## SESSION OVERVIEW

We live in an age of big data. Millions of reviews, posts, and other content provides a wealth of information for researchers to examine. But by itself, all that big data is just that. Data. How can researchers parse all this information to provide insight into consumer behavior?

This session integrates a variety of perspectives to showcase the value of language in understanding consumers. Why are some reviews seen as more useful? How do stories evolve as they are transmitted? When do consumer opinions predict marketplace success? And can language shape what becomes popular? Using a variety of data sources and diverse methods, this session provides insight into these and other questions and sheds light on the role of language in consumer behavior.

First, **Lafreniere, Moore, and Fisher** examine when, how, and why swearwords are effective in word of mouth. They propose that due to increasing acceptance and commonality, swearwords can actually generate a strong positive impact. Using 100,000 Yelp reviews, they demonstrate that consumers judge reviews with more swearwords as more useful. Five experiments show that the advantage of swearwords exists even above other intensifiers (“holy shit” vs. “wow”) and is especially prominent when swearwords provide particularly diagnostic information.

Second, **Melumad, Kim, Meyer, and Nenkova** use a telephone game to examine how language evolves through serial transmission. When passing things on, communicators increasingly inject cantankerous personal opinions which subsequent individuals take as an implicit signal to also supply their own opinions. This evolution occurs across both positive and negative stories and even when the motivation for sharing the stories is accuracy.

Third, **Rocklage, Rucker, and Nordgren** investigate the “positivity problem” whereby the positivity of consumers’ opinions is an untrustworthy predictor of marketplace success. Drawing from theories in the attitudes and affective science literatures, they demonstrate that while traditional surveys and aggregate star ratings are not accurate, the emotionality of consumers’ language is. Consumer lan-

guage predicts the table reservations made at over 1,100 restaurants, the number of brand followers a company accrues after their Super Bowl advertisement, and the revenue made by over 3,700 movies at the box office.

Finally, though some have argued that cultural success is unpredictable, **Berger, Kim, and Meyer** demonstrate that emotional volatility (i.e., quick shifts in emotional tone) can help explain why things catch on. Using automatic sentiment analysis across thousands of movies, they find that more emotionally volatile movies are evaluated more positively. Further, these effects are larger in movies where such volatility is desired (e.g., thrillers). These findings provide insight into popularity and the psychological foundations of culture.

Taken together, these papers highlight how language provides insight into important behavioral and cultural phenomena. Further, each offers a unique perspective on how researchers can use mixed methods and big data to glean psychological insights. The session should be relevant to anyone interested in attitudes, emotions, social influence, word of mouth, and cultural success, as well as those who are interested in using natural language processing and unstructured data sets to answer relevant CB questions.

## The Power of Potty Mouth in Word-of-Mouth

### EXTENDED ABSTRACT

People hear and use swearwords more often than ever before (Jay and Janschewitz 2008; Stapleton 2010), but there has been little research on swearwords in online reviews (Hair and Ozcan 2018). The limited research is perhaps unsurprising given the common view that swearwords are anti-social and offensive (Rassin and Muris 2005). Indeed, swearwords are generally defined as taboo words that suggest a high level of arousal (Andersson and Trudgill 2007; Jay 2009). Yet, swearwords may not always have negative effects. First, people are often not offended by swearwords (e.g., Daly et al. 2004; Henry, Butler, and Brandt 2014). Second, swearwords are losing their original meanings (Fairman 2007; Jay 1992). These changes coincide with the increasing use of swearwords, suggesting that they remain useful. To explore this idea, we conducted a pilot study.

The pilot study used 100,000 reviews randomly drawn from the 2017 Yelp dataset. We used LIWC (Pennebaker et al. 2015) to identify reviews containing at least one swearword (6.3%), and examined the relationship between swearwords and the number of “useful” votes that a review received. Negative binomial regression showed that the presence (vs. absence) of swearwords increased the number of useful votes received for negative, neutral, and positive reviews. Reviews containing two (vs. zero) swearwords evoked the largest positive effect. The effect became insignificant at three swearwords and negative at four swearwords. These results were robust to various model specifications and covariates (e.g., review valence, length, and age). While this dataset demonstrates that swearwords are useful to consumers, it does not explain the underlying process. We consider the meaning of swearwords as a possible explanation.

Currently, it is not clear what meaning swearwords actually convey (Jay and Jay 2015; Potts 2007). We hypothesize that swearwords convey two meanings about: 1) the speaker (i.e., the strength of the reviewer’s feelings about the product) and 2) the reviewed product (e.g., the intensity of a particular attribute). As such, relative to no swearwords and to non-swearword synonyms, when swear-

words qualify desirable [undesirable] product attributes (e.g., the show is damn funny [boring]), they should positively [negatively] affect readers' attitudes towards the reviewed product. These two meanings should function as independent mediators of the relationship between swearwords and product attitudes because they qualify different objects (i.e., the product and the reviewer). We focus on swearwords when they are used as intensifiers, which is their most common usage (Jay 1992; e.g., "fucking awesome," "holy shit!"). Intensifiers convey meaning about a subject by communicating that an attribute holds to a higher degree than average (e.g., this dish is *very* tasty; Gutzmann and Turgay 2012). We test this framework in four studies.

Study 1 was a one-factor (swearword: present vs. absent) between-subjects design. Participants imagined that they wanted to buy a power station, and were shown a seller's webpage with one positive review. The review's title contained the manipulations: "It charged my phone [fucking] fast". As predicted, the swearword conveyed two meanings: it increased the intensity of the product attribute (i.e., charging capability) and the strength of the reviewer's feelings. These two meanings increased product attitudes. A follow-up study demonstrated that a swearword qualifying an undesirable attribute decreased product attitudes.

Study 2 compared a swearword (*damn*) to non-swearword intensifiers (*super*, *insanely*). We hypothesized that, because they are taboo, swearwords would convey meaning more effectively than other intensifiers, particularly about the strength of the reviewer's feelings. Speakers often use swearwords to express strong feelings (Jay 2000), and listeners infer that a speaker who swears has strong feelings because they broke a taboo (Foolen 2015; Jay 2000). This study employed the same scenario as Study 1, except the product was a dishwasher. The review's title contained the manipulations: "The dishwasher is [damn/insanely/super] quiet!" Replicating Study 1, *damn* (vs. *super*) increased the intensity of the product's attribute and the strength of the reviewer's feelings, which both increased product attitudes. Further, *damn* (vs. *insanely*) increased the strength of the reviewer's feelings, which enhanced product attitudes. A follow-up study ruled out arousal, conversational norms, trust, and interpersonal closeness as alternative explanations.

Study 3 tested a boundary condition: swearwords should not affect product attitudes when the meanings they convey are redundant or non-diagnostic. We hypothesized that multiple swearwords in a review would reduce the meaning conveyed about the product's attribute, due to a change in causal attribution. Specifically, consumers should attribute multiple swearwords to characteristics of the reviewer rather than the product (e.g., the reviewer is prone to strong feelings; He and Bond 2015), thereby attenuating the effect on product attitudes. This study was a one-factor design (number of swearwords: zero vs. two vs. five), employing the same scenario as study 1. Replicating prior studies, two (vs. zero) swearwords increased the intensity of the product's attribute and the strength of the reviewer's feelings, which both increased product attitudes. Further, two (vs. five) swearwords increased the intensity of the product's attribute, which increased product attitudes.

Study 4 tested swearword diagnosticity using different product categories. We hypothesized that in reviews for intense experiences (e.g., white water rafting), a swearword would be non-diagnostic because it would not convey additional meaning. Swearing should therefore have no effect on product attitudes. This study was a 2 (intensifier: swearword vs. non-swearword) by 2 (diagnosticity: high vs. low) between-subjects design, employing the same scenario as prior studies except the product was a rafting excursion. The review title contained the manipulation: "[Holy shit/Wow] it was fun". Di-

agnosticity was manipulated in the product description. When diagnosticity was high, the excursion was a class 1 (e.g., "gentle moving water"); since this excursion is ambiguous in terms of fun, swearwords should offer discriminating information. When diagnosticity was low, the excursion was a class 5 (e.g., "adrenaline junkies only"); since this excursion is unambiguously fun, swearwords should be redundant. As predicted, when diagnosticity was high, product attitudes were higher in the swearword (vs. non-swearword) condition. This effect was attenuated when diagnosticity was low.

Overall, using field and experimental data, the current research suggests that marketers—and consumers—may benefit from swearwords in reviews.

## When News Gets Personal: The Evolution of Content in the Successive Retelling of Events

### EXTENDED ABSTRACT

What happens to the fidelity of news when it is retold among people? In recent years this question has drawn increased attention because of the growing role that social media now plays in the transmission of information. Because information carried over social media often takes the form of second-or-third-hand retellings of original source material, it has been widely blamed for the proliferation of misinformation, ranging from biased accounts of events to the creating and spreading of "fake news" and "alt facts" (e.g., Allcott and Gentzkow 2017; Tan, Friggeri, and Adamic 2016). Much like the children's game of "telephone", when social media users hear or read about an original news story and then post about it, the readers of that post are not seeing the original source, but rather a retelling that may reflect an unknown blend of the original facts, the writers' memory of the facts, and their interpretation—a blend that may hold little fidelity compared to the original (e.g., Allport and Prescott 1947; Carlson 2017; Marsh 2007).

In this research we report the results of two large-sample experiments in sequential summarization that offer new insights into how accounts of news events become distorted when they are repeatedly retold by different agents. We emerge with two major findings. The first is that summaries that start as dispassionate accounts of objective events tend to evolve into personalized gist-like accounts laced with injections of personal opinion—with the expression of disapproval being more dominant mode of expression. This *cantankerous personalization* effect is quite robust; it is seen across different kinds of original stories including when participants are given different explicit motivations for retelling. The shift to personalization occurs, for example, even when writers are instructed to be as "accurate as possible" when retelling news stories, and cantankerousness arises even in stories that are originally written with a positive tone.

The second finding is that this evolution appears to be the consequence of a linguistic mimicry process in which injections of opinion by one writer in a chain implicitly signals the next to do the same. Because negative content is typically seen as more salient than positive (the negativity bias; Baumeister et al. 2001), this process privileges the creation and retelling of more negative linguistic elements (e.g., expressions of disagreement over agreement). This increase in personalization, however has a perhaps unintended downstream effect on the appeal of summaries: while they may be more appealing to the writer, they are seen as increasingly less interesting to read by outside judges.

### Study Details

The two studies that utilized the same general methodology. In an initial wave of summarization, M-Turk workers read a news ar-

ticle, and were asked to write a synopsis as they would if they were summarizing it for others over social media. Their summaries were then passed on to a second wave of participants who were given the same task, but this time after reading just on the summary provided by a previous writer. This process was then repeated for a third wave of participants. The two studies manipulated two factors that prior research (e.g., Marsh 2007) had suggest might affect the fidelity of the summaries to the original source: the valence of the original story (Study 1) and the motivation given to the participants for retelling (Study 2). Each study involved the participation of over 1,000 different M-Turk respondents writing summaries across the three waves.

The contents of the summaries were analyzed both by automated text analysis tools and human judges. The automated tools included measures of linguistic specificity and diversity (e.g., Jensen-Shannon divergence), lexical novelty (e.g., the proportion of new words included in a summary) and semantic content (e.g., LIWC measures of affective content and style). Human judgments were provided by a separate pool of M-Turk participants who rated the summaries on each of 14 content dimensions (e.g., how detailed the summary was, how interesting it was to read, how positive or negative it was about the subject matter).

These analyses suggested that as the news events were retold, they underwent three major changes that were robust to the valence of the original story and writer's motivation:

### 1. *A transition from reporting to interpretation.*

With each passing wave the objective reporting of the facts of the events described in the original article increasingly gave way to subjective interpretations of facts, as evidenced by increased usage of subjective words and words suggestive of explanatory reasoning;

### 2. *A rise in cantankerousness.*

Across each summarization wave, judges of the summaries observed an increase in injections of cantankerous personal opinion, as evidenced by more frequent usage of first-person pronouns and more frequent expressions of disagreement; and

### 3. *A rise in uniqueness but a decrease in reader interest.*

Across waves the summaries became increasingly unique in style and content relative to the summaries in the previous waves, which was evidenced by increased overall linguistic divergence, increased novelty of words. That being said, the summaries but were also seen as decreasingly interesting to read by outside judges, as evidenced by decreased assessments of writing quality and interest.

To explain this pattern of results, we modeled the linguistic content of each summary as function of the content of the prior summary on which it was based. This analysis gave strong support for a hypothesized mimicry or style-matching process in which the injection of cantankerous opinions by one writer served as a catalyst that encouraged the next writer to do more of the same. Most importantly, while carry-over was observed for most linguistic features, expressions of opinion appeared to have a uniquely powerful influence on guiding the way the next writer in a chain crafted his or her summary.

We conclude with a discussion of the implications of the work for the prior theoretical research on information distortion that arises through re-transmission, as well as the possible impact of social media may be having on the style and tone of with which news is socially conveyed.

## The Positivity Problem: Using Mass-Scale Emotionality to Predict Marketplace Success

### EXTENDED ABSTRACT

Marketers often place a premium on both the measurement and maximization of consumers' positivity on social media and online reviews. The valence of consumers' reactions has been used to predict everything from purchasing behavior to the spread of word of mouth. Indeed, researchers across both behavioral and computer sciences have begun to measure mass-scale positivity ("sentiment") using online chatter and star ratings to predict movie box office revenue and book sales (Asur and Huberman 2010; Chevalier and Mayzlin 2006). Despite these successes, striking instances exist where positivity has been an inadequate predictor of success. For instance, positivity has shown little relation to a product's overall quality (de Langhe et al. 2016). Moreover, relying on online positivity is problematic as the average Amazon.com star rating is a 4.2 out of 5.0 with well over half of the reviews being 5-star ratings (Woolf 2017; McAuley et al. 2015). Thus, there is a *positivity problem* whereby valence provides a limited signal of consumer sentiment.

Given this positivity problem, how can objects of similar positivity be meaningfully distinguished? Drawing on theories from the attitudes and affective science literatures, we propose that the *emotion* behind consumers' evaluations offers a diagnostic signal. Indeed, research indicates that emotion provides a strong signal both to the individual and to others (Pham et al. 2001; Frijda and Mesquita 1994). We demonstrate this emotionality can be measured on a massive scale via consumers' language as quantified by the Evaluative Lexicon (EL; Rocklage, Rucker, and Nordgren in press; www.evaluativelexicon.com) and used to predict marketplace success across a wide range of items from advertisements to restaurants to movies.

In Study 1, we investigated whether emotionality signaled the future success of restaurants via the average number of daily table reservations made at that restaurant across a two-month period. Specifically, we followed all 1,139 restaurants in Chicago, Illinois that were also on OpenTable.com and recorded the number of reservations made each day ( $n_{\text{reservations}} = 1.30$  million). We also obtained the first 20 reviews for each restaurant on Yelp.com and averaged the positivity and emotionality of their text (results also hold when using 10 or 30 reviews). As a second measure of positivity, we included the average star rating from these reviews.

We found that star ratings were not predictive of table reservations, but that the positivity of the text was. Most importantly, over-and-above these effects we found that greater emotionality of the first 20 reviews predicted more table reservations. These results held controlling for the year when the restaurant first opened as well as the kind of restaurant (e.g., American, Indian).

In Study 2, we predicted the success of Super Bowl advertisements across two Super Bowls (2016 and 2017) via the number of new Facebook followers a company accrued each day in the two weeks following each Super Bowl ( $n_{\text{companies}} = 67$ ;  $n_{\text{commercials}} = 94$ ). To measure positivity and emotionality toward each commercial, we obtained all real-time tweets that occurred on the day of the two separate Super Bowls that mentioned the name of the company, a reference to the Super Bowl or a commercial, and an evaluation of the commercial as indicated by the EL ( $n_{\text{tweets}} = 187,206$ ). We then used the EL to quantify the average positivity and emotionality expressed toward each commercial across the tweets. Given that each company has only a single Facebook page, we analyzed the data at the level of each company by averaging across that company's commercials for each Super Bowl.

To predict the average number of daily new followers (log transformed), we used average positivity and emotionality as predictors. We also used USA Today's Ad Meter survey as a second measure of positivity, which scores each advertisement based on a large sample of respondents (1: poor; 10: excellent). Finally, we controlled for the average daily followers each company accrued in the lead-up to each Super Bowl (log transformed) to ensure that we assessed the *change* in daily followers.

Using a regression model, the USA Today survey did not predict brand followers and the average positivity of the tweets was, if anything, a *negative* predictor. However, over-and-above these effects, the greater the average emotionality of the tweets, the more followers a company accrued over the next two weeks. These results held across both Super Bowls and above-and-beyond the total number of tweets about each commercial as well as the number of positive (vs. negative) tweets.

In Study 3, we predicted movie success based on the final box office revenue a movie made. We obtained all US feature films on IMDb.com that also provided the box office revenue for that movie ( $n = 3,784$ ) and used the first 20 reviews to quantify positivity and emotionality. We found that star ratings were *negatively* predictive of box office revenue (log transformed), but that the positivity of the text was in the positive direction. Most importantly, however, over-and-above these effects, greater emotionality predicted greater box office revenue. These results held controlling for movie budget, release year, movie length, and across genres (e.g., action, romance).

Whereas consumer positivity tended to be a skewed and inconsistent predictor, the emotionality of consumers' language provided a signal of future marketplace success. These results build on theories from the attitudes literature proposing that the *basis* of individuals' evaluations matters (e.g., emotional vs. unemotional) and affective science demonstrating that emotionality provides an impactful signal to both individuals and others. We show that emotionality can be captured on a massive scale via natural language and is an important predictor of future marketplace success.

## Emotional Volatility and Cultural Success

### EXTENDED ABSTRACT

Why do some things catch on? Academics and popular writers alike have long been interested in cultural dynamics, or why some songs, movies, and other cultural items become popular. Some songs become hits while others fail and some movies become blockbusters while others don't. Why?

While some have argued that success is random (Salganik, Dodds, & Watts, 2006), we suggest that individual-level psychological processes can help explain cultural success. Culture shapes psychological process (Markus & Kitayama, 1991), but the reverse is also true: psychological processes shape the norms and practices that make up collective culture (Schaller & Crandall, 2004). Consequently, psychological processes may act as a selection mechanism, determining which cultural items succeed and which fail.

In particular, we suggest that period-to-period shifts in emotional tone—what we term emotional volatility, may shape success. Change creates uncertainty and surprise, which should increase emotional impact. In the context of generally positive experiences like books and movies, this should boost evaluations. Volatility should also provide stimulation and reduce hedonic adaptation, both of which should boost evaluation of positive experiences.

Unfortunately, empirically testing the link between emotional volatility and cultural success has been constrained by the ability to easily quantify volatility at scale. Measuring emotional responses

would usually require having people turn dials to rate their on-line experiences (Ruef & Levenson, 2007). But while possible for a small number of items, applying such methods on the scale needed to truly study culture would be challenging.

To address this issue, we use natural language processing to measure emotional volatility across thousands of films, testing whether more volatile movies are more successful.

First, we collected data on movie scripts. We gathered all English language movies from OpenSubtitles.com, leaving 4118 movies.

Second, we measure the sentiment of words in the script. We rely on prior work (Dodds, et al. 2011) which scored over 10,000 words based on how positive or negative they made people feel on a nine-point scale.

Third, we calculate emotional volatility. We focus on volatility between sizable chunks of a movie, like scenes, or portions of them and measure volatility using the standard deviation of differences in sentiment between adjoining chunks.

Fourth, we collected information on movie success. We recorded user ratings of each movie from IMDb.com.

Finally, OLS regression examines the relationship between emotional volatility and movie success.

Results indicate that more emotionally volatile movies receive higher ratings ( $b = 9.31$ ,  $s.e. = 0.78$ ,  $p < 0.001$ ). A 10.74% increase in volatility, for example, is linked to a 1% increase in ratings.

*Robustness.* While this relationship is supportive, one could argue it is driven by a host of other factors, so we included numerous covariates. We measure movie length, genre, presence of emotion, peaks and ends, complexity, overall positivity, extremeness of emotion, and release year. Even controlling for all these factors, however, the link between emotional volatility and success persists.

Results are also robust to different ways of dividing movies into chunks. Results remain the same in alternative approaches using different number of segments, different segment sizes, or different amount of overlap between segments.

While these relationships are suggestive, to best identify emotional volatility's effect, one would ideally keep all other movie aspects the same, vary emotional volatility, and measure its influence on success. To approximate this, we examine movies with sequels (e.g., Harry Potter). While many focal actors and production team members remain the same, emotional volatility varies across different movies in the series, providing a stricter test of volatility's impact. If among movies in a series, the ones that are more successful are the ones that are more emotionally volatile, this would support the notion that volatility, rather than some other factor, is driving success.

To test this possibility, we analyze the 175 movies that are part of a series (either the original or a sequel) using an analysis approach similar to difference-in-differences. We calculate the emotional volatility of each movie in a given series and compare its success relative to others within that same series.

Underscoring the prior findings, even within a series, more emotionally volatile films are evaluated more favorably ( $p = 0.04$ ). This holds even ignoring originals and just examining later films in a series (i.e., the 2nd vs. 3rd).

Further evidence for the notion that emotional volatility increases ratings comes from examining how the relationship varies across genres. If emotional volatility is truly shaping evaluations, as we suggest, it should have a stronger effect in genres where surprise and stimulation matter more (e.g. thrillers rather than romances). Consistent with this notion, the relationship was strongest in genres like thrillers ( $p < 0.001$ ) and mysteries ( $p < 0.001$ ) and weakest in

genres like music, documentaries, and romance ( $p = 0.46$ ,  $p = 0.13$ , and  $p = 0.05$  respectively).

Taken together, these results suggest that emotional volatility may shape cultural success. More emotional volatile movies are more successful. These findings also have a number of interesting implications. While researchers have studied peaks and ends, there has been less attention to dynamics of emotional experiences. Further, this work contributes to the burgeoning stream on literature on the psychological foundations of culture. When shared across individuals, psychological processes can shape the processing, sharing, and evaluation of cultural items, which in turn, shapes their success.

Finally, this work demonstrates how natural language processing can shed light on why things catch on. Researchers have long been interested in why some things succeed and fail, but measurement has been a key challenge. Natural language processing, however, provides a reliable method of extracting features, and doing so at scale.

### SESSION OVERVIEW

*“The greatest deception men suffer is from their own opinions.”*  
— Leonardo da Vinci

Ongoing reports of “fake news” have made us question if we can trust the information we receive from news outlets and social media. Yet, an even more worrisome question is, can we trust ourselves? This symposium investigates various ways in which people deceive themselves to maintain a positive self-concept.

People often use their choices to signal information about themselves to others (Berger and Heath 2007, Escalas and Bettman 2005). Recent work on self-signaling indicates that people also use their choices to signal information to *themselves* about desired traits and values (Gneezy et al. 2012, Savary et al. 2015, Toure-Tillery and Fishbach 2012; 2015). For example, a person might be more willing to donate to charity when doing so will make her feel “generous,” or to choose a piece of fruit (vs. candy) when doing so will make her feel “health-conscious.” People tend to cheat at tasks when they won’t have to label themselves as “dishonest” (Bryan, Adams, and Monin 2013), but toe the line when cheating would force them to question their integrity (Mazar, Amir and Ariely 2008).

However, the diagnostic signal of these choices is arguably merely an illusion: it does not change the objective outcome of the action. Donating \$2 will help others irrespective of how generous the donor feels, and fruit is healthy, whether the choice context encourages a self-attribution of “health-consciousness” or not. Cheating is dishonest, whether the cheat sees herself as dishonest or not. Thus, it seems consumers are readily able to deceive themselves into believing the signal from these strategic behaviors, which in turn influences their choices.

The first two papers in this session explore how consumers deceive themselves by strategically engaging in positive moral behaviors. **Paper #1** finds that consumers donate more when the context allows them to label their action as genuine altruism, which, surprisingly occurs when the donation choice is private. **Paper #2** indicates that when consumers mentally represent their self-concept as high (vs. low) in overlap, they tend to see their actions as more self-di-

agnostic, and hence behave more morally. However, as **Paper #3** shows, consumers can also deceive themselves by engaging in unethical behaviors, using dishonest means to augment the self-concept. Finally, **Paper #4** takes a step back to look at an often overlooked, but critical prerequisite of self-deception through self-signaling: a developed self-schema.

Together these papers explore the provocative possibility that we cannot always trust information, even when that information is a self-signal derived from our own actions. Across papers, we will discuss how consumers often ignore, or perhaps even sacrifice desired outcomes to maximize preferred self-attributions. In addition, these papers identify a range of strategies consumers use, either consciously or not, to allow themselves to make choices inconsistent with their long-term goals. As consumer researchers cast a wide net to investigate when to trust and when to doubt, this session provides a novel perspective on deception, specifically, when the source of deception of information comes from within ourselves.

