the very first sense humans develop (Atkinson and Braddick, 1982; Bernhardt 1987), and is also the most fundamental way we explore and interact with the world (Gallace and Spence 2009; Lederman and Klatzky 1987). Touching is ever-more important in consumption contexts as it not only provides important information about the product (Peck and Childers 2003), but also because doing so itself may induce positive affect (Peck and Wiggins 2006). Previous research has further shown that people also tend to incorporate non-diagnostic, irrelevant haptic cues into judgment and decision making (e.g., Ackerman, Nocera, and Bargh 2010; Kirshna and Morrin 2008).

Given the fruitful evidence, we propose that people have long been accustomed to gathering information through touch, and thus expect that touching would invariably prove to be useful. Similar to how internalized habits and heuristics continue to function in situations where they serve no purpose (Arkes and Ayton 1999; Baron 2000; Amir and Arieli 2007), we contend that people overgeneralize their belief in effectiveness of touch-for-information so as to predict that touching would aid their decisions even in situations where it explicitly provides no informative value. Our conceptualization is in line with the recent stream of research showing that people overgeneralize various kinds of beliefs. (Hsee, Yang, and Ruan 2015; Pyskovich and Rand 2015).

While people overgeneralize and expect that touching a target would help their decision even in cases where it shouldn't, we show that touching decreases decision confidence when people are actually given the opportunity to touch and realize that it gives them no valid information. That is, when touching fails to acquire useful information, expectation disconfirmation and thwarted information search effort renders individuals frustrated (Diehl and Poynor 2010; Raghubir and Krishna 1999; Strebels, O'Donnell, and Myers 2004; Sun and Spears, 2012) and less confident in their decision (Berkowitz 1989; Roseman 1984). Tinted by the inherent penchant towards touch, however, people fail to anticipate the dismay; only after they experience the frustration do they realize it.

In sum, we propose that consumers hold an overgeneralized naïve belief that touching would somehow help their decision even for

situations where touching noticeably provides no information. However, because touching actually provides no useful information in such cases, the positive expectation is shattered when given the opportunity to touch, and it thus ironically leads to decreased decision confidence. We further demonstrate the downstream consequences of diminished confidence including lower willingness-to-pay (e.g., Chaxel 2016) and lower choice satisfaction (e.g., Iyengar and Lepper 2000; Roster and Richins 2009). The proposed effect of touch is first shown in a controlled, non-product context for a cleaner test, and later generalized to product choice contexts.

## Studies 1A & 1B

Study 1A first establishes that people generally mispredict that nondiagnostic haptic information would enhance one's decision confidence. Participants were asked to imagine two people, A and B, participating in a lucky draw for a free chocolate bar individually. Participants were given an image of two identical opaque envelopes. They were told that each person had to pick from two envelopes where one has a winning card with the letter X on it, and the other has a non-winning card with the letter Y on it. They were further informed that the instructor had person A touch both envelopes before making a decision and had person B make a choice by pointing to one of the envelopes without touching. Without learning about the outcome, participants were asked to predict each person's decision confidence and the likelihood that they picked the winning envelope. Despite the fact that merely touching the two identical envelopes does not provide any useful information, participants predicted that doing so would increase confidence for the decision maker. The pattern favoring those who touched was replicated when the scenario was administered between-subjects (i.e., description of person A provided in one condition, and of person B provided in the other), and when scenario was altered to adopt a first-person perspective (i.e., asking participants in which case they would feel more confident, rather than making judgments about person A or B).

The results were reversed in Study 1B where we had participants actually go through the lucky draw procedure described in Study 1A. As in Study 1A, participants were told that one envelope had the winning card X while the other had non-winning card Y inside, and that they would win a free chocolate bar if they pick the envelope with the winning card. In the no-touch condition, the instructor held up both envelopes and participants made their choice by pointing to one envelope. In the touch condition, the instructor handed the two envelopes to participants so that they could touch the envelopes and make their decision. Participants' confidence and perceived likelihood of having picked the winning card was measured before the results were revealed. Counter to people's prediction, when given an opportunity to touch, experiencers felt less confident about their decision, and responded that they were less likely to have picked the envelope with the winning card.

## Studies 2A & 2B

We replicate this pair of results with an altered design to rule out an alternative explanation: touching increases attachment to both envelopes and makes it harder to forgo either option (Carmon and Wertenbroch 2003; Peck and Shu 2009), causing decreased confidence. Only one envelope was involved in the modified procedure. People were told that there were 20 envelopes in total of which 10

had a card with letter X and the other 10 had a card with letter Y written on it. The instructor would randomly pick one envelope and the lucky draw entrant's job was to guess which letter was inside the envelope. Participants in Study 2A (the predictors) expected the person with the opportunity to touch the envelope to have a higher confidence. However, participants in Study 2B (the experiencers) felt less confident when they actually touched the envelope compared to those who did not touch the envelope. We also measured involvement and ownership, but there were no differences between touch vs. no touch conditions in Study 2B.

### Studies 3A and 3B

Studies 3A (the predictors) and 3B (the experiencers) generalize the effect to product choice contexts. The predictors were asked to imagine two people, person A and person B trying to choose between two bottles of wine separately. Participants were shown two bottles of wines (both 2014 Napa Valley Cabernet Sauvignons) of equal price which they could enlarge to read the information on the labels. They were further told that one of the wines received a higher rating, and that each person was trying to choose the wine that received the higher rating (the two wines actually received similar ratings in reality). In the scenario, it was explicitly stated that both person A and person B were fully informed about the descriptions provided on the label of each wine, but they were not informed of the ratings. Note that we used wines as touching the two identical bottles does not provide any useful information. In line with the previous results, the predictors judged the person who had the opportunity to touch to be more likely to have picked the better wine.

For experiencers (Study 3B), we actually showed the two bottles of wine mentioned above and provided information about the two wines as in Study 3A (i.e., origin and price). They were further told that one of the wines received a higher rating, and were asked to choose the wine they thought received the higher rating, mirroring a typical purchase decision. We told participants that they would get a free candy if they pick the wine with the higher rating to motivate decision. In the no-touch condition, we held up the two bottles of wines so that the participants can see the front label. We asked "Can you tell us which one you think is the wine that received the higher rating?" and participants responded by either pointing to one of the wines, or by saying the name of the wine. In the touch condition, we handed over the two bottles of wine so that people can hold them and asked the same question mentioned above. The back label of the wine was removed to hold information constant across touch and no-touch conditions. Prior to disclosing which wine was better, participants' perceived likelihood of having picked the better wine was measured. In stark contrast to the pattern of predictors, people who actually touched both bottles of wine felt that they were less likely to have chosen the better wine (i.e., less confident) in comparison to the counterparts who made the decision without touching.

### Study 4

Study 4 (experiencers) replicates our findings using a different product (i.e., coffee pods), and utilizing a less obtrusive procedure. One could argue that 1) explicitly instructing participants to 'touch' the objects in the touch condition may be driving the effect (confound and/or demand characteristics) or 2) the way in which researchers interact with participants in the touch conditions could have led to decreased confidence. To address these concerns, we conducted a computer-mediated study in the lab to minimize experimenter effects. Also, we held the instructions constant across touch vs. no-touch conditions without using the word 'touch' nor 'feel'.

Specifically, participants in the no-touch condition were provided with a picture of two different flavors of coffee pods from the same brand priced equally. They were told that one of them received a higher rating for taste and that their job was to pick the better coffee pod. In the touch condition, the same information was given except that the two coffee pods were provided in a cup next to the monitor. Participants in both conditions were told "Please take a moment and examine the two coffee pods," and had to wait at least 10 seconds before they could proceed. Then, participants indicated their choice, followed by the two confidence measures, satisfaction for choice, and willingness to pay (slider scale from \$0 to \$2) for the chosen option. The results showed that participants who touched the two coffee pods felt less confident about their decision, and thought that they were less likely to have picked the better one. Also, participants were less satisfied with their choice when they touched the two coffee pods, mediated by the average of confidence and likelihood measure (5,000 bootstrap samples, 95% CI [068. 491]). Those in touch condition also reported significantly lower willingness to pay, again mediated by the two confidence measures (5,000 bootstrap samples, 95% CI [005. 056]). The significance of mediation analyses did not change when confidence and likelihood measures were used separately for both WTP and satisfaction.

We also measured expectation disconfirmation for those in the touch condition ("How informative was the experience of touching the two coffee pods? 1 = much less informative than I expected, 4 = equally informative as I expected, 7 = much more informative than I expected, Gurhan-Canli and Maheswaran 2000; Swan and Trawick 1981). In line with our conceptualization, participants reported that the touch experience was significantly less informative than expected ( $M = 3.05$ , vs. midpoint:  $t(125) = -7.75$ ,  $p < .001$ ).

### General Discussion

The results shed light on the optimistic bias people hold for touching, and how such belief may negatively influence their decision confidence. While people expect touching to increase decision confidence even in situations where touching should not generate any useful information, providing the opportunity to touch actually reduces confidence. The findings here extends our understanding of the role of touch in consumption contexts by providing pioneering evidence for when and how touching may have an undesirable effect on decision confidence. Further, our research shows that people hold a strong, positive naïve optimism towards touch, and overgeneralize its effectiveness. Thus, this paper joins the emerging stream of research examining how people may readily apply deeply-rooted beliefs and habits in irrelevant contexts (Hsee, Yang, and Ruan 2015; Peysakhovich and Rand 2015).

On the managerial side, the findings suggest that providing the opportunity to touch for consumers may not be a panacea. Specifically, for products for which haptic cues are irrelevant for decision making, touching may in fact decrease choice satisfaction and willingness-to-pay. The results imply that it may not be in the best interest of managers to facilitate touch for those products, even though consumers may seek to do so. Non-touch channels including online and catalogue retailers may also want to implement strategies that prevent people from automatically overgeneralizing their belief in touch.

# Beyond Subjectivity: Competing Governance Regimes and the Socio-Material Construction of Rational Consumer Action

Léna Pellandini-Simányi, Università della Svizzera italiana, Switzerland

## EXTENDED ABSTRACT

Rationality – originally assumed to be perfect, then to be more bounded – is the core tenet of economic theories of action. Consumer behavior provides a more nuanced picture with an entire sub-discipline dedicated to the different modalities in which consumers process information and make decisions (Mowen 1988; Novak and Hoffman 2009; Olshavsky and Granbois 1989; Solomon et al. 2006; Yoon, Sarial-Abi, and Gürhan-Canli 2012); only some of which, as an exception rather than a rule, resemble the rational decision-making model of economics.

In recent years, CCT research took a step back from the question of how consumers make decisions and inquired instead into how consumers evolve into subjects capable and willing to make certain decisions: how they become particular consumer subjects. Research on the formation of consumer subjects in CCT (Giesler and Veresiu 2014; Karababa and Ger 2011), sociology of governmentality (Langley 2007; Miller and Rose 1990) and history of consumption (Trentmann 2006) suggests that consumer subjectivity arises through particular, historically-specific discourses. Building on a Foucauldian tradition, many focused on how discourses assume and call forth particular consumer subjects, such as responsible consumers (Giesler and Veresiu 2014), active consumers (Karababa and Ger 2011) or ‘compliant patients’ (Thompson 2003).

Extending these studies, this paper focuses on rational choice and proposes a model of the construction of rational consumer action. We develop our arguments through the case study of mortgage borrowing in post-socialist Hungary, based on 50 interviews with borrowers, 49 expert interviews with bankers and regulators and extensive archive data. The model conceptualizes consumer choice as an outcome of ‘performance struggles’ (Callon, Millo, and Muniesa 2007) between devices and discourses produced by different organizations, which are shaped by organization-specific information on consumers, organizational interpretative frames and organizational aims.

We make three contributions. First, existing models imply that a particular consumer action is driven by a specific subjectivity. Hence, in these models, discourses and practices shape consumer action through subjectivity. We propose an alternative route in which discourses and practices shape consumer action without being necessarily accompanied by a shift in subjectivity. To develop this point, we draw on the work of Michel Callon (Callon 1998; Callon et al. 2007; Callon and Muniesa 2005). Callon and his followers argue that for rational action to take place, rational subjectivity is not necessary. Replacing personal agency with a distributed, sociomaterial view of agency, Callon suggests that rational action is a product of socio-material arrangements that enable people to act rationally, even if they do not fully possess the subjectivity of the *homo economicus* (Callon 1998). For example, by using an on-line credit calculator, people can make complex rational choices without possessing sophisticated calculative capacities. Drawing on this point, the literature on *market devices* documents how the material set-up of consumer choices and uses format consumer action, which may or may not be accompanied by a concomitant change in subjectivity (Callon et al. 2007; Cochoy 2008; Cochoy, Deville, and McFall 2017). This process differs from existing models of consumer subjectivity, which incorporates devices either as means of developing a subjectivity or, as in Giesler and

Veresiu’s (2014) notion of ‘capabilization’, to enable consumers to act on a subjectivity developed by discourses.

Our model does not deny that organizational discourses and devices shape consumer action through subjectivity. However, it suggests that it is only one of the modalities through which action is shaped; and stresses the importance of the alternative route when organizational discourses and devices act directly on consumer action without being mediated by subjectivity.

Second, building on recent calls (Askegaard and Linnet 2011), and prior research (Giesler and Veresiu 2014; Peñaloza 2000; Thompson and Tian 2008) to study how organizations shape meanings and consumer subjectivity, our model extends the focus on consumers to the producers of discourses and devices. Existing studies, drawing on a diverse body of theories, including governmentality (Foucault 1997; Knights 1997) and performativity (MacKenzie, Muniesa, and Siu 2007) show how a specific organization produces discourses and devices that not only reflect its ideas of the ‘consumer’ but also contribute to the emergence of the consumer fitting these ideas. Our model introduces a comparative aspect to this analysis. It shows that different types of organizations hold different ideas of how consumers are and how they should be. Organizational ideas are products of different institutional frames, theories and interests prevalent in the given organization.

These diverse ideas of the consumer materialize in institution-specific discourses and devices – all potentially capable of performing the consumer that they assume. The acknowledgement of this diversity leads to our last and key contribution. While existing research traces how a specific discourse or device shapes consumer subjectivity, our model stresses that consumers are simultaneously subject to multiple, competing discourses and devices that are conducive to different consumer actions; in our case, to different degrees and forms of rational choice. Using Callon’s (2007, 343) notion of ‘performance struggle’, we theorize actual consumer action as a temporary ‘win’ of one, or of a combination of, these competing devices and discourses. In this respect our model differs from Giesler and Veresiu’s (2014) P.A.C.T. (personalization, authorization, capabilization, and transformation) model, which suggests that competing discourses settle their battle first (through the first two stages), and then the winner agenda gets to create its corresponding consumer subject (till the battle is re-opened). Instead, it chimes with Thompson’s (Thompson and Tian 2008; Thompson 2003) approach that stresses power struggles among different discourses in shaping meanings and consumer subjects.

In our model, competing discourses and devices simultaneously act and struggle over the consumer choice. It is their relative power that matters in formatting behavior. While studies of power following a Foucauldian line of analysis highlighted the subtle ways in which power operates through instilling self-governing mechanisms (referenced as ‘governmentality’), our model follows Latour’s work (Latour 2005; Latour and Venn 2002) to add the very material, coercive power dimension of devices shaping consumer choice.

# Vicarious Pride: When Gift Customization Increases Recipients' Appreciation of the Gift

Marta Pizzetti, Università della Svizzera italiana, Switzerland

Michael Gibbert, Università della Svizzera italiana, Switzerland

## EXTENDED ABSTRACT

Traditionally, customization researchers have investigated whether and why consumers appreciate customization (e.g. Fiore, Lee, and Kunz 2004; Franke, Keinz, and Steger 2009). Consumers often customize products for someone else as a gift and value customization more highly if it is intended as a gift (Moreau, Bonney, and Herd 2011). However, it hasn't been examined the recipients' appreciation of customized gifts. The current paper focuses on how customization affects the gift appreciation.

We contend that gift recipients appreciate customized gifts because they experience vicarious pride. Pride is a pivotal consequence of customization: Customizers refer pride in the customized product, which increases the value placed on the product ('I designed it myself' effect; Franke, Schreier, and Kaiser 2010). We propose that a similar mechanism may occur when a recipient takes the perspective of a giver customizing a product: The recipient experiences pride vicariously. This proposition builds on simulation theory: Individuals react to others' mental states and actions by mentally replicating them, and this internal simulation elicits the same psychological effects as the actual performance of the action (e.g. Decety and Sommerville 2008; Rizzolatti and Craighero 2004). We propose a psychological transfer between giver and recipient: The feeling of pride generated by self-designing a product (Franke et al. 2010) translates from the customizer to the final user of the product (i.e., the recipient). To test this hypothesis, we conducted three experiments.

The aim of Study 1 is to demonstrate that recipients appreciate a gift more when it is customized (vs. selected between a set of standard options) because of vicarious pride. We recruited participants through the snowball-sample procedure. The study involved real pairs of friends. 74 participants (41.9% male,  $M_{age} = 25.45$ ) were involved in a single factor between-subjects design (gift: customized vs. not-customized). The gift was exactly the same in both conditions (a clothing look), but differently described. In the customized gift condition, the scenario presented a selection process carried out step by step via adding look attributes (vs. the look was selected between a set of predefined looks). Then, we measured vicarious pride (Franke et al. 2010) and allowed participants to change the attributes of the look they did not like as a proxy for gift appreciation – the lower the changes, the higher the appreciation. The amount of changes ranged from 0 (= no changes) to 4 (= all items were changed). The results showed that recipients experienced vicarious pride and were less willing to modify a gift when it was customized. Moreover, vicarious pride mediated the relationship between gift customization and appreciation.

In Study 2 we replicated the experimental design but with a different measure of gift appreciation (two items from Ward and Broniarczyk 2011) and including a second factor. Indeed, an alternative explanation might be that customization is perceived by gift recipients as a time- and energy-consuming activity for the giver. Such time and energy efforts might be a driver of gift appreciation, since recipients prefer gifts that require a high amount of time and energy to the giver (Robben and Verhallen 1994). 109 participants (42.4% male;  $M_{age} = 25$ ) participated in a 2(gift: customized vs. not-customized) x 2(time and energy: high vs. low) between-subjects design. The gift was exactly the same between the two conditions (a T-shirt), but we showed two different videos to manipulate the gift-selection process (customization process undertaken via online

toolkits vs. gift selection was made by surfing different websites) and process length. We found that recipients appreciated the gift more when it was customized, and the vicarious pride was greater in the customized gift condition. Vicarious pride mediated the relationship between gift and appreciation. These findings provide further support to the idea that recipients appreciate a gift more when it is customized thanks to vicarious pride. This effect appears to be independent from time and energy spent on selecting or customizing the gift.

Study 3 further examines the phenomenon and includes a relational factor, since gift exchanges have a strong effect on relationships (Ruth, Brunel, and Otnes 2004) and vicarious experiences are affected by relational factors (Hatfield, Cacioppo, and Rapson 1994). Here, we included relational anxiety because of its relevance in the gift-exchange literature (e.g., Nguyen and Munch 2014; Ward and Broniarczyk 2011). Specifically, we expect that that relational anxiety is an obstacle to vicarious pride, because it prevents emotional connection with others (Bartz and Lydon 2004). Thus, when the relationship is filled with anxiety, the vicarious pride is not elicited and consequently recipients do not appreciate more the customized gift. A 2 (gift: customized vs. non-customized) x 2 (anxiety: no vs. high) between-subjects design involved 184 participants (58.7% male,  $M_{age} = 32.73$ ). Relational anxiety was manipulated as difficulty (vs. ease) of being emotionally close to someone (Bartz and Lydon 2004). Then, the scenario about the gift (watch customization vs. watch selection between standard watches) was presented, followed by items on gift appreciation and vicarious pride. Analyses showed that vicarious pride was greater in the no-anxiety than in the high-anxiety condition and, in the no-anxiety condition, customized gifts elicited greater vicarious pride. Customized gifts were significantly more appreciated in the no-anxiety condition. A mediation analysis on the no-anxiety condition confirmed that vicarious pride mediated the relationship between gift customization and gift appreciation.

Three studies show that customization is a valuable source of gifts because of the activation of vicarious pride: Recipients are vicariously proud of the customized product. The parallelism in terms of pride between the giver and recipient also affects the gift evaluation: Customized gifts are more highly appreciated when givers and recipients are emotionally connected. Conversely, when the relationship is filled with anxiety, vicarious pride is prevented. The effect seems to be strong: we used two different measures of gift appreciation, visual and textual descriptions of the customization process, and different products. Future research should investigate whether and how other characteristics of the gift, such as the fit with the giver's desire, amplify or reduce the effect of vicarious pride.

# The Viciousness and Caring of Sharing: Conflicts and Motivations of Online Shamers

Chen Pundak, Tel-Aviv University, Israel

Yael Steinhart, Tel-Aviv University, Israel

Jacob Goldenberg, IDC Herzliya, Israel

## EXTENDED ABSTRACT

Public shaming is defined as informally punishing individuals who have deviated socially or morally, by informing the public about their conduct (Petley 2013). Our research focuses on individuals who engage in public shaming on social media (e.g., Twitter, Facebook) against a wrongdoer who has acted immorally. While public shaming has long been a tool of education, its embrace by the digital world enabling users to easily and effectively spread information about the misconduct (Goldman 2015; Jacquet 2015).

The decision to engage in public shaming consists of two contradictory motivations: informal enforcement against deviant behavior (thereby preventing offenses such as animal abuse or discriminatory customer service) and the violation of privacy rights and dignity (exposing the personal details of the wrongdoer).

We suggest that a person considering participating in online shaming may try to balance these opposing considerations. Specifically, when a wrongdoer identifiability is high (e.g., when a post describing the behavior is accompanied by a clear image or a full name), shaming that individual can give rise to both potential consequences described above. When the wrongdoer identifiability is low (e.g., a vague image is shown, or only a first name is presented), shaming is more likely to give rise to the potential positive consequences than to trigger the potential negative consequences. This tradeoff may lead prospective shamers to experience a moral dilemma, since moral concerns involve the desire to protect others but also restrain them from doing harm (Graham et al. 2011; Janoff-Bulman and Carnes 2013, Crocket, 2017). Therefore, users with high levels of moral concern are more likely to join in on public shaming when the wrongdoer's identifiability level is low rather than high.

A preliminary study ( $n=100$ ) confirmed the assumption that users acknowledge both positive (preventing similar cases and educating others) and negative (causing harm to the wrongdoer) sides of sharing shaming information. It further showed that users' evaluations of these consequences vary according to the level of wrongdoer identifiability.

In our first study we demonstrated how moral concern interact with identifiability levels of the wrongdoer in driving actual choices regarding participation in public shaming. Participants ( $n=141$ ) were presented with several posts and were asked to click "like" on one of the posts through their social media accounts. After making their choices, participants completed a moral concern scale. Logistic regression found that level of moral concern significantly predicted the likelihood to choose to "like" a shaming post in which the wrongdoer identifiability was low rather than high ( $\chi(1)^2=4.87, p=.027$ ). Specifically, the exp(B) value indicated that an increase of one unit in the average moral concern score was associated with an increase of 62% in the odds ratio of choosing a post that include low-level-identifiable wrongdoer. We replicated these results in a study ( $n=209$ ) that considered #METOO campaign posts.

In our second study, participants ( $n=278$ ) were presented with a shaming post that included a photo of a woman (the wrongdoer) dragging a swan out of a lake. We manipulated the identifiability of the wrongdoer by presenting different angles of the image: half the participants saw a high-level-identifiable wrongdoer, and half saw a low-level-identifiable wrongdoer. Participants were asked to rate the likelihood they would share this post.

As expected, the mean-centered interaction between moral concern and wrongdoer-identification (0=Low-identifiability, 1=High-identifiability) was significant ( $b=-.65, p=.0033$ ).

While in the high-identifiability wrongdoer condition, we found a significant positive association between moral concern and sharing likelihood ( $b = .69, SE = .15, t(274) = 4.53, p < .001$ ), under the low-identifiability wrongdoer condition, the association was not significant ( $b = .03, SE = .16, t(274) = .22, p = .83$ ).

In a replication study, participants ( $n=374$ ) were presented with a post that described a manager of a restaurant who had ignored a complaint about possible food poisoning. Half the participants saw a photo of the restaurant's manager, and the other half did not. Again, the interaction between moral concern and wrongdoer-identification condition had significant effect on participants' likelihood of sharing the post.

In our fourth study ( $n=393$ ), we attenuated the negative outcomes of shaming by presenting more than one target as being shamed, thereby reducing the likelihood that a given wrongdoer would be hurt: Participants were presented with a post describing either a spa receptionist or a group of receptionists who had ignored an elderly customer. A photo of the receptionist or receptionists was presented either from the back (low-identifiability) or from the front (high-identifiability). Also, we manipulated moral concern instead of measuring them. An ANOVA found a three-way interaction: Among participants under the high-moral-concern manipulation, those in the low-identifiable-single-receptionist condition were more likely to share the post than were participants in the high-identifiable-receptionist condition ( $M_{manipulation\_low-identifiable\_receptionist} = 4.55$  vs.  $M_{manipulation\_high-identifiable\_receptionist} = 3.46, t(385) = 2.59, p = 0.01$ ).

In our last study we focused on the underlying process of our interaction, as well as the moderating role of group relatedness. When a person is being shamed in his own community, the negative outcomes and the positive outcomes can be particularly strong. Participants ( $n=305$ ) were presented with a shaming post about an airline passenger who had misbehaved. The passenger's photo was either blurry (low-identifiable) or sharp (high-identifiable). Also, the passenger was described either as part of the participants' ingroup (same nationality) or as an outgroup member (different nationality). Higher moral concern were positively correlated with sharing likelihood when the wrongdoer was low-identifiable and an ingroup member ( $b=.25, t(297)=2.04, p=.04$ ). Surprisingly, we also found a significant positive effect for moral concern when the wrongdoer was high-identifiable and an outgroup member ( $b=.28, t(297)=2.83, p=.005$ ). The effect of moral concern on sharing likelihood was mediated by expected positive outcomes of sharing the post ( $b=-.21; 95\% CI: -.43, -.04$ ) but not by the expected negative outcomes.

Taken together, our studies suggest that while people acknowledge the dual outcomes of shaming, morality and the extent to which the wrongdoer is identifiable affect the decision to participate in public shaming. While negative outcomes are acknowledged, the expected positive consequences are the ones that drive potential shamers' decisions regarding whether or not to participate in public shaming.

# Names Are the Mirrors of the Soul: The Role of Possessive Brand Names in Brand Evaluations

Marina Puzakova, Lehigh University, USA  
Mansur Khamitov, Nanyang Technological University, Singapore

## EXTENDED ABSTRACT

Marketing practitioners frequently rely on brand anthropomorphism (i.e., endowing brands with humanlike features (Puzakova and Kwak 2017) as an effective strategy that increases affective reactions and product evaluations (Aggarwal and McGill 2012). One of the popular means that brand strategists rely on to encourage anthropomorphism is endowing a brand with a human name. For example, Lily takes photos of consumers' adventures, Dave assists customers with banking fees, and a cup of fresh coffee is served at Tim Horton's.

Furthermore, a more nuanced analysis of these humanlike names points out to subtle semantic variations in a way these brand names are formed. For example, marketers use a possessive form in Tim Horton's and Trader Joe's brand names, whereas a non-possessive version is used in the Lily and Dave brand names. Does this subtle difference matter, and if yes, in what way? In this regard, prior research in psychology and linguistics indicates that possessive forms have crucial affective consequences (Shi et al. 2011). Despite the widespread prevalence of humanlike brand names and theoretically important consequences of possessive semantic units, to the best of our knowledge, no prior studies have examined the effectiveness of using possessiveness as a linguistic cue in anthropomorphized brand names. In response, we attempt to fill this gap. Our key contribution lies in demonstrating an important role of brand name possessiveness in consumers' anthropomorphized brand inferences and evaluations. As a theoretical basis, we draw from both psychological ownership theory and linguistics research that demonstrate that perceptions of an individual's ownership toward an object is easily formed by presenting people with possessive pronouns preceding the target of ownership (Pierce, Kostova, and Dirks 2003; Shi et al. 2011). Thus, we propose that the use of a possessive form in brand names can lead to greater consumer inferences that a brand is owned by a specific external entity (implied in the brand name).

Our second contribution lies in identifying a novel process of this effect. Psychologically owned items are seen as extensions of people who own them (Belk 1988) and can help people communicate important aspects of their identity to others (White and Argo 2011). Because people frequently experience feelings of psychological ownership and signal their identity through owned items to others (Pierce et al. 2003), we propose that individuals are also likely to view others' owned items as signaling an owner's identity. As such, consumers are likely to perceive that an inferred brand owner's identity spills over to the brand, subsequently resulting in greater inferences of identity-relevant brand attributes. Importantly, we expect this effect to occur only for brand names that include an identity marker (i.e., a qualifier that provides consumers with the information about an inferred owner's identity). Because an identity marker provides unique information about an inferred brand owner's identity, consumers will view a possessive (vs. non-possessive) brand name with an identity marker as performing better on identity-relevant brand attributes, thus, resulting in more favorable brand evaluations.

We test these ideas in three studies. The results of study 1 (n=117, students at a U.S. East Coast university) reveals that a possessive brand name of a café (introduced via an advertisement) joint that includes an identity marker (Sweet Tatiana's) leads to more favorable brand evaluations than a non-possessive brand name with an

identity marker (Sweet Tatiana):  $M_{\text{possessive}}=5.45$  vs.  $M_{\text{non-possessive}}=5.02$ ;  $F(1,115) = 3.690, p=.057$ . Next, study 2 (n=186, MTurk participants) replicates the effect in a different service context (a hair-salon brand) and examines whether the positive effect of possessiveness holds only for brand names with an identity marker (e.g., Elegant Charlie's vs. Charlie's). The results of this study revealed that when an identity marker was present, the possessive (vs. non-possessive) brand name led to more favorable brand evaluations ( $M_{\text{possessive}}=6.14$  vs.  $M_{\text{non-possessive}}=5.68, F(1,182)=5.652, p=.018$ ). Conversely, in the absence of identity marker, brand evaluations did not differ between the possessive and the non-possessive brand name conditions ( $M_{\text{possessive}}=5.88$  vs.  $M_{\text{non-possessive}}=5.78, p=.594$ , Figure 1). Similar results were obtained for the word-of-mouth and purchase intentions. Overall, in line with our theorizing the effect of brand name possessiveness is mitigated when no identity marker is present.

Study 3 (n=186, MTurk participants) further examines the mediating role of consumers' attributions of identity-relevant brand attributes and considers potential alternative explanations for our results. We tested our effects with advertisements for a brand of catering: Artful Mark's vs. Artful Mark. Replicating results of studies 1 and 2, the findings reveal that a possessive brand name of a catering business that included an identity marker (Artful Mark's) led to more favorable brand evaluations than a non-possessive brand name with an identity marker (Artful Mark):  $M_{\text{possessive}}=6.03$  vs.  $M_{\text{non-possessive}}=5.74; F(1,184)=4.405, p=.037$ . Next, the results of the model testing the serial relationships (brand name possessiveness  $\rightarrow$  perceived brand ownership  $\rightarrow$  attributions of identity-relevant brand attributes  $\rightarrow$  brand evaluations; model 6; Hayes 2013) revealed a significant overall mediation effect ( $B_{\text{brand evaluations}}=.08, SE=.03, 95\% \text{ CI} [.03, .16]$ ). That is, a possessive (vs. non-possessive) form of a brand name led to greater inferences of brand ownership which in turn enhanced participants' attributions of identity-relevant brand attributes, thus, resulting in more favorable brand evaluations. Finally, our results further ruled out several alternative accounts: responsibility for service outcomes and inferred service quality.

Overall, this research identifies important consequences of inferring others' (or anthropomorphized brands') ownership states. In particular, studies 1 through 3 demonstrate that the use of a possessive (vs. non-possessive) form in anthropomorphized brand names with an identity marker leads to more favorable brand evaluations, word-of-mouth, and purchase intentions. Study 3 sheds light on the underlying process through greater attributions of identity-relevant brand attributes, while also ruling out alternative explanations.

Our findings add a new dimension to work on anthropomorphism (Aggarwal and McGill 2012; Puzakova and Kwak 2017). Although the use of both possessive and non-possessive humanlike names is a widely prevalent tactic that enhances brand anthropomorphism, scant research has systematically investigated nuances of this branding strategy. In response, our work highlights the impact of an important linguistic cue that market strategists can rely on to enhance new customers' brand perceptions.

# The Impact of Anthropomorphized Cute Brands on Consumer Preferences for Distinctive and Majority-Endorsed Products

Marina A. Puzakova, Lehigh University, USA

Nevena T. Koukova, Lehigh University, USA

## EXTENDED ABSTRACT

Marketers strategically use anthropomorphism (i.e., imbuing nonhuman objects with humanlike characteristics, motivations, intentions or behaviors; Puzakova, Kwak and Rocereto 2013) as a brand positioning strategy. Prior work identifies downstream consequences of using this strategy including positive brand evaluations and emotional reactions towards the brand (Aggarwal and McGill 2007; Delbaere, McQuarrie and Phillips 2011). However, previous research has not looked at how anthropomorphizing a brand can systematically affect consumer preferences for a different brand in a consumption sequence. An understanding of this phenomenon is both theoretically and managerially important because consumers frequently shop for products in predictable patterns (e.g., looking for coffee creamers after selecting a pack of coffee). Importantly, marketers carefully place products in particular sequences in retail stores and effectively utilize cross-selling tactics to increase the purchase of a full product line (Knott, Hayes and Neslin 2002).

In this paper we examine a specific brand positioning strategy—cute brand anthropomorphism (imbuing a humanized brand with specific configuration of infantile features; Wang and Mukhopadhyay 2015)—and demonstrate that consumer exposure to or interaction with a cute anthropomorphized (vs. nonanthropomorphized) brand has significant downstream consequences for preferences for products or brands positioned to be either distinctive or majority-endorsed (popular). We further establish that these unique effects of cute brand anthropomorphism hold only for male consumers. Specifically, we demonstrate that men's exposure to anthropomorphized cute products prior to exposure to a distinctive brand in a different product category can have a negative effect on the preferences for the distinctive brand. In contrast, exposure to anthropomorphized cute products enhances male consumers' preferences for majority-endorsed brands. The theoretical rationale is that anthropomorphized cute products threaten men's gender identity and activate self-protection responses. This activation of a self-protection response further facilitates an evolutionary response of "going with the group is safe" because standing out from the crowd limits one's chances of survival (Griskevicius et al. 2009). Thus, our work demonstrates that cute anthropomorphized products increase conformity in men; these products reduce attraction to distinctively-positioned brands and increase attraction to brands positioned as majority-endorsed.

We conducted three studies to test our hypotheses. Studies 1 and 2 demonstrate that exposure to cute anthropomorphized products reduces men's attraction to distinctive brands in a subsequent choice task, whereas this positioning strategy has no effect for women. Study 3 extends the findings of studies 1 and 2 by providing insights on the underlying process. Our conceptualization predicts that men's exposure or interaction with cute anthropomorphized brands threatens their masculine identity. If this is the case, then allowing consumers to reaffirm their identity before the second choice task should attenuate the negative impact of cute anthropomorphized brands on preferences for brands positioned to be distinctive. Study 3 highlights the underlying process using a moderation approach, and shows that the negative impact of cute anthropomorphized brands on preferences for brands positioned to be distinctive can be attenuated by allowing consumers to reaffirm their identity before evaluating the distinctive brand.

To summarize, we provide important insights regarding the downstream effects of consumer interactions with cute anthropomorphized brands on subsequent preferences for majority-endorsed and distinctive brands. To our knowledge this is the first investigation on how exposure to anthropomorphized brands systematically affects consumers' preferences for other brands during a subsequent consumption experience. Specifically, we argue that men associate cute anthropomorphized brands with femininity, which in turn threatens their gender identity. Hence, men's exposure to anthropomorphized cute products prior to choice in a different product category decreases their preferences for distinctive brands and enhances their attraction toward majority-endorsed brands. We further demonstrate the underlying process: allowing male consumers to reaffirm their gender identity before the second choice task attenuates the negative impact of cute anthropomorphized brands on their preferences for distinctive brands. While prior work sheds light on the impact of anthropomorphism on consumer preferences of an entity being anthropomorphized (Aggarwal and McGill 2007; Puzakova and Kwak 2017), our work establishes the novel downstream effects of interacting with cute anthropomorphized brands on subsequent consumption of other brands positioned as distinctive or majority-endorsed. On the practical front, our research highlights a very interesting interaction effect between gender and brand anthropomorphism in the context of a subsequent consumption task. The role of gender identity in consumer exposure to cute anthropomorphized brands is an interesting juxtaposition of factors that marketers may wish to consider when developing brand strategies while taking into consideration sequences of consumption choices.

# Trust, But Verify: A Multi-level Examination of Online Reviews and Persuasion Knowledge

Martin A. Pyle, Ryerson University, Canada

Andrew Smith, Suffolk University, USA

Yanina Chevtchouk, University of Glasgow, UK

## EXTENDED ABSTRACT

Stories of companies (and pranksters) manipulating online reviews are abound in the news. These actions potentially affect consumer trust not only at the review-level, but also their perceptions of specific websites (platform-level) and online reviews as a whole (system-level), as consumers struggle to discern real reviews from fake.

The Persuasion Knowledge Model (PKM, Friestad & Wright, 1994) offers a useful framework for understanding how consumers identify and respond to persuasion attempts. The basic idea behind this framework is that consumers develop contextualized persuasion knowledge (PK) about persuasion tactics, agents, and appropriate responses to allow them to navigate the marketplace. Researchers have explored PK in the context of direct persuasion situations, such as sales or advertising (Campbell & Kirmani, 2000; Kirmani & Zhu, 2007), but the relationship between PK and online reviews is less clear, largely due to the limited research on the topic.

From a broad perspective, online reviews can take many forms; from individual consumer reviews (e.g., Amazon, ePinions) to blogs and vlogs. Research suggests that subtler forms of sponsored content, such as branded editorials, do not always activate skepticism and recognition of persuasive intent (Boerman, Willemsen, & Van Der Aa, 2017). Consumer reviews may be particularly challenging, as those that are sponsored may be nearly identical to genuine perspectives. One study noted a wide variation in consumers' application of PK in this context (Bambauer-Sachse & Mangold, 2013), though the prevalence of fake reviews has received more attention in the media since this study, perhaps leading to greater PK activation. Thus, we investigate: to what extent does PK activation occur in the context of online reviews?

Based on two available studies, avoidance was the most prominent coping behavior when PK was activated in an online consumer review context (Bambauer-Sachse & Mangold, 2013; Reimer & Benkenstein, 2016). However, the focus was at the review level, and did not consider the effects on consumer perceptions of the platform or system-wide, of reviews in general. Therefore, we investigate a second set of questions: how does PK manifest at the system- and platform-levels? What subsequent coping mechanisms do consumers employ?

To investigate these questions, we use data from 22 semi-structured depth interviews (McCracken, 1988) that involved general questions as well as real online product searches, where informants narrated their thoughts, and responded to prompting questions. The data was analyzed through the PKM independently by two of the authors, who also met for cross-informant comparison.

The data indicates high levels of skepticism towards reviews from all informants, suggesting the development of PK surrounding this context. The PK schemata tended to include typical company approaches for influencing reviews (e.g., 'click-farms', sponsorship), and as expected, led to several reviews being avoided or counter-argued because informants felt they were fake. However, other coping behaviors were also revealed, such as using site-level heuristics to confirm consensus opinions. Notably, analysis revealed that many informants did not differentiate between sponsored and biased reviews, categorizing both as fake.

At the platform-level, certain sites were simply avoided because of preconceived notions of active filtering of negative reviews (e.g.,

branded websites) or past experience where content was largely sponsored (e.g., certain blogs). Third-party sites tended to receive greater trust, but in a qualified form; our informants' PK schemata at the platform-level included known barriers for posting content, and inferences about how that impacts the pervasiveness of deceptive reviews. Even when perceptions about a platform did not prompt avoidance, they still tended to heighten PK or lead to other coping mechanisms. As purchase importance increased, informants tended to cope by engaging in cross-platform comparisons.

At the system-level, informants continued to apply coping mechanisms intended to corroborate the information. While one informant practiced complete avoidance of online reviews, the remaining informants tended to complement the information from online reviews with offline sources (trusted people) or through directly visiting the retail outlet (webrooming). This verification and lack of reliance on online reviews increased in relation to the perceived importance of the purchase.

The consistent activation of PK at every level, and the resulting coping mechanisms are simultaneously troublesome and indicative of opportunities from a managerial perspective. Considering the role of online reviews—reducing risk (Hennig-Thurau & Walsh, 2003) and simplifying the decision making process, the extra steps consumers take to verify the information could lead to more people bypassing this information. However, this also suggests that efforts to highlight verified reviews (as opposed to eliminating fake ones) could be well-received by consumers.

# Bundle Variety and Preference: A Neuromarketing Study Using Event-related Potentials

Ruyi Qiu, Tsinghua University, China  
Xiaoang Wan, Tsinghua University, China

## EXTENDED ABSTRACT

Bundling has raised many interests for decades (e.g., Hansen & Martin, 1987; Janiszewski & Cunha Jr, 2004), but very few studies have been conducted to systematically examine the relationship between bundle variety and bundle preference. With the development of consumer neuroscience, three event-related-potential components, namely the P1, P2 and N2, have been linked to consumer preference for single products (Goto et al., 2017; Guo et al., 2016; Mickleborough et al., 2014; Telpaz et al., 2015; Zhang et al., 2011). However, it remains unclear whether these early components could reveal consumer preference for product bundles, and if so, how the component variety of bundles might modulate this effect. The present study addressed this issue to shed some light on the neural underpinnings of consumer's responses to product bundles.

In the present study, we chose bundles consisted of three cups of yogurt in fruit flavors as experimental stimuli, because variety seeking behavior was found to be more likely to occur with hedonic products (Baltas et al., 2017; Inman, 2001). We first run an online survey on 79 naïve participants to determine which yogurt flavors to use in the main experiment. Based on these results, we decided to use strawberry and yellow peach as two popular flavors (PFs), sea-berry and water chestnut as two unpopular flavors (UFs), as well as coconut, mulberry, and cherry as three flavors with moderate popularity (MFs). We used four types of bundles, including the 3PF, 3UF, 2P1U, and 3MF bundles. Importantly, the 3PF and 3UF bundles were identical bundles, whereas the 2P1U and 3MF bundles were coded as bundles with lower and higher variety, respectively.

Twenty young healthy participants took part in the main experiment which consisted of a pre- and a post-test survey, a wanting test, and a selection test. At the beginning of the experiment, the participants chose which one of the two popular flavors they preferred more, and which one of the two unpopular flavors they preferred less. The chosen flavors were then presented in the following tests for each participant. In both of the pre- and post-test surveys, participants were asked to indicate their liking of each bundle. The EEG signals were recorded during the wanting test in which participants viewed the picture of each bundle and used the mouse to pick a number from 0 to 100 to indicate their desire for it. Each participant completed two blocks of 120 trials each, while equal numbers of different types of bundles were mixed and presented in a random order. After the wanting test, participants were presented with pairs of bundles in the selection test, and they were asked to choose the preferred ones.

The rating results revealed some significant positive correlations among the wanting scores, preference scores (the total number of times each bundle was chosen by each participant), and liking scores, all  $r_s > 0.72$ ,  $p_s < 0.001$ , suggesting the validity of wanting and preference scores. The results also revealed some significant positive correlations between the N2 amplitude for each bundle and the wanting/preference scores, both  $r_s > 0.26$ ,  $p_s < 0.05$ . Next, we conducted a 2 (Bundle Preference: most- or least-preferred)  $\times$  4 (Electrode Site: Fz, FCz, CPz, or Pz) repeated-measure ANOVA on the N2 amplitude. The results revealed a significant main effect of Bundle Preference,  $F(1, 19) = 6.69$ ,  $p < 0.05$ ,  $\eta_p^2 = 0.26$ . Planned pairwise comparison showed that in electrodes Fz, FCz, and CPz, the N2 amplitude was significantly smaller for the most-preferred bundles than for the least-preferred ones, all  $t_s > 2.17$ ,  $p_s < 0.05$ , whereas no such effect was significant in electrode Pz,  $t(19) = 1.71$ ,

$p = .10$ . We also performed a 2 (Bundle Variety: lower or higher)  $\times$  4 (Electrode Site: Fz, FCz, CPz, or Pz) repeated-measure ANOVA on the N2 amplitude. The results revealed no significant main or interaction effects, all  $F_s < 1.66$ ,  $p_s > .21$ . That said, planned pairwise comparisons showed that only the N2 amplitude in electrode Pz was significantly smaller for bundles with higher variety than those with lower variety,  $t(19) = 2.60$ ,  $p < 0.05$ , Cohen's  $d = 0.61$ ; whereas there was no such effect in other electrodes, all  $t_s < 0.45$ ,  $p_s > .65$ .

Furthermore, the 2 (Bundle Preference: most- or least-preferred)  $\times$  2 (Electrode Site: P7/P8 or PO7/PO8)  $\times$  2 (Hemisphere: left or right) repeated-measure ANOVA on the P1 amplitude revealed a marginal significant main effect of Bundle Preference,  $F(1, 19) = 3.94$ ,  $p = 0.06$ ,  $\eta_p^2 = 0.17$ . However, the 2 (Bundle Variety: lower or higher)  $\times$  2 (Electrode Site: P7/P8 or PO7/PO8)  $\times$  2 (Hemisphere: left or right) repeated-measure ANOVA on the P1 amplitude showed no such effect of Bundle Variety,  $F(1, 19) = 1.87$ ,  $p = 0.19$ . By contrast, the analogous ANOVA on the P2 amplitude revealed a significant main effect of Bundle Variety,  $F(1, 19) = 7.82$ ,  $p < 0.05$ ,  $\eta_p^2 = 0.29$ ; whereas the 2 (Bundle Preference: most- or least-preferred)  $\times$  2 (Electrode Site: P7/P8 or PO7/PO8)  $\times$  2 (Hemisphere: left or right) repeated-measure ANOVA on the P2 amplitude showed no such effect of Bundle Preference,  $F(1, 19) = 0.001$ ,  $p = 0.98$ .

In conclusion, the present study provides the first physiological evidence investigating the relationship between bundle variety and bundle preference. The results revealed both associations and dissociations between consumer preference and variety seeking. Our findings suggest that the frontal area is more involved in inhibiting less preferred bundles (Aron et al., 2004, 2014), whereas the parietal area is linked to the categorization of bundles according to its variety level (Freedman & Assad, 2006, 2011; Levine & Schwarzbach, 2017). Furthermore, our findings suggest that bundle preference is associated with early configural processing, whereas later featural processing is important for bundle variety (Boutsen et al., 2006; Mercure et al., 2008; Wang et al., 2016). These findings not only have implications in helping researchers and practitioners better understand consumer preference and variety seeking, but also indicate the promising future of using ERP method in neuromarketing practice.

# A Rational Model to Predict Consumers' Irrational Behavior

Vahid Rahmani, Rowan University, USA

## EXTENDED ABSTRACT

The current research developed a mathematical model that could predict consumers' price-quality perceptions based on their ability and motivation to process the product information accurately. This model effectively demonstrates how the price can influence consumers' judgments of quality after they purchased and used the product. Furthermore, this model sheds light on the underlying reasons that price has different effects on consumers' perceptions of quality under different product categories. Finally, this model offers a powerful statistical tool that could be utilized to find the best price-points for products in dynamic environments.

The developed model is based on the reference-dependent utility model proposed by Kőszegi and Rabin (2006). They argued that expected utility is the sum of gain/loss utility [ $n(q|r)$ ], consistent with the predictions of prospect theory (Kahneman and Tversky 1979), and reference-dependent consumption utility [ $m(q|r)$ ], where  $m(q)$  denotes the experience of quality and  $m(r)$  denotes the expectation of quality:

$$(1) \quad U(q|r) = m(q|r) + n(q|r)$$

In this model, when  $m(q) - m(r) > 0$ , consumers will experience a gain utility equal to  $\eta[m(q|r) - m(r)]$ . In contrast, when  $m(q) - m(r) < 0$ , consumers will experience a loss utility of  $\eta\lambda[m(q|r) - m(r)]$ .  $\lambda$  is always greater than one because as proposed by Kahneman and Tversky (1979) losses have a greater influence on consumers' experienced utility (a strong negative effect) than gains. Furthermore, Kőszegi and Rabin (2006) argued that the consumption utility itself would depend on a reference point. As an example, driving a C-Class Mercedes-Benz would create a higher consumption utility when the reference product of the driver is a Toyota Camry than when it is a Rolls-Royce. This notion is consistent with the placebo effect of the price that is reported in the literature (Shiv, Carmon, and Ariely 2005).

To further develop the model, the arguments put forward by Gneezy, Gneezy, and Lauga (2014) were followed. Based on their study, Alpha was defined as the probability that the product was a high-quality product. Furthermore, as supported by numerous studies in the pricing literature, it was assumed that Alpha was a function of price:

$$(2) \quad \alpha = P(rqh) = f(\text{price})$$

$$(3) \quad m(r) = ql + \alpha(qh - ql)$$

After using the products, consumers acquire some additional information about the real quality of the product. For high-quality products, if consumers' expectations are consistent with the product quality, most would judge the quality as high (i.e., sqh). When consumers' expectations of quality are inconsistent with the actual quality of the products, a sizable percentage of them will make the wrong judgment about the quality of the product. Based on these arguments,  $\beta_c$  and  $\beta_i$  are defined as the probabilities that consumers' will accurately judge the quality when their expectations are consistent and inconsistent with the real quality, respectively. Therefore:

$$\beta_c = P(sqh | qh \text{ and } rqh; sq | ql \text{ and } rql); 1 - \beta_c = P(sq | qh \text{ and } rqh; sqh | ql \text{ and } rql)$$

$$\beta_i = P(sqh | qh \text{ and } rql; sq | ql \text{ and } rqh); 1 - \beta_i = P(sq | qh \text{ and } rql; sqh | ql \text{ and } rqh)$$

$$0 < \beta_i < \beta_c$$

Given the above conditions, the consumption utility of high-quality products [i.e.,  $m(qh|r)$ ] and the consumption utility of low-quality products [i.e.,  $m(ql|r)$ ] can be conceptualized as below:

$$(4) \quad m(qh|r) = ql + \alpha h \times (qh - ql); \alpha h = [(\beta_c - \beta_i) \times \alpha + \beta_i]$$

$$(5) \quad m(ql|r) = ql + \alpha l \times (qh - ql); \alpha l = [1 + \alpha(\beta_c - \beta_i) - \beta_c]$$

Therefore, the gain loss utility of the model [ $n(q|r)$ ] could be calculated as:

$$(6) \quad n(q|r) = \{\eta[m(q|r) - m(r)] \mid \alpha h > \alpha \text{ or } \alpha l > \alpha; \eta\lambda[m(q|r) - m(r)] \mid \alpha h < \alpha \text{ or } \alpha l < \alpha\} \text{ and } \lambda > 1$$

Based on the gain loss utility function, the total utility functions of high-quality [ $U(qh|r)$ ] and low-quality products [ $U(ql|r)$ ] could be conceptualized as below:

$$(7) \quad U(qh|r) = \{\eta[ql + \alpha h(qh - ql) + \eta(\alpha h - \alpha)(qh - ql)] \mid \alpha h > \alpha; ql + \alpha h(qh - ql) + \eta\lambda(\alpha h - \alpha)(qh - ql) \mid \alpha h < \alpha\}$$

$$(8) \quad U(ql|r) = \{\eta[ql + \alpha l(qh - ql) + \eta(\alpha l - \alpha)(qh - ql)] \mid \alpha l > \alpha; ql + \alpha l(qh - ql) + \eta\lambda(\alpha l - \alpha)(qh - ql) \mid \alpha l < \alpha\}$$

Note that if  $\alpha < \beta_i / (1 + \beta_i - \beta_c)$  then  $\alpha h > \alpha$ . Since  $0 < \alpha < 1$  and  $0 < [\beta_i; \beta_c; \beta_i / (1 + \beta_i - \beta_c)] < 1$ , we can define the  $P(\alpha h > \alpha) = \beta_i / (1 + \beta_i - \beta_c) = \gamma$ . Similarly, if  $\alpha < (1 - \beta_c) / (1 + \beta_i - \beta_c)$  then  $\alpha l > \alpha$ ;  $0 < (1 - \beta_c) / (1 + \beta_i - \beta_c) < 1$ ;  $P(\alpha l > \alpha) = (1 - \beta_c) / (1 + \beta_i - \beta_c) = 1 - \gamma$ . Given the calculated values of  $\gamma$ , we can rewrite the expected utility models as:

$$(9) \quad SQAh = ql + [\alpha h + (\eta\lambda + \eta\gamma - \eta\lambda\gamma)(\alpha h - \alpha)](qh - ql)$$

$$(10) \quad SQAl = ql + [\alpha l + (\eta + \eta\lambda\gamma - \eta\gamma)(\alpha l - \alpha)](qh - ql)$$

$$(11) \quad dSQAh/d\alpha = [(\beta_c - \beta_i) + (\eta\lambda + \eta\gamma - \eta\lambda\gamma)((\beta_c - \beta_i) - 1)](qh - ql)$$

$$(12) \quad dSQAl/d\alpha = [(\beta_c - \beta_i) + (\eta + \eta\lambda\gamma - \eta\gamma)((\beta_c - \beta_i) - 1)](qh - ql)$$

The predictions of the model were tested using several samples including 519,200 product/day observations from Amazon.com. The findings showed that the predictions of the developed model closely matched the observed relationships in the real-world data.

The findings of this paper could present companies with a powerful tool that they could use to find the best price points for their products based on consumers' product knowledge and thinking style. In practice, companies could conduct a small study to estimate the parameters of the model, and then use the model to find the ideal price points for their products. Furthermore, this article makes significant theoretical contributions. Extant literature in pricing suggests that the effect of price on consumers' perception of quality is not homogenous across different market segments. This article is the first to offer a mathematical model that can not only explain the previous

findings in the literature but predict consumers' price-quality perceptions based on consumer and product characteristics.

# Pangs from Persuasion: When Recommendations Undermine Consumers' Social Worth

Suzanne Rath, Queen's University, Canada

## EXTENDED ABSTRACT

Research on the Persuasion Knowledge Model (PKM) (Friestad and Wright 1994) has documented many negative responses to persuasion attempts (Isaac and Grayson 2017), including lower attitudes towards salespeople (Campbell and Kirmani 2000; Decarlo 2005; Main et al. 2007; Reinhard et al. 2006), advertisements (Campbell 1995; Campbell and Keller 2003; Darke and Ritchie 2007), and brands (Ahluwalia and Burnkrant 2004; Wei et al. 2008). To explain these responses, several mechanisms have been implicated having to do with perceived selling motives, such as suspicion of ulterior motives, inferences of manipulative intent, and consumer skepticism (Kirmani and Zhu 2007; Isaac and Grayson 2016). However, it is not completely clear why selling motives should necessarily incite these responses because goals to sell or make profits are well-known to consumers before exposure to a communication (Babin et al. 1995; Boush et al. 1994) and are often top of mind (Thompson 1972; Bhattacharjee and Dana 2017). An alternative possibility is that consumers may see attempts to persuade as deceptive. Although this may explain some empirical findings (Forehand and Grier 2003), perceived deception is unlikely to fully account for consumers' responses since they respond in the same way without deception (Campbell and Kirmani 2000; Main et al. 2007; Ahluwalia and Burnkrant 2004; Reinhard et al. 2006).

The current work investigates a different reaction consumers may have to perceived persuasion, which we suggest is responsible, in part, for their negative reactions. We suggest that consumers react to the interpersonal implications of being the target of a persuasion attempt. We argue that labelling a communication as "persuasion" activates consumers' beliefs that the agent is attempting to pursue their own interests instead of (and perhaps at the expense of) consumers' interests. This violates an important norm of interpersonal conduct – not taking advantage of others – conveying a lack of respect and value for the consumer. In short, we suggest that perceiving a communication as an attempt to persuade may convey threatening information about consumers' social worth.

Inferences of social worth (i.e. the extent to which an individual feels respected and valued by others) is a critical part of psychological and social functioning. They are an important part of self-esteem (Leary and Baumeister 2000; Leary 2005; Leary and Batts Allen 2011) and have a powerful influence over how individuals judge and respond to others. In particular, we tend to dislike, derogate, and withdraw from people we perceive hold us with low regard (Buckley et al. 2004; Leary, Twenge, and Quinlivan 2006; Miller 2001).

People can infer social worth from a wide variety of social cues. Sometimes this information is direct, for example, when others directly state their opinion (Smart Richman and Leary 2009). Other times, individuals infer (a lack of) social worth from actions that can be seen as exclusionary or are perceived as rejection (Buckley et al. 2004), even indirectly. For instance, a large literature in organizational psychology has found that individuals frequently infer social worth from organizations' processes and procedures (Blader and Tyler 2015), and work in consumer psychology has found that consumers interpret unfavorable prices and poor service in this way too (Ashworth and McShane 2012; Liao 2007). In a similar vein, we suggest that consumers may infer social worth from the assumptions they make about why an agent is attempting to persuade them.

Consistent with existing work, we start with the proposition that consumers often assume that persuasion is driven by agents' self-interest. In marketing contexts, this is typically a motive to sell. However, we also argue that this is typically well understood by consumers. The critical feature of a persuasion attempt is that it communicates to consumers that the agent is attempting to benefit from that particular consumer. Regardless of whether the agent actually benefits, this is important because it violates a norm of interpersonal conduct, to not take advantage of others. We argue that this conveys a lack of respect and value for the consumer, and that this is an important reason for consumers' subsequent reactions (derogating the agent and leaving the interaction).

In this paper, four studies test various aspects of our theorizing. First, we tested whether perceiving a communication as persuasion is sufficient to convey socially threatening information. Importantly, we found that a persuasion (vs. neutral) communication lowered consumers' perceived social worth (8-item, seven-point Likert scale i.e., the salesperson thought highly of you, did not think much of you (r); valued you as a customer, etc...). It also augmented advantage-taking beliefs, and it impaired all downstream consumer responses. We found results consistent with simple and serial mediation. This provides initial evidence of the basic effect. In the second study, we provide conceptual replication and extend the findings by varying the extent to which the salesperson benefits from the advocated action – something that should moderate the basic effect. We found that the effect of being a target of persuasion on social worth and advantage-taking beliefs was reduced when the salesperson would benefit less from the tactic compared to when they would benefit more. Additionally, we found serial moderated mediation, replicating the basic effect. Our third study provides a conceptual replication of moderation-of-process by varying the diagnosticity of the persuasive communication. We found that when features of the advocated action were less diagnostic of marketers' beliefs, the effect of being a target of persuasion on social worth and advantage-taking beliefs was attenuated. Our final study attempts to isolate social worth, demonstrating this is a critical element in consumers' overall reaction to persuasion. We showed that advantage-taking beliefs affect inferences of social worth when consumers view attempts to profit from others as a moral violation.

These four experiments provide evidence that persuasion attempts violate a norm of interpersonal conduct – not taking advantage of others – which conveys a lack of respect and value for the consumer, and leads consumers to derogate the agent and withdraw from the interaction. These findings suggest that researchers and marketers must be wary of the social consequences persuasion attempts can have on consumers' reactions and wellbeing.

# The Self-Bolstering Effects of Repeated Affirmations Over Time

Alejandra Rodriguez, Oklahoma State University, USA

Ted Matherly, Oklahoma State University, USA

## EXTENDED ABSTRACT

Should you listen again to that song you have been listening to on repeat, or should you listen to different song? We make consumption choices like this on a daily basis without really knowing if more (or less) variety is better for us—not just in terms of enjoyment (Galak, Redden, and Kruger 2009; Ratner, Kahn, and Kahneman 1999), but also psychological wellbeing. This is not an insignificant choice, however, since we regularly use consumption to help us cope when our perceptions of adequacy are called into question.

The abundance of and chronic nature of threats to one's adequacy can cause lasting negative effects on a person's physical, emotional, and mental wellbeing (Cook et al. 2012; Creswell et al. 2005; Jonas et al. 2014; Sherman and Hartson 2011). By encouraging reflection on valued aspects of the self, self-affirmation through consumption can be an effective way to prevent these harmful consequences since possessions and experiences can be closely tied to one's sense of self (Belk 1988; Carter and Gilovich 2012; Sherman and Cohen 2006; Steele 1988). A considerable body of research has confirmed the effectiveness of affirmations in restoring the self (Mandel et al. 2017), as demonstrated by higher levels of self-esteem, improved performance, increased optimism, and reduced stress levels (Sherman and Cohen 2006). However, this research has primarily investigated these outcomes in isolation, without accounting for the fact the individuals may be faced with a choice to either use a variety of affirmations, or to repeatedly use a single one to defend against the myriad threats they may face every day (Cohen and Sherman 2014; Cook et al. 2012). The purpose of this research is to investigate how the use of varied or repeated affirmations increases their effectiveness.

Prior work on satiation might suggest that repeatedly using an affirmation would make it less effective (Brickman and Campbell, 1971; McSweeney and Swindell, 1999). In this case, variety in affirmations should be beneficial to their effectiveness. Conversely, repetitive consumption can also be reinforcing, and thus beneficial, since it can increase enjoyment, perceived personal control, and agency (Frederick and Loewenstein 1999; Peterson 1999), enabling individuals to cope adaptively with threats (Jonas et al. 2014). Thus, we predict that there is a trade-off between variety and time between consumption, such that variety will be more effective in counteracting self-threats over longer periods; but as time between each affirmation decreases, its threat-reducing effect will attenuate as a reinforcement process bolsters the affirmations.

We believe the research put forth in this paper helps shed light on these issues and helps inform current work in multiple areas. First, this research contributes to the longitudinal perspective of compensatory consumption by exploring the effects of repetition and variety on affirming behaviors. Second, we extend theories on reinforcement by examining them within the context of affirming consumption. Lastly, understanding how marketers may help maintain the effectiveness of an affirmation can go a long way in ensuring consumers' sustained enjoyment and wellbeing. This can in turn, strengthen consumers' loyalty to the brands that facilitate the opportunity to self-affirm through meaningful consumption. In the rest of the paper, we discuss why the effectiveness of an affirmation changes over time depending on how often one consumes the same product, and what role variety plays in the process.

According to self-affirmation theory, it is not necessary to address a self-threat directly in order to maintain the perception of adequacy; it is also possible to do so by affirming one's overall self-concept (Steele 1988). For example, if a student's self-esteem has been threatened after failing an exam, they can restore their perceptions of adequacy by behaving in ways that signal other aspects they value about themselves, such as through the consumption of products that remind them of their athletic skills or social ties. Product choices that convey higher status have been shown to provide affirmational benefits to those whose self has been threatened (Sivanathan and Pettit 2010). In addition, a recent study by Townsend and Sood (2012) showed that participants who affirmed by writing a values essay were less likely to choose high design options (vs high functionality). In another study by the same authors, participants who chose the aesthetic product option were more open to arguments, similar to those who had affirmed by writing about their values.

Single affirmations like those in the previous examples have been shown to have lasting effects. Nonetheless, considering the wide range of sources from which threats may originate, a single affirmation may not be strong enough to counteract all the threats one might encounter on a daily basis (Cohen and Sherman 2014; Cook et al. 2012; Jonas et al. 2014; Mandel et al. 2017; Stinson et al. 2011). If an affirmation attempt is not successful, a person may no longer see themselves as adequate, and will need to find another way to affirm (Galinsky, Stone, and Cooper 2000).

It is common to provide participants in studies with a list of values which can be affirming (McQueen and Klein 2006), but which aspects of the self are affirmed naturally is usually determined by what is available and mentally accessible at the time for the individual (Steele 1988). For instance, in many cases a person's occupation or social affiliations are especially valued; for others their personal possessions, such as clothing and accessories, represent many aspects of an individual's self and as a result can become chronically salient. Often people lack awareness of who they are, but can infer qualities and characteristics from their own behavior (Bem 1972; Schooler, Ariely, and Loewenstein 2003), and consuming can provide crucial feedback—signaling to an individual that they are an adequate person (Bodner and Prelec 2003). Furthermore, because individual identities are mentally interconnected, the values and aspects that are central to a person's self-concept can become activated and interact with other identities during consumption through a spreading activation process (Anderson 1983; Reed and Forehand 2016; Swann and Bosson 2010; Verplanken and Holland 2002). Therefore, if an individual consumes more varied products that are personally meaningful and representative of what they value, the ability to affirm should increase since more aspects of the self are likely to be activated in the mind of the consumer. In this case, each time a consumer contemplates the painting they have hanging on their living room wall, new self-aspects can be reflected on and more meaning ascribed to the experience—reaffirming how they exemplify the value they place on art and aesthetic appreciation (Ahuvia 2005). Thus, we predict that variety will be beneficial to affirmations, such that:

*Hypothesis 1*    *Relative to repeating an affirmation, using a variety of affirmations will have a positive impact on self-esteem following repeated threats.*

However, during shorter consumption periods, there may be a positive effect of using the same affirmation, due to potential reinforcement effects. Repetition may lead to sensitization (Frederick and Loewenstein 1999; McSweeney and Swindell 1999), since pattern recognition and repetitive consumption have been shown to increase enjoyment, as well as provide a sense of stability, agency, and control over an individual's surroundings and self-concept (Frederick and Loewenstein 1999; Norton and Gino 2014; Peterson 1999; Whitson and Galinsky 2008). Furthermore, the familiar cues provided by the repetitive consumption can enable an approach motivation in dealing with future threats (Jonas et al. 2014). Reinforcement of valued aspects of the self could also help explain why people satiate slower to products that have more sentimental value associated with them, since sentimental value can be linked to memories of our relationships and other valued aspects of the self (Yang and Galak 2015). However, because these reinforcement effects require that consumers reflect consistently on a similar affirmation experience, we expect that they will only occur during relatively shorter time periods, when individuals can recall the thoughts and feelings surrounding previous uses of the affirmation. In other words, variety will not have as strong an effect in the short term due to the reinforcing effects of repetition.

*Hypothesis 2 The positive relative effect of affirmational variety, compared to repeating an affirmation, will be attenuated in shorter time periods.*

We tested these predictions in two longitudinal experiments, in which participants completed a threatening task, and then affirmed before completing the dependent measure assessing their self-perceptions. Because there were multiple observations for each participant, we employed models with individual fixed effects to capture these within subject variances.

The first study sought to provide an initial test of our predictions while employing a values essay task most commonly used in self-affirmation research (McQueen and Klein 2006). Ninety participants were recruited from the Amazon Mechanical Turk panel and asked to complete four rounds of the study, one to two days apart. Only participants who completed at least three rounds in total were included in the analyses ( $n = 54$ ). The study used a two-level (affirmations: same, different) between subjects design. The threat task was designed to threaten their competence and consisted of responding to difficult-to-impossible CAPTCHAs, a commonly used test used to distinguish human users from automated responses. Using a procedure adapted from Cohen, Aronson, and Steele 2000, after the first trial, participants ranked a list of values, and wrote an essay about their highest ranked value (same affirmation condition) or several values (different affirmation condition) after each round of CAPTCHAs. Finally, participants rated their self-esteem using two items adapted from Rosenberg 1979.

Results revealed a simple effect of time ( $\beta = .242$ ,  $t = 2.71$ ,  $p < .01$ ), qualified by a negative interaction effect of time and a dummy-coded same affirmation ( $\beta = -.288$ ,  $t = -2.05$ ,  $p < .05$ ). This indicates that, compared to those who used different affirmations, participants who used the same affirmation repeatedly in the face of threats had less positive self-perceptions, suggesting that variety improves an affirmation's effectiveness and supporting H1.

The goal of the second study was two-fold. First, we sought to replicate these results using actual consumption. Second, we wanted to demonstrate the boundary condition for the effectiveness of variety in affirmations proposed in our H2. Three hundred and thirty participants were recruited from MTurk to complete the study over four rounds. The study used a 3 (affirmation: same, different, control)

X 2 (time delay: short, long) between subjects design. In an initial task completed several weeks prior to the main study, participants provided a list of personally meaningful songs (adapted from Galak et al. 2009). In each round of the main study, participants first completed a threat task where they wrote a short essay on their personal insecurities. Then, they listened to either their top rated song (same affirmation condition), their top four rated songs (different affirmation condition). Lastly, participants completed the same measure of self-esteem used in Study 1. The time gap between affirmations was manipulated by having participants wait either 30-60 minutes (short gap) or 1-2 days (long gap) between rounds.

Replicating the findings of the first study, comparing the different and same affirmation conditions, in the long gap condition we observed a significant positive effect of time ( $\beta = .130$ ,  $t = 3.48$ ,  $p < .01$ ), qualified by a significant interaction effect ( $\beta = -.116$ ,  $t = -2.36$ ,  $p < .05$ ). However, in the short gaps condition, although there was a positive effect of time ( $\beta = .126$ ,  $t = 2.78$ ,  $p < .01$ ), the interaction effects were attenuated ( $\beta = .05$ ,  $t = .87$ ,  $p = .39$ ), indicating that using either varied or repeated affirmations had equally positive effects on self-esteem.

While consumption can provide many options and opportunities to affirm, there is also potential for repetition to reduce the effectiveness of an affirmation. Our results provide initial evidence which suggests that this not necessarily the case. Although variety seems to increase effectiveness of an affirmation over longer periods (hypothesis 1), repetition can be beneficial in the short term. Together, the results of two longitudinal studies support our prediction that using a variety of affirmations is more effective than repeatedly consuming an affirmation. However, over shorter periods, the reinforcing effect of using an affirmation repeatedly eliminates this difference. Thus, to counteract self-threats over time, it may be best to vary one's affirmations, unless there is a possibility of reinforcement of these effects.

By considering how using a particular affirmation repeatedly may influence its effectiveness in bolstering the self, the research presented in this paper provides several theoretical implications. First, in contrast to extant research on self-affirmation which has mainly looked at the effects of single affirmation interventions, our research delves deeper into understanding the effects of multiple affirmations. Second, our work extends the literature on product variety by exploring the novel context of affirming consumption. Third, this research also adds support for the effectiveness of indirect forms of compensatory consumption (Mandel et al. 2017). Our results show that it is not necessary to affirm within the same domain as a threat to one's self in order to address its negative psychological effects. Consumption provides many avenues for affirming the self that do not call more attention to the threat by addressing it directly (Lisjak et al. 2015).

These findings also help inform how marketers can tailor their offerings to help consumers sustain their products' affirmational benefits—encouraging them to keep consuming their favorite products. For example, products can be offered only during limited times, in which case variety would be beneficial (Sevilla and Redden 2014). The amount of variety provided, such as with video and streaming services, can also be modified depending on consumers' previous behavior. Controlling consumers' sense of variety (versus actual variety in options) may also help regulate their pace of consumption (Redden and Galak 2013), and thus improve affirmational benefits.

Finally, this research provides insight into enhancing consumer wellbeing, by highlighting ways in which individuals can adaptively cope with (and possibly prevent) self-threats through the intrinsically meaningful use of consumption (Kim and Rucker 2012; Schimel

et al. 2004). Enabling consumers to develop and sustain psychological resources can help in the short run to deal with experienced threats, and may also help in the long run to prepare for threats such as personal shortcomings and health recommendations (Ehret and Sherman 2014; Schmeichel and Vohs 2009; Taylor and Broffman 2011). By further exploring the affirmational benefits of consumption, we provide support for more natural and spontaneous ways to self-affirm (compared to writing values essays), which may possibly be used more often and proactively by consumers (Emanuel et al. 2016; Kim and Rucker 2012; Toma and Hancock 2013).

# Consumers' Journey into Access-Based Consumption: A Narrative Analysis Approach

Swapnil Saravade, University of Texas Rio Grande Valley, USA

Lorena Garcia-Ramon, University of Texas Rio Grande Valley, USA

Jacob Almaguer, University of Texas Rio Grande Valley, USA

Mohammadali Zolfagharian, University of Texas Rio Grande Valley, USA

Hazel H. Dadanlar, University of Texas Rio Grande Valley, USA

## EXTENDED ABSTRACT

Consumers are increasingly shifting from traditional ownership-based consumption to relatively novel access-based consumption (hereafter, ABC). Access involves transactions that are market mediated but without transfer of ownership rights (Bardhi and Eckhardt 2012 881). Typically, ABC manifests in the form of renting, sharing, subscribing, or borrowing. This manifestation could be in the context of public services such as parks, museums, and libraries or could be in the context of private services such as Netflix, Spotify, and Airbnb. The primary focus of this study, however, is consumer engagement with private services. Specifically, the current research focuses on business-to-consumer situations with internet as a platform that facilitates access of products/services to consumers. Examples of such private services include companies like Rent the Runway, and Bag Borrow or Steal, which enable consumers to access fashion products such as handbags and jewelry. Moreover, music streaming services such as Spotify and Pandora allow consumers to store music in cell phones as opposed to buying stacks of music CDs. Broadly, ABC is a part of the sharing economy, wherein consumers place underutilized assets as market offerings to make a profit (Pricewaterhouse Coopers (PWC) Consumer Intelligence Series Report 2015). As per the PwC report (2015), 19% of all US consumers participate in sharing economy transactions; 72% plan to participate in the near future; and 57% view access as the new ownership. These numbers paint an optimistic picture of ABC's promising growth in the future.