## **Unobserved Altruism: How Social- And Self-Signaling Motivations Shape Willingness to Donate**

### EXTENDED ABSTRACT

The question of what motivates people to donate to charitable causes has generated a great deal of discussion. In the current research we examine two such motivations; the desire to receive public recognition and reputational benefits, known as a social-signaling motive (Ariely, Bracha, and Meier 2009), and the desire to see oneself as genuinely altruistic, known as a self-signaling motive (Touré-Tillery and Fishbach 2012, 2015; self-diagnostic actions; Savary, Goldsmith, and Dhar 2015). A key factor that distinguishes social- and self-signaling is the intended audience: a social signal conveys information about one’s traits and values to an external audience, whereas a self-signal informs oneself (Bodner and Prelec, 2002) even when the action has no causal impact on these traits and abilities. We discuss some of the odd things that happen when self-signaling is introduced into an otherwise rational conception of action. We employ a signaling game perspective in which the diagnostic signals are an endogenous part of the equilibrium choice. We are interested (1. Often, these motives align, and a choice will signal the same information to either an internal or an external audience. As a result, some researchers have wondered if social-signaling and self-signaling motives are separable (Grossman 2015). In the current article, we attempt to empirically disentangle these motives in the context of charitable giving. We find that the two signaling motives can compete, and even inhibit each other.

Our proposal builds on two related ideas: (1) that the intrinsic motivation to engage in a behavior can be “crowded-out” by extrinsic incentives (Gneezy, Meier, and Rey-Biel, 2011) engagement-contingent, completion-contingent, and performance-contingent rewards significantly undermined free-choice intrinsic motivation ( $d = -0.40, -0.36, \text{ and } -0.28$ , respectively) and (2) recent findings that suggested that people believe a charitable act should be free from the potential taint of self-interest (Barasch, Levine, Berman, and Small, 2014; Berman, Levine, Barasch, and Small, 2015; Lin-Healy and Small, 2012, 2013; Newman and Cain, 2014) or advertise, their good deeds to others. Seven studies investigate how bragging about prosocial behavior affects perceived generosity. The authors propose that

bragging conveys information about an actor's good deeds, leading to an attribution of generosity. However, bragging also signals a self-ish motivation (a desire for credit).

Our main proposition is that that reminding people of potential public recognition can undermine donation rates, because when the social-signaling benefits of donating are made salient, it reduces an individual's ability to infer that their choice to donate is a genuine signal of altruism, and thus dilutes the value of the self-signal. We expect this to occur even though the self-signal of altruism is unrelated to the actual benefit the charities might receive, consistent with the notion of self-deception through self-signaling.

We tested this prediction using real and hypothetical choices. In all studies, some people are asked to donate in a private, unobserved choice. Others read that their donation will be observed, and that they may receive social-signaling benefits for their choice. Consistently, people are more likely to donate in the private conditions (see table 1 for all experimental results). Mediation analysis indicates that this occurs because the public choice is a relatively weaker self-signal than the private choice. The pattern attenuates when (1) the value of the social-signal is enhanced or (2) the overall decision context is non-diagnostic.

In **Study 1a**, participants read about a charity that posts "thank you" badges on their website for a \$5 donation. People were more likely to donate in the private condition (i.e., "Neither you nor anyone else will know which [badge] is yours") than in the public condition (i.e., "The badge will be posted on the website next to your full name"),  $M_{\text{private}} = 4.8$  vs.  $M_{\text{public}} = 4.1$ ,  $p = .011$ . **Study 1b** uses a different charity and scenario to show that the effect replicates when the dependent variable is participants' choice to donate real money,  $P_{\text{private}} = 54\%$  vs.  $P_{\text{public}} = 36\%$ ,  $p = .034$ .

Our proposal is that consumers see a private donation as a stronger self-signal of genuine altruism than a public donation. In **Study 2** we test this by measuring the perceived strength of the self-signal after the donation choice, "The choices I make reflect my inner goals." Again, people are more likely to donate when the choice is private ( $P_{\text{private}} = 41\%$  vs.  $P_{\text{public}} = 33\%$ ,  $p = .039$ ). In addition, people see the private donation as stronger self-signal ( $M_{\text{private}} = 4.0$  vs.  $M_{\text{public}} = 3.7$ ,  $p = .004$ ), which mediates the effect of condition on donation choice ( $b = -.09$  (.04), 95% CI [-.17 to -.02]).

**Study 3** indicates that when the value of the social-signal is high enough (because your boss is the audience, and a big believer in charity), it can offset the loss in self-signaling utility. When we experimentally enhance the value of the social benefits, we observe a reversal,  $P_{\text{enhancedsocialvalue}} = 71.9\%$ ,  $P_{\text{private}} = 40.9\%$ ,  $p < .001$ .

**Study 4** was a 2x2, which showed that when people's choices are non-diagnostic (because they make external attributions about their motives), and thus the self-signaling value of the choice is nullified, the effect attenuates. When the choice was diagnostic, people again donated more often in private vs. public ( $P_{\text{private/diagnostic}} = 64\%$  vs.  $P_{\text{public/diagnostic}} = 35\%$ ). However, when the choice was not diagnostic the pattern marginally reversed  $P_{\text{private}} = 41\%$  vs.  $P_{\text{public}} = 62\%$ , yielding a significant interaction,  $b = -1.02$  (.37),  $p = .006$ .

**Study 5** was also a 2x2, which showed that experimentally increasing the value of the social signal, via a social-threat manipulation, also attenuates the pattern, interaction  $p = .027$ .

These findings demonstrate a novel choice paradigm in which self-signaling benefits and social-signaling benefits not only diverge, but can counteract each other. To our knowledge, we are the first paper to empirically pit these forces against each other and illustrate that self-and social-signaling motives can have opposing effects on the choice to donate.

## No Self to Spare: How the Cognitive Structure of the Self Influences Moral Behavior

### EXTENDED ABSTRACT

It is no secret that people are motivated to maintain a positive self-concept (Gao, Wheeler, and Shiv, 2009; Schlenker, 1985; Steele, 1988; Prelec and Bodner, 2003). In particular, people will do the "right" thing when their actions seem most diagnostic for inferences about the self (i.e., self-diagnostic), but relax their standards otherwise (Touré-Tillery and Fishbach 2015). Many factors can elicit the perception that a choice is not self-diagnostic. For example, Touré-Tillery and Fishbach (2012) found that people were more likely to cheat in the middle (vs. beginning/end) of a sequence of actions, because they perceive the middle (vs. beginning/end) as less diagnostic for self-inferences. Within the same perspective, Bryan, Walton, Rogers, and Dweck (2011) found that when an action was explicitly linked to the undesirable identity of "cheater" ("don't be a cheater" vs. "don't cheat"), participants were less likely to cheat for money.

The present research explores how people's mental representations of their self-concept influences perceptions of self-diagnosticity, and hence moral behavior. Self-overlap refers to the extent to which people perceive their various self-aspects as interconnected (vs. distinct), such that they think of themselves similarly (vs. differently) across these self-aspects. We propose and find in four studies that people high (vs. low) in self-overlap tend to see their actions as self-diagnostic, and hence are more likely to behave morally—e.g., less likely to cheat and more likely to give to charity. Indeed, for a person high (vs. low) in self-overlap, positive or negative thoughts and feelings about one's identity after a good or bad deed will be more likely to spread to other identities.

**Study 1** tested the correlations between self-overlap, self-diagnosticity and moral behavior using a longitudinal design. Our final sample consisted of 165 US-based respondents (85 female,  $M_{\text{age}} = 35.65$ ,  $SD_{\text{age}} = 11.85$ ) recruited online. First, participants completed an established measure of self-overlap (Linville 1985; 1987) and the self-diagnosticity scale (SDS), which we devised to measure of individual differences in people's propensities to see their actions as representative of who they are. Then, several days later, they completed a scenario-based measure of unethical decision-making. We found the predicted a negative relationship between self-overlap and unethical decision-making ( $\beta = -.17$ ,  $t(163) = -2.19$ ,  $p = .030$ ;  $r = .17$ ), and a mediation of this effect by perception of self-diagnosticity ( $a \times b = -.1135$ ; CI = [-.2824, -.0067]).

**Study 2** tested the causal link between self-overlap and moral behavior in a naturalistic context on MTurk. The experiment employed a 2 (self-overlap: high vs. low) between-subjects design. Two hundred ninety-four MTurkers (133 females;  $M_{\text{age}} = 31.27$ ,  $SD_{\text{age}} = 10.39$ ) read that either high or low self-overlap leads to positive life outcomes and attempted to explain why. Based on the notion of motivated reasoning (Kunda and Sanitioso, 1989), participants who read that high (vs. low) overlap is good should be motivated to think of themselves as being high (vs. low) in self-overlap. Next, participants learned about a bonus survey in which they could earn extra money if eligible. Research shows MTurkers sometimes misrepresent their qualifications in order to take part in paid surveys (Chandler and Paolacci, 2017; Sharpe Wessling, Huber, and Netzer, 2017). We capitalized on this tendency by creating a situation in which all participants received direct feedback that they were not eligible for a bonus survey, but due to an ostensible programming error, gained access to the survey anyway. We then gave participants an opportunity to admit they were not eligible for the survey (honesty), or to keep silent in order to earn the bonus pay (dishonesty). We found a larger

proportion of participants in the high self-overlap condition (39.2%) honestly declined the bonus survey than in the low self-overlap condition (27.6%,  $\chi^2(1, 266) = 3.92, p = .048$ ).

In **Study 3** we used a longitudinal paradigm to test the moderating role of identity importance. The study employed a 2 (self-overlap: high vs. low)  $\times$  (identity importance: continuous). In part 1 we measured altruism identity importance. In part 2, several days later, 273 respondents (154 female,  $M_{\text{age}} = 36.23, SD_{\text{age}} = 10.91$ ) completed a manipulation of self-overlap, in which they discussed either the connections or the distinctions between their self-aspects. Then, they unexpectedly saw a charitable appeal soliciting donations from their compensation for the study. We found the predicted interaction of self-overlap by altruism importance on willingness to donate ( $\beta = .39; t(268) = 2.29, p = .023, r = .14$ ), such that at high levels of altruism importance, we replicated our previous findings: participants high (vs. low) in self-overlap donated more.

Finally, **Study 4** tested the moderating role of self-signal strength. The study employed a 2 (self-overlap: high vs. low)  $\times$  2 (self-signal: strong vs. weak) between-subjects design. An online consumer panel of three hundred eighteen US-based participants (170 female;  $M_{\text{age}} = 51.16, SD_{\text{age}} = 14.85$ ) completed the same manipulation of self-overlap as in Study 3 and read a charitable appeal. The wording of the weak-self-signal condition highlighted social-signaling motives for making a donation (or impure altruism), which should result in external attributions: "did it because I wanted people to think I care." By contrast, the strong-self-signal condition highlighted purely altruistic motives for making a donation, which should lead to internal attributions: "I did it because I wanted to help others." The results revealed the predicted interaction of self-overlap by self-signal strength on willingness to donate ( $F(1, 307) = 5.69, p = .018, r = .13$ ). When the self-signal was strong, participants in the high self-overlap condition chose to donate more money ( $M = 10.61, SD = 8.46$ ) than participants in the low self-overlap condition ( $M = 8.12, SD = 7.61; t(153) = -2.04, p = .042; d = .31$ ).

Taken together, these studies show that the mental representation of the self-concept is an important driver of moral behavior, because it influences a person's tendency to view her actions as self-diagnostic—and hence allows them to deceive themselves into maintaining a positive self-concept.

### Cheating Your Self: Diagnostic Self-Deceptive Cheating for Intrinsic Rewards

#### EXTENDED ABSTRACT

It often pays to cheat—better grades, more money—and previous models of cheating have accounted for such extrinsic incentives to cheating (Eide, Rubin, and Shepherd, 2006; Mazar, Amir, and Arieli, 2008). But some cheating acts only carry intrinsic rewards; only positively affecting the self-concept or self-perceptions. For instance, completing a crossword puzzle may increase the extent to which one feels intelligent.

Cheating to gain extrinsic rewards is clearly advantageous. Cheating for intrinsic rewards, however, is more complicated. The very act of cheating should hamper the intrinsic benefits. Any enhanced performance should be attributed to the act of cheating, and not to ability, unless the individual can deceive himself into believing otherwise. Thus, we argue that when only intrinsic benefits are available, consumers attribute their enhanced performance to their own ability as opposed to the agency given to them from the cheating opportunity, a process known as diagnostic self-deception.

Diagnostic self-deception involves drawing an invalid diagnostic inference in favor of a desirable trait (Fernbach, Hagmayer,

and Sloman, 2014; Sloman, Fernbach, and Hagmayer, 2010). This model of diagnostic self-deception assumes that there are two causal paths to any outcome. The first is any outside factor not under willful control, such as personal traits, skills, and physical features. The second is any behavior due to agency that can be willfully manipulated and thus is independent and non-diagnostic of any other underlying causes. Assume, for instance, that a student has the answer key to a test at his disposal and he scores an "A" on the exam. There are two causal paths for his grade. The agency factor is that he used the answers available to him. The outside factor not under his willful control is that he is an exceptionally intelligent individual. If the former is the true causal pathway, but the student adopts or gives more weight to the latter belief, then diagnostic self-deception has occurred.

Diagnostic self-deception occurs when an intervention by an individual leads to an outcome, but the individual does not attribute the outcome to his agency, but rather to a cause not under his willful control. It is therefore a form of self-serving attribution that allows individuals to reap intrinsic benefits of cheating. Moreover, such self-deception also protects my moral self and avoids such intrinsic costs (Mazar et al., 2008). In sum, we expect cheating for intrinsic rewards to result in diagnostic self-deception, resulting in a positive change in self-perceptions.

**Study 1** tests the effect of an intrinsic reward on cheating behavior. We asked participants to measure their resting heart rate and manipulated both their ability to cheat (by varying their control over the task) and the presence of intrinsic rewards (by telling some that lower resting heart rates are correlated with higher levels of fitness). Participants reported lower resting heart rates on average when it was easier for them to cheat at the task, but only when intrinsic rewards were present ( $F(1, 290) = 7.58, p = .0063$ ). When rewards were absent, the task presumably would not influence self-perceptions, and individuals did not cheat ( $F(1, 290) = .01, p = .91$ ).

Diagnostic self-deception can be thought of as a self-serving bias: when people perform well, they tend to attribute it to their own ability, but when they perform poorly, they are more likely to attribute their performance to external factors (Campbell and Sedikides, 1999). Given this, in study 2 we manipulated participants' ability to cheat on a task measuring intelligence (solving anagrams) and measured how prone participants were to self-serving bias (Nagin and Pogarsky, 2003). We found that self-serving bias moderated the effect of a cheating opportunity on performance ( $F(1, 286) = 5.11, p = .025$ ); cheating was more likely among those prone to self-serving bias ( $b = .22, t(286) = 2.17, p = .031$ ).

In **Study 3** we manipulated undergraduate business students' ability to cheat on a test indicative of their business knowledge. They then indicated their interest in an on-campus workshop about succeeding in business courses. Participants in the cheating condition performed better ( $F(1, 135) = 7.90, p = .0057$ ) and reported less interest in the workshop than those in the control condition ( $F(1, 134) = 7.90, p = .023$ ). Moreover, test scores mediated the effect of cheating condition on workshop interest ( $b = .11, SE = .069; 95\% CI = .0082 \text{ to } .2868$ ), providing indirect evidence of diagnostic self-deception.

**Study 4** used the anagram task from study 2, but also included measures of attributions and task legitimacy, both of which have been used in the self-serving bias literature (Campbell and Sedikides, 1999). Participants in the cheating condition performed better ( $F(1, 189) = 12.68, p = .0005$ ), made more internal attributions for their enhanced performance ( $F(1, 189) = 5.48, p = .020$ ), and were more likely to believe that the anagram task is an accurate test of intelligence ( $F(1, 189) = 6.39, p = .012$ ). We combined attributions and

legitimacy perceptions to create a self-attribution index, and, consistent with our theory, this index was driven by performance on the anagram task ( $b = .38$ ,  $SE = .12$ ; 95%  $CI = .1720$  to  $.6410$ ).

**Study 5** tests our full theoretical model using a cheating paradigm purportedly designed to measure fitness. We also measured performance attributions and self-perceptions. Compared to the control condition, those in the cheating condition performed better ( $F(1, 140) = 4.58$ ,  $p = .034$ ) and made more internal attributions ( $F(1, 140) = 4.76$ ,  $p = .031$ ). The indirect effect of cheating on healthiness self-perceptions, through the two mediators of performance and attributions, was significant ( $b = .018$ ,  $SE = .012$ ; 95%  $CI = .0028$  to  $.0540$ ).

Examining cheating in the presence of intrinsic rewards, we provide evidence of a dishonest means to augment the self-concept. We have all heard the adage, “when you cheat, you are only cheating yourself.” This appears to be especially true when cheating offers intrinsic incentives.

## How the Unconstructed Identity Relieves Consumers of Identity-Relevant Consumption

### EXTENDED ABSTRACT

Though consumers often have identity schemas to guide their behavior, there are times when consumers, either willingly (e.g., when they conceal identity relevant information; DePaulo 2004) or unwillingly (e.g., travel to an unfamiliar location), may not have an identity-schema to guide them. Temporary identity salience and chronically-held identities often result in identity relevant consumption (e.g., Bolton and Reed 2004; Forehand, Deshpandé, and Reed 2002), as identity irrelevant consumption is typically threatening (e.g., Ward and Broniarczyk 2011; see Berger and Heath 2008 for an exception). While identity salience is often seen as positive, this current research examines a potential downside of identity salience.

To date, research has explored how consumers behave when an identity that has been established in the semantic network is salient (e.g., Coleman and Williams 2015). To understand potential downsides of identity salience, we explore the *unconstructed identity*, or an identity that has not yet been developed semantically in the consumer’s mind. We argue that unconstructed identities can occur when an identity is novel to one’s self-concept or when a context is unfamiliar. A pilot test revealed that fifty five percent of consumers admitted to using a false identity in the marketplace, suggesting that consumers may, at times, prefer not to have an identity-schema to guide their behavior. We propose and test that when the consumer’s identity is salient and identity schemas are absent (vs. present), consumers are less likely to make identity relevant choices.

**Study 1.** Participants took part in a two level (identity schema: absent vs. present) between subjects design. Participants in the identity schema absent (present) condition were instructed to give a fake (real) name when asked in the survey (see Anthony and Cowley 2012 for similar manipulation). Participants were then asked for their name followed by “Hi [*fake/real name*]...” They then read details about the fundraiser, which discussed the university, making university identity salient and one of three cupcakes (two cupcakes were identity irrelevant and one was relevant). Choices were coded dichotomously for our dependent measure. Additional items (e.g., manipulation checks and demographics) were completed (in studies 1-4). Results reveal that when identity schemas were absent (vs. present), participants were less likely to choose a cupcake that was identity relevant ( $M_{identity\_schema\_absent} = .40$  vs.  $M_{identity\_schema\_present} = .20$ ;  $p = .04$ ).

**Study 2.** Participants took part in a 2 (identity salient: yes, no) X 2 (identity schema: present vs. absent) randomized between

subject design. We manipulated identity salience in this study since identity relevant consumption should not differ by identity schema presence when the relevant identity is not salient. Those in the prime condition were asked to write about why being a member of [university] was important to them (Chugani, Irwin, and Redden 2015). The control condition did not complete this task.

Participants then read either the present or absent identity schema manipulation from study 1. Next, on a “form” along with their real or fake name, participants were asked to choose one of three chip-clips (two were identity irrelevant). This dependent measure was calculated dichotomously. Results revealed a significant interaction ( $p = .04$ ). Contrasts revealed that when identity was salient, there was a marginal difference ( $P_{identity\_schema\_absent} = .83$  vs.  $P_{identity\_schema\_present} = .94$ ,  $p = .06$ ). When university identity was not salient, identity schema presence did not impact choice ( $P_{identity\_schema\_absent} = .86$  and  $P_{identity\_schema\_present} = .80$ ,  $p > .30$ ). In the identity schema present condition, participants were more likely to choose an identity relevant chip-clip when identity was salient ( $P_{prime} = .94$  vs.  $P_{control} = .80$ ,  $p = .02$ ). However, participants in the identity schema absent condition were less likely to consume relevant to their identity regardless of prime ( $P_{prime} = .83$  vs.  $P_{control} = .86$ ,  $p > .50$ ).

**Study 3.** Participants took part in a two level (identity schema: absent vs. present) between subjects design. Participants completed the identity schema manipulation from study 1 and then were asked to imagine that they were at a sandwich shop. They were presented with a menu (Bagchi and Block 2011) and asked for their order and name, where they either gave a fake or their real name. Likelihood to tip served as the dependent variable (on a 7-point scale), followed by a reliable measure of spending identity (i.e., tightwad-spendthrift scale; Rick, Dryder, and Loewenstein 2007). Results reveal a significant interaction ( $p < .01$ ) such that when identity schema was absent (vs. present), tightwads (Spending identity  $\leq -1.17$ ) were more likely to tip, while spendthrifts (Spending identity  $\geq 7.49$ ) were less likely to tip. These results indicate that consumers behave opposite to their chronically held spending identity when their identity schema is absent (vs. present).

**Study 4.** Participants took part in a two level (identity schema: present vs. absent) between subjects design. For generalizability, we used a different manipulation of identity schema in this study. Participants in the identity schema absent (present) condition were told to imagine they were out of town (in town) and staying at a hotel (at home) and that they went out to grab a beverage at a coffee shop they have never visited before (visit often).

Participants ordered from a menu and were informed of the coffee shop’s green initiative, for which they were selling reusable coffee cups. Participants indicated how likely they would be to purchase a reusable cup on a 7-point scale and completed a reliable measure of green identity (Haws, Winterich, and Naylor 2014). Results reveal a significant interaction ( $p = .02$ ). Higher green identities (Green Identity  $\geq .69$ ) were less likely to purchase the reusable cup when their identity schema was absent (vs. present), while those with lower green identities was not impacted as a function of identity schema.

In conclusion, these studies provide evidence that consumers, at times, pursue unconstructed identities. As a result, consumers can make less identity relevant choices as well as engage in less identity relevant behaviors. These findings have important theoretical and marketplace implications.

### SESSION OVERVIEW

Consumption experiences are a vital area of consumer research and have been studied from a variety of different perspectives as they pertain to various consumption phenomena (Akaka and Nar-dini 2017). For example, service researchers explore how customers' cognitive, emotional, behavioral, sensorial, and social responses to a firm's offerings (Lemon and Verhoef 2016) while CCT scholars examine how consumption experiences help consumers construct and represent reality, as part of both collective (Moscovici 1988) and individualistic pursuits (Richardson 1999). This research views the consumer experience as "a personal occurrence, often [but not necessarily] with important emotional significance, founded on the interaction with stimuli which are the products or services consumed" (Carú and Cova, 2003, p. 270).

Although prior CCT research has examined everyday and ordinary consumption experiences (Thompson, Locander and Pollio 1990; Carú and Cova 2003) and volitional reconsumption (Russell and Levy 2012), most research tends to examine experiences that are extreme, intensive, and spatially or temporally bounded (Arnould and Price 1995; see also Lindghard and Oostergaard 2015). Moreover, this stream of research often focuses on the individual outcomes of experiences, that is, to center on consumers who live the experience as subjects. Finally, with the recent exception of Scott, Cayla and Cova's (2017) work on painful experiences, we lack research on how consumers endure experiences that are not necessarily pleasant, easy, or leisurely.

This session aims at addressing these gaps by looking at consumption experiences that last over several years, often producing ambivalent and systemic outcomes. The four papers in this session explore extended consumption experiences, their cycles, rhythms and their outcomes over time. The first paper theorizes enduring consumption experiences as those that span through several years and are transformational at the individual, familial, and societal levels. Researching the context of schooling, the authors argue that enduring consumption experiences are not ordinary or extraordinary, and

neither purely pleasant nor painful, but present elements of all these types of consumption experiences.

The second paper investigates the temporal dynamics of a family identity, embedded in a family consumption experience (playing soccer) that spans multiple generations. The authors document the lifecycle of the identity, highlighting periods of dormancy, rekindling, growth, and decline and note the role of identity guardians in sustaining the consumption experience across these phases.

The third paper examines pursuit of passions through extended wilderness consumption experiences. They investigate 'dirtbags' who prioritize long-term wilderness adventures such as climbing, river and mountain sports. Diverse data collected over a two-year period reveal hero and trickster archetypal journeys of "heroic passion," fueled and celebrated by outdoor brands and media. Complexities of navigating passions and social norms can leave 'dirtbag' consumers perpetually caught between society and the wild.