Scholars have examined ABC from multiple perspectives. Since a wide range of activities pertain to access, there is a conceptual overlap in the literature regarding the semantics of ABC. As a result, there is certain degree of fragmentation and confusion regarding different terms such as sharing, collaborative consumption, renting, and access (Habibi, Davidson, and Laroche 2017; Habibi, Kim, and Laroche 2016). Belk (2007) defines sharing as "the act and process of distributing what is ours to others for their use and/or the act and process of receiving or taking something from others for our use" (126). In collaborative consumption, people coordinate the acquisition and distribution of a resource for a fee or other compensation (Belk 2014) while engaging in joint activities with additional consumers (Felson and Spaeth 1978). Furthermore, renting goods usually involves an agreement between two parties whereby the renter obtains the right to use the rented object and relevant benefits for a specified period of time and fee (Moeller and Wittowski 2010). In contrast to ownership, consumers in ABC, derive benefits from access to objects or networks which they could not afford to own due to spatial or environmental constraints (Bardhi and Eckhardt 2012). In the current research, we focus on ABC and follow the definition by Bardhi and Eckhardt (2012) as "transactions that may be market mediated in which no transfer of ownership takes place" (881). Specifically, we narrow our focus to consumption through internet enabled transactions with emphasis on online applications which facilitate the ABC.

Extant research focused on ABC characteristics (Bardhi and Eckhardt 2017), ABC benefits (Lambert and Rose 2012), and motivations for participation in ABC (Bardhi and Eckhardt 2012; Edbring, Lehner, and Mont 2016; Gruen 2016; Lawson et al., 2016). Overall, extant literature has mainly endeavored to understand the "what" and

the "why" of ABC, with little emphasis on the "how" question. For example, how do consumers first encounter ABC products and services? How do they proceed after early encounters? How do different events transpire in consumer ABC journeys? Answering these questions is important because emerging research has identified sharing economy as an economic opportunity allowing a sustainable form of consumption leading to a decentralized, equitable, and sustainable economy (Martin 2016). In addition, it is speculated that the economic impacts of the sharing economy could grow from \$15bn in 2013 to \$335bn by 2025 (PwC Consumer Intelligence Series Report 2015). Despite such positive outcomes, Schor et al. (2016) find that consumers engaged in some sharing economy practices actually employ distinction practices that deter others, who lack cultural capital, from partaking in the exchanges resulting in an inequitable marketplace. The mixed findings in ABC research warrants an in-depth account of consumers' engagement with ABC. Therefore, a narrative textual approach was employed. A narrative analysis approach allows entry into participants' minds through in-depth interviews, enabling the researcher to witness their stories and journeys (Reissman 1993). Using iterative analysis of consumer stories pertaining to their ABC experiences, this paper sheds light on the key "turns in the road" that consumers experience as they navigate ABC in the context of their daily lives (Cortazzi 1994; Reissman 1993).

## THEORETICAL BACKGROUND

### ABC Enablers: Internet and Apps

Sharing and accessing as an Internet phenomenon started with Napster and other peer-to-peer (P2P) file sharing networks, where users were able to share and access digital files, often illegally (Giesler 2006; Henning-Thurau, Henning, and Sattler 2007). The Internet served as the springboard for the creation of these access systems; however, it is the rising role of smartphones and their capability to access mobile applications that has truly enabled the adoption of access systems (Botsman and Rogers 2010; Zolfagharian and Yazdanparast 2017). Research has identified mobile applications as key drivers of access system adoptions such as car sharing and streaming services (Hamari, Sjöklint, and Ukkonen 2016; Molhmann 2015).

### Liquid Consumption

The current research draws on the logic of liquid consumption which is derived from the theory of liquid modernity. Liquid modernity "is a social condition where social structures are no longer stable or long-term" (Bauman 2007, 1). Flexibility, mobility, and openness to change are key components of liquid modernity (Bardhi and Eckhardt 2017; Featherstone 1995; Hannerz 1996). Recently, Bardhi and Eckhardt (2017) applied the theory of liquid modernity to the domain of consumption and conceptualized the logic of liquid consumption defined as access-based, ephemeral, and dematerialized. The access-based characteristic of liquid consumption is central to the current research. The primary focus of this study then is to understand consumer engagement with private access services. Consumer micro-narratives of ABC were viewed through the lens of liquid consumption and synthesized to understand consumers' journey with ABC.

## METHOD

Given the research purposes, a qualitative approach using in-depth interviews was employed to extract consumer ABC narratives. Narratives serve as an instrument for individuals to make sense of the events that happen in the world (Reissman 1993). Narrative analysis is considered to be an entry into the mind of an individual or, if analyzing a group of storytellers, into their culture (Cortazzi 1993). Researchers interested in the lived experiences of consumers have employed narrative analysis to interpret and make sense of these experiences (Braun, Zolfagharian, and Belk 2016; Stern, Thompson, and Arnould 1998). By employing narrative analysis, the current research analyzes consumers' interpretations of their experiences with ABC and important events as they occurred in the context of their lived experience.

Text was generated through semi-structured in-depth interviews that allowed researchers to delve deep into consumer narratives (McCracken 1988). All researchers were involved in the data collection process, resulting in a total of 19 interviews conducted in the South-west United States. The purpose of the interviews was to extract the experiences and stories of the participants as they transitioned (or not) into ABC. For this reason, a purposive sample of ABC users was recruited using the researchers' social network. Thus, the deciding criterion for recruitment was participants' prior experience with ABC. Participants' age ranged from 20 to 65, with an average age of 27 (see appendix A for respondent profile). Participants represented a variety of occupations such as retired professionals, graduate students, and working professionals. Additionally, the extent of experience with ABC services also ranged from participants who were very used to ABC and those who had not had much experience with it. The researchers encouraged respondents to tell their personal narratives and probed for specific experiences contingently during the dialogue. The interviews generated 196 single-spaced pages of text. Transcripts generated from interviews are among the most popular forms of text used by consumer researchers (Arnold and Fischer 1994; Braun et al. 2016; Stern et al. 1998).

Interviews started with general questions about participants' experiences with ABC that enabled them to provide as rich a description of their emotions and opinions as possible. A research protocol was designed to ensure that the conversation did not deviate from its intended direction and to remind researchers of important probes and follow-ups to enrich consumer narratives (Rubin and Rubin 2005). Moreover, the use of the interview protocol enabled coverage of intended domains across all interviews as well as consistency across interviewers (McCracken 1988). The researchers began the interviews by asking participants if they had any experience with ABC. In some cases, participants were not familiar with the term ABC so the researchers provided examples to bring consumers' experiences with ABC (if any) to the fore.

## ANALYSIS

Text generated from the interviews was subjected to an interpretive analysis where researchers moved from the text to the etic understanding in an iterative manner. This resulted in the discovery of stages emerging from the text, informed by the researchers' framework (McCracken 1998). Each interview was analyzed individually to identify the emergence of a micro-narrative and then considered in the "big picture" with the rest of the interviews to form an overarching macro-narrative. Once all interviews were transcribed, the researchers analyzed the text, searching for the underlying macro narrative that not only constituted the different plots of the overall story, but also identified the most plausible sequence of events. The macro-narrative materialized from the similarities and differences

uncovered by the researchers along the spectrum of the complete text (Reissman 1993). The iterative process was complete when consensus across researchers was reached (Schensul et al. 1999).

Throughout the generation and analysis of the text, the researchers took appropriate steps in order to ensure credibility, dependability, confirmability, and integrity (Wallendorf and Belk 1989). Credibility was established by debriefing participants to verify an appropriate representation of their narrated reality. Dependability was established by incorporating member checks in over half of the interviews where at least two members of the research team were present. This also allowed for the triangulation of participants and researchers. Confirmability was established by audio recording each interview and making the digital transcriptions available to all members of the research team. Lastly, integrity was established by creating rapport among participants and researchers and by assuring participants of the confidentiality of the research.

## FINDINGS

The macro-narrative is visually presented in Figure 1 in the form of a pinwheel, with each of its components representing specific characteristics of it. Moreover, the study identifies specific drivers of ABC that act as the "wind" making the pinwheel turn. The resulting macro-narrative describes the key milestones consumers undergo through their experiences with ABC. More specifically, eight sequential "turns in the road," four major and four deviant, emerged from the analysis of micro-narratives. The sequence of these "turns in the road" is: initiation/rejection, experimentation/renunciation, contamination/alternation, and devotion/reversion. It should be noted that not all participants' narratives described such journey, as some of them deviated from the journey at different points in time effectively abandoning ABC, while some remained in a specific stage never reaching the devotion stage.

While initiation, experimentation, contamination, and devotion represent key stages in consumers' engagement with ABC; rejection, renunciation, alternation and reversion demonstrate alternate points from which consumers deviate from ABC. The unique feature of the emergent macro-narrative is that, it not only captures consumers' journey of becoming a devout user of ABC, but also captures the deviant "turns in the road" from which consumers leave their journey with ABC.

Consumers' journey with ABC begins with "initiation" which is characterized by consumers' random or purposeful internet searches, confirmation to recommendations from trusted relationships, or through product or service referrals. Alternatively, this journey is ceased when consumers' outright "reject" the idea of engaging in ABC for various reasons. Even after transitioning from initiation to "experimentation" wherein consumers "test the waters" of ABC, some consumers become ambivalent. They either continue and contaminate their consumption patterns with ABC or decide to renounce use of ABC. Consumers who continue with their occasional experimentation eventually experience "contamination" of their consumption patterns with ABC. This "turn in the road" represents an important milestone for ABC consumers because it is from this point onwards that consumers start considering access-based products or services as feasible options in their consumption decisions. However, for some consumers this contamination is not compelling enough. Specifically, with "alternation", they continue their traditional consumption practices and integrate ABC whenever convenient. This alternation does not reflect the complete embrace of ABC, as traditional consumption is still present. While some ABC consumers may not move beyond the alternation milestone resulting from their lack of devotion to such services/products. Devotion marks the pin-

nacle of consumers' engagement with ABC, characterized by strong emotions and bonding behaviors toward access-based products or services. However, at the pinnacle of engagement, some ABC consumers experience inconsistency with the ideology, stance or overall functioning of the access-based products or services. It is at this point, that consumers who previously showed devotion to ABC, revert back to their previous consumption practices. This progression of consumers' journey with ABC through each of the milestones is powered by the driving forces which are characterized by flexibility, status seeking, temporary nature of use, and low price of engaging with ABC (Edbring et al. 2016).

## DISCUSSION

Our findings can inform and equip marketing managers with key insights in various areas such as market-driven strategies, customer satisfaction, market-driving practices, service recovery, product and/or service sales and consequently, firm profitability. As per the findings, some consumers acknowledged the benefits of ABC, while some cited excuses pertaining to physical safety, information security, negative experiences, and liability of newness of the service or products for distancing themselves with ABC. As prior literature has shown, alternative methods of consumption do not always result in the positive outcomes they had originally been intended to provide (Schor et al. 2016). Marketers can tap into the reservations consumers have for not engaging in ABC by providing safety and security assurance or employee training as a potential remedy for negative consumer experiences, among others.

The current research makes several contributions to the liquid consumption literature. First, it not only identifies the unique milestones involved in ABC, but also demonstrates that each of these milestones has an alternative component that forms an integral part of the macro-narrative. Second, by analyzing consumer stories, the findings provide a nuanced understanding of liquid consumption as manifested through ABC. Each of the unique milestones that emerged in the macro-narrative delves deeper into the experiences of consumers. This is important, because consumer research has shown that under certain conditions, experiences make consumers happier compared to material possessions (van Boven and Gilovich 2003). Lastly, this research contributes to the theory of liquid modernity which posits that social structures are no longer stable or long-term (Bauman 2000) by adding more shades to the theory of liquid modernity and explaining how consumers progress through different milestones in their ABC journey.

# Product Search on Crowded Retail Shelves: Impact of Vertical Product Location on Search Performance

Ana Scekkic, HEC Paris, France

A. Selin Atalay, Frankfurt School of Finance and Management, Germany

Cathy Liu Yang, HEC Paris, France

Peter Ebbes, HEC Paris, France

## EXTENDED ABSTRACT

In the context of FMCGs, consumers often arrive at the store with a choice of a product in mind. Their task then is to find their already chosen product among the products present at the point of purchase. In the current paper, we focus on this task of visual search for a target product on a shelf with a large assortment (i.e., a crowded shelf). Specifically, we investigate the influence of vertical location (VL) of a product on a crowded shelf on consumers' search performance. We provide initial evidence that, when the task is to find a target product on a shelf, the middle shelf (MS) is a position of disadvantage, when compared to the top shelf (TS) and the bottom shelf (BS).

Finding a target product on a crowded shelf is not easy. As the number of objects in any scene increases, it becomes difficult to distinguish the objects in that scene from one another. This is known as the "crowding effect" (Levi 2008; Whitney and Levi 2010). Among the factors influencing the strength of the crowding effect, is the location in the scene and the visual field. We investigate the influence of product location on search performance.

In a product choice context, products on MS and TS have been shown to get more attention and positive evaluation (Chandon et al. 2009; Valenzuela and Raghuram 2009; Atalay et al. 2012). The impact of product location on search, however, is underexplored.

According to the crowding literature, the ability of identifying an object in a crowded scene depends on that object's location by way of two mechanisms: *anisotropy* and *asymmetry* (Levi 2008; Whitney and Levi 2010). Anisotropy suggests that the crowding effect differs along the vertical axis of the visual field, and, specifically, is less strong in the lower visual field (He et al. 1996). Hence, the ability to identify an object's features is improved when the object is located in the lower visual field. Asymmetry refers to the role of surrounding (flanker) objects: a target object is more difficult to identify when it is presented with two flankers, positioned one on each side of the target, than when it is presented with only one flanker on one side (Bouma 1970; Bouma 1973). Thus, in a display of objects, the objects on the outer sides of the display will be easier to identify than the inner objects.

Drawing on these theories, we predict that there will be a main effect of vertical product location on search performance and that products on both top and bottom shelves (i.e., products in the outer locations) will be easier to find than products located on the middle shelf.

In study 1, 668 MTurk participants were asked to find a target (i.e., "sugar free" jam) among 25 different jams. The location of the target was manipulated in a between-participant design. On a 5x5 planogram, we rotated the target across the jams on TS, on MS, and on BS. Search performance was measured by search task duration, perceived duration of the task, perceived task difficulty, and satisfaction with task duration. Results showed a main effect of VL on task duration ( $F(2,653) = 5.12, p = 0.006$ ), perceived duration of the task ( $F(2,653) = 3.19, p = 0.042$ ), perceived task difficulty ( $F(2,653) = 2.69, p = 0.069$ ), and satisfaction with task duration ( $F(2,653) = 2.33, p = 0.099$ ). Planned comparisons suggested that MS is a position of disadvantage for product search when compared to BS and TS.

In study 2, 127 participants completed the study on a lab computer, and were asked to find the toothpaste for smokers on a shelf of 15 toothpastes arranged on a 3(columns) x 5(shelves) planogram. The VL of the target was manipulated in a between-participant design. Results showed a significant effect of VL on task duration ( $F(2,118) = 3.30, p = 0.04$ ), perceived task difficulty ( $F(2,118) = 3.75, p = 0.026$ ), and satisfaction with task duration ( $F(2,118) = 5.20, p = 0.007$ ). Planned comparisons suggested again that MS is a position of disadvantage for product search.

Eye-movement data showed that, when the target is on MS, the total number of fixations needed to explore the assortment is the highest ( $F(2, 118) = 3.93, p = 0.022$ ), the total duration of all fixations is the longest ( $F(2, 118) = 3.18, p = 0.045$ ), and the total duration of fixations that land on the target (i.e., total time needed to look at the target before "finding" it) is the longest ( $F(2, 118) = 4.03, p = 0.02$ ). The time to first fixation on the target did not differ significantly when the target was on MS or BS. However, the time elapsed since the first fixation on the target until the end of the task was shorter when the target was on BS than when it was on MS, suggesting that even though it takes the same time to look at the target product for the first time, the time necessary to recognize the target and complete the task is longer when the target is on MS than on BS.

A follow-up study, with a more pictorially depicted target that did not necessarily require reading to be found, provided additional evidence. Forty-nine participants searched for a box of almond-flavored cookies on a 5x5 planogram of cookies. Results confirmed that, when the target was on MS, rather than on TS or BS, the search task took the longest to complete ( $F(2, 46) = 3.39, p = 0.042$ ).

Taken together, our studies provide evidence for location effects on product search and a different take on location quality: while in a choice context the lower shelves are regarded as a position of disadvantage and the middle as a position of advantage, our results suggest that when the task is to search for a target product, MS may not be the best location, while BS gains value. Further research on factors influencing product search is needed, as it is a question relevant to consumers, retailers, and brand managers.

# The Psychological Impact of Annuities: Can Pension Payout Choice Influence Health Behavior?

Anja Schanbacher, London Business School, UK  
David Faro, London Business School, UK  
Simona Botti, London Business School, UK  
Shlomo Benartzi, UCLA, USA

## EXTENDED ABSTRACT

Across the world, a growing number of people face the important financial decision whether to take out their pension in the form of a one-time lump-sum payment or as monthly income, also referred to as an annuity. In the US and Australia, for instance, people have traditionally had the freedom to choose between these payout options, whereas some countries where annuitized pensions are traditionally more common such as the UK have recently introduced the option of cashing out one's pension as a lump-sum. Besides this increase in choice, the demographic development with aging populations implies that more and more people face the decision between an annuity and a lump-sum.

Policy makers have been debating whether people should be given a choice between annuitization and lump-sum payout, and whether choice of annuities should be encouraged or mandated. One consideration in this debate is self-selection. Specifically, it has been argued that individuals are to some extent aware of their own life expectancy, and that since the financial payout of annuities increases with growing length of life, those with a higher (compared to lower) life expectancy are more likely to choose an annuity. Indeed, literature has documented a positive relationship between receiving an annuity and longevity (Finkelstein and Poterba 2002).

In the present research, we raise the possibility that in addition to self-selection, a causal effect of choosing an annuity over a lump-sum on longevity may underlie this relationship. This proposal is based on the argument that for annuity (but not lump-sum) recipients, extending their lives implies a financial gain. Further, losing a substantial part of one's savings in the event of early death is a central concern regarding annuities (Hu and Scott 2007). As a result, positive consequences of reaching a high age may be particularly salient among annuity recipients. Hence, we hypothesize that individuals who perceive a higher likelihood of receiving an annuity will be more likely to engage in more (versus less) healthy behaviors as a means to increase life expectancy.

### Study 1

We recruited UK-based, currently employed participants through the website ProlificAcademic. Participants were randomly assigned to either a lump-sum- or an annuity- condition. The instructions stated that a recent policy change in the UK had given pensioners the freedom to choose between a lump-sum and an annuity. We then presented a short explanation of the two payout options. To facilitate comprehension, each participant also saw a table indicating the cumulative amounts of money that they would have received by certain ages with each option. The annuity payout was determined using current annuity rates. Both options were presented in counter-balanced order.

Next, participants in the annuity condition listed the one or two most important reasons for choosing an annuity and the one or two most important reasons against choosing a lump sum, whereas participants in the lump-sum condition listed the one or two most important reasons for choosing a lump sum and the one or two most important reasons against choosing an annuity. Our reasoning was that enhancing the accessibility of advantages of an option (and of

disadvantages of the alternative) would increase the subjective likelihood of choosing this option. As intended, participants in the annuity (vs. lump-sum) condition reported being significantly more likely to choose an annuity.

To measure health behavior, we then presented five scenarios involving a choice between a more and a less healthy behavioral option, and participants indicated which behavior they would be more likely to choose. The behaviors included selecting a costly comprehensive vs. a free basic health check, and joining a more strenuous exercise program that particularly benefits long-term health vs. continuing one's regular exercises.

The results confirmed our central hypothesis: Across scenarios, participants in the annuity condition were significantly more likely to select the healthy behavioral options than participants in the lump-sum condition.

### Study 2

The purpose of Study 2 was to replicate the effect that choice of an annuity vs. a lump-sum boosts health-related behavior in the context of real behavior. Participants were randomly assigned to a lump-sum- or annuity-condition. Upon arriving at the lab, participants exercised on a stationary bike for two minutes. A combined measure of the amount of calories burnt and distance travelled (z-scored) within these two minutes was included as a covariate in the main analysis to control for individual differences in exercising performance.

Next, participants were told they would participate in an unrelated study while taking a break between exercising tasks. In fact they completed the task manipulating perceived likelihood of choosing an annuity vs. a lump-sum from Study 1 – our manipulation of the financial decision. As intended, participants in the annuity (vs. lump-sum) condition indicated being more likely to choose an annuity for their own retirement.

After this manipulation was administered, participants exercised again on the bike for up to ten minutes. They were told that it was up to them how vigorously they wanted to exercise. Our main dependent variable was the combined measure of the amount of calories burnt and distance travelled (z-scored) within the ten minutes. In addition, participants indicated how likely they were to exercise later that day.

Addressing our main hypothesis, participants in the annuity-condition had significantly higher values on the exercising measure than participants in the lump-sum-condition, indicating that they had exercised more vigorously. In addition, participants in the annuity-(vs. lumps-sum-) condition reported being significantly more likely to exercise later that day.

Prior literature has focused on antecedents (Payne et al., 2013; Shu, et al., 2016) rather than consequences of choosing a lump-sum vs. an annuity pension. We manipulate expectations of choosing an annuity (vs. a lump-sum) and find evidence of a causal effect on health-related behaviors. Such potential consequences should be considered in the public policy debate on pension payout choice.

# Born to Shop? A Genetic Component of Deal Proneness

Robert M. Schindler, Rutgers University - Camden, USA

Vishal Lala, Pace University, USA

Jeanette Taylor, Florida State University, USA

## EXTENDED ABSTRACT

Price discounts, cents-off coupons, and other retail sales promotions have been found capable of eliciting strong consumer enthusiasm. Research on this sales promotion enthusiasm has shown that people have enduring differences in their likelihood of feeling it. The tendency to feel strong promotion enthusiasm has been termed *deal proneness* (Webster 1965). Given that deal proneness is both an interesting behavioral phenomenon as well as descriptive of an important market segment, it is worthwhile to gain a better understanding of the origin of this consumer disposition.

An early view concerning the origin of deal proneness is that consumers learn it from the shopping environment. However, virtually all consumers are exposed to sales promotions, but only some of these consumers become deal prone. The possibility that a financial need for price discounts leads people to become deal prone conflicts with data indicating that deal-prone consumers tend to be higher income, not lower income, individuals (e.g., Bawa and Shoemaker 1987). Rather, the tendency for some consumers to become deal prone is likely to be based on differences among consumers as to how they experience retail sales promotions. For example, some consumers may enjoy deals more than others because of the ego satisfaction they receive from them (Schindler 1998).

In addition to the possibility of acquiring deal proneness from the shopping environment, consumers could acquire it from their parents. Schindler, Lala, and Corcoran (2014) found that deal-prone consumers are likely to have deal-prone parents. Although they found evidence that factors related to the quality of family interactions affected the degree of deal-proneness similarity between consumers and their parents, the consumer-parent similarity raises the question of whether there is an inherited component to deal proneness. Supporting this are recent findings of inherited components to various types of consumer and financial decision-making (Cesarini et al. 2012; Cronqvist and Siegel 2014; Simonson and Sela 2011).

In this study, we test for an inherited component to deal proneness. We use a classical twin design to compare the similarity of monozygotic (MZ) and dizygotic (DZ) twins reared together. Because MZ twins have all of their genes in common, but DZ twins have, on average, only half of their segregating genes in common, a higher correlation in the amount of a trait between the members of MZ twin pairs than between the members of DZ twin pairs indicates some heritability of the trait. If MZ and DZ twin pairs are relatively similar in their correlations, then shared environmental influences are inferred to be at work in shaping the trait.

The twins included in this study were recruited with the assistance of the registrar at Rutgers University. All pairs of students who attended the university between the years 2016-2018 and who had the same last name, same birth date, and same gender were contacted by email and were invited to participate. A total of 108 twin pairs responded. To determine the zygosity of each set of twins, we asked each twin to complete a five-item self-report questionnaire that has been validated against DNA-based zygosity determination (Lykken et al. 1990). By these questions, 73 twin pairs were classified as MZ and 35 were classified as DZ.

Each of the twins in the sample completed the deal-proneness measure used by Schindler et al. (2014). The scale included 32 seven-point agree-disagree items with five or six items addressing each

of six deal types. The items measured the enjoyment and pleasure that was received from the deal types. For example, one of the six deal types represented was *free gift* (e.g., "I enjoy buying products that come with a free gift") and another was *coupon* (e.g., "Redeeming coupons makes me feel good").

The twins in the 73 MZ twin pairs in our sample showed a high degree of similarity with each other in their scores on the 32-item deal proneness scale ( $r = 0.55, p < 0.001$ ). The twins in the 35 DZ twin pairs in our sample showed a much lower degree of deal proneness similarity ( $r = 0.13, p = 0.46$ ). This greater similarity among the MZ twins than among the DZ twins is statistically significant (Fisher's  $z = 2.30, p = 0.024$ ) and is evidence for a high degree of heritability in deal proneness. Using Falconer's (1989)  $h^2$  measure of heritability, our results indicate that 84 percent of the variability in deal proneness is associated with genetic factors.

The MZ-DZ correlation differences did differ among the six deal types. There was considerably more similarity among the MZ twins than among the DZ twins in their interest in coupons, rebates, and items being on sale. For free gift deals, there was considerably more correlation among MZ twins than among DZ twins, but this difference was not statistically significant. For buy-one-get-one-free promotions and contests and sweepstakes, there were only small, non-statistically significant differences between the similarity among MZ twins and that among DZ twins. This suggests an effect of shared environment on those types of deals rather than heritability.

The greater deal-proneness similarity among MZ twins than among DZ twins provides strong evidence for the existence of an inherited component to deal proneness. This finding provides a basis for approaching the question of what factors make deals attractive to consumers. For example, Simonson and Sela's (2011) finding regarding the compromise effect suggests some heritability of the degree to which a consumer uses external stimulus information (e.g., whether an alternative is the middle option) over internal preference information (e.g., his or her liking of the alternative). Such use of external stimulus information over internal preference information may also be important in how promotional deals are experienced. For marketing practice, the finding of the heritability of deal proneness is further evidence that this trait tends to run in families and suggests that there might be a particular effectiveness of promotional deals that encourage interactions among consumers and their family members.

# “Eww, It Has a Face!” Anthropomorphizing Food Products Deteriorates Consumption Experience

Roland Schroll, University of Innsbruck, Austria

## EXTENDED ABSTRACT

Anthropomorphism – the attribution of human characteristics to nonhuman objects – is a popular marketing strategy used for various products (Aggarwal and McGill 2007; Epley, Waytz, and Cacioppo 2008). This research focuses on the anthropomorphization of food products – a fairly neglected area of research. To promote food products, companies frequently rely on anthropomorphized brand characters such as Mr. Peanut, Tony the Tiger, or the M&M mascots and endow products with humanlike characteristics. For example, *Nestlé* promotes its cinnamon toast crunch cereals by making the cereals appear alive and *Dunkin’ Donuts* recently introduced a smiley face donut. In addition, governmental institutions such as the *United States Department of Agriculture* (USDA) anthropomorphize fruits and vegetables to promote healthy eating to children.

What are the consequences of anthropomorphizing food products? While extant anthropomorphism research has focused predominantly on consumer responses before purchase (e.g., liking, purchase; e.g., Wen Wan et al. 2017), the current research takes a new perspective and investigates how anthropomorphizing food products impacts consumption-related outcomes. Drawing from mind perception theory, the central proposition of this research is that anthropomorphizing leads to the perception of *Experience* – that is, capacity to feel pain, pleasure and emotions (Gray, Gray, and Wegner 2007). Experience transforms an entity into a moral patient. A suffering moral patient triggers feelings of care and concern (Gray et al. 2007; Waytz et al. 2010b), which should negatively influence consumption-related responses.

Two studies provide evidence for the deteriorating effect of anthropomorphism on consumption experience. Study 1 ( $n = 46$ ), a field study, was presented as a new product evaluation task. Participants were instructed to choose one of two cookies (control vs. anthropomorphized), eat it, and, then, indicate how much they enjoyed it and how they felt after eating it. The results show that consumers enjoyed eating the anthropomorphized cookie significantly less and felt significantly worse after eating the anthropomorphized cookie compared to the non- anthropomorphized version (all  $p$ 's  $< .05$ ).

Next, study 2 shed light on the underlying mechanisms. Study 2 ( $n = 116$ ; MTurk sample) used a single-factor (control vs. anthropomorphized) between-subjects design. As stimulus, we used a recent *Chips Ahoy!* cookie advertisements. For the anthropomorphized condition, we used the original ad which featured a cookie with human face features. For the control condition, we removed the human face features from the cookie. The results showed that while anthropomorphizing enhances consumption experience due to greater whimsical cuteness, it simultaneously, and even more so, deteriorates consumption experience because of feelings of inflicted harm. Consumers feel as if they would hurt the anthropomorphized food product by eating it, which negatively influences consumption-related responses.

In doing so, the current research contributes to anthropomorphism literature in several ways. First, while existing anthropomorphism research focused predominantly on consumer responses before consumption (e.g., liking, evaluation), the current research outlines important downstream consequences of anthropomorphism. To the best of our knowledge, this is the first research to systematically document deteriorating effects of anthropomorphism on post-purchase consumer responses. This adds a novel chapter to an evolving stream of research investigating consumers differential pre- and

post-purchase responses (Lee and Tsai 2014; Wu et al. 2017). Second, while extant anthropomorphism research has mainly focused on the consequences of moral agency (i.e., the capacity to perform intentional actions), the current research is among the few exceptions that examine the consequences of experience – the second dimension of mind perception (Gray et al. 2007; Waytz et al. 2010b). This is relevant because many anthropomorphized entities do not act themselves but are acted upon (especially in a consumption context). Third, the current research has implications for prior research on consumption-related consequences of anthropomorphism. Research has demonstrated that anthropomorphizing a tempting consumption object increased consumption amount because anthropomorphizing reduced experienced conflict among consumers with a strong dieting goal (Hur et al. 2015). Our work extends this line of research by uncovering an additional mechanism that impacts consumers' consumption-related responses. We find that anthropomorphizing a food product inhibits consumption and leads to more negative emotional outcomes because consumers feel as if they would harm the anthropomorphized product by eating it. We believe that findings of Hur et al. (2015) do not contradict our results, but rather suggest an additional boundary condition. That is, for consumer with a strong dieting goal, the negative effect of anthropomorphism on consumption enjoyment should be attenuated because feelings of reduced conflict counteract perceptions of inflicted harm.

Lastly, the current research offers implications for marketers and public policy makers. For example, a negative consumption experience might lead to lower re-purchase likelihood and frequency, which is why marketers need to be aware of post-purchase consequences of an anthropomorphism strategy.

# When Lack of Belonging Means Bad News for the Planet: The Consequences of Low Belonging on Ethical Product Purchases

Ainslie Schultz, Providence College, USA  
Kevin Newman, Providence College, USA  
Scott Wright, Providence College, USA

## EXTENDED ABSTRACT

Consumers increasingly report feeling disconnected from others. They live farther from family, belong to fewer social groups, and are more likely to live alone than ever before (Pew Research Center 2015). Low belongingness is an aversive state for consumers, since belonging is a human need (like food, water, and shelter), and relationships with others provide access to survival benefits such as resources and protection (Buss 1990). Consumers often use ethical products to help them experience belonging since these products can signal altruism and convey status to others (Griskevicius et al. 2010; Van Vugt et al. 2007). But for individuals low in belongingness, investing in ethical products may not be worthwhile since they cannot harness social benefits of these products such as elevated group status and increased access to resources within groups.

Some literature suggests that low belongingness decreases prosocial actions (Baumeister et al. 2007). In this research, we predict that low belongingness may reduce interest in ethical products, leading individuals to view ethical products less favorably and pay less for them. We expect that these effects occur due to a lower focus on others, which results in less concern for social acceptance.

Experiment 1 predicts that consumers who experience lower (vs. higher) feelings of social belonging will evaluate ethically branded products less favorably. 80 students participated in a lab study. Participants read a passage about an invented brand called Ony. The passage allowed us to manipulate perception of the brand as either an ethical, socially responsible brand, or as a typically branded control.

Next, participants indicated their overall evaluation of the Ony brand: bad/good, unfavorable/favorable, and negative/positive ( $\alpha = .94$ ) as our dependent variable. Following, participants completed Twenge et al.'s belonging scale (2007,  $\alpha = .87$ ).

Using Hayes Process Model 1 (2013), we conducted a multiple regression. As expected, the analysis revealed a marginally significant two-way interaction (ethical or control  $\times$  belongingness,  $b = .25$ ,  $t(1,76) = 1.94$ ,  $p = .06$ ). Participants lower in belongingness ( $-1$  SD) showed less favorable evaluations of the ethical brand ( $M_{\text{low belongingness}} = 4.70$ ) than participants higher in belongingness ( $M_{\text{high belongingness}} = 5.57$ ,  $+1$  SD,  $t = 2.22$ ,  $p = .03$ ).

Experiment 2 tests the underlying mechanism "focus on others" and "concern for social acceptance" and suggests that individuals low in belongingness may display lower willingness to pay for ethical products due to a lower focus on others that leads them to lack concern for social acceptance. 258 participants were recruited on Mturk. Participants first completed a writing task to prime low belongingness (vs. control). In the low belongingness condition, participants wrote about a time they felt they did not belong; in the control condition, participants wrote about a TV show. Next, participants saw the Ony ethical product manipulations from experiment 1. As the dependent variable, participants indicated how much they would be willing to pay for a cup of Ony coffee. Afterward, participants answered the focus on others (from Winterich and Barone, 2011,  $\alpha = .89$ ) and concern with social acceptance scales (from Chen, 2017,  $\alpha = .96$ ), the mediators.

Using Hayes Process Model 1 (2013), we conducted regression to predict willingness to pay. Willingness to pay was transformed to account for extreme values. Due to the transformation, lower values

represent higher amounts. As predicted, we found a significant two-way interaction ( $t(1, 254) = 2.42$ ,  $p = .02$ ). Individuals who viewed the ethical product and were primed with low belongingness were willing to pay less for the ethical product than controls ( $M_{\text{low belongingness, ethical}} = .36$ ,  $M_{\text{control, ethical}} = .29$ ;  $t(1, 254) = -2.18$ ,  $p = .03$ ).

To explore the underlying mechanism, we conducted dual moderated mediation using Hayes Process Model 86. The results confirmed that both focus on others and concern with social acceptance mediated the moderated effect ( $[.001, .018]$ ). Among participants primed with low belongingness, the effect was significant (Effect =  $-.01$ , 95% CI =  $[-.015, -.002]$ ), suggesting that participants low in belongingness are less willing to pay for ethical products because they are less focused on others, which leads to less concern with social acceptance. Among controls, the effect was the opposite. Dual mediation was not significant when the order of the mediators was reversed.

Experiment 3 provides further evidence for the underlying mechanism, concern with social acceptance, by testing whether individuals who feel low belongingness gravitate toward minority (vs. control) endorsed products. 133 participants were recruited on Mturk. Participants completed the writing task from experiment 2 to prime low belongingness (vs. control). Next, participants saw one of two advertisements about a green brand, EcoTowel, encouraging them to purchase it and decrease their urban footprint. The advertisements were identical except for the manipulation: 1) Only 19% of American households look for green products when they shop (minority endorsed), or 2) no statement (control). Participants indicated their willingness to pay for the EcoTowel.

We transformed willingness to pay; lower values represent higher amounts. We found a significant two-way interaction ( $F(1, 129) = 4.47$ ,  $p = .04$ ). Among individuals primed to feel low in social belonging, those who viewed the minority endorsed advertisement (vs. control) reported a higher willingness to pay for the ethical product ( $M_{\text{minority endorsed, low belongingness}} = .15$ ,  $M_{\text{ethical control, control}} = .21$ ;  $F(1, 129) = 6.41$ ,  $p = .01$ ).

Experiment 3 shows that individuals low in belongingness gravitate toward ethical products that endorse the minority opinion, suggesting that these individuals may be less concerned with others and social acceptance. This finding provides an important contribution to past research on social influence, which has found that individuals are more likely to engage in ethical behavior, such as recycling and donating (Goldsmith, 2015; Goldstein, Cialdini, and Griskevicius, 2008), when majority norms are used. We suggest that this effect may vary for individuals low in belongingness.

Overall, our results reveal that individuals who feel low in belongingness (vs. controls) evaluate ethical products less favorably and are less willing to pay for them. Applied, our results suggest that feelings of isolation and low belongingness may engender unintended consequences for society and the environment.

# When Less is More - How Making Products More Personal Can Decrease Purchase Intention

Michael Schulz, University of Cologne, Germany

## EXTENDED ABSTRACT

Personalization (i.e., tailoring products and services to individual consumer needs) is central to many successful businesses (Kavadias, Ladas, and Loch 2016). Research on personalization has predominantly investigated the effects of consumers sharing personal information with companies (e.g., Zhang and Wedel 2009). Yet in various industries, companies are also sharing personal information with consumers (i.e., the flow of information is reversed): The furniture retailer IKEA provides names of product designers aside its products in its retail and online stores. The food manufacturer Ruedgenwalder Muehle displays pictures and job descriptions of product developers on its products' packages. The FMCG company Beiersdorf shares videographic stories of product developers online. These examples illustrate a novel approach to personalization (hereafter referred to as "personalization" (Fuchs et al. 2016)), which is different from traditional personalization in several aspects: Foremost, companies share personal information with consumers. Thus, the direction of information flow is reversed. Furthermore, personalization might make products appear to be more personal, yet they do not become more individual. Finally, consumers cannot opt out of personalization as there is no proactive consent necessary. Thus, the author believes that the existent research on personalization is only partially applicable to this matter. To the best of the author's knowledge, there is only one study specifically dedicated to this topic (Fuchs et al. 2016), which demonstrates that consumers choose personalized over non-personalized products in a series of choice-based experiments. Considering that personalization used in practice yet under-researched, the author examines positive and negative effects of personalization on consumer behavior in two studies.

The aim of Study 1 was to establish the underlying psychological processes of personalization. On one side, the author hypothesizes that personalization influences perceptions of anthropomorphism. Anthropomorphism "describes the tendency to imbue the real or imagined behavior of nonhuman agents with humanlike characteristics, motivations, intentions, or emotions" (Epley, Waytz, and Cacioppo 2007, 864). In marketing literature, different forms of anthropomorphism and their effects on consumer behavior have been discussed (e.g., Kim and McGill 2011). Also, research suggests that even non-diagnostic information, for example knowing a person's name, can influence consumers (e.g., Jiang et al. 2010). On the other side, the author hypothesizes that personalization influences perceptions of uniqueness (Snyder and Fromkin 1980). Compared to the majority of products, personalization still might be a distinctive feature making products unique. To test these hypotheses, data for Study 1 ( $N = 211$ ) was collected in a large Western European country. In a between-subjects design, participants were randomly assigned to one of two conditions. In both conditions, participants saw a snack foods product. In the treatment condition, participants were informed how and by whom (i.e., the product developer's name was explicitly mentioned) the product was developed. In the control condition, participants were only informed how the product was developed. Results suggest that participants had higher perceptions of anthropomorphism ( $t(209) = 4.90, p < .001$ ) and uniqueness ( $t(209) = 4.74, p < .001$ ) in the treatment condition. While the findings of a mediation model suggest that personalization has indirect effects on purchase intention via anthropomorphism ( $b_{a1 \times b1} = 0.50, CI_{90\%} [0.32, 0.69]$ ) and uniqueness ( $b_{a2 \times b2} = 0.16, CI_{90\%} [0.06, 0.29]$ ), there is no overall effect ( $b_c = 0.16, CI_{90\%} [-0.17, 0.49]$ ).

The aim of Study 2 was to replicate the findings of Study 1 and to identify potential downsides of personalization. Research in the domain of personalization suggests that over-personalization can induce negative consumer reactions (Doorn and Hoekstra 2013; White et al. 2008). To explain negative consequences of personalization, the author builds on social presence theory and the role of intimacy (Short, Williams, and Christie 1976). Personalization might enable an object to become a social participant in the environment of the consumer. Following social presence theory, the author hypothesizes that personalization can violate consumers' privacy in categories associated with a high level of intimacy (e.g., toiletries, hygiene products). Study 2 ( $N = 209$ ) followed the same between-subjects design as Study 1. Shower gel was chosen as a product associated with a high level of intimacy in usage. In both conditions, participants saw a bottle of shower gel containing a new formula. In the treatment condition, participants were informed by whom the new formula was developed (i.e., two product developers of the company). Additionally, a picture of the two developers was shown on the bottle. In the control condition, participants received no information on the product developers. Reconfirming the findings of Study 1, participants reported higher perceptions of anthropomorphism ( $t(207) = 1.90, p = .059$ ) and uniqueness ( $t(207) = 5.48, p < .001$ ) in the treatment condition. Also, participants perceived the treatment condition to be more intrusive to privacy ( $t(207) = 7.87, p < .001$ ). Subsequently, a mediation model was estimated. In line with Study 1, personalization has positive indirect effects on purchase intention via anthropomorphism ( $b_{a1 \times b1} = 0.21, CI_{90\%} [0.03, 0.40]$ ) and uniqueness ( $b_{a2 \times b2} = 0.15, CI_{90\%} [0.05, 0.26]$ ). Additionally, a negative indirect effect of personalization on purchase intention via intrusion to privacy ( $b_{a3 \times b3} = -0.19, CI_{90\%} [-0.34, -0.06]$ ) was found. The total effect of personalization on purchase intention was negative ( $b_c = -0.44, 90\% CI_{90\%} [-0.75, -0.12]$ ). These results suggest that for products associated with a high level of intimacy, personalization is perceived to be intrusive to consumers' privacy and thus decreases purchase intention.

These findings indicate that personalization is a double-edged sword. While personalization increases perceptions of anthropomorphism and uniqueness, it can be used in practice to differentiate products by making them appear to be more human and unique. However, this approach seems not to be appropriate for all categories. The findings highlight that for categories associated with a high level of intimacy, personalization can decrease purchase intention as consumers feel violated in their privacy.

# A Conceptual Framework of Violation of Trust and Negative Emotional Responses during Brand Transgressions

Karthik Selvanayagam, Indian Institute of Technology, India

Varisha Rehman, Indian Institute of Technology, India

## EXTENDED ABSTRACT

### Summary:

Though parallels to interpersonal relationships are drawn to explain various facets of consumer-brand relationships, seldom focus has been shown on explaining the nature of trust and its role in emotional responses, particularly its violations and negative emotions. By drawing from exchange and penetrations principles of social psychology theories, we build a conceptual model describing the development and decline of trust, and its possible outcomes in the consumer-brand dyad. We outline the growth of this relationship through Knapp's (1978) ten stage model and the evolution of trust over these stages by employing Lewicki's (1995) development and decline model of trust in relationships. We further posit the emergence of negative emotional responses from the consumers at times of breach of this trust.

### Conceptualization:

#### *Development of Trust*

Extant consumer behaviour literature predominantly examines the phenomenon of trust as purchase situation characteristics between exchange partners (Dwyer, Schurr, and Oh 1987; Das and Teng 1998; Sirdeshmukh, Singh, and Sabol 2002), or alongside consumer commitment to organizations as a result of marketing practices (see: Morgan and Hunt 1994; Shankar and Ron 1997). However, there is a need for a perspective of understanding the nature of trust in a consumer-brand relationship through stages of its development, to better establish its similarities and distinctions from interpersonal relationships. To this end, we correlate Lewicki's (1995) model of development of trust with Knapp's (1978) stages of formation and disintegration of relationships.

Knapp's (1978) ten stage relationship model describes the coming-together and coming-apart stages of an interpersonal relationship. It is through this model we describe the developmental stages of a consumer brand relationship, progressing from initiating and experimenting, to integrating and intensifying, and finally reaching the bonding stage, where the relationship partners are able to form a shared identity. As the relationship continues to develop, the nature of trust evolves alongside (Lewicki 1995). Lewicki's (1995) model describes the evolution of trust in relationships over three stages. The first stage of building of trust is the Calculus-Based Trust, where the validity of trust is confirmed through consistent meetings of expectations of both involved parties. The expectations in this phase are limited to calculated value in exchanges between the partners (Das and Teng 1998). The second stage of evolution of trust is the Knowledge-Based Trust, where trust develops by gaining more knowledge of the partners' needs, preferences, and priorities (Bhattacharya, Devinney, and Pillutla 1998). By reassuring the promised value propositions and creating a consistent brand personality in the consumers' minds over the period of the relationship, the consumer internalizes knowledge about the brand creating a stronger trust in it (Keller 2008). Consistency in this stage leads the consumer into developing a much stronger relationship with the brand, where the consumer beings to substitute a portion of the self-concept using the brand, creating a shared identity. The Identification-Based trust that

drives the consumer into adopting the brands identity comes from extending the knowledge about the brand into a more personal identification (Tanis and Postmes 2005). At this resonance stage bonding, there exists a trust equilibrium that maintains the relationship at its strongest level of development. An instability in this state of trust results from the perception of the behaviour of one party by the other as violating the mutual trust. This instability causes the perceiver to assess the situation at a cognitive and emotional level, leading to the relationship's decline or eventual disruption. Brand transgressions create instability in this state of trust in the relationship.

#### *Transgression and Decline of Trust – Dissatisfaction versus Violation of Trust*

Conflicts and misunderstandings arise out of situations where the behaviour of a partner does not fall into the boundary of the expected behaviour, leading to a sense of distress (Lewicki & Bunker, 1995). Dissatisfaction resulting from unmet performance expectations as against a sense of loss arising from violation of trust would lead to distinct outcomes on the relationship (Reimann et al. 2018) two studies shed new light into the experience of brand betrayal. A large-scale psychometric study shows that brand betrayal (vs. dissatisfaction). Though dissatisfaction causes negative emotional responses from the consumer, however, it would not be as strong or deeply rooted as responses resulting from a sense of moral violation (Romani et al., 2012; Reimann et al., 2018)discontent, dislike, embarrassment, sadness, and worry. While reactions to moral violations could lead to immediate termination of a relationship, dissatisfaction would more likely follow a path of separation much in similarity with an interpersonal relationship that would fall out of equilibrium, taking the five *coming-apart* stages of Knapp's (1978) ten stage relationship model (Anderson, Avtgis, and West 1998). Knapp's (1978) model lists five stages of *coming-apart* as a result of misunderstandings and conflicts in a relationship. It is also seen that stronger derived emotions emerge in the emotional-activity stage of the dynamics of trust violation in case of violation of trust, while the assignment of importance to the transgressing event happens in the cognitive-activity stage (Lewicki 1995). The role of transgressor response as a moderator is also pertinent, wherein the nature of the response from the brand could drive the outcome towards rupture, recalibration or restoration of the relationship.

### Major findings and Conclusions:

Drawing upon principles of social exchange and penetrations from social psychology theories, this work contributes in differentiating the distinct outcomes of a performance related transgression as against a perceived violation of trust by the brand, resulting in negative emotional responses from the consumer, and their subsequent impact on the consumer-brand relationship. Further conceptual and empirical contributions on the nature of this trust and its role in the context of different consumer-brand relationship types and stages, across cultures and product categories, will strengthen the field of humanizing brands that is increasingly gaining attention from marketing scholars. Furthermore, the role of trust as antecedent of consumer negative emotions towards brands, and its implications on consumption as well as consumer well-being also can be explored

to build on the similarities, and distinctions, between interpersonal and consumer-brand relationships.

Understanding the role of trust, and the negative emotional responses associated with a violation of trust in a consumer brand relationship would provide a predictive strength to practitioners aiming at creating strong bonds with consumers in a crowded marketplace.

# Round it up: Preference Exists for Rounded Totals (PERT)

Varun Sharma, Bocconi University, Italy  
Aradhna Krishna, University of Michigan, USA  
Zachary Estes, Bocconi University, Italy

## EXTENDED ABSTRACT

In recent years, charitable giving has stagnated. In the US, on average individuals only donate about 2% of their annual disposable income, a level of contribution that has remained fairly constant across the past four decades (Giving USA 2017). Such charitable contributions are positive and admirable, of course, but there remains a considerable and untapped upside of potential contributions in donors' mental budgets. We therefore present a simple method for nudging more people to donate more money to charities.

Our main hypothesis builds from prior research showing that rounded numbers (e.g., \$3.00) subjectively "feel right" (Wadhwa and Zhang 2015), and that people prefer offers with rounded prices (Yan and Pena-Marín 2017). We investigate charitable donations that, when added to the price of a product, sum to a *rounded total* i.e. for example, when purchasing a product for \$7.60, might people be more willing to donate an additional \$1.40 than \$1.20?

To the best of our knowledge, no research has investigated whether the *roundness of the total amount* affects donations, and if so, by what psychological process it operates. Moreover, although consumer researchers have revealed many important factors affecting charitable donations (e.g. Charness and Holder 2018; Koschate-Fischer, Stefan and Hoyer 2012; Krishna 2011; Goswami and Urminsky 2016; Hagtvéd and Patrick 2016), no prior research has examined donation behavior in the context of add on to a purchase. Here we focus on the roundness of a total amount, hypothesizing that a preference exists for rounded totals (henceforth *PERT effect*).

While rounded numbers could have positive effects, on the other hand, however, rounded numbers are also perceived to be bigger than nonrounded numbers (Thomas, Simon and Kadiyali 2010). This could lead consumers to feel that a rounded total is psychologically more costly than a comparable but nonrounded number. Thus, the presumed PERT effect is not a foregone conclusion; theoretically, the opposite effect could occur.

### Study 1

( $N=99$ ) tested whether a rounded total amount (product price + charity donation) is preferred over a nonrounded total, even though the rounded total was a higher overall cost.

Participants were asked to imagine that they visited an arts and crafts fair and purchased products costing \$27.30 (including taxes). They were asked whether they would like to donate to a charity associated with the fair from options: \$28.70 (donation of \$1.40), \$30.00 (donation of \$2.70), or no donation.

Despite the rounded total being a higher overall cost, about half of the participants ( $n=49$ ; 50%) chose to donate with this rounded total (\$30.00) while only 26% chose the other donation option (\$28.70). This preference for the higher, rounded total was significant,  $\chi^2(1)=7.05$ ,  $p<.01$ . These results provide a first demonstration of the PERT effect.

### Study 2

( $N=303$ ) replicated PERT effect, but instead examined the *likelihood* of donating. We show that more people prefer to donate if the donation option has a rounded total rather than a nonrounded total.

### Study 3

( $N=397$ ) tests if PERT effect also occurs when participants must mentally sum the purchase and donation amounts? We again used the art and craft scenario from the prior studies, using a 2 (total amount: present, absent)  $\times$  2 (rounded number: present, absent) between-participants design with only two options of donation or no donation in all conditions.

Moreover, in all conditions the only the 'donation' option varied across conditions and was presented either as a total (i.e., total cost) or as its component costs (i.e., purchase + donation). Thus, the 'donation' option was \$30.00 in the *rounded-present condition*, and \$29.84 in the *nonrounded-present condition*, while in these total-absent conditions, it was \$27.60 + \$2.40 in the *rounded-absent condition*, and \$27.60 + \$2.24 in the *nonrounded-absent condition*.

In the total present conditions, there was a significant preference for donating in the rounded-present condition ( $n=70$ , 71%),  $\chi^2(1)=16.98$ ,  $p<.001$  but not in nonrounded-present condition ( $p=.55$ ). More importantly, in the total-absent conditions there was a preference (marginally) for donating in the rounded-absent condition ( $n=59$ , 60%),  $\chi^2(1)=3.65$ ,  $p=.056$  but not in nonrounded-absent condition ( $p=.19$ ). The difference in donation choices was significant among the two total-present conditions ( $\chi^2(1)=11.54$ ,  $p<.001$ ) as well as for total-absent conditions ( $\chi^2(1)=5.18$ ,  $p<.05$ ). There was no statistical evidence of moderation ( $p=.33$ ). We show in this study that PERT effect is strongly associated with rounded totals.

### Study 4

( $N=197$ ) tested whether processing fluency mediates the PERT effect. With the same scenario, participants were assigned to one of two conditions (total amount: rounded, nonrounded) between-participants. The 'donation' option was \$30.00 (\$2.36 donation) and \$29.82 (\$2.18 donation) in the rounded and nonrounded conditions respectively. Participants also rated the total amount of the 'donation' option (i.e., \$30.00 in the rounded condition, \$29.82 in the nonrounded condition) in terms of simplicity (2 items) and ease of processing (2 items).

We again found support for PERT effect. There was a significant preference to donate in the rounded condition ( $n=66$ , 67%;  $\chi^2(1)=11.00$ ,  $p=.001$ ), but not in the nonrounded condition ( $n=52$ , 53%;  $p=.54$ ), and this preference for donating differed marginally between the rounded and nonrounded conditions,  $\chi^2(1)=3.80$ ,  $p=.051$ . Bootstrap mediation analysis (Hayes 2015, model 4, 10K samples) revealed a significant indirect effect,  $B=.32$ ,  $SE=.12$ , 95%  $CI [.12, .62]$  with fluency ( $\alpha=.92$ ). The rounded total increased fluency ( $B=.65$ ,  $p<.001$ ), which in turn increased the likelihood of donating ( $B=.49$ ,  $p=.001$ ). Thus, these results suggest that rounded totals increase donations because they are more fluently processed than nonrounded totals.

In the current research, we show that people prefer rounded total amounts over non-rounded ones. This makes them choose a charity donation option in addition to a purchase which makes the total amount rounded. In addition, we show that if the option to donate is presented as a total amount which is rounded, more people choose to donate. We also show that this effect exists as people find the rounded total amount to be simpler and easier to process. Our research has important implications for consumer research related to charity, as we show an easy way to make more people to donate and to increase donation amount if a higher donation option is rounded.

# Neural Pattern Similarity Reveals Brand Equity

Feng Sheng, University of Pennsylvania, USA

Michael Platt, University of Pennsylvania, USA

## EXTENDED ABSTRACT

Memory about a brand is associated with memory about the category of the brand's product (Hutchinson, 1983). Consequently, when thinking about products in that category, that brand is likely to be recalled by the activation of the associative network and to be considered for choice (Nedungadi, 1990). Therefore, the strength of mental association between a brand and its product category determines the top-of-mind accessibility of the brand in the product category and constitutes a fundamental aspect of consumer-based brand equity (Keller, 1993). Despite its importance, the structure of mental association between a brand and a product category is largely invisible in traditional behavioral measurements.

We posit that mental representation for a brand and for its product category can both be directly visualized as neural representations, and that mental association between the brand and the product category can be operationally defined as the similarity of the neural representations between the brand and the product category. Furthermore, we hypothesize that neural representational similarity between brand and product category will be predictive of mental accessibility of brand assessed by behavioral measurement such as brand recall. To demonstrate our neural definition of brand-category association and to test our hypothesis about the relationship between neural similarity and mental accessibility, in an fMRI study, we recorded consumers' brain activity in response to car brands and the concept of car in an MRI scanner as well as recorded the process of brand recall when they were cued by the product category "car" outside the scanner.

In the experiment, participants first completed a brand recall task without brain imaging. The brand recall task was designed to be done first because we intended to protect participants' memory of brands from being contaminated by any experimental exposure to brands. In the recall task, participants first saw a word indicating the product category (i.e., "car") on the screen of a laptop, and then recalled and typed down brand names of the product category in 10 minutes. The time at which they typed down the first letter of a brand was taken as the recall time for the brand.

Thereafter, in the MRI scanner, we recorded blood-oxygen-level dependent (BOLD) signals in participants' brains when they were presented with each of 14 car brands, including Ford, Toyota, Chevrolet, Honda, Nissan, Hyundai, Subaru, Volkswagen, Mercedes-Benz, Mazda, BMW, Chrysler, Volvo and Fiat. In addition to car brand names, we also recorded their brain activity to the word of the target product category, "car", as well as their brain activity to the word of a control product category, "computer". Each of the 14 car brand names and the 2 product category words was presented 24 times in two runs in a pseudorandom order. The presentation of each word lasted 2 s, followed by a fixation of varying durations (mean=2 s, ranging from 1 s to 10 s). Participants were instructed to think about the meaning of each word when they saw it. To monitor participants' attention, twenty four nonsense words were randomly inserted and participants were instructed to press a key when they saw a nonsense word.

fMRI data analysis primarily included three steps. In the first step, we obtained a whole-brain pattern of activation to each word and to each product category by estimating a general linear model on BOLD signals. In the second step, we performed a searchlight representational similarity analysis across the brain to compute the similarity of regional neural pattern between each brand and each product category. In the third step, we conducted a voxel-wise survival analy-

sis across the brain to find brain regions where the neural pattern similarity between a car brand and car was predictive of brand recall.

Neural representational similarity analysis revealed a whole brain map for each car brand that illustrated their neural similarity with the product category car. These whole-brain maps showed the variance of neural similarity across different brain regions and the gradient of neural similarity across different car brands. Survival analysis revealed that brand recall was predicted by neural similarity between car brand and car across a distributed brain network including ventral medial prefrontal cortex (VMPFC), posterior cingulate cortex (PCC), and lateral temporal cortex (LTC). Neural similarity at these brain regions were still predictive after neural similarity between car brand and computer were included as a control variable, suggesting that car brand recall was selectively predicted by neural similarity between car brand and the product category car rather than other product categories.

By performing pattern analysis with neural data acquired by fMRI, we illustrated the way to operationally define the structure of mental association between brand and product category by calculating neural similarity between brand and product category. Furthermore, we showed a neural network where the neural similarity between brand and product category was predictive of the accessibility of brands to consumers. The brain regions found to be predictive of brand recall in our study, including VMPFC, PCC and LTC, are largely overlapped with the neural network underpinning semantic knowledge (see Binder, et al., 2009 for a quantitative meta-analysis). This implies that the degree to which the knowledge about a brand is incorporated with the concept of a product category is critical for the mental accessibility of the brand in that product category.

Echoing with recent effort to imaging brain equity with neural pattern analysis (Chen, Nelson & Hsu, 2015), our measurement of neural similarity between brand and product category has potential to act as a new indicator for brand equity in the future. Importantly, estimating consumer-based brand equity with neural activity will be beneficial for grounding the concept of brand equity. In a more broad sense, redefining key concepts in marketing such as brand equity with neural evidence will guide marketing science to advance in a more quantitative and scientific direction.

# Seeing Brands Through Rose-Colored Lenses: When Fear of Being Taken Advantage Of Leads to Increased Trust

Steven Shepherd, Oklahoma State University, USA

Gavan J. Fitzsimons, Duke University, USA

## EXTENDED ABSTRACT

People often face issues and domains that they do not understand. As such, people are often dependent on experts to manage complex issues (Deci and Ryan 1985; Iyengar and Lepper 2000). In the context of products and services, a lack of knowledge and having to rely on others brings with it risk and the potential to be taken advantage of (Balafoutas, Beck, Kerschbamer, and Sutter 2013; Darby and Karni 1973; Ford, Smith, and Swasy 1990; Mitra, Reiss, and Capella 1999; Ostrom and Iacobucci 1995).

Uncertainty such as this is uncomfortable and people are motivated to avoid it (Hogg 2007; Kruglanski and Webster 1996). Although increased skepticism and minimizing interdependence is an intuitive strategy for managing this uncertainty, many domains exist that consumers cannot easily opt out of. Therefore, counterintuitively, some consumers may instead respond by putting on rose-colored lenses and bolster trust in those they are reliant on. The idea that interdependence-related concerns are regulated by bolstering the value of one's partner is found in a variety of literatures (de Jong, Van der Vegt, and Molleman, 2007; Murray et al. 2008; Murray and Holmes 2009; Shepherd and Kay, 2012; van der Toorn et al. 2011).

Who is most likely to engage in this process? Those high in victim sensitivity (VS) have a basic need to trust, but are also particularly sensitive to being victimized (Gollwitzer and Rothmund 2011). However, our reliance on products to manage complex domains is a relationship that is not always easy to opt out of. Because those high in VS are concerned about being taken advantage of, facing a complex domain that one does not understand (and can therefore be taken advantage of) may increase anxiety and actually lead them to bolster trust. In other words, bolstering trust in a brand's intentions and competency may be a defensive strategy that helps alleviate concerns about being taken advantage of.

*Hypothesis 1* When a domain is complex, those high (vs. low) in VS will see greater opportunity to be taken advantage of.

*Hypothesis 2* When a domain is complex, those high (vs. low) in VS will bolster trust in a product/product manufacturer that manages the domain at hand.

If this increase in trust is defensive in nature, such that it serves to manage anxiety and concerns about being taken advantage of, then it follows that:

*Hypothesis 3* When the opportunity to be taken advantage of is less present, the effect posited in H2 will be eliminated.

*Hypothesis 4* When domain complexity is high (vs. low) and the opportunity to be taken advantage of is present, VS will predict anxiety regarding one's knowledge of a domain, which will in turn predict increased trust.

Study 1 (N=150) had participants complete the VS scale and then presented them with either a simple or complex description of how the sun's rays affect one's skin. Participants then rated their perceptions of how easy it would be for a sunscreen manufacturer to take advantage of consumers (e.g., the product that does not actually work). Results showed that when the domain was complex (vs. simple), those high in VS saw it as more possible for a company to take advantage of consumers.

Given that domain complexity leads high VS consumers to see increased opportunity to be taken advantage of, and given their concerns about being victimized, one would expect that high VS consumers would respond with decreased trust. However, based on past work on defensive trust, we posited that high VS consumers will address this concern by bolstering trust. Study 2 (N=201) supported this; high VS consumers showed increased trust in a brand of sunscreen when the domain (how the sun's rays affect one's skin) was complex as opposed to simple. Study 3 (N=299) replicated this effect by first describing harmful bacteria in either simple or complex terms, and then measuring trust in a brand of kitchen cleaner.

Finally, if high VS consumers manage concerns about exploitation (i.e., when domain complexity is high) by bolstering trust, then we should observe that reducing the opportunity to be taken advantage of will eliminate the positive effect of VS on trust. We also predicted that high VS consumers would show increased anxiety when thinking about their knowledge of the domain at hand, but that this anxiety only translates into increased trust when complexity is high and concerns about being taken advantage of are present.

Study 4 (N=536) supported these hypotheses. When the opportunity to be taken advantage of was present, we replicated the effects observed in Studies 2 and 3; high VS consumers showed higher levels of trust in their brand of sunglasses when the sun's effect of one's eyes was described in complex (vs. simple) terms. However, this effect disappeared when participants were told that industry standards and regulations ensure that most sunglasses protect against UV rays (i.e., when the opportunity to be taken advantage of was reduced). Additionally, when the domain was complex and the opportunity to be taken advantage of was present, we found an indirect effect from VS, to anxiety, to trust, such that those higher in VS felt more anxious about their lack of knowledge regarding how the sun affects one's skin, and this anxiety predicted increased trust. This indirect effect was not present in any of the other three conditions. These effects further support the prediction that because those high in VS are especially concerned about being taken advantage of, they ironically bolster trust under conditions that one might expect to decrease trust; that is, when a domain is complex and poorly understood by the consumer, and when the opportunity to be taken advantage of is present.

Although existing consumer behavior research would not easily predict these effects, the current findings make sense in the context of a broader literature on domain complexity, interdependence, and defensive trust. This addresses a gap in the marketing literature regarding our understanding of consumer trust. Moreover, we introduce VS as a relevant construct to the marketing literature.

# The Effect of Future Focus on Self-Control is Moderated by Self-Efficacy

Rafay A. Siddiqui, Hong Kong Polytechnic University, China

Jane Park, University of California-Riverside, USA

Frank May, Virginia Tech, USA

## EXTENDED ABSTRACT

For consumers, sometimes the future may be very salient, while other times it may not be (Shipp, Edwards and Lambert 2009). Future focus is critical to self-control, as one cannot self-regulate without at least some consideration of future goals or consequences (Baumeister and Heatherton 1996). Indeed, companies that support self-control pursuits highlight this notion. For example, a Fidelity Investments advertisement featured the tagline “The Future is the Present,” while Weight Watchers highlights “My Bright Future” on its website. Not surprisingly, research has found that focusing on the future can be beneficial. For instance, future focus can lead to the choice of virtue foods (Winterich and Haws 2011), a greater likelihood of investing in retirement (Nenkov, Inman and Hulland 2008) and increased patience (Bartels and Urminsky 2011).

However, other research hints at special circumstances under which focusing on the future may actually lead to indulgence. For instance, when consumers are asked to consider future progress towards goals, it may lead to indulgence in the present (Fishbach and Dhar 2005; Laran 2010; Zhang, Fishbach and Dhar 2007). Similarly, simply anticipating a future opportunity to choose a healthy option can lead to indulgence (Khan and Dhar 2007). This research suggests that future focused individuals may lose self-control in the present if they foresee themselves balancing out the negative effects of current indulgence.

Thus, it is not entirely clear as to when future focus will lead to greater self-control, or what types of people will benefit from future focus. In addressing these issues, we posit that consumers' self-efficacy (Bandura 1994; Wood and Bandura 1989) will moderate the effect of future focus on self-control. Focusing on the future will lead to higher self-control when one foresees the negative outcomes of current indulgence, but will lead to lower self-control when one foresees successful counteractions in response to negative outcomes of current indulgence. We posit that self-efficacy can determine the extent to which people will focus on negative outcomes versus successful counteractions when thinking of the future.

Self-efficacy is defined as the belief in one's capabilities to undertake actions to meet situational demands and combat goal obstacles (Wood and Bandura 1989). A higher self-efficacy means a greater belief in one's capability to successfully cope with goal setbacks through action. However, individuals low in self-efficacy tend to visualize scenarios of goal failure (Bandura 1994). When one has an opportunity to engage in a goal inconsistent action, a focus on the future should bring to mind the consequences of indulgence. We expect that a future focused individual with low (high) self-efficacy would visualize goal failure and its consequences (successful counteractions to indulgence). Hence, we predict that when one is low (high) in self-efficacy, focusing on the future will increase (decrease) self-control.

## Studies

In study 1, we manipulated participants to either write a statement about focusing on the future or office products. Next, they imagined a scenario in which they had to choose between chocolate cake and fruit, and completed a self-efficacy scale (Chen, Gully and Eden 2001). Those low in self-efficacy chose the healthier option

more when focusing on the future, but the reverse emerged for those high in self-efficacy.

Study 2 replicated the effects we found in study 1 using the same future focus manipulation in the domain of spending. After the future focus manipulation, participants imagined that they were trying to save money but had come across a pair of shoes that they really liked. After indicating whether they would purchase the shoes, they completed a financial self-efficacy scale. Those low in self-efficacy were less likely to purchase the shoes when focusing on the future, but the reverse emerged for those high in self-efficacy.

Study 3 shows that our effects hold for real choice when both factors are manipulated. Participants completed a self-efficacy manipulation in which the scale to which they responded created the illusion of low or high success in goal achievement. Then, participants were asked to write about what comes to mind when they think about either the future or the present, and made a choice to receive either a Dairy Queen or Subway gift-card in a lottery. In the low self-efficacy condition, participants chose the unhealthy option, Dairy Queen, less when focusing on the future (vs. the present), but the reverse emerged for those in the high self-efficacy condition.

In study 4, we demonstrate process via mediation. Future focus was manipulated, then participants imagined that they were trying to save money, but had come across a pair of headphones that they could purchase. Next, we measured the degree to which participants perceived that the purchase would negatively impact their savings goals. Finally, participants completed a self-efficacy scale. The self-control results mirrored those of past studies, and these effects were mediated by the extent to which participants felt the purchase would negatively impact their savings goals.

In study 5, we demonstrate process via moderation. That is, we predict that our effects will diminish for those who believe that the future does not bring about change (i.e., entity theorists). In the low (high) self-efficacy condition, participants were asked to solve nine puzzles, and thereafter were told that they performed better than 30% (90%) of all other participants. Then, participants in the entity (incremental) condition were asked to write a statement in agreement with a passage that stated people's personalities could not be changed (could be changed) even late in their lives. Participants then imagined a scenario where they were determined to perform well in a course, and had an exam coming up, and chose between studying versus going to a party. Participants subsequently completed a future focus scale (Shipp et al. 2006). Our effects persisted in the incremental condition, but were attenuated in the entity condition.

## Conclusion

Our findings have significant implications. Theoretically, we delineate when and for whom a future focus may be detrimental to self-control. This has implications for consumer welfare, as asking consumers to focus on the future might not always be beneficial.

# The Asymmetry between Time and Money Compensation effect when feeling Scarcity: Time helps the Money Poor, but Money doesn't help the Time Poor

Jane So, University of Washington, USA  
Nidhi Agrawal, University of Washington, USA

## EXTENDED ABSTRACT

We examine two important aspects of scarcity. First, we identify a new scarcity effect on consumers' advice-taking tendency. Second, we show whether the abundance of one resource alters the scarcity effect of another resource in the domain of advice-taking and whether such interplays vary depending on the resource type (e.g. time abundance compensating for money scarcity vs. money abundance compensating for time scarcity).

Researchers found that feelings of resource scarcity systematically affect how consumers think, perceive, feel, and behave through scarcity mindsets (Shah et al. 2012; Shah et al. 2015; Roux et al. 2015). Adding to this line of research, we suggest that when feeling time or money scarcity, which are the two common scarcities that people experience, the scarcity mindset affects consumers' advice-taking tendency. We argue that when people are feeling time or money scarcity, people are less likely to change their pre-existing opinions based on someone else's advice. Resource scarcity signals that the environment is harsh (Laran and Salerno 2013; S. E. Hill et al., 2012; Griskevicius et al. 2013), such that people need to compete with others for the scarce resource (Kristofferson et al. 2017; Roux et al. 2015). Thus when people are feeling scarcity, the self becomes more important and people act in accordance to one's own benefit (Roux et al. 2015). Thus, time or money scarcity can make people focus on the self more, thereby leading to lower advice-taking tendency.

Another important gap in the literature is that research on resource scarcity examines the effect of scarcity in comparison to that of resource abundance (Shah et al. 2012; Shah et al. 2015; Mehta and Zhu 2016; Sharma and Alter 2010; Zhu and Ratner 2015). However, consumers often experience both resource abundance and scarcity at the same time. For example, busy people may feel time scarcity but they may also feel money abundance. Poor people may feel money scarcity but they may also feel time abundance. Thus in this article, we examine how feelings of resource abundance interplay with feelings of resource scarcity.

We suggest that time abundance compensates for money scarcity effect while money abundance does not compensate for time scarcity effect. We suggest that this asymmetric compensation of time (vs. money) abundance when feeling money (vs. time) scarcity is due to the difference in the nature of time (vs. money). First, people perceive money is a substitutable resource whereas time is not (Leclerc et al. 1995). Due to the greater fungibility of money, money scarce people may have a mindset that money can be substituted even with a different resource such as time. However, time is a less fungible resource than money, thus time scarce people may have a mindset that time cannot be substituted with any resources. Second, people may perceive time to greater value than money. Time is more laden with personal meaning than money (Aaker, Rudd and Mogilner 2011; Mogilner and Aaker 2009; Reed et al. 2007; Reed et al. 2015) and thus people may assign greater value to time than money. If this is the case, having such valuable resource, which is time, may compensate for lack of less valuable resource, which is money.

Study 1 first examined whether feeling time or money scarcity leads to lower advice-taking tendency. We used a one-way ANOVA (money scarcity vs time scarcity vs. control). After manipulation, we asked participants to imagine a wine bar that they did not like. Next, we showed a review that was very positive. After reading the review,

we asked participants to indicate their willingness to accept advice from the reviewer. As predicted, we found that compared to the control condition, the time scarcity condition and the money scarcity condition showed lower advice-taking tendency.

In study 2, we investigated the compensation effect. We used  $2(\text{scarcity: time vs. money}) \times 2(\text{abundance of alternate resource: abundance vs. nonabundance}) + \text{control condition}$  between-subjects design. We used the same wine bar scenario from study 1. Results showed that when people felt only time or money scarcity but no feelings of abundance, we replicated our previous effect that scarcity leading to lower advice-taking tendency. However, when money scarce participants also felt time abundance, time abundance compensated for money scarcity and increased participant's advice-taking tendency. Moreover, when time scarce participants also felt money abundance, money abundance did not compensate for time scarcity, showing asymmetric compensation effect.

In study 3, we investigated whether such asymmetric compensation effect is due to how people perceive value of time versus money. We used the  $2(\text{scarcity: time vs. money}) \times 2(\text{abundance of alternate resource: abundance vs. nonabundance})$  between-subjects design. In this study, we asked participants which option between diets and exercising is better for health and then showed an article about an opposing opinion. We then asked how willing they are to take advice from the article writer. After a filler task, we asked measured participants' belief about value of time compared to money. The results showed a significant three-way interaction. For those who believe time is more valuable than money, participants who felt only money scarcity showed marginally lower advice-taking tendency than those who felt only time scarcity. However, among those who believe time is more valuable than money, people who felt money scarcity and time abundance showed greater advice-taking tendency than those who felt time scarcity and money abundance. As expected, this effect was not significant for those who believe money is more valuable than time.

Finally in study 4, we examined the underlying process of asymmetric compensation effect by manipulating whether time and money are substitutable. In this study, we primed people the concept of time and money substitutability or imperfect substitutability. We used the same wine bar scenario from the previous studies. As expected, when primed with money can be substituted with time, the results replicated our previous findings that time abundance compensated for money scarcity. However, when the imperfect substitutability is primed, the time abundance no longer compensated for money scarcity.