Finally, while studying third-age runners, the last paper develops the Rhythmic Experiences Framework. Inspired by Lefebvre's (2004) theory, the authors describe how consumption practices' properties of place, time, and energy foster life rhythm experiences (of eurhythmia and arrhythmia), which, through time and repetition, and in linear and cyclical processes, may reinforce identity projects.

### Schooling as an Enduring Consumption Experience

#### EXTENDED ABSTRACT

*"I had to endure a highly transient lifestyle and attended seven different schools from Kindergarten through 8th grade...This was difficult. Very difficult. I was secure in my abilities and my potential in life, and at a young age, I knew the importance of education, but it was still very challenging...Some days will be extremely tougher than others and some days those accomplishments will glow, but giving up is not an option... It should make one stronger. It should make one want to reflect on how to beat all the odds. It should foster one's thinking that current challenges have been designed to build upon one's strength, not tear one down. That one's long-term goal can be fulfilled." (Dubiel 2015)*

Education is a fundamental human right (UN 1948) and a highly institutionalized practice. Schooling practices spill over other consumption spheres such as housing, workplace, celebrations and sports (Rojas Gaviria et al, 2018), converting it into one of the pillars of socialization (Doucet 2011). Hence, in addition to the cognitive engagement that is at the core of schooling, these interactions are frequently long-lasting, affect and emotion-laden, having physical and social implications for those involved in them and for society as a whole.

During schooling, various interdependent market actors (i.e. government, schools, consumers -parents, children, therapists, physicians, baby-sitters, tutors, etc.) engage in a myriad of interactions and negotiations that have little to do with teaching and learning. Our study describes the complexity involved in these interactions and shows that schooling is strikingly in contrast with the possibilities for escape and regeneration provided by extraordinary con-

sumption experiences. In fact, students and their families frequently experience schooling as entrapment and find the routine and rituals entailed by schooling and the numerous tasks needed to support it taxing and stressful, yet inevitable (see O'Reilly 2016; Doucet 2011, McLaren 1999). Nevertheless, school attendance and affiliation has been shown to significantly shape one's social and professional network, as well as future opportunities in life (Zimmermann 2016). Thus, given its all-encompassing nature and long-term transformative impact, schooling cannot be considered an ordinary experience as theorized by Carú and Cova (2003).

Moreover, schooling presents elements of pleasurable experiences, as in celebrations, prizes, gatherings and achievements, yet, over the course of the 12 years of basic education, and particularly in markets where performance is closely measured and high standards are required of students (Rojas-Gaviria et al., Forthcoming), it often resembles the painful experiences studied by Scott, Cayla and Cova (2017). We sustain that schooling cannot be seen as either ordinary or extraordinary, and neither purely pleasant nor painful, as it presents elements of all those types of consumption experiences. We thus propose that schooling is an enduring consumption experience. We theorize enduring consumption experiences as those that span through several years and are transformational at the individual, familial, and societal levels. In this study, we examine how Chilean families endure the experience of schooling by immersing ourselves on the private school market.

Primary data collection consists of in-depth interviews with families, service providers and school representatives as well as personal reflections about the schooling experience collected among recent high-school graduates using art as an elicitation technique (Tarr et al. 2017). This main dataset was complemented with media archives and online data collected from parenting blogs, blogs on education and online communities centered on schooling and education. Data analysis involved iterative reading and manual coding of the dataset by all three researchers, searching for patterns (Thompson et al. 1994).

Our findings illustrate how enduring consumption experiences differ from volitional reconsumption (Russell and Levy 2012), and ordinary (Carú and Cova 2003) and extraordinary consumption experiences (Arnould and Price 1995, Scott, Cayla and Cova 2017) in their characteristics, development, and outcomes. We sustain that other types of consumer experiences such as child or elderly care (Huff and Cote 2010; 2011; Barnhardt and Peñaloza 2013), chronic health conditions or disability (see for instance Pavia and Mason 2012) or migration (see Luedicke 2011; 2015) show similar characteristics and could also be considered enduring consumption experiences.

Through reflecting on enduring consumption experiences, we develop a framework that can assist consumer researchers in understanding several under-researched aspects of consumption such as its compulsory, routine, non-agentive (Askegaard and Linnet 2011) nature. Our findings also allow for a reconsideration of temporality and the ways in which different understandings and perceptions of time continuously shape consumption. Finally, this conceptualization opens avenues for additional research on the systemic aspects of enduring consumption experiences, such as their impact on family well-being and identity.

## Family Consumption Experiences Across Generations

### EXTENDED ABSTRACT

This research investigates how consumption experiences linked to a family identity evolve over time. Family identity is the set of

attributes and qualities that make a family unique and differentiate it from other families (Epp and Price 2008). This identity is shaped by, reflected in, and reinforced by a family's consumption practices (e.g., Barnhart, Huff, and Cotte 2014; Cross and Gilly 2014; Curasi, Price, and Arnould 2004; Epp and Price 2008; Epp and Price 2010, 2011; Moisio, Arnould, and Price 2004). Work exploring family identity has clearly articulated the role of consumption experiences in family identity and acknowledges that family identity, and the associated consumption experiences, are dynamic and have unique trajectories (Epp, Schau, and Price 2014; Reckwitz 2002; Warde 2005). However, we still know relatively little about these trajectories, how a family's identity related consumption experiences change over time, or how families grow into and out of particular consumption related identities. To redress this gap, we explore the following research questions: (1) How does a family identity evolve over time? and (2) How do consumption experiences and practices associated with a family identity transfer across generations? To inform our understanding of these issues, we appropriate theories related to the resurrection of collective identities in communities and organizations as a theoretical lens (Howard-Grenville, Metzger, and Meyer 2013). These theories articulate how collective identities are resurrected after experiencing a period of decline, noting the important role that experiences, emotion, and identity guardians (i.e., leaders who leverage community emotion and experiences to support an identity) play in reviving identities. This work also highlights the professional nature of identities, noting that they ebb and flow in and out of favor over time as communities and organizations evolve.

To address our research questions, we explored how a particular consumption experience—playing soccer—enters into families as a practice, collects into an identity, and evolves over time. The focal activity of “playing soccer” is an ideal context for this research as this consumption experience often reflects a lifetime of engagement and is frequently integral to family identity (e.g., “soccer family”) with multiple family members (children and parents) gathered into the practice as players, supporters, or volunteers. Given our interest in how family identity evolves over time and across generations, we adopted a novel methodological approach that allowed us to observe some of the dynamics of identity evolution within an empirically reasonable timeframe. In phase 1 of data collection, we conducted interviews with 66 parents and children from 22 U.S. families at different stages of adopting a soccer family identity (some families were in their first year of participation and other families noted 20 years of involvement with youth soccer). Here, our focus was on how children become socialized into the soccer experience and how their engagement with the activity impacts family identity. In phase 2, we conducted an in-depth analysis of a single, multi-generational family whose family identity includes playing soccer. The family consists of two parents, four adult children (2 male, 2 female) and their spouses, and nine grandchildren ranging in age from one to eight years old. All the adult children played soccer in their youth, with one of the adult children being heavily engaged with the activity as a child and remains so in his adult life. Interviews were conducted with all the adult members of this family and explored their recalled accounts of being a soccer family in the past as well as their current experiences as the newest generation of children enters into the world of organized sports. The focus in phase 2 was to explore issues related to the intergenerational transfer of consumption experiences and family identity.

Our findings show how key family consumption experiences and practices evolve over a long temporal period. We document how adult members of families act as identity guardians who protect and nurture the soccer family identity, sometimes through years of dor-

mancy but then rekindle the identity as the next generation of children age into the activity. Rekindling the identity may involve something seemingly innocuous like registering a child in a recreational soccer league and while also foregrounding positive elements of the experience in narratives, emphasizing benefits that accrue from engaging with soccer (e.g., exercise, fun, team-building skills). This introduction is embedded in a series of other influences that elevate it from a simple ‘registration’ to an important act of rekindling that sets the stage for practice evolution where the practice gathers force within a family.

Next, families take on increasing commitment to the practice and identity. At this point, other assemblages in which soccer is embedded may break into the consumption experience with competition and performance expectations penetrating the family’s identity. This can threaten the practice as engagement incites tensions between conflicting discourses, identities, and other practices. The survival of the practice at this stage is once again dependent on identity guardians who work to unify family members around the positive elements of the consumption experience. Families grapple with questions related to their feared and desired selves and try to determine what kind of family they want to be and what kind of people they want their children to be. Here, identity guardians forecast into the future and strategically think about how to pursue the family identity. Once determined, families continue enacting the soccer identity until the next phase of dormancy begins (often associated with children going to college and no longer playing soccer). During the dormancy phase, the soccer identity takes on a nostalgic quality, supported by related materialities curated by identity guardians (e.g., soccer themed baby clothes) that prepare the identity for eventual rekindling.

In summary, we explore the temporal dynamics of a family identity, embedded in a consumption experience that spans multiple generations. We document the lifecycle of the identity, highlight periods of dormancy, rekindling, growth, and decline and note the role of identity guardians in sustaining the identity during all four phases. Overall, this work enhances understandings of how family identity and consumption practices evolve over time.

### **Pursue Your Passions: Cultural Discourses about Consumer’s Heroic Wilderness Adventures**

#### **EXTENDED ABSTRACT**

Cultural discourses shape brand meanings and how consumers’ navigate market and social structures (Arnould and Thompson 2005; Bunderson and Thompson 2009; Chouinard 2006; Coskuner-Balli and Thompson 2013; Coulter, Price, and Feick 2003; Holt 2004; Holt and Cameron 2010; Holt and Thompson 2004; Luedicke, Thompson, and Giesler 2010; Thompson 2004; Thompson and Haytko 1997). Our research examines cultural discourses that encourage individuals to pursue their passions, especially how consumers integrate the pursuit of passion into their navigation of market and social structures. Consumers are urged to “pursue your passions” or “chase your dreams.” Similar to Campbell’s (1973) description of the Hero’s Journey, stories of successful athletes, artists, spiritual seekers, entrepreneurs and outdoor adventurers describe individuals who pursued a passion, overcame great difficulties, and were subsequently celebrated for their accomplishments.

Our research examines the pursuit of passions through extended consumption experiences in the wilderness. The wilderness, viewed as outside human control, is celebrated in ancient myths, American culture, and as places that challenge those who venture into them and for their transformative power (Arnould and Price

1993; Arnould, Price, and Tierney 1998a; Belk and Costa 1998; Celsi, Rose, and Leigh 1993; Hawes 2008; Kozinets 2002; Miller 1991; Thoreau 2006; Tumbat and Belk 2011; Turner 1969). Further, the wilderness may allow individuals to pursue their passions uninhibited by the strictures of society (Arnould, Price, and Tierney 1998b; Belk and Costa 1998; Canniford and Shankar 2013; Hyde 2010; Radin, Jung, and Kerényi 1972; Rickly-Boyd 2012; Rickly 2016, 2017; Schouten and McAlexander 1995).

Despite rich scholarship on transformative consumption and extraordinary consumption, relatively little is known about wilderness consumers’ temporally enduring pursuit of passions. For example, little is known about the role of brands in shaping and perpetuating passion driven journeys into the wilderness. Products such as the GoPro Hero personal camera, and brands such as Patagonia and North Face exemplify this discourse (Holt and Cameron 2010). Our research asks: (1) How do consumers draw on cultural discourses to inform wilderness brand and consumption choices; and (2) How do long-term wilderness adventurers integrate pursuit of their passions with market and social structures?

To inform our understanding of consumers who pursue their passions in the wilderness, we rely on trickster (Hyde 2010; Radin et al. 1972) and hero (Campbell 1973; Segal 1990) archetypes as enabling theories. Tricksters live morally ambiguous lives pursuing their passions on the boundaries of society. They are celebrated and condemned for their cunning ability to defy and survive outside of societal norms. The Trickster’s disruption of social order may infuse society with new vitality, or it may introduce destructive chaos (Babcock-Abrahams 1975). Heroes leave society, conquer evil forces, experience personal growth, then return to improve society.

To address our research questions, we focus on individuals who prioritize their passion for wilderness adventure over socially normative and expected priorities, such as shelter and financial well-being. These consumers refer to themselves as ‘dirtbags,’ and exist in a wide variety of outdoor pursuits, especially climbing, river sports and mountain sports (Rickly 2017). Dirtbags, sometimes referred to as “core users” by outdoor brands, are connected to the branding, product development and entrepreneurial creation of many outdoor service and retail businesses (Chouinard 2006; Harrison and Corley 2011; Holt and Cameron 2010; Taylor 2010). Dirtbags offer an ideal subject group for researching heroic wilderness pursuit of passions.

Our findings incorporate diverse sources of primary and secondary data. Data collection was concentrated over a two-year time span. Informants described experiences retrospectively, prospectively and as they were living them. Primary data was collected during participant observation at wilderness site visits, climbing competitions, and screenings of dirtbag movie memoirs resulting in field notes and photographs. Further, snowball sampling led to 17 semi-structured in-depth interviews of participants ranging from age 20–46, and included selective follow up interviews and communications. Secondary data included branded content, dirtbag themed documentaries sponsored by outdoor brands, memoirs, and approximately 30 hours of *The Dirtbag Diaries* podcasts. Further, Dirtbag themed blogs, newspaper content and dirtbag titled social media provided insight into how dirtbags portray themselves to others.

Our findings adopt an extended temporal perspective on consumption and show how the heroic pursuit of passions cultural discourse informs brand and consumer practices. We find that brands depict ‘heroic’ wilderness struggles and conquests, with the brand helping to launch the hero’s journey into the wilderness. Outdoor brands also occasionally integrate tricksteresque messages celebrating the edge-dwelling, norms-challenging aspects of passion pursuits in the wilderness. Popular and social media accounts similarly

describe wilderness adventures as heroic conquests with tricksteresque undercurrents. Media targeting in-group audiences, such as a blog post titled “The Sophisticated Dirtbag,” delve more thoroughly into morally questionable techniques dirtbags use to extend passionate wilderness pursuits, such as dumpster diving and illegal camping.

Our informants describe self-transformative, passion-driven wilderness conquests. However, they also highlight socially ambivalent themes, offering the promise of transcending social structures and reconfiguring consumption patterns, while simultaneously threatening to contaminate and undermine systems of order. Consumers who follow their passions for extended adventures into the wilderness enter a shapeshifting space defined by paradox and tension. Our informants sacrifice comfort, income, security, family relationships, old friendships, intimate relationships and health in pursuit of ‘essentially pointless’ conquests. These sacrifices lead to diverse internal tensions and tensions with society. Navigating tensions between the individual’s pursuits of passion and the social norms that inherently constrain them is a perpetual challenge for these consumers. Through their celebration of dirt, both literally and in the figurative sense of dirt as a rejected by-product of creating order (Hyde 2010), our informants highlight the paradoxical natures of meaningful consumption, work, relationships, autonomy and security. We find that pursuits of passion are characterized by tricksteresque ambivalence and may end heroically, tragically or as prolonged journeys into futility and irrelevance.

In summary, we explore the practices and lives of consumers who pursue their passions in the wilderness. Using data from diverse sources, we reveal the tricksteresque and sometimes heroic nature of passion pursuits, which differentially informs and influences outdoor brands, media and consumption practices. This work has implications for the broader cultural discourse of the pursuit of passion in many domains, including consumers who pursue their passions for video games, art, spirituality, entrepreneurship and athletics.

### **Running Through Time: How Life Rhythms Foster Identity Permanence**

#### **EXTENDED ABSTRACT**

Time experience is crucial for human emotion, motivation, action (Carstensen et al., 1999), and well-being (Gabrian et al., 2017) and it is a constitutional part of what individuals have when engaged in social activities and practices. Social practices induce a specific pattern of experienced temporality in those performing them (Woermann & Rokka, 2015) because personal time is embedded in interactional structures in which individuals synchronize their time with others (Brodowsky, 2008) in physical and social contexts (Cotte & Ratneshwar, 1999). Also, the lived-time experience is mediated through the body, derived by the sensory-motor experiences in each activity (Toyoki et al., 2013).

Recently, Woermann and Rokka (2015) developed the concept of timeflow in consumption practices, which is the ability of social practices to evoke experienced temporality. From their study, we know that consumption practices embed a specific temporal experience and that this experience is a quality of a practice given its bodily, material, situational and teleoaffective influences. We also know that consumption practices shape identities and lifestyles (Celsi et al., 1993; Goulding et al., 2009; Schau, Gilly & Wolfenbarger, 2009) and that the extended and continuous performance of consumption practices vest individuals with symbolic, cultural and social capital that feed their identity projects (Arsel & Thompson, 2011).

Nevertheless, the literature on consumer culture still lacks a proper understanding of the way temporal experiences embedded

in consumption practices (Warde, 2005) shape, reinforce or challenge identity projects, especially when consumption practices are performed over extended periods. In this research we ask, how does consumption practices temporal experience influence identity projects of individuals who engage in consumption practices for extended periods? We explore this research question in the context of third age individuals in Brazil who are engaged in the consumption practice of running, a context that represents many other consumption practices such as yoga, swimming, or jogging.

Running is a social practice with many adherents among third age in Brazil. According to Krutman (2018), third age runners account for between 8,5% and 12% of the individuals registered for street runs in Brazil (a reasonable number, given that 12% of the population in the country belong to the third age group).

We adopted the semi structured interview method (Kvale, 2007), starting with general open questions about the evolution of running practice throughout their life and evolving to their running routines, the feelings, benefits and meanings of running, whether and how running has changed their lives, the development of social ties through running, how they imagine they are perceived by their social groups, and their main identity projects. The first author interviewed twelve runners ranging from 60 to 78 years of age, all residents in the state of São Paulo, Brazil. The second author listened and read to all the interviews, which were recorded and transcribed. We recruited some of the participants during a six-month observation of two online communities of interest related to running and the others we recruited through snowball technique. For all the participants, in our judgment, running has been a crucial part of their lives. Analytically, we adopt the theory of rhythm analysis of Lefebvre (2004), which next, we explain in its main elements.

Through the use of rhythm - biological, psychological and social - as a tool for analysis, Lefebvre (2004) interrelates space, time and energy in the comprehension of the quotidian. Rhythm is a way to understand time and experience, with the body playing a central role in the theory. Repetition (of movements, actions, situations and differences), the interference of linear (originated from social elements) or cyclical (originated from nature) processes, comparison (to our own’ and to others’ rhythms), and cycles of birth, growth, peak, decline, and end are important analytical elements in his theory. We also borrow the concepts of eurhythmia (and arrhythmia), in which the various rhythms in life sequentially unite in accordance (and discordance) producing order (and disorder).

Inspired by Lefebvre’s theory we developed the Rhythmic Experiences Framework, which describes how consumption practices’ properties of place, time, and energy foster life rhythm experiences (of eurhythmia and arrhythmia), which through time and repetition, in linear and cyclical processes, may often reinforce identity projects. We find a process in which the elements of running consumption practice - physical commitment, self-monitoring, socialization, attendance, and personal transformation - all of them with specific properties of time, energy and place, foster rhythm experiences. These experiences are recurrent, linear and cyclical, of a eurhythmic nature that reinforces the identity project of being a runner, or of an arrhythmic nature - events that break with the routine or gradually changes it, such as injuries or slow decay - challenging the same identity project.

We complement prior studies on the role of temporal experiences in consumption practices (Goulding et al., 2009; Canniford and Shankar, 2013; Woermann and Rokka, 2015) and we extend this line of research in adding the role of rhythm in extended temporal experiences of consumption practices in fostering enduring identity projects of old age individuals.

## Paper #4: It's Surprisingly Nice to Hear You: Misunderstanding the Value of Talking (vs. Typing)

Amit Kumar, University of Chicago Booth School of Business, USA  
Nicholas Epley, University of Chicago Booth School of Business, USA

### SESSION OVERVIEW

People communicate through a variety of channels. They talk face-to-face, call on the phone, text, and post on social media. But while people often give little thought to the channel through which they communicate, might it actually have an important impact on social interaction?

This session integrates different perspectives to examine the value of voice. Listeners often react against persuasive appeals, but might shifting subtle paralinguistic, or vocal features of communication increase persuasion? Do charitable appeals seem more sincere when they are conveyed through voice rather than text? Can debating by voice rather than text increase attitude change by making people less likely to dehumanize their opponent? And might people prefer interacting by text (because they think it is less awkward), even though interacting via voice would actually bolster social connection? This session addresses these, and other questions, as it deepens understanding of how the voice shapes social interaction.

First, **Van Zant and Berger** examines paralinguistic persuasion, or the effectiveness of persuasion attempts executed through nonverbal properties of communicators' voice. While persuasion attempts often backfire, and fail to work, they demonstrates that paralinguistic attempts actually enhance persuasion because they make speakers seem more confident. People trying to persuade paralinguistically speak louder, and with greater variance in volume, which increases perceived confidence and thus persuasion.

Second, **Barasch et al.** examine how voice shapes sincerity. By dissecting charity appeals into separate parts (e.g., silent video, transcript, audio, etc.) they disentangle the unique value of each set of language cues (semantic, auditory, and visual cues). They find that hearing—but not seeing speakers—increases perceived sincerity.

Third, while people tend to dehumanize people with whom they disagree, **Schroeder** finds that voice can mitigate this effect. People who have a spoken (vs. typed) conversation are less likely to dehumanize their opponent and report greater attitude change. Further, rather than being driven by a different message people communicate, results reveal this is driven by voice more strongly conveying a person's intellect to the listener.

Finally, **Kumar and Epley** examine how the voice shapes social connection. When interacting for the first time, or reconnecting with old friends or, people tend to prefer text because they think voice-based interactions will be more awkward. They're incorrect. There are actually no differences in awkwardness between communication media, but anticipated awkwardness drives people to use text-based media to interact, decreasing social connection.

Taken together, these papers provide convergent evidence for the value of voice. Technology has changed how people communicate. More and more people now used text-based media (i.e., text, email, or social media) rather than talking on the phone or face-to-face. But as these four papers show, there are a number of important benefits to voice (e.g., confidence, sincerity, humanization, and connection) that help voice increase persuasion, attitude change, and social bonding.

This session should be of interest to a range of consumer behavior researchers, from those that study social influence and persuasion to those interested in prosocial behavior, social interaction, political discourse, and well-being

### How the Voice Persuades

#### EXTENDED ABSTRACT

Persuading others can be challenging. When people diagnose others' intent to persuade, they often defend themselves by ignoring or counter arguing against the message (Friestad & Wright, 1994). Consumers can diagnose common persuasion tactics like positively valenced statements (e.g., "exceeds your needs" versus "meets your needs"), for example, or rhetorical questions (e.g., "Mizuno shoes are beneficial for you, aren't they?"), which causes communicators' persuasion efforts to backfire (Campbell & Kirmani, 2000).

When studying persuasion, however, the literature have often examined written messages. It has looked at manipulating written arguments (Tormala & Petty, 2002), print advertisements (Kirmani & Zhu, 2007), and text-based hypothetical vignettes (Campbell & Kirmani, 2000).

In contrast, little work has examined persuasion attempts executed through *paralinguistic* channels, or nonverbal properties of communicators' voice. Communicators can deliver the same message with in different ways, varying acoustic properties like their pitch, volume, and speech rate. Might such shifts actually make communicators more persuasive?

We argue that, although communicators may struggle to persuade others through *what* they say (linguistic persuasion attempts), they may be relatively effective at persuading others through *how* they say it (paralinguistic persuasion attempts).

If paralinguistic persuasion attempts are effective, there are two possible reasons why. The first is that listeners fail to detect them, which may make them harder to resist. Whereas linguistic attempts are fairly easy for listeners to identify (and thus ignore or react against), paralinguistic persuasion cues may be more difficult to diagnose. Alternatively, paralinguistic persuasion attempts may increase persuasion through signaling confidence. Confidence is a credibility cue that enhances persuasion (Karmarkar & Tormala, 2009). If speakers sound more confident when they are trying to persuade, this may boost persuasion regardless of whether their attempts are detected.

Across three experiments, we examine (1) whether paralinguistic persuasion attempts enhance persuasion and (2) the mechanisms underlying this effect.

*Experiment 1-3.* First, we generated stimulus materials by recording a sample of speakers ( $N = 49$ ) reading a review of a TV aloud twice (randomized order): once when incentivized to persuade a future research participant (paralinguistic attempt condition) and once when not given such an incentive (control condition).

Second, using a (paralanguage: control, persuasion)  $\times$  2 (disclosure statement: no, yes) between-subjects design, we presented a separate sample ( $N = 713$ ) with a randomly selected recording from the stimulus materials. To test whether paralinguistic persuasion attempts work because they are less likely to be detected, we also manipulated whether listeners received information about speakers' intent to persuade (i.e., the presence or absence of a disclosed monetary incentive to persuade).

Finally, we measured whether participants were persuaded (4 items; e.g., "I would like to purchase this TV") and perceived the speaker as confident (2 items: confident, certain).

As predicted, paralinguistic attempts enhanced persuasion ( $p = .049$ ). This was not moderated by linguistic information about communicators' intent to persuade, however, indicating that even when persuasion was detected, paralinguistic attempts still enhanced persuasion. Instead, results are more consistent with a confidence account. Paralinguistic attempts made speakers appear more confident ( $p = .003$ ), which mediated the effect of paralinguistic attempts on persuasion.

While one could argue that the results of Experiment 1 are somehow driven by communicators' intent to persuade not being clear enough, Experiment 2 ( $N = 1,104$ ) finds the same effects on persuasion ( $p = .003$ ) and confidence ( $p < .001$ ), including mediation by confidence, even when communicators directly acknowledge their intent to persuade (i.e., "I would like to convince you to purchase this TV").

In Experiment 3, we allowed speakers ( $N = 45$ ) to craft both the verbal and nonverbal aspects of their appeals. We manipulated linguistic persuasion attempts by randomly assigning half just to compose a review (control condition) and asking the other half to compose a persuasive review (linguistic attempt condition). Then, as in the first two experiments, they read their review aloud twice, once while making a paralinguistic persuasion attempt.

Next, we presented a randomly selected recording from the stimulus materials to a separate sample of research participants ( $N = 1,086$ ) and assessed persuasion and confidence. Finally, to provide a stronger test of detectability, we directly assessed the extent to which participants could diagnose communicators' intent to persuade ("I thought it was pretty obvious that the speaker was trying to persuade me").

As predicted, paralinguistic attempts again enhanced persuasion ( $p < .001$ ). This occurred even through listeners accurately perceived speakers' greater persuasive intent ( $p < .001$ ), providing further evidence against detectability. Instead, the results again support the confidence account. Paralinguistic attempts made speakers appear more confident ( $p < .001$ ), which mediated the effect of paralinguistic attempts on persuasion.

In contrast, linguistic persuasion attempts slightly harmed persuasion (*ns*) and did not make speakers appear more confident despite being similarly detectable to paralinguistic attempts ( $p = .037$ ). This suggests that although participants could detect them, paralinguistic attempts were more effective than linguistic attempts because they signaled confidence.

*Exploratory Analysis of Speakers' Paralinguistic Cues.* To better understand *how* speakers' paralinguistic attempts enhanced persuasion, we also analyzed the recordings used in each experiment to explore *which* nonverbal vocal cues influenced the persuasion process. We extracted objective phonetic measures using the Praat program (Boersma & Weenik, 2017). Relative to the control condition, speakers increased their volume ( $p < .001$ ) and varied their volume to a greater extent ( $p = .014$ ) when attempting to persuade. Each of these cues enhanced their perceived confidence and, in turn, the extent to which they were persuasive.

*Conclusion.* Taken together, these findings suggest that because they signal confidence, paralinguistic persuasion attempts are effective even when they are diagnosed. Beyond *what* to say, focusing on *how* to say it can increase influence.

### Sincere Persuasion:

#### Cues in Language Used to Assess and Convey Sincerity

#### EXTENDED ABSTRACT

Sincerity is a valued aspect of personality (Anderson, 1968), emotional displays (Grandey, Fisk, Mattila, Jansen, & Sideman, 2005), and communication (Barasch, Berman, & Small, 2016). Sincerity can be persuasive because it assuages any concern about ulterior motive (Campbell & Kirmani, 2000). Furthermore, sincerity is a key input into many consumer decisions, such as whether to take a recommender's advice about purchasing a product (Tuk, Verlegh, Smidts, & Wigboldus, 2009).

But what determines whether persuaders are deemed sincere? The current research examines the language cues that people use to judge others' sincerity.

In particular, we focus on three primary sets of language cues that could be used to evaluate sincerity: semantic cues (i.e., the message content or actual words expressed), auditory cues (i.e., characteristics of the communicator's voice, such as tone or volume), and visual cues (i.e., characteristics of the communicator's visual appearance, such as facial expression). While previous research suggests that each of these cues affects judgments of a message (semantic: Packard & Berger, 2017; auditory: Schroeder, Kardas, & Epley, 2017; visual: De Waele & Claeys, 2017), it is unclear how important each cue is for assessing sincerity specifically, and how these cues interact to influence perceptions of a communicator. Our work tests this question in the context of persuasive charity appeals.

First, to examine consumers' lay beliefs about which cues best convey sincerity, we conducted an online survey ( $n = 104$ ) asking participants how effective different communication cues are for "convincing you [others] to support a cause." They evaluated three sets of cues: hearing a communicator's appeal (auditory cues), reading a communicator's appeal (semantic cues), or watching a communicator's appeal (visual cues). Participants believed auditory cues would be the most effective ( $ps < .002$ ), and that semantic and visual cues would be equally less effective ( $p = .757$ ). The same pattern of results emerged for ratings of how useful each medium would be for determining sincerity in others and expressing sincerity to others.

Next, we test whether lay people are correct by conducting three experiments. In each experiment, we used real charity appeals (videotaped;  $n = 36$  in Study 1;  $n = 93$  in Study 2;  $n = 76$  in Study 3; see Barasch et al, 2017 for a prior analysis of donations using these video appeals). We then manipulated the communication medium that observers evaluated. In Study 1 ( $n = 678$ ), we randomly assigned observers to 1) watch only the silent video (visual condition), 2) listen to only the audio (audio condition), 3) read only the content of the appeal (text condition), or 4) watch the video and audio (full

## Expressing Dissent: How Communication Medium Shapes Dehumanization and Attitude Change

### EXTENDED ABSTRACT

Disagreement often begets incivility. When one person disagrees with another, they tend to infer not only that the other person has deficient opinions but also deficient mental capacities (Kennedy & Pronin, 2008; Pronin, Lin, & Ross, 2002). In such a way, people tend to *dehumanize* those with whom they disagree: believing that their intellectual faculties are weaker, with mental capacity more like a thoughtless animal than a thoughtful human (Epley & Waytz, 2010). Some advocates for civil discourse, therefore, have suggested trying to “humanize” interactions between ideological opponents, for example by having opponents exchange opinions in person instead of online. Can changing the communication medium by which dissenting opinions are exchanged affect dehumanization, thereby influencing attitude polarization?

Prior research suggests at least two ways in which the interaction medium could affect dehumanization. First, the medium can affect a person’s message—that is, the words he or she selects to use in the conversation. Communicators may express more antagonistic and aggressive opinions online, because online interactions increase disinhibition in part because they create emotional distance (e.g., Suler, 2004). However, writing may provide communicators with more time to carefully compose their thoughts than speaking; communicators may write more eloquently than they speak (Hayes, 1988).

Second, beyond affecting how a message is generated, the medium affects how a message is consumed. For example, hearing a person’s opinions compared to reading the same opinions makes him or her seem more mentally sophisticated and is hence humanizing, in part because cues in a person’s voice such as tone and pauses convey their intellect (Schroeder & Epley, 2015, 2016; Schroeder, Kardas, & Epley, 2017).

To test how communication medium affects humanization and attitude change, Experiment 1 recruited 396 political opponents to exchange opinions for eight minutes in a pre-registered experiment. Participants first completed a pre-survey measuring their opinions on three pre-tested contentious political and social topics (e.g., the use of GMOs), were then paired based on disagreement, and finally randomly assigned to either have a spoken or written conversation. After meeting their partner, speaking-condition pairs went to a private room to have their conversation (which we recorded) whereas writing-condition pairs went to a computer lab and had their conversation online.

When the conversations were complete, participants completed a post-survey evaluating their partner (measuring humanization using a pre-validated scale; Bastian & Haslam, 2010) and the conversation and reporting their updated attitudes. Results revealed an effect of communication medium on humanization: opponents humanized each other more when speaking ( $M=5.21$  on 7-point scale) than when writing ( $M=5.67$ ),  $F=16.38$ ,  $p<.001$ ,  $\eta_p^2=.078$ . Moreover, they reported feeling more understood by their partner, enjoyed the conversation more, and reported more attitude change,  $F=24.82$ ,  $p<.001$ ,  $\eta_p^2=.113$ . The effect of speaking vs. writing on attitude change was mediated by humanization. But they experienced no different levels of conflict during the conversation,  $p>.250$  (i.e., ratings of how emotional, heated, contentious, and conflicted was the conversation).

The effect of interaction medium on humanization could be driven either by different types of messages being created in each medium or by differences in how the messages are consumed. In Experiment 1, the “creation medium” and “consumption medium”

condition). Each observer evaluated only one condition from one speaker, and subsequently assessed the speaker’s sincerity on six pre-validated items ( $\alpha = .94$ ). Participants’ mean-level assessments of speakers’ sincerity were highest in the full and audio conditions compared to the other conditions. Additionally, a follow-up analysis revealed that observers’ sincerity ratings in the full condition were predicted most strongly by observers’ ratings in the audio condition ( $\beta = .63$ ,  $p < .001$ ), followed by the text condition ( $\beta = .53$ ,  $p < .001$ ), and least strongly in the visual condition ( $\beta = .16$ ,  $p = .35$ ).

The results from Study 1 show that hearing someone’s voice signals sincerity significantly above reading their words or seeing them deliver an appeal. However, the comparison between auditory and visual cues in Study 1 contains a confound: a person’s voice contains both semantic and auditory cues whereas a silent video contains only visual cues without semantic information. To determine whether people also attend to visual information when semantic content is present, Studies 2 ( $n = 1,376$ ) and 3 ( $n = 2,262$ , pre-registered at <http://aspredicted.org/blind.php?x=fr88n2>) added a fifth experimental condition: watching video with subtitles (“subtitled video” condition). Results from both studies showed that subtitled videos added significantly more predictive validity above silent videos alone (Study 2:  $p = .006$ ; Study 3:  $p < .001$ ) and text alone (Study 2:  $p = .01$ ; Study 3:  $p = .001$ ). These studies also replicated Study 1’s finding that audio ratings predict full ratings above and beyond text ratings (Study 2:  $p = .04$ ; Study 3:  $p = .02$ ).

To better understand the pattern of results across all three studies, we conducted an analysis with all participants ( $n = 4,316$ ) controlling for study. This analysis revealed three key findings. First, observers attributed the greatest sincerity to persuaders in the audio condition compared to persuaders in the text and subtitled video conditions, and the least sincerity to the silent video condition. That is, hearing speakers—but not seeing speakers—meaningfully increased observers’ evaluations of people’s sincerity. This might suggest that auditory cues convey greater sincerity—or less insincerity—than visual cues, or that people naturally tend to use their voice to express sincerity more than their face or body.

Second, observers relied most strongly on semantic content and auditory cues to assess sincerity; they relied relatively less strongly on visual cues. This suggests that a sincere voice may be more powerful for conveying sincerity than a sincere face.

Third, semantic content combined with non-semantic cues, either auditory or visual, predicted sincerity judgments better than semantic content alone. One implication of this finding is that the words people use are significantly limited in conveying sincerity in the absence of vocal or visual cues. Rather, it is the combination of semantic and paralinguistic cues that make one’s words seem sincere.

In conclusion, four experiments demonstrate that auditory cues may be particularly important for judging others’ sincerity, and visual cues relatively less important. While lay people recognize the significance of auditory cues, they overestimate the significance of visual cues. This research has implications for many marketing contexts where successful persuasion depends on perceptions of sincerity, from salespeople convincing customers that clothing looks good on them, to celebrities convincing the public they are sorry for a transgression, to doctors convincing patients to take certain medications. If sincere, persuaders should prioritize being heard over being seen.

were conflated, making it impossible to disentangle which aspects of the medium affected humanization. To test between the effect of the creation and consumption medium, we created transcriptions of the spoken conversations and asked research assistants matched on gender to read aloud the written conversations (recorded). In Experiment 2, online observers ( $n=994$ ) either listened or read one of the conversations and evaluated the mental capacities of each interactant on the same humanization scale that the original participants used. Observers also reported their own opinions on the topics. Therefore, Experiment 2 used a 2 (creation medium: speaking vs. writing)  $\times$  2 (consumption medium: hearing vs. reading) design: Observers either heard or read an originally spoken or written conversation.

Two main effects emerged (no interaction). First, regardless of how the conversation was created, observers humanized communicators more when they heard the conversation than when they read it,  $F=4.41$ ,  $p=.036$ ,  $\eta_p^2=.004$ , suggesting that a person's intellect is more apparent when their voice is heard than when their words are read.

But second, the effect of the creation medium indicated that written statements humanized the communicator more than spoken statements: Observers rated the communicators who wrote their opinions as being more intelligent and consequently more uniquely human than the communicators who spoke their opinions,  $F=10.25$ ,  $p<.001$ ,  $\eta_p^2=.01$ . This suggests that, at least in this context, communicators were better able to convey their intellect by writing than by speaking.

To further test whether communicators exchanged less antagonistic or contentious messages when speaking than writing, we restricted our observer sample to only those who disagreed with communicators' opinions. Again, observers humanized the communicators who wrote (vs. spoke) marginally more highly,  $F=2.87$ ,  $p=.090$ ,  $\eta_p^2=.003$ , suggesting that communicators did not create more antagonistic messages when typing.

Overall, these results suggest that how a message is consumed may matter more for evaluations of an opponent than how it was created.

In summary, how people interact influences humanization, which in turn shapes attitude change. Opponents humanized each other more during in-person (spoken) interactions than online (written) interactions and consequently reported more change in attitudes. There was no empirical evidence that individuals create more intelligent or less divisive messages when they speak (vs. write) to each other. Instead, consistent with prior research (e.g., Schroeder et al., 2017), the cues in a person's voice may convey their intellect more clearly than do their words alone. In other words, how a person's opinions are consumed (heard or read) may be even more important for humanization than how the opinions are generated (via speaking or writing).

These findings have important implications for how technology may shape discourse. People who disagree can easily interact via online forums (e.g., Reddit, Facebook), which may discourage them from conversing in-person. This work suggests that these online interactions may subtly enhance dehumanization. Disagreement is born not just from harsh words exchanged but from the structure of the interaction itself.

### **It's Surprisingly Nice to Hear You: Misunderstanding the Value of Talking (vs. Typing)**

#### **EXTENDED ABSTRACT**

Social connections improve consumer welfare (e.g., Kahneman & Deaton, 2010). Technological advances offer many different ways of connecting with others across different communication media.

But do consumers choose the medium through which they connect wisely?

We predicted that people would feel a stronger bond with another person when they talked than when they typed, because interactions involving the human voice contain cues not present in text-based media (Kruger, et al., 2005; Schroeder & Epley, 2015), cues that may affect connectedness and that must be anticipated if consumers are to choose media for engagement optimally. We further predicted that people may not recognize the value of voice-based media for promoting connection, and that preferences for communication media would instead be guided by the expected awkwardness of an interaction.

To test these predictions, we ran an initial study with 300 participants who completed questionnaires on the Friday before New Year's Eve and the following Monday. At both points, participants rated how lonely they felt (Russell, 1996). In the follow-up survey, participants reported how much time they spent interacting with others in voice-based exchanges (face-to-face, phone, video chat) and in text-based exchanges (email, texting, social media). The more time spent in voice-based interactions, the less lonely participants felt after the weekend compared to before,  $p < .01$ . The amount of time spent on text-based communication was not related to changes in loneliness.

Experiment 1 asked participants to reconnect with an old friend they were once close to, but with whom they had fallen out of touch. Participants predicted how connected and awkward they would feel if they reconnected in two ways: over the telephone (using their voice) and over email (using text). They also indicated which option they preferred. Rather than give participants their chosen medium, we randomly assigned them to either reconnect over the phone or email.

Participants expected they would feel like they had formed a stronger bond with their friend over the phone than over email, and also anticipated that they would feel like they had "really connected" more strongly over the phone,  $ps < .0001$ . However, participants also expected that they would feel more awkward over the phone,  $p < .0001$ . Sixty-seven percent of participants indicated that they would prefer to interact over email than over the phone,  $\chi^2(N=200) = 23.12$ ,  $p < .0001$ . A regression predicting choice of communication media from expected connection and awkwardness revealed the strongest effect of expected awkwardness ( $p < .0001$ ).

When they actually reconnected, however, participants reported feeling a stronger bond when assigned to reconnect with an old friend over the phone than over email,  $p < .05$ , and also reported a stronger feeling that they "really connected" over the phone,  $p = .06$ . In contrast, participants did not feel any more awkward when they connected over the phone,  $p > .7$ .

Although the results of this naturalistic field experiment suggest that the presence of voice could be producing these effects, to more cleanly test our predictions, we designed a laboratory experiment that ensured perfect response rates, constrained topics of discussion, and more carefully controlled the media through which participants interacted. In Experiment 2 ( $N=302$ ), participants engaged in a modified "fast friends" procedure (Aron, et al., 1997) and chatted with a stranger on Skype, either over video, voice, or text. The video condition allowed us to test whether providing visual cues would increase connection compared to voice alone, or whether the voice uniquely provides a sense of social connection. Before interacting, participants predicted how connected they would feel to their partner and how awkward they expected the interaction to be. Unlike Experiment 1, in which participants predicted their experience in both the voice-based and text-based conditions, predictions here were made

between-subjects. Participants in this experiment predicted no differences across communication media in either connection or awkwardness (all  $ps > .1$ ).

Participants, however, again felt more connected when they communicated in a voice-based medium than when they only used text. Adding additional cues beyond voice in the video condition did not increase connection compared to the audio condition, suggesting that it is not simply the addition of more interpersonal cues that increases the sense of connection between consumers. We also observed no differences in experienced awkwardness between communication media conditions ( $ps > .2$ ). Because we collected predicted and actual ratings from participants for only the between-subjects condition to which they were assigned, we can directly compare predicted and actual experiences. Participants across all conditions significantly overestimated how awkward their interaction would be,  $p < .001$ , and underestimated how connected they would feel,  $p < .001$ . Moreover, the difference between predicted and actual ratings of connection was greater in the voice and video conditions than in the text condition,  $ps < .05$ . Note, though, that the gap between expected and experienced connection did not differ between the voice and video conditions,  $p > .8$ . These results suggest that connecting over voice-based media creates an especially surprising bond with another person.

A final experiment ( $N=50$ ) examined whether predictions of connection or awkwardness are more likely to guide decisions in daily life by having consumers consider a variety of scenarios. For each situation, participants indicated how connected they would feel and how awkward it would be to interact over the phone and over email. They then indicated the extent to which they would rather communicate by talking or typing. Preferences were better predicted by expectations of awkwardness than connectedness. Recall, however, that our prior experiments revealed no differences in actual awkwardness across communication media.

How a consumer decides to interact with another person has important consequences for how he or she feels towards that person. These results suggest that miscalibrated expectations of awkwardness could lead people to choose communication media that may not optimize their own wellbeing. This research sheds light on how consumers choose to interact with each other and the consequences of their choices. Understanding these consequences is necessary in order to choose effectively. Voice-based media increase connection without the expected costs of awkwardness.

### **SESSION OVERVIEW**

The world is a tumultuous place. The value of currency fluctuates constantly: by the day and the hour. Consumers struggle to mind their money through fiscally responsible decisions in the midst of chronic volatility and future uncertainty (Joireman et al. 2005; Sato 2011). In addition, the Edelman Trust Barometer shows there is declining trust in government and business (Harrington 2017). To cope with financial ambiguity, consumers adopt strategies including personal budgeting (Wagoner 2011), willful cognitive disengagement, rational ignorance (Caplan 2001), and boycotting traditional markets (Yosupov 2015). With varying levels of financial literacy, consumers navigate financial decision-making using a combination of prescribed and folk/lay semantics (Baroni et al. 2011), and utilizing and foregoing institutional advice, assistance, and programming.

This session tightly ties to the ACR 2018 conference theme, "Trust in Doubt? Consuming in a Post Trust World," addressing the issue of consumer financial decision-making in a low trust context. Two questions guide this session: 1) how do consumers orient to institutions when seeking fiscal responsibility in low trust contexts and 2) how do consumers operationalize semantics to make sound financial decisions. The first paper examines consumers' efforts to use pre-commitment programs to inspire healthy habits. The author shows that consumers sign up for a pre-commitment program through their health insurance provider and voluntarily risk guaranteed financial resources to incentivize themselves to engage in healthier eating. This provider-designed program motivates compliance by linking financial and healthful decisions. The second paper investigates how indebted consumers utilize debt management programs to strategize repayment, avoid future debt obligations, and enhance financial literacy. In this study, consumers engage in semantic manipulation to distinguish needs from wants and legitimize the purchase of certain wants in well-planned purposeful ways. The third paper illustrates how consumers collaborate to stretch their financial resources by actively opposing established market institutions. The authors reveal how consumer collectives adopt an antagonistic stance toward corporations, creating deals by bundling promotions across manufacturers, retailers and third-party payers. The final paper examines

the consumption of bitcoin, a new technology-enabled peer-to-peer currency, which allows consumers to opt out of traditional institutions. The authors show how cryptocurrency enhances financial decision-making by recording and tracking financial flows. With bitcoin, financial arrangements become transparent, as exchanges are catalogued and traced. This transactional transparency subverts established institutions, creating a new standard for financial responsibility, and new semantics to convey the standards.

Taken together, these papers show an array of ways consumers act fiscally responsible in low trust contexts: institutional reliance, institutional resistance, and institutional abandonment. The first two papers show consumers relying on traditional health insurance and financial institutions to assist their money minding while the last two papers show consumers turning their backs on institutions and creating and promoting peer-to-peer systems to enhance financial decision-making. All four papers demonstrate consumers engaging in active semantic manipulation to evaluate and implement fiscal responsibility. We expect the session to generate substantive discussion from researchers interested in consumer financial decision-making, Fintech, cryptocurrencies, and peer-to-peer collaboration.

### **Silencing the Call of the Sirens**

#### **EXTENDED ABSTRACT**

One of the most important lessons from the social and behavioral sciences is that people's surroundings influence their behavior, and to a much larger degree than people realize. Of course, some people and institutions care about an individual's long-term interests: their spouses and families, perhaps their religious organizations or maybe even retirement savings and life insurance companies—but these entities are not part of their moment-to-moment environment. The environment they live in is largely made up of entities that want them (us) to be impulsive and live in the right here, right now. Facebook updates, Google alerts and Gilt flash sales are their ammunition; and by making consumers feel good in the moment, they become too focused on satisfying short-term goals at the expense of long term well-being. In essence, those who bank on how easily people will give in to temptation increasingly shape consumer behavior.

Although it may seem that technology driven temptation can only be cured by better technological innovation, our analysis will draw on ancient literature for some modern day marketplace advice. In particular, we can look to the story of Ulysses and his sophisticated approach to avoiding the sirens. As the story goes, Ulysses knew he would be tempted by the call of the sirens and tied himself to the mast of his ship so that he could hear their enchanting song, but was physically restrained from acting on his impulse to leap overboard. Similarly, he instructed his crew to go below deck before they entered the treacherous waters, so they would not even hear the sirens and be tempted to their fates. In today's world, consumers navigate a sea of sirens that constantly tempts them with deals and alerts that slowly siphon their savings and leave them drowning in a sea of debt.

In this paper, I explore how commitment devices help people make better in the moment decisions by reminding them to exercise a little bit of self-control before the temptation to over-consume becomes too difficult. Commitment devices can range from simple strategies that encourage consumers to temporarily turn off certain apps or to automatically divert a small amount of their weekly coffee spend-

ing to a savings account. Research suggests that people welcome these strategies because they do not require major lifestyle changes, but rather focus on making smaller changes to behaviors that have inadvertently become bad habits. This inquiry focuses on identifying the behaviors that are most likely to benefit from commitment devices and what factors lead to their ultimate success or failure.

To investigate my questions about the appetite and success of commitment devices we examined the results of a broad range of studies that focus on health behaviors, education, and financial decision making. These seemingly disparate topics share self-control, or a lack of self-control, as the key problem underlying poor decision making. For example, our preliminary analysis suggests that commitment devices help people make a one-time decision (such as enrolling automatic payroll contributions to retirement) because they circumvent the need for ongoing self-control. Once consumers commit to saving a portion of their paycheck, they never have to think about the choice again. I also find that commitment devices can be particularly effective at helping people make better repeated decisions – related to everyday saving and spending – which require the ongoing and persistent self-control that psychologists warn can be depleting. Finally, I also find that there are situations in which commitment devices fail – not because consumers did not want them, but because the temptation to consume was still too great. These studies highlight some important boundaries of this approach.

To supplement our empirical inquiry, my data collection and analysis also focuses on the commercially available commitment devices in the marketplace. Once again these products exist in all forms – ranging from apps (e.g., Beeminder; Stickk.com) that offer financial incentives for better self-control (exercise, weight-loss, savings, and even language learning) to smart phone controls that block access to and from certain sites. Demand for these products and services are important to understand from a cultural perspective. Although consumers welcome and embrace much of the technology that makes it easier for them to gain access to almost anything in the marketplace, they are also becoming increasingly more aware of the downsides of frictionless marketplace. As I explore their appetite for devices that help them limit their access to temptation, I learn something very important about their tolerance for an all-access and unfiltered marketplace. Based on these results, I present an informed set of policy recommendations.