# The Subjective Experience of Goal Failure: How Choosing the Lesser Evil Eradicates the Negative Consequences of Goal Failure

Kamila Sobol, Concordia University, Canada

## EXTENDED ABSTRACT

Imagine that you're attending a morning meeting and are offered an assortment of pastries: muffins, donuts, and brownies. While deciding whether to indulge in one of these tempting options you remember your fitness goal, and therefore opt for the muffin since you perceive it as the healthiest of the three options – i.e. lesser evil. How will this choice affect your subsequent food-related decisions throughout the day? Will your initial indulgence encourage or discourage subsequent healthy eating?

The goal literature suggests that once we violate an activated goal, the resulting feelings of guilt and despair generally impel further transgressions (McGonigal 2011; Soman and Cheema 2004). Based on these findings, we would predict that the individual depicted in the introductory scenario who violated her fitness goal by eating a muffin is likely to temporarily disengage from the focal fitness goal, and continue to indulge throughout the day.

In the present paper, I suggest that violating a goal does not always demotivate behavior. Focusing on the decision context that offers exclusively vice alternatives (i.e. options that violate a goal), I suggest that the subjective experience of goal failure is dampened when choosing the lesser evil option – i.e. option that is least detrimental to the focal goal, by attenuating perceptions of goal digression. In this sense, even though a goal violation transpired, selecting the lesser evil can actually motivate subsequent goal-congruent choices, similarly as if no transgression was committed.

The present project contributes to the literature in at least three ways. First, while past research generally primed goal failure (i.e. goal failure versus no failure conditions), in the present paper, I manipulate the subjective perception of goal failure, and show that goal failure leads to further goal violation only when subjectively experienced. Second, I introduce an alternative mechanism that explains reform after goal violation (Taylor and Wilson 2015), namely perceptions of goal digression. Third, most goal research examines consumer motivation within a single decision task and focuses on the conflicting choice between a “vice” and “virtue” (Wang and Huang 2018). In the present study, I show how choosing the *lesser evil* within a two vice context motivates subsequent sequential consumer decisions.

Findings from four studies show that choosing the lesser evil attenuates perceptions of goal digression and as such prevents goal disengagement that generally occurs after a goal transgression. This effect is only prevalent when the lesser evil is considered alongside a greater vice, versus in isolation.

## STUDIES

### Study 1

The objective of Study 1 was to verify whether choosing the lesser evil improves motivation compared to choosing an alternative that is more damaging to the end goal. After a fitness goal prime, participants read a scenario in which they either selected the healthiest pastry (lesser evil), the unhealthiest pastry or did not buy a pastry for breakfast (control). In the scenario, they proceeded to go about their day, have lunch and now had a choice of dessert. The selected dessert's calorie count served as the dependent variable. Findings revealed that participants who initially chose the healthiest pastry, sim-

ilarly as those who forwent a pastry, subsequently selected a more healthy dessert than those who initially selected the unhealthy snack.

### Study 2

The main objective of Study 2 was to provide mediational evidence for the proposed model. After the goal prime, participants read a scenario in which they were asked to choose a snack at the movie theater: popcorn (lesser evil), M&Ms, or no snack. After their snack selection, participants were asked to report their perceptions of goal (fitness) digression. Finally, participants were asked to select a beverage to go with their snack: water or soda (using sliding scale: -50 to 50). A mediational analysis indicated a significant partial mediation supporting our premise that choosing the lesser evil attenuates perceptions of goal digression, preventing goal disengagement, as manifested by a higher likelihood of choosing water over soda.

### Study 3

In study 2, it is plausible that participants perceived popcorn as an authentically healthy snack, and therefore the results are a simple replication of past research demonstrating that choosing the virtuous (versus vice) option improves self-regulation (Knight and Boland 1989). In study 3, I show that choosing popcorn evokes the typical demotivating effects of goal violation when it stands alone. This demotivating effect disappears when the popcorn is presented alongside a greater evil. A 2 (choice: lesser evil; greater evil) x 2 (number of vices presented: one; two) between subject design was used. In the first two conditions, participants were exposed to, and selected one snack option: popcorn or M&Ms. In the remaining conditions, participants were told that they have a choice between the two snacks and either selected popcorn (condition 3) or M&Ms (condition 4). Participants were subsequently asked to make a beverage selection: water or soda. Findings confirmed that when only popcorn was offered, subsequent self-regulation was impaired, but when both popcorn and M&Ms were offered, selecting popcorn did not induce goal disengagement, but rather continued to motivate healthy choices.

### Study 4

The objective of study 4 was to replicate the main effect with real consumption. Participants read a scenario in which they either selected popcorn or M&Ms at the movie theater. In a seemingly unrelated task, participants were asked to evaluate the packaging for a fictitious chip brand. While completing the questionnaire, participants were given a bowl of chips and instructed to eat as many chips as they wanted. The consumption dependent variable was assessed by subtracting the weight of the bowl before and after the study was completed, representing the amount of chips the participants ate. Findings showed a significant difference of consumption between the two conditions, supporting that choosing the lesser evil enhances the likelihood to resist temptation, demonstrating goal perseverance, instead of goal disengagement.

The present research shows that consumers can reform after a minor goal violation since choosing the lesser evil prevents consumers from recognizing a goal digression, and therefore evades the negative motivational effects of typical goal failure.

# Is All That Glitters Gold?

## The Effect of Product Surface Glossiness on Consumer Judgments

Jiaqi Song, Hong Kong Polytechnic University, China  
Yuwei Jiang, Hong Kong Polytechnic University, China  
Gerald J. Gorn, Hong Kong Polytechnic University, China

### EXTENDED ABSTRACT

Glossiness describes how much the surface of an object reflects light in a specular (i.e. mirror-like) way (Nicodemus et al. 1977). Notwithstanding the importance of glossiness in product design, compared with other visual marketing elements such as shape, color, symmetry and boundary, there is little research on glossiness in the marketing realm, except the work by Meert, Pandelaere, and Patrick (2014), in which they explored the impact of glossiness originating from its biological association with water resources. In an attempt to fill this void, this research proposes that consumers have a general preference for products with a glossy, compared to a matted appearance, an effect which is mediated by psychological newness, and moderated by priming of the inconsistent association, feelings of nostalgia, and durability concerns.

Glossiness can be mentally associated with newness due to embodied cognition. Embodied cognition arises when a conceptual metaphor is built up due to the repeated association between a concrete sensory feeling (e.g., visual glossiness in this research) and a more abstract cognition (e.g., psychological newness; e.g., Lakoff and Johnson 1999). In particular, we argue that human beings may have learned that glossy things are usually newer. For example, automobiles, jewelry, and tableware can be very glossy when they are newly manufactured, but will become dull after usage and abrasion. Consequently, the mental association between glossiness and newness is established (associative network model; e.g., Wickelgren 1981). Meanwhile, as a pervasive logical fallacy in philosophy, *argumentum ad novitatem* (appeal to novelty; Bennett 2012) argues that individuals may pursue new things because of a belief that newness implies improvements, even if it is unnecessarily always the case (Jie and Li 2017). Hence, we suggest that the perceived newness induced by glossiness should result in more favorable product evaluations.

In five experiments, we found support for this proposition and evidence for three moderating factors. In Study 1, university students ( $N = 176$ ) were randomly given either a glossy version or a matted version of the same computer mouse, and were instructed to bid for it, where the winner could purchase the mouse at his/her indicated price. Following the bid task, chronic newness-seeking tendency was measured. The results revealed that the participants bid higher prices for the glossy, rather than the matted mouse, and this effect was more salient among those who has a higher chronic newness-seeking inclination.

Study 2 tested the mediating role played by psychological newness. One hundred mTurk participants were randomly given the image of a glossy or a matted set of mugs, and reported their evaluations and perceived newness of the mugs. Consistent with predictions, glossiness (vs. matte) induced increased perceptions of newness and subsequently resulted in more favorable product judgments.

In spite of the prevailing glossiness-newness mental association, priming of the inconsistent association (i.e. matte-newness) should at least temporarily weaken the positive link between product glossiness and evaluations. To verify this, in Study 3, mTurk workers ( $N = 309$ ) were randomly assigned to one of the 2 (glossy vs. matted)  $\times$  2 (consistent vs. inconsistent association) between-subjects conditions. Participants first performed a memory task with eight pairs of products (one labeled as the *old* version and the other labeled as the

*new* version). The new version of product in each pair either always looks glossier (the consistent-association condition) or looks more matted (the inconsistent-association condition) than the old version. Participants then completed a product evaluation task in which a glossy or a matted power bank (i.e. portable battery for mobile devices) was evaluated. As expected, preferences for the glossy over the matted power bank were significant and mediated by perceived newness only when the primed association was consistent with the default.

Study 4 investigated another moderator, i.e. feelings of nostalgia. Nostalgia refers to a situation in which people reminisce about a positive life episode in the past (e.g., Sedikides, Wildschut, and Baden 2004). Consumers are likely to prefer older products to new ones when nostalgic feelings are induced. Thus, we predict that the effect of glossiness on product attitude will be weakened among nostalgic consumers. Employing a 2 (glossy vs. matted)  $\times$  3 (nostalgia vs. control vs. baseline) between-subjects design, 397 undergraduate students listened to and rated three pretested old songs (the nostalgia condition), recent songs (the control condition), or skipped this task (the baseline condition). Afterwards, participants evaluate a glossy or matted chair. Consistent with our expectation, participants in the control and baseline conditions judged the glossy chair more favorably, whereas the matted chair was rated more favorably in the nostalgia condition.

The last study adopted a 2 (glossy vs. matted)  $\times$  2 (durability concern vs. baseline) between-subjects design on mTurk ( $N = 281$ ) to explore the moderating effect of durability concerns. Durability is one of the major quality dimensions (Garvin 1987). Glossy products could be seen as less durable than their matted counterparts, as glossiness induces the cross-modal perception of lighter weight and thinness (Cloonan and Decré 2015), which we reasoned as conceptually related to brittleness. In this study, participants in the durability concern condition first imagined that their previous mug was broken after just one week, whereas participants in the baseline condition were not given this information. Then all participants were given a set of glossy or matted mugs to evaluate. The results confirmed that participants' attitudes were more favorable toward the glossy (vs. matte) mugs in the baseline condition, but this effect was dismissed when durability concerns were elicited.

Taken together, the five experiments in the current research supported that consumers generally judge glossy products more favorably than matted ones, an effect promoted by a perception of newness and moderated by priming of the inconsistent association, nostalgic feelings, and durability concerns. The research contributes new knowledge to visual marketing, and to an attribute that thus far has hardly attracted any research, i.e. visual glossiness. It provides insight into not only why consumers generally prefer glossy products, but also the circumstances under which they are likely not to have this preference. In doing so, it provides managerial guidance for designing products.

# Decisional Conflict Predicts Myopia

Paul Edgar Stillman, Ohio State University, USA

Melissa Ferguson, Cornell University, USA

## EXTENDED ABSTRACT

Despite the integral role conflict plays in the subjective experience of self-control decisions, most work investigating conflict does not measure it directly. In the present paper, we use mouse-tracking (Freeman & Ambady, 2009, 2010; Wojnowicz, Ferguson, Dale, & Spivey, 2009) – an emerging technique in which researchers measure participants' computer-mouse movements while making a decision – to demonstrate the utility of a real-time measure of decisional conflict for studying self-control. Specifically, we investigated the directness of participants' mouse movements while they made intertemporal choices (e.g., \$5 today vs. \$10 tomorrow), with greater conflict inferred for decisions in which participants' trajectories were less direct (i.e., greater veering towards the unchosen option). Past work suggests that these deflections are a sensitive measure of response conflict (for a recent review, see Freeman, in press).

Across four studies, we first test how the relative subjective value of both options influences conflict as measured by mouse-tracking, predicting that the more similar the subjective values, the greater the conflict and therefore the less direct mouse trajectories will be. We then test whether (and how strongly) directness of these decisions predicts participants' myopia, as quantified by their hyperbolic discount rate.

## Methods

### Procedure

Participants completed 180-210 (depending on the study) intertemporal choice trials that pitted a smaller amount of money available immediately ("smaller-sooner") against a larger amount available at some delay ("larger-later"). Participants completed trials in blocks of 15, in which the delay of the larger-later was kept constant. At the start of each block, we told participants how long the delay would be for that block.

Each trial began with a screen that was blank except for a black box in the bottom center labeled "Start". Once participants clicked on the start box, their mouse cursor disappeared, and the delay information appeared in the top-left and top-right areas of the screen, followed by the magnitude information (e.g., \$25 and \$50). Participants' mouse-cursors then reappeared in the bottom-center of the screen, and they made their selection using the mouse.

## Results

### Metrics of conflict and myopia

To gauge conflict on a given decision, we analyzed the area under the curve (AUC). This metric quantifies the area between an ideal trajectory (i.e., straight toward the chosen option) and the participants' actual trajectory. To gauge myopia, we estimated participants' hyperbolic discount rate ( $k$ ) and inverse temperature parameter ( $\beta$ ).

### The relationship between conflict and trial difficulty

We first wanted to demonstrate that mouse trajectory directness was influenced by the response conflict present during a given decision (see also Dshemuchadse, Scherbaum, & Goschke, 2013; O'Hara, Carey, Kervick, Crowley, & Dabrowski, 2016). Specifically, we predicted that the differences in subject values on a given trial would predict greater conflict as measured by the degree to which mouse movements were attracted to the unchosen alternative. To in-

vestigate this, for each participant and for each trial, we used their discount rate to calculate their subjective value for both the larger-later and smaller sooner options. We then calculated the distance between the two subjective values and predicted trial-by-trial conflict from this difference, predicting that trials for which the subjective values are more similar should produce more conflict than trials for which the subjective values are further apart. Consistent with this, across all four studies, the further apart the two subjective values were, the less conflicted participants' mouse movements were ( $ps < .001$ ).

### The Predictive Power of Conflict

We next wanted to demonstrate that conflict within decisions was predictive of myopia more generally. Specifically, we hypothesized that curvature while resolving self-control conflicts should predict the participants' discount rates. To test this, for each participant, we divided their trials based on whether they selected the larger-later or the smaller-sooner option. We then calculated the average curvature within these two groups, yielding two metrics per participant -- average conflict when choosing the larger-later option, and average conflict when choosing the smaller-sooner option -- and used this to predict individuals' discount rate,  $k$  (log transformed, Kirby, Petry, & Bickel, 1999). Consistent with our hypotheses, across all studies we find a strong relationship between both measures of conflict -- conflict when choosing larger-later and conflict when choosing smaller-sooner -- and log discount rates. The greater conflict participants displayed when ultimately choosing the larger-later (i.e., delaying gratification), the higher their discount rates, and the greater conflict participants displayed when ultimately choosing the smaller-sooner (i.e., indulging), the lower their discount rates ( $ps < .001$ ). Further, across studies we explain a large amount of the variance in discount rates with our two metrics of conflict,  $R^2$  between .49 and .70.

## Discussion

Although conflict plays an integral role in both the subjective experience and theoretical understanding of self-control, conflict itself is rarely studied using real-time approaches. In the present paper, we used mouse-tracking to more directly tap into conflict while participants decided between immediate gratification and delayed rewards in an intertemporal choice paradigm. Across four studies, we show that the difference in the subjective values of the smaller-sooner and larger-later options strongly predicts conflict as indexed by the degree to which cursor movements deviated from a direct path towards the chosen option. These findings suggest that mouse-tracking is a sensitive measure of the conflict present in a given decision.

We further find that average conflict -- both when electing the larger-later reward over the smaller-sooner, and vice versa -- strongly predicts participants' myopia as indexed by their discount rate. Notably, our metrics of conflict are relatively uninformed -- they quantify only the average amount of conflict on decisions in which participants ultimately chose the larger-later or the smaller-sooner, and do not account for information regarding the magnitudes or delay for a given trial. Even with this relatively blunt measure of conflict, we are able to account for a large proportion of the variance in discount rate, with  $R^2$  ranging from .49 to .70. Together, these results demonstrate the predictive strength of direct measures of conflict for studying self-control.

# Love Is Blind: How Sensory Liking Impacts Perceptions of Unbranded Products

Jennifer L. Stoner, University of North Dakota, USA

Maria Rodas, University of Minnesota, USA

## EXTENDED ABSTRACT

Brand elements have been shown to impact perceptions of things even unrelated to the brand or product such as the consumer's environment (Rahinel and Nelson 2016) and group identity (Torelli et al. 2017). Even though brands have been demonstrated to impact perception, companies regularly use "blind" testing in the product development process. We suggest that this may be a mistake as it may lead to a different sensory experience in the testing process than would be experienced after purchase, when a brand is present.

While individuals may sense the same thing, their perceptions of these sensations may differ drastically. Individual perceptions of a sensory experience (i.e. how sweet, salty, strongly scented/flavored a stimulus is) are malleable, in that they are often influenced by environmental factors. Judgments about the taste or smell of a product have been shown to be affected by things such as ambient lighting (Oberfeld et al. 2009) and package design (Becker et al. 2010). Given the prevalence of brand imagery and the malleability of sensory perceptions, we hypothesize that the presence of a brand during consumption can impact perceptions of the sensory experience. Research on cultural symbolism supports this idea by demonstrating that taste evaluations can be impacted by the values a product embodies (Allen, Gupta, and Monnier 2008) and other product information (Lahne, Trubek, and Pelchat 2013).

There are groups of consumers who love a certain sensory experience (e.g. chocoholics). It seems likely that those who love a sensory experience will have very different perceptions of that experience than those who do not. In our case, we are limiting this sensory "love" to merely a strong positive attitude valence which has been considered one dimension of the brand love construct (Rauschnabel et al. 2015). We therefore hypothesize that the presence (versus absence) of a brand will differentially impact those who love the specific sensory experience (i.e. chocolate lovers) versus those that do not. We hypothesize that those who love a sensory experience will be reveling in that experience when they consume an unbranded product and be less able to judge perceptions of that experience. Conversely, when an unfamiliar brand is present consumers who love the particular scent or flavor being presented will be more mindful to the consumption experience in order to integrate the new product information with their existing knowledge and experiences.

In Study 1, using strong or weak scented peppermint shampoo and a fictitious brand, we demonstrated that high liking participants (+1 SD above the mean on a generally liking scale) rated both shampoos as equal in strength on a 100-point scale when there was no brand present ( $M = 81.41$  vs.  $80.40$ ,  $t(126) = .25$ ,  $ns$ ). Conversely, high liking participants who read a fictitious brand description prior to smelling the shampoo accurately judged the stronger scented shampoo as being stronger ( $M = 89.44$  vs.  $80.77$ ,  $t(126) = 2.18$ ,  $p < .05$ ).

Study 2 replicates this effect using the sense of taste and mild or sharp cheddar cheese as the stimuli. Once again there was no difference between judgments of strong or weak for people who loved cheese when no brand had been presented ( $M = 74.15$  vs.  $69.17$ ,  $t(122) = .81$ ,  $ns$ ); but cheese lovers who had read a fictitious brand descriptions accurately rated the sharp cheddar cheese as being stronger tasting ( $M = 78.64$  vs.  $58.53$ ,  $t(122) = 3.07$ ,  $p < .01$ ).

Study 3 attempted to find initial evidence for the role of mindfulness as the mechanism behind the effect. Additionally, it used a real brand, Yoplait, with a product that was described as new to

participants. Participants tasted either regular strawberry yogurt or strawberry yogurt that had been sweetened. They responded to four items regarding their mindfulness during consumption on a 7-point scale. Yogurt loving participants in the brand present condition that consumed the novel-tasting, sweetened product rated themselves as more mindful than those that consumed the normal strawberry yogurt ( $M = 78.64$  vs.  $58.53$ ,  $t(122) = 3.07$ ,  $p < .01$ ). There was no difference in mindfulness for yogurt lovers who had not been presented with a brand ( $M = 6.04$  vs.  $5.88$ ,  $t(136) = 0.60$ ,  $ns$ ).

Study 4 combines the findings of the first three studies but re-searching both strength perceptions and mindfulness in the same study. Strong or weak coffee was used and new 7-point rating scales of both strength and mindfulness. Once again coffee lovers rate the strong and weak coffee as equal in strength when no brand was present ( $M = 3.61$  vs.  $3.33$ ,  $t(156) = 0.84$ ,  $ns$ ) but different in strength when they had read a description of a brand prior to consumption ( $M = 4.11$  vs.  $3.10$ ,  $t(156) = 3.87$ ,  $p < .001$ ). Furthermore, the coffee lovers rated themselves as more mindful of the consumption experience when a brand description had been presented versus not ( $M = 4.70$  vs.  $3.80$ ,  $t(160) = 3.67$ ,  $p < .001$ ).

Our findings demonstrate the importance of understanding the interaction of sensory love and brands on judgments of sensory perceptions. By showing that individual who love a certain scent or taste may have difficulty in judging different sensory stimuli – in our case, the strength of the scent or taste. However, the presence of a novel brand can make these consumers more mindful of the consumption experience and thus better able to judge their sensory perceptions.

# Attentional Breadth Affects In-Store Exploration and Unplanned Purchasing

Mathias Streicher, University of Innsbruck, Austria

Zachary Estes, Bocconi University, Italy

Oliver Büttner, University of Duisburg-Essen, Germany

## EXTENDED ABSTRACT

Maximizing shoppers' in-store travel has become an important strategy to trigger unplanned purchasing (Gilbride, Inman, and Stilley 2015; Hui et al. 2013) because longer in-store travel exposes shoppers' to relatively more products which may remind about forgotten needs or may even evoke new ones (Inman, Winer and Ferraro 2009). No research has, however, addressed the role of attentional breadth in shaping store exploration and unplanned purchasing.

*Attentional breadth* refers to the focus that is directed to a wider or more limited area in processing visual scenes (Friedman et al. 2003). It is a malleable state and may become narrowed or broadened by prior visual processing. Relative to narrow attention, consumers with broad visual attention explore a larger proportion of the visual field, which increases their susceptibility to environmental stimuli (Wadlinger and Isaacowitz 2006). In retail setting, this should increase the likelihood to perceive objects of interest in the background, such as products in other areas of the store or signs and promotions. Because objects in background are spatially more remote than foreground objects approaching relatively more background products should increase the average travel distance per trip. And because longer travel distance further increases the likelihood to see a tempting product or one that reminds a consumer about forgotten needs (Gilbride, Inman, and Stilley 2015; Hui et al. 2013), we hypothesized that activating broad (vs. narrow) attention should increase unplanned purchasing ( $H_1$ ) by increasing the distance traveled in-store ( $H_2$ ). We further predicted that the effect of attentional breadth on unplanned purchasing would be accentuated among more impulsive buyers ( $H_3$ ) because prior research has shown that impulsive (vs. non-impulsive) shoppers are more susceptible to non-focal products (Büttner, Florack et al. 2014).

In all studies except Study 2, attentional breadth was manipulated by showing participants 20 object pairs on a computer display, one pair at a time (2 sec). Critically, each pair included one object in the center and one in a random corner (periphery) of the display. Participants in the narrow group were instructed to name the object appearing in the center, whereas participants in the broad group named all objects appearing in the periphery. All participants saw and named the same objects. In Study 2, the manipulation was presented as in-store advertisement using 20 products of the store and instead of presenting object pairs participant saw only one product at a time (without naming it).

To validate our attentional manipulation, a pilot study was conducted in a 400 m<sup>2</sup> retail shop using eye-tracking glasses ( $N = 79$ ). After the attentional manipulation, participants were guided to an aisle (~15 meter) and asked to walk down the aisle as if they were shopping. Shoppers with broad attention spent significantly more time walking through the aisle than with narrow attention, they fixated on more products than the narrow group, and also exhibited more cross-aisle saccades (e.g., visual switches between the left and right shelves) than the narrow group. Thus, our manipulation successfully affects subsequent store exploration.

Study 1 was conducted in a 3600 m<sup>2</sup> supermarket. First, shoppers ( $N = 192$ ) indicated their planned purchases on category level and then were released for shopping after the attentional manipulation except those in a control group. After their shopping, the experimenters recorded their unplanned purchases. Attentional breadth did

not significantly differ for planned purchases in all studies reported hereafter. Nevertheless, attentional breadth affected unplanned category purchases. The broad attention group purchased more categories unplanned compared to both the narrow the narrow attention group and the control group. The narrow attention and control groups did not differ. The same pattern of significance emerged for unplanned products and unplanned spending as dependent variable.

Study 2 used the same recording procedures as in Study 1 except that we placed a pedometer on participants after the attentional manipulation to record their travel distance and shopping time ( $N = 74$ ). Activating broad attention significantly increased unplanned categories and the pattern of significance was identical for unplanned products and unplanned spendings, respectively. Participants shopped longer with broad attention than with narrow attention and also travelled farther with broad attention than with narrow attention. A mediation analyses with attentional breadth as independent variable, distance travelled as mediator, and unplanned categories as dependent variable revealed a significant indirect effect.

Study 3 used the same recording procedures in a 3000 m<sup>2</sup> supermarket ( $N = 100$ ). Participants additionally reported their chronic buying impulsiveness (Rook and Fisher, 1995). Activating broad attention significantly increased unplanned categories, unplanned products, and unplanned spending. Chronic buying impulsiveness moderated the effect of attentional focus on these variables. Specifically, the attentional manipulation significantly affected those who scored high in chronic buying impulsiveness than those who scored low in chronic buying impulsiveness.

In sum, activating broad (vs. narrow) attention increased unplanned purchasing and increased in-store travel of shoppers ( $H_1$  and  $H_2$ ). This effect was more pronounced for chronically impulsive shoppers ( $H_3$ ). Theoretically, our studies complement prior theorizing on unplanned purchasing by showing that attentional breadth affects store exploration and unplanned purchasing. Our studies further imply that retailers may stimulate unplanned purchases by influencing shoppers' attentional breadth via digital devices such as displays on shopping trolleys and store aisles.

# How The Past Shapes The Present: The Assimilation of Enjoyment to Similar Past Experiences

Anika Stuppy, Erasmus University Rotterdam, The Netherlands  
Bram Van den Bergh, Erasmus University Rotterdam, The Netherlands

## EXTENDED ABSTRACT

Throughout their lives, consumers sample experiential products (e.g., movies, coffee). Obviously, the type and number of experiences that consumers accumulate varies greatly. Some gather a great variety, others only a few. Some collect the most amazing product experiences, others only experience mediocre products. A coffee aficionado, for instance, has sampled elite and abysmal coffee while an inexperienced coffee drinker might have mostly visited Starbucks. Past work found that consumers learn distributional information about numeric stimuli such as prices (e.g., the range, the mean) through prior experiences, which boosts sensitivity for value (i.e., knowledge factor, general evaluability theory; Hsee and Zhang 2010). While distributional information about past prices might affect perceptions of how cheap/expensive a product is, it is unclear whether these findings apply to more experiential products. Our investigation is the first to test *whether* prior experiences boost sensitivity for the hedonic value of experiences. We also examine *how* past experiences trigger sensitivity.

Consistent with evaluability theory, we suggest that prior experiences make consumers' enjoyment more attuned to the hedonic value of experiential products (figure 1; A). Their enjoyment of higher vs. lower value products differs more strongly. To illustrate, a coffee aficionado should enjoy coffee of higher hedonic value more than coffee of lower hedonic value while a coffee novice should be more insensitive. While evaluability theory assumes that greater knowledge would generally benefit consumers (e.g., greater knowledge helps determine whether a price is favourable or not), we predict that having (vs. lacking) knowledge not only has hedonic benefits ("blessing of expertise"), but also hedonic costs ("curse of expertise").

## How do Past Experiences Shape Present Enjoyment?

Prior research on the accumulation of experiences focused on processes during the knowledge acquisition phase, such as effects of the serial position of stimuli during sequential evaluation (e.g., primacy/recency or hedonic contrast effects; Ghoshal et al. 2015, Zellner et al 2002). Our research question differs substantially from these studies by examining what happens after, not during, the knowledge acquisition phase. By comparing more experienced with less experienced consumers, our inquiry extends previous work by examining whether and how the distributional information of past experiences affects enjoyment, after knowledge is acquired.

The distributions of experienced (figure 1; B) and inexperienced (figure 1; C) consumers differ in many ways. Given that distributions entail multiple features (e.g., sum, min, max, mean, rank, etc.), the question begs: Which aspect of consumers' distribution of prior experiences will affect present enjoyment?

Evaluability theory suggests that consumers become sensitive to hedonic value because their past experiences provide information about the range and average of hedonic value in the marketplace. As such, coffee aficionados may judge whether a new coffee is more or less enjoyable than their average coffee experience (Helson 1964; Hsee and Zhang 2010). Or, they might gauge how much better or worse the new coffee is compared to their all-time best or worst coffee experience (Hsee and Zhang 2010). Or they might compare it to the experience they typically have (i.e., the mode). Because more

novice coffee drinkers lack this reference system (mean, minimum and maximum), their enjoyment of coffee might be less attuned to hedonic value. Because evaluability theory and other theories on value sensitivity were mostly tested with relatively simple numeric stimuli, it is unclear whether these theories' predictions will hold up for more complex, multidimensional experiential stimuli. Indeed, previous work has shown that consumers use different strategies when evaluating the value of experiences rather than numbers (Martin et al. 2016).

This investigation pursued two goals. First, we aimed to demonstrate that more experienced consumers are more sensitive to the hedonic value of experiential products than less experienced consumers and thus, that greater knowledge might not be universally positive (e.g., the "curse of expertise" or the flipside, "blessed ignorance"). Second, we strived to elucidate *how* accumulating experiences boosts sensitivity. If consumers draw back on past experiences to gauge present enjoyment, do they:

- a) compare the new experience to the past *average* experience (Helson 1964; Hsee and Zhang 2010),
- b) do they use *range* information (minimum, maximum past experience; Hsee and Zhang 2010),
- c) do they determine the *rank* of the new experience (Stewart et al. 2010),
- d) or do they use a different strategy?

## Study 1: Measuring The Distribution

Study 1 explored how the distribution of consumers' past experiences with gaming apps affects their enjoyment of two target games. We measured the participants' past experiences with gaming apps with a distribution builder. Then, participants rated how much they enjoyed two target games of different hedonic value (lower vs. higher). Study 1 served to explore how different features of participants' distribution of past experiences (mean, sum, range, and standard deviation [SD]) would affect their enjoyment of the target games. We counterbalanced whether the distribution builder was completed before or after evaluating the target games to alleviate concerns that we artificially activated past experiences.

### Procedure

Participants (n=156) either reported their past experiences with gaming apps *before* or *after* we measured their enjoyment of two target games. The distribution of past experiences with gaming apps was measured with a distribution builder. Participants allocated balls (1 ball = 1 gaming app) across ten hedonic value categories (1 = horrible to 10 = world class) to indicate how many gaming apps they had experienced in each hedonic value category. They could allocate between 0 and 100 balls in total. We computed the range ( $M_{range}=5.87$ ), the standard deviation ( $M_{deviation}=1.78$ ), the sum ( $M_{sum}=12.65$ ) and the average valence of all past experiences ( $M_{average}=6.21$ ).

We measured participant's enjoyment of two new gaming apps. Participants watched two videos that introduced two gaming apps in random order. These apps were selected to be as similar as possible and involved navigating a green monster through a laboratory. However, a pretest confirmed that their hedonic value differed considerably (84% vs. 24% enjoyment rating). Participants' enjoyment

of each game was measured on 10-point scales (1=horrible game to 10=world class game).

### Results

We computed several separate mixed linear models where we regressed enjoyment on each distribution statistic (range, SD, sum, mean), game hedonic value (higher vs. lower), order (distribution builder first vs. games first), and all interactions. Game hedonic value was the within-subjects variable. No model revealed a 3-way interaction (all  $p > .27$ ). However, 2-way interactions between the range measures (standard deviation statistic and range statistic) and game hedonic value emerged which remained significant after controlling for the mean and sum statistics (all  $p < .08$ ). As an example, we dissected the interaction for the standard deviation measure. Participants' enjoyment was more sensitive (the difference in enjoyment of the good and bad game was larger) when they had consumed a broad (+1SD;  $\beta = 1.61$ ,  $p < .001$ ) rather than narrow range of gaming apps in the past (-1SD;  $\beta = .430$ ,  $p = .231$ ). The two-way interactions between game hedonic valence and sum or average were insignificant (all  $p > .243$ ).

Study 1 explored which feature of the distribution of past experiences would predict sensitivity to hedonic value. We find that sensitivity was only predicted by distribution features that captured the range (range and standard deviation) but not distribution features not directly related to range (sum and average). As such, the results raise doubts as to whether consumers compare new experiences with the average experience and whether the quantity of past experiences is important.

### Study 2: Reducing The Number of Experiences

Study 2 aimed to conceptually replicate study 1 by manipulating, instead of measuring, the range of past experiences in a "knowledge acquisition phase" (KAP). We also strived to provide process evidence.

Study 1 showed that the range, but not the sum or average, predicted sensitivity for hedonic value. In study 2, we thus eliminated moderate experiences from the participants' distribution of past experiences. Thereby reducing the number, while keeping the range of experiences constant.

To test whether, and how participants would compare a target experience to past experiences, we measured enjoyment in the KAP. We then examined the correlations between earlier enjoyment in the KAP and enjoyment of the target experience. Given that we provided a range of experiences, two comparison processes are possible: Consumers might assimilate to similar past experiences (hedonic assimilation: "This is as enjoyable as this other past experience") or contrast away from dissimilar past experiences – those at the opposite end of the range (hedonic contrast: "This is much more (less) enjoyable than this other past experience").

### Procedure

Study 2 manipulated prior experiences with drawings (relevant range – higher quantity, relevant range – lower quantity, irrelevant range) and the hedonic value of a target drawing (lower vs. higher) in a 3X2 between-subjects design. First, participants ( $n = 297$ ) completed the KAP. In the relevant range – higher quantity condition, participants saw 15 mountain drawings. The drawings' hedonic value was normally distributed to ensure a broad range. Participants evaluated three drawings of lower (enjoyment score pretest:  $M = 56$  on a 100-point scale), nine drawings of moderate ( $M = 68$ ), and three of higher hedonic value ( $M = 81$ ). In the relevant range lower quantity condition, participants only evaluated the three drawings of lower and the three drawings of higher hedonic value but no moderate

drawings. In the irrelevant range condition, participants saw 15 animal photographs. Participants rated their enjoyment of each stimulus on slider scales (1=do not enjoy at all to 100=enjoy extremely). Presentation order of stimuli was randomized.

Next, all participants completed six dot-estimation filler tasks. Thereafter, participants were randomly assigned to one of two novel, but similar drawings: one of lower or one of higher hedonic value. Those constituted a gift to take home. A pretest ensured that the targets were similarly enjoyable as drawings of lower and higher hedonic value in the experience building phase ( $M = 60$  and  $M = 79$  respectively). Enjoyment was measured with three items: How happy are you with this drawing, How much do you like this drawing, How beautiful is this drawing? (1=not at all to 9=extremely).

### Results

We regressed enjoyment on gift hedonic value (lower vs. higher), range (coded to compare the irrelevant range [animal pictures] to the other two conditions), and all interactions. Two significant 2-way interactions between gift hedonic value and relevant range – higher quantity (vs. irrelevant range) and relevant range – lower quantity (vs. irrelevant range) emerged (all  $p < .001$ ). Participants' enjoyment was more sensitive to hedonic value when they had experienced all 15 drawings ( $p < .001$ ) as compared to animal pictures ( $p = .18$ ). Participants' enjoyment was also more valence sensitive when they had exclusively seen extreme drawings ( $p < .001$ ) as compared to animal pictures. Sensitivity did not differ between the higher and lower quantity conditions ( $p = .99$ ).

Next, we tested whether present enjoyment was assimilated to similar or contrasted away from dissimilar past experiences. We computed each participant's average enjoyment of the three less ( $M = 42.80$ ) and the three more positively valued ( $M = 85.48$ ) drawings in the KAP. Next, we examined the correlations between these averages and gift enjoyment. The correlation pattern suggests assimilation to similar past experiences. We find no evidence for hedonic contrast.

Consistent with study 1, not the quantity but the range of past experiences increased sensitivity for the hedonic value of a target drawing. Participants with 6 past experiences were as sensitive as those with 15 past experiences. This finding raises doubts as to whether the sum of experiences or the average experience are relevant for enjoyment.

Extending study 1, we demonstrated which past experiences are driving the effects on enjoyment through measurement. Participants assimilated present enjoyment to similar drawings they had seen in the past. Our findings are inconsistent with the possibility that sensitivity was driven by hedonic contrast.

### Study 3: Manipulating The Range of Experiences

Study 3 aimed to test whether consumers rank experiences by manipulating the range of experiences in the KAP. We compared participants with a narrower range of experiences (15 moderate value drawings) with participants with a broader range (the 15 drawings from study 2). If the rank within the distribution determines enjoyment (Stewart et al. 2016), then consumers in the narrower range condition should be sensitive to hedonic value. Because the higher (lower) value target ranks highest (lowest) in their distribution, they should enjoy it very much (not at all).

### Procedure

Study 3 applied a 2 (range: broader vs. narrower) x 2 (hedonic value: lower vs. higher) between-subjects design ( $n = 193$ ). Participants in the broader range condition saw the 15 artworks from study 2 (3 high, 6 moderate and 3 low) while participants in the narrower

range condition saw 15 moderately enjoyable artworks (all similar to the 6 moderately enjoyable drawings from the broader range condition). The drawings were presented in random order. To rule out an explanation in terms of response scale during the KAP, participants did not rate their enjoyment in the KAP. We used study 2's items to assess enjoyment of the - randomly assigned -gift.

### Results

We examined the effect of range (narrower vs. more broad), gift hedonic value (lower vs. higher), and their interaction gift enjoyment. A significant 2-way interaction between hedonic value and range emerged ( $p=.016$ ). Participants' enjoyment was more sensitive to hedonic value when they had experienced the broader ( $p<.001$ ) as compared to the narrower range ( $p=.09$ ) of drawings.

Study 2 demonstrated that experienced participants assimilated to similar past experiences. The ability to draw back on similar past experiences may therefore be what distinguishes novices from experts and creates value sensitivity for experiential products. Study 3 supports this notion. When similar past experiences were absent, sensitivity declined. These findings again raise doubts as to whether consumers compare their experiences to an average or rank them.

### GENERAL DISCUSSION

Our experimental paradigm allowed us to manipulate knowledge. Consistent with evaluability theory, we show that acquiring product knowledge creates value sensitivity. However, we also show that in the domain of experiential products, knowledge has hedonic benefits ("blessing of expertise") but also entails hedonic costs ("curse of expertise"). Knowledgeable consumers enjoy elite products more than novices, but are less able to enjoy mundane products.

Extending beyond evaluability theory, we show which aspect of knowledge contributes to sensitivity. Our findings suggests that the process of acquiring knowledge for experiences differs from the process of acquiring knowledge for numbers. Sensitivity was not driven by the sum, or average experience, or the rank of an experience. Rather, a broad range of past experiences seems crucial because it provides similar past experiences that serve as assimilation standards (study 2). More importantly, our findings imply that expertise for hedonic experiences may be *local*. Consumers seemed sensitive to experiences within but not outside of their range of past experiences

(study 3). A finding that might be specific for experiential stimuli. When judging prices, for instance, consumers were sensitive to prices within and outside their range of past experiences (Janiszewski and Lichtenstein 1999).

Although many consumers strive to accumulate more product experiences to acquire knowledge, having this knowledge involves a cost. A coffee aficionado might need to walk past four Starbucks, sacrificing time and energy, to reach a coffee shop that offers elite coffee.

# A Complete Consumer Journey: Tracking Motivation in the Marketplace

Jacob Suher, Portland State University, USA

Szu-chi Huang, Stanford University, USA

Leonard Lee, National University of Singapore, Singapore

## EXTENDED ABSTRACT

Traditional models of shopper motivation assume that a consumer arrives at a store with a particular goal in mind and shops according to that goal. As a result, the majority of studies on in-store decision making have treated shopper motivation as a stable trip-level variable measured either before or after a shopping trip (Kaltcheva and Weitz 2006). In contrast, consumer behavior studies demonstrate that examining motivation and choice through a series of actions and across multiple time points helps to uncover the inherent dynamics of such behavior (Dhar et al. 2007; Khan and Dhar 2006). Studying in-store behavior in a continuous manner from the beginning to the end, therefore, is imperative to understanding consumer motivation in the marketplace.

In this research, we capture one facet of consumer motivation in the marketplace—the amount of time shoppers spend between product choices within a shopping trip. We refer to this measure as inter-choice time. A field study and two online shopping experiments contribute to the measurement and understanding of consumer motivation in the marketplace. First, we advance prior literature on shopper motivation by measuring consumers' in-store behavior in a continuous manner. Second, we add to growing research that uses shopper-tracking technology by drawing attention to an antecedent of in-store behavior—pre-trip planning—and capturing its divergent impact on consumers' motivation over the course of their shopping trips. Third, our findings add to the dialogue that consumer motivation can follow a linear trend (Kivetz, Urminsky, and Zheng 2006) or a curvilinear trend (Bonezzi, Brendl, and De Angelis 2011). We show that pre-trip planning determines whether a curvilinear motivational pattern emerges as a consumer progresses from one product choice to another in the store.

In study 1, 250 shoppers at a grocery store participated in a research study that included an entrance and exit survey as well as video tracking to record the timing and categories of all product choices. The dependent variable was the amount of time leading to each product choice (i.e., inter-choice time). We calculated inter-choice time as the time a participant began shopping to making the first product choice, and then the time from the first product choice to the second, and so on, until the time between the final two product choices. Inter-choice time was regressed on the cumulative trip duration at the moment of purchase, the square of the trip duration, a contrast code for usage of a shopping list (List = 1; No-List = -1), and the two-way interactions between the list code and trip duration and the list code and squared trip duration. The final data set consisted of 2,285 product choices made by 237 shoppers (video files from 13 participants were unusable). There was a positive interaction between squared trip duration and the list code ( $\beta = 0.0010$ , Wald  $\chi^2(1959) = 34.58$ ,  $p < .0001$ ), suggesting that whether a shopper's motivation followed a curvilinear trend depended on pre-trip planning. In the list condition, there was a positive linear effect of trip duration ( $\beta = 0.0247$ , Wald  $\chi^2(1959) = 37.79$ ,  $p < .0001$ ); the quadratic effect of trip duration was not significant ( $\beta = -0.0002$ , Wald  $\chi^2(1959) = 0.81$ ,  $p = .37$ ). In the no-list condition, in contrast, there was a negative quadratic effect of trip duration ( $\beta = -0.0023$ , Wald  $\chi^2(1959) = 56.02$ ,  $p < .0001$ ); the linear effect of trip duration was not significant ( $\beta = 0.0053$ , Wald  $\chi^2(1959) = 1.24$ ,  $p = .27$ ).

In study 2, the Prolific research platform recruited 120 participants to complete a shopping trip in a simulated online grocery store. We randomly assigned participants to one of two pre-trip planning conditions (List vs. No-List). In the list condition, participants received a budget of \$35 and created a list of four categories. In the no-list condition, participants received the same instructions but did not create a shopping list. The store included 15 categories with six items from a national US grocery retailer (Kroger) presented in a fixed order. As in study 1, the dependent variable was inter-choice time and we followed the same procedure to create a regression model. The final sample for analysis included 715 purchases made by 102 participants who remained within the specified budget. We again observed an interaction between squared trip duration and the list contrast code ( $\beta = 2.2482$ , Wald  $\chi^2(595) = 14.88$ ,  $p = .0001$ ). In the list condition, there was a positive linear effect of trip duration ( $\beta = 0.7363$ , Wald  $\chi^2(595) = 14.99$ ,  $p = .0001$ ), while the quadratic effect was not significant ( $\beta = 0.8258$ , Wald  $\chi^2(595) = 0.91$ ,  $p = .34$ ). In the no-list condition, there was a negative quadratic effect of trip duration ( $\beta = -3.6705$ , Wald  $\chi^2(595) = 14.92$ ,  $p = .0001$ ), while the linear effect was not significant ( $\beta = 0.3015$ , Wald  $\chi^2(595) = 1.78$ ,  $p = .1826$ ). We replicated these patterns with another 211 Prolific participants using the same paradigm as study 2 except the store randomized category order and the list condition used a pre-determined shopping list (N = 1,376 purchases from 190 participants).

An in-store field study and an online shopping experiment (plus a replication study) found that shoppers' motivational patterns diverged depending on whether they had a shopping list. Whereas consumers with shopping lists exhibited a deceleration of shopping speed over the course of their trip, consumers without lists showed a nonmonotonic increase then decrease in inter-choice time (i.e., a curvilinear pattern). These patterns reveal the role that reference points may serve for consumers in the marketplace. The moderating effect of list usage on shopper behavior adds a new angle to the literature demonstrating that pre-trip factors influence the dynamic patterns of in-store behavior. Future research can explore other consumer-based antecedents (e.g., the presence of a shopping partner or group; different purpose of the trip) and capture their effects on consumers' motivational patterns in the store. Capturing the dynamics of in-store motivation is critical to providing real-time and relevant messages to enhance the retail experience and consumer welfare (Lee et al. 2018).

# Dehumanization: Coping with Embarrassment in Consumer Purchases

Yixia Sun, Zhejiang University, China

Xuehua Wang, East China Normal University, China

Joey Hoegg, University of British Columbia, Canada

Darren Dahl, University of British Columbia, Canada

## EXTENDED ABSTRACT

Consumers often find themselves in encounters with service providers that can spark feelings of embarrassment. For example, they may need to speak to a pharmacist or a doctor about an embarrassing health condition. They may need to purchase embarrassing personal products (Blair and Roesse 2013). In situations such, consumers employ coping strategies to deal with the feelings of embarrassment, such as buying additional non-embarrassing items (Blair and Roesse 2013; Lewittes and Simmons 1975), shopping in less crowded environments, or avoiding salespeople (Brackett 2004). The current research considers another way that consumers cope with embarrassing interactions with service professionals: dehumanization.

Given that thoughts about what others are thinking leads to embarrassment (Dahl, Manchanda, and Argo 2001), a strategy to cope with embarrassment is perceiving others to be lacking in thoughts or feelings (Epley and Waytz 2010). For example, when buying condoms, consumers may feel embarrassed if they believe that the cashier infers they are promiscuous (Dahl et al. 2005). We propose that consumers in such situations reduce self-consciousness by thinking of the service provider as less like a human being and more like a robot who is simply “doing the job”. Someone who is not fully human should be more focused on the task and less likely to think about the consumer and the potentially embarrassing events that may have led the consumer to need the particular product or service. Thus, by perceiving the service provider as more robotic and less human, the embarrassment of the situation can be mitigated. In this paper, we investigate this subtle form of dehumanization as a coping mechanism consumers employ when buying socially embarrassing products or seeking embarrassing services. We have four hypotheses stemming from our conceptualization:

*Hypothesis 1* When consumers buy embarrassing products or consume such services, they will dehumanize the service provider to reduce embarrassment.

*Hypothesis 2* When consumers buy embarrassing products or consume such services, they will prefer a robotic service provider to a warm one. However, this preference will be reversed when they buy normal products or consume normal services.

*Hypothesis 3* Consumers will be more willing to make self-disclosures about an embarrassing product when the service provider is robotic than when he/she is warm. However, they will be more willing to make self-disclosures about a normal product when the service provider is warm than when he/she is robotic.

*Hypothesis 4* The effect of embarrassment on dehumanization (H1) will be more evident when consumers are of high (vs. low) self-consciousness.

Study 1 tested whether participants would choose a doctor with robotic (vs. warm) characteristics when seeking an embarrassing treatment (H2). Female participants imagined doing either a pelvic exam or an ear exam in a clinic. They were told that only male doctors were available and were asked to choose one between two doctors who were equally knowledgeable and professional but varied in style. Doctor A worked in an efficient, almost robotic way, whereas Doctor B was chatty and asked lots of questions. As predicted, participants seeking embarrassing treatment were more likely to choose the robotic doctor than those in the control condition (59.3% vs. 38.5%;  $\chi^2 = 6.88, p < .01$ ).

Study 2 tested whether embarrassing service contexts lead consumers to dehumanize service providers (H1). Participants read a scenario similar to study 1 but rather than having a choice of doctor, participants simply read that the doctor performed the exam and were asked to judge his style. Results confirmed that participants rated the doctor as more robotic in the embarrassment condition than in the neutral condition (3.84 vs. 3.10;  $F(1,82) = 6.36, p = .014$ ).

Study 3 was a field study conducted in a convenience store built in the lab. Each participant selected, at random, an envelope that contained the name of a product and redeemed it with a coupon. In fact, each envelope identified either an embarrassing product (e.g., condom) or a normal product (e.g., gum) to be redeemed. Results indicated that participants who bought embarrassing products perceived the cashier to be more robotic than those who bought normal products (4.40 vs. 3.39;  $F(1, 113) = 17.64, p < .001$ ).

Study 4 tested the effect of dehumanization on self-disclosure in a field experiment. (H3). An experimenter pretended to be a salesperson and invited passersby to do a survey for a small payment. Participants were told that they could stop answering questions anytime they wanted, without influencing their payment. A list of thirty-two personal questions was developed and the number of questions answered by each participant was recorded as the self-disclosure measure. Participants were told that the product being surveyed was either about condoms or gum, as a manipulation of embarrassment. The salesperson was trained to act in a warm or robotic manner. In the warm condition, the experimenter focused on the participant's eyes and spoke enthusiastically. In the robotic condition, he looked at the participant's face without focus and spoke in a monotone voice. Results confirmed that when the survey was about condoms, participants answered more questions when the salesman behaved robotically than when he behaved warmly (19.47 vs. 13.54;  $F(1, 133) = 18.19, p < .001$ ). This pattern reversed when the survey was about gum (22.35 vs. 28.56;  $F(1, 133) = 4.81, p < .05$ ).

A final study tested the moderation effect of self-consciousness (H4) and found that the effect of embarrassment on dehumanization of salespeople is mitigated for individuals low in chronic self-consciousness.

# A Meta-Analysis on the Endowment Effect in Experiments

Daniel Sun, University of Calgary, Canada

## EXTENDED ABSTRACT

### Previous Meta Research

While the discussion on the phenomenon of endowment effect has been on-going, it is surprising that few meta-analyses have examined this phenomenon exclusively. Three previous meta-analyses have investigated on the disparity that exists between Willingness-to-Pay (WTP) and Willingness-to-Accept (WTA). Experimental and survey studies often find that WTA is much greater than WTP; however, this disparity may not come exclusively from endowment of an object but could also be attributable to seller/buyer perspective, income effects, transaction costs (Randall and Stoll, 1980), commitment costs (Zhao and Kling, 2004), or other psychological variables such as framing (Thaler, 1980).

The most recent meta-analysis on the WTP/WTA gap, by Tuncel and Hammit (2014), is based on a previous meta-analysis by Horitz and McConnel (2002), which reviewed 45 studies and examined the effects of type of good and experimental conditions. Horitz and McConnel's main finding showed that the WTP/WTA disparity was greater for public goods or none-market goods compared to ordinary private goods. Tuncel and Hammit expanded the previous analysis by including new studies up until early 2012 with a total of 76 studies. Tuncel and Hammit replicate prior finding that there exists systematic differences in the WTP/WTA disparity by type of good. However, they showed that this disparity is related to participants' experience (real world experience and experimental trial experience) in valuing the good. Furthermore, the magnitude of this parity has decreased overtime. The third meta-analysis by Sayman and Onculer (2005) examined 39 studies and found that incentive-compatible designs (such as the goods are tangible or intangible) decreased the WTP/WTA disparity.

However, all of these previous three meta-analyses focused on the WTP/WTA disparity. While Tuncel and Hammit's (2014) analysis does include studies that focus on the endowment effect, their analysis and discussion do not offer any specific insight on the actual phenomenon of endowment. This current study is an updated and extension of Tuncel and Hammit but with a focus on the endowment effect. It expands the sample by including newer studies. Similar to Tuncel and Hammit, this meta-analysis uses the logarithm of the ratio of the elicited price from endowed and unendowed participants. This analysis examines several factors that may play a role in contributing to the endowment effect in experimental studies, such as country of origin, type of good, endowment method, price elicitation method, usage of actual endowment, and experimental procedures. Furthermore, regression analysis shows that unlike in Tuncel and Hammit's case where the WTP/WTA gap has diminished by publication date, the price gap due to endowment has increased in recent publications.

### Current Meta-Analysis

#### Data

To identify related studies, PsycINFO was used with keywords "WTA," "WTP," and "Endowment Effect" up to mid-2015. Since this analysis focuses on the study of the price gap due to endowment, none experimental studies and experimental studies that did not involve explicit pricing of a good or object were excluded. For example, in Sen and Block's (2008) study, the experimenters used rating scales and probability to measure participants' inclination to keep an endowed object. This and other induced-value experiments (e.g.,

using tokens) were excluded since they are not relevant to testing a difference between endowment pricings. Furthermore, studies that did not involve endowment (either actual or hypothetical) were also excluded. Few studies, such as Peck and Shu (2009), examined the effect of physical touch on perceived ownership. While the authors argue that theoretically physical touch enhances one's psychological ownership of the object and therefore may lead to an endowment effect, the endowment here is the dependent variable and not what is resulting in the price difference. Hence, such studies were excluded. There are 42 studies included in this analysis with 89 total experiments. The studies included are listed in the Appendix.

#### *Dependent Variable: Endowment Price Ratio*

Similar to Tuncel and Hammit (2014) which used a WTA/WTP ratio, this analysis uses the ratio of the mean price of the Endowed to mean price of Unendowed for each experiment in each study. Since there is no information on the price elicited from each participant in the studies, this analysis focusses on the group means in each experiment instead. Natural log is then used to transform this Endowed/Unendowed price ratio. The resulting Ln-Price-Ratio is a semi-normalized distribution. No outliers were identified during this vetting process and so no studies were excluded as a result.

#### *Independent Variables*

##### *Type of Good: Ordinary Private Goods, Lottery, and Others*

The type of good in each experiment was classified into three categories, ordinary private good, lottery, and others. Ordinary private goods are items that are often seen and bought in everyday transactions. Three most common used items used in endowment experimental studies are pens, mugs, and chocolate bars, all of which are ordinary private goods. Lotteries are a type of good that carries a probability of winning some pre-set face value. In endowment experiments, participants could either be endowed with such a lottery which they have some chance of winning a pre-set value of winnings (and have the option to sell such a lottery) or not have such a lottery but have the option to buy it. Others type of good in this category captures items that were used that were not explicitly captured by the other two categories (such as time) or explained as to what was used in the experiments.

##### *Endowment Method: Real vs. Hypothetical*

In some studies, the endowment experiment takes place with actual items given to the participants; in other studies, the experiment is scenario based and participants are asked to imagine to hypothetically possess (or not possess) some item. Past studies and meta-analysis have shown that the endowment effect is robust regardless of real or hypothetical method of endowment (Tuncel and Hammit, 2014).

##### *Physical Endowment: Physical vs. Non-physical*

In some studies, participants are given actual items to touch and use, while in other studies, participants may be told that the item they are endowed with will be provided to them at the end of the study. While the later experimental methods still uses real endowment where the participants are given an actual item, these participants do not have the opportunity to physically engage with the item itself. Prior studies have suggested that while endowment effect may still occur regardless of physical (or lack of) engagement with an item, physical contact does enhance the endowment effect (Shu and Peck, 2011; Peck and Shu, 2009).

Price Solicitation Method: Solo, Variable Range, and Other

In solo pricing method, participants are given an open ended question on how much they are willing to spend on or sell the item and are only required to provide one single price. In variable range method, participants are presented with several ranges of prices in a sequential manner and are asked under which range they would most likely to pay for or sell the item. The other solicitation method is a catchall for experiments that were not explicit on how pricing was elicited from the participants.

Experimental Procedure: KKT, BDM, and Other

In their seminal paper on the endowment effect and loss aversion, Kahneman, Knetsch, and Thaler (1991) outlined the methodology in which they conducted their experiments. In the KKT procedure, participants are randomly assigned to the endowed and unendowed groups; the endowed participants are the sellers and are asked for their WTA price and the unendowed participants are the buyers and are asked for their WTP price. Alternatively, endowment experiments could use a variation based on the Becker-DeGroot-Marschak (BDM) procedure (Becker, DeGroot, Marschak, 1964). The BDM procedure is commonly acknowledged as more incentive-compatible where it has higher accuracy in measuring one's WTP. In the variations of the BDM procedure, participants are asked to state their best selling or buying price for the endowed or unendowed item with the knowledge that there is a market clearing price (either based on a pre-set price by the experimenter or the mean of the other sellers and buyers in the experiment). If the participants' prices match the market price, they will have the opportunity to buy or sell the item.

Country of Origin: Western vs. Eastern

Finally, this analysis also examines the country where the experiments were conducted in each study. Western countries are categorized based on region (such as North America and Europe) and Language (such as English); Eastern countries are based on region which is mainly from oriental cultured countries (such as China, Japan, and Singapore).

Results

The association between the independent variables and the dependent variable (Ln of ratio between endowed and unendowed prices) is examined by univariate analysis.

Similar to prior research (Tuncel and Hammitt, 2014; Horitz and McConnel, 2002), the analysis reveals a statistically significant effect of type of good on the endowment price ratio. Pair-wise comparison analysis indicate that the main significance comes from the difference between ordinary private good and lottery ( $M_{\text{difference}} = .31$ ,  $SE = .13$ ,  $p = .017$ ). One potential explanation for this greater LN price ratio for lottery compared to ordinary private good is the inherent risk involved in a lottery. Since most people are risk-averse, it is reasonable to assume that owners and non-owners of the lottery would demand greater compensation for their selling and buying of the lottery, leading to the observed greater price ratio.

While there is an apparent statistical significance in the elicitation method used by the studies, pair-wise comparison reveals that the Other method is the main driver of the significance and that no significance exists between Solo and Variable Range methods ( $M_{\text{difference}} = .06$ ,  $SE = .1$ ,  $p = .57$ ).

Using publication year as a factor, a regression analysis was run on the endowed/unendowed price ratio. The regression analysis show a significant effect of publication year on price ratio ( $R^2 = .045$ ,  $b = .21$ ,  $t = 2.0$ ,  $p = .05$ ). While only 4.5% of the change in price ratio may be explained by the publication year, a one standard deviation increase in publication year leads to a .21 unit increase in the endowed/unendowed price ratio. By using a median split based

on the publication year ( $Md = 2011$ ), a marginal interaction is found between publication date and price elicitation method ( $F = 2.44$ ,  $p = .09$ ). This marginal effect may be attributable to the increase in Other price elicitation method since the year 2011 ( $M_{\text{before2011}} = .33$ ,  $M_{\text{after2011}} = .87$ ) since Solo and Variable Range elicitation methods did not change much.

**Discussion**

This meta-analysis takes a closer examination at the effect of endowment on pricing. While it shares some similarities to prior research on WTP and WTA gap, it is theoretically different in the manipulation and the examination of the resulting pricing gap. This study is unique in that it examines exclusively the experiments conducted on the endowment effect with the endowment takes place either in real world situation or in hypothetical scenario. Furthermore, it adds more recent studies while focussing on the experimental studies in the area of endowment.

This result of analysis replicate the findings from Tuncel and Hammitt (2014) and Horowitz and McConnel (2002) that type of good used in experiments has an effect on the gap between prices due to endowment. This analysis shows that lottery endowment leads to greater price gap compared to ordinary private good endowment, a caveat that was missed by prior meta-analyses. This has some interesting implications for future research. Since lottery carries inherent risks, it is possible that risk averse individuals will demand greater compensation in the form of price gap between sellers and buyers to compensate for the potential risk. This is also consistent with the loss aversion account of the endowment effect where individuals demand greater value for losing (or selling) an object compared to gaining (or buying) the same object (Khaneman, Knetsch, and Thaler, 1991).

The publication year also appear to play a role in influencing the effect of endowment on pricing where the pricing gap appears to increase as publication year increased. This result is contrary to Tuncel and Hammitt's (2014) where they showed a diminishing WTP/WTA price gap as a result of increased publication year. One reason for this difference may be because Tuncel and Hammitt's meta-analysis is on the WTP/WTA price gap whereas the current meta-analysis focussed on the endowment effect price gap. Whereas the WTP/WTA is a methodological price elicitation process, the endowment price gap is attributed to fundamental psychological variables such as loss aversion (Khaneman, Knetsch, and Thaler, 1991), ownership effect (Aggarwal 2004; Aggarwal and Law 2005), and even self-enhancement (Dommer and Swaminathan, 2013; Chatterjee, Irmak, and Rose, 2013). There may be two potential explanations for this endowment price gap as a result of publication year. First, participants in general are becoming more loss averse or attached to their endowed objects. This may have some interesting implication in terms of sociology or personal psychology on how our society may be evolving compared to years past. Second, since the current endowment effect price gap seems to be marginally moderated by the change in price elicitation method, there may a change in experimental settings that is resulting in greater endowment price gap. This may have some negative implication in which experimenters are artificially inflating the effect of endowment through experimental settings and procedures.

This current meta-analysis has some limitations. First, while it focusses on the endowment effect in the experimental setting, it ignores the effect through other research methods such as quasi-experiments and surveys. This reduces the power and the scope that could have brought out to examine a larger picture of the endowment effect. Second, since the data used are means from experiments (or the ratio of the price means), it lacks some statistical tools to further refine the relationship between the factors.

One potential way to address both of these limitations is to examine the endowment effect but through a different psychological variable: psychological ownership, the degree to which an individual feels or believes that he or she owns an item with or without actual or physical ownership. Furthermore, the dependent variable could be changed to include not only pricing gaps but also rating or preference gaps that are a result of psychological ownership. This would expand the level of analysis beyond experimental studies and include correlational studies, which more refined meta-analytical tools are available for detailed analysis of the data.

## EXTENDED ABSTRACT

Many companies annually launch uncertain reward campaigns, where consumers are given a chance to win a prize with each purchase. Uncertain reward campaigns offer consumers a probability (e.g., one in four chances) to win a gradient of prizes, ranging from nominal to valuable. For example, Tim Hortons' *Roll-Up-The-Rim* campaign gives explicit odds of a 1 in 6 chance to win, with the prizes ranging from a hot beverage to a new car (Roll-Up-the-Rim Website, 2017). Similar uncertain reward campaigns include Coca Cola's *Sip & Scan*, Pepsico's *Win Every Hour*, M&M's *When We Win, You Win*, and Wendy's *Dip & Squeeze and Win*. The gradients in the prizes exist to elicit interest, but there is anecdotal evidence to suggest that these campaigns may be changing consumer behavior.

Specifically, a recent article in the Huffington Post suggests that consumers are purchasing larger products (or 'supersizing') during Tim Horton's *Roll-Up-The-Rim* campaign (Yum, 2013). Although the company regularly advertises otherwise, it thus appears that customers behave as if larger beverage sizes bring better odds (Yum, 2013). This speculation has incited customers to catalogue the prize frequency and distribution across cup sizes (Roll Up the Stats Website, 2015). The results of over 14,000 crowdsourced reports reveal no statistical variation of wins by cup size (Aspler, 2016). Yet this supersizing tendency persists.

In the current article, we propose the intriguing possibility that supersizing during uncertain reward campaigns is occurring because consumers infer that their odds of winning the most elusive prize are better in the larger sized offerings. Thus, we propose that it is not that consumers are rejecting or ignoring explicit information about their overall odds of winning, but rather they are engaging in tactics to elevate a sense of control over a desirable, but elusive outcome. Of course, from a rational standpoint (e.g., Expected-Utility Theory; Bernoulli, 1738; von Neumann and Morgenstern, 1945), if the goal is to maximize one's chances of winning, consumers should purchase the smallest product offering and enter the lottery twice for an equivalent price. Yet if the goal is to gain a sense of control over seemingly insurmountable odds, then such a tactic may serve an adaptive function.

Across four studies, we sought to test the veracity of the supersizing phenomenon and reveal the underlying process that in fact nudges consumers to purchase larger products during uncertain reward campaigns. As a whole, our findings support the existence of a supersizing tendency during uncertain reward campaigns and further support that it may be a byproduct of consumers' need to increase a sense of control over the elusive grand prize.

In study 1, we begin by confirming the Huffington Post article, validating that consumers do indeed tend to purchase larger products during uncertain reward campaigns. Undergraduate students ( $N = 206$ ) were randomly assigned to one of two conditions (Uncertain Promotion vs. No Uncertain Promotion). While participants in the no uncertain promotion condition chose the coffee cup size they would purchase from Tim Hortons on a normal day, participants in the uncertain promotion condition chose the coffee cup size they would purchase during a time when *Roll Up the Rim* campaign was active (which offered a chance to win one of the prizes that ranged from a cup of coffee to a car). An independent samples t-test with average cup size selected as the dependent variable (1 = small to 4 = extra-

large) revealed that participants in the uncertain promotion condition chose larger cup sizes ( $M = 2.08$ ,  $SD = .83$ ) compared to participants in the no uncertain promotion condition ( $M = 1.87$ ,  $SD = .62$ ),  $t(204) = 2.10$ ,  $p < .05$ ,  $d = .29$ . Consistent with the supersizing anecdote, this mean difference was driven predominantly by variations in the largest offering. Specifically, the extra-large cup was chosen by 8% of participants in the uncertain promotion condition compared to only 1.9% in the no uncertain promotion condition,  $\chi^2(1) = 4.16$ ,  $p < .05$ ,  $\phi = .14$ . Reliable choice shifts for other product sizes were not observed ( $ps > .12$ ). Hence, the results suggested that consumers are indeed more likely to supersize their product purchases during an uncertain reward campaign.

Larger products are usually more expensive than their smaller alternatives. Thus, one plausible explanation for this behavior is the somewhat rational belief that firms are housing larger, and thus more costly, prizes in the most profitable options. One way of ruling out this possibility is by holding prices constant across product sizes. As such, in Study 2, participants ( $N = 148$ ) were randomly assigned to one of two conditions (Uncertain Promotion vs. No Uncertain Promotion). All participants were told that, for a limited time, Starbucks was conducting a promotion where *all product sizes are equally priced*. An independent samples t-test with average cup size selected as the dependent variable (1 = Short to 4 = Venti) revealed that participants in the uncertain promotion condition chose larger product sizes ( $M = 3.39$ ,  $SD = .86$ ) compared to participants in the no uncertain promotion condition ( $M = 3.11$ ,  $SD = .95$ ),  $t(146) = 1.91$ ,  $p = .058$ ,  $d = .31$ . Follow-up contrasts confirmed that this effect occurred because participants were more likely to choose Venti in the uncertain promotion condition (59.5%) than in the no uncertain promotion condition (43.2%),  $\chi^2(1) = 3.90$ ,  $p < .05$ ,  $\phi = .16$ . Reliable choice shifts for other product sizes were not observed ( $ps > .25$ ). The results of study 2 suggest that the supersizing tendency during uncertain reward campaigns goes beyond just-world beliefs, perceptions of equity, or other more rational inferences based on price (e.g., ulterior motives).

If price inferences did not underscore the supersizing phenomenon, then it could be that consumers inherently associate larger products with greater chances of winning. Further, it was possible that this association was specific to the elusive grand prize. Indeed, prior literature suggests that consumers often focus on their odds of winning the grand prize, because nominal prizes are far too frequently won (Yan & Muthukrishnan, 2014). To test these possibilities, Study 3 employed a 2 (Prize: small vs. large)  $\times$  3 (Product Size: Small vs. Medium vs. Large) between-subjects factorial design. All participants ( $N = 240$ ) read that Lays was currently conducting an uncertain reward campaign. Participants were then shown all sizes of Lays chips included in the campaign (small, medium, and large), but were randomly asked to rate the likelihood of winning one prize with only one of the bags. A two-way ANOVA on likelihood revealed no difference across product sizes on perceived likelihood of winning the nominal prize ( $p = .99$ ). However, participants' perceived likelihood of winning the grand prize did vary by product size,  $F(2, 234) = 10.62$ ,  $p < .001$ ,  $\eta^2 = .08$ . As expected, participants believed the larger bag was more likely to win the grand prize ( $M = 6.29$ ,  $SD = 3.54$ ) relative to the small ( $M = 3.97$ ,  $SD = 2.68$ ),  $F(1, 234) = 13.09$ ,  $p < .001$ ,  $\eta^2 = .05$ , or medium bags ( $M = 3.56$ ,  $SD = 2.29$ ),  $F(1, 234)$

= 18.13,  $p < .001$ ,  $\eta^2 = .07$ . These results converged with studies 1 and 2 to show that supersizing corresponds with biased inferences of chance, and these inferences are restricted to the chance of winning the grand prize.

In our final study, we then turned to confirm that the phenomenon relates to consumers establishing a greater sense of control in the presence of the elusive and desirable grand prize. Participants ( $N = 300$ ) were randomly assigned to one of four conditions in a 2 (No Uncertain Promotion vs. Uncertain Promotion)  $\times$  2 (Power: High vs. Baseline) between subjects factorial design. The procedures, stimuli, and choice task were the same as study 1 with one exception. In an effort to extend beyond measuring our mediator, we introduced a pretested power manipulation before the main scenario (adapted from Galinsky et al., 2003). Because high feelings of power reduce consumers' motivation to acquire control (Inesi et al. 2012), we expected high power condition to serve as a boundary condition to supersizing phenomenon.

The results converged with our expectations. That is, participants in the baseline power condition selected larger product sizes on average in the uncertain promotion condition ( $M = 2.63$ ,  $SD = .90$ ) than in the no uncertain promotion condition ( $M = 2.33$ ,  $SD = .83$ ),  $F(1, 296) = 4.34$ ,  $p < .05$ ,  $\eta^2 = .014$ . Critically, this pattern was eliminated in the high power condition,  $p = .36$ . Similarly, participants in the baseline condition indicated feeling more in control when choosing a size during the uncertain promotion ( $M = 3.17$ ,  $SD = 1.39$ ) than when there was no uncertain promotion ( $M = 2.69$ ,  $SD = 1.47$ ),  $F(1, 296) = 4.65$ ,  $p < .05$ ,  $\eta^2 = .015$ . This pattern was eliminated in the high power condition,  $p = .16$ . Finally, we conducted a mediated moderation analysis (Hayes 2012; Model 8). Perceived control mediated size choices in the baseline condition (95% CI: .002, .129), but not in the high power condition (95% CI:  $-.096$ , .003). These results confirmed that consumers supersize as a way of enhancing control over a desirable but extremely unlikely outcome, which is eliminated when consumers' feeling of power is reinforced.

Promotional lotteries account for over \$1.8 billion in annual marketing expenditures in the U.S. alone (Smith, 2009). McDonald's *Monopoly* and Tim Hortons' *Roll-up-the-Rim* are but two examples of a prevalent industry practice. Our findings converge with anecdotal evidence to suggest that consumers do indeed tend to supersize their product choices during lottery promotions. Consistent with prior evidence suggesting a link between larger products and control (Dubois et al., 2011), we found that the act of supersizing elevates a sense of control in a scenario where people would otherwise have no power to control the odds.

Possessing a feeling of control has long been considered a fundamental human motivation. Given that the odds of winning the grand prize in any lottery is extraordinarily small, it is not surprising that people look to cues that they believe influences the outcomes beyond their reach. While the cues and superstitions that people look

to range from the subtle to the outlandish (Damisch et al., 2010), researchers have yet to explore how a variety of novel ways of entering a lottery might affect consumer beliefs about their chances. This represents a unique contribution of the current work. Rationally speaking, the decision of how to enter a lottery should not affect one's odds. And yet, if the goal is to gain a sense of control, supersizing may serve as a way of coping with the insurmountable odds associated with the desirable grand prize.

# Green Experiences: Using Green Products Improves the Accompanying Consumption Experience

Ali Tezer, HEC Montréal, Canada  
H. Onur Bodur, Concordia University, Canada

## EXTENDED ABSTRACT

The current research examines how using green products (e.g., environmentally friendly headphones) influences the enjoyment of the accompanying consumption experience (e.g., listening to music). Results reveal that consumers enjoy accompanying experiences more with green (vs. conventional) products and feelings of warm glow drive this effect.

Green products are available to consumers in various product categories but research on how green products influence consumer behavior at the consumption stage is scarce. In order to predict how using green products would influence the consumption experience, we draw from research on warm glow.

Theory of warm glow giving posits that people feel good upon a prosocial behavior, including proenvironmental behavior (Andreoni 1990; Giebelhausen et al. 2016). One thing common in research on warm glow is that people make a conscious choice to behave in a prosocial manner (e.g., donation). Extending this stream of research, we suggest that simply using a green product, even if the product is given to consumer without choice, will elicit warm glow feelings. In case the green product (e.g., a pair of headphones) has an accompanying experience (e.g., listening to music), the warm glow feelings that arise due to using green products will enhance the enjoyment of the consumption experience.

In the first experiment, sixty undergraduate students participated in a music consumption study (43.3% females;  $M_{\text{age}} = 21.53$ ;  $SD = 2.80$ ) and listened to 45-second excerpts from three songs. Results revealed that participants who were told the headphones were produced from recycled materials enjoyed listening to songs more than those who did not receive such an information (1 = not at all enjoyable, 7 = enjoyable;  $M_{\text{green}} = 4.64$ ;  $SD = .84$  vs.  $M_{\text{conventional}} = 4.09$ ;  $SD = 1.02$ ;  $F(1, 58) = 5.33$ ;  $p = .025$ ;  $\eta_p^2 = .084$ ).

The second experiment was a short-essay task. Sixty five undergraduate students were given a pen to write a short essay on how they spend their spare time (49.2% females;  $M_{\text{age}} = 20.95$ ;  $SD = 2.18$ ). In the green product condition, participants were told that the pen was produced from recycled materials. In the comparison group, the pen was presented as the recipient of “The Most Practical Product of the Last Decade” award. After writing the short essay, enjoyment of writing (1 = not at all, 9 = very much) and feelings of warm glow ( $\alpha = .85$ ).

Results revealed that participants in the green pen condition ( $M = 5.55$ ;  $SD = 2.14$ ) enjoyed writing the short-essay,  $\eta_p^2 = .068$ ). Furthermore, the indirect effect of product type on enjoyment of experience through warm glow ratings revealed an indirect-only mediation ( $\beta_{\text{indirect}} = .75$ ;  $SE = .31$ ; 95% CI = [.26; 1.51]).

Experiment 3 tests whether the positive effect of using green (vs. conventional) on the enjoyment of the accompanying consumption experiences can be generalized to strength-related products. Eighty undergraduate students participated in a dishware sanitization task (40% females;  $M_{\text{age}} = 20.69$ ;  $SD = 2.37$ ) were given a dishware sanitizer. In the green product condition, participants learned that the dishware sanitizer is made with plant-based and biodegradable ingredients. Participants in the conventional product condition did not receive this piece of information. Next, participants sanitized dishware and reported how much they enjoyed cleaning the dishes (1 = not at all, 9 = very much) and warm glow ( $\alpha = .96$ ).

Participants who cleaned the tableware with the green sanitizing product ( $M = 5.78$ ,  $SD = 2.02$ ) enjoyed the experience more than those who used the conventional sanitizing product ( $M = 4.70$ ,  $SD = 2.37$ ;  $F(1, 78) = 4.78$ ,  $p = .032$ ,  $\eta_p^2 = .058$ ). Mediation analysis indicated an indirect-only mediation through feelings of warm glow ( $\beta_{\text{indirect}} = .70$ ,  $SE = .33$ , 95% CI = [.07; 1.38]).

Experiment 4 tests whether negative beliefs about green products serves as a boundary condition. One hundred and eighty-one undergraduate students were given a grip ball to do a set of hand exercises (54.7% females;  $M_{\text{age}} = 21.75$ ;  $SD = 3.53$ ). Prior to the hand exercises, half of the participants learned about a fictitious research report which found that green products have negligible environmental impact. Participants in the baseline condition did not receive this information. In the green product condition, participants were told that the grip ball was environmentally friendly. Participants in the conventional product condition did not receive such information. Next, participants did four hand exercises and reported enjoyment (1 = not at all, 9 = very much) and warm glow.

In the baseline condition, participants who used the green product ( $M = 6.15$ ;  $SD = 1.41$ ) enjoyed the hand exercise more than those who used the conventional one ( $M = 5.28$ ;  $SD = 1.62$ ;  $F(1, 177) = 6.40$ ;  $p = .012$ ,  $\eta_p^2 = .035$ ). However, among participants who were told that the environmental impact of green products is negligible, the enjoyment of the exercise did not vary as a function of product type ( $M_{\text{green}} = 5.10$  vs.  $M_{\text{conventional}} = 5.40$ ,  $F(1, 177) < .1$ ,  $p > .30$ ,  $\eta_p^2 < .01$ ). Furthermore, in the baseline condition, a significant indirect effect of warm glow was observed ( $\beta_{\text{indirect}} = .25$ ;  $SE = .11$ ; 95% CI [.04, .49]). In the negligible impact condition, the indirect effect of warm glow was absent ( $\beta_{\text{indirect}} = -.03$ ;  $SE = .12$ ; 95% CI [-.27, .20]).

The current research examines the effect of green products at consumption stage. More importantly, vast amount of research documents potential negative effects of green product attributes (Luchs et al. 2011; Newman et al. 2014). The current research presents a novel and positive effect of green products on the consumption experience and extends research on green products. The current research further contributes to research on warm glow by showing that even without making a conscious choice to engage in a prosocial behavior, using green products leads to warm glow. From a managerial standpoint, the current research shows that when it comes to products used to consume experiences, brands can benefit from going green.

# Indigenous Trust and Readiness towards Development

Ding Hooi Ting, Universiti Teknologi PETRONAS, Malaysia

## EXTENDED ABSTRACT

The primary consumption of indigenous people across the world is related mostly to the jungle and its produce. The consumption practices that stem from this primary consumption and its relatedness to the jungle are vivid in most indigenous culture and practices. In other words, consumption is demonstrated by the active social clustering (Coleman & Williams, 2013)—the dynamics of the interactions between individuals and dyadic ties, and other social interactions between actors. The interaction of these will jointly develop the social identity and attachment.

According to Lichrou, O'Malley, and Patterson (2014) sense of place integrates place attachment and place meanings. The jungle becomes their sanctuary and living sources. The reliance on the jungle becomes inseparable from their lives. Scannell and Gifford (2017) asserted that most people have at least one place to which they are emotionally attached. Place attachment refers to the experience of long-term affective bond to a specific geographic area and the meaning assigned to that bond (Ramkissoon, Weiler, & Smith, 2012) and that place becomes one anchor of identity (Anton & Lawrence, 2014; Hay, 1998) and to regulate affect (Schmalz & Orth, 2012). But with the new developments, the urge to modernize the internal and remote areas becomes one of the development agendas.

The objective of this study is to explore the influence of place attachment (the emotional and functional ties that connect the indigenous communities to their home), trust towards development and the readiness of the community to embrace change. The study areas are non-tourist areas.

In Malaysia, the development of the lands of the indigenous communities has spelt out scepticism and distrust towards the main streams. The following excerpts painted the initial picture (Mah Meri), "My child, I hope that you are here with good intention..."

The impact of change (disruption) to place attachment has altered the bonds between person and location that are typically latent (Chen, Dwyer, & Firth, 2014; Devine-Wright, 2009). The Social Representations theory (Moscovici, 1988) is used to understand the study context—the emphasis placed by the disruption within the "common senses of the scientific inquiries" (a contradiction between scientific knowledge), and the consensual universe of social representation through power relations between different actors.

The respondents from this study are indigenous who were born and raised up in the remote areas. In order to ensure the reliability of the data collected, these indigenous must be either still staying in the remote areas and must have at least stayed in the remote areas for 15 years. Five of the ethnic group in Sarawak, Malaysia (Kayan, Penan, Kenyah, Iban and Kelabit indigenous ethnic groups) that the researchers visited is located far into the remote areas—five to eight hours of four-wheel rides into the bumpy forest tracks that are opened by timber loggers. The other four ethnic group in Peninsula Malaysia (Mah Meri, Kensiu, Temuan and Kintaq ethnic) are easily accessible through tar road.

There were two study phases in this study; study 1— basic questionnaire survey and study 2— phenomenology. A basic questionnaire on the place attachment was distributed to 525 respondents in these villages—place identity and place dependence (Williams, Patterson, Roggenbuck, & Watson, 1992; Williams & Vaske, 2003),

nature bonding (Kals, Schumacher, & Montada, 1999; Schultz, 2001), social bonding (Kyle, Graefe, & Manning, 2005), connections to family and friends (Raymond, 2009) and the life satisfaction scale (Diener, Emmons, Larsen, & Griffin, 1985), on a seven-point Likert scale (1 = "strongly disagree," 7 = "strongly agree").

From the data collected, Cronbach's alpha measurement for internal consistency was computed for the different dimensions. Reliability values for all dimensions were above .80. A simple ANOVA analysis to test the surveyed questionnaire (whether there are any differences among the indigenous groups). A test on the equality of means suggests that they are insignificant ( $p > .05$ ), hence there are no differences among the indigenous groups on their perceptions.

In study 2, the researchers spent about six days in each village or settlements. In each village or settlements, between 12 – 15 indigenous people were recruited to understand the study context. Altogether, 117 informants spoke about their life-story. The informants were asked about their life in the jungle, the symbiosis between them and the jungle, the disruption caused by external parties, and how they manage their life after a disruption. Since the researchers stayed with the indigenous, the interviews and dialogues take place throughout the stays and visits around the places in the villages.

Interview findings from 117 informants revealed that the indigenous community associates the jungle with their life. The consumption of the jungle produce has provided them with the strong attachment as their life lingers around the jungle. The following themes and categories were extracted from the analyses: Attachment; Lifestyle; Sustenance; Integration; Disruption; Coping; Readiness.

With the vast development and the philosophies of the government underpinning the economic and welfare booster of the indigenous communities, many plans to develop the remote areas and the communities have taken place. Though the planned development could be beneficial, for many tribal communities, the conceptualization and implementation of development are themselves disparate from the indigenous epistemologies and indigenous values and systems (Chino & DeBruyn, 2006). However, the indigenous communities have a different set of definition as opposed to those of the mainstream. The value system and the consumption practices of the indigenous communities are far underexplored. In most cases, the development mindsets are different from what the indigenous needs.

The limitation of this study lies in the original understanding of the indigenous practices and value system. Though the researchers have good exposure and sound knowledge on the indigenous communities, the underpinning indigenous values and narratives are never understood by external parties, which compromises the richness of the study.

This study will shed light on the mainstream and development planners to re-consider their ambitious development thrust unto the indigenous homes and jungle. The sensitivity of the indigenous communities and the environment should be fully understood before further adversities towards the wealth of the indigenous values and system vanish.

# The Effect of Fertility on Women's Word-of-Mouth Behavior

Sevincgul Ulu, Rutgers University, USA  
Kristina Durante, Rutgers University, USA  
Jonah Berger, University of Pennsylvania, USA  
Aekyoung Kim, Rutgers University, USA

## EXTENDED ABSTRACT

The current research explores whether fertility influences women's desire to share word-of-mouth (WOM). We propose that women share more WOM near the fertile phase of the ovulatory cycle and do so with other women, not men. Sharing more near ovulation may function to form alliances with other women and mitigate mate competition.

The ovulatory cycle spans about 28 days and women can become pregnant only during the days of peak fertility near ovulation. Research finds that ovulation influences women's mating motivations and consequently women's behavior (Durante et al. 2011; Thornhill and Gangestad 2008). For instance, near ovulation, women are more sexually attracted to men who are socially dominant and have symmetrical, attractive faces (Durante et al. 2012; Gildersleeve, Haselton, and Fales 2014). And, fertility also enhances women's desire to compete with other women (Durante et al. 2014). For example, fertility enhances women's motivation to appear more attractive and dress sexier especially when there are many other desirable women in the local area (Durante et al. 2011).

Some research hints at the possibility that women may become more social at ovulation. Research finds that ovulating women are more likely to volunteer and have an increased desire to attend social events (Fessler 2003; Haselton and Gangestad 2006). But, it is not clear whether women share more WOM near ovulation and if so with whom. Because the first hurdle to attracting a high quality mate is to mitigate competition with rivals (Durante et al. 2014), we propose that an increase in WOM at ovulation may be related to competition, not courtship. If so, then women's WOM at ovulation should be directed toward women, not men. Finally, because WOM is a form of social grooming/bonding (Berger 2014; Dunbar 1998), and female non-human primates form alliances with select females to gain support in competitive interactions with rivals (Seyfarth 1980), we predicted that women's WOM at high fertility is likely related to alliance formation.

Study 1 was a field study and tracked women's Facebook activity across the cycle to test the following predictions. First, we predicted a positive association between fertility within the cycle and women's activity on social media. Second, we tested whether women's activity on social media was directed toward men or other women. Participants provided a screenshot of their Facebook activity log for a 30-day period and we tracked each woman's fertility by using hormone tests to detect ovulation. There was a positive association between fertility and social media activity ( $p = .03$ ). As fertility within the cycle increased, so too did women's activity on Facebook. Further analysis using the activity directed toward other users revealed a significant fertility by target gender interaction ( $p = .035$ ). There was a positive effect of fertility on Facebook activity directed toward other women ( $p = .024$ , Figure 1), not men ( $p = .43$ ). One limitation of the Facebook study is that there might be more females on Facebook (Lin and Lu 2011) and this may be the reason fertility was significantly related to communicating with other women, but not men. Thus, study 2 was designed to further test the boundary condition of target gender in an experiment using a large sample of women

Study 2 was designed to further investigate whether the fertility-regulated-increase in women's desire to share information is targeted toward other women, men, or both. This study used a forced-choice question to determine the gender of target person and a different method of assessing fertility status. Five hundred and twenty-one women (Mean age = 29.9) participated for payment via MTurk. Consistent with our prediction, a logit analysis with target gender and conception probability revealed a significant main effect of conception probability ( $\beta = -5.93$ ,  $z = -2.09$ ,  $p < 0.04$ ). In addition to a main effect of target gender, there was no effect of fertility on general sociability,  $p = .39$ , and no interactions emerged when sociability was entered into the full model. This provides additional evidence that the effect of fertility on WOM is more strongly related to intra-sexual competitive motivations at high fertility, as opposed to fertility activating a general desire to socialize with others.

Study 3 aimed to replicate the findings of Study 1 and Study 2 in an experimental design. We tested whether fertility increases women's desire to share information in a lab environment and used an online chat platform option for the communication tool (high vs. low fertility-confirmed via hormone tests). Participants indicated whether they wanted to share information about a product or service they recently bought in a live online chat with another woman. Within subject analysis showed that women were more interested in sharing at high versus low fertility ( $p = .006$ ).

Study 4 tested whether fertility-regulated WOM functions to form alliances with other women. To determine whether the effect is specific to mating contexts, Study 4 included both mating and non-mating experimental conditions. Participants imagined being at a party and having a conversation with two women—Sarah and Tracy—and one man. Half of the participants were told that Sarah and Tracy were fellow partygoers and that the man was their romantic partner (mating condition). The other half was told Sarah and Tracy were work colleagues and the man (Jon) was their supervisor (non-mating condition). In both situations, Sarah was the rival and Tracy the potential ally. In the non-mating condition, Sarah was up for the same promotion as the participant. In the mating condition, Sarah was flirting with the participant's partner. Participants then made two forced-choice decisions about who to share WOM with: Sarah or Tracy. There was a significant fertility by condition interaction ( $p = .007$ ). In the mating condition, women were significantly more likely to choose to share WOM with Tracy (non-rival choice) compared to Sarah (rival choice) ( $p = .0006$ ), suggesting that women are using WOM to form an alliance when faced with a mating-related threat at high fertility. There was no effect of fertility in the non-mating condition ( $p = .82$ ).

Four studies found that fertility positively influenced women's social media activity and desire to share WOM with other women, not men. The effect of fertility on WOM may function to build alliances with other women to ensure coalitionary support in mating-related competitive interactions. Our findings can offer guidelines for practitioners to optimize the benefits of WOM by personalizing the timing of the deals/campaigns in accordance with women's cycles. Ovulating women might be especially responsive to advertising, promotions, and messages that emphasize friendship and alliance messages relative to other women.

### Implications

Broadly, documenting a shift in women's tendency for WOM communication at the peak fertility has implications for understanding how mating goals in general affect women's information sharing behavior. The results offer important managerial insights regarding the role of hormonal changes on women's WOM behavior.

Our findings can offer guidelines for practitioners to optimize the benefits of WOM by personalizing the timing of the deals/campaigns in accordance with women's cycles. More than 200 fertility tracking apps are available in the market and they are downloaded by more than 200 million people. Companies can partner with these apps and use their data to track women's fertility. Additional to apps, big companies can use their own database to pattern women customers' shopping behavior and calculate their cycles by just tracking behavior change of the women. Ovulating women might be especially responsive to advertising, promotions, and messages that emphasize friendship and alliance messages relative to other women. For example, messages like "show how good friend you are" or "gain other women's trust" might be more impactful to catch their attention. In other words, companies can benefit from hormone cycles with manipulation of message content. Similarly, marketers may receive different responses from female consumers depending on where the latter are in their menstrual cycle. Although marketers are unable to recognize women's cycle information directly, they can serve promotional messages directly through various fertility tracking apps or use individual purchase histories to forecast cycle phase and adjust the timing of promotional mails/emails. To persuade female consumers more efficiently, marketers might send different types of promotion messages for different phases of the cycle.

Additional to promotions, since high fertile women have a tendency to share the news with other women, companies can ask female consumers to share their feedback or leave a review during their fertile period. Companies can create more buzz and better feedback system by managing their strategies according to the women cycles.

### Limitation and Future Studies

Not unlike other empirical research efforts, the results presented in this study are limited by a number of factors—many of which can be addressed in future studies. First, we do not know which type of WOM women would share during ovulation (e.g., negative or positive information). Second, why do women share more during ovulation? There are two potential reasons. First, it can be related to status orientation. High fertile women would like to show other women that "they are better" by sharing the information. The second possibility is that women can want to be friends with others and expand their network for future communication. They can be examined as a future study.

We did not examine how ovulation alters women's WOM behavior depending on their current relationship status. It will be an

intriguing question to test whether ovulation differently affects desire in information sharing behavior when women are single or in committed relationships.

Finally, to enhance ecological validity and to demonstrate in the real world the effect of women's fertility on WOM behavior, researchers might consider directly investigating real purchase secondary data. For example, women's responses to email promotions using various types of messages across the cycle can show the real world impact of the fertility. It is also possible to examine the relevant patterns of WOM behavior by observing a wide range of behaviors during their cycle. Women might post on social network sites about the brands and recommend brand pages to her friends more frequently near ovulation.

# Cohesion or Coercion? Why Coordinated Behavior Backfires in Marketing Contexts

Noah VanBergen, University of Cincinnati, USA

## EXTENDED ABSTRACT

Consumers often see brands and other organizations in the marketplace engaging in various actions. Moreover, subordinate representatives of an overarching organization (e.g., sub-brands, product lines, branches, departments, etc.) can each engage in actions that may or may not be the same as other representatives from the same organization. For example, NFL teams have raised awareness for breast cancer for many years, and each team performed the same actions to promote this unified cause. However, in 2017, the campaign changed such that teams could elect to support different types of cancers—teams performed different actions. The present research asks which strategy consumers perceive to be more effective: Should organizational actors coordinate their actions, or should they engage in various actions?

Previous research in entitativity provides one potential answer. Entitativity refers to the extent to which individuals are perceived to form a single coherent group (Hamilton and Sherman 1996). This literature has demonstrated that when group members coordinate their actions, the group is perceived as more competent (Callahan and Ledgerwood 2016; Ip, Chiu, and Wan 2006). Thus, entitativity suggests that organizational actions should be coordinated, not varied.

However, I propose that consumers apply a different set of assumptions about the motivating force behind actions performed by organizational entities (vs. individual people): Individual people are assumed to have agency over their own actions; therefore, coordination is a signal of group cohesiveness and increases perceived competence (Ip et al. 2006). On the other hand, organizational actions are determined by superordinate levels of the hierarchy. Therefore, coordination may signal coercion rather than cohesiveness, whereas non-coordination may signal non-coercion—i.e., that subordinate entities have agency over their actions. If this is the case, observing varied (vs. coordinated) actions should increase the perceived impact of the actions.

I tested these predictions across four studies. Study 1 tests my main hypothesis using a three-cell design with  $N=106$  Mturk participants. I described a fictitious corporation comprised of four brands engaging in a charitable campaign. I manipulated whether each brand performed the same actions in this campaign (i.e., donating the same percentage and running the campaign during the same time period) or performed different actions (i.e., donating different percentages during a different time period). I also included a control condition that did not specify donation percentages or time frames. The dependent measure was the perceived impact of the campaign. Results showed significantly higher perceived impact of varied actions ( $M=4.85$ ) than coordinated actions ( $M=4.08$ ;  $p=.025$ ). The control condition was equivalent to the varied condition ( $M=4.74$ ).

Study 2 built on study 1 by using a different (non-numerical) manipulation of actions in a two-cell design with  $N=106$  undergraduates. I described a fictitious brand comprised of four sub-brands engaging in a philanthropic campaign. Each sub-brand donated the same percentage of revenue in each condition; however, in the coordinated action condition, all the money raised went to the same cause, whereas four different targets received donations in the varied action condition. I measured perceptions of the campaign's success as well as perceptions of each sub-brand's agency in the campaign. Results showed that varied actions ( $M=4.92$ ) significantly increased perceived success ( $M_{\text{coordinated}}=4.35$ ,  $p=.04$ ). I also found that varied (vs. coordinated) actions increased the perceived role of the sub-

brands in determining the details of the campaign ( $M_{\text{varied}}=5.48$  vs.  $M_{\text{coordinated}}=6.15$ ;  $p=.017$ ), that each sub-brand had more freedom ( $M_{\text{varied}}=3.04$  vs.  $M_{\text{coordinated}}=2.39$ ;  $p=.028$ ), and that each sub-brand contributed more to overall success ( $M_{\text{varied}}=4.37$  vs.  $M_{\text{coordinated}}=3.78$ ;  $p=.029$ ). Further, agency perceptions mediated the impact of varied (vs. coordinated) actions on perceived campaign success.

Study 3 extended the investigation of varied vs. coordinated actions beyond the donation context. I also aimed to rule out a potential alternative explanation for the above results, whereby consumers respond most favorably to scenarios that depict both a source of variability and a source of coordination (e.g., donating different amounts to the same cause, or vice versa). To rule this out, study 3 used a 3-cell design with  $N=179$  undergraduate business students in which I described university departments implementing a campaign to make campus greener: In the same-same condition, the same goal (increase recycling) was served by the same actions. In the same-different condition, this same goal was served by four different actions. In the different-different condition, different goals (recycling, energy use, water conservation, and emission reduction) were served by four different actions. The dependent measure was perceived impact of the campaign, and I again measured agency perceptions. Results showed that both the same-different ( $M=5.13$ ) and different-different ( $M=5.23$ ) conditions led to greater perceived impact than the same-same condition ( $M=4.41$ ,  $ps<.01$ ). This pattern was also found for agency perceptions, which mediated perceived impact.

My final study aimed to demonstrate when varied (vs. coordinated) actions will no longer improve perceived success of organizational actions by moderating the process. According to my conceptualization, if agency is signaled by cues other than varied/coordinated actions, variation should no longer improve perceptions. To test this, study 4 used a 2 (action: coordinated vs. varied)  $\times$  2 (agent: corporate vs. individual) between-subject design involving  $N=203$  Mturk participants. I manipulated coordinated vs. varied actions through a non-profit campaign, similar to studies 1 and 2. I manipulated the agent by describing who made the announcement about the campaign: In the corporate (individual) condition, the company's CEO (manager of each sub-brand) made the announcement. I again measured perceived impact and agency. Results showed a significant two-way interaction on both items ( $ps<.05$ ), such that varied (vs. coordinated) actions led to greater perceived impact and greater perceived agency in the corporate condition ( $ps<.05$ ) but not the individual condition ( $ps>.08$ ). Again, perceived agency mediated perceived impact. My studies demonstrate that coordination is not always a signal of cohesiveness, and lack thereof is not necessarily negative. These results contribute to research on branding and entitativity by showing that, in hierarchical organizational contexts, varied (vs. coordinated) actions signal agency and increase perceived impact. Further, these findings relate to a wide range of consumer research interests spanning such topics as branding, charitable behavior, entitativity, and organizational behavior.

# Nostalgicising: A Performative Theory of Nostalgic Consumption

Ela Veresiu, York University, Canada

Thomas Derek Robinson, City University London, UK

Ana Babić Rosario, University of Denver, USA

## EXTENDED ABSTRACT

Nostalgia—commonly conceptualized as a longing for the past—plays an important role in shaping contemporary consumer behavior and market offerings (e.g., Belk, Ger, and Askegaard 2003; Brown, Kozinets, and Sherry 2003; Thompson and Tian 2008). However, purely retrospective nostalgia is difficult to frame in relation to marketing as a discipline, which is overall future-oriented by focusing on “unrealized potentialities” among consumers and ways to translate them into “personal needs and desires” (Zwick and Cayla 2011, 7) through branding, advertising, and other marketing mechanisms.

This conceptual paper aims to establish a performative theory of nostalgic consumption, which we term *nostalgicising*. We define *nostalgicising* as reflective (future-oriented) consumer nostalgia that is not innate or an emotion, but rather performatively enacted through five specific dimensions. Extant marketing and consumer research typically theorize that nostalgic consumption and consumers’ memory work, while occurring in the present, are retrospective in nature, and therefore inherently about the past. In contrast to this dominant view, we bridge Butler’s (1990) conceptualization of performativity with the age of crisis concept and Boym’s (2008) notion of reflective nostalgia to theorize how contemporary individuals are increasingly engaging in a performative consumption of nostalgia not to relive or remember a bygone past, but rather to playfully reflect on or reenact possible futures during a present time.

Boym (2001; 2008, 61) was the first to theorize reflective nostalgia as a playful, funny, and creative narrative that articulates “the relationship between past, present, and future.” Bradbury (2012, 341) subsequently noted that, “nostalgia is not only a longing for the way things were, but also a longing for futures that never came, or for horizons of possibilities that seem to have been foreclosed by the unfolding of events.” However, we know very little about what forms of reflectivity consumer nostalgia can take in the current age characterized by more intense and frequent global crises, ranging from coffee crises (Vega, Rosenquist, and Collins 2003) to trust crises (Humphreys and Thompson 2014). Hence, in extension, we ask: *What dimensions of reflectivity mediate nostalgic consumption in the age of crisis?*

To begin answering our research question, we first engaged in a qualitative meta-analysis of extant consumer culture theory research (e.g., Castilhos, Dolbec and Veresiu 2017; MacInnis 2011) on nostalgic consumption. Specifically, we coded 36 relevant articles for emerging themes and theoretical gaps. This allowed us to uncover what we believe is a sizeable gap in the literature, which has so far focused on either consumer-driven or producer-driven but past-oriented nostalgic consumption.

From a consumer-oriented perspective, nostalgic consumption has implied a “preference toward objects (people, places, or things) that were more common (popular, fashionable, or widely circulated) when one was younger [...] or even before birth” (Holbrook and Schindler 1991, 330). According to Belk (1988; 1990), consumers transcend their immediate confines by incorporating objects from their past and physical environment into their present identities. Researchers have demonstrated that there is something about the past that brings comfort (e.g., Rutherford and Shaw 2011). When individuals feel sad and powerless, they experience higher levels of nos-

talgia and prefer objects that provide short-term distraction from the present. Nostalgia can thus serve as a means of consumer escapism (Goulding 2000; Stewart 1988).

From a producer-oriented perspective, nostalgia presents numerous possibilities for the creation of unique market offerings. For instance, Callcott and Alvey (1991) illustrate how advertisers’ prime consumers’ personal memories and elicit nostalgia with the use of characters. Brown, Kozinets, and Sherry (2003) demonstrate that consumers resort to retro brands to connect to communities that once shared those brands, which has led Brown (2007) to develop a retro-dominant logic of marketing. Furthermore, nostalgia has been used in heritage attractions (Goulding 1999), in high street shopping (Maclaran and Brown 2001), and in cinematic experiences like remakes, sequels, and prequels (Brown 2001). From the perspective of producers or memory makers, consumers “interact with the cultural meanings of nostalgic brands and expand them into social universes composed of stories fuelled by the yearning for what is gone but not forgotten” (Giesler et al. 2014). Hence, more than one type of nostalgia exists.

Yet, the distinctions of consumer-driven or producer-driven nostalgic consumption summarized above all focus on the past-orientation of nostalgia rather than also including nostalgia’s future-facing potential. Using extant theory outside the field of marketing and consumer research, we offer an extension to the study of nostalgic consumption: reflective consumer nostalgia. As such, we are able to shift the focus to future-oriented nostalgic consumption. Following Butler’s (1990, 25) conceptualization of gender performativity, where “gender is always a doing, though not a doing by a subject who might be said to pre-exist the deed,” we argue that nostalgia is not a pre-existing (innate) emotion, but rather a narrative that emerges as individuals engage in doing the act of reflecting across five different dimensions which shape the construction of self in an age of crisis: language, space, social systems, community, and style. Lastly, we argue that reflective consumer nostalgia, rather than stressing continuity or flow of consumer time, plays an important structuring role in producing the social imaginary resources necessary for articulating a temporal rupture. That is, *nostalgicising* allows consumers to playfully engage with the future, while living in the present, using past-oriented market offerings.

We see reflective consumer nostalgia as making “a project of *oneself*” (Zwick and Cayla 2011, 7) by introducing new possibilities for the future. Thus, rather than merely being mobilized in regard to “specific preferences and limitations of the capitalist present” (Brunk, Giesler, and Hartman 2017, 2), reflective consumer nostalgia engages with the social imaginary of the future (Castoriadis 1987). This process plays a pivotal role by replenishing the symbolic resources available for “imaginative anticipation of, or speculation about, the future” (Campbell 1987, 83). As such, *nostalgicising* contributes to the work investigating the dimension of time in consumer behavior (e.g., Woermann and Rokka 2015). However, unlike Woermann and Rokka (2015) which emphasizes the present and continuity of time-flow, our study shows how the past can inform imagined futures and horizons of expectation.

# Social Class and Prosocial Behaviors

Yan Vieites, FGV/EBAPE, Brazil

Rafael Goldszmidt, FGV/EBAPE, Brazil

Eduardo B. Andrade, FGV/EBAPE, Brazil

## EXTENDED ABSTRACT

Consumer researchers have long been interested in the association between social class and consumer preferences or “tastes” (Henry and Caldwell 2018; Martineau 1958). They have also shown interest in prosocial behavior and what influences prosociality (Goswami and Urmitsky 2016; Simpson, White, and Laran 2018). With inequality growing in many regions of the world (OECD 2015) “title” : “In it Together: Why Less Inequality Benefits All”, “type” : “book” }, “uris” : [ “http://www.mendeley.com/documents/?uuid=abd51e4f-a22a-49e1-b3a9-76b7169a303d” ] } ], “mendeley” : { “formattedCitation” : “(OECD 2015 and charity institutions increasingly competing for funds (Weerawardena, McDonald, and Mort 2010), understanding the role played by social class on prosocial acts becomes of major importance. In the present research, we examine how social class relates to prosociality.

Although psychologists and economists have recently delved into this topic, there are a few distinguishable gaps. First, the evidence is mixed and still incipient. While some have documented that those who have less give more (Chen, Zhu, and Chen 2013; Côté, House, and Willer 2015; Guinote et al. 2015; Piff et al. 2010) including many children left behind by parents who had migrated to urban areas for work, played the DG. Stickers comprised the resource, while recipients in the game were assumed to be either their friends or strangers, with the social distance (i.e., strangers compared to friends, others have proposed and shown that affluent people donate, help, and volunteer more than those with less resources (Benenson, Pascoe, and Radmore 2007; Gittell and Tebaldi 2006; Korndörfer, Egloff, and Schmukle 2015). Second, the vast majority of the studies have been conducted in nations where the levels of poverty and inequality are relatively low, which leaves open the question of how social class and prosociality would relate to one another in societies where extreme inequality prevails and resource scarcity can be shockingly high. Finally, the literature has paid little attention to the potential interactions between social class and type of prosocial behavior.

We address these gaps in a series of three field studies by examining the extent to which coming from the opposite ends of the socioeconomic spectrum in a highly unequal region influences different prosocial behaviors as well as the same prosocial behavior serving different purposes. Given the incipency of the phenomenon under investigation, the plausibility of the conflicting mechanisms, and the array of prosocial acts examined, we deliberately chose to follow an inductive path in study 1. More precise hypotheses are established prior to studies 2 and 3.

Study 1 examined the relationship between social class and prosociality on 13 behaviors originated from a qualitative pilot study ( $n=56$ ). Four hundred forty-six residents from wealthy (south zone) and poor (Favela da Maré) areas of Rio de Janeiro indicated how often they performed each of the 13 prosocial behaviors in the previous year, reported the frequency of opportunities and the amount of resources they had to perform these behaviors, and filled a socio-demographic questionnaire. A series of ordered logistic regressions indicate that social class is overwhelmingly negatively associated with prosociality. In fact, those occupying higher social classes reported behaving less prosocially in all behaviors, except for donating money and donating blood. While donating blood presented a consistently

positive relationship with social class, monetary donations were more nuanced. Although money donations increased with social class when no opportunity and resource controls were included, the relationship vanished when these two variables were accounted for.

The subsequent studies sought to conceptually replicate the findings from study 1 in a consequential scenario. Since it is difficult to assess all 13 behaviors, studies 2 and 3 allowed participants to help or to donate to a food donation cause and/or a blood donation cause. If the results obtained in study 1 held true, we would expect a negative relationship between social class and prosocial behavior when the cause was food-related, but a positive relationship when the cause was blood-related.

In study 2, higher- and lower-class individuals were offered the opportunity to expend their time/effort to help an NGO. Four hundred twenty-five high- and low-social class individuals completed a filler questionnaire and were then told that the purported study had come to an end. However, before they had the chance to leave, respondents learned that interviewers were also collecting information about blood and food donation on behalf of a partner NGO. Participants then indicated how many of 24 possible questions they would like to answer about each topic to help the institution. Unbeknownst to participants, this choice served as our dependent variable. The interaction between social class and type of donation was consistent with our prediction ( $\beta=-.77$ ,  $t(416)=-4.00$ ,  $p<.001$ ). Higher social class individuals responded less questions about food when compared to their lower-class counterparts ( $\beta=-.56$ ,  $t(416)=-2.03$ ,  $p=.043$ ), but the tendency reversed and failed to reach significance for blood donations ( $\beta=.21$ ,  $t(416)=.74$ ,  $p=.46$ ).

In study 2, higher- and lower-class individuals were offered the opportunity to donate money to food- and/or blood-related campaigns. Three hundred and four participants received five R\$2.00 bills in return for their participation in an unrelated study. Upon completion of the filler questionnaire, respondents learned that research assistants were collecting resources for two campaigns, one related to blood donation and the other to food donation. Participants were then given two envelopes and were instructed to allocate the money they were willing to donate (including any) using the adequate envelopes and then deposit them in an urn placed a few meters away. Again, the interaction between social class and type of donation confirmed our prediction ( $\beta=-2.17$ ,  $t(296)=-3.50$ ,  $p=.001$ ). Higher class individuals donated less money than their lower-class counterparts to a cause related to food donation ( $\beta=-1.12$ ,  $t(296)=-2.89$ ,  $p=.004$ ), but donated more money to a cause related to blood donation ( $\beta=1.04$ ,  $t(296)=2.20$ ,  $p=.028$ ).

This research demonstrates that despite the general negative trend, the relationship between social class and prosocial behavior may vary as a function of the behavior under analysis, the social cause one aims to help, and even the empirical approach (i.e., whether resources and opportunities for prosociality are considered). Taken together, these findings join a burgeoning, but still very limited, body of research that progressively reconciles previous conflicting results by showing that social class is imbued with both selfishness and generosity and the degree to which these contrasting inclinations are manifested across the social spectrum is highly context-dependent (Côté et al. 2015; Kraus and Callaghan 2016; Whillans, Caruso, and Dunn 2017) contexts that can foster a sense of entitlement among

higher-income individuals that, in turn, reduces their generosity. Analyzing results of a unique nationally representative survey that included a real-stakes giving opportunity (n = 1,498).

# Small but Sincere: The Impact of Firm Size and Gratitude on the Effectiveness of Cause-Marketing Campaigns

Eline L.E. De Vries, University Carlos III Madrid, Spain

Lola C. Duque, University Carlos III Madrid, Spain

## EXTENDED ABSTRACT

Companies are increasingly forced to respond to various morality concerns of consumers and stakeholders to “do good” and behave ethically. Our study focuses on a specific strategy to do good, known as Cause-Marketing (CM). CM consists of “marketing activities that are characterized by an offer from the firm to contribute a specified amount to a designated philanthropic cause” (Varadarajan and Menon 1988, p. 60). CM enables consumers to contribute to a cause while the firm acts morally and gains profit (Pracejus and Olsen 2004).

CM seems a promising marketing strategy (Nielsen 2015). But is it effective irrespective of firm size? And what roles do perceived sincerity and feelings of gratitude play? The great majority of CM research has focused on big firms (File and Prince 1998; Lepoutre and Heene 2006), producing little insight into the effectiveness of CM campaigns for smaller firms. This gap in knowledge is particularly relevant as the proportion of firms that is small lies around 99% across Europe and the United States (European Commission, 2015; Grover and Suominen 2014). And even more important, research into the affective response of consumers to CM campaigns is lacking. The current research addresses both issues.

## Theoretical background

An obvious shortcoming of small compared to big businesses is the more limited cash budgets and access to external financial resources. This implies that, even if small businesses may want to engage in CM campaigns to support a philanthropic cause, they may need to dedicate their capital to more immediate needs.

Another shortcoming for small firms is their lack of visibility. When spending time and effort on social causes, they should relatively heavily invest in marketing expenditures to make consumers aware of their campaign. This means a further increase in costs for small firms, required to capitalize on their responsible actions (Spence, Jeurissen, and Rutherford 2000).

Taking these arguments together, we hypothesize that small firms, disadvantaged compared to big firms in terms of financial and human resources necessary to engage in charitable donations, are perceived as doing a bigger effort and hence are perceived as more sincere once they *do* contribute to a worthy cause. More specifically, we posit that consumers will infer from the company’s perceived effort put into contributing to a cause, the perceived sincerity of the company’s motives (Morales 2005). With higher levels of effort perceived as more sincere and trustworthy, signaling a real societal concern and genuine intention to support the cause.

We further argue that the perceived sincerity of a firm’s motives to engage in CM is particularly relevant for CM effectiveness as consumers who are skeptical about the company’s underlying motives to engage in the charitable behavior, will not experience feelings of gratitude, and so will not feel motivated to reciprocate the company for its efforts (McCullough et al., 2001; Morales, 2005).

Feelings of gratitude have been defined as a “positive emotion that typically flows from the perception that one has benefited from the costly, intentional, voluntary action of another person” (McCullough, Kimeldorf, and Cohen 2008, p. 4) intentional, voluntary effort on their behalf. Experiencing gratitude motivates beneficiaries to repay their benefactors and to extend generosity to third parties.

Expressions of gratitude also reinforce benefactors for their generosity. These social features distinguish gratitude from related emotions such as happiness and feelings of indebtedness. Evolutionary theories propose that gratitude is an adaptation for reciprocal altruism (the sequential exchange of costly benefits between nonrelatives. Gratitude motivates to behave pro-socially towards the benefactor (McCullough et al., 2001).

Feelings of gratitude arise even if consumers do not directly or tangibly benefit from the action (Fredrickson, 2004). Within the context of CM campaigns, the tangible benefit goes to the philanthropic cause. But on top of the firm’s contribution to the cause, we argue that consumers may be grateful towards companies engaging in CM campaigns as buying their products provides a way to contribute to the cause themselves and to satisfy their own social goals (Romani, Grappi, and Bagozzi 2013).

Our reasoning implies that, if we are right that smaller firms engaging in CM are perceived as doing a bigger effort than larger firms, and hence are perceived as more sincere, consumers will experience stronger feelings of gratitude towards small firms engaging in CM and hence are more likely to reciprocate by purchasing the CM-promoted product, translating into greater CM effectiveness for small compared to larger firms.

## Methods, Results and Discussion

In Experiment 1, a field study, we examined the impact of firm size (small/big/control) on CM effectiveness (actual purchase behavior of CM-promoted product) and the mediating role of feelings of gratitude. A mediation analysis (Hayes, 2013) confirmed that the influence of firm size on actual purchase behavior is mediated by feelings of gratitude. These findings directly support our hypotheses that the effectiveness of CM may be higher for small than for big firms, as consumers have greater feelings of gratitude towards small than towards big firms engaging in CM.

In Experiment 2 we delved deeper into the underlying reasons. Participants got a scenario describing a CM initiative. We expected and found that the effect of firm size (big/small) on CM effectiveness (purchase intention) is first mediated by perceived effort, then by perceived sincerity of motives and then by feelings of gratitude (Model 6, Hayes 2013; see Figure 1). The results confirmed our hypotheses. Compared to big firms, small firms engaging in CM are perceived as doing a bigger effort and hence score higher on perceived sincerity. As a result of these sincerity perceptions, consumers experience stronger feelings of gratitude towards small firms engaging in CM, translating into greater purchase intentions of CM-promoted products of small compared to big firms.

In conclusion, the current research is of academic and managerial relevance by being the first that examines the impact of firm size on CM effectiveness, identifying the important role of gratitude that consumers feel towards small firms for providing a charitable donation opportunity.

# Unexpected Benefit Framing: Impact of Framing a Benefit as Unexpected on Product Desire

Monica Wadhwa, Temple University, USA  
JeeHye (Christine) Kim, HKUST, China  
Amitava Chattopadhyay, INSEAD, France  
Wenbo Wang, HKUST, China

## EXTENDED ABSTRACT

Companies commonly perform pre-launch product testing. During such product testing, brands could learn that the product can deliver originally unintended benefits. We explore how brands should frame such unexpectedly discovered benefits in their marketing communication. Should they frame such a benefit as unexpected or not?

Research on intentionality suggests that when consumers believe a product benefit was intentionally designed, as opposed to unexpectedly discovered, they should infer that the company has a higher ability and motivation to develop it (Malle and Knobe 1997). Thus, this research would suggest that unexpected framing should hurt consumer preferences. An alternate possibility, arising from research on reward motivation, is that unexpected framing could positively impact consumer preferences. Specifically, this research raises the possibility that when one is in a heightened motivation to seek rewards, a benefit framed as unexpected might act as a cue leading prospective consumers to anticipate other potential benefits from the product and, thereby, increase their desire to experience the product (Spanagel and Weiss 1999, McClure, Berns and Montague 2003).

In sum, while research on intentionality suggests that unexpected benefit framing should hurt consumer preferences, research on reward motivation suggests the opposite. The current research examines the two opposing predictions.

Study-1 was run in collaboration with a retailer on WeChat. Prospective customers on the retailer's mobile store were sent an advertisement for a sunscreen, positioned against a hedonic backdrop. Ad presented two benefits of the sunscreen—UVA-rays protection and even-toning. Prospective customers either received the version of the ad that framed even-toning as unexpected or the version that did not frame it as unexpected.

A logistic regression revealed that the purchase rate for the sunscreen spray was higher when unexpected framing was used (5.70%), compared with when it was not used (4.73%;  $Wald \chi^2 = 9.96, p = .002$ ). These findings, thus, support predictions arising from research on reward motivation—unexpected framing increased sales when the reward sensitivity was heightened (when the consumption-context was hedonic).

Study-2 examined the unexpected framing effect in both hedonic and utilitarian consumption contexts. Participants imagined that they were buying a sunscreen for either an upcoming vacation (hedonic-consumption context) or a business trip (utilitarian-consumption context; Wadhwa and Zhang 2015). Participants read description of a fictitious sunscreen brand, which communicated two benefits, UVA-rays protection and even-toning. Even-toning was framed either as unexpected or as expected. Participants indicated their WTP (in USD) for the sunscreen.

In the consumption-context hedonic condition, participants indicated a higher WTP when unexpected framing was used ( $M=11.54$ ), compared with when it was not used ( $M=8.11; p = .013$ ). No such difference was found for the utilitarian consumption-context ( $p = .34$ ). Thus, unexpected framing enhanced WTP when the consumption context was hedonic, but not when it was utilitarian.

Research suggests that those high, versus low, on behavioral activation system (BAS) exhibit heightened reward sensitivity (Carver

and White 1994). We argue that the unexpected framing effect should be demonstrated among those high on BAS, but not for those low on BAS. In Study-3, participants viewed an antioxidant ad, which presented two product benefits— supports healthy skin and healthy eye-function. Healthy eye-function benefit was either framed as unexpected or as expected.

Participants indicated their WTP for the supplement, and finally responded to the BAS-scale. A regression showed a significant two-way interaction between BAS and benefit-frame ( $B = 3.93, p = .011$ ). A spotlight analysis indicated that those high on BAS (+1SD) indicated higher WTP when unexpected framing was used than when it was not used ( $B = 4.79, p = .045$ ). Those low on BAS (-1SD) revealed a non-significant effect of the benefit-frame ( $p > .1$ ).

In Studies 1-3, the benefit framed as unexpected was congruent with the product category; that is, it was not unexpected, given the product-category. It is likely that the unexpected framing effect should be attenuated when the unexpected benefit is incongruent and, therefore, is already unexpected, given the product-category. We tested this prediction in Study-4.

Participants imagined that they were buying a body lotion for a vacation and saw description for a lotion brand; this description presented two benefits. While skin-firmness was presented across conditions, the second benefit was either even toning (congruent-benefit) or aids in sleeping better (incongruent-benefit). Additionally, either both the benefits were described as expected or one of the two benefits, even-toning in the congruent condition and sleep-aid in the incongruent condition, was framed as unexpected. Participants indicated their WTP for the lotion.

In the congruent-benefit conditions, participants indicated a higher WTP when unexpected framing was used ( $M=11.08$ ), compared with when it was not used ( $M=8.95; p = .052$ ). In the incongruent-benefit conditions, unexpected framing effect was eliminated ( $p > .12$ ). These findings show that unexpected framing is a more effective communication approach, but only when the unexpected benefit is congruent with the product-category.

Study-5 examined the impact of framing an undesirable characteristic (side effect) as unexpected on product desirability. We examined whether unexpected framing could negatively impact product desire for those who have a heightened sensitivity to losses (measured by the BIS scale; Carver and White 1994).

Participants read a description of a fictitious collagen-supplement brand, which informed participants of both the benefits and the potential side effects of the supplement. One of the side effects was either framed as unexpected or neither side-effect was framed as unexpected.

Participants indicated their likelihood to purchase the supplement and then responded to the BIS scale. A regression showed a significant interaction between BIS and side-effect frame ( $B = -.43, p = .071$ ). A spotlight analysis indicated that those high on BIS (+1SD) indicated lower likelihood to purchase the supplement when unexpected framing was used, compared with when it was not used ( $B = -.80, p = .042$ ). A similar spotlight analysis revealed a non-significant effect of the frame factor for those low on BIS ( $p > .5$ ). This study shows that framed a negative feature as unexpected can reduce

***830 / Unexpected Benefit Framing: Impact of Framing a Benefit as Unexpected on Product Desire***

product desirability, especially amongst those who have a heightened sensitivity to negative outcomes.

The current research delineates when framing a product benefit as unexpected versus not, a task that can be managed by marketers during the process of marketing communication, can enhance the potential consumers' desire.

# The Upside of Incompetence: How Discounting Luxury Affects Retailer Price Image

Karen Wallach, Emory University, USA

Ryan Hamilton, Emory University, USA

Morgan Ward, Emory University, USA

## EXTENDED ABSTRACT

“Luxury” is typically defined partly by its premium pricing (Bain and Co. 2014; Grossman & Shapiro 1998; Kim & Ko 2010). Theories on luxury management emphasize that consumers draw inferences on the basis of the price of luxury offerings, and there may be a perceived skepticism when luxury products are sold at a lower price (Kapferer 2015, Uggla 2017).

While historically luxury items were rarely discounted, in recent times, retailers are breaking with tradition. For instance, both Macy’s and Lord & Taylor have recently announced plans to discount luxury cosmetics brands like Bobbi Brown and Estée Lauder across all stores (Kapner and Terlep, 2017). Likewise, in a different category, Carnival Cruise Lines has pursued a similar strategy in pricing offerings on its ships. Goods and services from “luxury” categories (e.g., steak & lobster) tend to be priced low relative to other cruise lines, where more pedestrian offerings (e.g., beach towels and sweatshirts) are comparable to competitors’ prices.

The purpose of this research is to investigate the effects of discounting luxury products, on the retailer’s overall reputation for pricing. Specifically, we examine whether discounting luxury offerings will reduce the retailer’s price image more than taking similar price reductions on non-luxury offerings.

We propose that discounting luxury items will indeed have a larger influence on price image, than discounts of the same size on non-luxury items. This prediction is based on the notion that, given the importance of premium prices in defining luxury, retailers that reduce the price of luxury items will be seen by consumers as less competent, because they don’t understand the value of their own offerings. Specifically, we propose that discounting on luxury (versus not luxury goods) will result in lower price image perceptions, which is mediated by a reduction in the perceived competence of the retailer. We tested these predictions in a series of five experiments across four distinct retail settings: a liquor store, a hair salon, a cruise line, and a mass retailer.

Our first experiment tested our prediction that discounted luxury goods and services are stronger signals of a lower price image than are similarly discounted non-luxury goods and services. The scenario for Experiment 1A was a hair salon, a service provider offering non-branded services, which were described in either luxury or non-luxury descriptive terms. We recruited participants for a paid online survey through Amazon Mechanical Turk. We randomly assigned participants to one of two conditions: discounted luxury goods or discounted non-luxury goods. Participants were given a hypothetical scenario in which they were told to imagine that they were visiting a new city and stopped into a local hair salon. They were shown a list of six services that the hair salon offered. Three of the services were luxury services, described using language meant to convey extravagance (hair rejuvenating indulgence regimen, relaxation & hydration scalp massage, balayage platinum smoothing treatment). Three of the services were non-luxury services, described using functional language (classic bang & neck cut, basic shampoo & style, standard woman’s cut & trim). Before selecting our stimuli, we performed a pretest of these hair salon services to measure perceived luxury. Results revealed that participants considered the luxury services to indeed be more of a luxury than the non-luxury services.

The six services and their prices were presented in a table, along with reference prices for the same services at the average hair salon. In the discounted luxury condition, the price of each of the 3 luxury services was less than the average salon prices for each luxury service, whereas for the discounted non-luxury condition, the price of each of the 3 non-luxury services was less than the average. In each group, the discounted prices were the same (i.e. \$17, \$19, \$24) and the non-discounted prices were the same (i.e. \$30, \$32, \$35). Thus, the total potential savings in each condition was the same. The order in which services were presented in the table was randomized across participants.

After reviewing the prices of the hair salon, all participants rated the overall price image on two items: “How would you rate the prices at this salon?” and “How would you evaluate the prices at this salon compared to other salons?” measured on a 10-point scale anchored on 1=inexpensive and 10=expensive. These questions were collapsed into a single measure of overall price image ( $\alpha = .826$ ). Throughout this research, this two-question index serves as the primary measure of price image.

As predicted, consumers in the discounted luxury condition formed a lower price image of the retailer than those in the discounted non-luxury condition. Consistent with this prediction, an analysis of variance including discounted luxury vs. discounted non-luxury as the predictor variable and overall price image as the dependent variable revealed that participants in the discounted luxury condition had a lower price image of the hair salon than participants in the discounted non-luxury condition ( $M_{lux} = 3.79$  vs.  $M_{nonlux} = 4.58$ ;  $F(1, 94) = 4.7, p = .03$ ).

This finding was replicated in Experiment 1B, in the scenario of a cruise line that sold non-branded products from both luxury and non-luxury categories. Three of the items were luxury offerings (i.e. lobster dinner, 3-course steakhouse dinner, bottle of champagne). Three of the items were non-luxury offerings (i.e. cruising tote bag, beach towel, souvenir sweatshirt). In each group, the discounted prices were the same (i.e. \$20, \$26, \$35) and the non-discounted prices were the same (i.e. \$45, \$50, \$60). Consistent with our results from Study 1A, data revealed that participants in the discounted luxury condition had a lower price image of the cruise line than participants in the discounted non-luxury condition ( $M_{lux} = 4.08$  vs.  $M_{nonlux} = 4.95$ ;  $F(1, 99) = 9.211, p = .003$ ).

The objective of Study 2 was to replicate our main effect in a different domain and to test the psychological phenomenon behind it. We further examined the impact of discounting luxury by using the hedonic category of liquor. An inherent part of luxury is the hedonic nature of the products. Indeed, alcohol purchase or consumption is predominantly related to pleasure, rather than utility. For the stimuli in Experiment 2, we test to see if the luxury vs. non-luxury brands within this category would still signal a lower price image. In this experiment, participants were shown six liquor options, described by brand name, size, and price. Three of the brands were luxury offerings (i.e. Veuve Clicquot champagne, Grey Goose vodka, and St. Germain Elderflower liqueur). Three of the brands were non-luxury offerings (Popov Vodka, Everclear Grain alcohol, and Pabst Blue Ribbon). Pretests and a manipulation check confirmed that these brands were appropriately categorized as luxury and non-luxury.

In each group, the discounted prices were the same (i.e. \$16, \$18, \$21) and the non-discounted prices were the same (i.e. \$26, \$30, \$36). Bottle sizes were manipulated to ensure appropriate pricing to marketplace standards across discounted luxury and discounted non-luxury conditions. For example, a 375 ml bottle of Veuve Clicquot champagne and a 1.5 L bottle of Popov vodka were both \$30.

Consistent with our predictions, an analysis of variance including discounted luxury vs. discounted non-luxury as the predictor variable and overall price image as the dependent variable revealed that participants in the discounted luxury condition had a lower price image of the liquor store than participants in the discounted non-luxury condition ( $M_{lux} = 4.07$  vs.  $M_{nonlux} = 4.59$ ;  $F(1, 144) = 4.76$ ,  $p = .031$ ).

Subsequently, we measured perceived competence using an index of 3 questions based on specific personality traits from Aaker's (1997) brand personality scale. The 3 questions measured on 1-10 Likert scales were: (1) "How intelligently do you think this retailer is managing prices?" (2) "What do you think of this retailer's strategy?" and (3) "What do you think of this store's owner?" After reverse coding the answers to #1, the 3 questions were collapsed into a simple measure of overall perceived competence ( $\alpha = .89$ ). The data revealed that perceptions of competence significantly mediated the relationship between our conditions (discounted luxury/discounted non-luxury) and overall price image. In a bootstrap analysis, we found that the 95% bias-corrected confidence interval for the overall size of the indirect effect excluded zero (95% CI = .0755 to .4555), suggesting a significant indirect effect. Our mediation analysis demonstrated that the overall price image of the retailer was indeed mediated by the perceived competence of the retailer.

Experiment 3 featured a 2 (time duration: short term vs. long term) x 2 (discounted group: luxury vs. non-luxury) between-subjects design. Participants were shown 6 prices from a hypothetical department store that carried both luxury (e.g. Versace jacket) and non-luxury (e.g. Rug Doctor vacuum) goods. In each group, the discounted prices were the same (i.e. \$335, \$400, \$550) and the non-discounted prices were the same (i.e. \$670, \$800, \$1100). One objective of Experiment 3 was to see if the duration of the discount (short vs. long term) would impact the inferences of price image. In the short-term condition, the discount was available for only a limited time, while in the long-term condition, the discount was discussed as being part of a permanent pricing strategy for the retailer. As it turned out, the length of the discount did not affect participants price image perceptions: short vs. long term pricing strategies were not significantly different ( $M_{short} = 4.59$  vs.  $M_{long} = 4.46$ ;  $F(1, 266) = .367$ ,  $p = .545$ ).

Experiment 3 replicated the central finding of the previous experiments: discounting luxury items resulted in a lower overall price

image than did discounts of the same size on non-luxury items ( $M_{lux} = 4.11$  vs.  $M_{nonlux} = 4.95$ ;  $F(1, 266) = 15.122$ ,  $p = .00$ ). This experiment also replicated and extended the mediation results from Experiment 2. The results showed a significant indirect effect for a mediation path through perceived competence and perceived discount size: discounted luxury items (vs. non-luxury items) resulted in a decrease in perceived competence of the retailer, which in turn increased the size of the perceived discount at the retailer, ultimately leading to a lower price image.

This research contributes to the literature on behavioral pricing by identifying discounted luxury as a category with a disproportionate influence on a retailer's price image. For retailers looking for efficient ways to lower their price image, this research suggests that discounting luxury items may be an effective strategy. Using a serial mediation model, we found that perceived competence causes the price discounts to seem larger, resulting in a lower retailer price image. However, this strategy comes with a cost to the retailer: reductions in the retailer's perceived competence in response to these discounts.

# Perceptions of Epistemic vs. Aleatory Uncertainty Affect Stock Investment

Daniel Walters, INSEAD, France

Gülden Ülkümen, University of Southern California, USA

Carsten Erner, FS Card, Inc., USA

David Tannenbaum, University of Utah, USA

Craig R. Fox, UCLA, USA

## EXTENDED ABSTRACT

The decision to invest in a stock entails uncertainty. Prior work shows that people intuitively distinguish two independent dimensions of uncertainty: (i) “epistemic” uncertainty that is seen as inherently knowable, given sufficient information; and (ii) “aleatory” uncertainty that is seen as inherently random. We hypothesized that: (1) as investors perceive more epistemic uncertainty in stocks, they will be more sensitive to their own level of ignorance, and will manage this uncertainty by seeking expert advice; and (2) as investors perceive more aleatory uncertainty in stocks, they will be more sensitive to their exposure to risk, and will manage this uncertainty by diversifying their portfolios. We tested these predictions using four incentive-compatible lab studies, one survey of self-reported investment behaviors from lay investors, and one survey of practicing financial advisors.

In Study 1A, 354 investors with at least \$1,000 in stock investments assessed their perceptions of stock market uncertainty using the Epistemic-Aleatory Rating Scale (EARS; Fox et al., 2018) and reported their own investment behaviors. Confirming our predictions, investors who perceive stock market uncertainty to be more epistemic were more likely to pay for financial advice and traded stocks more frequently. In contrast, investors who perceive stock uncertainty as more aleatory held less concentrated portfolios (i.e. a greater number of distinct stocks).

Study 1B further examines the perceptions of uncertainty across experts and lay investors. To do this, we compared perceptions of uncertainty of lay investors in study 1A to those of 37 practicing financial advisors (recruited through an executive education program at UCLA) who also evaluated stock market investing using the EARS. In a separate sample t-test we find that financial advisors perceived lower epistemic uncertainty in stock investing, compared to non-professional investors. However, perceptions of aleatory uncertainty did not differ between financial advisors and non-professional investors. This result suggests that less experienced investors may be overestimating the predictability of the stock market.

In Study 2, we recruited 201 participants from a Qualtrics panel, who read the quarterly earnings release for two companies. We experimentally manipulated epistemic uncertainty by having participants consider future company performance by elaborating on either a single outcome (singular reasoning) or a set of possible alternative outcomes (distributional reasoning), (Tannenbaum, Fox, and Ülkümen, 2017). Participants then estimated the revenues of these companies in the same quarter following year, and place 90% confidence intervals around their estimates. We had the participants rate their uncertainty about the following year revenue using the EARS. Next, we asked participants to imagine investing \$100 dollars between the two companies. Some participants were randomly selected to receive the actual payout of their investment decisions after six months.

Confirming our prediction, participants primed with aleatory uncertainty provided wider confidence intervals, than those primed with epistemic uncertainty participants. Also as predicted, participants primed with aleatory uncertainty concentrated their investments less than participants primed with epistemic uncertainty.

In Study 3, we manipulated perceptions of stock uncertainty by asking participants to read a short article about the importance of knowledge in investing (which enhanced perceived epistemic uncertainty) or how experts are often incorrect (which diminished perceived epistemic uncertainty). Next, as part of an ostensibly different study, participants invested \$50 over the next 6 months across three unfamiliar stocks. Participants then were offered research reports on the three companies for \$2, which would be deducted from the value of their investments at the end of 6 months. Finally, participants made an investment allocation across the three companies. As predicted, priming participants with higher (vs. lower) epistemic uncertainty led them to be more (less) likely to pay for financial information. Moreover, perceived epistemic uncertainty partially mediated this relationship, whereas aleatory uncertainty did not.

In Study 4, we predicted that investors would be more sensitive to financial information to the extent that they perceived stock uncertainty to be epistemic (but not aleatory). Participants indicated whether they thought Apple stock in 6 months would be: (1) above its current price of \$140 or (2) the same or below as its current price of \$140, and then chose between: (a) \$50 for sure, or (b) \$150 if their prediction about Apple is correct. Next, participants were presented with a real research report predicting that Apple stock would appreciate in the coming months, and then repeated their Apple forecast and investment choice. As predicted, company information had greater impact on willingness to invest in Apple among participants who rated stock uncertainty as more epistemic; meanwhile, aleatory uncertainty had no such effect.

In Study 5, we explored the impact of perceived aleatory uncertainty on behavior. We first assessed risk preference by asking participants to choose among chance gambles. We next presented participants one-paragraph descriptions of eight companies (from Reuters), then asked them to assess uncertainty concerning each stock’s return over the coming week on the EARS. Finally, participants predicted whether each stock would appreciate more or less than the S&P 500 over the coming week, and chose between: (a) \$30 for sure, or (b) \$90 if their stock forecast is correct. As predicted, willingness to accept investment prospects significantly increased with the interaction between rated aleatoriness of stocks and the participant’s risk tolerance; meanwhile there was no significant interaction between rated epistemicness and risk tolerance. This finding suggests that to the extent that an investor sees stock movements as random, her willingness to bet on stock movements more closely resembles her preference to bet on chance outcomes.

In sum, we find that investment behaviors are influenced by investors’ subjective perception of the two independent dimensions of uncertainty. Our results across six studies show that investors who believe that stock returns are relatively more epistemic seek information and expert advice to manage their uncertainty, whereas investors who believe that stock returns are relatively more aleatory diversify their assets to manage their uncertainty. These findings hint at the possibility that shifting beliefs about epistemic and aleatory market uncertainty may prove to be a useful intervention for improving investment decisions.

# To Trace is to Trust: From Product Traceability to Brand Trust

Jing Wan, University of Groningen, The Netherlands

Pankaj Aggarwal, University of Toronto, Canada

Min Zhao, Boston College, USA

## EXTENDED ABSTRACT

As consumers become more conscious of and concerned with the ingredients that constitute their products and how their purchases can impact the environment, they are paying more attention to the origin of their products and the process by which these products are made. The present paper examines how merely labelling products as “traceable” to their origin can help brands establish their transparency and build trust between consumers and brands.

The concept of tracing products to their origin has gained traction over the last two decades (e.g., knowing where/how the product was made; van Rijswijk and Frewer 2008). Although traceability can evoke thoughts of safety and quality to consumers (van Rijswijk et al. 2008), the ability to trace products does not necessarily provide consumers with actual safety information or the exact production process (Hobbs et al., 2005). Currently, there is little research in the marketing domain of how consumers react to traceability labels and how brands should make use of these labels to build relationships with consumers.

Individuals infer that their relationship with a partner is more intimate and close when personal information is divulged (human-to-human interactions: Aron et al. 1997; Laurenceau et al. 1998; human-to-computer: Moon 2013). Similarly, the presence of a traceability label signals the willingness of a brand to disclose information that is typically kept private, allowing consumers to infer that they may have a closer and more trusting relationship with the brand. Further, research on signaling has indicated that consumers infer low store price from price-matching policies (Srivastava and Lurie 2001), suggesting that a mere signal in the absence of factual information can still induce positive evaluations. In addition, consumers feel more confident about products when they know they can retrieve information about them from the Internet (Bhargave et al. 2016). Hence, we propose that in the presence of a traceable label, which gives consumers the option to retrieve information about production origin online, consumers would infer greater transparency of the production process, more positive qualities about the brand and its products, even in the absence of actual information. Five experiments were conducted to confirm this predicted effect.

Experiment 1 tests how the traceability label, in the absence of actual production information, can affect quality perceptions of the brand. Further, it tests how a traceability label which does not convey any ethical information measures up against an ethical label like fair trade. Participants read about a chocolate brand and were assigned to one of three conditions: control (no production information), traceable label (label-only, signaling that tracing is a possibility), and fair trade label. The brand was rated on its trustworthiness, honesty, transparency, and social responsibility. Participants in both treatment conditions reported significantly higher brand trust scores compared with the control condition; in addition, participants viewed the traceable brand just as trustworthy as the fair trade brand.

Experiment 2a and 2b examine how providing traceable *negative* information affects trust and whether or not having a traceable label can mitigate the negative effects of poor production processes. In Experiment 2a, participants read about a milk brand and were assigned to one of four conditions: control, traceable label (label-only), positive traceable information, and negative traceable information. In the latter two conditions, participants saw the traceable label and

actually “traced” production/origin information about the milk; the information consisted of positive or negative facts about the production process. The brand was rated on its trustworthiness. The presence of the traceable label improved trust ratings compared to control, with or without positive production information, suggesting that participants infer positive production processes in the presence of a traceable label, even without factual evidence. Negative information decreased trust compared with the trace label and positive-trace conditions; however, the negative-trace condition did not significantly differ from the control condition, suggesting that providing negative information about production practices under the label of traceability does not decrease trust compared with giving no information at all.

Experiment 2b used a 2 traceability label (absent vs. present) x 2 valence of information (positive vs. negative) between subjects design. All participants received information about the milk brand’s production process that was either positive (above standard) or negative (below standard). Half of the participants saw a traceability label *before* the production information. The other half received the production information without the traceable label. Participants rated the brand on its trustworthiness. Adding a traceable label to the positive information did not change trust ratings; however, when the production information was negative, preceding the negative information with a traceable label increased trust ratings compared with showing the negative information alone.

Experiment 3 investigates if traceability increases consumers’ willingness to reciprocate by sharing their own information with the brand, through increased brand trust. Participants read about a chocolate brand, and the chocolate was either traceable or not. Participants perceived the brand offering traceability as more trustworthy and they were more willing to share their personal information with the traceable brand. Level of trust mediated the relationship between presence of traceability and reciprocation.

Experiment 4 examines whether the mere presence of traceability can improve overall product evaluation, through increased brand trust. Participants read about a baking soda brand, and the baking soda was either traceable or not. Participants perceived the brand as more trustworthy and the product as more desirable when the baking soda was traceable. Level of trust mediated the relationship between presence of traceability and product evaluation.

Overall, although the mere presence of traceability is not associated with any specific ethical practice, consumers infer that the willingness of a brand to potentially disclose private information must signal transparent and socially responsible practices, similar to actual ethical labels such as fair trade. Brands that employ traceability labels indicate to consumers that they can retrieve production information on-demand, and hence, the mere presence of the label is enough to evoke trust within consumers. Our research sheds insight into the consumer inference process and offers practical recommendations to brands on strengthening their relationships with their customers.

# Show Me More! Powerlessness Drives Variety Seeking

Wangshuai Wang, Shanghai University of International Business and Economics, China

Raj Raghunathan, University of Texas at Austin, USA

Dinesh Gauri, University of Arkansas, USA

## EXTENDED ABSTRACT

People play different power roles every day. A stern boss who runs a company may be a docile son in the presence of his parents; a tender wife at home can turn into a tough professor when supervising her students. The rapid switch of power state leads to an interesting and important research question, i.e., the downstream consequences of power on human behaviors. Yet, little research speaks to the potential effect of power on variety seeking behavior, leaving an intriguing question unexplored.

We propose that feeling powerless will enhance variety-seeking behavior and that need for autonomy accounts for this effect. Prior research provides initial theoretical support for these hypotheses. For example, researchers consistently find that feeling powerless is aversive (e.g., Keltner, Gruenfeld, and Anderson 2003; Rucker and Galinsky 2008). In particular, Lammers et al. (2016) show that powerless experiences threaten individuals' perceived autonomy and freedom. Furthermore, Levav and Zhu (2009) document that freedom deprivation leads to variety seeking. We conducted five studies to test these hypotheses.

In Study 1, 77 consumers were randomly assigned to high versus low power conditions. First, they recalled an experience in which they had or lacked power (Galinsky, Gruenfeld, and Magee 2003). Then we measured need for autonomy. After that, participants were told to imagine they would be served one box of chocolate in the following 5 weeks and decide which one they would like to have for each week (Huang and Wyer 2015). Results revealed that low-power participants sought more variety than high-power ones ( $F(1, 75) = 4.78, p < .05$ ). Furthermore, a 5,000 bootstrap revealed a significant indirect effect via need for autonomy, 95% CI = [-.26, -.01].

In Study 2, 48 consumers were randomly assigned to high versus low power conditions. In this study, we adopted a more subtle manipulation of power (Chen, Lee-Chai, and Bargh 2001), whereby participants either sat in a tall chair (high power condition) or on an ottoman (low power condition). Then they completed a survey that included questions measuring a general interest in variety seeking (Fishbach, Ratner, and Zhang 2011). Specifically, participants indicated whether they preferred the same or different products in various consumption situations. Results revealed that low-power participants sought more variety than high-power ones ( $F(1, 46) = 3.87, p = .05$ ).

In Study 3, 62 undergraduate students were randomly assigned to high versus low power conditions. Another manipulation of power was adopted (Jin, He, and Zhang 2014). Specifically, each participant was told that he or she was best suited for the role of manager (high power) or subordinate (low power). Then they were asked to choose their gifts for participating in the experiment. We provided four flavors of lollipops as gifts and they could choose three lollipops of any flavors (Chen, Zheng, and Zhang 2015). Again, results revealed that low-power participants sought more variety than high-power ones ( $F(1, 60) = 3.32, p = .07$ ).

139 undergraduate students participated in Study 4. They were randomly assigned to the cells of a 3 (power: high vs. low vs. control)  $\times$  2 (need for autonomy: satiated vs. unmet) between-subjects design. In the high (low) power condition, participants were told to imagine being a boss (employee) at a company (Rucker, Dubois, and Galinsky 2011). Then participants in the satiated condition were told to imagine: It is a social norm to wear black clothes. However,

you like blue and thus often wear blue ones (Warren and Campbell, 2014). We followed Levav and Zhu (2009) to measure variety seeking by asking participants to indicate their likelihood of donating to unfamiliar charities.

A two-way ANOVA yielded a significant interaction effect ( $F(2,133) = 3.12, p < .05$ ). A contrast analysis revealed significant differences in the need for autonomy unmet condition ( $F(2,133) = 5.68, p < .001$ ), such that low power participants had a higher variety seeking intention compared with those in the high and control power conditions. In contrast, variety seeking behavior did not vary across different power levels when need for autonomy was satiated.

Study 5 provides evidence using scanner data. The data comes from Nielsen Scanner Panel data for one year on two product categories: Yogurt and Laundry Detergent. We used occupation information as the indicator of power (Rucker, Galinsky, and Dubois 2012). To classify variety seekers, we followed Trivedi and Morgan (2003) by computing the number of distinct brands that the panelists purchased.

The results showed that in high power occupations, there were more low variety seekers compared to high variety ones (55.71 % vs. 43.06 % in Yogurt; 54 % vs. 38.3 % in Laundry Detergent) while in low power occupations, there were more high variety seekers compared to low variety ones (31.94 % vs. 20 % in Yogurt; 51.06 % vs. 32 % in Laundry Detergent). We then estimated an ordered logit model and found a significant impact of high versus low power occupations (.55,  $p < .10$  for Yogurt; .62,  $p < .05$  for Laundry Detergent).

The findings from the current research carry important theoretical contributions. First, while much contemporary literature examines the interpersonal consequences of power, the current research is one of a burgeoning stream of studies that investigate how power exerts an influence on intrapersonal consumption behavior. Second, we add to the literature on compensatory consumption by demonstrating how variety seeking serves as a subtle way to deflect powerless state. Third, our research contributes to the variety seeking literature by documenting consumers' power state as a new psychological determinant of variety seeking behavior.

# Dimming the Light Offers A Creative Lens: The Impact of Ambient Illuminance on Creativity Assessment

Chen Wang, Drexel University, USA

Ravi Mehta, University of Illinois at Urbana-Champaign, USA

Rui (Juliet) Zhu, Cheung Kong Graduate School of Business, China

Jennifer Argo, University of Alberta, Canada

## EXTENDED ABSTRACT

Creative ideas are prevalent in everyday consumption. The creative professionals always hope that consumers could understand and acknowledge the creativity displayed in their work. But is it always the case? In other words, can consumers usually get the “Aha!” moment when viewing a creative work? Unfortunately, creativity is only in the eye of the beholder. As consumers are not directly involved in the creation process, oftentimes they cannot share the perspectives of the creators and appreciate their creativity (West, Kover, & Caruana, 2008).

This has raised a fundamental yet important question: How to make consumers assess creativity in a more effective way? Creative assessment is the attempt to identify or recognize creative characteristics in the assessment target (Hennessey & Amabile, 1999). While existing research has suggested some solutions such as inviting consumers into the creation process (Kover, et al., 1997), it usually requires vast investment in labor and finance. Given that contextual variables are usually inexpensive and easy to control, if researchers can start to identify ambient factors that impact consumers' creativity assessment, it would offer valuable insights into how to help consumers appreciate innovation, and ultimately enhance their product desirability and purchase intention (Horn & Salvendy, 2009). The current research aims to address this void by being the first work to identify ambient illuminance as a contextual variable to influence consumers' creative assessment.

The central thesis is that dim (vs. bright) illuminance reduces individual's inhibition, which subsequently leads to higher creativity assessments. When the illuminance is dim (vs. bright), the mind is less alert to distinguish between differential concepts, and thus less likely to filter and restrain (i.e., inhibit) irrelevant thoughts or concepts. Prior research has provided support for this argument. For example, it has been shown that darkness induces a sense of illusory anonymity thereby reducing inhibition (Zhong et al., 2010). Research on sleep behaviors also suggests that dim illuminance helps sleepiness (Lowden, Åkerstedt, & Wibom, 2004) by slowing down physiological reactions in terms of heart rate, body temperature, and cortisol production, which are highly correlated with alertness and inhibition (Lockley et al., 2006). We next argue that such reduced inhibition subsequently enhances creativity assessment. This is because reduced inhibition enables people to loosen the boundaries between concepts and consequently embrace less filtering and more open-minded processing (Enright & Beech, 1993; Green & Williams, 1999). As a result, when consumers are presented with creative ideas, they likely do not consider these concepts isolated and distinct. Rather, they are able to recognize and understand the underlying remote connections between those distal concepts. Such comprehension of the latent inter-conceptual links enables them to give higher creativity ratings of the assessment target. A set of three studies provides support for our hypotheses.