### **Institutional Influence on Indebted Consumers’ Understanding of Wants and Needs**

#### **EXTENDED ABSTRACT**

In this paper, we investigate consumers’ rhetoric of want and need by examining the lived experience of indebted consumers coping with deprivation. Consumers participating in a debt management program (DMP) are living on a reduced budget as they attempt to pay off their debts. Anything that a consumer considers buying that is not clearly definable as a “need” becomes a contested decision. When tempted, we find DMP participants cleanse wants by turning them into needs; ignore constraints, at the moment of purchase and blame impulsiveness; invoke deprivation and cumulative deprivation; and actively subvert the moral norm of prioritizing “needs” over “wants.” When wanting is contested, our results indicate that consumers fluidly employ rhetorical devices and subvert budgeting practices to escape moral arguments against acquiring wanted products.

Wants and needs are foundational concepts and categories in economics and marketing. To date, consumer research has explored consumer desire qualitatively as a unique construct (Belk et al. 2003) while giving less attention to consumer experiences of wanting and

needing. Wants are typically conceptualized as being less legitimate than needs, with economists arguing that wants are artificially created by advertising. While economists generally define needs as anything urgent and necessary for survival (Galbraith 1998), marketing scholars are more likely to conceptualize needs as those goods society would deem to be “decencies” or “social necessities,” which are items needed to preserve a certain level of decency (Berry 1994; Belk 1999; Buttle 1989). Given the ever-increasing selection of goods, the broadening of status and lifestyle games in modern economies (Holt 2004; Thompson and Haytko 1998), and the ability of marketers to make luxuries seem to be basic life necessities (Hamilton and Dennis 2005), it is not surprising that consumers themselves often struggle to categorize wants and needs. The socially prescribed bundle of necessary consumer goods has increased over time in parallel with expanding credit card usage (Bernthal et al. 2005; Beaune et al. 2016; Peñaloza and Barnhart 2011), further blurring the distinction between wants and needs.

We began our study with a focus group of nine counselors at a Consumer Credit Counseling Service (CCCS) in Southern CA where the discussion centered on who succeeds in a debt management program (DMP) and why, as well as the educational approach taken with clients. The purpose of the focus group data collection was to broaden our understanding of theories applied in the field by experienced employees.

CCCS identified clients in their DMP who have email addresses. The President of CCCS sent an initial email explaining the study; we provided a link to enroll in the study and accepted participants until the sample size reached 100. Participants who completed the initial questionnaire were emailed a questionnaire link once each week for the next 11 weeks.

Participants were from a wide range of backgrounds: 73% are female, 46% are married, and 43% have children 18 or younger. Almost half were White (48%), with the remaining participants Hispanic (29%), Asian (11%), African-American (4%), Other (1%), or “decline to state” (7%). Household income is diverse, with the average falling somewhere between \$70,000 and \$79,999. Compared to the population of 71,754 individuals who visited CCCS during 2006 to 2010, our sample contains more women (73% vs. 60%), is a little younger (median age is 31-40 while the median for the larger sample is 47), and has comparable ethnicity.

Questions regarding temptation were included in each week’s survey to provide insight into participants’ thinking about wants and needs. Data were collected once per week over 12 consecutive weeks, where the questionnaire contained weekly reflections and experiences over an extended time period. By asking about recent experiences, participants’ memories were more likely to be fresh and vivid.

We also asked open-ended questions about why participants had gotten into debt, and their goals for entering the DMP. We originally believed that a client’s reason for debt (self/circumstances/mixed) would be related to success in the program, with participants who had suffered from challenging external circumstances (e.g., job loss, medical problems) being better able to cope financially in a DMP.

Consumers often draw upon mainstream discourses of want and need, that suggest wants are hedonic and unnecessary, while needs are utilitarian and urgent. In particular, because budgets are tight, participants frequently invoke the difference between wants and needs to help them prioritize expenditures. The experience of wanting appears in the narratives as a wish. Consumers are inventive when it comes to legitimating a want. We learned that participants struggled to separate wants and needs. By convincing themselves they had more discretionary income and fewer financial constraints, DMP members could then rationalize purchasing wanted products.

## Beyond Needs and Wants: How Networked Hyper-rational Economic Actors “Win” the Deal but “Lose” the Shopping Trip

### EXTENDED ABSTRACT

Traditional economic theory postulates a prevailing assumption of an actor that is both economic and rational (Persky 1995). Known as the “rational man” (Leibenstein 1976) this actor seeks to maximize value in exchange, paying little or no attention to use value and hedonic experience (Camerer and Fehr 2006). The rational economic actor is assumed to be independent, having nearly perfect market information (Hayer 1945) and the ability to accurately calculate the price of alternative market offerings (Sen 1977). We examine a specific case of rational consumer behavior where independent rational actors embedded in a technology-enabled network collaborate to construct elaborate combinations of marketing promotions, which they term “deals” (Yih et al. 2004). Combining, or “stacking” promotions that emanate from various links along the value chain (manufacturer, retailer, aggregator and third party payers), these actors collaboratively construct “deals” that maximize unintended value (Sela, Simonson, and Kivetz 2013; Thompson et al. 2015), that is realizing value grossly beyond that anticipated by the value chain partners. Consumers are also shown to perceive promotions that are unintended for them as more valuable. In contrast to what would be expected from a purely rational perspective, such savings surprisingly can inspire irrational over purchase that goes beyond any possible need or want.

Using a comprehensive netnography of the two largest “deal” forums in the United States, our data include naturalistic and participant observation, as well as interviews with both forum members and site administrators. The observational data allow us to access and catalogue ongoing behaviors and the practices they scaffold. Interviews provide members’ rationales for their behaviors, allowing us to understand the meanings behind the behaviors and the norms and order the practices enable. Forum threads are longitudinal and archived, providing a record of how the forum operates over time. Together, the observation, interviews and archived content form a robust corpus of data for our netnography (Kozinets 2002).

We find that while consumers engaged in this technological system likely have traits such as deal proneness and value consciousness (Lichtenstein et al. 1990; Lichtenstein, Netemeyer, and Burton 1995), it is the collaborative technological system that enables the identification and construction of their complex “deals.” Members of the technological system are diverse on a variety of dimensions including geography, market expertise, and experiences. Our data demonstrates that entire consumer collectives exist solely for the purpose of co-producing promotional value perceived as unintended by firms. We highlight that pursuing unintended value often requires broad knowledge and experience, factors that make online collectives particularly fertile environments for the identification and refinement of such deals. The technological system of the online forum allows such diversity to combine, resulting in the networked collective identifying promotional information to much greater degree than any one individual acting alone. The collaborative environment also enables division of labor to occur in co-production (Fuller 2010; Nambisan 2002; Muniz and Schau 2007), distributing responsibility for deal improvement among a large number of consumers, and enabling more complex deals to be developed.

We demonstrate that this collaborative environment encourages and supports enhanced economic rationality, or hyper-rationality. This is reflected by members’ extreme focus on the economic aspects of a deal (value-in-exchange), often at the expense of other consid-

erations such as time, effort, storage, redistribution, necessity, etc. A hyper-rational focus on the economic angle is understandably beneficial when identifying, constructing, and vetting deal opportunities. However, such a hyper-rational focus on the economic value of a deal can backfire, leading consumers to irrationally purchase items because they are empirically “good deals.” This includes over purchase as well as the purchase of superfluous items, either of which can result in stockpiling, gifting, and resale. Purchasing leading to such outcomes is irrational but is a byproduct of an extreme focus on rational decision-making. This suggests that the exploitation of unintended value possibly shifts consumers to focus on unintended value regardless of any need or want.

Focus on purchase rather than use is apparent in how participants often do not use the goods and services they purchase themselves. While some may sell items, such sale is typically a means of disposal and not a motivator for purchasing a deal. Instead gifting deal items to others, or engage in stockpiling for eventual, but perhaps unrealized, use is commonplace. While members do not seem to be deriving value from using their purchases, they get tremendous value from co-producing with the collective deals that provide unintended value. The processes involved in identifying and capturing such unintended value are often time-consuming and effortful, and often offer returns to a consumer that are simply not worth the time cost involved. In fact, in some cases executing such deals may be a burden to a consumer, making capturing unintended value the *only* motivator for a consumer to purchase an item. Unlike existing research identifying how communities and collectives help consumers realize value from using their purchases (Muñiz and Schau 2011), deal collectives are focused on realizing value almost solely through purchase and the unintended value that such purchase provides.

Our analysis makes several important theoretical contributions to literatures on networked economic rationality (hyper-rationality), unintended value, and promotion co-production. Through examining a consumer network that is both brand-agnostic and principally focused on finding and acquiring deals, we show that hyper-rational consumers act in concert to “win” – realizing maximal value that is unintended by marketers. This finding suggests that perceptions of winning against the marketer are a powerful motivator for consumers and one that goes above and beyond the typical affective reactions provided by a simple bargain. However, we show that “winning” in an economic sense often comes at the expense of “losing” in other arenas such as time, effort, and even money. We show that consumer co-production of elaborate, non-intuitive deals is a key driver of participation. We argue this unique form of knowledge is strengthened through networked collaboration, identifying opportunities to realize unintended value which are almost unattainable by independent actors.

## Trading Crypto Currency: The Ideological Shaping of Consumer Financial Decision Making

### EXTENDED ABSTRACT

*“A mysterious new technology emerges, seemingly out of nowhere... Political idealists project visions of liberation and revolution onto it; establishment elites heap contempt and scorn on it... technologists – nerds – are transfixed by it. They see within it enormous potential and spend their nights and weekends tinkering with it. Eventually mainstream products, companies and industries emerge to commercialize it; its effects become profound; and later, many people wonder why its powerful promise wasn’t more obvious from the start. What technology am I talking about? Personal computers in 1975, the Internet in 1993, and – I believe – Bitcoin*

in 2014.” (Marc Andreessen, Co-founder of Netscape, quoted in “Why Bitcoin Matters,” *NYTimes*, 2014)

As illustrated in the above quote, technology markets, especially those involving radically new innovations like crypto currency, are highly contested terrains, causing consumer financial decision making to be a confusing and convoluted activity. Indeed, technology consumption itself is “a complex affair, laden with history, imbued with ideologies, driven by institutions, [and] supported by society” (Kozinets 2008, 878). Yet, by privileging the experiences of (financial) technology consumers, previous consumer researchers presume that (financial) technological innovations are naturally objects of consumption (e.g., Belk 2013; Bernthal et al. 2005; Epp et al. 2014; Giesler 2008; Mick and Fournier 1998; Penaloza and Barnhart 2011; Schau and Gilly 2003; Tian et al. 2014).

In this paper we challenge this precept by adopting an institutional perspective. Specifically, we explore the role of influential public and private institutions such as governments, universities, corporations and banks in the creation of a consumable financial technology. Building on the sociology of financialization (Epstein 2005, 3), defined as “the increasing role of financial motives, financial markets, financial actors and financial institutions in the operation of domestic and international economies,” we unpack the institutional process by which new technologies (with anarchist or otherwise disruptive meanings) are transformed into objects of consumer investment and financial speculation.

Our context of inquiry is the digital crypto currency of bitcoin. Bitcoin was originally envisioned as a decentralized infrastructure that operates outside the control of centralized financial and state institutions by relying on cryptographic technologies to process electronic payments (Nakamoto 2009). Today, however, bitcoin is equated with blockchain, which is “a vast, global distributed ledger or database running on millions of devices and open to anyone, where not just information but anything of value — money, but also titles, deeds, identities, even votes — can be moved, stored and managed securely and privately” (Tapscott and Tapscott 2016b). With the recent emergence of new blockchain platforms (e.g., Ethereum) and applications (e.g., smart contracts, crowd funding), interest in cryptographic technologies has moved beyond tech-minded political activists like cyberpunks to global corporations like IBM and Microsoft, as well as to governments, regulators, and consumers around the world (Mougayar 2016).

Our data collection efforts began with a four-month immersion into the blockchain technology space in Toronto, Canada, which is known as “the global blockchain hub” (Tapscott and Tapscott 2016a). We attended bitcoin/blockchain events and conducted ten in-depth interviews with blockchain entrepreneurs, technologists, and digital strategists. To better understand the overall context of cryptographic technologies, we then expanded our data collection efforts to include bitcoin/blockchain related books, newspaper articles, as well as industry, government, and company reports published in and beyond Canada. We complemented this archival dataset with a netnography of bitcoin/blockchain blogs, discussion forums, and podcasts.

Our analysis identifies the ideological struggles between techno-libertarian and techno-collectivist interests in transforming blockchain from a radical to a market-compatible technology. Techno-libertarians prioritize the individual and freedom of choice, while attempting to minimize the scope of state coercion in solving social and economic problems. Conversely, techno-collectivists believe that cyber-choices should be guided by the State according to public interest (Dahlberg 2010; Winner 1997). We find that transforming a radical innovation, such as blockchain, into a technology consump-

tion system requires the depoliticization and translation of techno-collectivist expectations and demands into consumption and market-compatible technology definitions. This is achieved by adopting the Californian ideology (Barbrook and Cameron 1995), which is defined as “a bizarre mish-mash of hippie anarchism and economic liberalism beefed up with lots of technological determinism.” Specifically, we have identified an institutional process that consists of three strategies: imagineering, through which disruptive technology visions are depoliticized and turned into market-compatible visions; validating, where the new market-compatible technology vision is verified by techno-visionary experts; and reconfiguring, where the new market-compatible technology vision is materially instantiated in the form of use-studies, hackathons, crowd-funding platforms, etc.

### **SESSION OVERVIEW**

People constantly make probability judgments, and believe those judgments to be strong predictors of actual outcomes (Lieberman and Tversky 1993; Reyna and Brainerd 1994; Ronis and Yates 1987). In the last few years, however, we have witnessed mishaps of inaccurate estimations of probabilities yielding unexpected outcomes all around the world. For instance, vast majority of media predicted a significantly high chance of U.K. voting against Brexit as well as Clinton winning the 2016 U.S. presidential election. Yet the actual outcomes left the world with one less country in the E.U. and President Trump. These incidents allude to the possibility that people are not as accurate as they expect themselves to be when it comes to estimating probabilities (Tversky and Kahneman 1974). If that indeed is the case, what factors bias people to inaccurately make probability judgments? And if these inaccurate judgments are so prevalent, do people derive satisfaction from accurately making these judgments? In this session, four papers answer these questions by examining various aspects of probability estimates.

The first two papers explore the impact of contextual factors related to numeric and visual cues on probability perceptions. Specifically, Sevilla and Bagchi investigate the effect of numeric roundness on probability perception. They show consumers perceive predictions that end with non-round numbers (e.g., 29%) as more likely to occur than with round numbers (e.g., 30%) because consumers perceive non-round numbers as more concrete and easier to materialize.

Relatedly, Duclos and Khamitov examine how different visual representations of the same numeric information influence gamblers' perceived probability of winning. They show that manipulating the visual representation enhances the ease of processing probability, which then artificially inflates gambling behavior.

The next two papers look at how motivational factors affect antecedents and consequences of making probability judgments. Hong, Longoni, and Morwitz provide an alternative, motivational account in explaining the effect of physical distance on the probability estimates. Because people have self-enhancing motives to keep positive elements close and push negative ones away, the authors document that people predict positive events to be more likely to occur if they are physically close (vs. far), whereas negative events are seen as less likely if physically close (vs. far).

Finally, Morewedge, Russman, Mijovic-Prelec, and Prelec examine how two conflicting motives – self-enhancement and self-verification – jointly affect consumers' satisfaction from being accurate. In five experiments, people made guesses about facts and outcomes that each had 50% chance of being correct. The findings indicate that people derive pleasure when they correctly guess the answers even when the answers imply misfortunes to themselves and the world.

We now live in a dynamic and unpredictable world in which the news media are not always trusted but are rather doubted. At times like this, people inevitably rely on heuristics which can easily bias their perceptions of the world (Tversky and Kahneman 1974). The four papers in this session unearth contextual and motivational factors that influence one of the most prevalently made judgments: probabilities. In so doing, they document new biases consumers should be aware of.

## **How Numeric Roundness Influences Probability Perceptions**

### **EXTENDED ABSTRACT**

Consumers routinely make choices associated to their preferences for particular numbers (e.g. Boyd 1985; King and Janiszewski 2011; Pavia and Costa 1993). These choices involve preferences for alphanumeric brand names (e.g. Boyd 1985; King and Janiszewski 2011; Pavia and Costa 1993), the selection of PIN numbers or passwords, sports jerseys' numbers or even gambling or lottery tickets. This last type of numeric choice differs slightly from the rest. While all of them involve the choice of number related items based on their preferences for them, in the case of lotteries the selection is closely associated to the perceived probability that the chosen number may be randomly drawn. Similarly, consumers often need to make purchase decisions based on other forms of probabilistic assessments based on numbers. For example, they need to decide what type of insurance to buy or what medical procedures to get based on probabilities expressed with numbers or percentages.

The current paper tackles the question of what type of numeric formats consumers prefer and find more likely to materialize in this type of contexts. Specifically, we study how the roundness of a number affects probability perceptions and preferences associated to it. In contrast with past work on numeric fluency and roundness, which demonstrates that consumers have a preference for round numbers (e.g. Dehaene and Mehler 1992; King and Janiszewski 2011; Kirby and Schindler 1997), we show that in lottery and other probability related contexts, people have a preference for non-round numbers, as they believe these have higher probabilities of occurrence. We propose that this occurs because odd numbers are usually perceived as being more concrete or real, while round numbers are often seen

as more abstract or general, as people often use them to round out numeric information (e.g. Dehaene and Mehler 1992).

The effect presented in this work focuses on the contexts of lotteries and the evaluation of probabilistic information expressed in percentages. We conducted four experiments to provide evidence for the effect of numeric roundness on probability perceptions and preference. In our experiments, round numbers were operationalized as those ending on “0” or “5” (Dehaene and Mehler 1992). Experiment 1 tested the ecological validity of the effect and employed real life data from the Mega Millions lottery. We looked at the randomly drawn winning numbers of this lottery during a span of more than 13 years and found that while overall randomly drawn winning numbers were not more or less likely than chance to be round ( $z = 1.01, p = .31$ ), this was not the case for randomly drawn winning numbers that were claimed, as these were less likely than chance to be round ( $z = 2.26, p = .02$ ). This finding is consistent with our prediction, which proposes that people are less likely to buy round ticket numbers as they are perceived as being less likely to be drawn as winners.

Experiment 2A was a computer based study where participants were told that they would be participating in a lottery in which they could pick one ticket number among four potential two-digit options. Two of these numbers were round (“10” and “50”) and the other two were not (“37” and “89”). Participants were told that if the number they selected matched the last two digits of the winning number of the upcoming Mega Millions lottery, they would be receiving a \$20 prize. As expected, we found that non-round numbers were selected at a rate more likely than chance ( $z = 5.77, p < .01$ ). Experiment 2B was a similar design and offered the same incentive as Experiment 1A but differed from this in that participants were allowed to select any number from 0 to 99 as their winning number. Again, we found that non-round numbers were chosen at a rate that was more likely than chance ( $z = 12.41, p < .01$ ). This design constituted a more robust showing for the effect as past research has shown that round numbers are more likely to be generated (Dehaene and Mehler 1992) and that was not the case in a context involving probabilistic assessments.

Experiment 3 extended the effect to the domain of selecting insurance policies. In this case we provided participants with probability information associated to a natural disaster and found that those who were exposed to probabilities expressed with non-round numbers expressed a higher likelihood of buying insurance than those exposed to probabilities expressed with round numbers, even if these numbers were slightly higher ( $\beta = .65, Wald = 4.61; p = .03$ ). Furthermore, this study showed that the effect was mediated by how concrete the target numbers were perceived to be ( $\beta = .24, 95\% CI: [.07, .56]$ ).

Together, this set of studies demonstrates that non-round numbers may be preferred in contexts involving probabilistic assessments, as these are associated to higher likelihood of occurrence. We show that the effect is mediated by non-round numbers being perceived to be more concrete than round numbers.

### **Thou Shalt Not Look! When Processing the Odds Visually Biases Gambling Behavior**

#### **EXTENDED ABSTRACT**

Scant research has examined directly and experimentally how consumers absorb visually and process quantitative information to, in turn, make financial decisions (Raghubir and Das 2010; Duclos 2015). Aiming to contribute to this literature, the present work investigates how visual biases in data-interpretation influence gamblers’

perceptions of their probability of winning and, consequently, the amount of money they bet.

Breaking ground in this area, Raghubir and Das (2010) initiated a line of work dedicated to how visual displays of quantitative information bias risk-perceptions. When reviewing financial performance on a graph, investors do not consider every datapoint equally. Rather, they sample the local minima and maxima to infer variation around a trend line and, in turn, estimate risk. Accordingly, the higher the *run-length* (i.e., the greater the number of consecutive movements in the same non-horizontal direction), the further apart are the local minima and maxima. And as the distance between minima and maxima increases, so do perceptions of the underlying asset’s riskiness.

Building on this work, Duclos (2015) examined how visual biases in data-interpretation impact actual risk-taking. Lo and behold, the author finds that investors attend disproportionately (and unduly) to the last trading days of a stock. Graphs depicting a stock-price closing upward (downward) foster upward (downward) forecasts for tomorrow and, accordingly, more (less) investing in the present. Coined *end-anchoring*, this bias occurs even when stock-price distributions are generated randomly (i.e., when no upward/downward trend can be identified in the data).

The present work extends the above research stream by examining (i) another form of visual aid, (ii) another form of quantitative information, and (iii) another form of financial decision. Namely, drawing on fluency theory, four experiments examine how gamblers visually process quantitative information (i.e., their odds), forecast their chance of winning, and bet.

Using variants of roulette wheels as experimental paradigm, study 1 shows that manipulating the visual (i.e., graphic) representation of probabilities (not probabilities themselves) can artificially increase gambling. That is, wheels depicting odds in large (small) blocks led gamblers to bet more (less) even though the statistical likelihood of winning remained identical across conditions. Study 2 replicates these results using a between-subjects design and a consequential dependent variable.

Study 3 replicates these findings while shedding light on the underlying process. Namely, increasing processing fluency by lumping together (i.e., in large blocks) the odds of winning on a roulette wheel inflates the perception one has of his likelihood to win, which in turn escalates the amount of money bet. However, encouraging gamblers to process their odds numerically (rather than visually/graphically) helps lessen this bias.

Providing converging evidence, this time in a simulated-casino setting, study 4 brought people to the lab to play a real-world game of roulette. We find again that manipulating the visual presentation of probabilities can sway gambling behavior predictably and substantially.

Methodologically, three of the four studies place participants in situations to actually win and lose money. In terms of populations surveyed, experiments 2 and 3 recruited M-Turk volunteers whereas experiments 1 and 4 relied on university students. Regardless of methods or samples, the four studies produce convergent evidence testifying to the robustness of the phenomenon and lending credence to our theorizing.

Most of the extant literature on gambling has revolved around either the psychopathology of betting behavior (Cyders and Smith 2008; Rodda et al. 2013) or the economics of gambling (Grinols and Mustard 2001; Littlewood 2011). To date, however, relatively little is known about the context effects of gambling (e.g., how *the environment at the time of gambling* manipulates bets). To this end, the present article focused on the biasing effects of the visual representation of odds. Our findings are important because they (i) document a bias

not yet accounted by the judgement and decision-making literature, and (ii) shed much-needed light on how humans absorb and process quantitative information (Duclos 2015; Raghubir and Das 2010).

These findings also contribute to the perception literature by documenting a novel pathway via which perceptions influence cognitions and behavior. Specifically, by documenting when and how the encoding of visual stimuli (e.g., seeing small vs. large blocks) can shape betting decisions, this article unearths and explains a context-effect not yet accounted by the literature. So doing, our work echoes and extends that of Deng et al. (2016) who also invoke processing fluency to explain why seeing products assorted horizontally (rather than vertically) is usually preferred.

Lastly, our findings contribute to the anchoring literature. Anchoring research revolves around the notion that seemingly-innocuous pieces of data encountered at time 1 have unanticipated consequences on judgement and decision-making at time 2 (Tversky and Kahneman 1974). Our results suggest that a different form of anchoring operates on decision making. This anchoring is just as spontaneous and automatic as the one described before us but its nature is more *perceptual* than cognitive. Indeed, in our paradigm, we did not rely on any heavy-handed manipulations (e.g., fixating respondents' attention on a specific number) to produce our results. Rather, we merely (dis)aggregated the visual representation of statistical data (i.e., increased or decreased the size of landing slots in roulette wheels) in order to sway processing fluency. Accordingly, our findings extend recent research by Raghubir and Das (2010) and Duclos (2015) by establishing perceptual anchoring as powerful influence on financial risk-taking, a phenomenon not yet accounted by the literature. We conclude by hoping this work will help spur interest in how people process quantitative information.