Study 1 demonstrates the main effect of ambient illuminance on creativity assessment. The ambient illuminance was manipulated by the number of lights in the room. Specifically, in the dim (bright) condition, the room was lit by 2 (20) fluorescent light tubes mounted to the ceiling, with the total luminance of 150 (1500) lux. Partici-

pants were presented with a survey packet containing five print advertisements, one per page in random order. They were asked to rate the creativity of the advertisements. As hypothesized, we found that those in the dim (vs. bright) condition assessed the presented advertisements more creative.

Study 2 examined the underlying process by testing the mediating role of inhibition. Participants completed the study in either a dimly (150 lux) or a brightly (1500 lux) lit room. To measure inhibition, they were asked to complete Hayling's sentence completion test (Burgess & Shallice, 1996; Kemps & Wilsdon, 2010). Specifically, participants were presented with two sets of sentences in which the last word was omitted. For each sentence, there was a high probability of one particular response (e.g., “George must keep his dog on a \_\_\_\_\_”). In the first set, participants were asked to provide a response that would complete the sentence in a reasonable way (e.g., “leash”). By contrast, in the second set, they were asked to provide a word that made no sense (e.g., “book”). That is, they must inhibit the rational response that easily comes to mind to have a correct answer. Participants were instructed to respond as quickly as possible within 60 seconds for each set. Hence, participants' inhibition level was scored as the ratio of the number of correctly completed sentences in the second set (i.e., nonsensical responses) on the number of correctly completed sentences in the first set (i.e., reasonable responses), controlling for the individual difference in response rate. A higher score indicated greater inhibition (Kemps & Wilsdon, 2010). Next, all participants assessed 10 novel products on how creative they thought they were. As expected, those in the dim (vs. bright) condition rated the products more creative. Further, their inhibition score mediated the effect of illuminance on creativity assessment.

Finally, Study 3 offered additional evidence of the underlying process by examining the joint effect of illuminance and inhibition (measured as trait Openness to Experience) on creativity assessment. Participants first completed the Openness to Experience scale (John & Srivastava 1999) in a room with typical illuminance (450 Lux). Next, they were led to a room where illuminance was either dim or bright. Here they completed a product evaluation task, in which they indicated willingness to buy a new and innovative product over a traditional one for five pairs of products, a behavioral measure of creativity assessment. We found that individuals who were high in openness (i.e., chronically low on inhibition) showed higher willingness to buy innovative products irrespective of the illuminance condition. However, replicating results from previous studies, dim (vs. bright) illuminance induced higher likelihood of buying innovative products for low openness (i.e., chronically high on inhibition) individuals.

Taken together, this research advances prior work by demonstrating the impact of illuminance on consumer's creativity assessment and providing evidence of the underlying mechanism. Our findings also have important practical implications for creative professionals and marketers selling novel and innovative products.

# Restrained by Resources: The Joint Effect of Scarcity Cues and Childhood Socioeconomic Status (SES) on Consumer Preference for Feasibility

Lili Wang, Zhejiang University, China  
Yanfen You, New Mexico State University, USA  
Chun-Ming Yang, Ming Chuan University, Taiwan

## EXTENDED ABSTRACT

Consumers' current socioeconomic status (SES) has been widely acknowledged as an important factor that affects various aspects of their behavior, such as aggression (Greitemeyer and Sagieglou 2016), prosocial behavior (Piff et al., 2010) and variety-seeking (Yoon and Kim 2017). However, scant marketing literature examines whether and how consumers' childhood SES affects their behavior. Compared to consumers' current SES, childhood SES represents consumers' early life environments and functions more like a latent factor. Thus, once activated by situational factors, the behavior patterns that people have formed in childhood are likely to affect their decision-making regardless of their current SES. Therefore, it is important to put childhood SES in the spotlight and to examine its interactive effect with important situational factors in shaping consumer behavior.

To address this void, we study the interplay of childhood SES and resource scarcity cues. Specifically, drawing from research on scarcity cues (Mehta and Zhu 2016; Roux, Goldsmith, and Bonezzi 2015), life history theory (Griskevicius et al. 2013; Laran and Salerno 2013; Mittal and Griskevicius 2014), and construal level theory (Liberman and Trope 1998), we propose and demonstrate that the combination of low childhood SES and resource scarcity cues leads to a low construal level and thus propels consumer preference for feasibility in product choices.

Study 1 consisted of a three-level between-subjects design (resource availability: scarcity vs. abundance vs. control) with childhood SES measured continuously. Results suggested that, for participants with lower childhood SES (-1 SD below mean), scarcity cues (vs. the control condition) increased their preference for feasibility. No significant difference was found between the abundance and control conditions. In contrast, for those with higher childhood SES (+1 SD above mean), there was no significant difference in preference for feasibility among the three conditions. As indicated by Study 1, there was no significant difference between the control and abundance conditions and that our effect was driven by scarcity. Thus, we did not include the control condition in other studies.

Study 2 utilized counterfeit products to represent products with feasibility (Jiang and Cova 2012). Results revealed a significant interaction between childhood SES and resource availability. Floodlight analysis indicated that participants who scored lower than 4.64 on childhood SES ( $B_{JN} = .49$ ,  $SE = .25$ ,  $p = .05$ ) were more likely to purchase counterfeit products after exposure to scarcity cues than after exposure to abundance cues.

Study 3 examined the underlying mechanism for the interactive effect. The results revealed a significant moderated mediation. Among those with a relatively low childhood SES (-1 SD below mean), scarcity cues primed them with a relatively low construal level, which in turn increased their preference for feasibility. Among

those with a relatively high childhood SES (+1 SD above mean), construal level did not mediate the effect of scarcity cues on product preference.

Study 4 further tested the mediation role of construal level by directly manipulating construal level. Taking low construal level condition as the base group, analysis revealed a significant three-way interaction among resource availability, childhood SES and construal level. Specifically, in the control condition, we replicated the previous interaction effect. In the low construal level condition, only the main effect of scarcity cues was significant. However, in the high construal level condition, scarcity cues led people with low childhood SES to prefer low feasibility. These results speak to the important role of construal level in driving low childhood-SES consumers' preference after exposure to scarcity cues.

Across four experiments, we examined how childhood SES and resource scarcity cues jointly affect consumers' construal level and their subsequent product choices. This research contributes to research on childhood SES, construal level theory, and resource scarcity cues.

# Foods for Sharing: The Social Value of Handmade Foods

Xin Wang, Nanjing University, China  
Chunqu Xiao, Nanjing University, China  
Xingyu Duan, Nanjing University, China  
Hong Zhu, Nanjing University, China

## EXTENDED ABSTRACT

Mass-manufactured foods are ubiquitous in busy daily life. However, consumers still search for food products with handmade feature (Pieniak, Perezcueto, and Verbeke 2009). Market surveys and academic research indicate that handmade products are more attractive than machine-made ones (Fuchs, Schreier, and Osselaer 2015; Ga et al. 2013). Why are handmade foods so popular?

Numerous research have documented the necessity of involving interpersonal relationship in food choices research. Food is widely regarded as a means of expression and a hallmark of social relationships (Cramer, Greene, and Walters 2011). The type of food we select and the amount of food we consume reflects social relationships (White and Dahl 2006) and social motives (Meiselman 2008) when we eat with others. For example, when women have relationship formation motives, their food choices are susceptible to men's choice (Hasford, Kidwell, and Lopez-Kidwell 2018). While men are influenced by females' choices when they have relationship maintenance motives (Hasford et al. 2018). Choosing handmade foods may serve as a cue to signal social motives, since handmade products are imbued with love, which assists people in conveying affection (Fuchs et al. 2015).

In the present research, we propose that the social motives to initiate or maintain a close relationship may direct people to choose handmade foods over machine-made foods. The current article contributes to our understanding of how social motives influence consumers' predilection for handmade foods and beverages. We find that, consumers prefer handmade foods when they have motives to form a relationship with a new acquaintance or maintain a relationship with a familiar person. In addition, the current article provides insights for advertisers and managers in promoting handmade foods and beverages, and implications that could improve consumers' well-being in social life.

*Hypothesis 1 Consumers prefer handmade foods and beverages to machine-made foods and beverages when they eat with others.*

*Hypothesis 2 (formation motives) The social motive to form a relationship with a new acquaintance will increase the preference towards handmade foods and beverages compared with machine-made.*

*Hypothesis 3 (maintenance motives) The social motive to maintain a close relationship will increase their preferences towards handmade foods and beverages compared with machine-made foods and beverages.*

Study 1 experimentally manipulated the foods production modes (handmade vs. machine-made) to test consumers' commensal intention. We chose nine common foods and beverages with handmade and machine-made feature: beer, burgers, chips, chocolate, coffee, cookie, ice cream, nougat and pizza. Participants (N = 782) from MTurk were randomly assigned to handmade foods condition

or machine-made foods condition. In each condition, three of the nine foods and beverages were randomly presented. They firstly reported the hunger level, then estimated the price of a unit of foods or beverages in dollar and answered whether they would like to eat/drink with others with a binary decision: yes or no. Results showed that participants were more willing to eat with others if handmade foods were available. In addition, people gave higher price estimation for handmade foods than machine-made foods. We also found the dominate process of sentimental value that led to willingness to eat with others, rather than quality and price.

Study 2 aimed to test the handmade effects according to maintenance motives. We manipulated relationship familiarity as a proxy for maintenance motives (Hasford et al. 2018). Participants were 35 male and 28 female students. The experiment was a mixed-design with eating companions (familiar person vs. unfamiliar person) as a between-subject factor, types of coffee (pour over vs. machine-made) as a within-subject factor. They were randomly assigned to one condition (with familiar vs. unfamiliar person) to imagine a chat with an acquaintance in a coffee house, and they could choose to buy pour over coffee, machine-made coffee or neither. The number of coffee types chosen by participants was significantly different across two conditions. According to adjusted standardized residuals from the Post Hoc testing, when with a familiar person, participants are more likely to choose pour over coffee, on the contrary, with an unfamiliar person, they were more likely to choose machine-made coffee (H3).

Study 3 sought to detect the social value of handmade foods and beverages according to formation motives. We induced explicit social motive to provide the process evidence. The experiment was a 2 (social motives: with vs. without, between)  $\times$  2 (process type: handmade vs. manufactured, within)  $\times$  2 (snack type: candy, cookie, within) mixed design. The dependent variable was purchase intention. Participants were 46 male and 63 female students. They imagined that they had high tea in a café together with a new acquaintance. In social motive condition, they were informed to initiate a relationship, where in no social motive condition, such information was not given. Participants in both conditions read the menu and indicated their intention to purchase cookies and candy with a 7-point scale separately. The interaction between process type and social motive was significant. In social motive condition, participants had significant higher intentions to purchase handmade snacks compared with machine-made snacks (H2). While in no social motive condition, participants showed significant higher intentions to purchase machine-made snacks.

Foods and beverages labelled as handmade are more popular than machine-made in social interaction. We are probably the first to address how individuals' social motives influence food choices process mode (handmade vs. machine-made) preferences. When having meals with acquaintances with whom people prefer to form or maintain a relationship, they would prefer handmade foods. For consumer well-beings, handmade foods signal social motivations to co-eaters, which facilitates an enjoyable part of our daily experiences in the company of other people, reduces loneliness and improves mental and emotional well-being. In practical, we suggest that companies and restaurants can use our findings to advertise handmade foods in social interaction contexts that encourages consumers to share and interact with others, which could boost sales.

# Cultural Values and Consumers' Brand Preference

Jessie J. Wang, Miami University, USA  
Ashok K. Lalwani, Indiana University, USA  
Devon Delvicchio, Miami University, USA

## EXTENDED ABSTRACT

Consumers routinely need to choose between mass-market (e.g., Häagen-Dazs) and niche brands (e.g., Halo Top), yet little research has examined the factors that influence such choices (Dalgic and Leeuw 1994). Can consumers' cultural background and orientation affect their choices? How and why? Are there any strategies firms may use to influence consumers' choices? In the current research, we propose that power distance belief (henceforth, PDB) is associated with greater risk aversion and, hence, a greater preference for mass-market over niche brands.

PDB is defined as the degree to which individuals accept and endorse hierarchy and inequalities in power (Hofstede 1984, 2001; Zhang, Winterich, and Mittal 2010). Research suggests that that people in high (vs. low) PDB societies are more likely to stay within their comfort zone and cling to the familiar (Hofstede 1984, 2001; Carl 2004). Therefore, we expected high (vs. low) PDB consumers to be more risk averse.

Risk aversion refers to one's tendency to avoid uncertainty rather than avoid loss, and a risk-averse person avoids a gamble in favor of a sure thing (Isen, Nygren, and Ashby 1988; Kahneman and Tversky 2013). Mass-market brands are seen as tried and tested by the market, and are accepted by a majority of consumers (Desarbo et al. 2002; Raj 1985; Kim and Chung 1997). We suggest that mass-market brands are perceived to be less risky because following the crowd appears less risky, compared to following a new path (Devenow and Welch 1996; Olsen 1996). Following the same logic for mass-market brands, niche brands that lack the endorsement of the majority may be perceived as risky (Munshi 2004; Huang and Chen 2006; Desarbo et al. 2002). Because risk-averse (vs. risk-taking) consumers have been found to take fewer risks associated with products (Grewal, Gotlieb, and Marmorstein 1994; Kahn and Sarin 1988; Mandel 2003), we propose that high (vs. low) PDB consumers would prefer mass-market brands to niche brands because they are more risk averse.

Furthermore, because the risk associated with a brand or a product can change depending on its use (Dowling and Staelin 1994; Campbell and Goodstein 2001), we suggest that product usage moderates the effect of PDB on brand preference. Specifically, we suggest that high (vs. low) PDB consumers prefer mass-market to niche brands in low or moderate product-usage risk contexts. However, in high product-usage risk contexts, low PDB consumers also become risk-averse and their preference for mass-market brands increases, compared to baseline conditions. In contrast, because high PDB consumers are risk averse to begin with, they should not become more risk averse when the product usage indicates risk (i.e., ceiling effect).

A multi-method approach was used to establish reliability and generalizability across four studies. Our pilot study used a secondary dataset from the footwear industry in 42 countries and revealed that countries high (vs. low) in PDB have a greater market share of mass-market, compared to niche, brands. Study 1 further ascertained the link between consumers' PDB and their preference for mass-market versus niche brands in the lab. We also gained confidence in the causal role of PDB by manipulated it in this study. A GLM revealed that the PDB significantly affected consumers' brand preference ( $F(1,144) = 4.37, p < .04$ ). A follow-up independent t-test suggested

that high (vs. low) PDB consumers preferred mass-market to niche brands ( $M_{\text{low-PDB}} = 2.39, M_{\text{high-PDB}} = 2.96; t(144) = -2.02; p < .05$ ).

Study 2 examined the mechanism underlying the relationship between PDB and brand preference. First, the effect of PDB on brand preference was significant and positive ( $\beta = .17, t(320) = 3.97, p < .001$ ), which suggested that high (vs. low) power distance consumers preferred mass-market to niche brands. Next, a bootstrapping procedure with 10,000 iterations (Zhao, Lynch, and Chen 2010) showed that the mean indirect effect of PDB on brand preference through risk aversion was negative and significant ( $\beta = -.03, SE = .01, CI95 = -.06, -.01$ ) as predicted.

Study 3 assessed a boundary condition based on product-usage context – high or moderate. A linear regression model revealed significant main effects of PDB and product usage contexts ( $ps < .05$ ). More importantly, the interaction effect of PDB x product usage contexts was also significant ( $\beta = -.27, t(240) = -2.29, p < .03$ ). A follow-up analysis (Johnson and Neyman 1936; Spiller et al. 2013) revealed that there was a significant positive effect of product usage context on brand preference for participants whose PDB score was less than 2.91 ( $B_{JN} = .33, SE = .17, p = .05$ ), but not for those whose PDB score was more than 2.91. Hence, low PDB consumers' preference for mass-market (vs. niche brands) significantly increased in the high product-usage risk contexts, compared to the moderate risk contexts. However, high PDB consumers' brand preferences did not change by varying the risk involved in product usage context, supporting H3.

The current research offers several theoretical and managerial contributions. We provide novel insights on how respondents' cultural orientation, specifically their PDB, influences preference for mass-market versus niche brands. We also shed light on the underlying mechanism by showing that consumers high (vs. low) in PDB prefer mass-market to niche brands due to a greater risk aversion. In addition, we highlight a boundary condition that identifies when low PDB consumers switch their preference to mass-market, instead of niche, brands. Our findings have implications for brand managers' promotion efforts by providing insights for firms targeting consumers who are more receptive to either mass-market or niche brands based on their PDB. Second, managers may prime consumers to be risk-averse or risk seeking which in turn is expected to influence brand preference. Third, firms can vary the product usage contexts to make some types of consumers to switch from niche to mass-market brands.

# Contagion and Product Physicality: A Study of Consumer Response to Recycled-content Products.

Qizhou Wang, University of Connecticut, USA  
David A. Norton, University of Connecticut, USA  
Robin A. Coulter, University of Connecticut, USA  
William T. Ross, Jr., University of Connecticut, USA

## EXTENDED ABSTRACT

The purchase of recycled-content products poses dilemmas for consumers. Consumers may want to preserve the environment, but simultaneously can be concerned about potential contamination resulting from prior use. We focus on understanding how prior history of recycled-content products might affect consumer perceptions and consumption of recycled goods. Specifically, we attempt to answer the following questions about consumer perceptions of recycled-content products using contagion theory. To what extent do consumers devalue certain recycled-content products, but appreciate others? To what extent do consumers perceive an essence transfer from old materials to new products—that is, would a recycled-content product inherit some internal characteristics or properties from its original materials? What are the product factors that amplify or dampen a perceived essence transfer in a current consumption context?

Prior research has suggested the importance of physical interactions in activating contagion (e.g., Newman, Diesendruck, and Bloom 2011). However, most scholars have studied physical contact as a dichotomous variable and assumed that contagion is dose-insensitive to contact (Rozin and Nemeroff 2002). By focusing on how consumers infer the amount of physical contact from product physicality and functions, we explore the relationship between consumers' anticipated physical contact and the prevailing contagion on recycled-content products. We argue that consumers should perceive greater contagion from recycled materials that have more physical contact with past users than from materials that have minimal physical contact with past users. Also, we extend this discussion to the way in which the implied physicality of recycled-content products informs consumers of the magnitude of contagion. We suggest that consumers infer different degrees of physical contact from products with different forms. For example, consumers may perceive greater physical contact with a pair of gloves that cover the entire hand than a pair of potholders which touches only the palm of the hand. We suggest that consumers should be more attentive to contagion cues when the use of a product suggests having more (vs. less) physical contact.

To test our hypotheses, we conducted three studies ( $N_1 = 132$ ;  $N_2 = 326$ ,  $N_3 = 144$ ). Study 1 and study 2 were conducted online using MTurk. Study 3 was conducted in a controlled laboratory setting. Textile recycling (i.e., recycling of linen products) was chosen as the context because it enabled us to identify: 1) a more (vs. less) desirable supplier of materials (e.g., 5-star hotel vs. a 2-star hotel); 2) recycled source material with more (vs. less) previous body contact (e.g., bed sheets vs. curtains); 3) recycled products with more (vs. less) physical body contact with the consumer (e.g., winter gloves vs. pot holder). From a managerial perspective, it is also notable that recycling of linen products becomes important because of growing expenditures on textile wastes (e.g., U.S. spent \$523 million land-filling textile waste in 2013). After reading a shopping scenario on textile recycling, participants completed several measures including purchase intention toward recycled-linen products.

The findings indicate that consumers engage in a contagion-oriented thinking process when purchasing recycled-content products that are associated with a negative context (i.e., contamination or

transfer of undesirable essence). In study 1, we showed that participants were more likely to purchase recycled-content products made with materials from a more (vs. less) desirable source ( $F(1, 128) = 8.03$ ,  $p < .1$ ). Also, participants were more likely to purchase recycled-linen products made with recycled materials that had less contact with past users than those that had more contact with past users ( $F(1, 128) = 2.80$ ,  $p < .1$ ). In study 2, we replicated the effect of physical contact with past users ( $F(1,317) = 5.62$ ,  $p < .05$ ). More importantly, we demonstrated that consumers were more likely to purchase recycled-linen products that would incur less (vs. more) physical contact with their bodies ( $F(1,317) = 4.85$ ,  $p < .05$ ). Moreover, our analysis suggests that disgust is a key mechanism underlying these effects. In study 3, we sought to test the strength of these effects in a context where consumers are interacting with actual products (e.g., dusting cloths vs. dusting gloves). We replicated prior findings and found a significant interaction effect between the degree of physical contact with past users and the degree of physical contact with current users ( $F(1,138) = 3.95$ ,  $p < .05$ ). That is, when a product is made with used, recycled materials, consumers are more likely to purchase a product that would incur less (vs. more) physical contact with their bodies during product consumption.

Prior research has suggested that consumers are more critical of recycled-content products than conventional products. We attempt to understand these attitudes through the theory of contagion. We argue that the contagion effect, derived from consumers' magical beliefs that certain essences can transfer from one to another, may explain consumer negativity toward certain recycled-content products. More importantly, we argue that when purchasing recycled-content products, consumers tend to engage in a unique evaluation process that involves both contagion-related constructs (i.e., disgust) and heuristics for conventional purchases (i.e., quality perceptions). Our research makes two contributions to the existing contagion literature. First, whereas most of the past literature has assumed that the contagion effect is insensitive to the degree of physical contact, we have demonstrated that consumer perception of contagion varies with the degree of physical contact. For example, we showed that the small difference in physical contact between wearing a pair of gloves versus using a pair of potholders facilitated different degrees of disgust among consumers. Second, we have explored how aspects of a product's physicality such as forms may influence the magnitude of the contagion effect. We expect that business managers and policy makers may find our research helpful because we have identified ways to potentially manage consumers' response to recycled-content products through the amount of perceived essence transfer.

# Product Retention (vs. Acquisition) Choices and Preference for Person-Related Features

Liad Weiss, University of Wisconsin-Madison, USA

## EXTENDED ABSTRACT

People regularly make choices about products they already own, such as which of two sneakers bought through Zappos.com to retain. However, decision research has focused on situations where choice precedes ownership, or *acquisition*, whereas situations where choice follows ownership, or *retention*, remain understudied.

Previous research finds that people use ownership as a source of information to categorize objects relative to the category of “self” (Weiss and Johar 2013; Weiss and Johar 2016); simply thinking of an item as owned (unowned) fosters item classification in (outside of) the self (Turk et al. 2011). Relatedly, classifying an item in a category makes it easier to process category-applicable (vs. -inapplicable) features of the item (Barsalou 1982; Medin 1989). Building on these findings, we suggest that simply thinking about items as already (vs. not yet) owned (and thus classifying these items as “self”) would allow one’s self-concept to facilitate the processing of information about certain item features. Specifically features like “resilience” or “daringness” that commonly apply to describe people, or *person-related* features, would become easier to process and understand. Consequently, because the information that people process more (vs. less) easily has greater impact on choice (Schwarz 2004), people may afford greater decision-weight to person-related features when people think about items as already (vs. not yet) owned, specifically when making a retention (vs. acquisition) choice. Notably, such fluency advantage in retention (vs. acquisition) choices is *not* predicted for features like “portability” or “smoothness,” which primarily are applied to describing products, or *product-related* features.

In our conceptualization, the predicted effect of thinking of items as already (vs. not-yet) owned are driven by the use of the self as an organizing category for material objects (Weiss and Johar 2018). The effect therefore should appear (disappear) when consumers (do not) mentally construe the self in terms of the objects it includes. Recent research shows that priming *product-independent* identities attenuates usage of the self as a category for objects (Weiss 2018). An identity is product-independent if carrying out that identity does *not* rely on any product. For example, carrying out the identities of “musicophile” or “walker” only requires using the physical senses (e.g., one’s hearing to enjoy music) or the physical body (e.g., one’s legs to engage in walking). This independence on the use of products render these identities *product-independent*. Conversely, carrying out the identities of “audiophile” or “hiker” necessitates specialized gear (e.g., hi-fi headphones to appreciate sound or hiking boots to hike), rendering these identities product-dependent. Thus, we predicted the effect of choice-frame to disappear following the activation of product-independent (vs. product-dependent) identities. Relatedly, self-important (vs. unimportant) identities are more integral to the self-concept (Reed II 2004) and thus can better support the utilization of the self-concept for processing information. Therefore, we expected the predicted effects to manifest mainly among individuals who consider the focal product-dependent identity as self-important.

Four studies supported the above predictions. In study 1 [2(primed-identity) x 2(search-cue-frame), between-subjects], participants in the product-independent (product-dependent) identity prime wrote two things about themselves that reflect their musicophile (audiophile) side. Participants in the already (vs. not-yet) owned frame condition imagined that they received (considered) two sets of high-quality headphones but could only keep (acquire) one. Participants then played an *incentive-compatible* word-puzzle

game that contained a total of 12 features, six person-related (e.g., “intuitive,” “smart”) and six product-related (“portable,” “smooth”). Participants did not receive the list of words to be found rather had to find as many words as they can within a 60 seconds. To test whether person-related features are easier to process for items consumers think of as already (vs. not-yet) owned, participants were asked to search words using a provided search cue, specifically the headphones that participants initially thought of either as already or as not-yet owned. Finally, all participants rated the self-importance of the identity “audiophile.” Consistent with predictions, data analysis showed a marginally significant 2-way interaction between search-cue frame and identity: framing the search cue (i.e., the headphones) as already (vs. not-yet) owned increased the number of person-related words found, but only when the primed identity was audiophile. This 2-way interaction was qualified by the importance of the identity audiophile, yielding a significant 3-way interaction. Specifically, the two-way interaction pattern described above appeared only when the identity “audiophile” was self-important.

Next, to test the predicted effects on decision weight, in Study 2a [2 (primed-identity) x 2 (choice-frame), between-subjects], participants in the product-independent (product-dependent) identity prime wrote two things about themselves that reflect their hiker (walker) side. Participants in the retention (acquisition) choice frame imagined buying (considering) two pairs of high-quality shoes, with the intent to keep (acquire) and use one of them. Participants then allocated 30 points among attributes according to their importance in choosing shoes. Two of the attributes were person-related (e.g., “outdoorsiness,” “daringness”) and two product-related (e.g., “smoothness,” “compactness”). Consistent with predictions, data analysis showed a significant 2-way interaction between choice frame and primed identity. Specifically, framing choice as retention (vs. acquisition) increased the importance of person-related features, but only when the primed identity was hiker. Study 2b replicated these results in a lab study that manipulated real (rather than imagined) ownership with a different product category (winter hats).

Next, to test the predicted effects on choice, in Study 3, the identity “audiophile” was primed for all participants. Choice frame was manipulated using study 2a’s manipulation. Participants were then presented with the rating of two headphones along 4 attributes, two person-related and two product-related. Ratings created a tradeoff between the product-related and the person-related attributes (i.e., one set of headphones was rated higher on the person-related features and the other on the product-related features). Participants in the retention (acquisition) choice frame chose which headphones to keep (buy). Finally, all participants rated the self-importance of the identity “audiophile.” Consistent with predictions, data analysis showed that framing choice as retention (vs. acquisition) increased choice in the headphones with higher ratings on person-related features. This effect mainly appeared when the identity “audiophile” was self-important, yielding a significant 2-way interaction. Implications for ownership research and marketing practice are discussed.

# Growing Up Rich and Insecure Makes Objects Seem Human: Childhood Material and Social Environments Predict Anthropomorphism

Jodie Whelan, York University, Canada  
Sean T. Hingston, Western University, Canada  
Matthew Thomson, Western University, Canada  
Allison R. Johnson, Western University, Canada

## EXTENDED ABSTRACT

The socioeconomic environments in which people grow up have a lasting influence on how they think and behave. Of unique interest to this research, social class can influence people's preferred strategies of coping with environmental threats and stressors. In particular, people who grow up wealthy are taught to prioritize the self over community, independence over interdependence, and autonomy over relatedness (see Markus and Kitayama 2003 for a review), and their preferred coping strategies reflect these lessons. But, what if these same people also grow up with unmet relationship needs? How do they simultaneously protect their prized autonomy and fulfil their need for relatedness—a motivational quandary that, theoretically, does not exist for people growing up with fewer material resources and more community-oriented models of agency?

Here, we propose that *anthropomorphism may be an especially attractive coping strategy for people who grew up wealthy and insecure in their personal relationships*. Anthropomorphism refers to the attribution of human-like characteristics, motivations, or mental states to nonhuman entities (for a review, see Epley, Waytz, and Cacioppo 2007). From gadgets to brands, people frequently treat nonhuman agents as human-like. Although anthropomorphized objects may seem like inferior relationship partners because they lack human interaction, research has shown that engaging with anthropomorphized objects can not only help people cope with unmet social needs (Chen, Wan, and Levy 2017; Mourey, Olson, and Yoon 2017), but also, some people may actually prefer relationships with objects precisely because they do not require human intimacy (Price and Arnould 1999; Thomson and Johnson 2006; Whelan et al. 2016).

To test this proposition, we investigate the interactive effects of childhood SES and attachment style, which reflects how (in)secure people felt in their relationships with their primary caregivers, on anthropomorphism. Specifically, we hypothesize that people who grew up wealthy and insecurely attached will be the most likely to anthropomorphize. **Study 1** provides initial support for this hypothesis. American adults participated in an online survey. The study began with the Individual Differences in Anthropomorphism Questionnaire (Waytz, Cacioppo, and Epley 2010). Next, participants completed the Experiences in Close Relationships Scale, which examines attachment styles as a function of two dimensions: *anxiety* and *avoidance* (ECR-S; Wei et al. 2007). When individuals are low on both dimensions, they have a *secure* attachment style; when individuals are high in one or both dimensions, they have an *insecure* attachment style.

The study concluded with childhood and current family income. Analyses revealed the predicted three-way interaction between childhood family income, anxiety, and avoidance: childhood family income positively predicted anthropomorphism for those with insecure attachment styles (i.e., when anxiety and avoidance were both high and/or at the mean).

**Study 2** used a longitudinal design to replicate and extend these findings. In particular, we examined whether the increase in anthropomorphism among participants with wealthy childhoods and insecure attachment styles subsequently predicted the likelihood that consumers include important brands as part of their self-concept.

American adults participated in a two-part online survey. Part 1 of the survey consisted of the anxiety and avoidance scales used in study 1 and established three-item measures of childhood and current SES (Griskevicius et al. 2011). Approximately one week later, participants completed the gadget task (Epley et al. 2008), which measures the anthropomorphism of four gadgets, and the Brand Engagement in Self-Concept scale (BESC; Sprott, Czellar, and Spangenberg 2009). Analyses revealed the predicted three-way interaction between childhood SES, anxiety, and avoidance: when participants had insecure attachment styles, childhood SES positively predicted their tendency to anthropomorphize, which subsequently increased the likelihood that they include brands in their self-concept.

**Study 3** sought evidence for our proposed mechanism by examining if the effect of childhood SES is mediated by the extent to which people's parents adopted a family communication style that emphasized the importance of personal autonomy (i.e., a concept-oriented communication style; Grougiou and Moschis 2015; Moschis 1985). American adults participated in a two-part online survey. Part 1 consisted of our predictor variables: the childhood SES, current SES, anxiety, and avoidance scales used in study 2, as well as a four-item measure of concept-oriented communication style (Baker et al. 2016). Approximately one week later, participants completed the gadget task (Epley et al. 2008). Analyses revealed that concept-oriented communication style significantly mediated the effect of childhood SES: when participants had insecure attachment styles, the effect of childhood SES on anthropomorphism via concept-oriented communication style was significant.

These findings make a number of contributions. First, we contribute to a growing body of work examining how childhood SES influences adult consumer behavior (Ahuvia and Wong 2002; Connell, Brucks, and Nielsen 2014; Mittal and Griskevicius 2016; Richins and Chaplin 2015; Whelan and Hingston 2018). To the best of our knowledge, not only are we the first to show that anthropomorphic tendencies vary depending on people's childhood socioeconomic environments, we are also the first to empirically investigate the interactive effect of childhood SES and attachment style on adult psychology. In addition, we answer calls to go beyond childhood SES as "merely a proxy measure" (Mittal and Griskevicius 2014, 633; Whelan and Hingston 2018) and demonstrate that the effect of childhood SES on people's tendency to anthropomorphize is mediated by the extent to which their parents adopted a family communication style that emphasized the importance of personal autonomy.

Last, our findings contribute to growing interest in the root causes of individual differences in anthropomorphic tendencies. To date, most anthropomorphism research has focused on either the extent to which specific nonhuman agents are anthropomorphized, the accuracy of anthropomorphic inferences in describing these agents, or the consequences of anthropomorphism (Waytz, Morewedge, et al. 2010). Consequently, "the psychological determinants that explain and predict variability in the tendency to anthropomorphize" have remained largely unaddressed (Waytz, Morewedge, et al. 2010, 411). Accordingly, our findings suggest that individual differences in the tendency to anthropomorphize arise from differences in childhood material and social environments. Indeed, it's difficult to imagine two more proximal causes.

# Paying to Purchase a Conversation Topic

Hillary J.D. Wiener, University at Albany, USA

Josh Wiener, Oklahoma State University, USA

## EXTENDED ABSTRACT

People want to express themselves (Berger and Heath 2008), and signaling research has found that they use products to do so (Escalas and Bettman 2003). However, sometimes people do not want to silently signal to others, they want to talk to them (Kahneman et al. 2004). Can products also play a role in facilitating conversation? Initial evidence suggests they can; displaying some self-relevant products (conversation pieces) increases the likelihood that their owner will have an enjoyable conversation (Wiener, Bettman, and Luce 2015). In this investigation, we look at whether consumers predict that non-self-relevant products can also facilitate conversation, and when they will pay a premium to purchase products that might do so.

We investigate this issue by examining consumers' likelihood to purchase expensive products that are associated with product related stories, such as those about the product's history or making. Importantly, the stories are about the products, rather than the purchaser, and are not self-relevant. We predict that people will pay a premium for a story-associated product if they think they can use it to facilitate conversation.

Conversation facilitation is not the only reason people might pay more for a product with a story. People perceive products with stories more positively (van Laer, Ludwig, and Escalas 2017) and as more authentic (Newman and Dhar 2014). Therefore, we include a situation moderator in all studies: whether the situation allows participants to use the product to facilitate conversation. In studies 1 and 2, we manipulate whether they will use it alone or socially, and in study 3 we manipulate whether they can mention it. We predict that people are more likely to purchase expensive products with stories when they can use them to facilitate conversation than when they cannot.

Study 1 examines whether people are more likely to purchase an expensive product with an interesting story associated with it when they will have the opportunity to use it in a social situation than when they will not. Study 1 ( $n = 245$ ) had a 2 (social v. alone)  $\times$  2 (interesting story v. boring story) between-subjects design. Participants read that they had moved to a new city and were either going to a potluck to meet new people or spending the night alone. Then all participants chose between purchasing a \$21.00 cake with an interesting (boring) story or a \$15.00 cake with no story. In all studies, the interesting story is about the history of their new city—an appealing, but not self-relevant, topic.

There was a marginal interaction between the situation and whether the expensive product had an interesting story ( $p = .074$ ). When the expensive cake had an interesting story, 55% of participants in the social condition, but only 24% percent of participants in the alone condition, purchased it ( $p < .0001$ ). When it had a boring story, there was no effect of situation on purchase (social = 37%, alone = 28%;  $p = .27$ ), suggesting that interesting stories are more valuable in social situations.

In study 2 we replicate the results of study 1 with a different story manipulation and look for mediation. We predict that the additional value of a product with a story in a social situation comes from its ability to facilitate conversation. Therefore participants should predict that they would tell the stories associated with the product in the social situation, and this prediction should mediate the effect of the interaction on likelihood to purchase the expensive product.

Study 2 ( $n = 664$ ) had a 2 (social v. alone)  $\times$  2 (interesting story v. no story) between-subjects design. Study 2 was nearly identical to

study 1, but the expensive cake had either an interesting story or no story. All participants indicated on an 11-point scale how likely they would be to buy the expensive cake. They then answered our key mediator indicating how likely they would be to “tell people some stories about the cake I bought.”

There was a significant interaction between the situation and whether the expensive product had a story ( $p = .036$ ). When the cake had a story, participants were more likely to purchase it in the social condition than alone condition ( $p = .001$ ); there was no effect for situation when it had no story ( $p = .80$ ). The proposed mediator, likelihood to tell stories about the product, showed the same pattern ( $p = .019$ ), and the index of moderated mediation was significant ( $b = -.35$ ; 95% CI  $[-.70--.08]$ ). Likelihood to tell stories mediated the effect of situation on likelihood to purchase the expensive cake when it had a story ( $b = -.21$ ; 95% CI  $[-.45--.02]$ ), but not when it did not ( $b = .14$ ; 95% CI  $[-.06-.36]$ ). Study 2 shows that people's predictions that they would tell others the product's stories are important in leading to their purchase of expensive, story-associated products.

Study 3 replicates the interaction with a cleaner manipulation of the situation. Study 3 ( $n = 453$ ) had a 2 (product-mention allowed or forbidden)  $\times$  2 (interesting story v. no story) between-subjects design. Study 3 was similar to study 2, but for the situation manipulation, all participants attended the potluck, and the potluck rules did or did not allow talking about what you brought. Again participants chose between purchasing an expensive cake with an interesting (no) story or an inexpensive cake with no story on the scale used in study 2.

There was a significant interaction between the situation and whether the expensive cake had a story ( $p < .0001$ ): being allowed to talk about their potluck contribution increased likelihood to purchase the expensive cake when the expensive cake had a story ( $p < .0001$ ), but not when it did not ( $p = .24$ ).

In three studies, we show that people are willing to pay a premium to purchase products that are associated with interesting, conversation-facilitating stories when they can use the product in a social situation, providing preliminary evidence that the ability to foster, even non-self-relevant, conversations is a source of value to consumers.

# A Model of Consumer Self-Regulation Failure

Keith Wilcox, Columbia University, USA

## EXTENDED ABSTRACT

Self-regulation is fundamental to consumers' ability to achieve their goals. Most existing self-regulation models focus on the psychological processes that promote goal-consistent behavior. These models often assume that when individuals are motivated and have the ability to regulate their behavior, they are more likely to act consistently with their goals (Shiv and Fedorikhin 1999). However, there is abundant evidence that external factors can lead to self-regulation failures, even when consumers are sufficiently motivated and have the ability to self-regulate. Thus, a more complete model of consumer self-regulation is needed to account for how consumers respond to external factors.

The current research introduces a model of consumer self-regulation failure that explains how external factors shape consumers' ability to act consistent with their goals and when these factors are more likely to undermine self-regulation. The model proposes that many self-regulation failures occur because two processes involved in self-regulation (performance monitoring and the inhibition of behavior) make consumers more likely to rely on external cues.

A key process involved in self-regulation is performance monitoring, which involves a comparison of behavior (past or current) with a desired end state (Carver and Scheier 1990). During this process, however, consumers may disengage from the goal, if they perceive that the goal has been achieved or violated in some way. While consumers often determine goal achievement or failure by explicitly tracking their goal performance, consumers also rely on external cues associated with goal achievement and failure. Thus, when these cues are present, people who are more engaged in performance monitoring during efforts at self-regulation should act more inconsistently with their goals.

Even when consumers are sufficiently motivated to pursue their goals, effective self-regulation requires the inhibition of responses that undermine goal pursuit. When consumers inhibit alternatives that are inconsistent with a goal, they are more likely to behave consistently with the goal (Förster and Liberman 2007). However, the process of inhibiting behavior may also undermine self-regulation because inhibition not only makes consumers more sensitive to threats, but it also makes them more sensitive to rewards. Thus, self-regulation efforts should be more likely to fail when external factors either reduce the perception of threat or increase consumers' attention to rewards.

The purpose of study 1 was to demonstrate that performance monitoring makes consumers more susceptible to cues associated with goal failure. This was investigated by examining how the presence of credit card debt, which is associated with goal failure (Wilcox et al. 2011), influences spending. Whether or not consumer had credit card debt was made salient to them prior to participating in an auction where they submitted bids on products. The extent to which they engaged in performance monitoring during the auction was then measured. As expected, participants who were highly focused on performance monitoring who had debt submitted higher bids than those who did not have debt. Spending did not differ between those who did (vs. did not) for those who were less focused on performance monitoring.

The objective of study 2 was to demonstrate that performance monitoring makes consumers more susceptible to cues of goal achievement. Specifically, it examined whether performance monitoring would moderate consumers' response to incidental pride,

which has been shown to induce a sense of goal achievement that reduces self-regulation (Wilcox et al. 2011). Participants wrote about a "pride" experience or their typical day (control group). They then participated in the same auction as study 1. As predicted, participants who experienced pride submitted higher bids than the control group when they were highly focused on performance monitoring. Pride did not influence spending for those who were less focused on performance monitoring.

Study 3 sought to demonstrate that the inhibition of behavior makes consumers more susceptible to external cues that reduce the perception of goal threat. Based on previous research which finds that using a currency with a small nominal value is less threatening to spending goals (Raghubir and Srivastava 2002), it was predicted that when consumers used a currency with small (large) nominal value they would be less (more) likely to regulate their spending, an effect that would be strongest for participants focused on inhibiting their behavior. Participants submitted bids in an auction using a new currency where the nominal value was set at either a multiple (large nominal value) or a fraction (small nominal value) of the US dollar. As expected, participants submitted higher bids when the nominal value was small (vs. large) when they were highly focused on inhibiting their behavior. Spending did not differ between conditions for those who were less focused on inhibition.

Study 4 sought to demonstrate that the more focused consumers are on inhibiting their behavior, the more likely their self-regulation will be undermined by reward cues. Based on previous research that demonstrates that the decision to reject (vs. choose) options makes people more likely to elaborate on hedonic features during a decision (Dhar and Wertenbroch 2000), it was predicted that consumers would be more likely to select a higher priced option with more hedonic benefits when they rejected (vs. chose), an effect strongest for participants highly focused on inhibiting their behavior. Participants made a decision between two apartments to rent: one that was affordable, but not close to entertainment options and one that was more expensive, but close to entertainment options. Participants in the rejection (choice) condition were asked to decide which apartment to reject (choose). As predicted, participants were more likely to select the more expensive, but hedonically rewarding apartment when they rejected (vs. chose), but this effect primarily emerged for consumers who were highly focused on inhibiting their behavior.

This research contributes to existing models of self-regulation by integrating situational factors and the decision context into self-regulatory efforts. While other models suggest that external factors can reduce consumers' ability to regulate their behavior, many of these models focus on external constraints on mental resources. The current model suggests that in addition to the amount of resources consumers have available, their interpretation of the environment also plays a critical role in self-regulation efforts.

## INTRODUCTION

Self-regulation is fundamental to consumers' ability to achieve their goals. It allows them to save for retirement, adhere to social standards and maintain their health (Fishbach and Shah 2006). Self-regulation failures are associated with a number of harmful behaviors including overspending, unhealthy eating and procrastination. Thus, understanding the factors that lead consumers to fail to regulate their behavior is important because self-regulation is a significant mechanism for maintaining well-being.

Most existing self-regulation models focus on the psychological processes that promote goal-consistent behavior. These models often assume that when individuals are motivated and have the ability to regulate their behavior, they are more likely to act consistently with their goals (e.g., Baumeister, Vohs and Tice 2007; Shiv and Fedorikhin 1999). However, there is abundant evidence that external factors can lead to self-regulation failures, even when consumers are sufficiently motivated and have the ability to self-regulate (e.g., Fishbach and Dhar 2005). Thus, a more complete model of consumer self-regulation is needed to account for how consumers respond to external factors.

The current research introduces a model of consumer self-regulation failure that explains how external factors shape consumers' ability to act consistent with their goals and when these factors are more likely to undermine self-regulation.

## A MODEL OF CONSUMER SELF-REGULATION FAILURE

### *The Model*

As Figure 1 shows, a precondition for self-regulation is that consumers must perceive a conflict between a goal and a competing alternative (Myrseth and Fishbach 2009). Whether it is the consideration of a temptation or the presence of alternative goals, goal conflict initiates the need for self-regulation.

Once consumers experience goal conflict, the model proposes that consumers' behavior is influenced by two self-regulatory processes: performance monitoring and the inhibition of behavior. Performance monitoring refers to the monitor of past and current behavior relative to a standard to ensure that behavior is consistent with a focal goal (Carver and Scheier 1990). Inhibition of behavior refers to the suppression of responses (e.g., thoughts and actions) that threaten goal pursuit (Förster and Liberman 2007). If individuals monitor their performance and inhibit their behavior, this often results in goal-consistent behavior.

Environmental factors and decision context factors, however, can undermine self-regulation by serving as external cues. These factors result in goal-inconsistent behavior by serving as cues of goal achievement, goal failure, goal threat and reward. Performance monitoring makes consumers more likely to rely on cues related to goal attainment and goal failure. The inhibition of behavior makes consumers more reliant on cues related to goal threat and reward.

In sum, the model proposes that many self-regulation failures occur because two processes involved in self-regulation (performance monitoring and the inhibition of behavior) make consumers more likely to rely on external cues. Testable hypotheses are developed next.

### *Performance Monitoring*

A key process involved in performance monitoring is the detection of goal discrepancies, which involves a comparison of behavior (past or current) with a desired end state. When consumers detect that their behavior is discrepant with their goals, they adjust their behavior to ensure that it is consistent with their goals. During this process, however, consumers may disengage from the goal, if they perceive that the goal has been achieved or violated in some way.

Consumers often determine goal achievement or failure by explicitly tracking their goal performance. However, research demonstrates that consumers also rely on external cues associated with goal achievement and failure. For instance, consumers are less likely to regulate their behavior when they derive a sense of achievement from environmental and decision context factors such as acts of charity (Khan and Dhar 2006) and the composition of a choice set (Wilcox et al.

2009). Similarly, environmental factors associated with goal failure, such as missing deadlines (Soman and Cheema 2004), can undermine self-regulation. Moreover, simply anticipating failure due to environmental factors can undermine self-regulation (Bandura 1986).

The implication of these findings is that performance monitoring should make consumers more likely to rely on external cues associated with goal achievement and goal failure. Thus, when these cues are present, people who are more engaged in performance monitoring during efforts at self-regulation should act more inconsistently with their goals. While this proposition has not been empirically tested, indirect support comes from research demonstrating that consumers high in self-control, who should be more focused on monitoring their behavior, are more susceptible to external factors associated with goal achievement and goal failure (Wilcox et al. 2009; Wilcox et al. 2011).

*Hypothesis 1*    *The more focused consumers are on performance monitoring during efforts at self-regulation, the more likely their self-regulation will be undermined by external cues associated with goal achievement.*

*Hypothesis 2*    *The more focused consumers are on performance monitoring during efforts at self-regulation, the more likely their self-regulation will be undermined by external cues associated with goal failure.*

### *Inhibition of Behavior*

Even when consumers are sufficiently motivated to pursue their goals, effective self-regulation requires the inhibition of responses that undermine goal pursuit. Inhibition involves directing attention away from information that might interfere with the pursuit of a focal goal (Förster and Liberman 2007). When consumers inhibit alternatives that are inconsistent with a goal, they are more likely to behave consistently with the goal.

However, the process of inhibiting behavior may also undermine self-regulation because inhibition not only makes consumers more sensitive to threats, but it also more sensitive to rewards (Gendall et al. 1998; Jappe et al. 2011). Thus, self-regulation efforts should be more likely to fail when external factors either reduce the perception of threat or increase consumers' attention to rewards. Consistent with this perspective research finds that chronic dieters, who tend to be more focused on inhibiting food responses, are more likely to overeat in the presence of external cues, such as smaller package sizes (Scott et al. 2008), indicating that a food item is less threatening. Additionally, chronic dieters have been shown to be less likely to regulate their food intake because of more accessible thoughts about food (Gendall et al. 1998).

*Hypothesis 3*    *The more focused consumers are on inhibiting their behavior during efforts at self-regulation, the more likely their self-regulation will be undermined by external cues that reduce the perception of goal threat.*

*Hypothesis 4*    *The more focused consumers are on inhibiting their behavior during efforts at self-regulation, the more likely their self-regulation will be undermined by external cues associated with rewards.*

## STUDY 1

The purpose of study 1 was to demonstrate that performance monitoring makes consumers more susceptible to cues associated with goal failure (H1). This was investigated by examining how the presence of credit card debt, which is associated goal failure (Wilcox et al. 2011), influences spending.

### *Participants and procedure*

153 participants from an online panel were recruited for a small payment ( $M_{\text{Age}} = 36$ ; 46% female). After completing several demographic questions, participants were asked to indicate whether they currently had credit card debt (yes/no). Thus, goal failure was made salient before participants attempted to regulate their spending. Afterwards, participants were instructed that the purpose of the study was to test a new auction web site and that they would be making actual bids on products. They then submitted bids on two products: a digital camera and a fitness tracker.

Afterwards, performance monitoring was measured on a two-item scale that asked participants the extent to which they monitored their performance [progress] relative to their spending goals while making their bids (1 = "not at all" and 7 = "very much",  $r = .75$ ). Inhibition of behavior was then measured on a two-item scale by having them indicate how focused they were on inhibiting [controlling] their behavior while making their bids (1 = "not at all" and 7 = "very much",  $r = .84$ ). Inhibition of behavior was measured to rule out the possibility that other processes involved in self-regulation may moderate consumers' response to goal failure.

### *Results*

The predicted debt by performance monitoring interaction was significant ( $t(149) = 2.14, p = .03$ ). Consistent with hypothesis 1, a floodlight analysis found that participants who had debt submitted higher bids than those who did not have debt for performance monitoring scores above 4.49. Spending did not differ between those who did (vs. did not) have debt for scores below this threshold. A similar analysis with inhibition of behavior did not find that it moderated the effect of debt on spending (interaction:  $t(149) = .62, p = .54$ ).

## STUDY 2

The objective of study 2 was to demonstrate that performance monitoring makes consumers more susceptible to cues of goal achievement (H2). Specifically, it examined whether performance monitoring would moderate consumers response to incidental pride, which has been shown to induce a sense of goal achievement that reduces self-regulation (Wilcox et al. 2011).

### *Participants and procedure*

150 participants from an online panel were recruited ( $M_{\text{Age}} = 35$ ; 45% female). Participants were instructed that they would be participating in two unrelated studies. The first study manipulated pride by having participants write about a "pride" experience or their typical day (control group). The second study was the same auction from study 1 that included the same measures of performance monitoring ( $r = .73$ ) and inhibition of behavior ( $r = .86$ ).

### *Results*

The predicted pride by performance monitoring interaction was significant ( $t(146) = 2.06, p = .04$ ). In support of hypothesis 2, a floodlight analysis found that participants who experienced pride submitted higher bids than those in the control group for performance monitoring scores above 4.43. Spending did not differ between those who did (vs. did not) experience pride for any score below this threshold. The inhibition of behavior did not moderate the effect of pride on spending (interaction:  $t(146) = -.20, p = .84$ ).

## STUDY 3

Study 3 sought to demonstrate that the inhibition of behavior makes consumers more susceptible to external cues that reduce the perception of goal threat (H3). Based on previous research which finds that using a currency with a small nominal value is less threatening to spending goals (Raghubir and Srivastava 2002), it was predicted that when consumers used a currency with small (large) nominal value they would be less (more) likely to regulate their spending, an effect that would be strongest for participants focused on inhibiting their behavior.

### *Participants and Procedure*

152 participants from an online panel were recruited for a small payment ( $M_{\text{Age}} = 36$ ; 49% female). Participants were instructed that they would be testing a new auction web site that would require them to make bids using a new currency where the nominal value was set at either a multiple (large nominal value) or a fraction (small nominal value) of the US dollar. Participants then placed bids on the same products and completed the same measures of performance monitoring ( $r = .76$ ) and inhibition of behavior ( $r = .85$ ) as previous studies.

### *Results*

The predicted nominal value by inhibition of behavior interaction was significant ( $t(148) = 2.54, p = .01$ ). Supporting hypothesis 3, a floodlight analysis found that participants submitted higher bids when the nominal value was small (vs. large) for inhibition of behavior scores above 5.41. Spending did not differ between nominal value conditions for any score below this threshold. Performance monitoring did not moderate the effect of the nominal value on spending (interaction:  $t(148) = -.51, p = .61$ ).

## STUDY 4

Study 4 sought to demonstrate that the more focused consumers are on inhibiting their behavior, the more likely their self-regulation will be undermined by reward cues (H4). Based on previous research that demonstrates that the decision to reject (vs. choose) options makes people more likely to elaborate on hedonic features during a decision (Dhar and Wertenbroch 2000), it was predicted that consumers would be more likely to select a higher priced option with more hedonic benefits when they rejected (vs. chose). However, this effect was predicted to be strongest for participants highly focused on inhibiting their behavior.

### *Participants and Procedure*

200 participants from an online panel were recruited for a small payment ( $M_{\text{Age}} = 37$ ; 44% female). Participants were instructed that they were deciding between two apartments to rent: one that was affordable, but not close to entertainment options and one that was more expensive, but close to entertainment options. Participants in the rejection (choice) condition were then asked to decide which apartment to reject (choose). Participants then completed the same measures of performance monitoring ( $r = .74$ ) and inhibition of behavior ( $r = .87$ ) as previous studies.

### *Results*

The predicted decision framing by inhibition of behavior interaction was significant (Wald  $\chi^2 = 22.40, p < .001$ ). In support of hypothesis 4, a floodlight analysis found that participants were more likely to select the more expensive, but hedonically rewarding apartment when they rejected (vs. chose) for any inhibition of behavior scores above 4.59. Selection of the expensive apartment did not differ between nominal value conditions for any score below this threshold. Performance monitoring did not moderate the effect

of the framing of the decision on spending (interaction: Wald  $\chi^2 = 1.24, p = .27$ ).

## DISCUSSION

This research introduces and tests a model of self-regulation failure that explains how external factors influence consumers' efforts to regulate their behavior. The model proposes that environmental factors and decision context factors can undermine self-regulation by serving as external cues for goal achievement, goal failure, goal threat and rewards. The results of four studies demonstrates that self-regulation failures often occur because two key processes that typically facilitate self-regulation, performance monitoring and the inhibition of behavior, make consumers more likely to rely on these external cues.

This model contributes to existing models of self-regulation by integrating situational factors and the decision context into self-regulatory efforts. While other models suggest that external factors can reduce consumers' ability to regulate their behavior, many of these model focus on external constraints on mental resources. The current model suggests that in addition to the amount of resources consumers have available, their interpretation of the environment also play a critical role in self-regulation efforts.

This research has implications for policy makers and companies who want to facilitate Self-regulation by suggesting ways to improve consumers' ability to stick to their goals. If self-regulatory efforts are shaped by how consumers think about their environment, self-regulation efforts should be improved by designing interventions that train consumers on more effective ways to respond to their environment.

One limitation of this research is that it only examines consumers' response to goal conflict in situations that involve tradeoffs between temptations and long-term goals. However, this model should also apply to other self-regulation contexts where goal conflict does not necessarily involve temptation. Nevertheless, future research is necessary to explore whether the same predictions hold in other self-regulation contexts.

# Is Warm Always Trusting? The Effect of Seasonality on Trustworthiness

Gretchen R. Wilroy, Penn State University, USA

Margaret G. Meloy, Penn State University, USA

Simon J. Blanchard, Georgetown University, USA

## EXTENDED ABSTRACT

Sensory marketing has shown that non-conscious triggers and sensory experiences influence consumers' perceptions, judgments, and behaviors (Krishna 2012). The current work focuses on temperature and how it subsequently affects perceptions of trustworthiness. Past research often suggests warm (vs. cold) ambient temperatures increase feelings of social proximity (IJzerman and Semin 2009), and more directly, that warm temperatures increase interpersonal trust (Kang et al. 2011).

We contend that ambient temperature is only part of the story. We incorporate research on thermoregulation, the need to maintain a core internal temperature for survival (Tavassoli 2009). Bruno, Melnyk, and Volckner (2017) found that when consumers were physically cold (warm) they perceived emotionally warm (cold) stimuli more positively. Thus, although past research has focused on ambient temperature in an absolute sense, it has yet to examine the effect in a relative sense (e.g., interaction of seasonality and indoor temperature). In the context of evaluating trust in service providers, we demonstrate that an unexpected ambient indoor temperature that contrasts with the temperature outside affects consumers' trust.

## STUDY 1: LONGITUDINAL STUDY

Study 1 was conducted longitudinally to investigate whether trust and inside temperature are affected by the summer season. Using the same MTurk participants over time allowed us to ensure that temperature variations were consistent within person. We predicted that, in contrast to prior research, consumers would be more trusting when it is colder inside.

The study was conducted over a two-month period (June-August). The initial survey was sent to 600 participants and 221 remained at its conclusion (42% female, median age=34). Five consumer scenarios, all focusing on service providers, were randomly presented to each participant, approximately every two weeks. Participants rated how trustworthy the representative in the scenario appeared and the actual inside temperature of their current location.

A fixed effects regression found a marginally significant *negative* relationship between trust and inside temperature ( $b = -0.02, p = .065$ ). This finding provides preliminary evidence that during the summertime, when it is colder inside, individuals are more trusting of service providers.

## STUDY 2: SEASONALITY, TEMPERATURE, AND TRUST AT THE DENTIST

Study 2 examined the interaction between seasonality and inside temperature in a medical domain. We designed an experiment which varied the temperature inside a dentist's office and the season. We predicted that if the inside temperature at the dental office did not stabilize a person's core temperature, trust in the dentist would be lower.

Students ( $n = 234$ , 47% female, median age=19) completed the study. Six participants failed an attention check, leaving 228 participants. In a 2 (inside temperature: warm, cold) x 2 (season: summer, winter) design, participants imagined they were heading to their dental cleaning. The waiting room was described as either very warm or freezing cold.

Participants then completed trust measures modified from Mayer and Davis (1999) on three dimensions: ability, benevolence, and integrity. Participants rated each statement on a 7-point scale (1 = strongly disagree, 7 = strongly agree). Finally, we asked two manipulation check questions, which confirmed the success of the temperature manipulation.

An average trust score was calculated: ability ( $\alpha = .980$ ), benevolence ( $\alpha = .976$ ), and integrity ( $\alpha = .821$ ). Neither the main effect of temperature ( $F(3, 222) = 1.055, p = .369$ ) nor season ( $F(3, 222) = .370, p = .774$ ) was significant. There was a marginally significant interaction between temperature and season on overall trust,  $F(3, 222) = 2.12, p = .098$ . Importantly, ability, benevolence, and integrity individually all showed a significant temperature by season interaction: ability,  $F(1, 224) = 4.83, p = .029$ , benevolence  $F(1, 224) = 6.17, p = .014$ , and integrity  $F(1, 224) = 4.77, p = .03$ .

In winter, trust did not differ whether it was warm or cold inside. However, in summer, trust ratings were significantly higher when it was cold inside the office compared to warm: ability ( $M_w = 4.61, M_c = 5.10, p = .02$ ), benevolence ( $M_w = 4.13, M_c = 4.74, p = .007$ ), and integrity ( $M_w = 3.98, M_c = 4.53, p = .006$ ). This contradicts prior research findings – here, cold temperatures in the summertime led to higher trust ratings.

## STUDY 3: SEASONALITY, TEMPERATURE, AND TRUST AT A RESTAURANT

Similar to the design of study 2, temperature inside a restaurant was manipulated. We predicted that trust would be highest when the inside temperature met the expectations of the consumer, subconsciously aiding thermoregulation.

MTurk participants ( $n = 244$ , 50% female, median age=36) were randomly assigned to one of four conditions – season (summer/winter) and inside temperature (cold/warm) in a 2x2. As in study 2, participants completed trust measures modified from Mayer and Davis (1999). A manipulation check question confirmed the manipulation.

An average trust score was calculated for ability ( $\alpha = .894$ ), benevolence ( $\alpha = .908$ ), and integrity ( $\alpha = .790$ ). A 2(temperature: warm vs. cold) x 2(season: summer vs. winter) on the three trust measures indicated a marginal main effect of temperature ( $F(3, 238) = 2.24, p = .08$ ). The main effect of season was not significant ( $F(3, 238) = 1.48, p = .22$ ). These main effects were qualified by a significant interaction between temperature and season,  $F(3, 238) = 3.65, p = .01$ . Each element of trust had a significant temperature by season interaction: ability  $F(1, 240) = 7.58, p = .006$ , benevolence  $F(1, 240) = 10.52, p = .001$ , and integrity  $F(1, 240) = 9.99, p = .002$ . In the summer, there was not a significant difference when the restaurant was warm or cold. However, in winter, the trust measures were significantly affected by indoor temperature. Trust was higher when it was warm inside the restaurant compared to cold: ability ( $M_w = 5.13, M_c = 4.37, p < .001$ ), benevolence ( $M_w = 4.65, M_c = 3.79, p < .001$ ), and integrity ( $M_w = 4.43, M_c = 3.79, p < .001$ ). In this domain, the findings are consistent with prior research that warm temperatures engender feelings of trust. However, we did not find this to be true in the summer scenario. These findings broaden our understanding of temperature and trust – warm does not always positively boost trust.

## DISCUSSION

While previous research has consistently demonstrated a positive relationship between warmth and closeness/trust, we show that a boundary exists. The trustworthiness of a retailer/service provider is reduced when season and inside temperature are not what the consumer expects.

# “I Desire A Brand When I See How They are Different from Me”: Differential Effects of Blatant and Subtle Brand Rejection

Jun (Wendy) Yan, University of Manitoba, Canada  
Fang Wan, University of Manitoba, Canada  
Americus Reed II, University of Pennsylvania, USA

## EXTENDED ABSTRACT

People choose brands to express their self-concepts (Carroll and Ahuvia, 2006, pp. 82). When the brand they aspire to does not consider them as valuable consumers, they feel being rejected. In this work, we conceptualize two forms of communication strategies of brand segmentation—blatant and subtle mode of brand rejection and distinguish their effects on consumers' brand desire.

In prior work, blatant prejudice is to avoid any contact with out-group members, whereas subtle prejudice is to emphasize cultural differences between groups (e.g., Hamburger and Hewstone, 1997). We conceptualize Blatant Brand Rejection (BBR) as a market segmentation that emphasizes consumers are “not good enough,” and consumers get a direct and explicit signal that they are not wanted by this brand as one of its important consumers. Subtle Brand Rejection (SBR), by contrast, emphasizes the brand's target consumers, and consumers get an indirect, concealed, and implicit signal that they are different from the target consumers.

Both SBR and BBR reject “unwanted” brand recipients, but we argue that they have different effects on consumers' psychological and behavioral reactions. When consumers pursue a brand but encounter BBR, the explicit signal is a threat to their positive self-concept, activating defense mechanism (Baumeister, Dale and Sommer, 1998) and making consumers to avoid the rejecting brand. Whereas, encountering a subtle mode of rejection from a brand, consumers tend to compare themselves with the target consumers. When the target consumers are perceived to be a higher standard, this aspiration effect motivates consumers to (1) decrease the “distance” (e.g., Van, Pecher, and Zwaan, 2008), and (2) work harder to join the group of target consumers (e.g., Park, Young and Eastwick, 2015).

However, this positive effect of SBR is contingent on the attainability of group standards (Dyczewski and Markman, 2011). When the perceived attainability of becoming a group member is low, a sense of self efficacy and self control is threatened (Coffee, Rees and Haslam, 2009). This threat will reduce their brand desire as defense mechanism. Therefore, we hypothesize that

*Hypothesis 1* SBR (vs. BBR) will increase (vs. decrease) brand desire of a rejecting brand, when the brand is perceived to be attainable. The positive effect of SBR is mitigated when consumers perceive the rejecting brand is unattainable.

*Hypothesis 2* SBR (vs. BBR) will increase (vs. decrease) brand desire of a rejecting brand, when the brand is perceived to be attainable, mediated by their increased (vs. decreased) belonging needs to the target consumers.

Study 1. It is a 3 (BBR vs. SBR vs. neutral) by 2 (perceived attainability: high vs. low) between subject study. 297 university students (Mage = 20.6, Male: 50.5%) were recruited in an online study. A hotel brand unknown to subjects is adopted. In the BBR condition: “Based on our analysis of your information, unfortunately, you are not a target consumer of Banyan Tree Restaurant & Hotel.” In the SBR condition, participants were shown some information about

Banyan Tree's target consumers, which was pretested to be different from the university students. In the control condition, participants were told to complete a questionnaire. Next, all participants were measured their brand desire (Gountas, et al., 2012), perceived attainability of the rejecting brand, manipulation check and demographic questions.

Compared with the control group, both BBR and SBR make participants feel they are being rejected ( $M_{BBR} = 3.95$ ,  $M_{control} = 2.37$ ,  $p < .000$ ;  $M_{SBR} = 3.19$ ,  $M_{control} = 2.37$ ,  $F(1, 198) = 21.45$ ,  $p < .000$ ). BBR is perceived as more explicit than SBR, ( $M_{BBR} = 4.67$ ,  $M_{SBR} = 3.26$ ,  $p < .000$ ). Interaction results supporting our hypothesis 1, that the effect of brand rejection on brand desire is moderated by perceived attainability ( $t = -1.99$ ,  $p < .05$ ).

Study 2. First, 284 American participants ( $M_{age} = 38$ , Male: 40%) recruited online were told that Parliament Pub is a local political-themed pub for the \_\_\_\_ Party (this blank was customized based on participants' choice about their supporting Party). Second, participants were randomly assigned to complete one of two surveys relevant to their volunteer (vs. work) experience with the \_\_\_\_ Party. A pretest revealed that to have volunteer (vs. work) experience for a Party was considered more attainable ( $M_{volunteer} = 5.92$ ,  $M_{work} = 5.10$ ,  $p < .000$ ). After that, participants were then randomly assigned to one of three conditions: BBR, SBR, or control, as similarly manipulated in Study 1. Finally, brand desire, Want-to-Pay (WTP), manipulation check, and demographic questions were measured.

When the rejecting brand was perceived as attainable (vs. unattainable), SBR (vs. BBR) led to an increased brand desire ( $M_{SBR} = 5.17$ ,  $M_{BBR} = 3.45$ ,  $t = -3.37$ ,  $p < .001$ ) and WTP ( $M(\log WTP)_{SBR} = 1.57$ ,  $M(\log WTP)_{BBR} = 1.09$ ,  $t = -2.17$ ,  $p < .05$ ). Furthermore, the attainable (vs. unattainable) SBR even generated more brand desire and WTP than control group ( $M_{SBR} = 5.17$ ,  $M_{control} = 4.32$ ,  $t = -2.20$ ,  $p < .05$ ;  $M(\log WTP)_{SBR} = 1.57$ ,  $M(\log WTP)_{control} = 1.15$ ,  $t = -3.13$ ,  $p < .005$ ).

Study 3. To test the mediation effect of need for belongingness, this study replicated study 2 except that the control condition was dropped and another variable—measurement order—was added. We predicted that participants whose brand desire was measured first would show the same results as in Study 2, while participants whose belonging needs were measured first would have no increase in brand desire (White, Argo, and Sengupta, 2012), because the activated belongingness to other groups is one coping mechanism of threat (Knowles and Gardner, 2008) and the affirmation of self-concept (Cohen et al., 2000). Results supported the hypothesis that the brand desire of consumers who experiencing attainable SBR decreased significantly when belong need was measured first than when it was measured after brand desire ( $F(1, 98) = 7.08$ ,  $p < .01$ ). The opposite pattern was observed when belong need was measured after brand desire ( $M_{SBR} = 4.77$ ,  $M_{BBR} = 2.98$ ,  $p < .000$ ). The results of Want-to-Pay (WTP) indicated a similar pattern. Therefore, belong needs mediate the interaction effect of mode of rejection and perceived attainability on brand desire and WTP.

# The Slippery Slope of Green Consumption: The Nonlinear Effects of Social Class

Li Yan, Monash University, Australia  
Hean Tat Keh, Monash University, Australia  
Jiemiao Chen, Monash University, Australia

## EXTENDED ABSTRACT

As environmental issues grow increasingly acute, more research is needed to understand the impact of individuals' behaviors on sustainability. Given that green consumption can reflect status differentiation (Griskevicius et al. 2010), and social class serves as a dimension of consumer distinctiveness (Grier and Deshpandé 2001), we propose that social class, as a means of consumer differentiation, will influence their propensity for green consumption.

Social class is defined as a combination of individuals' material resources (i.e., income, education, and job status), and self-perceptions of their own rank in the society vis-à-vis others (Kraus et al. 2012). It has profound psychological and cultural effect on individuals' feelings, thoughts, and behaviors (Grossmann and Huynh 2013). However, scant research has examined how social class shapes consumer behaviors (Shavitt et al. 2016; Yoon and Kim 2018).

The present research proposes a nonlinear (i.e., inverted U-shaped) effect of social class on green consumption, such that individuals at the middle position of the class continuum show greater green propensity than those at the lower or upper position (H1). Although striving for a higher social rank is a fundamental motive for individuals, the means for rank advancement differ (Belmi and Laurin 2016). Specifically, lower-class individuals believe that they need to make prosocial contributions to advance their status, and are thus driven by social acceptance for green consumption (H2a). However, as the intrinsic benefits associated with social hierarchy grow exponentially, individuals proximal to the top attach more importance to justifying their advantaged standing using ideological means such as essentialism. Essentialism refers to the belief that social class category is predetermined and immutable, and such ideology helps to justify disparities in social rank (Kraus and Keltner 2013). Thus, we propose that essentialism would demotivate individuals from engaging in green consumption (H2b). Finally, we propose that individuals' belief in a just world (BJW) moderates the nonlinear effect of social class on green consumption (H3). BJW refers to the belief that the world is a just place where people deserve what they get and get what they deserve (Lerner 1980). We suggest that high BJW promotes individuals' acquiescence of perceived differences in social class, which attenuates the nonlinear effects of social class difference on green consumption.

We tested our hypotheses in four experiments. **Experiment 1** examined the main effect of social class (H1). **Experiment 1** used a 3 (primed social class: lower vs. middle vs. upper)  $\times$  2 (product greenness: green vs. regular) between-participants design. A 3  $\times$  2 ANOVA revealed only a significant interaction effect of social class and product greenness ( $p < .05$ ). Decomposing the interaction showed that social class significantly influenced purchase intentions for the green product ( $p < .05$ ), but not for the regular product ( $p > .20$ ). Importantly, polynomial contrast showed a significant quadratic effect of social class on purchase intention for the green product ( $p < .001$ ), but no linear effect ( $p > .50$ ). Specifically, participants in middle-class condition showed higher purchase intention for the green product than those in the lower-class ( $p < .05$ ) and upper-class conditions ( $p < .05$ ). In contrast, the three class conditions were not significantly different in purchase intentions for the regular product (all  $ps > .14$ ). Thus, H1 was supported. For all studies, controlling for the objective social class indicators (i.e., income, education) and other covariates

(e.g., political ideology, religiosity, and ethnicity) did not change the results.

**Experiment 2** provided process evidence for the nonlinear mediation effect of social acceptance at the lower level of social class (H2a). It used a one factor (product greenness: regular vs. green) between-participants design. Social class was measured as a continuous variable. A moderated hierarchical regression analysis showed a significant and negative quadratic-by-linear effect of  $SC^2 \times$  product greenness on purchase intention ( $\beta = -.72, p < .05$ ) after controlling for the effects of the linear terms and covariates. Decomposing the quadratic-by-linear interaction showed that the nonlinear effect of social class was significant and negative for the green product ( $\beta = -.37, p < .01$ ), but not significant for the regular product ( $p > .50$ ). MEDCURVE analysis (Hayes and Preacher 2010) revealed a significant and negative effect of the quadratic term ( $SC^2$ ) on social acceptance ( $b = -.24, p < .05$ ), which was positively related to purchase intention ( $b = .25, p < .01$ ). Analyses of the instantaneous indirect effect ( $\theta$ ) at lower (-1 SD) and higher (+1 SD) levels of social class revealed that social acceptance could explain the positive effect at the lower level of social class ( $\theta = .21, 95\% CI = .057, .476$ ), but not at the higher level of social class ( $95\% CI = -.092, .112$ ), which supported H2a.

**Experiment 3** examined the mediating effect of essentialism at the higher level of social class (H2b). It used a one factor (product greenness: regular vs. green) within-participant design. Social class was measured as a continuous variable using subjective SES. Regression with both linear and quadratic terms ( $SES$  and  $SES^2$ ) in the equation showed a significant and negative effect of  $SES^2$  on preference for green product ( $SES: \beta = .08, p > .14, SES^2: \beta = -.14, p < .05$ ). MEDCURVE analysis revealed a significant and positive effect of  $SES^2$  on essentialism ( $b = .04, p < .05$ ), which was negatively related to preference for the green product ( $b = -.23, p < .05$ ). Analyses of the instantaneous indirect effect showed that essentialism could explain the negative effect at the higher level of social class ( $\theta = -.05, 95\% CI = -.128, -.008$ ), but not at the lower level of social class ( $95\% CI = -.170, .064$ ), supporting H2b.

**Experiment 4** tested the overall model and the moderating effect of BJW using a similar design as experiment 3. Moderated regression results revealed a significant and negative effect of  $SES^2$  ( $\beta = -.20, p < .01$ ), and a significant and positive quadratic-by-linear effect of  $SES^2 \times$  BJW on preference for the green product ( $\beta = .20, p < .05$ ). Further analysis of the quadratic-by-linear interaction indicated that the effect of  $SES^2$  was significant at low BJW ( $b = -.19, p < .001$ ), but not at high BJW ( $p > .50$ ). Thus, H1 and H3 were supported. MEDCURVE analyses showed that social acceptance could explain the positive effect at the lower level of social class ( $\theta = .04, 95\% CI = .000, .111$ ) while essentialism could explain the negative effect at the higher level of social class ( $\theta = -.05, 95\% CI = -.104, -.001$ ), supporting H2a and H2b.

Taken together, four experiments using varying products and designs provided consistent evidence for the nonlinear effect of social class on green consumption, as explained by social acceptance and essentialism, and moderated by BJW. This curvilinear result can help reconcile conflicting findings in the literature based on the two-level approach. In particular, it addresses the middle class, an under-theorized social category, which is a powerful category for self-iden-

tification and plays an important role in economic growth, political transformation, and social restructuring in many societies. In sum, our findings contribute to the literature on consumer differentiation, social class and sustainable consumption, as well as have important practical implications.

# Do You Trust the System? Interaction Effect between Perceived Economic Mobility and Socioeconomic Status on Fair Market Ideology and Consumer Responses

Chun-Ming Yang, Ming Chuan University, Taiwan  
Chia-Chi Chang, National Chiao Tung University, Taiwan

## EXTENDED ABSTRACT

The increasing inequality of wealth in modern societies may limit the ability of low socioeconomic status (SES) consumers to achieve a higher SES. Although there have been extensive studies on inequality and SES in the fields of psychology and economics, scant research has examined how consumer SES and perceived economic mobility (PEM) jointly influence decisions (Yoon and Kim 2016, 2018).

On the basis of system justification theory, the author predicts that high-PEM consumers have a higher degree of fair market ideology (FMI) than other consumers (Jost et al. 2003). High FMI leads to various responses, including higher price–quality relationship beliefs and even the rejection of government health policies. FMI, defined as the tendency to view market-based processes and outcomes as legitimate and just, is a cognitive underpinning of economic system justification. People with high FMI have a high propensity to defend and justify the existing economic system. The author argued that consumers with high PEM would report higher FMI than those with low PEM, because consumers with high PEM rely on the current economic system to provide resources and opportunities to move upward in the economic hierarchy. This argument is consistent with recent findings in social psychology (Day and Fiske 2017).

In the current study, it was predicted that the effect of PEM on FMI would be stronger for consumers with a low SES. This is because, compared with high-SES consumers, low-SES consumers have fewer resources with which they can secure future wellbeing. The current social system largely determines whether they can achieve a higher SES. If they have the opportunity to move upward, they should tend to justify the system and even accept social inequality. PEM should not be a concern for high-SES consumers, because they have sufficient financial resources. A series of studies tested our predictions and provided supporting evidence.

In the pilot studies, participants from Taiwan and the United States completed an online questionnaire. Regression analyses revealed a consistent pattern in both samples. Supporting our hypothesis, PEM had a positive effect on FMI. Moreover, these effects were qualified by a significant PEM–SES interaction. Further analyses indicated that for low-SES consumers, PEM had a positive effect on FMI; however, PEM did not affect high-SES consumers.

In Study 1, Taiwanese consumers were randomly assigned to either a high-PEM or low-PEM condition. Participants first read the statement “Everyone has a fair chance at moving up the economic ladder.” Participants in the high (low) PEM conditions respectively wrote three arguments in support of (against) this statement. Participants then reported their price–quality relationship belief, FMI, childhood SES, and current SES. A regression analysis indicated a significant PEM–SES interaction. For low-SES consumers, PEM positively affected the perception of a price–quality relationship. However, the effect of PEM was not observed for high-SES consumers. A significant PEM–SES interaction was also revealed in relation to FMI. For only low-SES consumers, PEM positively affected FMI. The results of a bootstrap analysis confirmed the indirect path from PEM through FMI to the price–quality relationship belief.

In Study 2, the author predicted that high-PEM consumers would affect consumer’s willingness to support underdog brands. The author also predicted that this effect would be stronger for low-SES

consumers and mediated by FMI. To test our prediction, adult U.S. consumers were randomly assigned to either a high-PEM or low-PEM condition. In the high-PEM and low-PEM conditions, participants read an article that compellingly presented arguments for high and low economic mobility in the United States, respectively. The articles were similar in length and style. After reading the article, participants were asked to choose between purchasing coffee from Starbucks or an independent coffee shop. Regression analyses provided supporting evidence. Using FMI as the dependent variable, the results replicated the findings observed in previous studies. A bootstrap analysis supported the indirect path from PEM through FMI to the tendency to support underdogs support.

In the literature, it has been suggested that a consumer’s attitude toward consumer-related policy is affected by system confidence (Shepherd, Chartrand, and Fitzsimons 2015). For participants with a high degree of system confidence, policy arguments that appeal to the dominant U.S. social ideology (i.e., power) will be more persuasive than arguments appealing to universalism; simply supporting these arguments may diminish consumer wellbeing. Therefore, we predicted that high-PEM consumers would evaluate power appeal arguments as being more persuasive than their low-PEM counterparts would. Adult U.S. participants were first asked to evaluate the persuasiveness of an argument against a ban on trans fats by the U.S. Food and Drug Administration. After reading the argument, participants used seven items to evaluate the argument’s persuasiveness. Regression analyses suggested that PEM had a positive effect on persuasiveness. We also observed a marginally significant PEM–SES interaction. For low-SES consumers, PEM positively affected persuasiveness; however, PEM had no effect on persuasiveness for high-SES consumers. The relationship between PEM and persuasiveness was mediated by FMI.

Our research contributes to the literature in several ways. First, we demonstrated that consumer PEM and SES are critical but underexplored factors influencing consumer decisions through assessing FMI as a novel psychological consequence. Second, the findings of Study 1 and 2 have crucial implications for practitioners. When using price to signal product quality, high-PEM consumers are the better target group, and practitioners should design marketing messages to enhance consumers’ PEM. Moreover, our findings contribute to social mobility literature by demonstrating that high-PEM consumers not only rationalize inequality but may also reject consumer-related policies if they believe that these policies are against the dominant social ideology. Future research should determine which factors eliminate the effect of FMI on policy rejection.

# Why Do People Who Have More Enjoy Horror More?

Haiyang Yang, Johns Hopkins University, USA

Kuangjie Zhang, Nanyang Technological University, Singapore

## EXTENDED ABSTRACT

From horror films and TV series to haunted house attractions and terrifying Halloween goods, people consume a wide variety of horror-related experiences and products. In fact, the market demand for horror consumption has been rising in the past decades, making the genre of horror one of the most widely consumed form of entertainment. Yet, the extant understanding of this type of consumption remains relatively limited (Andrade and Cohen 2007). For example, when might consumers be more or less likely to engage in horror consumption? What might underlie such difference in preference? Our research seeks to help answer these questions.

Recent research suggests that consumers frequently experience perceived scarcity (vs. abundance) in resources such as goods and wealth (e.g., Booth 1984; Mullainathan and Shafir 2013; Shah, Mullainathan, and Shafir 2012; Roux, Goldsmith, and Bonezzi 2015; Zhu and Ratner 2015; see Cannon, Goldsmith, and Roux 2018 for a review). Such differences in perceived resource availability can trigger a generalized mindset, impacting subsequent consumer behavior in unrelated contexts (e.g., Mehta and Zhu 2015; Roux et al. 2015). Complementing and extending these prior findings, the current research explores how and why consumers' activated resource availability mindset can shape their preference for counterhedonic consumption. We propose that consumers with a resource abundance (vs. scarcity) mindset tend to have a higher preference for consuming horror. This occurs because resource abundance (scarcity) mindset increases (decreases) one's sense of control, which serves as a type of 'protective frame'—the feeling that danger and threat one is experiencing will not cause actual harm (Apter 1992; Andrade and Cohen 2007)—and hence allows consumers to experience more pleasure when consuming horror.

In four experimental studies, we test our propositions in a variety of consumption contexts. In study 1, using an established procedure (Roux et al. 2015), participants were primed with a resource abundance, scarcity, or control mindset. All participants were then presented with a poster ad for a haunted house experience, and were asked to indicate how much they would enjoy visiting the haunted house. Supporting our proposition, those primed with a resource abundance/control (vs. scarcity) mindset reported higher enjoyment ratings. This occurred even though a pretest showed that the particular priming procedure we used did not lead to significantly different affective reactions (a pattern consistent with prior research [e.g., Mehta and Zhu 2015; Roux et al. 2015]). Thus, potential affective differences induced by the mindset manipulation might not easily account for the results.

In study 2, participants were first primed with either a resource abundance or scarcity mindset. In a randomized order, they watched and rated two movie clips—one from the horror film *The Conjuring 2* and the other from the comedy-adventure film *Finding Dory*. Following Andrade and Cohen (2007), participants were asked to indicate how much positive and negative emotions they experienced when viewing each of the clips. For the horror film clip, participants primed with a resource abundance (vs. scarcity) mindset experienced more positive emotions when viewing the clip, but their experience of negative emotions did not differ. For the comedy clip, however, no difference was found for either the positive or negative emotions. These results thus further supported our propositions and showed that

potential affective differences due to the mindset manipulation we used, might not easily explicate the pattern of results we observed.

Studies 3 and 4 tested our proposed sense-of-control based mechanism. In study 3, participants primed with a resource abundance (vs. scarcity) mindset indicated an increased sense of control, which mediated the higher likelihood that they would consume a haunted house experience. Study 4 directly manipulated participants' sense of control and showed that the advantage of resource abundance (vs. scarcity) mindset on horror consumption was eliminated after participants' sense of control was reduced via a control deprivation manipulation (Whitson and Galinsky 2008).

Our research findings contribute to the literature in multiple ways. First, complementing the extant research on consumption of experiences that engender negative emotions (Andrade and Cohen 2007; Scott et al. 2017), we show that resource availability mindset can shape consumers' preference for horror-related experiences and products. Our findings also add to this literature by demonstrating that consumers' sense of control serves as an important type of 'protective frame,' enabling them to derive more pleasure from consuming horror. That is, activating a resource abundance (scarcity) mindset can increase (decrease) sense of control, thereby boosting (dampening) consumers' preference for horror consumption. Moreover, our research adds to the growing stream of research on the impact of resource scarcity versus abundance on consumer behavior (e.g., Cannon et al. 2018; Mehta and Zhu 2016; Shah et al. 2012; Roux et al. 2015; Zhu and Ratner 2015) by offering further evidence of how situationally induced resource availability mindset can subsequently shape consumers' preference for products and experiences in unrelated contexts.

# Material Gifts as Relationship Mnemonics: Why More Material Gifts Are Given Than Wanted?

Adelle X. Yang, National University of Singapore, Singapore  
Minjung Koo, Sungkyunkwan University, Korea  
Jaewon Hwang, Sejong University, Korea

## EXTENDED ABSTRACT

How do people choose material and experiential purchases when these purchases are intended as gifts for others? Following van Boven and Gilovich's (2003) initial distinction between material and experiential purchases centering on "people's intentions when investing in their happiness", the present research examines how people's interpersonal motives affect their choice between material gifts and experiential gifts.

Although recent research supports the superior effectiveness of experiential gifts at inducing receiver's satisfaction (Chun and Hiang 2016) and fortifying relationship between the receiver and the giver (Chan and Mogilner 2017), givers may not have such foresight. In particular, material gifts may appear more suitable than experiential gifts to symbolize the giver's ingratiating action as a physical, visible and durable mnemonic in the receiver's surroundings. This mnemonic, however, may be viewed in different light by a giver versus a receiver. In social reciprocation, people tend to egocentrically believe that their salient input to a favor can induce feelings of appreciation, whereas receivers tend to overlook the others' input and focus on the benefits that they can derive from the favor (Flynn and Adams 2009; Zhang and Epley 2009). Moreover, when reminded of the others' favor, the receiver tends to feel indebted, pressured, and obliged to reciprocate, a sentiment not as desirable as the giver may believe (Belk and Coon 1993; Greenberg 1980; Emerson 1976). Therefore, we theorize that givers tend to endow receivers with more material gifts (vs. experiential gifts) than receivers want them, because givers overestimate the extent to which material gifts facilitate bonding as mnemonics of their kind act, compared with receivers' prediction. We present five studies and a registered replication to test these predictions.

**Study 1** is an incentive-compatible study with 2 (giver vs. receiver) between-subjects conditions. Students ( $N = 216$ ) were randomly paired up. After a brief interaction, those randomly assigned to the giver condition were told that they could choose one of two options as an extra reward for their partner whereas their partner was separately asked to indicate their preference between the same options. The choice was between a mini postcard and a mini movie featuring the same cartoon characters, rated as a typical material gift and a typical experiential gift, and pretested to be similar in most aspects (e.g., desirability, attractiveness, perceived cost). Givers were more likely to choose the postcard over the movie compared with receivers (postcard choice: giver 66.4% vs. receiver 48.6%;  $\chi^2 = 6.94$ ,  $p = .009$ ).

**Study 2a** has the same 2 (giver vs. receiver) between-subjects conditions. First, we asked MTurkers ( $N = 149$ ) to list the name of an acquaintance that they would like to bond with, then list a life achievement important to the acquaintance and a life achievement important to themselves. After that, we randomly assigned participants into the giver or receiver conditions and asked them to list a gift that they would like to give to or receive from the listed friend, to celebrate the desired life achievement. Participants then indicated whether the gift was a material gift or experiential gift and briefly described it. Two independent coders rated the gift descriptions on two separate scales to determine the extent to which a gift was intended for possession (5-point scale), and the extent to which it was

intended for consumption (5-point scale), respectively. Their ratings were highly correlated and thus averaged for each scale. Givers and receivers' own categorization of gifts indicated that more givers listed a material gift than receivers did (48.6% vs. 31.2%;  $\chi^2 = 4.73$ ,  $p = .044$ ). Coders' ratings of the gift descriptions further suggest that gifts listed by givers were intended for possession to a greater extent than those by receivers ( $M_{giver} = 2.83$ ,  $SD = 1.46$  vs.  $M_{receiver} = 2.22$ ,  $SD = 1.38$ ;  $t(145) = 2.63$ ,  $p = .010$ ), while intended for consumption to a lesser extent than those by receivers ( $M_{giver} = 3.88$ ,  $SD = 1.17$  vs.  $M_{receiver} = 4.25$ ,  $SD = 1.03$ ),  $t(145) = -2.03$ ,  $p = .045$ ). These findings suggest two parallel causes contributing to the overall giver-receiver preference discrepancy between material and experiential gifts: givers had a stronger preference to endow material possessions than receivers wanted them, consistent with the mnemonic account; at the same time, givers had a weaker preference to give experiences than receivers wanted them, consistent with recent theorizing that givers often perceive higher social risk to choose experiential gifts to match receivers' uncertain preferences (Goodman and Lim 2018). All of these results were replicated in **Study 2b**, a registered replication ( $N = 276$ ).

In **Studies 3 and 4**, we further examined the psychological processes underlying the mnemonic account. We found a mediation in Study 4 ( $N = 490$ ) with perspective (giver vs. receiver) as the independent variable, difference in predicted bonding instrumentality of gifts as the mediating variable, and gift choice as the dependent variable (indirect effect = .57,  $SE = .28$ , 95% CI = [.04, 1.14]). We further manipulated motivation to bond in Study 4 ( $N = 445$ ) and found that a lower level of motivation to bond attenuated givers' overestimation of the relative bonding instrumentality of material gifts and mitigated their relative preference for the material gift ( $F(1, 441) = 3.37$ ,  $p = .067$ ).

Last, we examined a practically relevant boundary condition in **Study 5** ( $N = 183$ ). The mnemonic account predicts that givers desire to be thought of frequently yet would avoid being associated with negative events in receivers' memory. Consistent with this prediction, we found that the giver-receiver preference discrepancy was mitigated when the gift was to be associated with a negative life event instead of a positive one. A two-way ANOVA revealed the predicted interaction between perspective and event valence ( $F(1, 179) = 8.80$ ,  $p = .003$ ).

In sum, this research demonstrates that the trade-off underlying an interpersonal decision between material and experiential purchases systematically differs from that underlying an otherwise identical self-oriented decision. In particular, unlike what givers wish, their strong desire to bond may color their judgment and yield rather counterproductive bonding consequences.

# Consumer's Local-Global Identity and Price-Quality Associations

Zhiyong Yang, University of North Carolina at Greensboro, USA

Sijie Sun, University of Texas at Arlington, USA

Ashok K. Lalwani, Indiana University, USA

Narayanan Janakiraman, University of Texas at Arlington, USA

## EXTENDED ABSTRACT

Previous literature documents multiple factors that influence consumers' price-quality associations (PQA)—their tendency to use price as an indicator of perceived quality, including prior knowledge (Monroe 2003), product information (Kardes et al. 2004), and cultural background (Lalwani and Shavitt 2013). However, no research has examined the effect of local-global identity on PQA. Extending prior research, we investigate the role of local-global identity in influencing PQA.

Individuals whose local identity is salient ('locals') are faithful and respectful of local traditions, and identify with local community, whereas those with a salient global identity ('globals') favor globalization, and view the world as a "global village" (Ng and Batra 2017). We expect that locals and globals differ in perceived quality difference among brands in the marketplace which, in turn, affects PQA. Suppose the comparison objects are two alarm clocks. When global identity is high (vs. low), individuals focus on standardization and see things as homogeneous and similar to each other, leading to lower perceived quality differences between the alarm clocks. Further, if the brands are perceived as similar in quality, consumers less likely use any cues (e.g., price) to distinguish between them, thereby reducing PQA. Specifically, perceived similarity between themselves and others helps globals iron out the differences across people and drives them to focus not on specific attributes, but rather on "a general way of making sense of the world" (Oyserman 2009, p. 256).

However, when local identity is high (vs. low), individuals "zoom in" on the two alarm clocks and focus on finer details, which subjectively increases perceived dissimilarity between these two clocks. Indeed, perceived difference makes locals rely more on the distinction between themselves and others and leads them to focus on specific elements and direct experiences to make sense of the world (Ng and Batra 2017). When evaluating products, the focus on dissimilarities leads locals to use price—one of the most direct and obvious cue for brand comparison (Lalwani and Forcum 2013)—to distinguish among brands, thereby increasing their PQA.

We test our hypothesis via a field study and two lab experiments. Study 1 was conducted in a large shopping mall with real consumers ( $N=164$ ). Respondents were given a brochure either describing "Think Local Movement" or "Think Global Movement," which served as local and global identity manipulation, respectively (Gao, Zhang and Mittal 2017). Afterwards, participants rated quality, reliability, and dependability (1=Very Low and 7=Very High; Lalwani and Shavitt 2013) of three shoes that differed in prices. These three items ( $\alpha's>.89$ ) were averaged to form quality evaluation. The correlation between retail price and subjective quality evaluation for the shoes was calculated and served as the dependent variable PQA. As predicted, participants in the local (vs. global) identity condition had significantly higher PQA ( $M_{Local}=.68, M_{Global}=.40; t(162)=2.98, p<.01$ ).

Study 2 ( $N=122$ ) featured a 2 (identity: local vs. global)  $\times$  2 (price: high vs. low) between-subjects design. Local-global identity was manipulated through sentences unscrambling task (Zhang and Khare 2009). Afterwards, participants read information about three brands each of alarm clocks and microwaves: the target brand and two other comparison brands, which provided baseline price information (Lalwani and Shavitt 2013). Participants were randomly as-

signed to either high or low price condition, using identical product descriptions. The target brand was priced the highest (lowest) in the high (low) price condition, with equal price difference toward the other two baseline brands. After reading brand descriptions, participants rated the target brand on the three-item quality measures as in Study 1 ( $\alpha's>.85$ ). These three items were averaged to form a quality index. A 2 (identity)  $\times$  2 (price) ANOVA with the quality index as the dependent variable revealed a significant identity  $\times$  price two-way interaction ( $F(1,118)=4.82, p<.05$ ). As expected, locals rated the target brand as having higher quality in the high ( $M=4.99$ ) than in the low ( $M=3.97, t(61)=4.70, p<.01$ ) price condition. In contrast, for globals, the quality ratings did not vary across two price conditions ( $M_{Low}=.424, M_{High}=.454; t(57)=1.25, p=.22$ ).

Finally, Study 3 ( $N=277$ ) adopted a 2 (identity: local vs. global)  $\times$  2 (price: high vs. low)  $\times$  2 (product type: services vs. goods) between-subjects design to examine the moderating role of product type. Given that services are intangible and heterogeneous, perceived quality difference of services is by nature greater than that of physical goods (Lovell and Gummesson 2004). The greater variation in the quality of services (vs. goods) should increase globals' PQA—whose baseline tendency to differentiate brands (and hence, PQA) is low and has greater potential for increase. In contrast, since locals' tendency to differentiate brands (and hence, PQA) is already high, there is little room to increase it further ("ceiling effect"). As a result, they should exhibit little change in PQA when evaluating services (vs. physical goods). As expected, globals exhibited PQA when evaluating services ( $M_{Low Price}=.442, M_{High Price}=.515; t(62)=3.01, p<.01$ ) but not physical goods ( $M_{Low Price}=.474, M_{High Price}=.458; t(66)=-.79, p=.43$ ), whereas locals had PQA when evaluating both services and physical goods ( $p's<.05$ ).

This research contributes to the literature in two significant ways. First, it represents a first attempt to explicitly examine the effect of local-global identity on PQA. Second, it is also a pioneer to uncover perceived quality difference as a new qualitative difference between local and global identity.

# The Impact of Price and Size Comparisons on Consumer Perception and Choice

Jun Yao, Macquarie University, Australia  
Harmen Oppewal, Monash University, Australia  
Yongfu He, Monash University, Australia

## EXTENDED ABSTRACT

In packaged-goods retailing, manufacturers and retailers seek to set price levels and select package sizes such that their products are optimally competitive. In doing so they can choose to differentiate on price or on product size. For example, suppose Kraft offers a 330 ml bottle of salad dressing for \$2.51, implying a unit cost of \$0.76 per 100 ml. When a higher positioned competitor such as Praise aims to offer its product at the higher unit cost of \$0.84 per 100 ml, it can either offer a similar sized package at the higher price of \$2.76 or resize its product to 300 ml and match Kraft's price of \$2.51. In both cases Praise's unit cost stays at \$0.84 as intended and the difference between the Kraft and Praise products can be deemed economically equivalent. We define the two situations as the two comparison modes: price comparison (PC) mode and size comparison (SC) mode.

In the context of promotions, prior research has identified that, while a bonus pack and a price discount both represent a saving, consumers generally tend to prefer a bonus pack over an economically equivalent price discount (Diamond and Sanyal 1990). The monetary cost being zero for a bonus pack makes that it is processed independently of its price and so is perceived as a pure gain. In contrast, a price discount is more likely to be integrated into the regular price and is perceived as a reduction in loss (Chandran and Morwitz 2006). A pure gain looms larger than a reduction in loss on the value function, this results in a preference towards a bonus pack over a price discount in most instances.

Extending and generalizing the theorizing to our price-size comparison context, on the value function, a price difference elicits an incremental change (or a decremental change which is directionally opposite but magnitudinally the same as an incremental change) in loss whereas a size difference elicits a pure change in loss or gain. According to the principle of diminishing sensitivity in prospect theory, an incremental change is further away from the reference point, resulting in a lower sensitivity to the change than that of a pure change, which is adjacent to the reference point. In turn, due to their positions on the value function, pure changes generally loom larger than economically equivalent incremental changes. We therefore predict that consumers perceive a greater difference in value when two products differ in size (i.e., SC mode) than when they differ on price (i.e., PC mode). We call this the price size comparison (PSC) effect.

A series of experimental studies examine how differences in price or size affect consumer value perceptions and choices when purchasing grocery products. Studies 1 aimed to provide initial evidence for the proposed PSC effect. The study comprised a 2 (mode: PC vs. SC)  $\times$  2 (magnitude of difference: small vs. large) between-subjects design. Every participant saw a pair of unbranded biscuits either with a small (approximately 5%) or with a large (approximately 18%) difference in the retail prices or sizes of the options. Participants evaluated the magnitude of the value difference between the two product options on a seven-point bipolar scale with two items ( $r = .75$ ) (i.e., "how do you rate the difference between these two products in terms of value: 1 = small difference between products, 7 = large difference between products; 1 = narrow value range, 7 = wide value range"). Results showed that a comparison on size results in a greater perceived value difference between product options than a comparison on price.

Study 2a and 2b aimed to test numerosity (Pandelaere, Briers, and Lembregts 2011) as an alternative explanation for the PSC effect by expressively varying the numerosity of package size and the numerosity of price. In study 2a, in the SC mode, the size difference was either numerically larger (e.g., 1900 ml – 1800 ml = 100 ml) or smaller (e.g., 1.9 liter – 1.8 liter = 0.1 liter) than the price difference in the PC mode (e.g., \$8.54 – \$8.09 = \$0.45). In study 2b, prices are framed either in dollars (e.g., \$2.01 vs. \$2.45) or in Indonesian Rupiahs (e.g., Rp20,100 vs. Rp24,500) thus price differences are numerically either smaller or larger than the size difference (e.g., 160g vs. 195g). Results showed that value differences were perceived as larger in the SC mode than in the PC mode, this effect on perceived value difference did not interact with the comparison mode thus numerosity can be excluded as an alternative account underlying the PSC effect.

Study 3 tested if computational ease (Thomas and Morwitz 2009) is a possible alternative explanation by manipulating the ease of comparing price differences and size differences. Results showed that the ease of computation had neither a main effect nor an interaction with comparison mode thus computational ease is rejected as an alternative account underlying the PSC effect.

Study 4a revealed a downstream consequence of the PSC effect on product choice. Results showed that the probability of choosing the low-end option was higher in the SC condition (i.e., the choice share of the larger package size option) than in the PC condition (i.e., choice share of the lower price option). The effect of comparison mode on choice is mediated by perceived value difference. Study 4b demonstrated that the PSC effect on choice holds even in the presence of unit price information.

The price or size comparison effect on consumer responses is of direct and significant interest especially to marketers concerned with inter-brand competition. Owing to consumers' greater susceptibility to size differences, a more beneficial approach to the pricing of a brand with a low-end positioning may be to carry the same price as the competing brand but provide more product volume. On the other hand, for a brand with a high-end positioning a more appropriate strategy is to offer a package that is of equal size as the competing brand, avoiding any adverse feelings associated with size loss, and instead differentiating the product by charging a higher price.

# Feature a Benefactor or a Victim? How Charity Appeals with Different Protagonist Foci Affect Donation Behavior

Bingqing (Miranda) Yin, University of Kansas, USA

Jin Seok Pyone, University of Kansas, USA

## EXTENDED ABSTRACT

Charities often emphasize victims' plight in their appeals (e.g., an emaciated, hunger-stricken child featured in UNICEF's ads) and extensive donation research focuses on studying victim appeals. However, victim appeals have their limitations. Factors such as donors' emotional exhaustion (Ein-Gar and Levontin 2013) or donors' perceptions of justice (Lee, Winterich, and Ross 2014) tend to weaken the effectiveness of victim appeals. Crucially, when charity recipients are out-group members, even charity appeals featuring an identified victim lose their effectiveness (e.g., Kogut and Ritov 2007).

In this paper, therefore, we consider featuring an alternative protagonist in the charity appeal, especially when soliciting donations for out-group members. Instead of a distressed victim, a charity can feature a person who renders help to the needy to accomplish the charity's mission—a benefactor. In practice, some charities have already been featuring a benefactor in their appeals. For example, *United Way*, in early 2017 launched a docu-series named "The Hero Effect," in which each episode features an ordinary citizen having a life-changing impact on an individual or a community. Yet, little is known about whether the benefactor appeal is more effective than the victim appeal in eliciting charitable donations, and if so, when and why.

We suggest that while both a victim and a benefactor appeal can be useful in soliciting donations, these two appeals operate by evoking different emotions. A victim appeal often induce negative emotion, making people feel sorry, sad, or even upset about the victim's distressful situation, in an attempt to trigger donors' charitable actions. In contrast, we posit that a benefactor appeal can evoke a specific positive moral emotion—moral elevation, the warm, uplifting feelings that people experience when witnessing others' moral excellence (Haidt 2000), which trigger people's desire to do a charitable act for others. We further propose that the effectiveness of a benefactor appeal, relative to a victim appeal, depending on the charity recipients' group membership. When recipients are in-group members, people's donation intentions are less likely to be influenced by the charity appeal protagonist. However, when recipients are out-group members, featuring a benefactor should be more effective as the benefactor appeal leads people to focus on their own desire to be a better person by helping others, not the victim's distressful situation.

We further suggest that the group membership of the benefactor also influences the effectiveness of benefactor appeals. We specifically theorize that this is because the benefactor's group membership influences the extent to which people act upon the emotion evoked by the benefactor—moral elevation, which affects their donation behavior.

We test our hypotheses in five experiments. In experiment 1A (N=81), we test the main effect of protagonist focus on charitable donation and the underlying mechanism. Participants were randomly assigned to one of the two conditions—a charity appeal featuring either a benefactor or a victim. Results showed that participants indicated higher donation likelihood to the benefactor appeal than the victim appeal ( $p < .05$ , two-tailed).

Using PROCESS (model 4; Hayes 2013) with 10,000 bootstrapped samples, the indirect effect of charity appeal focus on donation amount was mediated by moral elevation (95% Bootstrap CI: .45, 1.54). Overall, the results support that a benefactor appeal can

be more effective than a victim appeal and the effect is driven by moral elevation.

In experiment 1B (N=81), we intend to replicate the effect by designing a new set of stimuli. Participants were randomly assigned to read either a benefactor appeal or a victim appeal. The charity provides vision care to out-group recipients (African victims). Replicating the results from experiment 1A, participants who read the benefactor appeal were more willing to donate than those who read the victim appeal ( $p < .05$ , two-tailed). Mediation analysis based on 10,000 bootstraps (Hayes 2017, model 4) showed that the indirect effect of moral elevation was significant (95% bootstrap CI: -1.36, -.40). These results provides further evidence that a benefactor appeal can promote charitable giving because of moral elevation.

In experiment 2 (N=124), we examine the moderating effect of charity recipients' group membership. This experiment employs a 2 (charity appeal: benefactor vs. victim) X 2 (recipients' group membership: in-group vs. out-group) and participants were randomly assigned into one of the four conditions. As predicted, results showed a significant interaction ( $p = .05$ , two-tailed). Pairwise comparisons revealed that, when recipients were out-group members, participants who read the benefactor appeal were more willing to donate than those who read the victim appeal ( $p = .03$ , two-tailed). On the other hand, when recipients were in-group members, both appeals elicited similar levels of donation intention ( $p = .59$ ).

In experiment 3 (N=612), we included two more conditions where an out-group benefactor helps in-group/out-group recipients. We used a 3 (charity appeal: in-group benefactor vs. victim vs. out-group benefactor) X 2 (recipients' group membership: in-group vs. out-group) between-subjects design. As predicted, results showed a significant two-way interaction ( $p = .02$ , two-tailed). In pairwise comparisons, when the recipients were out-group members, donation likelihood was higher for the in-group benefactor appeal than the victim appeal and the out-group benefactor appeal (all  $p$ s < .03, two-tailed), though both the in-group and out-group benefactor appeals led to similar levels of moral elevation ( $p > .04$ ). On the other hand, when the recipients were in-group members, no donation intention difference was found among the three appeals (all  $p$ s > .18, two-tailed).

In experiment 4 (N=166), we focus on the out-group recipients conditions and investigated the underlying mechanism of the benefactor's group membership on donation. Participants were randomly assigned to read one of the three charity appeals featuring a victim, an in-group benefactor, or an out-group benefactor. Results showed that an out-group benefactor appeal, though elicited similar levels of moral elevation as an in-group benefactor appeal ( $p > .10$ ), led to donation amount ( $p = .02$ ). Mediation analysis revealed a significant indirect effect of feeling versus reasoning based decision process (95% bootstrap CI: .02, .18), such that people who read the out-group (vs. in-group) benefactor appeal relied less on their feeling (vs. reasoning), resulting in lower donation amount.

Taken together, we develop a theoretical framework on when and why a benefactor appeal elicits more donations. Five studies involving both behavioral intention and real donation measures test and confirm the theoretical model. We contribute to research on charitable donation, moral elevation and demonstrate to charities that a benefactor appeal can be effective in promoting donations.

# Charity Begins at Home: How Incremental Theory Enhances or Reduces Charitable Giving

Alyssa Yoon, Korea University, South Korea  
Jongwon Park, Korea University, South Korea

## EXTENDED ABSTRACT

People's generosity declines with the self-other distance (Dovidio et al. 1997; Jones and Rachlin 2006). While the negative impact of distance on prosocial outcome is well understood, can the perception of distance between self and others chronically differ? In this research, we demonstrate that subscribing to incremental theory (vs. entity theory) leads to higher charitable intention, and such effect arises because the beneficiaries viewed as changeable, as in the lenses of incremental theorists, feel closer to the self.

Individuals differ in the extent to which they view human qualities as malleable (Dweck, Chiu, and Hong 1995). While *incremental theorists* believe that people can change and improve who they are, *entity theorists* view others to be consistent across time and situation. Consequently, incremental theorists' impressions of others constitute the contextualized factors (e.g., situation and needs), whereas entity theorists seek to assess the unchanging, global traits (e.g., personality and ability) of others (Molden, Plaks, and Dweck 2006). Such low- (vs. high-) level focus is known to embody the construal of proximate (vs. distant) others (Nussbaum, Trope, and Liberman 2003; Rim, Uleman, and Trope 2009). In the similar vein, entity theorists were shown to endorse the stereotypes more readily (Hong et al. 2004), and incremental theorists accord more individuating elements to out-group members (Levy, Chiu, and Hong 2006). All evidence taken together suggests that compared to incremental theorists, entity theorists have a clearer demarcation between self and other, which is a traditional hallmark of social distance (Liviatan, Trope, and Liberman 2008).

We test the proposed mechanism in two ways, one via direct measures of social distance (study 2) and the other via moderation by campaign goal progress (studies 3 and 4). Because whether one will pursue a collective goal (i.e., donation campaign) is an interactive effect of one's sense of closeness with its beneficiaries and, importantly, the perceived goal progress (Fishbach, Henderson, and Koo 2011; Williams and Karau 1991), we expect a moderating role of donation goal progress in the link between the donors' implicit self-theories and their intention to contribute. Specifically, individuals who view the victims as remote are more likely to question if the campaign is worth joining and thus become more motivated if the accumulated progress is high rather than low. However, ones who feel closer to victims and thus already consider the donation campaign as worthwhile will be more driven when the progress is unsatisfactory (Fishbach, Koo, and Finkelstein 2014; Williams and Karau 1991). Drawing on the motivation literature, we propose and observe a reversed effect such that a high-progress campaign leads the entity theorists to become more charitable than their incremental counterparts.

Study 1 (n=120) provided initial confirmation of the main effect of incremental theory on donation. Participants' chronic incremental theory significantly increased their intention to donate to help Sierra Leone ( $b = .26, t = 2.36, p = .02$ ). In study 2, participants (n = 178) were asked the amount they were willing to give out of \$100 to a Nepal earthquake relief. Perceived social distance was measured ("How distant/close do you feel to people of Nepal?" and "Despite the fact that Nepal earthquake did not affect me, I can identify with the people in Nepal"; reverse-coded). Positive effect of incremental theory on donation was replicated ( $b = .08, t = 2.47, p = .01$ ). Social distance predicted willingness to donate ( $b = .72, t = 7.23, CI_{95\%}: .53 \text{ to } .92, p < .001$ ), reducing the incremental theory effect on donation to nonsignificance ( $b = .05, t = .58, CI_{95\%}: -.12 \text{ to } .22$ ).

Finally, we investigated the moderating role of campaign goal progress, both when perceived (study 3) and manipulated (study 4). In study 3, participants (n = 181) read a donation appeal with a goal amount but no progress indicator and then estimated the donation goal progress. Theory priming did not affect the progress perception ( $M_{\text{entity}} = 2.88$  vs.  $M_{\text{incremental}} = 3.06$ , NS). As anticipated, implicit self-theories and the perceived progress had a significant interaction ( $b = -.39, t = -2.93, p < .01$ ). Floodlight analysis revealed two significant regions, suggesting that when perceived progress was high (vs. low), those who adopted the entity (vs. incremental) theory were more willing to donate.

In study 4 (n = 118), participants were assigned to either low (20%) or high (80%) campaign progress. Implicit theories and the progress manipulation significantly interacted ( $b = -.43, t = -3.96, p < .001$ ). Spot-light analysis showed that the effect of progress on donation was positive among entity theorists ( $b = .50, t = 2.04, p = .04$ ), but negative among incremental theorists ( $b = -.87, t = -3.59, p < .001$ ). Further, a mediated moderation analysis (Model 8; Hayes 2013) indicated that their primary drivers differ, supporting our theorizing that incremental theorists feel closer to others and thus more committed to help (Fishbach et al. 2011). Specifically, we measured the perceived need for progress (e.g., "my participation is important"), and the perceived value of goal (e.g., "the campaign goal will be reached"). We confirmed that the entity theorists' higher donation intention in the high-progress condition was mediated by the perceived value of goal ( $b = .33, SE = .12, CI_{95\%}: .12 \text{ to } .61$ ), but not by the need for progress ( $b = .26, SE = .16, CI_{95\%}: -.02 \text{ to } .58$ ). By contrast, the incremental theorists' higher charitable intention in the low-progress condition was mediated by the need for progress ( $b = -.36, SE = .15, CI_{95\%}: -.67 \text{ to } -.10$ ), not by the goal value ( $b = .08, SE = .08, CI_{95\%}: -.03 \text{ to } .28$ ).

Through four experiments, we found that incremental theorists are more likely to feel close to the victim and make donations as a result. However, when donation campaign is highly progressed, the entity theory increases charitable giving. Further research replicating our findings in real donation campaign settings is underway. Meanwhile, our findings urge that marketers and policy makers take into account consumers' implicit self-theories when seeking to encourage charitable behavior.

# Toward Optimal Symbolic Recovery: Comparing “Thank you” and “Sorry” in Addressing Service Delays

Yanfen You, New Mexico State University, USA  
Xiaojing Yang, University of Wisconsin-Milwaukee, USA  
Lili Wang, Zhejiang University, China  
Xiaoyan Deng, Ohio State University, USA

## EXTENDED ABSTRACT

Service delay, or unexpected delay after a service has been scheduled (Taylor 1994), is the most common type of service failure (Goodwin and Ross 1992). Unlike product failure that usually requires utilitarian recovery efforts to alleviate the “financial pain” felt by consumers (Dunn and Dahl 2012) researchers have found that consumers feel better about the product failure after complaining about it. In contrast, the authors show that when consumers are to blame for product failure, complaining has a detrimental effect on consumer reactions to the product. In this context, self-threat from the product failure is shown to motivate defensive processing in both the content of complaints and the subsequent downstream product evaluations. The authors establish the role of self-threat in product failure in two ways: (1), service delay is a typical process failure in which marketers could strategically employ symbolic recovery efforts to ease consumers’ “psychological pain” (e.g., feeling of not being respected). According to the sociometer theory of self-esteem, people’s feelings about themselves are affected by the extent to which they believe other people have accepted or rejected them (Leary et al. 1995, 1998). As consumers perceive an unscheduled delay as a signal of the marketer’s lack of attention to their interest and lack of effort in protecting their welfare (Seiders and Berry 1998) financial institutions, and financial elites gain greater influence over economic policy and economic outcomes. Financialization transforms the functioning of economic systems at both the macro and micro levels. Its principal impacts are to (1, their self-esteem is threatened. Therefore, “*what to say*” to customers after service delays is especially important for marketers to repair consumers’ thwarted self-esteem and restore their satisfaction.

Despite research on speech acts suggesting that apology (e.g., “Sorry about the delay”) and appreciation (e.g., “Thank you for your patience”) are equally logical marketer responses to service delays (Coulmas 1980), prior work has only discussed apology as a symbolic recovery strategy (e.g., Witz and Mattila 2004). Apology has been shown to reduce victims’ unfairness perception, anger and aggression (e.g., Darby and Schlenker 1982) which are often manifestations of the feelings of being disrespected (Dunn 2016; Seiders and Berry 1998). As such, apology is effective in repairing consumers’ thwarted self-esteem (Tyler, DeGoey, and Smith 1996).

Drawing from research on service recovery and the self, we expect that appreciation goes beyond this reparative effect of apology on self-esteem which is through acknowledging marketers’ mistake and accountability. Appreciation shifts the focus from marketers to consumers by placing them in the benefactor position and highlighting their merits and contributions in the service delivery, thereby signaling approval and acceptance. Based on the sociometer theory (Leary and Baumeister 2000), positive approvals and acceptance from others boost self-esteem. The elevation in self-esteem in turn increases customer satisfaction because based on the self-enhancement theory, people are motivated to pursue positive self-views (Heine et al. 1999; Schaumberg and Wiltermuth 2014) and their self-regard is salient, they will be less likely to use the comparison information when judging their standing in the domain. Participants in Study 1 estimated their standing on risk factors for two health problems, and some did

so after their self-regard was made salient. Some received information that challenged participants’ self-serving comparative beliefs. As expected, estimates of personal risk factor standing among high self-regard salience/comparison information participants were less correlated with similar estimates collected 2 months earlier, suggesting the estimates had become less inductive. There was also tentative evidence that, in this condition, self-esteem played a greater role in constructing these estimates. In Study 2, participants were led to believe that their comparative standing on risk factors was better than it actually was, and in this case, they were more likely to use this information when making self-judgments about their personal risk. Evidently, the extent to which people use diagnostic comparison information inductively when making self-inferences depends on the favorability of that information. (PsycINFO Database Record (c and therefore respond positively to those who boost their positive self-views (Colman and Olver 1978). As such, appreciation is more effective in promoting post-recovery satisfaction than apology. Across six studies, we provide support for our theory and its process explanations.

Study 1 examined our hypothesis in a real-world delay situation. After completing lab experiments, participants were promised that they would receive their compensation on the same day. However, they were not contacted by the lab assistant until the following day. Using a mobile payment app, the assistant greeted them with either “*Thank you for waiting for such a long time!*” or “*Sorry for keeping you waiting for such a long time!*” and distributed the compensation. A follow-up survey link was sent to participants to collect feedback. Results revealed a higher response rate (91% vs. 78%) and more satisfaction ( $M_{\text{appreciation}} = 5.52$  vs.  $M_{\text{apology}} = 5.11$ ) in the appreciation condition.

Study 2 measured self-esteem in a one-way (symbolic recovery: appreciation vs. apology vs. control) between-subjects design. Participants first read about a product delivery delay and were told that they either received an apology, an appreciation or nothing from the online store. Recovery satisfaction, overall satisfaction, positive WOM intention, and self-esteem were measured. Results revealed significant effects on recovery satisfaction ( $M_{\text{control}} = 3.03$  vs.  $M_{\text{apology}} = 4.40$  vs.  $M_{\text{appreciation}} = 5.07$ ), overall satisfaction, WOM, and self-esteem ( $M_{\text{control}} = 3.10$  vs.  $M_{\text{apology}} = 4.14$  vs.  $M_{\text{appreciation}} = 4.80$ ). Furthermore, self-esteem mediated the effect of recovery strategy on recovery satisfaction (relative indirect effects:  $b_1 = -.74$ , 95% CI  $-1.16$   $-.31$ ;  $b_2 = .46$ , 95% CI:  $.03$   $.94$ ), overall satisfaction and recommendation intention.

Study 3 utilized in a 2 (self-esteem: low vs. high)  $\times$  2 (recovery strategy: apology vs. appreciation) between-subjects design. Self-esteem was manipulated by informing participants that their performance in an English word generation task was ranked in the bottom (top) 10%. Then they read about a restaurant service delay situation in which the server either apologized for the delay by saying “*I’m sorry for keeping you waiting! I apologize,*” or appreciated their patience by saying “*Thank you for your patience! I appreciated it.*” Participants reported their satisfaction with the server, tipping likelihood and tip amount. Results showed significant interactions of self-esteem and recovery strategy on all dependent variables ( $p$ ’s

< .06). Specifically, in the low self-esteem condition, appreciation led to higher satisfaction, tipping likelihood, and tipping amount ( $p$ 's < .05). However, the superiority of appreciation disappeared in the high self-esteem condition ( $p$ 's > .09).

Study 4 provided triangulating evidence for the underlying mechanism by utilizing narcissism as a moderator because it determines the strength of consumers' desire to be well regarded by others. It featured a 2 (recovery strategy: apology vs. appreciation)  $\times$  narcissism (continuous) design using the restaurant scenario as the context. Narcissism was measured based on Ames et al. (2006). Floodlight analysis revealed that the superiority of appreciation (vs. apology) existed only among participants whose narcissism index was higher than 3.47 (BJN = .59,  $p = .05$ ). Study 5 examined the role of service delay severity and demonstrated that the superiority of appreciation disappeared when the delay was perceived to be minor. Study 6 showed that when consumers' attention was drawn to service providers' fault, apology was more effective than appreciation.

Our research connects research on service recovery, linguistic framing, and self-concept to show how service providers can strategically frame their response to increase customer recovery satisfaction.

# Promoting Pi Day: Consumer Inferences About Special Day-Themed Promotions

Daniel M. Zane, University of Miami, USA

Kelly L. Haws, Vanderbilt University, USA

Rebecca Walker Reezek, Ohio State University, USA

## EXTENDED ABSTRACT

Using marketing promotions to attract customers is so prevalent that it takes something special for a given promotion to stand out (Kalwani and Yim 1992). In the Internet age, firms can ensure that a promotion is distributed on a specific day and thus offer more promotions around “special days” (e.g., a 31.4% discount for Pi Day on March 14<sup>th</sup>) in addition to typical holiday promotions (e.g., standard Christmas discounts). Are such special day-themed appeals effective? This research explores the effectiveness of special day-themed promotions and outlines important boundary conditions for their effectiveness.

Research on marketplace metacognition demonstrates that consumers often think about and draw inferences from marketers’ actions and intentions (Wright 2002). For example, consumers reward marketers with an increased willingness-to-pay for products when they infer that marketers put extra effort into designing product displays (Morales 2005). Based on the metacognition literature more generally, which shows that people are particularly likely to draw inferences about unexpected/atypical experiences (Schwarz 2004), we argue that consumers are likely to draw inferences about atypical special day-themed promotions compared to standard promotional events. Specifically, we expect consumers to infer that the marketer is creative when they encounter a special day-themed promotion (subject to boundary conditions). Consumers then reward marketers for their creative effort with more positive evaluations of the promotion and increased purchase intentions.

In study 1, we conducted a field study with a small company that sells dog gear. Customers ( $n = 239$ ) received one of two versions of a promotional email. In the special day-themed promotion condition, they saw a 25% discount on dog gear in honor of the anniversary of the day the company rescued its mascot (a dog). The email in the standard promotion condition contained a 25% discount for a standard one-day sale, with no mention of the special day. Customers in the special day-themed promotion condition were significantly more likely to click on the “shop now” button compared to those in the standard promotion condition (19.30% vs. 10.00%;  $\chi^2 = 4.16, p < .05$ ). Sales data showed a similar pattern.

In study 2, participants in all three conditions imagined receiving an email promotion for a clothing retailer on March 14<sup>th</sup> (Pi Day). In the special day-themed promotion condition, participants saw a 31.4% discount for an “Ultimate Pi Day” one-day sale. In the standard smaller [larger] promotion condition, they saw a 30% [35%] discount for a standard one-day sale. Participants then assessed their liking of the promotion. Participants in the special day-themed promotion condition had significantly more positive evaluations of the promotion ( $M = 3.49$ ) compared to participants both in the standard smaller promotion condition ( $M = 2.29; t(168) = 5.30, p < .0001$ ) and standard larger promotion condition ( $M = 2.14, t(186) = 5.88, p < .0001$ ). Thus, consumers appear to even like a special day-themed promotion more than an objectively better promotion not attached to the special day.

Study 3 extends these findings using a different special day and different promotion held constant across conditions. Additionally, we explore an important boundary condition by measuring participants’ familiarity with the holiday. All participants viewed a promotion for Lego valid on May 4<sup>th</sup> only (the study was conducted in real-time on the actual holiday): “Buy any 3 Star Wars Lego items, Get the 4<sup>th</sup>

Star Wars Lego item FREE.” In the special day-themed promotion condition, the promotion was linked to “Star Wars Day” and the accompanying slogan, “May the Fourth Be With You.” In the standard promotion condition, the advertisement included no mention of this holiday or slogan. Participants then evaluated the promotion using the study 1 measure. A significant interaction emerged between the promotion manipulation and participants’ familiarity with the holiday ( $\beta = 0.12, t(148) = 2.44, p < .05$ ). Among participants who were familiar with the holiday (above 6.23; ~38% of participants), those who viewed the special day promotion had significantly more positive evaluations than those who viewed the standard promotion. This pattern was attenuated as familiarity declined and began to reverse at low levels of familiarity. Thus, special day-themed promotions are only effective when consumers can understand the marketer’s creativity and might actually backfire otherwise.

Study 4 establishes direct process evidence that inferences about the marketer’s creativity drive consumers’ liking of special day-themed promotions. We also demonstrate that positive evaluations of these promotions drive increased intentions to use them. All participants viewed a 30% discount for a shoe store valid “today only.” Because the study was run on June 1<sup>st</sup> (i.e., National Go Barefoot Day), participants in the special day-themed promotion condition viewed a National Go Barefoot Day sale with the tagline “You might not need shoes today, but we’ve got you covered for tomorrow!” Participants in the traditional event-themed promotion condition viewed a Start of Summer sale with the same tagline. In the no event promotion condition, participants saw a standard one-day sale not linked to any event at all with the same tagline. Participants reported their evaluations of the promotion, perceptions of the marketer’s creativity, and intentions to use the promotion.

Participants in the special day-themed condition had significantly more positive evaluations of the promotion ( $M = 5.04$ ) than those in the traditional event-themed ( $M = 4.43$ ) and no event promotion conditions ( $M = 4.50, t(297) = 2.82, p = .005$ ). The same pattern resulted for participants’ perceptions of the marketer’s creativity. Finally, serial mediation models revealed that increased perceptions of the marketer’s creativity in the special day-themed promotion condition led to more positive evaluations of the promotion, which then led to higher intentions of using the promotion to make a purchase, compared to both the traditional event-themed promotion condition and no event promotion condition.

Together, these studies provide evidence that special day-themed promotions boost participants’ evaluations and lead to increased usage intentions (study 1) even compared to standard promotions that are more favorable financially (study 2), as long as participants understand the marketer’s creativity (study 3). Ultimately, consumers reward marketers for their creative effort in offering special day promotions (study 4).

# Predicting Memory-Based Consumer Choices from Recall and Preferences

Zhihao Zhang, University of California, Berkeley, USA  
Aniruddha Nrusimha, University of California, Berkeley, USA  
Ming Hsu, University of California, Berkeley, USA

## EXTENDED ABSTRACT

Consumers often need to make choices when some or all of the information relevant to the decision is not physically present. To deal with this, they need to retrieve the necessary information from their own memory (Lynch, 1982), e.g. a list of brands within a category, prior experiences with a brand, and knowledge about key attributes of certain products. The processes mediating consumer recall, and their downstream effects on consumer choice, have been subject to intense study by consumer researchers. An extensive literature in consumer research strongly indicates a positive role of memory in consideration and choices. Brands that have higher awareness or accessibility are more likely to be chosen (Hoyer & Brown, 1990; Posavac, Sanbonmatsu, & Fazio, 1997). Furthermore, increasing brand accessibility or strengthening category-brand association boosts the likelihood of consideration and choice for a brand of interest (Nedungadi, 1990; Posavac, Sanbonmatsu, Cronley, & Kardes, 2001).

To date, however, it remains challenging to understand and predict how effects of marketing actions on memory are translated into actual behavior. In particular, what is the nature and force of processes by which stronger brand memory leads to more choices of the brand? Could brand memory be a proxy for preference or a component of preference? Do brand memory and preference operate independently? Without such mechanistic insights, it is difficult for marketers to predict or validate consumer memory measures with actual purchase data, or to estimate the return on investment (ROI) of an advertising campaign that is projected to increase brand awareness (Rust, Lemon, & Zeithaml, 2004).

Accordingly, we sought to take a step toward addressing these questions by building on influential multi-stage decision-making models (Manski, 1977; Manzini & Mariotti, 2014; Roberts & Lattin, 1991) that explicitly capture process-level insights into memory-based choices. Specifically, our model (hereafter called two-stage model) incorporates both recall and evaluation as sequential stages in the decision-making process as follows. Prompted with the category cue, the agent is assumed to first construct a menu by retrieving a set of relevant brands from memory, and the inclusion of a certain brand is determined probabilistically by the strength of the category-brand association. Next the agent makes a choice based on relative preferences for the brands on the menu.

To test this model, we collected independent datasets for brands from two product categories (fast food restaurants and running shoes) in order to define three measures: (1) brand accessibility, the percentage of participants recalling the brand of interest when prompted with a category cue; (2) brand preference, the percentage of participants choosing the brand of interest in stimulus-based choices or SB-C (with a menu listing a large number of brands in a category); and (3) memory-based brand choices or MB-C, the percentage of participants choosing the brand of interest in memory-based choices (category cue only, no menu). We then used these measures as the input to our proposed model to compute predicted memory-based choice probabilities for all brands.

Predictions of MB-C probabilities for brands were generated from the proposed two-stage model, as well as models using preference or memory information alone. These predictions were then compared against the empirically measured MB-C probabilities in our sample (Figures 1A-C). A quantitative examination of predic-

tions from different computational models shows that the two-stage model robustly outperformed models using preference or memory information alone in both categories (Figures 1D) (Fast food: memory + preference  $R^2 = 0.937$ ; preference-only  $R^2 = 0.455$ ; memory-only  $R^2 = 0.803$ ) (Running shoes: memory + preference  $R^2 = 0.993$ ; preference-only  $R^2 = 0.859$ ; memory-only  $R^2 = 0.593$ ). Non-overlapping 95% confidence intervals indicated that the differences in prediction performance between the memory + preference model and the other two models were statistically significant (Figure 1D).

These findings echo and extend the extensive prior literature on the influence of memory on brand choice processes (Coates, Butler, & Berry, 2006; Nedungadi, 1990; Posavac et al., 1997). Importantly, our study proposes and validates a simple mechanism by which higher accessibility of brand memory translates into advantages in memory-based consumer choices, which is independent with preference. In this mechanism, the key component mediating the effect of memory is the intermediate step of internal menu generation in the proposed two-stage model. The higher the accessibility of a brand, the more likely it will be included in the internal menu.

This component in the two-stage model is closely related to the substantial literature on consideration sets (Manzini & Mariotti, 2014; Shocker, Ben-Akiva, Boccara, & Nedungadi, 1991). In particular, the second stage of our two-stage model that expresses the problem as a preference-based choice from a given choice set (menu) resembles previous models in this literature (Manski, 1977; Roberts & Lattin, 1991; Shocker et al., 1991). The key conceptual differences, however, lie in how the intermediate menus are generated. Most extant studies on consideration sets did not focus on memory factors; instead, they modeled the formation of consideration sets in choice problems as a rational, voluntary choice based on a tradeoff between the potential benefit and the cost of considering one more option (Brown & Wildt, 1992; Hauser, 2014; Roberts & Lattin, 1991). In contrast, our models describe menu generation as probabilistic processes governed by the strength of category-brand associations, and hence the composition of the choice set is less of an active choice by the agent. It is worth pointing out that highlighting the role of memory does not necessarily contradict the possible existence of consideration sets generated from voluntary inclusion/exclusion of options; rather, it is much more appropriate to view the two accounts as complementary. It will be fruitful in future work to combine both aspects in a single model of memory-based choices.

By linking brand memory and brand choice in a predictive model, our approach presents both conceptual and methodological advances capable of estimating the impact of changing brand awareness and accessibility on market performance. Furthermore, it also offers a flexible toolkit for brand managers to evaluate marketing campaigns in a wide variety of competitive landscapes.

# Sizes are Gendered: Impact of Size Cues in Brand Names on Brand Stereotyping

Kuangjie Zhang, Nanyang Technological University, Singapore

Shaobo Li, Nanyang Technological University, Singapore

Sharon Ng, Nanyang Technological University, Singapore

## EXTENDED ABSTRACT

What comes to your mind when you think of the brand name Mini Cooper or Grand Cherokee? Physical size would probably be among the first few associations that come to mind - Mini Cooper is physically smaller, whereas Grand Cherokee is physically bigger. However, size cues in brand names also evoke other associations?

This research proposes that such size cues would trigger ingrained gender associations. Specifically, we argue that size cues of “smallness” (e.g., little, small) versus “bigness” (e.g., grand, big) in brand names can activate female versus male gender associations, which subsequently affect the warmth and competence perceptions of the brand.

This possibility arises from anecdotal evidence and linguistics research. With some exceptions, men are generally physically bigger in size than women (Touraille and Gouyon 2008). Linguistically, people tend to generate descriptions such as big (vs. little) when they evaluate an object that has a masculine (vs. feminine) grammatical gender in their native language (Aikhenvald 2016; Boroditsky, Schmidt, and Phillips 2003).

These findings lead to the proposition that consumers have a general mental association between size (small vs. big) and gender (female vs. male). As such, brand names involving size cues related to smallness (vs. bigness) would evoke female (vs. male) gender associations, and this has important implications on how consumers perceive a brand. Specifically, it has been well-established that women are stereotyped as warm whereas men are stereotyped as competent (Fiske et al. 2002; White and Gardner 2009). Building on this stream of research, we hypothesize that size cues in brand names can evoke gender associations, which subsequently affect consumers' perceptions of warmth and competence of the target brand.

Further, building on prior research (Aaker, Vohs, and Mogilner 2010; Dubois, Rucker, and Galinsky 2016), we hypothesize that the downstream consequence of size cues in brand names on brand evaluation depends on the relative importance of warmth and competence in the consumption context. We identify two situational factors, consumption goals and brand gender positioning, which interact with size cues in brand names to influence consumers' brand evaluation.

Seven studies were conducted to test the proposed hypotheses. Study 1 used a standard IAT to test the basic premise. In this IAT, participants sorted either size cues (e.g., small, big) or person names (e.g., David, Mary). The results show that the average D-score was positive and significantly greater than zero, supporting our key premise that participants indeed associate smallness with femininity and bigness with masculinity.

Study 2A and 2B examined the effect of size cues on perceptions of warmth and competence of a brand among Chinese and US consumers. In study 2A, Chinese participants were randomly assigned to one of the two size cue (small vs. big) conditions. Specifically, participants were presented with the same brand logo and information, but with different brand names (Kaiyuan Small Pavilion vs. Kaiyuan Big Pavilion). Results showed that brand name with size cue of smallness (vs. bigness) was perceived to be higher in warmth but lower in competence. In study 2B, we replicated these findings among US consumers using different brand names (Little Salon vs. Grand Salon).

Study 3 replicated previous findings by utilizing yet another consumption context (Little Cafe vs. Grand Cafe). Importantly, in this study we also measured the extent to which participants associate the brand names with maleness (vs. femaleness). We showed that participants associated the brand name containing small (vs. big) size cue more strongly with femaleness (vs. maleness), and that such gender association mediated the effect of size cues in brand names on both warmth and competence perceptions.

Study 4 ruled out an alternative explanation related to physical size. This study followed a 2 (semantic size: small vs. big) × 2 (physical size: small vs. big) between-subjects design. To manipulate semantic size, we followed the same method used in previous studies by using different brand names (Small Kitchen vs. Big Kitchen). To manipulate physical size, we manipulated the visual size of the target store on a map as either smaller or bigger than other stores. A two-way ANOVA revealed only a significant main effect of semantic size cues on warmth and competence perceptions. In other words, we found that physical size of the store did not affect warmth and competence perceptions.

Studies 5 and 6 explored the downstream consequence of size cues in brand names on brand evaluation depending the relative importance of warmth and competence in the consumption context. Study 5 examined the role of consumption goals (communal vs. agentic). Participants imagined they were looking for a restaurant at which to meet either an old friend (communal goal) or a business associate (agentic goal). A significant interaction between size cue and consumption goal on purchase intention emerged. Participants indicated greater purchase intentions for the brand name with a size cue of smallness (vs. bigness) when they had a communal goal (i.e., meeting with a friend). Conversely, they indicated greater purchase intentions for the brand name with size cue of bigness (vs. smallness) when they had an agentic goal (i.e., meeting with a business associate).

Study 6 examined the role of brand gender positioning (feminine vs. masculine). Participants were told that the brand was a perfume brand (feminine) or a cologne brand (masculine). A significant interaction between size cue and brand gender positioning on brand evaluation emerged. Specifically, participants indicated more favorable evaluations when a feminine brand (i.e., perfume) incorporated the size cue of smallness versus bigness in the brand name. Conversely, participants indicated less favorable evaluations when a masculine brand (i.e., cologne) incorporated a size cue of smallness versus bigness in the brand name.

Taken together, we show that size cues of smallness (vs. bigness) evoke femininity (vs. masculinity) gender associations and thereby increase the warmth (vs. competence) perceptions of brands. We further show that such gender associations evoked by the size cues have important downstream consequences on consumers' brand evaluation, depending on the salience of consumption goals (communal vs. agentic) and the brand's gender positioning (feminine vs. masculine). Theoretical and managerial implications of this research are discussed.

# A Phenomenological Examination of Internet Addiction: Insights from Entanglement Theory

Mohammadali Zolfagharian, Bowling Green State University, USA  
Atefeh Yazdanparast, University of Evansville, USA  
Reto Felix, University of Texas Rio Grande Valley, USA

## EXTENDED ABSTRACT

Due to the scale, scope, and complexity of its impact, digital technology has been referred to as the fourth industrial revolution (Schwab, 2017). Researchers have called for a better understanding of such impacts and raised questions about the possible consequences of digital technology use for consumers (Turel, et al., 2017). Emerging research and practice commentary has started to point out the complex and often alarming ways in which digital technology use affects individuals, organizations, and society, forming a field of inquiry referred to as the dark side of digital technology (Rosen et al., 2013; Turel et al., 2017).

Considering that Internet is the most important driver of the digital revolution, it is not surprising that the dark side of digital technology has been studied with reference to Internet and Internet addiction (IA). Similar to other addictions, IA represents a compulsive usage and repetitive engagement in a behavior that leads to undesirable consequences for addicts as well as non-addicts (Lee et al., 2014; Thomee et al., 2011). However, two important aspects of IA make it distinct from other addictions. First, whereas in the case of addictions to drugs or cigarettes, the object of the addiction is relatively concrete and tangible, in the case of IA, it is not clear to what exactly individuals are addicted. This ambiguity has prompted some researchers to distinguish between addiction *to* Internet and addiction *on* Internet (e.g., Griffiths, 2010). While addiction to Internet relates to a generalized use of Internet, addiction on Internet represents specific types of IA such as online gambling, online shopping, and online pornography (Brand et al., 2014; Montag, 2017).

Offering an alternative view, we posit that even specific types of IA represent addictions to underlying physiological, psychological, and social reward systems. Thus, our approach dissolves the duality between being addicted to Internet and being addicted on Internet. We introduce a doubly-mediated model of IA with the first mediation layer consisting of Internet, and the second mediation layer consisting of specific activities (gambling, shopping, social media, etc.) on Internet facilitated by various digital platforms (e.g., smartphones). We examine human-digital technology relationships at the level of lived experiences to provide a better understanding of how IA and its various forms are shaped.

Second, IA is substantially different from other addictions, because due to our reliance on Internet, it becomes increasingly difficult to function without it. Thus, we identify a constant tension between relying on Internet and the risk of becoming addicted to it. We draw on entanglement theory (Hodder, 2012) and explore the entanglement of dependences and dependencies that lead to Internet entrapment (Hodder, 2014). Entanglement theory posits humans in relation to material things and proposes a “dialectical relationship between dependence (the reliance of humans and things on each other) and dependency (the constraints that humans and things place on each other)” which potentially leads to entrapment (Hodder and Mol, 2016, p. 1067). The state of entrapment describes a human condition where individuals are caught in the interplay between the enabling nature of things and their undesired tendency to make individuals dependent users craving for more (Hodder, 2012).

We employ a qualitative research approach based on phenomenological interpretation (Hycner, 1985; Thompson, 1997) to pursue a

more sensitive approach capable of capturing the transitions and nuances of IA at the level of lived experiences. The phenomenological insights came from an interpretive analysis of consumer narratives. The text was developed through in-depth interviews and personal essays in the Southwestern United States. Each narrative was first read as an isolated case to discover its own relevant meanings, and then compared against all other cases so as to identify the pervasive, common, minority, unique, and deviant cases and instances.

The findings juxtapose three enabling themes representing Internet dependence (immediacy, task multiplicity and multi-tasking, and intimacy and self-disclosure) with three themes that depict the perils of Internet dependency (context agnosticity, automaticity, and corporal craving). Undeniably, Internet provides us with ways to find important information instantly (i.e., immediacy), to be more efficient (i.e., multi-tasking), and to easily communicate with others and develop close relationships (i.e., intimacy). However, we identify the fine line between dependence and dependency and the path to entrapment through forming dependences and dependencies. For instance, to some of our participants, Internet has become anthropomorphized and is depicted as a friend who listens to them and someone who can be trusted. Such intimacy could in turn facilitate further Internet use and disclosure to the extent of getting addictive and.

Internet is omnipresent and grabs our attention, no matter if at work, at school, at home, or when being with family or friends; an aspect of Internet dependency that we termed “context agnosticity.” Automaticity refers to the phenomenon that being connected to Internet becomes an automatic process, thus skipping the typical first step of need recognition in decision-making. In other words, we connect to Internet for being connected, rather than for a higher-level goal. Finally, we find multiple accounts of corporal craving which our participants expressed vividly as a “thirst,” “hunger,” or “itch” for Internet. Consistent with entanglement theory, we find that the interplay between the enabling aspects of Internet (dependence) and the factors related to the dark side of digital technology (dependency) results in consumer entrapment. We suggest that the multiple accounts of IA denial are largely motivated by the inherent nature of Internet dependence versus dependency. Specifically, even though many of our informants acknowledged their excessive use of Internet, they frequently neglected the potential harm resulting from compulsive Internet use because they find it easy to point out how Internet improved their lives. Moreover, the widespread use of Internet and changing societal norms as related to use of mobile devices make excessive Internet use seem a generally accepted behavior as opposed to other forms of addiction in which the addict is not proud of his or her compulsive behavior.

# Time-of-Day Effects on Consumers' Social Media Engagement

Ozum Zor, Rutgers University, USA  
Kihyun Hannah Kim, Rutgers University, USA  
Ashwani Monga, Rutgers University, USA

## EXTENDED ABSTRACT

Imagine that it is early in the morning and you have a couple of minutes to spend on Twitter. Which article would you “like” more: an article that guarantees a fun time with its catchy title or one that signals long-term benefits with its profound title? Would your pattern of “likes” change by the evening? Is it possible that the pattern depends on whether the information is perceived to be a virtue (i.e., not tempting, but offering later benefits) or a vice (i.e., tempting, but with few later benefits)? In four studies, including one using data from Twitter, we demonstrate time-of-day effects such that the consumption of vice (relative to virtue) increases as morning turns to evening.

Engagement with social media continues to grow, and US firms are expected to spend \$67 billion on digital advertising by 2021 (Fisher 2017). Consequently, consumer behavior researchers have started to explore the psychology that underlies engagement over social media (Barasch and Berger 2014; Toubia and Stephen 2013; Wilcox and Stephen 2013). What remains unexplored, however, is how social media engagement may change through the day, and if there is any asymmetry in engagement with different types of content. We show that the time of day matters, and matters differently for vices versus virtues.

Our theorizing follows from the literature of self-control. Just as muscles are weakened after physical exertion, self-control weakens after subsequent mental exertions (Muraven and Baumeister 2000). Individuals are faced with multiple self-control challenges through the day, as they try to avoid activities and foods that may be tempting, but are not good for them in the long run. Exerting self-control over and over again is depleting. Consequently, self-control is strongest in the early hours of a day but weakens as the day progresses (Dai et al. 2015; Kouchaki and Smith 2014). What is not yet understood is how self-control depletion may emerge for information consumption. One may simply expect depletion effects of the kind that have been observed earlier. That is, because consumers get tired through the day, they process less information because they are not left with adequate resources to read and understand more information. We reveal a different result.

We argue that the effects of depletion may be different for different types of information. Specifically, we discover an asymmetry in the consumption of vice versus virtue information. A relative virtue represents immediate costs with long-term benefits, but a relative vice reflects an instantaneous pleasure with little delayed benefits and perhaps even negative consequences (Khan, Dhar, and Wertenbroch 2004; Siddiqui, May, and Monga 2017; Wertenbroch 1998). Thus, an article on the financial markets in Forbes could be considered virtue information by many who find it hard to understand, but appreciate the long-term benefit of becoming more knowledgeable on the topic. However, salacious gossip in the Cosmopolitan could be considered vice information by many who are tickled by the instantaneous pleasure, but know that there is no long-term benefit from it. We argue that the self-control depletion arising at the end of the day is likely to reduce the resources to process the Forbes article, but make one more likely to succumb to the immediate gratification from reading the Cosmopolitan article. That is, self-control depletion through the day may shift consumption toward vice information and away from virtue information.

We observe such a pattern across four studies. In study 1, we explored the factors urging Twitter usage and the attractiveness of different topics in the morning and the evening hours. We found initial evidence that individuals are interested in both long-term and short-term benefits on Twitter and this interest may shift towards vice content through the end of the day. In study 2, we manipulated magazine type (vice vs. virtue), and asked participants about their likelihood of reading the articles tweeted by given magazines in the morning and the evening. Likelihood to read vice (vs. virtue) magazines was lower in the morning but preference in the evening shifted toward vice magazines. In study 3, we again manipulated magazine type (vice vs. virtue), but measured the time at which participants responded to the survey (between 10 am and 6 pm). We asked participants about their likelihood of reading the articles tweeted by given magazines, and observed a significant interaction effect. Specifically, the reading likelihood shifts away from virtue towards vice as the day progresses. Finally, in study 4, we collected more than two million tweets over a hundred twenty-five days, and then analyzed the unique tweets (after eliminating retweets and duplicates within a day). While controlling for a variety of factors (e.g., total number of tweets by a magazine), we observed a significant interaction between time-of-day and magazine type. Specifically, social media engagement as measured by “likes” increases overall as the day progresses, but there is a statistically significant shift toward vices rather than virtues.

We add to the self-control literature by revealing not only that depletion during a day influences the consumption of information overall, but that such depletion results in asymmetry for vices versus virtues. Implications also arise for marketers who, depending on the nature of the social media content, may want to release different content at different times during the day in order to maximize the engagement of consumers.

# Charity Donors' Response to Cause-Related Marketing: The Role of Attachment Styles

Sondes Zouaghi, Nimec, IAE de Caen, France

Aïda Mimouni Chaabane, Thema, University of Cergy-Pontoise, France

## EXTENDED ABSTRACT

Cause-related marketing (CM) is a type of sponsoring activity whereby firms, for a limited period of time, donate a certain amount of the sales price of the firm's product or revenue to a specific cause. While literature is prolific on how the firm (Mende, Bolton and Bitner 2013), the consumer (e.g., Krishna 2011), or, more marginally, the cause (e.g., Lafferty and Golsmith 2005) benefit from CM, charity donors responses are a neglected area. This topic is however important because the increased need for charitable giving necessitates a large, strong, and stable portfolio of loyal donors who adhere to the charity's strategy. Consequently, the present research focuses on the charity donors and not on consumers who buy CM offers. The research question is thus the following: How do charity donors' respond to CM implemented by their charity?

As the literature is silent on the issue of donors' response to CM, we resort to an exploratory qualitative approach in Study 1 (22 semi-directed interviews). With no surprise, donors' response to CM implementation seemed to be influenced by their history with CM (i.e., general attitude, familiarity). More importantly, the analysis revealed that the style of informant relationship with the charity, called attachment style (AS), seemed to affect their response. Some respondents talked about their charity in a very consistent and emotionally positive way and seemed to have a good level of involvement and commitment toward it. They seemed to consider CM as a possible funding source and even willing to propose adjustments to optimize its implementation for the charity. Another group of respondents seemed to have an unemotional speech. They analyzed the CM with a certain distance, and expressed doubts about the reason that drives charities to participate to CM. Their reactions ranged from indifferent to negative. Finally, some respondents seemed to have high levels of expectations and recognition needs toward the charity. Their speech appeared as very emotional but instable and paradoxical. On the one hand, they seemed highly involved in the charity and desired an exclusive relationship with it. On the other hand, they seemed to feel insecure and unable to explore new ideas of fundraising opportunities by fear of losing or damaging the relationship they entertain with the charity. These respondents expressed rather negative emotions and reactions (e.g., sadness, anger).

Study 1 provides insights into donors' relational profiles likely to accept or reject CM. The key construct that emerged from our analysis in response to CM implementation by the charity is AS. AS are conceptualized by two dimensions: avoidance and anxiety (Fralley, Waller, and Brennan, 2000). A high level of avoidance indicates poor perception and lack of trust in others. A high level of anxiety means lack of self-confidence and high need of reassurance. Based on this view, early research distinguishes between three AS: secure, avoidant and anxious (Collins and Read 1990; Hazan and Shaver 1987; Simpson 1990). In Study 2, we examine how (i.e. the mechanisms under which) AS influence donors' response to CM.