### Proximity Bias: Interactive Effects of Event Valence and Event Nearness on Probability Estimates

#### EXTENDED ABSTRACT

Probability judgments are ubiquitous—from estimating the chance of landing a job, to predicting the movements of the stock market—and typically plagued by numerous errors and biases (Kahneman and Tversky 1973). We add to this stream of research by identifying a novel *proximity bias* in probability judgments, whereby event valence and event nearness systematically interact in determining probability estimates.

When it comes to the relationship between event valence and probability estimates, a robust finding is people's tendency to predict that they are less likely than others to experience negative events, and more likely than others to experience positive events (Perloff and Fetzer 1986). This optimistic bias is so pervasive that some consider it an adaptive regulatory function for protecting the self (Taylor and Brown 1988).

We extend this research by uncovering a novel bias: That proximity of an event moderates people's optimistic bias in probability judgments. Specifically, we theorize that the physical nearness of an event accentuates self-enhancing tendencies when predicting positive events, and self-protective tendencies when predicting negative events. Across five studies we manipulate (a) the valence of an event (i.e., whether the outcome of an event is positive or negative) and (b) the physical proximity of this event (i.e., whether the event takes place in a location that is nearby or far away), and then measure people's probability estimates. We consistently find interactive effects of event valence and nearness, such that near, positive events are predicted to be more likely than near, distant events. On the contrary, near, negative events are predicted to be less likely than distant,

negative events. Boundary conditions underscore the motivational underpinnings of this bias.

In study 1 ( $n = 284$ ), participants read a lottery scenario. Participants in the positive condition were told there was a 60% chance of winning a lottery for a laptop. In the negative condition, we told them there was a 60% chance of losing the lottery and the \$20 they had paid to participate. We manipulated proximity by describing the lottery draw taking place in a location that was nearby or far away. We measured probability estimates as the likelihood of winning (positive condition) or losing (negative condition) the lottery. Significant valence vs. proximity interaction ( $p < .01$ ) revealed that winning the lottery seemed more probable when the draw took place nearby than far ( $p = .03$ ). Conversely, losing the lottery seemed less probable when the draw occurred nearby than far ( $p = .05$ ). In study 2 ( $n = 295$ ), we replicated the same findings with two different events where positive event is not the opposite of negative event.

In study 3 ( $n = 485$ ), we directly examined the hypothesized motivational nature of this bias. We hypothesized that the proximity bias is due to a tendency to be self-enhancing with respect to positive outcomes and self-protecting with respect to negative outcomes. If this is indeed the case, it follows that this bias should emerge for probability estimates made for a self-relevant outcome, but not for a self-irrelevant outcome. In a job-offer scenario, participants read that a hiring decision would take place in either a close or far location. Participants estimated the probability of either getting an offer (positive-condition) or not getting an offer (negative-condition), for either themselves (self-relevant-outcome) or another similarly qualified candidate (self-irrelevant-outcome). Results revealed significant three-way valence x proximity x relevance ( $p = .01$ ) and two-way valence x proximity interactions for the self ( $p < .01$ ) but not for other ( $p = .43$ ). As predicted, participants estimated they were more likely to get an offer when the event was close than far ( $p = .04$ ), and less likely to lose an offer when the event was close than far ( $p = .04$ ), but this effect did not emerge when estimating likelihood for another individual.

Providing converging evidence for the motivational account, in the next two studies, we manipulated (un)desirability of an outcome while keeping outcome valence constant. We expected to replicate our previous results in case of a highly (un)desirable outcome. However, we expected an attenuation of the proximity bias in case of a less (un)desirable outcome. In study 4A ( $n = 607$ ), participants estimated the likelihood of highly undesirable and moderately undesirable outcomes. Participants read that they were experiencing symptoms that could indicate either a severe disease or a mildly severe disease. They were further told that their blood sample was being tested at a hospital located 2 miles or 200 miles from where they were. Participants then estimated the likelihood of testing positive for the disease. When considering a highly undesirable outcome, participants predicted that they were less likely to contract the severe disease when the hospital was located nearby ( $M = 37.78\%$ ) than far ( $M = 45.62\%$ ;  $p = .006$ ). When estimating the likelihood of contracting the mild disease, however, that difference disappeared ( $M_{close} = 46.34\%$ ,  $M_{far} = 45.90\%$ ;  $p = .88$ )

In study 4B ( $n = 385$ ), we used positive outcomes only. Using a simulation of an online-dating app, participants viewed the profiles of two potential dates who were either nearby or far away (between-subjects), and whose attractiveness varied (within-subjects). Participants estimated their probability of getting successfully matched with both dates. As expected, when considering a highly desirable date, participants predicted that they were more likely to be successfully matched if the potential date was nearby ( $M = 58.69\%$ ) than faraway ( $M = 50.91\%$ ;  $p < .001$ ). However, the difference was weak-

er when considering a moderately desirable date ( $M_{close} = 48.97\%$ ,  $M_{far} = 46.37\%$ ;  $p = .34$ ).

In summary, we extend prior research on biases in probability judgments by documenting a novel proximity bias. Importantly, by corroborating the motivated nature of the effect, we demonstrate our findings cannot be accounted for by existing theories explaining how people make probability judgments, such as construal level theory (Wakslak and Trope 2009; Wakslak 2012), which is agnostic to motivated reasoning effects on predictions. In so doing, this research extends prior work on biases in judgments and decision making.

### The Pleasure of Being Right (Even When the World Is Bad)

#### EXTENDED ABSTRACT

Conflicting motivations are at work in the resolution of uncertainty. On the one hand, people have a positivity bias. When people are not 100% sure about particular outcomes, they anticipate and want such uncertainty to be resolved in favor of themselves and their world (e.g., Batson 2014; Bentham 1789; Kunda 1990; Taylor and Brown 1988). People even explicitly wish that they were more optimistic about future outcomes than they already are (Armor, Massey and Sackett 2008). On the other hand, people have a motivation to be accurate. They seek feedback that confirms they have a valid perception of themselves and their world (e.g., Swann, Pelham, and Krull 1989).

We examine how these conflicting motivations influence responses to the resolution of uncertainty. When events do not guarantee either better or worse resolutions, which motives influence how people feel about those resolutions? Are people uniformly happier when there is a high probability of world turning out to be good than bad? Or do people take some pleasure in being accurate, even when it means that the world is bad? Across five experiments, we show that people derive pleasure from predicting outcomes that are uncertain, regardless of the valence of those events.

In our first experiment, we asked participants ( $N = 123$ ) to guess the lifespan of a series of animals (e.g., dolphins, cats, penguins). For each question about an animal, participants had a 50% chance of guessing the correct answer. Specifically, they were shown two values—a shorter and a longer lifespan—and then guessed which was the correct lifespan. The values were counterbalanced across participants so that for some, the correct answer was higher and for some it was lower. After each guess, the correct answer was revealed and participants reported how they felt about the answer on a 100-point scale with endpoints, 0 “Terrible” and 100 “Wonderful.”

In a “bad news” condition, for instance, participants saw a picture of an indoor cat and two values of lifespan, 28 years and 14 years, and then guessed which of the two is the correct lifespan. In a “good news” condition, the two options were 14 and 7 years. All participants then learned that the real lifespan of an indoor cat is 14 years, and reported how they felt about that fact.

Not surprisingly, participants were happier when the resolution of uncertainty was good (14 rather than 7) than bad (14 rather than 28). More important, participants were happier when they learned that they correctly guessed the answer than when they did not, regardless of the resolution. In other words, participants were also happier in the “bad news” condition when they correctly guessed the shorter lifespan.

We replicated and extended the first study in a second experiment in which participants ( $N = 111$ ) made three kinds of guesses in a similar paradigm: the lifespan of people living in different countries, the lifespan of different species of animals, and the lifespan

of species of plants. We found the same pattern of results across for all three targets (humans, animals, and plants). Participants again were generally happier when the resolutions were good than bad, but were happier with bad news when they had correctly predicted that people, animals, and plants lived the shorter lifespan.

To address the possibility that taking pleasure in foreseen misfortunes is due to the fact that accuracy about “bad” facts provides valuable diagnostic information about the self (e.g., that one possesses valuable information about the world), we tested this effect in two additional experiments in which participants predicted random probabilistic good and bad outcomes: Participants guessed whether a coin would land heads or tails.

In Experiment 3 ( $N = 169$ ), participants estimated the outcome of another person’s misfortune. If the coin landed heads, another person would win the money equivalent in value to coin. If it landed tails, that person would lose its equivalent value. Participants again exhibited pleasure in foreseeing misfortune. In fact, participants were happier when they correctly guessed that the person would lose money than when they incorrectly guessed that the person would win.

In Experiment 4 ( $N = 100$ ), the person who won and lost money was the participant herself. Even in this case, participants were happier when they accurately predicted their own misfortune than when they inaccurately forecasted their fortune.

A fifth experiment ( $N = 109$ ) ruled out an alternative account that surprise may underlie these effects. Accurate participants were insensitive to whether another person won or lost money, but were happier when their guess was right than wrong, whether the odds of good and bad outcomes were 10%:90%, 50%:50%, or 90%:10%, respectively.

Our findings illustrate how optimism and accuracy motivations influence a new facet of uncertainty resolution—its hedonic impact. All things equal, people are happier to discover that the world is good than bad. However, people do see a silver lining and take pleasure in predicting the accurate outcomes in the first place, even if those outcomes imply that the world is bad.

## **SESSION OVERVIEW**

Decisions about money are among the most consequential ones for consumers, influencing not only their financial well-being, but also happiness, relationships, and other aspects of life. However, do consumers think of money in the way that is assumed by economic principles? Moreover, how can consumers achieve long-term financial success? A deeper understanding of the consumer psychology around money, and financial decision-making more broadly, can inform recommendations, and this session provides new insights.

The first two papers offer new views on the cognition of money. Money is a *value symbol* that serves as a *fungible medium of exchange* (Furnham and Lewis 1986). However, consumers' cognition of money does not always align with this normative definition. For example, research on mental accounting (Thaler and Johnson 1990) challenges the fungibility aspect of money -- and the first two papers continue this pursuit. Specifically, Paper 1 (Li and Tu) proposes that consumers view money as if it is a (non-fungible) material object, rather than a fungible medium of transaction. As a result, consumers feel a lingering sense of connection to the money they previously possessed (i.e., their ex-money) after money exchange, and thus feel further connected to the outcome associated with their ex-money. The authors dub this effect the 'ex-money effect,' and explore its behavioral implications and boundary conditions. While money is often used as an objective measure of the value for objects and resources, Paper 2 (Polman and Maglio) investigates whether people's valuation of money itself can be subjective. Building on the literature of psychological distance, the authors propose and document that people believe the same amount of money has more purchasing power when it is perceived to be closer, and discuss its implications on the science of spending and saving.

The latter two papers present new evidence on the effectiveness of different money management strategies. Paper 3 (Kan, Fernbach, and Lynch) focuses on budgeting and argues that, although budgeting mitigates overspending in the current period, it (1) makes spending less enjoyable and (2) gives people license, both resulting in an in-

crease in spending in the next period. Across three field experiments and one longitudinal dataset, the authors demonstrate that the impact of budgeting on long-term financial success is limited. Finally, although saving for retirement is usually deemed as a personal financial activity, through a large-scale field experiment, Paper 4 (Shah et al.) identifies that securing one's family's financial future might be more motivating in making people save for retirement. Compared to more typical individualistic appeals, a family appeal exerted a long-term effect (6 months after the prompt) and was most effective for a middle-aged group.

Through multiple angles and various scopes, the four papers in this session offer new insights on the interrelated cognition (papers 1 and 2) and management (papers 3 and 4) of money that together influence consumers' financial well-being. This session will appeal to a wide audience interested in financial decision-making, judgment and decision making, and transformational consumer researchers who aim to impact societal well-being and public policy.

## **The Ex-Money Effect: When and Why People Feel Connected to Outcomes that Involve Money They Previously Had**

### **EXTENDED ABSTRACT**

Money is the most common medium of exchange which frequently changes hands. Normatively, after consumers exchange money for resources of equivalent value, where their previously held money goes next and what it generates should be personally irrelevant. For example, suppose a friend helped you break a \$10 bill (you gave her a \$10 bill and she gave you \$10 worth of change) and later donated the \$10 bill she received to UNICEF or spent it on lottery tickets. Since you (the previous holder of that \$10 bill) no longer own that \$10 bill after the exchange (it's your "ex-money") and did not make the donation/purchase decision, neither UNICEF nor the lottery outcome would become more personally relevant. However, this paper documents the "ex-money effect"—that people feel connected to outcomes of their previously held money—and explore its mechanism, boundary condition, and downstream consequences.

We propose that, although money is a fungible medium of exchange that only symbolizes value, people (1) perceive money possessed by different individuals as non-fungible (Polman, Effron, and Thomas 2018; "my \$10 bill is different from your \$10 bill") and (2) treat money as a material good whose concrete physical features (e.g., bills, coins), not just its abstract value, matter (Mishra, Mishra, and Nayakankuppam 2006; Raghurir and Srivastava 2009). Because people feel lingering ownership of (non-fungible) material goods after transaction (Brough and Isaac 2012), to the extent they conceptualize money as a non-fungible material good, they should feel the same for money that left their possession. Consequently, people feel concerned with the outcomes of their ex-money. Further, because the physical features of money matter, we predict that the ex-money effect should attenuate when ex-money changes form. Next we report 4 studies that demonstrate the ex-money effect and its downstream consequences.

Study 1 established the main effect. Participants imagined lending a friend a \$10 bill and getting another \$10 back later. They further imagined that their friend bought some lottery tickets using the \$10 bill borrowed from them (vs. a \$10 bill from his/her own

wallet) and a CD using a \$10 bill from his/her own wallet (vs. the \$10 bill from them); the lottery purchase resulted in a \$1,000 prize one month later. Supporting our hypothesis, participants reported a greater personal connection to their friend's lottery winning when the friend (incidentally) spent their ex-money on lottery (vs. CD) (4.41 vs. 2.81;  $t(64) = 3.31, p = .002$ ). Consequently, they felt more deserving to share the lottery prize (3.16 vs. 2.06,  $t(64) = 2.64, p = .010$ ) and claimed a larger amount (\$127.81 vs. \$36.18;  $t(64) = 2.80, p = .007$ ) in the former condition. A set of follow-up studies replicated these effects when participants assumed the role of the money borrower or a third-party observer, suggesting that the ex-money effect stems from a shared conceptualization of money that is independent of one's role or interest. We also replicated these effects when presenting these two scenarios in a within-participants manner, suggesting that people do not consider the ex-money effect irrational (albeit it is counter-normative).

Study 2 replicated the ex-money effect using a behavioral proxy. University students learned that their university spent income from tuition and fees in the previous fiscal year (i.e., their ex-money) on private equity investment (PEI) or another project and could choose to learn more about the investment. Although participants had exchanged tuition for education and access to university facilities and we made it clear that reading the information was not obligatory, those who learned that their ex-money went in PEI were more likely to seek information about it (16%, 14/88 vs. 4%, 4/89;  $\chi^2(1) = 6.31, p = .012$ ), which suggests a greater sustained connection.

Study 3 tested the proposed boundary condition—a change of the physical form of one's ex-money, using a 2 (ex-money usage: lottery vs. CD)  $\times$  2 (ex-money form: unchanged vs. changed) between-participants design. We used a lottery-purchase scenario similar to that in study 1, except that in the form-changed conditions the friend changed the \$10 bill into coins and subsequently used the coins to buy the lottery tickets or the CD. A 2  $\times$  2 ANOVA yielded the predicted interaction effect on perceived connection to the money used in lottery purchase ( $F(1, 216) = 4.96, p = .027$ ) and perceived deservingness of some prize ( $F(1, 216) = 3.38, p = .068$ ); the ex-money effect replicates when the format stayed unchanged (3.23 vs. 1.96;  $F(1, 216) = 18.65, p < .001$ ) but attenuated following a format change (2.28 vs. 1.76; ns).

Study 4 explored the potential of using the ex-money effect as a minimalistic nudge to promote desired behavior – increasing support for a seemingly unattractive yet important charity: UNICEF. We asked participants to bring a \$10 bill to the lab for a cover study titled “bills in circulation.” After participants completed a related questionnaire, we collected their \$10 bill and gave them a different \$10 bill in return. We told participants that after the completion of the cover study, we would donate these bills to UNICEF (pretested to be unattractive) and WWF (pretested to be attractive); critically, the money collected in the lab session they attend would go to “UNICEF,” or “WWF,” or “UNICEF and WWF” (baseline). On their way out, participants could choose to wear either a UNICEF or WWF sticker to show their support. Learning that one's ex-money would go to UNICEF increased choice of wearing the UNICEF sticker compared with the baseline (59.6% vs. 25.9%;  $\chi^2(1) = 12.31, p < .001$ ) (whereas the WWF condition shows a ceiling effect compared with the baseline (81.1% vs. 74.1%; ns)).

Taken together, this paper makes three related contributions. First, we document a counter-normative effect. Second, we provide a novel theoretical account—the ex-money effect stems from people conceptualizing money as a non-fungible material good. Third, because private and public organizations transact with consumers daily, we suggest that ex-money effect can be utilized as a minimalistic

and low-friction nudge to promote desired behaviors following such transactions.

## Money and Psychological DiStance

### EXTENDED ABSTRACT

How “far” can money go? Economists operationalize the purchasing power of money as the amount of a given good or service that can be purchased for a fixed sum of money. Thus, when people estimate how far their money can go, they are guessing how much they can buy with a certain monetary sum. In the current research, we propose that people act as if money can go farther when it is felt as psychologically closer. Traditional economic theory has not considered whether purchasing power of money varies according to whether money is subjectively close or far, yet should this factor exert a substantial influence on money's worth, it could result in making adjustments to traditional economic analyses, which are thought to depend heavily on perceptions (Bernanke 2007).

Addressing the question, “how far can money go?” requires defining the perceived value of money. At first blush, it might seem peculiar to generate a prediction about the value of money, because value is money's most fundamental and essential quality, and value is often defined in monetary terms. For instance, in studies on the endowment effect (Morewedge and Giblin 2015), it is typical to ask participants how much they value something – from mugs to the environment – in monetary terms. Yet research has found that people value money differently, and that the same amount of money can seem like a subjectively higher or lower amount (as though it is more or less valuable), depending on the situation (for a review, see Bijleveld and Aarts 2014).

Despite research conducted so far on the subjective value of money, the notion that psychological distance could affect money's perceived purchasing power remains an open but important question for marketing, especially as an increasingly globalized and dynamically changeable economy makes distance more ubiquitously salient in everyday monetary transactions. Here, a critical question is what may determine the subjective value of close money in relation to distant money – and likewise what it means when people judge money as “close” or “distant.” The unique perspective offered by recent conceptualizations of psychological distance (Lieberman and Trope 2014) proposes a framework through which to investigate how far money can feel, and how far money can go. When people think about how close or distant something feels, they can think about it along a number of distinct dimensions: along temporal distance, geographical space, social space, and likelihood (Trope, Liberman, and Wakslak 2007). For each of these dimensions, money can be psychologically distant when it is set apart from one's direct experience. Which is to say that money is respectively close or distant when it, for example, encompasses current versus future earnings (temporal distance); is tracked in one's own versus foreign countries' stock markets (spatial distance); belongs to one's spouse versus an acquaintance (social distance); or furnishes the prize of a relatively high-chance versus low-chance lottery (hypothetical distance).

Of most relevance to the current context of money, research comparing decisions about people, places, events, or things that are proximate to the self (versus more distant) has provided evidence consistent with the idea that distance can have a “shrinking effect” (Maglio, Trope, and Liberman 2013). For example, study participants reported that a 3-month period starting in 12 months felt shorter than a 3-month period starting in the present (Zauberman, Kim, Malkoc, and Bettman 2009). Likewise, the number of calories comprising a food item was estimated to be lower among participants primed

with greater (versus proximate) distance (Williams and Bargh 2008). Building on and extending this research, we predict that, when thinking of money, people will think that money is smaller when imagined at a greater psychological distance.

In three studies, we asked 1403 participants to rate the perceived purchasing power of money in conditions in which the money was made to feel close or distant. Extending earlier work on psychological distance, we used new manipulations of psychological distance (studies 1 and 2) as well as a previously-used manipulation (study 3). Throughout, the results showed that holding the sum of money constant, people believed they could buy more products with a subjectively close (versus distant) amount of money.

In study 1 ( $N = 500$ ), we manipulated how close money feels by changing its unit of measurement from a whole amount (\$100) to an equivalent amount of money that is framed in smaller parts. Based on previous work on the unit-scaling effect, which describes that distance appears closer when measured in fewer-larger units than in many-smaller units (Maglio and Trope 2011), we found that money framed in fewer-larger units was felt as closer, and had more purchasing power,  $d = 0.27$ .

In study 2, we shed more light on psychological distance by manipulating whether 263 participants thought about an increasing or decreasing amount of money. Consistent with recent research on psychological distance (Maglio and Polman 2014, 2016), participants responded to increases and decreases of their money in a predictable way, believing that when money increased, they could buy more with it than when it decreased (despite the sum of money being the same after each change),  $d = 0.31$ .

Finally, in study 3, we examined how much 672 participants contract money when money is perceived from afar, by having participants specify the perceived value that corresponds to the length of a line. Because we predicted that psychological distance subjectively contracts (“shrinks”) the value of money, people should perceive the line to cover a smaller segment of a money’s sum, which we found to be the case,  $d = 0.16$ . Furthermore, we found that when it is included as a separate variable in a regression model, it absorbs a significant part of the variance between money’s distance and its perceived purchasing power (consistent with a mediation model).

In closing, our research informs the science of spending and saving. By linking the work on psychological distance with money, our research shows how psychological distance influences a fundamental perception on which almost all choices that people make rest: what consumers think they can acquire in exchange for their money.

### Personal Budgeting: Does It Work?

#### EXTENDED ABSTRACT

Budgeting is a commonly recommended financial activity, and about half of Americans report keeping a budget (FINRA, 2016). Despite its prevalence however, there is little systematic evidence on whether budgeting actually helps people achieve their financial goals over the long term. Research in mental budgeting and mental accounting has explored the potential benefits and unintended side effects that can arise while budgeting (Zhang and Sussman, 2017), but much of this work has focused on short time frames. Survey evidence has concentrated primarily on propensity to engage in budgeting and its correlates (FINRA 2016, CFPB 2015), such as demographic factors and financial outcome measures, but it is difficult to draw causal conclusions. The present work aims to fill this gap.

We explore the effects of budgeting in both the short run and the long run. Aspects of budgeting, such as setting and tracking, increase the clarity with which people understand their own personal finan-

cial situation, but this clarity can have both positive and negative consequences.

In the short run, setting a budget can help to translate abstract goals into clear standards (Krishnamurthy and Prokopec 2010), which are an important part of successful self-regulation (Baumeister 2002). Thus we suggest that setting a clear budget should help people to mitigate overspending. We test this in study 1. Participants from mTurk completed a two-phase study over the Black Friday shopping weekend. Prior to Black Friday, participants were randomly assigned to budget for their Black Friday gift shopping in a manner such that their total spending limit was either clear (budgeted gift recipients were listed on one page, with the total spending limit summed up and provided back to the participant), or ambiguous (each gift recipient was listed on a separate page, without an explicit summation of the total cost). After Black Friday, participants reported on their total spending. All participants overspent their original budgets, but the magnitude of overspending was lower for participants whose total gift spending budgets were clear (Interaction:  $F(1, 251) = 5.87, p = .016$ ).

While financial clarity can be helpful in mitigating overspending, it can also be unpleasant. Tracking a budget may reduce the enjoyment associated with spending by increasing pain of paying through a tightened link between costs and benefits (Gourville and Soman 1998; Soman and Gourville 2001), and by increasing awareness of opportunity costs through higher perceived constraint (Spiller 2011). This should be especially acute for those facing higher financial constraint, as it increases the likelihood that people are spending from the bottom dollar in their budget (Soster et al., 2014). Study 2 explores this effect, and subsequent intentions to continue budgeting. A different group of mTurk participants completed a two-phase study over the Black Friday shopping weekend. Prior to Black Friday, participants were randomly assigned to track either their Black Friday shopping or their regular shopping. We also measured financial constraint (1=low constraint, 11=high constraint). After Black Friday, participants rated how much they enjoyed spending on each expense category, and whether they intended to continue tracking their budgets. A floodlight analysis revealed that for people facing high financial constraint (JN point = 8.67), tracking expenses decreased the enjoyment they derived from spending money on those expenses (Interaction:  $F(1, 328) = 4.89, p = .028$ ). Decreased spending enjoyment was in turn related to lower intentions to continue tracking expenses in the future.

In the long run, budgeting can also have dual consequences. Financial clarity helps people know when they’ve spent too much money, and they need to reduce their spending. However, it also informs people when they’ve done well managing their money. People may use the perceived progress as an excuse to take a break (Fishbach and Dhar 2005) and may splurge a little more during the next period. If people correct in both directions, there may be little net benefit. Such a pattern would mirror effects found in dieting research; diets tend to work well in the short run, but in long run, dieters exhibit weight cycling and do not often maintain their weight loss (Mann et al. 2007).

Study 3 investigated how budget tracking impacts period-to-period spending adjustments in the long run. At the beginning of the semester, undergraduate students set a financial goal, and created a budget for the next 10 weeks that would help them realize that goal. Half were randomly assigned to track their budgets, while the other half did not. At the end of 10 weeks, all students reported on their expenses and income. We ran a multi-level spline model to explore how net income in one period changed as a function of net income in a prior period, budget tracking condition, and their interaction.

The spline allowed us to separately observe reactions after periods of overspending, and reactions after periods of underspending. When people overspent their budgets in one week, they corrected by spending less the following week. This correction was stronger for those who tracked their budgets ( $z = 5.18, p < .01$ ). However, when people spent *less* than they budgeted in a particular week, they reacted by spending *more* the following week. This reaction was also stronger for those who tracked their budgets ( $z = 4.20, p < .01$ ). The net effect was that budget trackers were no more likely to attain their financial goals than those who did not track their budgets ( $ps > .20$ ).

In study 4, we observe period-to-period spending adjustments over the long run using a longitudinal dataset from a popular budgeting app. We observe a similar pattern of behavior as in study 3. People who tracked their budgets more exhibited stronger corrective action after periods of above average spending ( $z = 10.42, p < .01$ ). However, people who tracked their budgets more were also more apt to splurge after periods of fiscal restraint ( $z = 3.48, p < .01$ ). This suggests that budget tracking tightened the link between period-to-period financial behavior, but not necessarily in a manner that was beneficial in the long run.

### Can Making Family Salient Improve Retirement Contributions? Evidence from Field Experiments in Mexico

#### EXTENDED ABSTRACT

Despite good intentions, consumers regularly struggle to reach their retirement savings goals. There are small barriers and obstacles that prevent individuals from forgoing consumption today in order to secure a better financial pathway for the future. However, these decisions may not be solely based on the individual alone. Could nudges focusing on the benefits of saving for other people, such as the individual's family members, influence the motivation to save for the future?

Individuals may make decisions in order to improve their family's welfare in addition to their own utility. However, the decision for an individual to choose to save for their own future consumption may be perceived to be in potential conflict with the value of consuming with one's family in the present. Individuals may avoid putting money into savings because they view that savings decision to be more self-focused and individualistic and thus, would instead prefer to have the money easily accessible for their family today. Consistent with previous research which finds that future-minded reward responding may not be an exercise in delay of gratification, but rather may reflect a proficiency in episodic future thinking (Peters and Büchel, 2010) as well as research on the improving sequence hypothesis (Loewenstein and Prelec 1993; Magen et al. 2008), individuals may see saving for their own retirement as being in direct opposition to their family's utility for consumption in the present. Thus, we argue that an appeal that focuses on framing that savings decision as a means of having more money to help their family in the future will be particularly effective relative to other more individualistic appeals. More specifically, we propose that family oriented appeals may effectively reduce these perceived tradeoffs by highlighting that saving for one retirement can also improve their family's future utility and welfare by creating a more direct comparison between enjoying a small reward for one's family in the present or enjoying a larger reward for one's family in the future.

To test this, we use a large-scale field experiment ( $N = 97,149$ ), partnering with a retirement company in Mexico. We sent out five different types of SMS text messages to a randomized sampling of their client base in order to encourage individuals to save for their

retirement and compared these treatments against a control group who did not receive a message ( $n = 13,902$ ) as well as measured the effectiveness of the messages against each other. The messages were a gain frame ( $n = 13,859$ ), a message emphasizing a pennies-a-day approach ( $n = 13,877$ ), a fresh start for savings message ( $n = 13,882$ ) message, a message emphasizing securing one's own financial future ( $n = 13,901$ ), and finally a message emphasizing securing one's family's financial future ( $n = 13,853$ ). As compared to a contribution rate of 0.48% in the control group, only the family message generated a statistically significant increase in the proportion of individuals making a retirement contribution (44% increase over control,  $p = 0.018$ ) and was significantly different as compared to the other treatment groups ( $p < 0.05$ ).

To further dig into the potential behavioral mechanism underlying the family message, we estimated our regression specifications on three different age brackets: individuals less than 27 years of age, those between 28 and 42, and individuals older than 42. The average age of marriage in Mexico is 27 years old, and married individuals are likely to have children in the house until the child is a teenager. Hence, age could be a moderator of our effects, as we would expect the impact of the family message to be largest for the middle group of people. The impact of the treatment on contribution incidence, both immediately after the intervention and three months later, is positive and significant for the middle age bracket, as expected ( $p < .05$  in all comparisons). Interestingly and consistent with our theory, the effect on the younger age group is negative ( $p = 0.04$ ). In other words, family appeals can potentially backfire for those whom family is not as strong or an immediate priority. Encouragingly we also look at the long-term effectiveness of our effects and find that the family-oriented appeal also significantly improves contribution rates even six months after the experiment (34% over control,  $p = 0.032$ ).

In order to more definitively determine the mechanism driving our results, we ran a hypothetical laboratory experiment using Amazon's Mechanical Turk ( $N = 200$ ). We randomized participants into two conditions: the hidden zero condition and the explicit zero condition (Magen et al. 2008). In the hidden zero condition, we framed the retirement contribution choice as a way to secure one's future, while in the explicit zero condition, similarly to our field experiment, we framed the retirement contribution choice as a way to secure their family's future. Consistent with our prediction, highlighting the explicit zero and one's family's future led individuals to significantly save more for the future than the hidden zero condition ( $p = .02$ ). Interestingly, and consistent with our field results, this result was moderated by whether participants had a family themselves. Single individuals were as a result less likely to save for the future when given the explicit zero condition ( $p < .01$ ).

The results from the field experiment and the lab experiment shed light on a novel potential approach to improve financial decisions related to retirement. We demonstrate that family messaging prompts significantly improve voluntary contribution rates in comparison to the control condition and in relation to other treatments in comparison to the control condition, both in the short term (over a three-month period) and in the following period (six months later). Designing messages and frames geared to increase the salience of family significantly improves consumers' ability to make positive financial choices (i.e., retirement contributions) in the long-run, even potentially over traditional nudges.

## SESSION OVERVIEW

For centuries, scholars have wondered where and how people find happiness. More recently, researchers have started to examine the role of consumption in driving happiness. In particular, articles on gift-giving (Belk and Coon 1993; Joy 2001), consumer experiences (Bhattacharjee and Mogilner 2013), and variety-seeking (Etkin and Mogilner 2016) have illustrated how diverse aspects of consumption can influence consumers' levels of happiness and well-being.

One key factor of consumption that has been unearthed in driving consumer happiness is consumers' resources (e.g., time and money). Prior work has explored how different allocations of resources can influence happiness (Aknin et al. 2011; Dunn, Aknin, and Norton 2008, 2014; Mogilner and Norton 2016), how thinking about different resources (time vs. money) can influence happiness (Liu and Aaker 2008; Mogilner 2010; Quoidbach et al. 2010), and how our conceptualization of happiness itself can depend on how much time or money we think we have (Mogilner, Kamvar, and Aaker 2011). While this work clearly establishes an important link between consumers' resources and their happiness, there are still many open questions: What are the optimal levels of time and money in order to be happiest? Once we have "enough" (time and money), how should we allocate them to maximize happiness? When resources are scarce, where do we turn for happiness?

Contributing answers to these questions and adding to this area of research, this session presents four novel perspectives on the role of resources—in particular, their availability and allocation—in driving consumer happiness and well-being. The first two papers explore how the availability of resources impacts consumer happiness. Paper 1 (Sharif, Mogilner, and Hershfield) illustrates a curvilinear relationship between discretionary time and life satisfaction: while too little free time negatively affects life satisfaction, too much free time does not necessarily enhance it (and may even reduce it). Paper 2 (Catapano, Quoidbach, Mogilner, and Aaker) reveals that the two forms of

well-being (meaning and happiness) converge to a greater extent in populations where resources (e.g., income) are scarce.

Papers 3 and 4 examine how different allocations of resources can impact consumer happiness. Paper 3 (Rifkin and Cutright) shows that allocating time during an experience to make spur-of-the-moment decisions (vs. making those decisions in advance) can enhance that experience's meaning and increase well-being over time. Finally, Paper 4 (Whillans and Dunn) explores how feelings of guilt prevent consumers from allocating their money towards time-saving purchases (e.g., hiring house cleaners), thereby reducing satisfaction and well-being.

These four papers explore how the availability and allocation of resources like time and money influence consumer well-being. The papers approach this issue by examining diverse contexts spanning multiple countries, by testing predictions across experiments and large-scale datasets, and by looking at both local (i.e., single experience) and global (i.e., life in general) evaluations of happiness. This session will have broad appeal to scholars interested in consumer well-being, resource-based processes, and mixed-method research.

## The Effects of Being Time Poor and Time Rich on Happiness

### EXTENDED ABSTRACT

Between their myriad obligations, people today feel like they don't have enough time and yearn for more. This time famine reaches across the globe (Hamermesh and Lee 2007) and is particularly acute amongst Americans, who report feeling more time constrained than ever before (Carroll 2008; Roxburgh 2004). Though both prioritizing time over money and spending money to buy more free time have been empirically linked to greater happiness (Hershfield, Mogilner, and Barnea 2016; Whillans et al., 2017; Whillans, Weidman, and Dunn 2016), would *actually* having more time make people better off? Across two largescale datasets, we examine the relationship between the amount of discretionary time people have and their satisfaction in life.

The likely harm of having too little time is straightforward. People who work longer hours and have a greater proportion of their schedules consumed by obligations have less control over their lives and less time to undertake desired activities. Less discretionary time means less time socializing and engaging in active leisure—two ways of spending time that are linked to happiness (Kahneman et al. 2004; Lathia et al. 2017; Mogilner 2010). While a negative effect of being temporally impoverished seems likely, what is the effect of time abundance? Is it possible to have too much discretionary time? Emerging work tangentially suggests so. People dread being idle and are happier when busy, even if this busyness is externally compelled (Hsee, Yang, and Wang 2010). In fact, busyness has become a status symbol, signaling competence, ambition, and being in high demand (Belezza, Paharia, and Keinan 2016). Further, with too much discretionary time, people may infer lack of purpose or meaning (Csikszentmihalyi 2000)—thus feeling less satisfied in their life.

Even though many people in modern society feel time-stressed and want more time, we hypothesized that actually having more discretionary time would not always be associated with greater happiness. More specifically, we predicted a negative quadratic relationship between discretionary time and life satisfaction, such that

beyond a certain amount of discretionary time, more time would not just fail to further increase happiness, but may actually be associated with *less* happiness. Drawing on prior research (Holbrook and Lehmann 1981), we define discretionary time as the amount of “time spent on leisure activities or on other non-routine pursuits—where the primary function is the use of time for pleasure or some other intrinsically worthwhile purpose.” Therefore, discretionary time is not simply whatever time is leftover outside of paid work; it is instead the portion of people’s waking hours spent doing what they want.

In Study 1, we analyzed the data of 13,639 working Americans who participated in the National Study of the Changing Workforce (NSCW) between 1992 and 2008. Participants reported the amount of discretionary time they had (“On average, on days when you’re working, about how many hours [minutes] do you spend on your own free-time activities?”) and their life satisfaction (“All things considered, how do you feel about your life these days?”).

Consistent with our prediction, we found a significant negative quadratic relationship between people’s amount of discretionary time and their life satisfaction ( $N = 13,639$ ;  $\beta = -.003$ ,  $P < .001$ ) This relationship held when controlling for gender, age, parental status, marital status, race, education, and respondent income ( $N = 11,649$ ;  $\beta = -.003$ ,  $P < .001$ ). Lastly, using Simonsohn’s two-lines approach (Simonsohn 2017), we find that life satisfaction increases with more discretionary time up to approximately 2 hours; after that point, more discretionary time does not predict greater life satisfaction.

Study 2 sought to test whether this negative quadratic relationship replicates in a different dataset that includes individuals who are in the labor force as well as those who are out of the labor force, and uses different measures for discretionary time and life satisfaction. Here, we analyzed the data of 21,736 working and nonworking Americans who participated in the American Time Use Survey between 2012 and 2013. In answering the American Time Use Survey, respondents provide a detailed account of the activities that filled their prior 24 hours—indicating the time period and duration of each activity. We assessed discretionary time by calculating the amount of time people spent on discretionary activities in a day.

Because there is no standard definition for which specific activities count as discretionary, we used a crowd-sourcing platform (Amazon’s Mechanical Turk) to determine the activities that most people (i.e., over 90%) consider to be discretionary time. Applying this crowd-sourced metric for determining which activities count as discretionary, we calculated the total amount of time each American Time Use Survey respondent spent engaging in these discretionary activities over the previous 24 hours. Replicating the results from Study 1, we again found a significant negative quadratic relationship between the amount of discretionary time people have and their life satisfaction ( $N = 21,736$ ;  $\beta = -.004$ ,  $P < .001$ ). This effect held controlling for gender, age, parental status, marital status, race, education, respondent income, and employment status ( $N = 20,275$ ;  $\beta = -.004$ ,  $P < .001$ ). Lastly, using Simonsohn’s two-lines procedure, we demonstrate that life satisfaction increases with more discretionary time up to certain point (approximately 3.42 hours), but after that point, life satisfaction *decreases* with more discretionary time.

In two largescale datasets representing both fully-employed Americans as well as those outside of the labor force, we tested the relationship between life satisfaction and the objective amount of discretionary time people have in their daily lives. Our results empirically substantiate the emotional burden of *feeling* time-constrained (Hamermesh and Lee 2007; Kasser and Sheldon 2009) by revealing that having a dearth of discretionary hours in one’s day is indeed linked to lowered life satisfaction. However, although too little time is bad, we importantly show that having more time is not always bet-

ter. Though so many people in modern society yearn for more time in their days to do what they want, they really only need a few hours to enjoy optimal satisfaction in life.

## Finding Happiness in Meaning and Meaning in Happiness: Where, When, and For Whom Happiness and Meaning Converge

### EXTENDED ABSTRACT

“What makes for a good life?” is a central human question that scholars of philosophy, religion, political science, and psychology strive to answer. Indeed, for millennia, thinkers have grappled with the relative roles of happiness versus meaning in cultivating a well-lived life, going back to Aristotle who articulated the distinction between these pursuits as *hedonia*, which involves feeling pleasure and enjoyment, and *eudaimonia*, which is rooted in a sense of purpose and fulfillment (Aristotle, trans. 1985; Ryan and Deci 2001; Ryff et al. 2006). Whereas some have proposed that the ultimate goal in life is to pursue happiness (Kahneman et al. 1999) others have argued for the more virtuous pursuit of meaning (Waterman 1993). But beyond theoretical debates and divergent prescriptions for ways to live, how truly different is the experience of happiness and meaning in most people’s lives?

To address this fundamental question, we conducted the largest research program to date examining the relationship between happiness and meaning worldwide. This investigation assessed the correlation between happiness and meaning for over 800,000 individuals across 151 countries. Relying on three large data-sets in the U.S. (Study 1), France (Study 2), and worldwide (Study 3), we compared correlations between population segments. To identify *when* happiness and meaning converge, we compared the correlations across the lifespan. To identify *for whom* happiness and meaning converge, we compared the correlations for people at different levels of income and education. To identify *where* happiness and meaning converge, we assessed correlations across countries and cultures.

Study 1 ( $N=524,673$ ) used the Gallup U.S. Daily Data to investigate the convergence of happiness and meaning across segments. Overall, happiness and meaning were related: individuals who experienced more meaning also tended to experience more happiness ( $r=.40$ , 95%CI[.39, .40]). However, the level of convergence depended on when and for whom. Happiness and meaning converged more as people got older, such that the correlation between happiness and meaning was higher for older individuals than younger individuals ( $r_{\text{under}25}=.29$ ,  $r_{25-34}=.32$ ,  $r_{35-44}=.36$ ,  $r_{45-54}=.42$ ,  $r_{55+}=.43$ ,  $\chi^2=1698$ ,  $p<.001$ ). We also found higher convergence for both lower income levels and lower education levels. That is, individuals in poorer income brackets exhibited higher correlations between happiness and meaning than did wealthier individuals ( $r_{\text{low}}=.45$ ,  $r_{\text{mid}}=.38$ ,  $r_{\text{high}}=.32$ ,  $\chi^2=1181$ ,  $p<.001$ ). Further, individuals with less education exhibited higher correlations than more educated individuals ( $r_{\text{primary}}=.44$ ,  $r_{\text{secondary}}=.41$ ,  $r_{\text{some-college}}=.41$ ,  $r_{\text{technical-school}}=.41$ ,  $r_{\text{college}}=.36$ ,  $r_{\text{postgrad}}=.36$ ,  $\chi^2=338$ ,  $p<.001$ ). Together, these results suggest that in the U.S., happiness and meaning are more linked among people who are old, poor, and uneducated. However, what remains unclear is whether these trends are specific to the U.S. or represent something more fundamentally human.

Therefore, in Study 2 ( $N=35,964$ ) we turn to a different country (France), and replicate our findings. Overall, happiness and meaning were related ( $r=.61$ , 95% CI [.60, .62]), but the magnitude of correlation differed across age, income and education. Older people displayed greater convergence than younger people ( $r_{\text{under}25}=.57$ ,  $r_{25-34}=.59$ ,  $r_{35-44}=.63$ ,  $r_{45-54}=.64$ ,  $r_{55+}=.62$ ,  $\chi^2=46.03$ ,  $p<.001$ ), poorer people

showed greater convergence than richer people ( $r_{\text{low}}=.62$ ,  $r_{\text{mid}}=.59$ ,  $r_{\text{high}}=.56$ ,  $\chi^2=33.86$ ,  $p<.001$ ) and less educated people showed greater convergence than more educated people ( $r_{\text{technical-highschool}}=.64$ ,  $r_{\text{regular high school}}=.62$ ,  $r_{\text{some-college}}=.61$ ,  $r_{\text{college}}=.61$ ,  $r_{\text{postgrad}}=.58$ ,  $\chi^2=25.01$ ,  $p<.001$ ).

However, France and the U.S. have a number of characteristics in common, including the use of WEIRD (Western, educated, industrialized, rich, and democratic) samples (Jones 2010). Given that culture may influence experienced happiness (Diener and Suh 2000) and meaning (Baumeister et al. 2013), we sought a broader view beyond these two country's samples. Therefore, in Study 3, we relied on the Gallup World Poll data, collected from 151 countries to assess the prevalence of these patterns around the globe ( $N=260,401$ ).

Around the world, meaning and happiness were related ( $r=.14$ , 95% CI [.13, .14]). More precisely, in 129 out of the 132 countries, the relationship between meaning and happiness was positive, with 112 of these countries showing significant relationships, suggesting that the relationship between meaning and happiness is highly consistent across cultures. Further, as in Studies 1 and 2, the correlation between happiness and meaning increased with age ( $r_{\text{under25}}=.07$ ,  $r_{25-34}=.09$ ,  $r_{35-44}=.10$ ,  $r_{45-54}=.13$ ,  $r_{55+}=.19$ ,  $\chi^2=470$ ,  $p<.001$ ), for those who were poor vs. wealthy ( $r_{\text{low}}=.16$ ,  $r_{\text{mid}}=.16$ ,  $r_{\text{high}}=.10$ ,  $\chi^2=11.3$ ,  $P=0.003$ ), and for those who are less educated vs. more educated ( $r_{\text{primary}}=.16$ ,  $r_{\text{secondary}}=.14$ ,  $r_{\text{tertiary}}=.13$ ,  $\chi^2=21.5$ ,  $p<.001$ ).

In Study 4, we directly manipulated subjective financial scarcity in order to obtain initial causal evidence for this account. Participants ( $N=783$ ) were instructed either to write about the factors that constrain their finances or a matched writing task (Tully, Hershfield, and Meyvis 2015). Then, they were asked to report either a recent happy experience or a recent meaningful experience and then rate how happy and meaningful it was. Regardless of whether participants wrote about a happy or meaningful experience, participants in the constrained condition showed greater convergence between happiness and meaning than those in the control condition ( $r_{\text{happy/constrained}}=.71$ ,  $r_{\text{happy/control}}=.54$ ,  $\chi^2=7.75$ ,  $P=.005$ ;  $r_{\text{meaning/constrained}}=.57$ ,  $r_{\text{meaning/control}}=.37$ ,  $\chi^2=6.44$ ,  $p=.01$ ). This finding suggests that there is a causal relationship between scarcity and the convergence of happiness and meaning. In addition, the consistency of this effect both for happy and meaningful experiences suggests that it is bidirectional in nature, such that happiness contributes to meaning and meaning contributes to happiness in these circumstances.

These results highlight that despite being distinct constructs, meaning and happiness are related around the world. Furthermore, in addressing the questions of when and for whom they converge, we find evidence for the “wisdom in scarcity” principle—that the degree of convergence relates to people's access to external sources of happiness (i.e., age, money, education). This finding builds on emerging research which suggests that meaning and happiness can indeed serve as inputs to the other (Kashdan et al. 2008; King et al. 2006; Sheldon 2013). Given the motivating power of scarcity (Shah, Mulainathan, and Shafir 2012), as well as people's tendency to manufacture their own happiness in the face of dire circumstances (Gilbert 2006; Quoidbach and Dunn 2010), this research suggests another way that those who suffer from conditions of scarcity may boost their own happiness and well-being, by deriving meaning from happiness and happiness from meaning.

### Making Sense of Spontaneity: In-The-Moment Decisions Promote More Meaningful Experiences

#### EXTENDED ABSTRACT

Whether spending free time with friends or celebrating a milestone anniversary, many consumers are increasingly spending their

discretionary dollars on experiences. As such, recent research has focused on understanding what drives happiness from consumer experiences (Bhattacharjee and Mogilner 2014; Tonietto and Mal-koc 2016; Van Boven and Gilovich 2003). One prevailing notion for maximizing happiness is to allow consumers ample opportunities to co-create, or make decisions about, their experience (Pralhalad and Ramaswamy 2004). While this strategy can confer experiential benefits (e.g., Norton, Mochon, and Ariely 2012), one open question surrounds *when* such experience-relevant decisions should be made: in advance of the experience, or in the spur of the moment?

We suggest that the timing of experience-relevant decisions will affect how meaningful an experience feels. Our theory stems from prior work examining when and why people desire to understand their experiences. Prior work shows that people are driven by a fundamental need to understand their environment (Camus 1942/2000; Dweck 2017; Frankl 1963/1984). As such, after people undergo experiences that do not conform to their pre-existing frameworks (e.g., a trauma or simple expectancy violation; Bruner and Postman 1949; Joseph and Linley 2005; Janoff-Bulman 2010) or when they undergo experiences for which they have no framework, they are motivated to engage in sense-making processing to restore understanding.

Building on this work, we suggest that the decisions consumers make for their experiences (e.g., the courses one orders at a dinner, the excursions one books for a vacation) can serve as the framework that guides an experience. As such, when experience-relevant decisions are made *in the moment*, consumers enter into their experiences without a pre-existing framework; instead, they construct that framework as the experience unfolds. As a result, we theorize that in-the-moment decisions will increase the likelihood that consumers engage in sense-making processes after the experience (Park 2010). By contrast, when experience-relevant decisions are made in advance, the experience *is* guided by a pre-existing framework. As such, in-advance decisions should be less likely to spark sense-making processes.

Given prior work establishing the link between sense-making processes and the meaning derived from experiences (Park 2010), we predict that, compared to in-advance decisions, in-the-moment decisions will be more likely to spark a sense-making mindset, resulting in greater meaning evaluations.

Study 1 provides initial support for our predictions using participants' real experiences. We surveyed engaged women ( $N = 149$ ) about their expectations regarding wedding decisions, timing, and meaning, and we surveyed recently-married women ( $N = 54$ ) about the most meaningful moments from their wedding day (and how planned or spontaneous they were). While engaged participants believed that spur-of-the-moment decisions would undermine their wedding's meaning ( $M_{\text{agreement}} = 4.96$  on 1-7 agreement scale), 65% of married participants listed moments involving spontaneous decisions. Thus, memories of spur-of-the-moment decisions emerged as unexpected, important sources of meaning.