AS are rooted in the first years of life where the emotional effects of relationships with the parental figure are experienced and activated at each interaction with others (Ainsworth et al. 1978; Bowlby, 1969). We thus postulate that depending on their AS, donors will exhibit positive (e.g., happiness and confidence in the charity's decision to resort to CM) or negative (e.g., disappointment by the decision, anger and discontent) emotions toward CM implementation by the charity. As emotions represent motivational intentions

(Frijda 2016), they will result in pro- (i.e., favorable actions such as increasing one's donations) or anti-charity (i.e., harmful actions such as spreading negative word of mouth or revenge) behavioral intentions. We hypothesize that positive emotions mediate the relationship between secure donors and pro-charity behavioral intentions (H1). We also hypothesize that anxious style of attachment is characterized by ambivalence (emotions and behavior) (H2). Finally, as they are devoid of emotions, avoidant donors decrease their loyalty (H3).

262 French donors were asked to choose a particular charity to which they made at least one donation (monetary, time or other). Then, we measured the respondents' AS, their familiarity with CM, and their attitude toward CM in general. In the next phase, we asked respondents to imagine that their charity was about to implement CM. We then measured the mediating and dependant variables (positive emotions, negative emotions, pro-charity and anti-charity behavioral intentions, with items presented randomly) and socio-demographics.

To test the effect of attachment style dimensions on pro- and anti-charity behavior, we used model 4 from the Preacher-Hayes script for bootstrap analyses of indirect effects, with 5.000 resample (Preacher and Hayes 2004). The results provide support for H1 and H2 ( $p < 5\%$ ) and a partial support for H3 ( $p < 10\%$ ).

This research enriches the attachment style literature. First, in line with previous work in marketing (e.g., Mende et al. 2013; Thomson et al. 2012), the findings provide additional empirical support to the predictive power of AS. More precisely, AS have a significant direct and indirect effect on behavioral intentions, even when taking into account the donors' previous history with CM and the type of their donation. The findings also highlight the theoretical relevance of this concept: philanthropic relationships, as commercial (e.g., Mende et al. 2013) and interpersonal relationships (e.g., Collins and Read 1990), are characterized by secure and insecure AS. Second, the present research offers a framework for explaining the attachment process based on emotions. Given the importance of these findings, charity managers are encouraged to embrace a bigger vision of CM impact by balancing its potential benefits in terms of notoriety and image with the potential risk of upsetting and eventually losing donors. In particular, they are encouraged to measure the AS of their donors in order to isolate donors segments that have the potential to be more or less responsive to CM, and tailor CM implementation and communication accordingly. Charity managers should also explain the necessity of resorting to CM in order to build a positive general attitude, especially among donors who volunteer their time. Further research should explore interventions that could blunt the negative impact of CM on the anxious donors and test the generalizability of findings to other contexts of altruism.

# Videography

## Alternative Worldviews on Human – Nonhuman Relations: The Turkish Case

N. Alican Mecit, HEC Paris, France

Tina M. Lowrey, HEC Paris, France

Literature foundations: Consumer research studies how we attribute meaning to commodities and bring them into our lives (Belk 1988, Miller 2008). Through singularization, commodities take on meaning and enter the universe of unique objects (Kopytoff 1986). Until they are recommodified, they remain less available for exchange (Epp and Price 2010). Today, in most cultures, the permanent constituents of the universe of singular objects are only humans as it is unthinkable to exchange humans for money (Kopytoff 1986). Humans, however, used to share this particular universe with animals who lived parallel lives to humans and roamed freely without any owner (Berger 2009). Today, animals, even historically the closest to us - cats and dogs - are reduced to a level at which they require humans to pull themselves out of the universe of commodities. For example, a cat is a de facto commodity until one pays its price and brings him or her to the universe of singular objects (Corrigan 1997). Intended contribution and findings: To explore an alternative worldview, we went to Istanbul, Turkey where cats and dogs still roam freely. We questioned the commodity status of animals and talked to the local people. We situated these animals in the universe of singular objects, deserving the same rights as humans. As the presence of animals in the universe of singular objects is a companionship offered to our loneliness as species, we also focused on the implications of the cohabitation with another kind in this conceptual universe. Method: The videography reports our observations of human – nonhuman relations in Istanbul, interviews with the local people, and the secondary sources that we relied on to triangulate our interim findings.

## Augmented Reality, Augmented Trust: How Augmented Reality Enhances Consumer Trust In Online Shopping

Alberto Lopez, Tecnológico de Monterrey, Mexico

Rachel Rodriguez, Tecnológico de Monterrey, Mexico

Claudia Quintanilla, Tecnológico de Monterrey, Mexico

Raquel Castaño, Tecnológico de Monterrey, Mexico

Intended Contribution to Knowledge: Online shopping has become a common practice among consumers worldwide (Nielsen, 2017). Since the transactions over the internet take place without personal contact, consumers are generally concerned about their purchases (Chen & Dhillon, 2003). It is therefore important for brands and companies to generate consumer trust in online contexts. On the other hand, Augmented Reality (AR) has emerged as a relevant interactive technology in the marketing environment. It is the ability to overlay the physical environment with virtual elements that can interact with the physical environment in real time. It consequently holds the potential to alter many consumer activities. Hence, there is a growing need to better understand its impact on consumer behavior (Javornik, 2016). In this research, we aim to study how the technology of AR affects consumer trust in an online shopping context. Literature Foundations: This study builds on consumer trust theory and adoption of new technologies. Research Method: Following an ethnographic approach, participants used AR in their homes as an opportunity to mix their personal spaces with virtual furniture within a mobile app that was developed for this purpose. Findings and implications: This research suggests that AR technology can serve as a coping strategy to either increase or decrease consumer trust in online contexts. We add to the literature by proposing that this new technology increases consumer trust by six motivators (problem-solving, benevolence, reduced psychological distance, interactivity, novelty, and enjoyment) and decreases consumer trust by two demotivators (need for touch concerns and feeling of intrusion). The authors also illustrate a few age differences regarding the adoption and usage of this new technology. Furthermore, it was found that AR also affects both, consumers and brands. Some marketing cases affected by the usage of AR are consumers' expertise and satisfaction, brand evaluations and purchase intention.

## **Crossing Race and Markets: Introducing the Race in the Marketplace Research Network**

Kevin D Thomas, University of Texas at Austin, USA  
Sonya Grier, American University, USA  
Guillaume D Johnson, Université Paris-Dauphine, France

Both research and practice reveal that race plays a key ideological role in the functioning of consumption markets worldwide (Nopper 2011; Thomas 2017; Zerofsky 2016). However, scholarship on race-related issues in the context of marketplaces has generally been limited, overlooked or marginalized in the marketing/consumer research discipline. However, the tangibility, reality, and brutality of racial dynamics are increasingly “front-page news” and marketing scholarship increasingly emphasizes issues of inclusion and exclusion (Henderson and Williams 2013). As a result, the absence of scholarship- and scholars- who prioritize impactful work on race in marketing presents a challenge to move the discipline towards more inclusive scholarship, employment, and pedagogy. This film explains impediments to scholarship at the intersection of race and markets by examining the evolution of the RIM Research Network (RIM). Developed in 2017, RIM is a response to the marginalized status of race-related scholarship and scholars in the marketing domain. While marketing scholars and scholarship that focus on race and racism have long suffered a marginalized status, attempts to attract private sector dollars has resulted in large-scale shifts in institutional cultures and priorities which has served to exaggerate pre-existing hierarchies within research topics, disciplines, and methodologies (Moleworth, Scullion, and Nixon 2010). Areas and methods most deemed able to benefit the bottom line of potential donors and strategic partners garner the most attention and praise, while critical race scholarship and other forms of research perceived as discordant with present-day marketplace functioning are further marginalized. The conceptual equivalent of consumers, these scholars find a dwindling marketplace in which to cultivate community, acquire funding, secure publication outlets, and gain a sense of legitimacy in the broader academic canon. In this marketized environment, research that focuses on diversity and multiculturalism often take precedence over critical examinations of marketplace activities that expressly investigate racism since the former tends to obscure or ignore systemic issues of power, oppression, and privilege, thereby leaving inherent marketplace inequities largely intact and unquestioned (Grier, Thomas, and Johnson 2017). RIM seeks to establish and legitimize a cohesive critical perspective which foregrounds the reality of power, privilege and oppression, question existing marketing strategies and link them to an overall intersectional framework that can promote inclusive, just and liberatory marketplaces. This film chronicles RIM’s quest to counteract the current academic environment by innovating a transdisciplinary approach to the understanding of race in the marketplace that will produce a space within academia wherein RIM-related scholars and scholarship can thrive.

## **Don’t Troll Me Bro: A Study of Griefing in Video Games**

Elana Harnish, Ohio University, USA  
Jacob Lee Hiler, Ohio University, USA

**Intended Contribution to Knowledge:** The purpose of this study is to examine consumer grieving and toxicity in the context of video games, and seeks to uncover the antecedent, define the process, and discuss the outcomes of the phenomenon. **Literature Foundations:** This videography contributes to research in consumer culture theory by exploring an underexplored but timely topic, consumer grieving and toxicity, in the context of video games. **Research Method:** A combination of videographic, netnographic, and experimental methods were used in this study. Five semi-structured interviews were conducted with gamers and approximately 50 hours of grieving footage was collected via YouTube and Twitch. Additionally, a field experiment was conducted through 46 matches of a popular MOBA game over approximately 20 hours. This research was filmed in accordance with the videography practices set forth by Belk & Kozinets (2005). **Findings and implications:** This research uncovers the antecedents, process, and outcomes of consumer grieving and toxicity in video games, and demonstrates that toxicity has a tangible effect on players win rate in competitive games.

## **From a Culinary Phantasm to an Eudaimonic Well-Being: Exploring The Experience of Amateur Cooking Classes**

Virginie Brégeon de Saint-Quentin, Ferrandi Paris, France  
Ophélie Mugel, Chaire SDSC AgroParisTech, Université Paris Est, France

**Intended contribution to knowledge :** This research, Consumer Culture Theory and Grounded Theory driven, focuses on the dimensions of the « learning by doing » experience of amateur cooking classes. **Literature foundations :** This exploration refers, a posteriori, to an eudemonic approach of well-being (an individual fulfillment relating to self-actualization leading to a series of meaningful experiences). It echoes with the three psychological needs of Self-Determination Theory (the needs for competence, autonomy and relatedness) and the optimal experience of flow. **Research Method :** Through an interpretive approach, we conducted ethnographical observations, recorded films, took photographs and interviewed amateur cooks and professional Chefs in five cooking classes, three in France and two in Japan. **Findings and implications :** Thanks to an in depth analysis, we designed a framework for cooking class experience and noticed six dimensions : (1) Expertise, as the desire to reproduce Chef’s technical gestures and collect expert information about products and recipes ; (2) Immersion, as strategies of imitation and roleplay ; (3) Convivialité (and commensality), as the pleasure of sharing ; (4) Identity, as a self pursuit and affirmation and cultural heritage ; (5) Sensoriality, as five senses synesthesia ; (6) « Naturality », concerning authentic, seasonal or healthy products and sustainable practices. Also, in a Transformative Consumer Research perspective, public policy and healthcare stakeholders are encouraged to promote cooking competences in order to improve consumers’ food well-being. These dimensions can also be manipulated to enhance motivation and satisfaction of cooking school trainees as well as for raising cooking classes profitability and for developing cooking class concepts adapted to the new generation of millennials worldwide.

## **Meat the Needs: Ahold Delhaize Sustainable Retailing Model**

Darrell Eugene Bartholomew, Pennsylvania State University, USA  
Maggie M Mehalko, Pennsylvania State University, USA

**Intended Contribution to Knowledge.** Zero waste initiatives are having a real impact on reducing food waste of edible and inedible parts of food. There are good zero waste practices for diverting food away from landfills to be used to generate energy such as in a food digester or to be used as compost. Better practices help to divert food for human consumption. Many grocers do a lot of good things for the food banks and their local community partners such as shelters and soup kitchens to relieve hunger. The purpose of this paper is to illustrate an innovative zero waste food rescue program that can be used as an example of best practices in sustainable retailing. Literature Foundations. Recent research has focused on this intersection of sustainability, marketing and public policy which are all part of green retail strategies (Iyer and Reczek 2017). Food waste prevention is a goal of most grocers, food service companies, farmers, and food manufacturers (Block et al. 2016). Perceived risk to brand (Murray and Schlacter 1990) and challenges of food safety and handling procedures as well as consumer behavior and perception of inventory were all issues that Ahold Delhaize had to address when the program was piloted. Research Method. Using a case methodology Giant Foods meat rescue program will illustrate this innovative program from the perspective of the decision makers that created the 'Meat the Needs' Program. Findings and Implications. The impact of this innovative program has effectively altered the supply chains at six major food banks in the Northeastern U.S. challenging traditional methods of food banking and creating several new opportunities for food rescue programs involving ugly produce, fruit rescue, and milk rescue in addition to the original meat rescue program.

## **Tattoo: A Perspective Beyond Esthetics**

Luana C. Moraes, Universidade de Sao Paulo, Brazil  
Gabriela L. Pinheiro, Universidade de Sao Paulo, Brazil  
Nathalia S. Arthur, Universidade de Sao Paulo, Brazil  
Eliani C. Flores, Universidad Catolica del Peru, Peru  
Jose Mauro C. Hernandez, Centro Universitário FEI, Brazil

Over the past 20 years, tattoos have become extremely popular in Western countries, spreading among several audiences and becoming a very popular form of body modification. Through the centuries, body modification has been an important part of human's life as an expression of the self. Until recently, tattoos were exclusive to marginalized groups such as sailors, prostitutes, and criminals, and portraying a tattoo was motive for being prejudiced. It was not until the 60's that tattoos assumed a new role in our society. First, as an expression of self-identification of youth movements and lately as a cultural phenomenon of body embellishment. Today, tattoos are increasingly seen as a form of art adorning the human canvas and, as such, tattoos compete in the body adornment industry. Our videography sets out to uncover the meanings associated with the tattooing consumption experience. In our journey, we found that the tattooed body is seen by their owners as a canvas or as a media. When the body serves as a canvas, the tattoo is an expression of art whose pure objective is the body embellishment; the symbolic meaning attached to the tattoo can be extremely important or not important at all – in this case, the tattooing is just the art for the art's sake. When the body serves as a media, the tattoo expresses the cultural, religious, philosophic, gender, sociological, and political ideology of the owner and the defining aspect of the tattoo is its meaning. Interestingly, due to its perennality, the tattoo is re-signified as the individual matures and a canvas can be transformed into a media and vice versa – the art becomes an ideology and the ideology becomes an art.

## **Teaching Consumer Resistance in Jamaica: Subvertising in Action**

Michelle Renee Nelson, University of Illinois at Urbana-Champaign, USA  
Yanyun (Mia) Wang, University of Illinois at Urbana-Champaign, USA  
Kathy Tian, University of Illinois at Urbana-Champaign, USA  
Gail Ferguson, University of Illinois at Urbana-Champaign, USA  
Rachel Powell, CDC Foundation, USA  
Candace Wray, University of West Indies, Jamaica

Our videography features a 'subvertising competition' among adolescents and mothers in Jamaica, as part of an intervention to build persuasion knowledge by teaching consumer resistance through creativity. Although all Jamaicans are inundated by U.S. media, those who internalize U.S. culture via "remote acculturation" are especially vulnerable to negative health habits promoted by U.S. advertising (Ferguson et al. 2017). To address this problem, we developed the J(amaican and) U(nited) S(tates) Media? Programme (2-session workshop teaching nutrition and persuasion knowledge). The film allows viewers to see the intervention (Belk et al. 2017); the critiques are performance acts of consumer power. Through art, poetry and song, families give voice to their skepticism. Literature/Contribution. We focus on family as an important consumer socialization force (e.g. Moore, Wilkie and Desrochers 2017) to build persuasion knowledge (PK; Friestad and Wright 1994). Not much is known about PK in developing countries or how to teach consumer resistance. Subvertisements simultaneously allow audiences to critically evaluate media content and to construct subversive narratives, often through parody (Harold 2004). We taught families to ask: What information is missing? What is the ad really saying? Then, families critiqued, created, and competed. Method. 92 teen-mother dyads in Kingston were selected based on higher remote acculturation and unhealthy eating. Dyads were randomly assigned to control or intervention groups. Food intake and media literacy/PK were measured at multiple points. Focus groups about the subvertisements were held. Findings.

Overall, the intervention groups scored higher than control group in media literacy (PK) and fruit consumption. Focus groups revealed knowledge of health consequences and persuasion. This pragmatic, substantive videography (Belk et al. 2017) shows the promise of trans-disciplinary, theory-driven interventions to change real-world behavior (Lynch et al. 2012). The narrative follows a problem-solution format with the 'process' and 'performances' highlighted and findings embedded (Cayla and Arnould 2013).

## **Time and Space for Robots and AI**

Marat Bakpayev, University of Minnesota Duluth, USA

The specific gap in the knowledge our videography seeks to address is the influence of robot/artificial intelligence (AI) technology representation on consumer-level timeflow. We study how robot/AI time-space imaginations are presented in news. We aim to use evocative power of moving images (Hietanen, Rokka, and Schouten 2014). The videography contributes to study of spatial and temporal perspectives in consumer research (Castilhos, Dolbec, and Veresiu 2017; Robinson 2018; Woermann and Rokka 2015). Woermann and Rokka (2015) identified the elements that shape consumer experiences on micro-level. Our study shows how temporality and spatiality are presented by technology chronotopes on meso-level. Drawing from literary theory, we examine discourse on robots and AI. Focusing on representation of time and space in news, we contextualize Bakhtin's theory of chronotope (Bakhtin 1981). Chronotope is "the intrinsic connectedness of temporal and spatial relationships that are artistically expressed in literature" (84). We identify four main chronotopes in the narratives on these technologies: Fantasies of the Past, Present Timeflow, Human-Master Future, and Robot-Master Future. Fantasies of the Past are rich with references to historical mythology of machines and failed expectations of AI. Present Timeflow portrays various relationships that exist now – robots/AI born in research labs and science-fiction films move to our roads, streets, homes, hospitals, schools, offices, restaurants, and so on. Future is the most dominant element of the storytelling. We have Human-Master Future and Robot-Master Future - two central ideological representations of utopia and dystopia. Human-Master may incorporate the use of robots/AI, and this chronotope calls for "robot-enhanced humanity" with robots serving humans. Robot-Master Future is a more predominant rhetoric. That chronotope assumes "robot apocalypse." This is where machines are presented as "demons" and "supervillains" that most likely will "destroy humanity."

# Workshop Summaries

## WORKSHOP

### **Better Marketing for a Better World**

Jonah Berger, University of Pennsylvania, USA  
Jonathan Zev Berman, London Business School, UK  
Darren Dahl, University of British Columbia, Canada  
Markus Giesler, York University, Canada  
Rebecca Hamilton, Georgetown University, USA  
Gita Venkataramani Johar, Columbia University, USA  
John Lynch, University of Colorado, USA  
Andrea Morales, Arizona State University, USA

In this session leading consumer behavior researchers will discuss what research in their area would look like using the lens of “Better Marketing for a Better World.”

## WORKSHOP

### **Trust in Doubt: Co-Chair’s Invited Panel**

Adam Berinsky, Massachusetts Institute of Technology, USA  
John Gray, MentionMapp.com, Canada  
Andre Spicer, City University of London, UK

In a special invited session panel members from political science management and the online research business each provide their perspectives on the post-trust world its effects and that way that they are seeking to understand it. This session intends to provide consumer researchers with alternative perspectives on post-trust phenomena that will help broaden and enrich our collective view of our changing social environment.

## WORKSHOP

### **Conducting Consumer-Relevant Research**

Jeffrey Inman, University of Pittsburgh, USA  
Margaret C. Campbell, University of Colorado, USA  
Amna Kirmani, University of Maryland, USA  
Linda L Price, University of Oregon, USA

This workshop will include perspectives on how to conduct conceptually based consumer-relevant research that offers practical insights.

# Forum Summaries

## FORUM

### Using Multi-Methods in Behavioral Pricing Research

Haipeng Chen, University of Kentucky, USA  
David Hardesty, University of Kentucky, USA  
Akshay Rao, University of Minnesota, USA  
Lisa Bolton, Pennsylvania State University, USA

Behavioral pricing has been shaped by and is helping to shape the nascent trend towards cross-disciplinary multi-method research in consumer behavior. The proposed roundtable aims to bring together a group of scholars in the area of behavioral pricing within and outside of marketing to discuss the unique opportunities and challenges researchers in this area face with the multi-method approach. The roundtable together with the January 2021 JACR special issue and a mini-conference (to be sponsored by the University of Kentucky) aims at spurring additional interest and enthusiasm in research using multi-methods among consumer researchers interested in behavioral pricing and beyond.

## FORUM

### What's Your Construct? Exploring the Different Definitions and Operationalizations of Scarcity

Kelly Goldsmith, Vanderbilt University, USA  
Rebecca Hamilton, Georgetown University, USA  
Caroline Roux, Concordia University, Canada  
Meng Zhu, Johns Hopkins University, USA

This forum aims to encourage constructive discussions around the different definitions and operationalizations of scarcity in order to 1) start delimiting the boundaries of the construct 2) overcome some of the challenges for advancing this literature given the differences between various scarcity-related manipulations and 3) stimulate future collaborations.

## FORUM

### Promoting Well-being and Combating Harassment in the Academy

Ekant Veer, University of Canterbury, New Zealand  
Zeynep Arsel, Concordia University, Canada  
June Cotte, Ivey Business School, Canada  
Jenna Drenten, Loyola University Chicago, USA  
Markus Geisler, York University, Canada  
Lauren Gurrieri, RMIT University, Australia  
Julie L. Ozanne, University of Melbourne, Australia  
Nicholas Pendarvis, California State University Los Angeles, USA  
Andrea Prothero, University College Dublin, Ireland  
Minita Sanghvi, Skidmore College, USA  
Rajiv Vaidyanathan, University of Minnesota Duluth, USA  
Stacy Wood, North Carolina State University, USA

This roundtable has been proposed to address a growing concern over well-being and safety in academia. This roundtable will discuss issues of harassment experienced by academics in order to better advocate for policies systems and a culture that will help protect all members of the academic community whilst carrying out their teaching learning administrative and research duties. This may be in their classrooms in the field at conferences and/or online. The roundtable will offer an opportunity for those attending to discuss broad issues associated with harassment and discuss different means to promote a safe and welcoming academic community free from harassment of any form. The feedback from this roundtable will be later collated by the roundtable organizers and distributed to attendees so as to provide guidance for university administrators (such as participants' Deans department chairs etc). The collated feedback will also be used to help inform ways in which ACR's newly formed anti-harassment working committee can work to support its members. The roundtable aims to bring a sense of empowerment and encouragement to those in attendance to combat these issues. To this end it should be noted that the purpose of the roundtable is to share broad ideas to combat harassment and promote well-being and safety. It is NOT a place to developed finalized policy or an opportunity to air specific grievances or make accusations against individuals. This will be strictly enforced by the roundtable chair.

# Working Papers

## **I8. How Food Images on Social Media Influence Online Reactions**

Annika Abell, University of South Florida, USA  
Dipayan Biswas, University of South Florida, USA

The results of four studies including two field experiments show that an image of a female gets fewer positive online reactions and is evaluated less favorably when she is pictured next to an unhealthy (vs. a healthy) item; these effects get reversed for males.

## **D11. A Hidden Cost of Advocating: Attitude Depolarization After Recommending**

Ravini Savindya Abeywickrama, University of Melbourne, Australia  
Gergely Nyilasy, University of Melbourne, Australia  
Simon M. Laham, University of Melbourne, Australia

The consequences of word-of-mouth recommendations on advocates themselves have largely been neglected in consumer research. The current work demonstrates paradoxical effects of advocacy on consumer attitudes by illustrating reduced-level product evaluations following a consumer word-of-mouth episode. The results demonstrate a self-persuasion theory-based depolarization effect mediated by metacognitive processing.

## **C1. Promoting Subjective Preferences in Simple Choices During Sleep**

Sizhi Ai, First Affiliated Hospital of Xinxiang Medical University, China  
Yunlu Yin, University of Hong Kong, China  
Yu Chen, Peking University, China  
Lin Lu, Peking University, China  
Lusha Zhu, Peking University, China  
Jie Shi, Peking University, China

Combining target memory reactivation method with a food evaluation/choice task we find that presenting verbal cueing during sleep but not wakefulness shifted food preferences and decisions in simple choice pointing to a potential for nudging human behavior with subtle manipulation of memory processing during sleep.

## **R3. In Experiences We Trust: From Brand-centric Experiences to Experience-centric Brands**

Melissa Archpru Akaka, University of Denver, USA  
Ana Babic Rosario, University of Denver, USA  
Gia Nardini, University of Denver, USA

Experiences are replacing brands as the most sought-after market offerings. In the context of American Yoga we investigate the role of brands in the assemblage of extended consumption experiences. We find that consumers' shifting institutional logics influence their polygamous relationships with brands and guide the reassemblage of experiences over time.

## **G8. How Does Pronunciation Difficulty of Brand Names Influence Consumer Responses? The Role of Self-Construal**

Gunben Ceren Aksu, Rutgers University, USA  
Yeni Zhou, Rutgers University, USA  
Alokparna (Sonia) Monga, Rutgers University, USA

We find that when a brand name is difficult-to-pronounce consumers with independent (vs. interdependent) self-construal respond more favorably. However when a brand name is easy-to-pronounce consumers with interdependent (vs. independent) self-construal respond more favorably. Further we show that differences in desire for uniqueness is the underlying mechanism.

## **B8. Factors Influencing Collaborative Consumption Usage in the US market: An Exploratory Study**

Pia Annette Albinsson, Appalachian State University, USA  
B. Yasanthi Perera, Brock University, Canada  
Bidisha Burman, University of Mary Washington, USA  
Lubna Nafees, Appalachian State University, USA

Businesses are increasingly developing collaborative consumption-based (CC) models. To capitalize on opportunities they must understand what drives and deters consumers' CC participation. This research examines how attitudes trust sustainability materialism risk propensity and generosity affect consumers' CC usage. We find that attitude trust sustainability and generosity predict CC usage.

## **A4. Persuasive Messaging in the Modern Media Landscape: Character Assassinations in Social Network's Echo Chambers**

Niek Althuisen, ESSEC Business School, France  
Sourjo Mukherjee, ESSEC Business School, France  
Negin Latifi Kasani, ESSEC Business School, France

In an empirical study we investigated if disinformation from unverified sources through social media affects people's opinions about characters who played a role in the US 2016 presidential election and its aftermath. The results show that opinions are malleable and character boost might be more effective in altering perceived source integrity.

## **R6. The Anatomy of a Rival: The Influence of Inequity and Resentment on Rival Brands**

Diego Alvarado-Karste, University of North Texas, USA  
Blair Kidwell, University of North Texas, USA

The authors examine whether brand rivalries can be formed and why they influence consumer's perceptions of brands and subsequent intentions to purchase. We propose a new model that incorporates the emotional side of rivalries beyond current research to demonstrate that inequity and resentment are the drivers of these unique relationships.

## **A1. Trusting and Acting on Chance Online**

Shivaun Anderberg, University of Sydney, Australia  
Ellen Garbarino, University of Sydney, Australia

Gambling and games of chance have become more common in the online environment present in mobile games advergames and sales promotions. This study explores how the nature of the stimuli used to visually depict probabilistic components online affects people's trust in them being truly random and subsequent engagement behavior.

## **K10. The Acronym Effect: Acronym and Buzzword Use Lowers Consumer Persuasion**

Sumitra Auschaitrakul, University of the Thai Chamber of Commerce, Thailand  
Dan King, University of Texas Rio Grande Valley, USA  
Ashesh Mukherjee, McGill University, Canada

Many organizations use well-known acronyms such as CSR to represent full referents such as corporate social responsibility which itself is a shortened referent to represent performing actions that benefit the community. We show that shortening referents has the surprising consequence of lowering perceptions of genuine emotions underpinning social responsibility.

## **J14. You Reflect Me: Narcissistic Consumers Prefer Anthropomorphized Arrogant Brands**

Norah Awad, Hongik University, South Korea  
Nara Youn, Hongik University, South Korea

Narcissism is a trait commonly associated with arrogance and impacts people's interactions with others; prior research has shown that narcissists love other narcissists like they love their own reflections. Our research examines narcissists' attitudes toward anthropomorphized brands that have arrogant personalities and the role of self-congruence in this interaction.

## **E11. Influence of Ethical Beliefs and Trust on Purchase Decisions: The Moderating Effect of Involvement**

Marija Banovic, Aarhus University, Denmark  
Athanasios Krystallis, Athens University of Economics and Business, Greece

We test the moderating effect of involvement on the relationship between ethical beliefs, trust, and purchase decisions. The higher the ethical beliefs and trust in a product's ability to deliver the value, the higher the likelihood of the product being bought and vice-versa. Trust holds more relevance for high- than low-involved consumers.

## **Q11. The Effect of Message Ephemerality on Information Processing**

Uri Barnea, University of Pennsylvania, USA  
Robert Meyer, University of Pennsylvania, USA  
Gideon Nave, University of Pennsylvania, USA

Ephemeral communication - the transmission of messages which can be accessed only a limited number of times - is ubiquitous in social interactions (e.g. verbal conversations, Snapchat messaging). In three studies we find that message ephemerality increases attention, improves memory recall, and leads to longer observation time.

## **P13. Self-Selected versus Fixed Price Bundling: The Effect of Bundle Type on Perceived Quality**

Burcak Bas, Bocconi University, Italy  
Gulen Sarial Abi, Bocconi University, Italy

This research explores the effect of bundle type on perceived quality. A lab experiment shows that self-selected (versus fixed) price bundling increases perceived quality and psychological ownership is the mechanism underlying this effect.

## **Q5. Conceptualizing the Digital Experience in Luxury**

Wided Batat, American University Beirut, Lebanon

This research introduces a theory of digital luxury experience, conceptualizing what it is and identifying its drivers. This is of importance to luxury consumption as it offers a conceptual framework to understand digital luxury, an empirical phenomenon which has gained prominence in the last 10 years and has remained poorly understood.

## **F5. Alternative Food Consumption (AFC) Adoption and Low SES Youth Food Well-Being: From Precontemplation to Maintenance**

Wided Batat, American University Beirut, Lebanon

This research will exemplify the overall mission of marketing and public policy researchers in four ways. First, we empirically show how allocentric and idiocentric factors of AFC adoption affect low SES young consumer well-being according to different stages of change.

## **J15. The Deliberation Effect on the Judgment and Choice of Anthropomorphized Products**

Juliana M. Batista, EAESP Fundação Getúlio Vargas, Brazil  
Jose Mauro C. Hernandez, Centro Universitário FEI, Brazil

The study investigated the anthropomorphized products' effect on purchase intention and choice and the moderating role of deliberation and rational personality. The first study demonstrates that personifying a product leads to higher purchase intention through product's anthropomorphization. Studies two and three show that deliberating inhibits the anthropomorphization process.

## **N10. How Does It Make You Feel? Emotional Reasoning and Consumer Decisions**

Andrea Rochelle Bennett, University of North Texas, USA  
Blair Kidwell, University of North Texas, USA  
Jonathan Hasford, University of Central Florida, USA  
David Hardesty, University of Kentucky, USA  
Molly Burchett, University of Kentucky, USA

The authors examine how consumers' think about their emotions and the favorable outcomes that result. The conscious contemplation of emotions in decision making (emotional reasoning) was found to improve consumer choice quality beyond the effects of other types of emotional processing including trust-in-feelings and affect-as-information.

## **I4. Pink Tax: Are Some Marketing Practices Discriminatory?**

Andrea Rochelle Bennett, University of North Texas, USA  
Audhesh Paswan, University of North Texas, USA  
Kate Goins, University of North Texas, USA

Are some marketing mix elements inherently unethical? For example via the "pink tax" products aimed at women are priced higher than similar products aimed at men. While segmentation targeting and differentiation are legal can they become unethical? This study explores this phenomenon using the pink tax as the research context.

## **L13. The Recipient Effect on Consumers' Preference for Products Displayed in Different Horizontal Locations**

Sheng Bi, Washington State University, USA  
Nik Nikolov, Washington State University, USA  
Julio Sevilla, University of Georgia, USA

This research proposes a recipient effect on products displayed in different horizontal locations. The congruence between recipient and product position increases information processing fluency leading to favorable product attitudes. This effect is mitigated by making consumers conceptualize time vertically or by changing purchasing scenarios from buying for others to selves.

## **F2. Can Stricter Ethical Standards Increase Tolerance for Ethical Misconduct?**

Olya Bullard, University of Winnipeg, Canada  
Sara Penner, University of Manitoba, Canada  
Kelley Main, University of Manitoba, Canada

Can stricter ethical standards increase tolerance for ethical misconduct? The current research begins to answer this question. Relying on the anchoring and adjustment heuristic we demonstrate that stricter ethical standards can increase tolerance for ethical misconduct by lowering the category mean on which judgments of transgression severity are anchored.

## **L4. Attentional Breadth Moderates the Effect of Store Environments on Product Evaluation**

Oliver B. Büttner, University of Duisburg-Essen, Germany  
Benjamin G. Serfas, University of Duisburg-Essen, Germany  
Daria Euler, University of Duisburg-Essen, Germany  
Mathias Clemens Streicher, University of Innsbruck, Austria

In an eye-tracking experiment we primed attentional breadth (broad vs. narrow) and assessed the influence of context valence (attractive vs. unattractive store environments) on product evaluation. Participants liked products more when they were presented in attractive (vs. unattractive) store environments. This difference was more pronounced with broad (vs. narrow) attention.

## **B6. A Study About the Moderator Effect of the Information Trust in the Relationships Between the Users' Participation in Virtual Communities and the Benefits Obtained**

Sara Campo, Autonomous University of Madrid, Spain  
Jano Jiménez, Autonomous University of Madrid, Spain  
Natalia Rubio, Universidad Autónoma of Madrid, Spain  
Nieves Villaseñor, Universidad Autónoma of Madrid, Spain  
M<sup>ª</sup>Jesus Yague, Universidad Autónoma of Madrid, Spain

This study compares the role of information trust in virtual communities domain. The participants' level of trust in the community contents reinforces their hedonic and social benefits. Those who trust to a lesser extent in the information shared feel more expert as a result of their participation in the virtual community.

## **N9. Effects of Awe on Consumers' Preferences for Bounded Brand Logos**

Fei Cao, Renmin University of China, China  
Xia Wang, Renmin University of China, China

Two studies probe and demonstrate that experiencing awe a positive emotion characterized by perceived vastness and need for accommodation compared with neutral emotion enhances consumers' preferences for bounded brand logos and this effect is probably driven by loss of control. The effect is stronger for chronic promotion-focused (versus prevention-focused) consumers.

## **D3. Social Exclusion and WOM about Past versus Future Experiences**

Melis Ceylan, Koc University, Turkey  
Ezgi Akpınar, Koc University, Turkey  
Selin Atalay, Frankfurt School of Finance and Management, Germany

This research explores how social exclusion affects WOM. The authors demonstrate that socially excluded individuals compared to their non-excluded counterparts are more likely to talk about personal events that happened in the past to help others be prepared for a similar experience and consequently strengthen their social connections with them.

## **K4. Movie Reviews and their Sentiments: Evidence of a Bandwagon Effect in Individualistic Cultures**

Subimal Chatterjee, SUNY Binghamton, USA  
Ning Fu, SUNY Binghamton, USA  
Qi Wang, SUNY Binghamton, USA

We analyze how the Chinese and American audience rate a common set of 173 movies released in both countries and find a bandwagon effect in the American audience in that their ratings mimic the positive sentiments of the review they read last before posting their own.

## **H11. Not for Me: Identity Needs and Consumer Interest in Different Types of Co-creation**

Lagnajita Chatterjee, University of Illinois at Chicago, USA  
David Gal, University of Illinois at Chicago, USA

This research investigates the influence of identity needs on choices between different product designing routes (e.g. self-customization crowdsourcing). Two experimental studies explore the influence of uniqueness and assimilation needs of individual consumers on selection of different product-designing formats. In future the role of moderating factors like expertise will be explored.

## **H6. The Influence of Anthropomorphized Service Toolkit on Consumer Satisfaction in Service Coproduction**

Rocky Peng Chen, Hong Kong Baptist University, China  
Kimmy Chan, Hong Kong Baptist University, China

As technology evolves anthropomorphized entities become increasingly pervasive in the service context like service coproduction. This research finds that anthropomorphized service toolkit can have either positive or negative impacts on consumer satisfaction in service coproduction depending on whether the coproduction task is self-expressive or not.

## **N14. The Bright Side of Sadness: How Mood Affects Goal Initiation**

Yunqing Chen, Chinese University of Hong Kong, China  
Leilei Gao, Chinese University of Hong Kong, China

How does mood affect people's likelihood to initiate a long-term goal pursuit? Two studies show that compared to happy individuals sad individuals have stronger preference for self-discontinuity which leads to greater motivation to start pursuing a long-term goal.

## **P9. Gift Budget Adherence and Price Discounts**

Yuna Choe, Texas A&M University, USA  
Christina Kan, Texas A&M University, USA

This research suggests that people are more likely to spend extra money to adhere to their budgets when the budgeted purchase is sold at a discount if that budget is for a gift than if it is for the self.

## **J1. The Effect of Identity Abstractness on Information Processing Styles**

Woojin Choi, University of Seoul, South Korea  
Min Jung Kim, Manhattan College, USA  
HyukJin Kwon, University of Seoul, South Korea  
Jiyun Kang, Texas State University, USA

This study suggests that how a social identity is construed (i.e. identity abstractness) would influence one's information processing style. Specifically we predict that when a social identity with high (vs. low) identity abstractness is activated a person is likely to process information more abstractly (vs. concretely).

## **I7. Male Spokespeople: Antecedents and Consequences of Social Comparison**

Hsuan-Yi Chou, National Sun Yat-sen University, Taiwan  
Xing-Yu (Marcos) Chu, Nanjing University, China  
Chieh-Wen Cheng, National Sun Yat-sen University, Taiwan

This study demonstrated that highly attractive male spokespeople revealing muscles or gazing directly at viewers evoked upward comparisons and stronger envy emotions from male consumers. Stronger relative benign envy facilitates advertising effects. Female image and beauty type moderate the formation of envy. Results contribute to social comparison and envy theories.

## **O1. Choice, Rejection, and Context Effects**

Shih-Chieh Chuang, National Chung Cheng University, Taiwan  
Yin-Hui Cheng, National Taichung University of Education, Taiwan

Most research on the context effect (compromise effect and attraction effect) has focused on choice-making tasks rather than rejection tasks. The data reported for two experiments show that the context effect is alleviated when decision-making tasks are performed in a selection scenario rather than a rejection scenario.

## **P4. Consistent Price Endings Increase Consumers Perceptions of Cheapness**

Shih-Chieh Chuang, National Chung Cheng University, Taiwan  
Yin-Hui Cheng, National Taichung University of Education, Taiwan

Should marketers make the last digit of a sale price consistent with the last digit of the original price? Across multiple studies including field studies and a variety of product categories this research shows price perception and purchase intention are related to consistency between the sale price and original price

## **Q9. Free or Fee? Consumers' Decision to Pay for the Premium Version of a Music Streaming Service Rather than Using its Free Version**

Sebastian Danckwerts, Heinrich-Heine-University, Germany  
Peter Kenning, Heinrich-Heine-University, Germany

This research examines factors that influence consumers' likelihood of subscribing to the chargeable premium version of a music streaming service rather than using its free basic version. The results show that both the similarity between the two versions' functionality and the perceived quality of personalized content significantly affect consumers' decision.

## **A5. Trusting the Tweeting President: Inside the Donald's reality: Gaslighting, psychometrics and social media**

Dianne Dean, University of Hull, UK  
Fiona Walkley, Hull University Business School, UK  
Robin Croft, Brunel University, UK

Research examines how Donald Trump's unconventional campaign. Using cultural branding theory this research critically evaluates Donald Trump's propagandist narrative. For success it needed to be believable erode the credibility of opposing candidates; create a reality that emphasizes the lost values of the American Dream and apportion blame to a significant 'other'.

## **F3. The Dark Side of Happy Brands: A Case Study of Newport Cigarette Advertising**

Timothy Dewhirst, University of Guelph, Canada  
Wonkyong Beth Lee, Western University, Canada

This qualitative study uses the tobacco industry's consumer research made public from litigation to examine how happiness appears particularly applicable to hedonic consumption such as smoking even though products and brands pertaining to hedonic consumption may not ultimately be beneficial or healthy to consumers.

## **D4. How the Product Positioning Affect the Influence of Online Consumer Reviews on Consumer Intentions**

Helison Bertoli Alves Dias, Federal University of Paraná, Brazil  
José Carlos Korelo, Federal University of Paraná, Brazil  
Danielle Mantovani, Federal University of Paraná, Brazil  
Cecilia Souto Maior, Federal University of Paraná, Brazil  
Paulo Henrique Muller Prado, Federal University of Paraná, Brazil

Research in marketing indicates that different review types lead consumers to distinct intentions. However an important element of this relationship has not received enough attention: the reviewed product positioning. This paper shows that product positioning influences such relationship. Further this interaction between products and reviews is explained by reviews diagnosticity.

## **F7. Mere Packaging and Consumer Choice**

Tim Philipp Doering, University of Michigan, USA  
Katherine Burson, University of Michigan, USA  
Andrew D Gershoff, University of Texas at Austin, USA

Despite retailer and consumer efforts packaging still makes up the biggest proportion of municipal solid waste. Two studies show that though consumers prefer packaged goods they are willing to buy unpackaged goods significantly more often if they are in control of unpackaging the product.

## **I6. How Does Runner's World Shape a Runner's World? Understanding Representations of the "Ideal" Female Body in Fitness Advertising**

Carly Drake, University of Calgary, Canada  
Scott Radford, University of Calgary, Canada

The female body is salient at the intersection of sport the marketplace and media. In this critical review we interpret representations of the female body in fitness advertisements targeting female recreational endurance runners. We argue that they offer conflicting – and often unhealthy – directives on how to achieve the "ideal" body.

## **O7. Helpful Mental Shortcuts or a Shortcut to Bias? Two Perspectives on Heuristics and One New Direction for Consumer Research**

Carly Drake, University of Calgary, Canada  
Mehdi Mourali, University of Calgary, Canada

Consumer research tends to follow a perspective on heuristics that argues heuristics bias and mislead those who use them. However a second perspective posits that heuristics may be more efficient and accurate than complex computations despite using less information. We explore what this perspective can offer future consumer research.

## **Q6. Online Social Status Predicts Subjective Well-being: a Two Population Study**

Rui Du, University of Hawaii, USA  
Miao Hu, University of Hawaii, USA

Through three studies across two populations we identified a novel construct: online social status. Online social status is positively related to consumers' subjective well-being (Study 1 and Study 2). Additionally only when online and offline identities were highly overlapped online social status is related to subjective well-being (Study 3).

## **L14. Christmas Decorations in September – What Happened to Halloween? The Effect of Prospective Event Markers on Time Perceptions and Attitudes Towards Promotions**

Chaumanix Dutton, University of Southern California, USA  
Kristin Diehl, University of Southern California, USA

We propose that reminders of future events such as holiday promotions trigger prospective event markers which affect time perceptions and attitudes towards the promotion. In three studies we show that event-related markers decrease time perceptions rendering early holiday promotions more acceptable while unrelated event markers have opposing effects.

## **G5. The Phenomenon of Brand Noise and Related Consumer Preferences in the Luxury Industry**

Daria Erkhova, University of Bern, Switzerland  
Elena Ehrensperger, University of Bern, Switzerland  
Harley Krohmer, University of Bern, Switzerland  
Wayne Hoyer, University of Texas at Austin, USA  
John Zhang, University of Pennsylvania, USA

This paper introduces the concept of brand noise as a new comprehensive approach to “loud” and “quiet” luxury branding. Further we empirically show that consumer preferences toward loud and quiet goods are not always driven by social status but also by personality traits such as extraversion and openness to experience.

## **M13. Keep Consistency in Good Old Days: The Effect of Nostalgia on Consumers’ Consistency Seeking Behavior**

Yafeng Fan, Tsinghua University, China  
Jing Jiang, Renmin University of China

The present research explored how nostalgia affects consumer’s consistency seeking behavior. Three studies demonstrated that nostalgic feelings increase consumers’ consistency seeking behavior in consumption. The results showed that nostalgia (vs. control) condition participants higher self-continuity preference which increases their consistency seeking behavior in subsequent consumption situation.

## **M9. Exploring Historical Nostalgia and its Relevance to Consumer Research**

Matthew Farmer, University of Arizona, USA  
Caleb Warren, University of Arizona, USA

Historical nostalgia a sentimental longing for a time outside of one’s own personal past appears to draw a comparison between present-day values and past values making it a potentially distinct construct from personal nostalgia. We report a pilot study that supports this claim and develop a program of promising research.

## **I5. Take That Mirror Away From me! Clothing Consumption by the Elderly and the Self-identity of the Young**

Daniela Ferreira, Federal University of Rio de Janeiro, Brazil

This study focuses on the impact of elderly’s clothing consumption on the self-identity of the young in the Brazilian context. Using netnography and interviews and building from Terror Management Theory we found that moral condemnation of the elderly represents youngers’ fear to challenge their self-identity and privileged status in society.

## **N12. Untangling Different Envy Episodes and their Effects on Brand Attitude**

Kirla C Ferreira, EAESP-FGV, Brazil & City University of London, UK  
Delane Botelho, EAESP-FGV, Brazil  
Suzana Valente Battistella-Lima, EAESP-FGV, Brazil

An envy episode develops in various directions depending on individual and contextual factors and its effect on brand attitude varies accordingly. Based on three studies we suggest that brand attitude decreases linearly across envy episodes (from no envy benign envy malicious envy by luck to malicious envy by deceit).

## **H3. Does the Style Looks More Expensive? The Effect of Visual Complexity on Luxury Perception of Art Infused Products**

Cheng Gao, Nanjing University, China  
Chunqu Xiao, Nanjing University, China  
Kaiyuan Xi, Nanjing University, China  
Hong Zhu, Nanjing University, China

Experiments results demonstrate that consumers perceive products infused with complex visual arts are more luxury. This is because complex arts tend to capture consumers' attention and broaden their pupil size which in return is explained by arousal of that stimuli. Stimuli's artistic level is found to moderate the mechanism.

## **B9. The Power of Self-Effacing Brand Messages: Building Trust and Increasing Brand Attitudes**

Tessa Garcia-Collart, Florida International University, USA  
Jessica Rixom, University of Nevada, Reno, USA

Self-enhancing messages convey information in a boastful and arrogant manner while self-effacing messages do so in a more modest and humble way. We propose that compared to self-enhancing self-effacing marketing appeals will increase consumers' brand attitudes by lowering consumer skepticism and increasing brand trust.

## **M2. Of Expectations and Experiences: The Moderating Effect of Valanced Expectations on Enjoyment of a Positive versus Negative Experience**

Brian Gillespie, University of New Mexico, USA  
Molly McGehee, University of New Mexico, USA

Some extant literature argues that expectations drive enjoyment of experiences while other literature argues that expectations only comparatively influence enjoyment. The current work addresses this discrepancy and demonstrates that while positive expectations do result in favorable enjoyment of experiences negative expectations result in the comparative process suggested by others.

## **A7. Credible Critters: Source and Message Expectancy Violation and Influence on Perceived Trustworthiness and Credibility**

Justin Graeber, University of Texas at Austin, USA

Trustworthiness and credibility are essential traits of effective leaders journalists and spokespersons. This paper explores whether pairing formal and informal messages with different sources can yield a positive expectancy violation that builds trust reinforces credibility and challenges previous biases against traditionally formal sources.

## **H7. Too Risky to Be Luxurious: Stigmatized Luxury Product Attributes Can Weaken or Increase Social Risk to Determine Conspicuous Consumption**

Jerry Lewis Grimes, Grenoble Ecole de Management, France  
Yan Meng, Grenoble Ecole de Management, France

There are circumstances when conspicuous luxury consumption becomes socially stigmatized and this overt display of luxury is actually harmful to the consumer. Two studies show that stigmatized product attributes (i.e. antisocial or distasteful) generally reduce purchase intentions however low social visibility can undermine social stigma increasing luxury product purchase intentions.

## **L2. Wish List Thinking: The Role of Psychological Ownership in Consumer Likelihood to Purchase or Remove a Product from an Online Wish List**

Christopher Groening, Kent State University, USA  
Jennifer Wiggins, Kent State University, USA  
Iman Raoofpanah, Kent State University, USA

Psychological ownership of products on a consumer's wish list increases the likelihood of purchase and decreases the likelihood of removal from the wish list. This effect becomes curvilinear when the product has been on the wish list a long time or the wish list is publicly viewable.

## **C4. The role of Attachment to a Human Brand in Improving Eating Habits**

Amélie Guèvremont, Université du Québec à Montréal, Canada

This research studies behavioural change by demonstrating the power of a human brand in influencing eating habits (through a culinary blog). A netnography and eleven interviews identify four categories of behavioural changes and substantiate the role of attachment. Two attachment antecedents are identified: brand-self connection and satisfaction of individual needs.

## **L7. The Joy of Shopping: Reconciling Mixed Effects of Positive Emotions on Shopping Behavior**

Kelley Gullo, Duke University, USA  
Duncan Simester, Massachusetts Institute of Technology, USA  
Gavan Fitzsimons, Duke University, USA

The current work develops a framework to identify when positive emotions lead to increased shopping behavior. A field experiment with over a million transactions and a controlled lab study provide initial evidence that the environment in which a positive emotion is felt shapes the behavioral outcomes of that emotion.

## **E6. The Effect of Crowding Perception on Helping Behavior —Is Squeeze Warmer than Isolation?**

Qingqing Guo, Shanghai Jiao Tong University, China

Based on 7 studies (991 participants) we investigated crowding perception on helping behavior. Consumers in crowds have a stronger willingness to help others as they tend to experience a self-other overlap and stronger social connection as well as empathy in serial in crowds. The composition of crowds moderated the effect.

## **N1. The Experiential Advantage in Eudaimonic Well-being – An Experimental Assessment**

Aditya Gupta, University of Nebraska-Lincoln, USA  
James Gentry, University of Nebraska-Lincoln, USA

Despite the documented hedonic superiority of experiential purchases to material purchases a focus on their relative well-being implications remains unexplored. Given that the very idea of well-being is changing the authors report results from two experimental studies that evaluate the experiential advantage in terms of a new framework – eudaimonic well-being.

## **N2. The Devil Wears FAKE Prada: Dual Envy Theory Explains Why Consumers Intend to Purchase Non-Deceptive Luxury Counterfeits**

Tanvi Gupta, Indian Institute of Management Bangalore, India  
Preeti Krishnan Lyndem, Indian Institute of Management Bangalore, India

Applying the dual envy theory to understand why consumers deliberately intend to purchase non-deceptive luxury counterfeits we posit that benign envious intend to purchase such counterfeits when they cannot afford the original whereas malicious envious are driven to purchase such counterfeits by a desire to punish the unfair original brand.

## **J8. Exchange with The Rich, Concern with The Poor: The Effects of Social Class on Consumer Response to Brand Relationship**

Bing Han, Shanghai Jiao Tong University, China  
Liangyan Wang, Shanghai Jiao Tong University, China

This article proposes that consumer-brand relationship position (exchange vs. communal) should be built in accordance with the social class of consumers. Through three experiments in manufacturing and service industries the authors find that a matching effect between brand relationship and social class can enhance brand evaluation and brand attitude.

## **R13. Brand Humanization: Applying Two Dimensions of Humanness to Brand**

Myciah L Harrold, Washington State University, USA  
Andrew Perkins, Washington State University, USA

We create a measure of brand humanness that unlike past measures of anthropomorphism is easily applied to a variety of study paradigms. We situate brand humanness along two independent dimensions: characteristics descriptive of basic human nature and characteristics that identify ways in which humans are unique from other species.

## **H1. How Anthropomorphized Roles Influence Consumers' Attitude Towards Innovative Products**

Yuanqiong He, Huazhong University of Science and Technology, China  
Zhou Qi, Huazhong University of Science and Technology, China

This research explores effects of anthropomorphism strategy for innovative products. The results indicated that friend role is more suitable for ergonomic innovative product while servant role is more suitable for feature innovative product. Meanwhile perceived product innovativeness by consumers will moderate this effects. This study enriches the field of anthropomorphism.

## **K12. Use Language to Change People's Mind: The Persuasive Power of Online Marketing Communications**

Xun He, Katholieke University Leuven, Belgium  
Barbara Briers, Vlerick Business School, Belgium  
Luk Warlop, Norwegian School of Management, Norway

Marketing and economics depend mainly on persuasive success. This study investigates which and how linguistic features influence a target's actual persuasiveness of messages in the setting of online marketing communications.

## **N6. Not Myself: The Impact of Secret-Keeping on Consumer Choice Regret**

Dongjin He, Hong Kong Polytechnic University, China  
Yuwei Jiang, Hong Kong Polytechnic University, China

This research investigates how the experience of secret-keeping affects consumers' perception of their previous choice. Three studies reveal that the experience of secret-keeping increases consumers' regret for the consumption choices they made previously and show that this effect is driven by the perceived low intrinsic motivation for the chosen option.

## **C3. Using Goal Theory to Promote Habit Formation During and After a Bike-to-Work Campaign**

Bettina Rebekka Höchli, University of Bern, Switzerland  
Claude Messner, University of Bern, Switzerland  
Adrian Brügger, University of Bern, Switzerland

Health interventions are often ineffective because people discontinue the targeted behavior after the intervention period. Forming habits could maintain the behavior beyond the intervention. We show that combining a superordinate goal with a subordinate goal can produce stronger habits than focusing on a subordinate goal alone.

## **Q13. Liquid Consumption From Another Perspective: The Case of "Investomers"**

Carina Hoffmann, Heinrich-Heine-University, Germany  
Lasse Meißner, Heinrich-Heine-University, Germany  
Peter Kenning, Heinrich-Heine-University, Germany

To extend recent theorizing on liquid consumption and to add a new perspective to this field we investigate the case of investors turning into consumers or reverse ("investomer"). We assume commitment and trust as "coupling" factors between these two categories and find support for this assumption.

## **O12. When do People Waste Time? Testing a Mechanism for Parkinson's Law.**

Holly S Howe, Duke University, USA  
Tanya Chartrand, Duke University, USA

Parkinson's law states that work expands to fill the time available for its completion. In a series of studies we demonstrate this law and identify a possible mechanism. Specifically we demonstrate that people who allot too much time to complete a task fail to use time-saving strategies.

## **Q8. Avatars, Consumers and Possession in Online Gaming**

Feihong Hu, Lancaster University, UK  
Xin Zhao, Lancaster University, UK  
Chihling Liu, Lancaster University, UK

This study seeks to re-examine the relationship between consumers and their possessions. We observed online gamer interactions and conducted depth-interviews with Chinese online gamers. Initial findings have generated rich insights into how consumers experience and manage the relationships between their sense of self avatars and virtual possessions.

## **O10. Individual Differences in Consumers' Need For Cognition and Affect: A Neuromarketing Study Using Voxel-Based Morphometry**

Jianping Huang, Tsinghua University, China  
Yang Sun, Tsinghua University, China  
Jie Sui, University of Bath, UK  
Xiaoang Wan, Tsinghua University, China

We revealed the anatomical variations in consumers' need for cognition (NFC) and need for affect (NFA) in a neuromarketing study. The right lingual gyrus was associated with NFC whereas the right inferior occipital gyrus was linked to NFA.

## **L8. Recover the Unrecoverable: How Co-Recovery Shifts Consumers 'Attribution Following a Failed Recovery**

Bo Huang, HEC Montreal, Canada  
Yany Grégoire, HEC Montreal, Canada  
Matthew Philp, HEC Montreal, Canada

Exploring the impact of co-recovery on consumers' attribution the present research finds that when consumers are highly participative in a failed recovery episode (i.e. co-recovery) they blame themselves more than the firm. However this effect is reversed when they participate less and disappeared when they do not participate at all.

## **M7. The Mixed Effects of Nostalgia on Consumer Switching Behavior**

Zhongqiang (Tak) Huang, University of Hong Kong, China  
Xun (Irene) Huang, Nanyang Technological University, Singapore  
Yuwei Jiang, Hong Kong Polytechnic University, China

This research shows that contrary to conventional wisdom nostalgia can increase consumer switching behavior. However this effect only occurs when consumers focus on the consumption outcome and it is reversed when consumers are led to focus on the process of consumption. These findings provide a nuanced understanding of nostalgia marketing.

## **D5. Bragging about Effort? Personal Effort Decreases Word-of-Mouth**

Jiexian (Chloe) Huang, Hong Kong Polytechnic University, China  
Yuwei Jiang, Hong Kong Polytechnic University, China

Three experiments revealed consumers were less likely to share a positive achievement to others through word-of-mouth if they spent personal effort in pursuing it than if no effort was involved in the pursuit. We further found the effect was dismissed when consumers' interpersonal warmth was assured by other contextual cues.

## **O9. The Role of Numerical Identification in Customer Reaction toward Service Failure**

Jiexian (Chloe) Huang, Hong Kong Polytechnic University, China  
Yuwei Jiang, Hong Kong Polytechnic University, China

This research investigates the consequence of assigning numbers to customers (e.g. room numbers) in a service context. Two experiments show that after being identified by a number customers would be more tolerant of service failure. This effect is found to be driven by the self-dehumanization process triggered by numerical identification.

## **A3. Why People Still Do Not Trust Algorithmic Advice in Decision Making**

Jaewon Hwang, Sejong University, South Korea  
Dong Il Lee, Sejong University, South Korea

The current research examines why people don't trust on algorithmic advice in decision making and verifies the underlying mechanism of this effect. The present study shows that people trust advice from algorithms less than advice from people and low trust in the algorithm is caused by the low attribution externality.

## **C2. The Bad Taste of Healthy Food Discounts**

Iina Ikonen, Vrije Universiteit Amsterdam, The Netherlands  
Aylin Aydinli, Vrije Universiteit Amsterdam, The Netherlands  
Peeter Verlegh, Vrije Universiteit Amsterdam, The Netherlands

Price promotions have often been suggested as a way to increase healthy consumption but research suggests they may be less effective in healthy food categories. Through four experiments we offer a potential explanation: they lower the pre-purchase tastiness perceptions of healthy foods by increasing reliance on the unhealthy=tasty intuition.

## **K8. Framing Matters. How Comparisons to Ideal and Anti-Ideal Reference Points Affect Brand Evaluations**

Magdalena Zyta Jablonska, SWPS University of Social Sciences and Humanities, Poland  
Andrzej Falkowski, SWPS University of Social Sciences and Humanities, Poland

We test how comparisons to ideal and anti-ideal reference points affect brand evaluations in political and consumer context. The results support the negativity effect showing that negative comparisons have a stronger effect than their positive counterparts.

## **R14. Are Lonely Consumers Loyal Consumers? Loneliness Breadth and Depth**

Eunyoung Jang, Oklahoma State University, USA  
Zachary Arens, Oklahoma State University, USA

People feel loneliness either due to inadequate closeness in their relationships or inadequate number of relationships. Across two studies we show that lonely people who lack deep relationship exhibit higher brand loyalty whereas lonely people who lack broad relationships choose a larger variety of brands.

## **G10. The Effects of Self-Construal on Evaluations of Brand Logo Colors**

Eunmi Jeon, Sungkyunkwan University, South Korea  
Myungwoo Nam, Georgia Tech, USA

The present research investigates the effectiveness of different types of color combinations on brand evaluations. In this research we propose that consumers' self-view influences the effectiveness of analogous versus complementary color combinations. We suggest that consumers' self-views would influence effectiveness of analogous versus complementary color combinations used in brand logos.

## **G3. Warm or Cold? The Effect of Color Temperature of Logo on Evaluation of For-Profits and Nonprofits**

Eunmi Jeon, Sungkyunkwan University, South Korea  
Myungwoo Nam, Sungkyunkwan University, South Korea

The current research examines the fit effect between color temperature and organization type and how it influences product evaluations. We suggest that product evaluations of for-profits were higher when the logo color was in cooler colors compared to nonprofits.

## **J12. The Influence of Pet-Ownership on Consumer Behavior**

Lei Jia, Ohio State University, USA  
Xiaojing Yang, University of Wisconsin - Milwaukee, USA  
Yuwei Jiang, Hong Kong Polytechnic University, China

Across four studies we show that pet ownership influence consumers' regulatory focus such that dog (vs. cat) owners are more promotion- (vs. prevention-) oriented. Their different regulatory orientations can carry over to influence their financial decisions attitudes toward ads and purchase intentions.

## **Q7. Desire in Performed Consumption: Examining the Case of Korean Beauty Vlogging**

Marie-Eve Jodoin, HEC Montreal, Canada  
Marie-Agnès Parmentier, HEC Montreal, Canada

This research project examines the processes of territorializing and sustaining desire on YouTube in the context of Korean beauty vlogging. It finds that in consuming the performed consumption of vloggers material desire social desire and desire for otherness are territorialized on the network and are sustained outside of bodily-reality.

## **E9. “Power Distance, Social Aspiration, and Fair Trade Products” – the Interaction Effect of Power Distance Belief and Status Motivation on Fair Trade Product Consumption**

Sunghee Jun, Seoul National University, South Korea  
Libby Youngjin Chun, Seoul National University, South Korea  
Kiwon Park, Seoul National University, South Korea

Research on power distance belief shows that people with high (vs. low) PDB engage in prosocial behaviors more. Marrying these research results we conducted one preliminary field study and lab experiments to demonstrate that when PDB is high high status motive individuals are more likely to purchase fair-trade products.

## **M12. From the Occult to Mainstream – Tracing Commodification of the Spiritual in the Context of Alternative Spiritualities**

Richard Kedzior, Bucknell University, USA

In this paper we focus on examining various institutional logics that facilitated the evolution of a sacred object into a marketplace phenomenon.

## **G12. The Effect of (Non-)appetizing Ambient Scents on Consumers’ Affinity Toward Vices and Virtues in the Retail Environment**

Corinne M Kelley, Florida State University, USA  
Anders Gustafsson, Karlstad University, Sweden  
Poja Shams, Karlstad University, Sweden  
Martin Mende, Florida State University, USA  
Maura Scott, Florida State University, USA

Appetizing (non-appetizing) ambient scents decrease consumers’ personal control and increase their affinity toward vice (virtuous) offerings. Appetizing scents increase affinity toward vice offerings via increased visual attention enhancing recall of vice products desire for vice products and store attitude. Effects are tested in three field studies at three different retailers.

## **F6. Can CSR Save a Firm From a Crisis? A Role of Gratitude in the Buffering Effect of CSR on Consumer Vindictive Behavior.**

Junghyun Kim, NEOMA Business School, France  
Taehoon Park, University of South Carolina, USA  
Myungsuh Lim, Sangji University, South Korea

This research examines the buffering effect of corporate social responsibility (CSR) on consumers vindictive behaviors during a product-harm crisis. Three studies demonstrate how CSR plays a critical role in reducing consumers intention to engage in vindictive behaviors (e.g. negative word-of-mouth) and propose a mediating role of consumer gratitude.

## **R8. Brand Perceptions and Consumer Support in the Face of a Transgression: Warmth Over Competence**

Summer Hyoyeon Kim, University of Kansas, USA  
Jessica Li, University of Kansas, USA  
Jenny Olson, Indiana University, USA  
Shailendra Pratap Jain, University of Washington, USA

We examined the role of brand perception in consumer judgment and support following a brand transgression. Consumers blame warm brands less for the same product failure. They are also more likely to support warm brands following a moral transgression. We explain this link through the process of moral decoupling.

## **B3. The Effect of Temporal Distance on Online Reviews' Recommendation Power: The Role of Spontaneous Retrieval and Perceived Trust**

Kyu Ree Kim, Seoul National University, South Korea  
Wujin Chu, Seoul National University, South Korea

We challenge lay belief that reviews on recent experience are more powerful. We examined that reviews written on the experiences of distant past have stronger perceived recommendation power. We also examined the mediation effect of perceived trust and the effect of retrieval process (spontaneous vs. deliberate) on perceived trust.

## **P7. Consumer Evaluations of Sale Prices: The Role of the Spatial Representation of Time**

Yaeun Kim, Temple University, USA  
Joydeep Srivastava, Temple University, USA

Based on the ease of the subtraction task we tested whether value perception is influenced by the interaction between sale price displays and temporal information. The findings revealed that participants perceived the price offer as more valuable with time information. The studies contribute to the pricing and fluency literature streams.

## **P5. Can(Can't) Control, thus Try to Save (Earn): The Joint Effect of Perceived Control and Financial Deprivation on Financial Decisions**

Min Jung Kim, Manhattan College, USA

This research suggests that one's preference for earning vs. saving will depend on their personal control and financial deprivation. We predict that individuals who perceive low personal control are more likely to prefer earning to saving but such a tendency can be reversed when their financial deprivation is considered.

## **I12. The Effect of Susceptibility-Induced Threat in the Preventative Communication**

Moon-Yong Kim, Hankuk University of Foreign Studies, South Korea

This research investigates gender differences in responding to the preventative communication by varying the level of susceptibility-induced threat. Specifically it is predicted that higher level of susceptibility is more likely to have a negative effect on persuasion for females (vs. males) due to their maladaptive responses to the threatening message.

## **G11. Sensory Placebo Effects: The Role of Sensory Signaling in Enhancing Marketing Placebos and Consumer Outcomes**

Dan King, University of Texas Rio Grande Valley, USA  
Sumitra Auschaitrakul, University of the Thai Chamber of Commerce, Thailand

Pairing a placebo expectation with a sensory stimulus ("sensory placebo") elicits significantly stronger placebo effects in both cognitive and physical domains. Participants given a sensory placebo solved more word puzzles and were better at lifting weights and the outperformance over standard placebos was mediated by phantom sensations of placebo energization.

## **L11. Consumer Search Mode Produces Unintended Marketing Consequences**

Dan King, University of Texas Rio Grande Valley, USA  
Sumitra Auschaitrakul, University of the Thai Chamber of Commerce, Thailand

Recently marketers have migrated consumers from written to voice search assuming that this produces positive outcomes. We show that this elicits unintended negative outcomes such as delays in willingness to purchase products and lowered spending. We show that differences in mindsets when people use their voice account for this effect.

## **D10. It's Meant for Me: When Serendipity Increases Word-of-Mouth**

Colleen Patricia Kirk, New York Institute of Technology, USA  
Joann Peck, University of Wisconsin - Madison, USA  
Claire Hart, University of South Hampton, UK  
Constantine Sedikides, University of South Hampton, UK

High narcissistic consumers are more likely than low to spread word-of-mouth about serendipitous events. We explain this effect in terms of two distinct paths motivated by narcissistic admiration and narcissistic rivalry. We further offer empirical evidence for the role of psychological ownership motivation in driving word-of-mouth.

## **J3. You Think I'm Yours but, Trust Me, I'm Not: How Consumers Value Dogs and Cats**

Colleen Patricia Kirk, New York Institute of Technology, USA  
Samantha Renee Kirk, Boston College, USA

Two experiments reveal that dog owners are willing to pay more for life-saving surgery and related expenses than cat owners. This effect is sequentially mediated by perceived behavioral control psychological ownership and emotional attachment. This first examination of psychological ownership of living creatures offers implications for pet owners and marketers.

## **J13. The Good and Bad of a Delayed Indulgence: Effects on Self-Perceptions and Purchase Satisfaction**

Argiro Kliamenakis, Concordia University, Canada  
Kamila Sobol, Concordia University, Canada

We show that the mere act of delaying an indulgent purchase can evoke the same level of perceived self-control as not indulging at all—a level that is higher than in instances of immediate indulgence. Paradoxically the bolstered perceptions of self-control resulting from a delayed indulgence subsequently reduce purchase satisfaction.

## **K5. Advertising Organizational Culture as a Selling Tactic for For-Profit Organizations**

Dejun Tony Kong, University of Houston, USA  
Maria Ng, University of Houston, USA

By conducting four experiments we found that advertising organizational culture can be an effective selling tactic for for-profit organizations particularly in a stereotypically fun industry. Specifically advertising fun (vs. neutral) organizational culture appeared to enhance consumers' perception of organizational warmth which elevated their positive anticipated emotions and subsequent purchase intention.

## **O11. Have Less, Compromise Less: How the Perception of Resource Scarcity Influences Compromise Decisions**

Kate Kooi, University of Miami, USA  
Caglar Irmak, University of Miami, USA

The compromise effect has been shown to be robust however the current research seeks to illuminate a circumstance under which it is less predictive by demonstrating that under the perception of resource scarcity consumers are less susceptible to the compromise effect because of their proclivity for status-seeking and risky choices.

## **R1. How Consumers Deal With Brand Failure-An Individual Differences Approach**

Melika Kordrostami, California State University-San Bernardino, USA  
Elika Kordrostami, Rowan University, USA

The impact of individual differences (regulatory focus and attachment style) on consumers' reactions at the time of brand failure is studied. Our three studies showed that higher promotion leads to higher positive and lower negative behaviors. Furthermore this effect is moderated by individuals' attachment styles.

## **E8. Perceptions of Out-Group Members: The Effects of Language Abstraction**

Afra Koulaei, University of South-Eastern Norway, Norway  
Daniela Cristian, City University of London, UK

One way to reduce the discrimination towards the members of stigmatized groups is to describe their situations or behaviors in a more concrete (vs. abstract) form. Concrete descriptions lead people to attribute the homelessness to the situational cause (as opposed to individual) which in turn leads to greater helping behavior.

## **J11. The Myth of Return – Success or Failure? Consumer Identity and Belonging in the Case of Repatriate Migrants**

Sonja N. Kralj, University of Augsburg, Germany  
Michael Paul, University of Augsburg, Germany

This poster introduces a new migration pattern into research on consumer migration and acculturation. Investigating structural individual and relational factors we stress the dynamic nature of how consumption identity and belonging are related in the case of consumers having returned from the diaspora to the ancestral homeland after generations.

## **K11. Effects of Emotional vs. Rational Thinking on Consumer Responses to Verbal Precision**

Ann Kronrod, University of Massachusetts, USA  
Guang-Xin Xie, University of Massachusetts Boston, USA  
Shai Danziger, Tel Aviv University, Israel

We define verbal precision and examine consumer responses to more and less verbally precise communication. Results suggest that emotionally (vs. rationally) oriented recipients are more sensitive to verbally precise messages. For these consumers higher verbal precision increases perceived conversational cooperativeness of the source and results in more positive product attitudes.

## **Q4. The Notion of Self-Optimization in Context of Self-Tracking and Beyond**

Agnieszka Krzeminska, Leuphana University Lüneburg, Germany  
Dorthe Brogård Kristensen, University of Southern Denmark, Denmark

The aim of this paper is to analyse the metaphors and ideologies of optimization with a special consideration of the notion of self-optimization which is being prevalently used in descriptions of goals of people using self tracking devices or apps (e.g. Lupton 2014 Ruckenstein 2014 Selke 2016).

## **I11. Self-Presentation in the Mating Market: The Influence of Gender and Sexual Orientation on Profiles on Tinder and Grindr**

Chaim Kuhnreich, Concordia University, Canada  
Lilian Carvalho, FGV/EAESP, Brazil  
Gad Saad, Concordia University, Canada

Examining how people signal potential mates on Tinder and Grindr males are more likely to use conspicuous consumption in their profiles when compared to women. However in the homosexual community males are actually more likely to display sexually suggestive pictures and signs of physical fitness as opposed to conspicuous consumption.

## **N4. Induction of Construal-Level Mindset via Surprise and the Follow-up Effect on Consumer Evaluations and Judgments**

Atul A Kulkarni, University of Missouri, USA  
Joëlle Vanhamme, EDHEC Business School, France

We find that an experience of surprise may influence response to subsequently presented stimuli in the same fashion as abstract/concrete processing would do. Three studies show that when primed with positive (negative) surprise participants evaluated promotionally (preventionally) framed ad messages more favorably and leaned toward desirability (feasibility) laden shopping options.

## **F4. Social Support First, Money Later: Perceived Economic Mobility Increases Happiness When Perceived Social Support Opens the Door**

Yong Ju Kwon, Seoul National University, South Korea  
Sara Kim, University of Hong Kong, China  
Youjae Yi, Seoul National University, South Korea

Our research shows that perceived economic mobility (PEM) has a positive effect on happiness. More importantly perceived social support moderates the effect of PEM on happiness: people with high PEM are happier than those with low PEM only when they meet a certain level of perceived social support.

## **B4. Prestige is the Truth: Luxury Branding Drives for Fairness Perception of Non-physical Attribute Based Dynamic Pricing**

Edward Yuhang Lai, Virginia Tech, USA  
Cindy Yoonjoung Heo, Ecole hôtelière de Lausanne, Switzerland

Dynamic pricing is widely adopted in experience products. However consumers may not perceive different pricing policies as equally fair. An experiment finds evidence that consumers feel ambiguity in judging differential pricing policy based on non-physical (vs. physical) attribute and perceive such policy as fairer for luxury brands (vs. economy brands).

## **M8. Nostalgia Increases Healthy Attitudes and Behaviors**

Jannine Lasaleta, Yeshiva University, USA  
Carolina O. C. Werle, Grenoble Ecole de Management, France  
Amanda Pruski Yamim, Grenoble Ecole de Management, France

This research tests nostalgia as a motivation force in healthful food consumption. Across three studies we find support for the hypothesis that nostalgia increases positive attitudes and behaviors toward healthy food but decreases them toward unhealthy food. Moderated mediation evidence demonstrated this effect is driven by nostalgia-evoked social support.

## **C9. Filling the Expectations: How Packaging Sustainability Influences Consumers' Inference of Product Attributes**

Olga Lavrusheva, Aalto University, Finland  
Alexei Gloukhovtsev, Aalto University, Finland  
Kristina Wittkowski, Aalto University, Finland  
Tomas Falk, Aalto University, Finland  
Pekka Mattila, Aalto University, Finland

Our study aims to investigate the effect of sustainable packaging materials on the perceptions of taste quality and health-related benefits of food products and whether this effect would then facilitate consumers' purchase intention.

## **C10. Beyond Self-control: A Field Exploration of the Interactive Effect between Cue-induced and Prospective Decision Making on Long-term Weight Loss**

Wanyu Li, McGill University, Canada  
Laurette Dube, McGill University, Canada  
Yu Ma, McGill University, Canada

This research goes beyond the episode-level self-control and examines how the cue-driven tendency interacts with the endophenotype underlying prospective judgment in shaping the longer-term dynamics of weight management.

## **N13. Smaller Self but Larger Tips? The Effect of Awe on Consumers' Tipping Intention**

Ran Li, Chinese University of Hong Kong, China

Two experiments showed that feeling awe can systematically affect consumers' tipping intention. Specifically this awe-tipping relationship is driven by two countervailing processes: feeling awe makes consumers feel closer to the server (which increases the tendency of tipping) but simultaneously decrease their power distance belief (which decreases the tendency of tipping).

## **H2. Influencing Consumer Response to Products with High Styling: The Role of Mindsets**

Ying-Ching Lin, National Chengchi University, Taiwan  
Angela Chang, Northeastern University, USA

This research investigates the conditions under which consumer response to products with a high level of styling will more likely be positive. Empirical studies demonstrate that consumers evaluate a high-styling (vs. low-styling) product more favorably when they are in an abstract rather than a concrete mindset.

## **L10. How Physical Distance and Power Distance Belief Affect Salesperson Evaluations and Purchase Intentions**

Chia-Wei Joy Lin, University of Tennessee at Chattanooga, USA  
Saerom Lee, University of Texas at San Antonio, USA  
Bingxuan Guo, University of Texas at San Antonio, USA

Consumers with lower (vs. higher) PDB report lower evaluations of the salesperson who stays physically close to (vs. far from) them and subsequently have lower purchase intentions in the shopping context. This is because lower PDB consumers are more likely to infer disrespect from the physical closeness of the salesperson.

## **K9. Measuring Internet Slang Style in Advertisement: Scale Development and Validation**

Shixiong Liu, Shenzhen University, China  
Yi Wu, Tsinghua University, China  
Wu Gong, Shenzhen University, China

Drawing on linguistics and stylistics theories this paper introduces and conceptualizes the construct of Internet slang style (ISS) to describe characteristics of Internet slang. A dimensional ISS framework consisting of four dimensions (amiability overtness candor and harshness) is proposed. The corresponding scale was developed and validated across five studies.

## **A6. “Alexa, let’s make a trade”: Search Behavior, Trust, and Privacy with Voice-Activated Assistants**

Weizi Liu, University of Illinois at Urbana-Champaign, USA  
David William Ross, University of Illinois at Urbana-Champaign, USA  
Kieshana M. Williams-Beeler, University of Illinois at Urbana-Champaign, USA  
Yoonah Lee, University of Illinois at Urbana-Champaign, USA  
Michelle Renee Nelson, University of Illinois at Urbana-Champaign, USA

Through 16 interviews with owners of voice-activated assistants (VAA) we explore user trust and search practices as they occur in voice interactions with their device. We uncover preferences for visual elements and less cognitive search tasks when seeking information as well as cautious trust in the device’s maintenance of privacy.

## **J7. Alienation from Ourselves, Alienation from Our Products: A Carry-over Effect of Self-alienation on Self-possession Connection**

(Joyce) Jingshi Liu, Hong Kong University of Science and Technology, China  
Amy Dalton, Hong Kong University of Science and Technology, China

When consumers feel alienated from the self they also feel alienated from their products which is an important part of the self. Moreover this effect only applies to products that are relevant to the self and is attenuated among consumers with an interdependent (vs. independent) mindset.

## **E3. Having Power, Giving More? The Effect of Psychological Power on Consumers’ Charitable Giving of Time**

Wumei Liu, Lanzhou University, China

Will high power increase consumers’ charitable giving of time? Existing research has not addressed this research question yet. We propose that high (vs. low) power will increase consumers’ illusory control over time and consequently their readiness to donate when encountering volunteering appears. The boundary condition is also examined.

## **J4. A Large Pack of Toilet Paper is Bad for Me: Self-control and Consumers’ Responses to Product Quantity**

(Joyce) Jingshi Liu, Hong Kong University of Science and Technology, China  
Keith Wilcox, Columbia University, USA  
Amy Dalton, Hong Kong University of Science and Technology, China

We examine the association between product quantity and self-control using utilitarian products a product domain that does not generally threaten self-control. We find a bidirectional effect between product quantity and self-control whereby exposures to large product quantity decrease self-control and activation of self-control decreases evaluation of product quantity.

## **G13. Odor Priming and Product Preferences: When Smells Regulate Preferences for Semantically-Congruent Products and Brands**

Ramona De Luca, EAESP-FGV, Brazil  
Delane Botelho, EAESP-FGV, Brazil

This article extends the idea that olfactory stimuli influence consumer preferences even when they are perceived unconsciously. Two laboratory experiments demonstrate that incidental exposure to odors unconsciously activate a mental representation when they are matched for valence and when are related to the intended semantic category thus regulating product preferences.

## **D1. When Intention to Share on Social Media Increases Variety-Seeking: The Role of Self-Enhancement**

Jingjing Ma, Peking University, China  
David Dubois, INSEAD, France  
Fei Jin, Peking University, China

This research investigates how calls to sharing online affect decisions. It shows that consumers would seek variety to self-enhance when they intent to share with others. This effect is stronger when the consumption is non-conspicuous and when consumers are non-experts. Six studies using lab and field data support these effects.

## **I10. Can Body Size Influence the Judgments of Warmth and Competence?**

Trang Thanh Mai, University of Manitoba, Canada  
Olya Bullard, University of Winnipeg, Canada  
Luming Wang, University of Manitoba, Canada

We propose that the effect of body size on social evaluation extends beyond the association between thinness and beauty. Specifically we posit that body size has implications for warmth and competence judgments made by observers: a thin (vs. heavy) body signals competence whereas a heavy (vs. thin) body signals warmth.

## **I2. Can Skinnier Body Figure Signal Higher Self-Control, Integrity, and Social Status?**

Trang Thanh Mai, University of Manitoba, Canada  
Luming Wang, University of Manitoba, Canada  
Olya Bullard, University of Winnipeg, Canada

Currently conventional wisdom as well as much of social psychology literature equates thinness with beauty and attractiveness in Western societies. We propose that a thin body signals valuable characteristics—self-control and integrity—that lead to the perception of social status because they represent social capital in a Western society.

## **E12. Green versus Premium Choice and Feelings of Pride**

Cecilia Souto Maior, Federal University of Paraná, Brazil  
Danielle Mantovani, Federal University of Paraná, Brazil  
Rafael Demczuk, Federal University of Paraná, Brazil

We showed that choosing a green product over a premium option increases (vs. decreases) authentic (vs. hubristic) pride perceptions. These same effects are found when participants need to justify their choice in public. When participants are aware that their decision is private the choice does not differently impact pride facets.

## **F12. Matching Green Advertising Strategies and Brand Positioning to Improve Brand Evaluation**

Danielle Mantovani, Federal University of Paraná, Brazil  
Victoria Vilasanti, Federal University of Paraná, Brazil  
Marcelo Vinhal Nepomuceno, HEC Montreal, Canada  
Cecilia Souto Maior, Federal University of Paraná, Brazil

This study shows that brand evaluations are highest when luxury positioning is used with green demarketing and when fast fashion is used with environmentalism. Ad believability mediated this effect. Environmentalism and demarketing have an equal positive effect on self-brand connection and brand attitudes of notoriously green brands.

## **G1. Enchantment through Retro Product Consumption in a Digital World**

Varala Maraj, City University of London, UK  
Fleura Bardhi, City University of London, UK  
Caroline Wiertz, City University of London, UK

This study examines the role of materiality in how consumers are managing the experience of disenchantment resulting from dematerialized digital consumption practices. We show that consumption of retro products revivals of outdated technology objects complements digital consumption by providing historical atmospheric value nostalgic time value and a greater perceived authenticity.

## **G2. You Run When Time Flies: Time Metaphors Affect Inferences from the Speed of Time**

N. Alican Mecit, HEC Paris, France  
L. J. Shrum, HEC Paris, France  
Tina M. Lowrey, HEC Paris, France

In two lab experiments we show that the subjective experience of time serves as a cue that people use to infer their speed. When time is perceived to have passed quickly depending on the time perspective people speed up and suffer from cognitive trade-offs such as accuracy problems and impulsivity.

## **G9. The Voice From Afar: How Reverberation Affects Consumer Cognition**

Johann Melzner, New York University, USA  
Jochim Hansen, University of Salzburg, Austria

How do acoustic parameters in the human voice affect consumers? Drawing on literature in acoustics and construal level theory this research proposes that reverberation an intuitive cue in auditory distance perception affects consumers' inferences about both spatial and non-spatial distances and increases construal level with consequences for judgments and decision-making.

## **E13. Rooting for Rocky or Apollo? Underdog Narratives and Crowdfunding Success**

Hua (Meg) Meng, Longwood University, USA  
César Zamudio, Kent State University, USA  
Yiru Wang, Kent State University, USA

This research investigates how underdog narratives in crowdfunding pitches influence crowdfunding success. Results show that backers are more willing to pledge when reading underdog (vs. top dog and neutral) narratives because they are more narratively transported and activate a higher level of empathy and altruism.

## **F9. Protection against Deception: The Moderating Effects of Knowledge Calibration on Consumer Responses to Ambiguous Advertisement Information**

Joel Alan Mohr, Queens University, Canada  
Peter A. Dacin, Queens University, Canada

A common characteristic of deceptive persuasion tactics is information ambiguity. This research demonstrates that whether consumers perceive high (vs. low) ambiguity advertisements as more deceptive depends on whether their topic knowledge is sufficiently calibrated. While calibrated knowledge provides a safeguard against deception miscalibrated knowledge biases persuasive information elaboration.

## **F13. A Story of Waste: Trust, Symbolic Adoption & Sustainable Disposal**

Marwa Gad Mohsen, Babson College, USA

This working paper reflects on behavioral challenges in relation to pro-environmental waste management. A proposed combined theorization of symbolic adoption and Construal Level Theory (CLT) with the mediating effect of consumer trust aims at building a potential model exploring consumer likelihood to adopt ethical disposal practices.

## **B7. Conceptualizing Brand Arrogance and Its Impact on Consumer Trust**

Sampoorna Nandi, University of Connecticut, USA  
Robin A. Coulter, University of Connecticut, USA

Our research addresses the under-researched construct of brand arrogance. We conceptualize and define brand arrogance and explicate brand-related factors that feed consumer perceptions of brand arrogance. We explore the impact of brand arrogance on consumer trust and propose that perceived product quality brand use and consumer arrogance moderate this relationship.

## **M4. How Consumption Experiences Create Value**

Gia Nardini, University of Denver, USA  
Melissa Archpru Akaka, University of Denver, USA  
Deborah MacInnis, University of Southern California, USA  
Richard J Lutz, University of Florida, USA

Consumption experiences are the heart of consumer behavior. However research in this area varies widely. We integrate prior literature to develop a conceptual framework of consumption experience. Our framework organizes the fragmented literature on consumption experience and identifies avenues for future research in investigating how consumption experiences drive value creation.

## **J6. Cozying up to the Kardashians: A Theory for Consumers' Affinity towards Celebrity Gossip**

Jayant Nasa, Indian School of Business, India  
Tanuka Ghoshal, Baruch College, USA  
Raj Raghunathan, University of Texas at Austin, USA

The present research examines celebrity gossip consumption using the lens of compensatory consumption. Two experiments show that people exhibit an increased propensity to consume celebrity gossip after experiencing a psychological threat and such consumption has a restorative effect on their self-worth. These effects are moderated by the consumers' trait self-esteem.

## **I3. Hormonal Effects on Materialism and the Moderating Role of Intrasexual Competition**

Marcelo Vinhal Nepomuceno, HEC Montreal, Canada  
Cristina Maria de Aguiar Pastore, Pontifical Catholic University of Paraná - PUCPR, Brazil  
Eric Stenstrom, Miami University, Ohio, USA

Across two studies we demonstrate how digit ratio (2D:4D) an indicator of prenatal exposure to estrogen and testosterone is predictive of materialism. Furthermore we show how intrasexual competition the rivalry with same-sex others over access to romantic partners moderates the association between digit ratio and materialistic tendencies.

## **A8. Do You Accept The Terms And Conditions? The Role Of Trust And Hedonic Content On Self-Disclosure To Apps**

Carla Freitas Silveira Netto, Federal University of Rio Grande do Sul, Brazil  
Simoni F Rohden, Federal University of Rio Grande do Sul, Brazil  
Marina de Wallau Lugocho, Federal University of Rio Grande do Sul, Brazil  
Natalia Englert, Federal University of Rio Grande do Sul, Brazil  
Valentina Ortiz Ubal, Federal University of Rio Grande do Sul, Brazil

Online consumers disclose personal data in exchange for mobile apps. The role of trust endorsement familiarity risk perception privacy concerns and hedonic content of the app were analyzed in this working paper. Results from three different experiments suggested the positive effect of trust and negative effect of hedonic content.

## **K2. Influence of Attentional Breadth on Processing and Memory of Brand Advertisements**

Nicolas Noack, University of Duisburg-Essen, Germany  
Lynn Brinkmann, University of Duisburg-Essen, Germany  
Oliver B. Büttner, University of Duisburg-Essen, Germany

This research examined the influence of attentional breadth on ad perception and brand recall. Eye-tracking data reveals increased gaze towards the ad background for broad attention. Additionally broad attention enhanced brand recall. The findings suggest that ad background acts as an additional memory cue.

## **P1. Constructed Preferences in Time-Money Tradeoffs: Evidence for Greater Violation of Procedural Invariance for Time as Opposed to Money Elicitations**

Nazli Gurdamar Okutur, London Business School, UK  
Jonathan Zev Berman, London Business School, UK

When are preferences for time-money tradeoffs likely to be constructed? We argue that due to the ambiguous value of time consumers tend to construct their preferences and exhibit failures of procedural invariance more when their preferences are elicited based on the time (vs. money) dimension of the tradeoff.

## **A10. Opting Opt-in or Out? Effects of Defaults on Perceived Control and Valuation of Personal Data**

Iris van Ooijen, University of Twente, The Netherlands

This work hypothesizes and finds that opt-in (compared opt-out) choice designs with regards to online data disclosure requests enhance individuals' experienced control over personal data and their data valuation in turn. By doing so it emphasizes the importance of 'privacy by design'. Follow-up studies are currently being conducted.

## **K7. Responses to Online Behavioral Advertising Disclosures: Effects of Disclosure Source Trustworthiness and Message Type on Advertising Outcomes**

Iris van Ooijen, University of Twente, The Netherlands

This work demonstrates that for a less trusted online platform (Facebook) the source of online behavioral advertising (OBA) disclosures affects consumer responses to personalized ads. Specifically OBA disclosures only increase advertising effectiveness when the source is a trusted third party and when the message is framed as a notice (vs. warning).

## **D7. 'That's (Not) My Business': Examining Behavior, Interactions and Implications of Consumer Brand Advocates and Brand Adversaries in Social Media**

Marcus Opitz, University of Vienna, Austria  
Sabine Einwiller, University of Vienna, Austria

Word-of-mouth and related advocacy and adversary behavior disseminated by consumers in an online environment are among the most trusted forms of brand communication. This study offers a first systematic content analysis of the communicative behavior of advocates and adversaries and the factors influencing it within the context of brands' Facebook profiles.

## **G7. The Presence of Dividing Line Decrease Perceived Quantity**

Jun Ouyang, Xiamen University, China  
Yanli Jia, Xiamen University, China  
Zhaoyang Guo, Xiamen University, China

Three studies showed that participants reported smaller quantity estimates when shown a set of items separated with a dividing line than when shown them as a whole. We attributed the results to that the dividing line might attract participants' attentions from the items thus leading them to underestimate items' quantity.

## **M5. The More Expensive a Gift Is, the More It Is Appreciated? The Effect of Gift Price on Recipients' Appreciation**

Jooyoung Park, Peking University, China  
Mengshu Chen, Tencent Holdings Limited, China

Two studies show that a gift with a higher or lower price than the recipient expects decreases their appreciation. Our findings suggest that recipients perceive givers as being less thoughtful when the gift price is lower than expected whereas they feel burden to repay when the gift price is higher.

## **P10. Omission Bias in the Gain vs. Loss Domain**

Jen H. Park, Stanford University, USA

This paper examines whether individuals exhibit greater omission bias in a loss-framed risky choice (lose \$10000 or lose \$0) compared to the gain frame (earn \$0 or earn \$10000). While prior studies reveal mixed results this research introduces anticipated regret as a moderator and uses the Monty Hall problem.

## **P14. Financial Behavior Among Young Adult Consumers: The Influence of Self-determination and Financial Psychology**

Heejung Park, University of Wyoming, USA

Research of the consumer financial behavior has been investigated in various ways. Better financial behaviors are essential for improving quality of life. Specifically young adult consumers have particular difficulty making decisions involving accruing debt. Therefore this paper deals with the financial behavior of young adult consumers through self-determination theory.

## **N8. Effect of Awe on Collectable Consumer Experience**

Eujin Park, Washington State University, USA  
Andrew Perkins, Washington State University, USA  
Betsy Howlett, Washington State University, USA

It has been known that awe is caused by encountering an unexpected event and stimulates explanation-seeking via a need for cognitive accommodation (Valdesolo Shtulman and Baron 2017). Collectable experiences are often unusual and unconventional (Keinan and Kivetz 2010). Hence we hypothesize that awe increases individual's preference for collectable consumer experience.

## **P12. Disclosure of Project Risk in Crowdfunding**

Jooyoung Park, Peking University, China  
Keongtae Kim, Chinese University of Hong Kong, China

This research examines whether and how risk disclosure of crowdfunding projects influences crowdfunders' project perceptions and funding decisions with a particular focus on the contrast between technology and non-technology projects. We find that crowdfunders respond to the risk disclosure of projects but differently between technology projects and non-technology projects.

## **R9. The Asymmetric Effects Of Attitude Toward The Brand (Symbolic Vs. Functional) Upon Recommendation System (Artificial Intelligence Vs. Human)**

Kiwan Park, Seoul National University, South Korea  
Yaeri Kim, Seoul National University, South Korea  
Seojin Stacey Lee, Seoul National University, South Korea

We investigated how the recommendation system types (AI vs. Human) affect brand attitude depending on the brand image (Symbolic vs. Functional). We found consumers are reluctant to accept a recommendation from AI where in symbolic brand (Study1). This effect was further explained by uncanny-feeling toward the AI recommendation system (Study2).

## **D2. When a Negative Review Can Help the Company: The Role of the Unfairness and Empathy**

Maria Alice Pasdiora, Federal University of Rio Grande do Sul, Brazil  
Cristiane Pizzutti, Federal University of Rio Grande do Sul, Brazil  
Natalia Englert, Federal University of Rio Grande do Sul, Brazil

This work extends literature on the influence of justice perception on consumer behavior by showing that consumers sensitized with injustice perpetrated on companies by other consumers. We demonstrate that injustice episodes trigger feelings of empathy and consequently lead witnesses to present favorable attitudes and more purchase intention towards the company.

## **Q10. Social Media Agency: Exploring the Role of Social Media Structures in Shaping Consumers' Identity Projects**

Gabrielle Patry-Beaudoin, Queens University, Canada  
Jay Handelman, Queens University, Canada

Drawing on the mediatization theory (Hjarvard 2008) this study analyzes the role of social media in shaping consumers' online identity projects. Our qualitative empirical investigation contributes to the consumer identity literature by examining how three YouTube structures create unique tensions for consumers that affect their identity projects.

## **J5. Buy Better, Buy Less: Future Self-Continuity and Construal Level Affect Investment in Sustainable Consumer Products**

Rebecca Peng, Northeastern University, USA  
Daniele Mathras, Northeastern University, USA  
Katherine Loveland, Xavier University, USA

Results of three studies reveal that consumers who believe their future selves will be similar (vs. dissimilar) to their current selves are most likely to embrace a "buy it for life" mindset. Specifically higher future self-continuity promotes higher level construal and ultimately ratings for brands that sell long-lasting products.

## **Q3. Academic Branding on Social Media: Examining the Influence of Personal Brands on the Professor-Student Relationships**

Edita Petrylaite, Northumbria University, UK  
Darija Aleksic, University of Ljubljana, Slovenia

With the increasing interaction on social media and its proliferated impact on personal image professionals including university lecturers communicate on digital channels for work and personal purposes. This research aims to find out how personal branding using the same social media account influences professors' relationships with students as university clients.

## **P6. Marginal Cost Consideration**

Ethan Pew, Stony Brook University, USA  
Hyunhwan Lee, University of Miami, USA

A large-scale study (N=12003) examines how price presentation influences choice. Six experimental conditions present absolute and marginal prices (across 30 price levels) for a flight selection task. Highlighting savings accruing from choosing the lower price option results in greater choice share for the higher priced option particularly as prices increase.

## **K6. Persuading the Moral Consumer: Matching Messages to Attitude Basis**

Aviva Philipp-Muller, Ohio State University, USA  
Andrew Luttrell, Ball State University, USA  
Richard Petty, Ohio State University, USA

We explored the persuasive effects of moral versus practical counter-attitudinal messages on individuals with varying levels of moral conviction toward recycling. Across two studies when pro-recycling moral conviction was high the moral (vs. practical) anti-recycling message was more persuasive but the effects reversed when moral conviction was low.

## **F10. Food Waste: On the Normalization of Structural Violence**

Andreas Plank, Privatuniversität Schloss Seeburg, Austria

While more than one billion tons of palatable food are thrown away every year (FAO 2013b) about 900 million people are undernourished worldwide (FAO 2013b). This article tries to answer the research question: How do international organizations (i.e. organizations dealing with the phenomenon food waste institutionally) frame food waste?

## **B1. Dynamic Pricing in Stationary Retailing - The Role of Consumer's Trust**

Maximilian Clemens Pohst, Heinrich-Heine-University, Germany  
Caspar Krampe, Heinrich-Heine-University, Germany  
Peter Kenning, Heinrich-Heine-University, Germany

The integration and application of electronic shelf labels (ESL) enables retailers to implement dynamic pricing practices. Therefore this research work investigates how the use of ESL is perceived by consumers. Preliminary findings revealed that consumer's trust positively affects the perception of ESL as well as perceived price fairness and loyalty.

## **R4. Human Brands and Their Consumers: How Consumers Reform Brand Understandings Following Critical Incidents**

Kimberley Mosher Preiksaitis, Siena College, USA

Human brands offer consumers cultural material that differs from traditional brands. When human brands encounter critical incidents consumers face the tension of separating the celebrity from the person to understand their relationship with the brand. This paper offers insights of three ways consumers reform brand understandings following critical incidents.

## **19. From Childhood Toys to Grownup Choices: Understanding the Gendered Appeal of Violent Media**

Martin A. Pyle, Ryerson University, Canada

Why do men seem to enjoy violent media more than women? This research addresses this question by examining how childhood toys influence perceptions of media as adults. This research contributes to our understanding of the appeal of violent media by demonstrating a cohesive link between socialized values and media choice.

## **R5. Autonomy or Enjoyment? The Contingent Nature of Brand Ritual**

Yaxuan Ran, Zhongnan University of Economics and Law, Vietnam  
Echo Wen Wan, University of Hong Kong, China

Brand rituals can affect consumers' feelings and experience. Adding to this literature the present research demonstrates the contingent nature of brand ritual by showing that brand ritualization can increase enjoyment but simultaneously decrease autonomy both of which increase WTP. Furthermore brand personality moderates the relative salience of the two perception-processes.

## **G4. That's So Sweet: Baby Cuteness Semantically Activates Sweetness to Increase Sweet Food Preference**

Shaheer Ahmed Rizvi, University of Alberta, Canada  
Sarah G Moore, University of Alberta, Canada  
Paul Richard Messinger, University of Alberta, Canada

We examine the semantic association between baby (kindchenschema) cuteness and sweetness and how kindchenschema cuteness increases preference for sweet foods. Kindchenschema cuteness semantically activates the construct of sweetness thereby increasing preference for sweeter foods. Through moderation we show that kindchenschema and not whimsical cuteness produces this increased desire for sweets.

## **L5. Understanding the Components and Effects of the Omnichannel Seamless Experience**

Paula Rodríguez-Torrico, Universidad de Burgos, Spain  
Lauren Trabold, Manhattan College, USA  
Sonia San-Martín, University of Burgos, Spain  
Rebeca San José, University of Valladolid, Spain

This paper aims to investigate empirically the concept of Omnichannel Seamless Experience (OSE) and its impact on Social Media Engagement (SME). Results confirm the multidimensionality of the OSE namely consistency freedom in channel selection and synchronization which directly impact on consumer satisfaction with the omnichannel interaction and indirectly on SME.

## **M1. How Rewarding is Your Rewards Program? Experiential vs. Material Rewards**

Ayalla Ruvio, Michigan State University, USA  
Farnoosh Khodakarami, Michigan State University, USA  
Clay Voorhees, Michigan State University, USA

The research on loyalty rewards programs focuses on material rewards. In four studies we explore consumers' preference for experiential (vs. material) rewards. They view experiential (vs. material) rewards as having greater expected utility which in turn increases their behavioral intentions and engagement with the loyalty program.

## **D9. Consumption Closure as a Driver of Positive Word of Mouth**

Christina Saenger, Youngstown State University, USA  
Veronica Thomas, Towson University, USA

Consumption closure affects consumers' cognitive processing and WOM. Manipulating closure through packaging consumers who experience closure (single-serving package) as opposed to those who do not (equivalent amount from multi-serving package) provide more positive WOM due to increased attitude certainty. Marketers may benefit by encouraging reviews of single-serve packages.

## **E10. Sustainable Initiatives: Cultural Identity, Regulatory Focus, and Construal Perspective**

Ekaterina Salnikova, Aarhus University, Denmark  
Yuliya Strizhakova, Rutgers University, USA  
Klaus G Grunert, Aarhus University, Denmark

We integrate cultural identity regulatory focus and construal theory perspectives to examine effectiveness of sustainable product initiatives. Across five studies we demonstrate strong moderating effects of cultural identity in consumer responses to sustainability framing. Globally-oriented consumers are more engaged with sustainability framed in promotion and more distant terms.

## **P8. Understanding Financial Literacy: A Meta-Analysis of the Antecedents, Consequents and Moderators**

Fernando De Oliveira Santini, Universidade Do Vale Do Rio Dos Sinos, Brazil  
Frederike Monika Budiner Mette, ESPM, Brazil  
Mateus Canniatti Ponchio, ESPM, Brazil  
Wagner Junior Ladeira, Universidade Do Vale Do Rio Dos Sinos, Brazil

A meta-analysis was conducted to evaluate the antecedents consequents and moderators of financial literacy. We obtained 13 significant antecedents of the financial literacy construct and four significant consequent constructs. The observations reflected the moderating effect of culture and the level of economic development of the country of origin.

## **E5. Volunteer Motivations for Direct versus Indirect Service**

Abigail Schneider, Regis University, USA  
Eric Hamerman, Iona College, USA

Nonprofit organizations rely heavily on volunteers yet recruitment and retention of volunteers is a major challenge. We explore the different motivations for volunteer tasks finding that different drivers of behavior (categorized by the Volunteer Functions Inventory) correspond differently to indirect and direct service activities that require differing levels of skill.

## **N3. Emotion Regulation and Memory for Negative Emotion Ads**

Sandra Segal, Ben Gurion University, Israel  
Hila Riemer, Ben Gurion University, Israel  
Shai Danziger, Tel Aviv University, Israel  
Gal Sheppes, Tel Aviv University, Israel

People may employ emotion regulation to process negative emotion stimuli. We find that when people use emotion regulation they regulate high-arousal negative ads using distraction and low-arousal negative ads using reappraisal resulting in better memory for low-arousal ads. When they do not use emotion regulation people better remember high-arousal ads.

## **E7. Pronouns in Fundraising Appeals – The Impact of I vs. S/He on Donations**

Amir Sepehri, Western University, Canada  
Rod Duclos, Western University, Canada  
Hamid Elahi, Western University, Canada

Donors evaluate online fundraisings partly on their linguistic characteristics. Extending prior research showing negative (positive) emotions increase (decrease) donations we show 1) self-related (other-related) pronouns result in lower (higher) donations and 2) the negative (positive) effect of self-related (other-related) pronouns is stronger when negative (positive) emotions increase.

## **E2. Donation versus Adoption: How the Mode of Helping Moderates the Effect of Emotions on Helping**

Ziqi Shang, Renmin University of China, China  
Xiuping Li, National University of Singapore, Singapore  
Aradhna Krishna, University of Michigan, USA

Ads asking for donations depict help-recipients' sad or happy emotions. We examine if the effect of help-recipients' emotion on observers' helping intention varies depending on the helping mode. We find that the decision to adopt(donate) makes people more self-focused(oth-er-focused) and more(less) likely to help when seeing happy (vs. sad) help-recipients.

## **J10. Transnational Consumer Lifestyle**

zahra Sharifonnasabi, Queen Mary University of London, UK  
Fleura Bardhi, City University of London, UK

In a world of increasing global mobilities this study investigates the nature of consumption when individuals inhabit multiple countries simultaneously. First four meanings of place have emerged in our findings each representing specific meanings relationships and consumption practices. Second we introduce the notion of transnational consumption.

## **M6. Approaching Negative Experience**

Liang Shen, Shanghai Jiao Tong University, China  
Fengyan Cai, Shanghai Jiao Tong University, China  
Ying Yu, Huazhong Agricultural University, China

Because approaching unfamiliar negative experiences could dissipate one's uncertainty of the environment we propose that people are more curious about and hence more likely to choose a negative experience over a positive experience. Three experiments provide preliminary evidence for this effect.

## **M10. I Need a Hero: How Loneliness Interacts with the Symbolic Meaning of Products to Affect Consumer Attitude**

Sirajul Arefin Shibly, SUNY Binghamton, USA  
Jinfeng Jiao, SUNY Binghamton, USA

While extensive literature exists on symbolic meaning of products and on loneliness how the interaction of these two concepts can affect attitude development towards a product has not been assessed. The current paper demonstrated that lonely people have a more positive attitude towards products that bear a superhero symbolic meaning.

## **Q12. Exploring Effects of Perceived Authenticity of Instagram Models on Aad and Buying Intentions**

Heather Shoenberger, University of Oregon, USA  
Eunjin Kim, Southern Methodist University, USA

This study suggests that consumers' ad evaluations and purchase intention are highest when a plus size not-airbrushed model is featured on a brand's Instagram account. More importantly this study confirms that perceived authenticity plays a significant mediating role for the effects of model-image modification and body size on ad evaluations.

## **A11. When Political Neutrality Backfires**

Ike Silver, University of Pennsylvania, USA  
Alex Shaw, University of Chicago, USA  
Rob Kurzban, University of Pennsylvania, USA

Politicians and public figures often refrain from taking sides on hot-button social issues to avoid alienating potential supporters. Two studies (n=751) find that this strategy can backfire: Neutrality is sometimes interpreted as indicating a strong strategically concealed opinion and can lead to diminished trustworthiness and voting support in such cases.

## **E4. Doing Good for Nothing: Motive Inferences from the Probabilistic Profits of Prosociality**

Ike Silver, University of Pennsylvania, USA  
Jackie Silverman, University of Pennsylvania, USA

We explore how the probability of profiting from prosocial behavior impacts perceived motive. Eight studies (N=3557) demonstrate that agents whose prosocial actions may return large rewards but may also return nothing are evaluated more positively than those whose prosocial actions yield small certain rewards of equal expected value.

### **M3. #FOMO: How the Fear of Missing Out Drives Consumer Purchase Decisions**

Michelle van Solt, Florida International University, USA  
Jessica Rixom, University of Nevada, Reno, USA  
Kimberly Taylor, Florida International University, USA

This research focuses on consumers' purchase decisions motivated by FOMO. Two studies demonstrate that purchase intent is higher when participants' imagine that their close social groups will attend an event mediated by FOMO. Furthermore the type of experience (ordinary extraordinary) moderates the relationship of social groups (close distant) on FOMO.

### **N5. Mixed Feelings, Mixed Baskets: How Emotions of Pride and Guilt Drive the Relative Healthiness of Sequential Food Choices**

Julia Storch, University of Groningen, The Netherlands  
Koert van Ittersum, University of Groningen, The Netherlands  
Jing Wan, University of Groningen, The Netherlands

Although healthy diets start with healthy shopping baskets previous research primarily investigated factors influencing the healthiness of isolated food purchases. Instead we propose that dependencies exist between the healthiness of shoppers' sequential choices. We address this research gap and investigate whether emotions experienced while shopping underlie these dependencies.

### **R7. How and Why Life Transition Influences Brand Extension Evaluation**

Lei Su, Hong Kong Baptist University, China  
Alokparna (Sonia) Monga, Rutgers University, USA  
Yuwei Jiang, Hong Kong Polytechnic University, China

Life transition is a ubiquitous aspect of life and occurs as people transcend various life stages. Four studies showed that life transition resulted in higher perceived fit and more favorable brand extension evaluation. This effect is mediated by self-concept ambiguity and consequently dialectical thinking.

### **I13. Ambient Light, Gender, and Creativity**

Courtney Szocs, Louisiana State University, USA  
Franziska Metz, EBS, USA  
Dipayan Biswas, University of South Florida, USA

The findings of our experiment demonstrate that females are more creative with bright (vs. dim) ambient light while males are more creative with dim (vs. bright) ambient light. The findings of our research also help in resolving the inconsistency in the prior literature for effects of ambient light on creativity.

### **O8. Valuation and Allocation of Bought Time**

Eisa Sahabeh Tabrizi, University of Southeast Norway  
Marit Engeset, University of Southeast Norway  
Luk Warlop, Norwegian School of Management, Norway

We show when consumers buy time by outsourcing their tasks they may be willing to pay less for the service and are more likely to find the price unfair. We propose this is driven by higher domain self-efficacy. We also document consumers' tendency for allocating bought time more to hedonic activities.

## **C11. More of a Bad Thing: How Consumers Ignore Pollutant Levels in Healthiness Assessment**

Aner Tal, Ono Academic College, Israel  
Yaniv Gvili, Ono Academic College, Israel  
Moty Amar, Ono Academic College, Israel

Consumers appear to consider only the presence rather than the quantity of pollutants in food in assessing healthiness. The current studies demonstrate this with assessment of healthiness of food containing pesticides as well as demonstrate effective debiasing by providing a standard of assessment.

## **O13. Pain of Loss: How Losing in a Promotional Competition Influences Consumer Attitude**

Arash Talebi, ESSEC Business School, France  
Sonja Prokopec, ESSEC Business School, France  
Ayse Onculer, ESSEC Business School, France

This research shows that the increase in brand attitude of the winners of an uncertain promotion comes at the cost of a greater decrease in the attitude of the losers; in turn that leads to an overall decrease in brand attitude. We show that the solution lies in unresolved uncertainty.

## **L6. The Influence of Social Exclusion on Consumers' Perceptions of and Responses to Consumer-Dense Retail Environments**

Veronica Thomas, Towson University, USA  
Christina Saenger, Youngstown State University, USA

Social exclusion affects consumers' perceptions of and responses to consumer-dense retail environments. Socially excluded (v. included) consumers exhibit increased crowd-size estimates perceive higher neutral and positive (but equal negative) crowding and prefer crowded retailers. Socially excluded consumers' heightened affiliation motivation increases crowding perceptions enhancing intentions to spend time and money.

## **C5. Krabby Patties, Kelp Chips, or KitKats?: Exploring the Depictions of Food Featured in Children's Television Shows**

Kathy Tian, University of Illinois at Urbana-Champaign, USA  
Regina Ahn, University of Illinois at Urbana-Champaign, USA  
Michelle Renee Nelson, University of Illinois at Urbana-Champaign, USA

Time spent watching TV may contribute to unhealthy eating yet most studies only review food advertising. We examine food and beverage references within 64.5 hours of children's television programs. Our results show prevalence of un-branded and less healthy food and beverages primarily as snacks. Ramifications for child obesity are discussed.

## **C8. Can Packaging Imagery Fill Your Stomach? Effects of Product Image Location on Flavor Richness, Consumption Quantity, and Subsequent Choice**

Taku Togawa, Chiba University of Commerce, Japan  
Jaewoo Park, Musashi University, Japan  
Hiroaki Ishii, Seikei University, Japan  
Xiaoyan Deng, Ohio State University, USA

Through three studies we found that an image placed at the bottom of a food package increased consumers' perception of flavor richness (Study 1) decelerated their food consumption (Study 2) and led them to choose a healthy snack after consumption (Study 3).

## **F11. Anti-Consumption for Sustainability: The Environmental Impact of Anti-Consumption Lifestyles, Environmentally Concerned Individuals and Ethical Consumers**

Laurie Touchette, HEC Montreal, Canada  
Marcelo Vinhal Nepomuceno, HEC Montreal, Canada

We compare the environmental impact of anti-consumption lifestyles ethical consumption and environmental concern. Environmental impact is lowest for tightwadism (i.e. an anti-consumption lifestyle) unrelated with environmental concern and highest for ethical consumption. Such findings suggest that resisting consumption offers a viable and effective way towards sustainable consumption.

## **Q2. Why do Kids Love Watching Unboxing Videos? Understanding The Motivations of Children to Consume Unboxing Toy Videos**

Teresa Trevino, Universidad de Monterrey, Mexico  
Mariela Coronel, Universidad de Monterrey, Mexico  
Valeria Martínez, Universidad de Monterrey, Mexico  
Ivanna Martínez, Universidad de Monterrey, Mexico  
Daniela Kuri, Universidad de Monterrey, Mexico

Unboxing videos are videos that shows the opening gathering and exhibit of products across social media platforms such as YouTube. This paper contributes to the literature of consumer behavior by shedding light on the motivations of children to consume unboxing videos and its effects on brand engagement with toy brands.

## **A2. A Window to the Brand's Soul: How Models' Eyes Affect Consumers' Attitudes**

Maria Giulia Trupia, IESE Business School, Spain  
Martina Cossu, Bocconi University, Italy  
Zachary Estes, Bocconi University, Italy

Three studies tested the impact of pupil dilation on consumers' ad attitudes. Models whose pupils are constricted (versus dilated) improved ad attitudes (Study 1). Models' perceived attractiveness and trustworthiness mediate the effect (Study 2). Moreover evidence of pupil mimicry was found but it did not affect ads' evaluations (Study 3).

## **B5. Money Doesn't Buy Happiness, But What About Buying Trust? The Effectiveness of Financial Compensation in Restoring Trust After Double Deviation**

Valentina Ortiz Ubal, Federal University of Rio Grande do Sul, Brazil  
Cristiane Pizzutti, Federal University of Rio Grande do Sul, Brazil  
Katja Gelbrich, Catholic University Eichstätt-Ingolstadt, Germany

Situations in which a financial compensation is effective to rebuild trust after a double deviation have been neglected by marketing literature. We show that financial compensation could be more effective than non-financial tactics (apology promise) in recovering trust after double deviation when the initial failure causes a financial loss.

## **O6. Be Aware of Your Suspicion: When "Being Suspicious" Ironically Leads to Suboptimal Judgment- and Decision-Making**

Julie Verstraeten, Ghent University, Belgium  
Tina Tessitore, INSEEC Business School, France  
Maggie Geuens, Ghent University, Belgium

Contrary to the belief that "being suspicious" benefits judgment- and decision-making four studies demonstrate the opposite to hold true. Suspicion rendered judgments and decisions suboptimal for money and food in an unrelated context. As suspicion is ever-prevailing in nowadays' marketplace these findings highlight relevant and important consequences for consumer welfare.

## **O2. The Streaking Star Effect: Why People Want Individual Winning Streaks to Continue More than Group Streaks**

Jesse Walker, Cornell University, USA  
Thomas Gilovich, Cornell University, USA

In seven studies participants exhibited a greater desire for streaks of individual success to continue than identical streaks of success by groups. Fairness or concern about the other competitors and the experience of awe inspired by an individual streak mediate this effect. This phenomenon has downstream consequences for consumer behavior.

## **P2. The Upside of Myopic Loss Aversion**

Daniel Wall, Carnegie Mellon University, USA  
Gretchen Chapman, Carnegie Mellon University, USA

Broad brackets lead to increased risk taking which is normative without reinvestment but can be disastrous with reinvestment. In our study narrow bracketed participants are more loss averse—a better decision—yielding higher expected log wealth. Myopia can be good.

## **R12. Brand Primes Can Satisfy (Important) Consumer Goals**

Darlene Walsh, Concordia University, Canada  
Chunxiang Huang, Concordia University, Canada

In Study 1 we show that exposure to a brand can satiate a previously primed brand-related goal. However the satiating effect only occurs when the goal is important to the individual. In Study 2 we show that perceived goal progress can in part explain this effect.

## **E1. Effects of Recipients' Emotional Expressions on Donors' Preference for Helping with Development versus Survival**

Xue Wang, University of Hong Kong, China  
He (Michael) Jia, University of Hong Kong, China  
Sara Kim, University of Hong Kong, China

Across three studies the current research shows that emotional expressions of recipients influence donors' relative preference for developmental helping versus survival helping to the recipients through altering donors' optimistic belief about the recipients.

## **J9. The Beautified Me is Me: How Interdependence Increase Usage of Beauty App**

Qin Wang, Arizona State University, USA  
Andrea Morales, Arizona State University, USA  
Adriana Samper, Arizona State University, USA

This research investigates when people are more likely to use photo-editing beauty apps and why. Two studies show that people with an interdependent (vs. independent) self-construal have higher intentions to use beauty apps because they see larger overlaps between their beautified selves and their true selves.

## **D6. How to Boast Appropriately When Word of Mouth Flows Internationally?**

Xingyu Wang, Huazhong University of Science and Technology, China  
Yaping Chang, Huazhong University of Science and Technology, China  
Jun Yan, Huazhong University of Science and Technology, China

The current research explores the interaction effect between “Prophase Word-of-Mouth” and “Boastful Communication Strategy” on consumers' purchase intention. Through two experiments we found when PWOM valence is high managers should use a high-level “Boastful Communication Strategy” when PWOM valence is low managers should use a low-level boasting strategy.

## **C7. The Visually Simple = Healthy Intuition and Its Effects on Food Choices**

Yan Wang, Renmin University of China, China  
Jing Jiang, Renmin University of China, China

This research proposes an outcome discounting relationship between visual simplicity of packages and food healthiness perception. Across three experiments we find that consumers tend to perceive the food healthier when it is packed visually simple (vs. complex) and thereby more likely to choose the food.

## **F1. Reach out in the Darkness: How Unfair Treatments Shape Social Connection Motivation**

Yijie Wang, Hong Kong Polytechnic University, China  
Yuwei Jiang, Hong Kong Polytechnic University, China  
Mandy Mantian Hu, Chinese University of Hong Kong, China  
Ninghua Zhong, Tongji University, China

Individuals who were unfairly treated exhibited a higher need to belong and exert more effort to connect with acquaintances and strangers than fairly treated peers. Furthermore this effect was mediated by the feeling of resource deprivation after experiencing injustice and was more salient among individuals with relatively low self-esteem.

## **C6. How Does Unsatisfied Curiosity Stir Our Craving For Food?**

Chen Wang, Drexel University, USA

Curiosity cues abound where consumers make their food choices. However little is known about how curiosity influences consumers' subsequent food decisions. This research explores the impact of incidental curiosity on consumers' food choice. We propose multiple outcomes determined by the food options available and the nature of curiosity.

## **H9. Market Emergence: the Alignment Process of Entrepreneurs' Socio Cognition and Consumers' Perception of the Market**

Hao Wang, University of South Florida, USA

Drawing on social constructive perspective this study bridges entrepreneurial decision-making and legitimacy underlying the micro-foundation of the market creation. I argue that the extent to which the market is legitimate depends on the alignment between entrepreneur's socio cognition of the market and consumers' perception of the market.

## **L9. To Save Face or Follow My Heart: Salesperson's Inquiries of In-Group Identity on Consumers' Purchase**

Lingru Wei, Tencent Holdings Limited, China  
Jooyoung Park, Peking University, China

This research shows that the salience of in-group identity (e.g. a student of a prestigious school) leads to purchase due to enhanced self-presentation concern especially when customers sense the possibility of violating social norms. Our finding suggests that simple conversation between salespersons and consumers can change sales.

## **N7. Emotion Or Information? Effects of Online Social Support on Customer Engagement**

Chuang Wei, Tsinghua University, China  
Maggie Wenjing Liu, Tsinghua University, China  
Qichao Zhu, Tsinghua University, China

Short Abstract: This paper investigates the interactive effect and the underlying mechanism of social support and source on customer engagement. We conducted a study to show that consumer engagement in online brand communities is affected by the support type (informational vs. emotional) and the effect is moderated by source of support.

## **O4. Will Winning Always Encourage Risk Taking? The Effect of Competition Results and the Closeness of These Results**

Beixi Wen, Renmin University of China, China  
En-Chung Chang, Renmin University of China, China  
Chunya Xie, Renmin University of China, China

In this research we found that winning a competition or hearing news that a familiar team has won a game will increase people's risk preference. However a close result can reverse this effect; that is compared with narrow-winners narrow-losers will be more willing to take risks.

## **B2. The Prevention Oriented Chameleon: Mimicry in a Prevention Orientation Leads to More Brand Trust**

Judith Willberger, Technical University of Munich, Germany  
Gavan Fitzsimons, Duke University, USA

Will customers trust a brand and its products more when their trust and security needs are fulfilled? This study shows that customers trust a brand and its products more when their trust need is fulfilled by being mimicked and their security need by being aware of the brand's prevention orientation.

## **L1. The Effects of Cultural Syndromes on Customers' Responses to Service Failures: A Perspective-Flexibility-Based Mechanism**

Vincent Chi Wong, Lingnan University, China  
Robert Wyer Jr., University of Cincinnati, USA

Customers with a collectivistic (vs. individualistic) orientation or a long-term (vs. short-term) orientation are likely to attribute a service failure more to the service provider's contextual factors and less to the service provider's dispositional factors. These effects are mediated by the flexibility of perspectives customers take when making a judgment.

## **H8. The Beneficial Side of Haze: Air Pollution Promotes Innovation and Creativity**

Yi Wu, Tsinghua University, China  
Yifan Chen, Tsinghua University, China  
Yuhuang Zheng, Tsinghua University, China

a counterintuitive hypothesis that air pollution promotes innovation and creativity. Two archival studies (Study 1-2) found that air pollution predicted innovation at country- and company-level. Study 3a-3b experimentally established causal connection between air pollution and creativity. Study 4 replicated hypothesis in real weather context and proved arousal's mediating role.

## **P11. A Price Premium on A Trivial but Weak Preferred Attribute Increase Choice: The Roles of Scarcity, Arousal and Perceived Risk**

Yueyan Wu, Hunan University, China  
Chunyan Xie, Western Norway University of Applied Sciences, Norway  
Zhi Yang, Hunan University, China  
Luluo Peng, Hunan University, China

We add to extant research on trivial attribute by addressing a "small price premium effect" on choice and providing a psychological mechanism. Results showed that a small price premium on a trivial attribute increases choice share of weak preferred options. Large price premium eliminates this kind of effect. Underlying mechanisms were explored.

## **F8. Dual Routes for Consumer Responses to Corporate Social Responsibility: The Role of Positive Moral Emotions, Attitudes, and Empathy**

Chunyan Xie, Western Norway University of Applied Sciences, Norway  
Richard P. Bagozzi, University of Michigan, USA

We add to extant CSR research by investigating both cognitive and affective processes underlying consumer reactions to CSR. Results showed that both positive moral emotions and positive attitudes mediate the impact of CSR actions on consumer positive responses toward the company. Further empathy regulates the elicitation of positive moral emotions.

## **K1. The Impact of Moral Violation and Advertising Appeals on Brand Attitude**

Chunya Xie, Renmin University of China, China  
En-Chung Chang, Renmin University of China, China  
Beixi Wen, Renmin University of China, China

This study found that moral violators possess a more positive attitude towards brand advertised in two-sided (versus one-sided) message appeals while moral violation witness possess a more positive attitude towards brand advertised in one-sided (versus two-sided) appeals.

## **B10. Wearing V Neck, Getting More Trust: An Evolutionary Psychology Approach to Examine the Effect of Collar Style on Trust**

Jialiang Xu, University of Manitoba, Canada  
Fang Wan, University of Manitoba, Canada  
Chenbo Zhong, University of Toronto, Canada

“What a strange power there is in clothing” — Isaac Bashevis Singer. Three experiments findings show that one’s collar styles (V neck vs. turtleneck) can affect others’ trust of him or her.

## **H5. Being Looked Up or Being Looked Down? The Divergent Effects of Camera Angle on Nonanthropomorphized and Anthropomorphized Product in Ads**

Changchun Xuan, Xiamen University, China  
Rui Chen, Xiamen University, China  
Jing Jiang, Suzhou Broadcasting System, China  
Bin Yu, Tsingtao Brewery Company Limited, China  
Jingjia Peng, Icartoon Culture & Media Corporation Ltd, China  
Shengdong Lin, Xiamen University, China

This paper finds that for anthropomorphized product being presented in the downward-looking angle lead to higher product evaluation compared with being presented in upward-looking angle. On contrast for nonanthropomorphized product the effect of camera angle is reversed. The two different mechanisms underlying the effect of camera angle were also tested.

## **Algorithm Attraction versus Aversion: The Role of the Perceived Self-Efficacy of the Decision Maker**

Gizem Yalcin, Erasmus University Rotterdam, The Netherlands  
Anne-Kathrin Klesse, Erasmus University Rotterdam, The Netherlands  
Darren Dahl, University of British Columbia, Canada

Nowadays algorithms are used to generate recommendations in numerous areas including ones that are pure matter of taste. Across four studies we demonstrate that consumers value the same recommendation differently depending on the framing of its source—an algorithm versus human expert—and their own perceived level of self-efficacy.

## **G6. Brightness Increases More Positive Views of Humanity and Prosocial Behavior of People Low in Moral Identity Internalization**

Jun Yan, University of Manitoba, Canada  
Luke Zhu, University of Manitoba, Canada  
Fang Wan, University of Manitoba, Canada

This paper tests an interactive effect of ambient lighting and Moral Identity Internalization (MII) on prosocial behavior. Individuals low (vs. high) in MII are more likely to help others in bright than dark environment because the brightness increases their positive views of humanity.

## **A9. I know It's not real, but I like it!**

Junxian Yang, Singapore University of Social Sciences, Singapore  
Yue Wang, Singapore University of Social Sciences, Singapore  
Jufinnie Lim, Singapore University of Social Sciences, Singapore  
Yu-chen Hung, Singapore University of Social Sciences, Singapore

Questionable practices in online advertising have triggered cautiousness among consumers when they encountered information on social media. While consumers do not completely trust it our studies demonstrate that they remain influenced. We further explore why people fail to discount information on social media even when they question its authenticity.

## **O3. The Effect of Numeric Information on Product Evaluation**

Zhen Yang, Drexel University, USA  
Yanliu Huang, Drexel University, USA  
Dengfeng Yan, University of Texas at San Antonio, USA

This research proposes that precise number will polarize product evaluation making the judgment of positive product information more positive and negative information more negative. It happens because processing precise number is more arousing and the heightened arousal leads to evaluative extremity. Three studies were conducted to test our predictions.

## **O5. The Effect of Synchrony on Non-Human Objects Involved in the Synchronous Performance**

Xiaoyin Ye, Xiamen University, China  
Jun Ye, Xiamen University, China

Drawing from an embodied cognition framework this study examines the main effect and the mediating mechanism of synchrony on product evaluation. Four experiments were conducted and our findings indicate that exposure to synchrony experience activates the concept of harmony which has a spillover effect that positive product evaluation.

## **K13. When Does Humor Increase Sharing?**

John Yi, University of Arizona, USA  
Caleb Warren, University of Arizona, USA

Are consumers more likely to share content (stories social media posts etc.) when it is humorous? Not always. Although adding humor increases the likelihood that consumers share negative content (e.g. embarrassing stories complaints etc.) adding humor does not increase the likelihood of sharing positive content (e.g. happy stories praise etc.).

## **L12. Should I Stay or Should I Go: When Our Companies Have Eyes for Other Consumers**

Na Ri Yoon, Indiana University, USA  
Jenny Olson, Indiana University, USA  
Adam Duhachek, Indiana University, USA

To attract new customers companies may lose existing customers. Our research examines how consumers' attachment styles influence the likelihood of switching companies. When new customers receive exclusive benefits existing customers' attachment anxiety predicts switching. Attachment avoidance predicts greater switching regardless of benefit recipient. Perceived betrayal and firm commitment underlie switching.

## **H10. No Pain, No Out-of-Box Thinking: An Examination of the Effects of Self-Threat on Creativity**

Huan You, University of Manitoba, Canada  
Fang Wan, University of Manitoba, Canada  
Luke Zhu, University of Manitoba, Canada  
Haiyang Yang, Johns Hopkins University, USA

Two experiments examined the effect of self threat on creativity. Findings suggest that type of threat matters; a threat from a dynamic domain enhances divergent creativity and a threat from fixed domain enhances convergent creativity.

## **D12. Future Decisions and Temporal Contiguity Cues: When Absence of Temporal Contiguity Cues Increases Online Reviews' Persuasiveness.**

Francesco Zanibellato, Ca' Foscari University, Venice, Italy

Past research shows that temporal contiguity cues make online reviews more persuasive. However rooting in Construal Level Theory we show that when consumers face a distant-future consumption timeframe they are more persuaded by online reviews without temporal contiguity cues.

## **L3. Categorizing Engagement Behaviors from the Perspective of Customer Resources**

Xianfang Zeng, University of Calgary, Canada  
James Agarwal, University of Calgary, Canada  
Mehdi Mourali, University of Calgary, Canada

From the perspective of customer resources the authors propose a typology of customer engagement behaviors (CEBs). This perspective well aligns with the service-dominant (S-D) logic (Vargo and Lusch 2004) that has evolved into an important paradigm in the marketing area.

## **P3. Cash Costs You: The Pain of Holding**

J Zenkic, University of Melbourne, Australia  
Kobe Millet, Vrije Universiteit Amsterdam, The Netherlands  
Nicole Mead, University of Melbourne, Australia

Cash can have an associated psychological cost: the pain of holding. This pain is aversive varies with the physical properties of money – such as the differences in weight and bulk between coins and notes - and may in turn encourage needless spending.

## **H12. Does Economic Development Influence Consumer Innovativeness?**

Fuchun Zhan, University of Wisconsin - Madison, USA  
Nancy Wong, University of Wisconsin - Madison, USA  
Julie Anne Lee, University of Western Australia, Australia

This research explores the relationship between income frugality and consumer innovativeness. Results show that income positively affects innate innovativeness but only for the higher income countries while an indirect effect through frugality is found in lower income countries. Frugality has no direct effect on intention of innovative behavior.

## **I1. Blaming Him or Them? A Study on Attribution Behavior**

Chun Zhang, University of Dayton, USA  
Michel Laroche, Concordia University, Canada  
Yaoqi Li, Sun Yat-Sen University, China

The current work examines the gender difference in attribution behavior. Results show that males are more likely to blame individuals while females are more likely to blame groups which can be explained by relational and collective interdependent self-construal. Furthermore similarity and service failure magnitude moderate the gender effect.

## **D8. Why Employees Communicate Positive eWOM on Social Networking Sites: Motivations and Moderators**

Jing Zhang, Huazhong University of Science and Technology School of Management, China  
Ya Zhang, Huazhong University of Science and Technology School of Management, China

This paper aims at exploring what motivate employees to voluntarily create positive eWOM on SNS. Its theoretical contributions and managerial implications are connecting eWOM and OCB literature from perspective of internal employees distinguishing from employees' knowledge sharing research elaborating the way to motivate employees to create positive eWOM for managers.

## **M11. Motivated to Be Moral: The Effect of Nostalgia on Consumers' Recycling Behavior**

Xiadan Zhang, Renmin University of China, China  
Xiushuang Gong, Jiangnan University, China  
Jing Jiang, Renmin University of China, China

Prior research on nostalgia has primarily focused on its psychological and social functions. However little has been done about whether and how nostalgia affects individuals' pro-environmental behaviors. Through two studies we demonstrate that nostalgia can increase consumers' intention to recycle and this effect is mediated by moral purity.

## **J2. Consistence vs. Variety: The Effect of Temporal Orientation on Variety Seeking**

Yuan Zhang, Xiamen University, China  
Shaoqing Zhang, Quanzhou Normal University, China

The research examines the effect of temporal orientation on variety seeking and demonstrates that people in past orientation chose less variety than those in future orientation (Study 1) and preference for consistence was the underlying mechanism (Study 2). However the effect disappeared in self-irrelatively condition (Study 3).

## **K3. Goal or Knowledge? Exploring the Nature of Culture and its Consequential Effect**

Xiaohua Zhao, Tsinghua University, China  
Fang Wan, University of Manitoba, Canada  
Antonios Stamatogiannakis, IE Business School, IE University, Spain  
Haiyang Yang, Johns Hopkins University, USA

Prior research has largely focused on how cultural values get activated but has not distinguished whether cultural values are semantic knowledge or goals. As the salience of them tends to fluctuate and subsequently impact judgments and behaviors we proposed an approach to distinguish culture values between semantic knowledge and goals.

## **R11. The Influence of Brand Rituals on Perceived Brand Authenticity**

Lijing Zheng, University of Hong Kong, China  
Echo Wen Wan, University of Hong Kong, China  
Zhongqiang (Tak) Huang, University of Hong Kong, China

Built on literature of ritual and brand authenticity we predicted that consumers will perceive greater brand authenticity from brand rituals and that this effect is driven by perceived symbolism in the brand. Three studies provide initial evidences for our hypotheses. This research provides new insights into the influence of brand rituals.

## **R10. Emotional-Transference or Exclusivity? an Emotional Attachment Approach to Brand Extension for Cultural and Creative Products**

Wu Zhiyan, Shanghai University of International Business and Economics, China  
Luo Jifeng, Shanghai Jiao Tong University, China  
Liu Xin, Shanghai University of International Business and Economics, China

This research uses three studies to examine how brand fit and self-construal moderate the relationship between brand attachment (emotional-transference versus exclusive) and the brand extension effect and how online social interaction moderates the moderating effect of self-construal on the relationship between brand attachment and the brand extension effect.

## **H4. Anthropomorphism Moderates the Effect of Ownership on Self Perceptions**

Qiang Zhou, University of Texas at San Antonio, USA  
Dengfeng Yan, University of Texas at San Antonio, USA

Previous literature has shown that consumers often perceive themselves to have the characteristics of the products that they own. We proposed and found that this effect is mitigated by anthropomorphism because individuals are less likely to include a product into the self-category once it is anthropomorphized.

## **R2. Brand-to-Brand Communications: How Consumers React to Flattery Between Brands**

Lingrui Zhou, Duke University, USA  
Katherine Crain, Duke University, USA  
Keisha Cutright, Duke University, USA

Should brands go out of their way to talk positively about their competitors? We find that brand-to-brand flattery changes the consumer's perception of how a brand values its relationships globally which influences brand trust and subsequently brand evaluations.

# **DataBlitz**

## **Always Trust in Your Friends? Cross-cultural Effects of Review Source and Incentives on Trustworthiness**

Dionysius Ang, Leeds University Business School, UK

Will culture affect how consumers perceive incentivized reviews from friends? Amongst Taiwanese participants incentivized reviews were deemed as breach of trust. Thus incentivized reviews from friends were deemed less trustworthy than incentivized reviews from strangers. Amongst Americans reviews from friends were more trustworthy than reviews from strangers regardless of incentive.

## **Consuming Time-Space Imaginations: Bakhtin's Chronotope on Robots and Artificial Intelligence**

Marat Bakpayev, University of Minnesota Duluth, USA  
Alima Yesmukanova, KIMEP University, Kazakhstan

We examine developing discourse on two controversial phenomena - robots and Artificial Intelligence. Drawing from literary theory we focus on the representation of time-space in news articles. We contextualize Bakhtin's theory of chronotope identifying how temporality and spatiality presented by technology narratives.

## **Teaching Old Dog New Tricks... and Old Bottles New Jeans. The Role of Implicit Theories in the Evaluation of Recycled Products**

Alessandro Biraglia, University of Leeds, UK  
J. Josko Brakus, University of Leeds, UK  
Lucia Mannetti, Sapienza University of Rome, Italy  
Ambra Brizi, Sapienza University of Rome, Italy

Across three studies involving real choice implicit associations and purchase intention we show how incremental theorists prefer recycled products more than entity theorists. Entity theorists can nevertheless be persuaded in buying more recycled products if they attribute the merit of the transformation to the internal characteristics of the materials.

## **Understanding the Role of Gifts in Managing Marriage and Family Relations: The Case of the Male Phoenix in China**

Jia Cong, Lancaster University, UK  
Xin Zhao, Lancaster University, UK  
Chihling Liu, Lancaster University, UK

This paper seeks to understand the role of gifts in managing an inter-class marriage from the perspective of the-male-phoenix in contemporary China. Through fieldwork our initial findings show that gift plays a significant role for male-rural-migrants to manage class disparity and maintain harmonious relationships with urban families they marry into.

## **What a Waste: Effects of Food Consumption Choices and Traffic Light Labelling on Disposal**

Marit Drijfhout, University of Groningen, The Netherlands  
Jenny van Doorn, University of Groningen, The Netherlands  
Koert van Ittersum, University of Groningen, The Netherlands

The large amount of food wasted by consumers suggests a mismatch between consumers' planned consumption decisions and their actual consumption behavior. We show that food waste occurs when consumers impulsively prefer unhealthy vice foods over healthy virtue foods initially chosen and that traffic lights aggravate rather than mitigate food waste.

## **Associative versus Relational Processing: The Role of Elaboration in Evaluative Conditioning**

Xiaomeng Fan, Northwestern University, USA  
Galen V. Bodenhausen, Northwestern University, USA

This research shows that evaluative conditioning involves both associative and relational processing. Relational processing can be promoted when people can allocate their cognitive resources in evaluations.

## **“It’s Not You, It’s Me”: How Corporate Social Responsibility Decreases Customer Citizenship Behavior**

Sofia Batista Ferraz, EAESP-FGV, Brazil  
Andres Rodriguez Veloso, University of São Paulo, Brazil  
Diogo Hildebrand, Baruch College, USA

This paper analyzes how CSR activities influence helping behaviors among customers. Across two studies we demonstrate that participants faced with an opportunity to satiate self-defining goals through CSR had a reduced propensity to help other customers. Besides we propose entitlement as a driver of customer helping behavior.

## **‘Family Tech-Support’: Consequences for Family Assemblages and Non-Purchase Decision Technology Adoption**

Pao Franco, University of Melbourne, Australia

Consumer technology adoption research frames tech products entering into consumers’ lives as purchase decisions (e.g. computers wearables). What about situations that are not purchase decisions? This research explores technology adoption in non-decision situations (e.g. shared-at-home gifts) through a qualitative investigation of families and ‘family tech-support’ – utilizing an assemblage approach.

## **Is CSR for Sale? Investigating the Effects of Acquisition of Socially Responsible Brands on CSR Perceptions**

Bianca Grohmann, Concordia University, Canada  
Argiro Kliamenakis, Concordia University, Canada  
H. Onur Bodur, Concordia University, Canada

This research examines whether firms can increase consumers’ CSR perceptions by acquiring socially responsible brands. Two experiments demonstrate that (1) firms are more likely to increase CSR perceptions through acquisition of a functional (vs. symbolic) brand and (2) for symbolic brands new brand development (vs. acquisition) enhances CSR perceptions.

## **A Penny for Self-disgust: The Effects of Favorable Review Reward on Consumers Behavior**

Qingqing Guo, Shanghai Jiao Tong University, China  
Liangyan Wang, Shanghai Jiao Tong University, China  
Bing Han, Shanghai Jiao Tong University, China

Through three experiments this study shows that a monetary reward has a backfire effect on consumer behavior because it leads receiving consumers to self-disgust for the referral. This effect is attenuated for consumer who has an exchange relationship norm while sharpened for consumers who has a communal relationship norm.

## **Less Time, More Procrastination? The Impact of Time Pressure on Task Initiation**

Jing Jiang, Renmin University of China, China  
Alisa Yinghao Wu, Columbia University, USA

When under time pressure individuals are more likely to postpone the initiation of tasks—whether these are routine errands or consumption tasks. The rationale is that time pressure impairs an individual’s momentary ability to focus on tasks and leads to subsequent postponement of task initiation.

## **The Effects of Glossy Versus Matte Imagery on Consumers' Decision Making**

Yoonho Jin, INSEAD, Singapore  
Amitava Chattopadhyay, INSEAD, Singapore

Three studies collectively suggest that the use of glossy imagery in advertising because of its embodied meaning of easygoingness could increase consumers' optimistic perception of target consumption thereby enhancing purchase intention. The studies also show that priming either the danger of slipperiness or optimistic orientation may attenuate the effects.

## **When Humans Consume Humanlike Animals: Anthropomorphism, Power, and Cruelty-free Consumption**

Ji Myoung Danny Kim, University at Buffalo, USA  
Sunyee Yoon, University at Buffalo, USA

The interaction of anthropomorphism of animals and consumers' sense of power explains preference and attitude towards cruelty-free products. The research suggests low-power individuals engage in prosocial behavior selectively depending on perceived similarity with the beneficiary.

## **When CSR Becomes a Liability for Firms in Crises: Effects on Perceived Hypocrisy and Consumer Forgiveness**

Argiro Kliamenakis, Concordia University, Canada  
H. Onur Bodur, Concordia University, Canada

This research examines circumstances under which positive CSR reputation amplifies negative consumer responses to firm crises. Although a positive CSR reputation becomes a liability for firms experiencing values-related crises it may still offer a shielding effect but only for ambiguous crises (i.e. crises that may or may not constitute transgressions).

## **Morality Matters in the Marketplace: The Influence of Morally Based Attitudes on Consumer Purchase Intentions**

Andrew Luttrell, Ball State University, USA  
Jacob Teeny, Ohio State University, USA  
Richard Petty, Ohio State University, USA

In social psychology morally based attitudes have been shown to strongly predict attitude-consistent behaviors. However whether this basis predicts equally well in consumer research remains unanswered. Across five studies we show that morally based attitudes are indeed a reliable predictor of consumer purchase intentions even above other important factors.

## **Tackling Over-Consumption: How Proximal Depictions of Unhealthy Food Products Influence the Consumption Behavior**

Sumit Malik, IE Business School, IE University, Spain  
Eda Sayin, IE Business School, IE University, Spain  
Kriti Jain, IE Business School, IE University, Spain

Do spatially proximal depictions of unhealthy (but not healthy) food products within an advertisement image increase the desire to eat? Across a pilot and three main studies we find support for the influence of proximal ad depictions on food consumption outcomes. These results have implications for the phenomena of over-eating.

## **Stating the Obvious: How “Ugly” Labels Can Increase the Desirability of Odd-Shaped Produce**

Siddhanth Mookerjee, University of British Columbia, Canada  
Yann Cornil, University of British Columbia, Canada  
Joey Hoegg, University of British Columbia, Canada

Food producers and retailers throw away large amounts of food that fail to meet beauty standards. Our research demonstrates that using the words “ugly” as part of an advertising message increases the desirability of odd-shaped produce that would otherwise go to waste. Perceived brand credibility mediates this effect.

## **The Influence of Goal Specificity on Planning Effectiveness: A Meta-Analysis**

Ekaterina Napolova, University of Technology Sydney, Australia  
Francois Carrillat, University of Technology Sydney, Australia  
Leona Tam, University of Technology Sydney, Australia

This meta-analytic study aims to investigate the effectiveness of various planning strategies depending on the level of goal specificity. The paper presents the largest meta-analysis on the implementation intentions (planning) effectiveness in the health domain and provides important insights for researchers consumers practitioners and policy makers.

## **Thank You = Trust Me: When Gratitude Expressions Help Promote New Products**

Maria Ng, University of Houston, USA  
Dejun Tony Kong, University of Houston, USA  
Vanessa Patrick, University of Houston, USA

Drawing upon risk and trust theories we find in four experiments that in one-off (transactional) new product promotion interactions a salesperson’s gratitude (vs. neutral) expression could elicit consumers’ felt appreciation and then influence their product evaluation via enhanced trust and reduced psychological risk. These positive reactions drive consumers’ purchase intentions.

## **How Matte Product Surface Enhances Perceived Durability**

Taehoon Park, University of South Carolina, USA  
Junghan Kim, Singapore Management University, Singapore

Prior literature has shown that different perceptual qualities can be inferred from object surface features. Extending prior work we propose reflected light on surface (glossy vs. matte) as an inferential cue that can shape product quality. Across three studies we show that matte (vs. glossy) product surface enhances perceived durability.

## **Influence of Visual Crowding and Space Between Products on Consumer Choice**

Ana Scekkic, HEC Paris, France  
Selin Atalay, Frankfurt School of Finance and Management, Germany  
Cathy Liu Yang, HEC Paris, France  
Peter Ebbes, HEC Paris, France

We investigate the effect of assortment size and of spacing between products on consumer choice. We provide initial evidence that in large (i.e. crowded) assortments distancing the products on the shelf from one another leads to greater perceived variety in the assortment and to a choice experience perceived as easier.

## **The Interaction Effect of Food Variety and Simulation of Eating on Consumers' Calorie Estimation**

Liang Shen, Shanghai Jiao Tong University, China  
Fengyan Cai, Shanghai Jiao Tong University, China  
Ying Yu, Huazhong Agricultural University, China

Given the inconsistent findings about the relationship between food variety and calorie estimation this research proposes simulation of eating as one moderator. Specifically we propose that when a simulation of eating is (not) stimulated food variety decreases (increases) consumers' calorie estimation. Three experiments demonstrated this proposition and its underlying mechanism.

## **Gaze Reflects Loss Aversion**

Feng Sheng, University of Pennsylvania, USA  
Arjun Ramakrishnan, University of Pennsylvania, USA  
Darsol Seok, University of Pennsylvania, USA  
Puti Cen, University of Pennsylvania, USA  
Michael Platt, University of Pennsylvania, USA

By modeling individuals' gaze traces on potential gains and losses while they decided whether to accept or reject gambles in an eye-tracking experiment we demonstrated that loss aversion reflected the overweighting of information about potential losses relative to potential gains sampled during visual inspection of gambles.

## **Memory-Based Models of Predicting Inferences about Brand Quality**

Yvetta Simonyan, University of Bath, UK  
Dan Goldstein, Microsoft Research, USA

How are consumers' inferences about product quality related to information in memory? By modelling inferences as well as confidence in inferences via belief distributions this paper aims at explaining some unsolved phenomena regarding the relationship between quality perceptions on one side and recognition and other memory information on the other.

## **Digital Storytelling and Post-Trust Online Sperm Marketing**

Jennifer Takhar, Institut Supérieur de Gestion, Paris, France  
Laetitia Mimoun, HEC Paris, France

This paper examines extended sperm donor profiles and blogs from two international sperm bank websites and reveals the post-trust digital storytelling strategies they use to convince prospective buyers. We also identify three dimensions of post-trust digital marketing: over-determined authenticity consumer fantasy and loss of distinction.

## **When Waste Costs: The Influence of Price on Consumers' Perceived Waste and Purchase Intention of an Excessive Amount of Product**

Tao Tao, Hong Kong Baptist University, China  
Robert Wyer Jr., University of Cincinnati, USA

This paper suggests that price can serve as an indicator of waste perception and help to decrease excessive purchase behavior. Two studies supported our proposition that controlling the price as the same consumer's purchase intention of an excessive offer over an adequate one is lower when the price is higher.

## **Paper Box or Plastic bag? Structural Package Design Elements Affect Health Perception and Consumption.**

Joyce De Temmerman, Ghent University, Belgium  
Iris Vermeir, Ghent University, Belgium  
Hendrik Slabbinck, Ghent University, Belgium

This paper explores whether structural package design elements bias health perception and consumption. We propose that material (paper vs. plastic) and format (box vs. bag) can lead to higher health perceptions of the package and the packaged product and hence increase consumption.

## **Prices in Red: When a Red Price Becomes a Stop Sign**

Hongjun Ye, Drexel University, USA  
Siddharth Bhatt, Drexel University, USA  
Rajneesh Suri, Drexel University, USA

“Sale” and “stop” are both referential meanings attached to the color red. This study shows that prices presented in red in store flyers influence consumers memory of prices and their evaluation of the deal of not just the focal product but also the products surrounding the red price.

## **Safety or Luxury: The Effect of Competitiveness on Consumer Preference in Social Crowding**

Lijun Zhang, Nanyang Technological University, Singapore  
Yee Ling, Elaine Chan, Nanyang Technological University, Singapore

Prior research suggests that people prefer safety products in crowded environments. This research contributes to the literature by examining the moderating effect of competitiveness. While people low in competitiveness prefer safety products people high in competitiveness prefer status consumption over safety consumption in crowded environments.