Study 2 causally tests the effect of decision timing on meaning and the underlying role of sense-making. Participants ( $N = 204$ ) who celebrated New Year's Eve wrote about their celebrations, and we varied whether they described decisions they made in the moment or in advance. As expected, compared to those who focused on in-advance decisions ( $M = 5.08$ ), those encouraged to focus on in-the-moment decisions appraised their New Year's Eve experience as more meaningful ( $M = 5.43$ ,  $p = .050$ ). Supporting the underlying role of sense-making, compared to the in-advance condition ( $M = 2.69$ ), the writings of those who focused on in-the-moment decisions were judged (by independent coders) to be more like a coherent narrative ( $M = 3.26$ ;  $p = .001$ ), indicating greater levels of sense-making

(Hinchman and Hinchman 1997). Thus, study 2 demonstrates that focusing attention on in-the-moment decisions from a prior experience increased the degree of sense-making that occurred after the fact (as evidenced by the storied nature of their writings), which enhanced the experience's meaning ( $ab = -.08$ , 95% CI [-.20, -.005]).

Study 3 further tests our theory using a process-by-moderation design. If the effects of decision timing are indeed driven by sense-making processes, then the effects should be attenuated when sense-making is disallowed. To test this reasoning, study 3 manipulated both decision timing (in advance vs. in the moment) and whether participants had the opportunity to engage in sense-making (i.e., they either wrote about their experience prior to evaluating it, as in study 2; or, they were not allowed this opportunity). The significant 2 (Decision Timing)  $\times$  2 (Sense-Making) interaction on meaning ( $p = .026$ ) supported our predictions: When participants had the opportunity to engage in sense-making, experiences containing in-the-moment decisions were more meaningful than those containing in-advance decisions ( $M_{\text{In-The-Moment}} = 5.11$  vs.  $M_{\text{In-Advance}} = 4.40$ ;  $p = .004$ ). However, when sense-making was disallowed, these effects disappeared ( $M_{\text{In-The-Moment}} = 4.85$  vs.  $M_{\text{In-Advance}} = 4.87$ ; *NS*).

In study 4, we created a consumer experience in the laboratory and tested whether the predicted effects extend to marketing-relevant outcomes. Participants ( $N = 285$ ) tested an ostensibly new educational app by reading three brief articles of their choosing. We varied whether participants chose their articles during (vs. in advance of) the app-testing experience. After measuring how meaningful their experience was, we measured how likely they would be to purchase the app, provide a positive review, and "like" it on social media (collapsed to a form a "behavioral intentions" index;  $\alpha = .85$ ). Compared to those who made decisions in advance, those who made decisions in the moment rated their experience as more meaningful ( $M_{\text{In-The-Moment}} = 3.78$  vs.  $M_{\text{In-Advance}} = 3.32$ ;  $p = .017$ ), and had stronger intentions to engage in the future ( $M_{\text{In-The-Moment}} = .13$  vs.  $M_{\text{In-Advance}} = -.13$ ;  $p = .005$ ). Underscoring the managerial importance of these effects, in-the-moment decision-making enhanced how meaningful the experience was, which drove greater future engagement intentions ( $ab = -.16$ , 95% CI [-.28, -.03]).

Four studies demonstrate that making in-the-moment (vs. in-advance) decisions is more likely to spark sense-making processes, thereby increasing meaning. This research has practical implications for marketers and consumers of experiential consumption, and contributes to the literatures on experiential consumption, choice and well-being, and sense-making.

### Guilt Undermines Consumer Willingness to Buy More Meaningful Time

#### EXTENDED ABSTRACT

Trying to keep up with the demands of daily life, such as shopping and doing laundry, can chip away at the time we might otherwise spend engaging in the kinds of activities that endow life with meaning. Indeed, people find activities such as volunteering, meditating, and spending time with their children more worthwhile and meaningful than tasks such as shopping and housework (White and Dolan 2009). Outsourcing mundane tasks may provide a pathway to purpose by endowing people with the time they need to engage in purposeful pursuits. Despite this possibility, the vast majority of consumers fail to spend money in ways that would enable them to have more meaningful time—even when they can afford to do so (Whillans et al., 2017).

Building on this research, we propose a previously unexplored barrier to making time-saving purchases: feelings of guilt. Qualita-

tive research points to the role of guilt in couples' decisions about whether to outsource childcare (Epp and Velagaleti 2014). Building on this research, we propose that time-saving purchases are likely to promote guilt because these purchases often involve burdening other people with our own disliked tasks. Feelings of guilt are a painful affective experience encompassing remorse, self-blame, and regret (Mosher 1980). Thus, we predicted that feelings of guilt that can arise from outsourcing would suppress the satisfaction that consumers experience and their likelihood of making these purchases in the first place. Specifically, we predicted that when time-saving purchases involve the salient effort of other people ("effort-visible time-saving purchases"; e.g., housecleaning), consumers would be especially likely to experience guilt, undermining their satisfaction and purchase intentions.

First, to examine the role of guilt in predicting consumers' satisfaction and their intentions to make time-saving purchases, we conducted two large-scale survey studies, including a nationally representative sample of Americans (Study 1a&b). In these studies, respondents were asked to think about a task that they disliked doing, and to describe in 1-2 sentences how they would arrange to buy themselves out of this task. Then, respondents reported how much guilt they felt when thinking about buying themselves out of this task, and their purchase intentions. Lastly, respondents were asked whether they spontaneously considered a time-saving purchase that involved another person (an effort-visible purchase) or not.

Reporting the results from the nationally representative sample of Americans (for illustrative purposes), respondents who thought about the person or people who would have to complete the disliked task on their behalf (effort-visible) reported greater guilt as compared to respondents who did not think about the person who would have to complete the disliked task on their behalf,  $B=13.60$  (3.68),  $\beta=0.21$ ,  $p<0.001$ , 95%CI[6.36, 20.84]. These results held controlling for age, gender, whether respondents spent money on time-saving purchases in a typical month, marital status, number of kids living at home, and personal income),  $B=11.87$  (3.82),  $\beta=0.18$ ,  $p<0.001$ , 95%CI[4.35, 13.38]. Respondents who considered effort-visible purchases experienced greater guilt, which in turn undermined their intentions to buy themselves out of this disliked task in future, *indirect effect* = -0.23 (0.11), 95%CI[-0.50, -0.07] and their anticipated satisfaction from making these purchases, *indirect effect* = -3.07 (1.21), 95%CI[-5.72, -1.02]. To rule out potential confounds that might result from the spontaneous recollection of effort-visible purchases, we designed a novel lab paradigm to examine the causal role of effort-visibility on feelings of guilt, purchase satisfaction (Study 2), and purchase intentions (Study 3).

In Study 2, participants were randomly assigned to outsource a disliked task to a specific other person ("effort-visible") or not, were provided with 30 minutes of free time, and were asked how much guilt and how much pleasure they felt during this 30 minutes of free time. Consistent with our correlational data, participants who were randomly assigned to make effort-visible time-saving purchases experienced greater guilt ( $M=34.40$ ,  $SD=30.45$ ) as compared to participants who were assigned to the effort invisible condition ( $M=24.01$ ,  $SD=27.49$ ),  $F(1, 321)=10.21$ ,  $p=0.002$ . These feelings of guilt in turn undermined participants' satisfaction during the 30 minutes of free time, *indirect effect* = -1.07 (0.052), 95%CI[-2.46, -0.31].

In Study 3, participants earned \$7 and were asked to consider giving up this \$7 to buy themselves out of a disliked task. Once again, participants who were randomly assigned to the effort-visible condition reported that choosing to pay money to have more free time would cause them significantly greater feelings of guilt ( $M=38.90$ ,  $SD=30.52$ ) as compared to participants who were randomly assigned

to the effort-invisible condition ( $M=29.74$ ,  $SD=30.58$ ),  $t(348)=2.73$ ,  $p=0.007$ , 95%CI[2.56, 15.76]. Furthermore, participants who were assigned to the effort-visible condition reported higher feelings of guilt, which in turn undermined their willingness to exchange their \$7 payment for 30 minutes of free time, *indirect effect* = -0.16 (0.07), 95%CI[-0.33, -0.04]. These studies provide causal evidence that feelings of guilt that often arise when making time-saving purchases—such as in the case of outsourcing to a specific other person—can undermine our satisfaction with the free-time and our purchase intentions.

In Study 4, we sought to intervene on consumers' feelings of guilt. To this end, we adapted ads from the website of a sharing economy company, *HelloAlfred*. We randomly assigned some participants to view ads that focused on the benefits of the purchase for the service provider—including highlighting the meaning that the service providers derived from helping others with daily tasks. Other participants viewed ads focused on the benefits of the purchase for the consumer. As predicted, participants who were randomly assigned to view the ad that emphasized the benefits to the service provider reported significantly lower feelings of guilt when thinking about using the service ( $M=25.04$ ,  $SD=27.38$ ) as compared to participants who were randomly assigned to view the advertisement that emphasized the benefits to the consumer ( $M=32.21$ ,  $SD=30.05$ ),  $t(390)=6.06$ ,  $p=0.014$ , 95%CI[-12.88, -1.44]. In turn, the provider-benefits ad reduced guilt and increased anticipated purchase satisfaction and intentions.

Across five studies, guilt undermined consumer willingness to buy more and potentially more meaningful time. This adds to a growing body of research examining how people should spend money to promote happiness, and why we often do not (Dunn, Aknin, and Norton 2008).

### SESSION OVERVIEW

Recently, people have increasingly focused on obstacles faced by vulnerable populations, or those most potentially susceptible to harm or neglect (Aday 1994), including children and those facing mental or physical maladies. Vulnerable individuals may have limited influence on or barriers to making their own health and life decisions, face stereotyped person perception, and even be described in an exclusionary way (Corrigan 2004; Fiske et al. 2002; Dunn and Andrews 2014). Such stigma shapes the consumption experiences of vulnerable individuals, those making decisions for them, and those who stigmatize them. However, despite the importance of and the call for consumer research on such topics (Mick 2006), many questions remain about the factors and consumption implications associated with vulnerable consumer groups. This session provides new, vital perspectives on this area.

Four papers explore important issues for vulnerable consumers: vaccination decisions for children, health messaging for individuals living with mental health issues, consumer inferences of the physically disabled, and implications of identity label use for stigmatized groups generally. The first three focus on unique vulnerable groups while the last unites this work by examining broad implications associated with vulnerable, stigmatized groups.

First, **Sherman and colleagues** examine a crucial consumption choice (vaccination) within a vulnerable group whose decisions are often made by others: children. In two studies conducted in collaboration with Children's Hospital of Philadelphia, they show that, due to anticipated moral culpability, parents with strong omission bias respond negatively to physician vaccine policy, which in turn negatively impacts pediatrician trust and vaccination intent.

Second, **Achar and Agrawal** then shift to examine vulnerable individuals living with mental health issues. They show that health messages emphasizing certain aspects of mental health stigma (i.e.,

discuss perceptions that someone with mental health issues is not "normal") are more effective than those that do not address the stigma. The responsiveness to accentuating aspects of stigma is moderated by the nature of individuals' moral beliefs.

Third, **van der Sluis, Samper, and Kristofferson** examine another vulnerable population, those with physical disabilities, and find that people perceive those with physical disabilities as having elevated moral character and that these inferences can have downstream persuasion consequences in retail settings.

Finally, **Uduehi and Reed** conclude by exploring more broadly how vulnerable, oft-stigmatized groups are described by others. They unpack language about people in stigmatized groups, identifying for the first time important inferences (i.e., controllability, willingness to change) associated with using person-first (i.e., person with obesity) versus identity-first (i.e., obese person) labeling.

Together, these papers shed light on understudied, vulnerable consumer populations, and connect them to a variety of consumer behaviors. As protections previously afforded to vulnerable groups are loosened in our "post trust" world, consumers no longer trust that social or government institutions will ensure the safety and well-being of vulnerable individuals. This collection contemplates the issues facing vulnerable populations as well as interventions that may benefit these groups. We expect this session to have a broad appeal to scholars interested in socially relevant research, morality, identity, stigma, and the connections between them.

## **When Taking Action Means Accepting Responsibility: Omission Bias Predicts Reluctance to Vaccinate Due to Greater Anticipated Culpability for Negative Side Effects**

### EXTENDED ABSTRACT

Omission bias describes the tendency to prefer harm from inaction over equivalent harm from action (Baron & Ritov 1994), and can lead individuals to avoid behaviors with potential negative outcomes even when inaction carries equivalent or greater risk. Previous research has considered the contribution of omission bias to vaccination decisions (Asch et al. 1994; Connolly & Reb 2003; Ritov & Baron 2004). We extend this work by exploring whether moral psychology—namely, anticipated culpability for potential harm—helps explain why individuals prone to the omission bias might be hesitant to vaccinate their children despite recognizing the value of vaccines.

In two studies, we examine how individual differences in omission bias impact patients' responses to physician-level vaccination policy. We demonstrate that omission bias predicts negative emotional responses to physician vaccination policy, which in turn undermines trust of the physician providing information and doctors more generally, and reduces the perceived importance of vaccination behaviors. We show that anticipated moral culpability helps to explain why parents with strong omission bias respond negatively to physician vaccine policy and, as a result, lose confidence in their child's pediatrician and in the importance of vaccinating on schedule. In exploring the omission bias in the context of vaccine-related decision making, we contribute to the relatively limited literature on provider-patient relationships to show how provider policy affects compliance and relationship-related outcomes.

Three hundred parents from the United States completed the study. Using multi-item scales we assessed vaccination beliefs, emotional response to vaccine policy, trust in one's physician, and gen-

eral trust in the medical profession. Omission bias was measured and participants completed demographic items.

We used path analysis (i.e., SEM) to test the pathways from omission bias to negative emotional response to the policy and then to the two trust outcomes. As predicted, parents with stronger omission bias responded to the dismissal policy with stronger negative emotion ( $p < .001$ ), and expressed having less trust in their pediatricians ( $p < .001$ ) and doctors in general ( $p < .001$ ). Parents' negative emotional response toward the policy predicted less trust in the pediatrician ( $p < .001$ ) and less general trust in doctors ( $p < .001$ ). Tests of the two indirect effects indicated that negative emotion in response to the policy partially explained the relationship between omission bias and provider trust ( $p = .002$ , 95% CI: [-.24, -.11]) and general trust in doctors ( $p = .001$ , 95% CI: [-.18, -.07]). Importantly, all pathways and indirect effects remained significant if the sample was restricted to parents who prioritize vaccination, suggesting that this effect is not limited to those that hold strong anti-vaccination beliefs.

Study 1 established that omission bias predicts parents' emotional response to physician vaccination policy and trust in doctors (both their child's pediatrician and doctors in general). Study 2 was designed to extend these findings by testing our contention that anticipated moral culpability is an important psychological mechanism underlying these relationships, and to extend the downstream consequences to vaccination priority.

Three hundred twenty-six parents from the United States completed the study. Participants rated their vaccine priority at the onset of the study. Participants then imagined that they were taking their child(ren) to the pediatrician's office for their next appointment and were informed about the pediatrician's policy regarding patient vaccines. They completed measures of omission bias, anticipated culpability for (in)action, emotional responses to vaccine policy, and trust in physicians and medical providers. Finally, participants restated their vaccine priority and a comparison from the original statement was used to calculate a change in vaccine priority score and provided demographic information.

In a single structural equation model, we tested the pathways from omission bias to negative emotional response to the policy via the two anticipated culpability measures, and from negative emotional response to change in vaccination priority and the two trust measures. Compared to parents with weaker omission bias, parents with stronger omission bias anticipated feeling less culpable for harm that might result from not vaccinating ( $p < .001$ ) and more culpable for harm that might result from vaccinating ( $p = .008$ ). The emotional response to the policy was more negative for parents who anticipated more culpability for potential harm of vaccinating ( $p < .001$ ) and less culpability for potential harm of not vaccinating ( $p < .001$ ).

There was a significant total effect from omission bias to negative emotional response to the policy ( $p < .001$ , 95% CI: [.09, .31]). There was evidence that the two anticipated culpability measures explained this relationship, at least in part. The combined indirect effect via the two culpability variables was statistically significant ( $p < .001$ , 95% CI: [.06, .17]). Once accounting for the indirect effect, the direct effect from omission bias to negative emotional response was no longer significant ( $p = .10$ , 95% CI: [-.02, .20]). This negative emotional response was consequential: parents who experienced more negative emotion toward the policy reported that the policy made them trust their pediatrician less ( $p < .001$ ), reported less trust in doctors in general ( $p < .001$ ), and had a greater decrease in vaccination priority ( $p = .003$ ).

Together, our studies explore the role of omission bias in vaccine-related outcomes. Distinct from prior literature, we implicate anticipated moral culpability as a driver of our observed effects, suggesting a unique source of patient vulnerability related to the omission bias.

Healthcare decisions are complex and vaccination decisions are no exception. Although vaccine hesitancy is often positioned in the popular press as resulting from misinformation regarding the safety risks of vaccines, we find that psychological biases also play a role. In this research, we focused on how consumers (patients) respond to a service policy in a complicated industry (i.e., healthcare) and in relation to what is sometimes an emotional decision (i.e., childhood vaccination). In doing so, we contribute to a limited literature on how policy changes and the manner in which they are communicated can affect patient compliance and the quality of the provider-patient relationship, and highlight consumer vulnerability driven by the omission bias.

### **When Stigma Does Good: Accentuating Certain Aspects of Stigma Enhances Effectiveness of Mental Health Messages**

#### **EXTENDED ABSTRACT**

In the U.S., 45 million adults were estimated to be living with any mental illness in 2016 – of which, only 41% received health services (NIMH Reports, 2016). Along with serious social consequences of large groups of vulnerable consumers being untreated, there is also a stunning economic cost: untreated serious mental illnesses cost the U.S. \$193.2 billion in lost earnings per year (Insel 2008). Significant research suggests that one barrier to seeking mental healthcare services is the stigma associated with mental issues (e.g., Corrigan 2004, Pietrzak et al. 2009). Despite the stigma – or probably because of it – advertisements that encourage consumers to seek help with mental health issues do not usually address the mental health stigma, or when they do so at all, they evoke the general concept of 'stigma'.

In this research, we propose that rather than not addressing stigma at all, accentuating certain aspects of mental health stigma might have positive consequences on the effectiveness of mental health appeals. Drawing from past work in mental health (Corrigan 2004, Clement et al. 2015), we consider two aspects that contribute to the social stigma surrounding mental health: a) harm-causing aspect (perceptions that an individual experiencing mental health issues may be violent) and b) norm-deviating aspect (perceptions that an individual experiencing mental health issues is not 'normal'). Second, we propose that the effects of the two aspects is moderated by the nature of moral beliefs held by consumers. Stigma surrounding health issues is a barrier to seeking healthcare because it endows the health issue with a sense of being 'bad' and unacceptable (Corrigan 2004). Thus, we reason that an individual's processing of stigma is moderated by their view of what is 'good' versus 'bad', that is, the nature of their moral beliefs. However, consumers may vary on what they believe to be moral. We use the framework of rights-based versus duty-based moral belief systems (Dworkin 1978; Chiu et al. 1997) to capture this variance. In this framework, individuals with rights-based moral beliefs believe individual freedom and rights are fundamentally moral; whereas to individuals with duty-based moral beliefs believe in supporting a system and following one's duty.

We hypothesize that when the norm-deviating (vs. control vs. harm-causing) aspect of mental health stigma is made salient, individuals with rights (vs. duty)-based moral beliefs are not deterred by the stigma to seek healthcare, since according to their beliefs,

being different from the norm is not a moral violation. However, when the harm-causing (vs. control vs. norm-deviating) aspect of stigma is made salient, individuals holding both rights-based and duty-based beliefs are defensive against mental health stigma since causing harm to others is a moral violation according to both belief systems. We tested these predictions in three experiments.

382 ( $M_{\text{age}} = 21.9$  yrs, 167 females) undergraduates participated in this study in exchange for course credit. They were randomly assigned to a condition in a 2 (Moral Beliefs: Rights-based vs. Duty-based) X 2 (Stigma Aspect: Harm-causing vs. Norm-deviating vs. Control) design.

As a first task, participants were presented a "Memory Task", that manipulated the rights (vs. duty)-based moral beliefs system. They were provided with a definition of morality, which varied by the rights-based (duty-based) condition and asked to write about an incident from their life in which they acted moral according to this definition of morality. Next, they were presented with 1 of the 3 types of mental health message. The messages were titled "People with mental health issues are still seen as being 'different' ('violent') in the norm-deviating (harm-causing) variant. The control message was titled "Look out for mental health symptoms" and did not mention stigma. The rest of the message was constant across conditions and summarized various mental health issues common among students. After reading the message, the participants were told that as compliments for participating, they could take a useful 'contacts card' discretely placed in their cubicle. These were pocket-sized 3.5"X2" cards, which contained information on accessing professional help for mental health problems on campus. A hypothesis-blind RA noted whether participants took the card (1) or not (0).

A binomial logistic regression using card taking as DV and moral beliefs and message type as IVs was significant ( $1.5 = 12.81$ ;  $p = .025$ ). There was no main effect of moral prime ( $p = .11$ ) or message type ( $p = .29$ ), only a significant interaction effect ( $p = .013$ ). Participants in norm-deviating (vs. harm-causing vs. control) message condition were significantly more likely to pick up the mental health services information card (table 1).

We replicated this effect in Study 3 among 445 ( $M_{\text{age}} = 40.79$  yrs, 252 females) Mturk participants, using another behavioral DV: amount of time spent reading mental health messages.

Study 2 was the same design as study 1 and was conducted with 785 ( $M_{\text{age}} = 36.05$  yrs, 380 females) Mturk participants. In this study, we used to measure moral beliefs as an IV that was premeasured before showing them one of the three message types. Participants were asked to estimate their susceptibility to experiencing depression: "What is the likelihood that you have experienced symptoms of depression?" 1 = highly unlikely to 10 = highly likely and "Indicate the likelihood that you might have symptoms of depression" on a visual scale 0 = not at all to 100 = definitely have symptoms. On the next page, participants were asked to indicate their intentions to seek professional help for depression ( $\alpha = .89$ ) on three 10-point items.

An ANOVA using perceived susceptibility as DV was significant ( $F(6, 777) = 34.07$ ,  $p < .001$ ) and showed a significant interaction ( $p = .03$ ). Further probing of the interaction indicated that participants were significantly more likely to recognize their susceptibility to depression after reading the norm-deviating (vs. harm-causing vs. control) message (see table 1). A moderated mediation analysis (Model 8, Hayes 2013;  $b = .06$ , CI: .01, .11) showed that the increased risk recognition lead to stronger intentions to seek help ( $b = .90$ ,  $p < .001$ ) with a significant indirect effect ( $b = .18$ , CI: .02, .36).

Overall, this research contributes to understanding consumer behavior theory by examining various aspects of stigma and their differential consequences. In addition, this enquiry provides insights

to healthcare marketers and policymakers on enhancing mental health persuasion.

## Perceptions of Disability in the Marketplace: Moral Character Inferences and Persuasion

### EXTENDED ABSTRACT

In 2016, 44.3% of employed people with disabilities worked in sales and service occupations (U.S. Bureau of Labor Statistics 2016), contexts that typically require significant customer contact and interactions. While past research has shown that people perceive those with disabilities as high in warmth but low in competence (Fiske et al. 2002), it has not focused on moral traits, which play an important part in person perception (Goodwin, Piazza, and Rozin 2014), or examined perceptions of physical disabilities in the marketplace.

In the present research, we make the prediction that consumers attribute a moral halo to individuals with disabilities (S1), and that such effects are mediated by the increased adversity people with disabilities are assumed to have endured (S1, S2). We further show these effects are bounded when explicitly immoral behaviors take place (S3), and finally, that within a sales context, salespeople with a physical disability elicit greater compliance and higher satisfaction even when persuasion knowledge activation is high (S4).

Study 1 establishes that a physical disability (i.e., wheelchair use) elicits perceptions of higher moral character and examines potential mediators. In a two-cell (disabled, able-bodied) design, 116 undergraduates read a profile about man named Alex. In addition to details about his life (e.g., job, hobbies, relationship status), they learned he was physically disabled (vs. not), then assessed his moral character (Aquino and Reed 2002;  $\alpha = .96$ ). We found that participants assigned Alex higher moral character when he was disabled (vs. not) ( $M_{\text{disabled}} = 6.72$ ,  $M_{\text{not disabled}} = 5.93$ ;  $p = .01$ ). Further, participants perceived Alex to have overcome more life adversity when he was disabled (vs. not) ( $M_{\text{disabled}} = 5.60$ ,  $M_{\text{not disabled}} = 4.04$ ;  $p < .0001$ ) and felt more empathy towards him ( $p < .001$ ). Mediation analysis revealed only a significant indirect effect through overcoming adversity (Model 4; Hayes 2013;  $B = .41$ ,  $CI_{95\%} : .14, .73$ ).

Study 2 replicates the moral halo effect and manipulates our proposed mediator to support our causal chain (Spencer, Zanna, and Fong 2005). Within a three-cell (disabled, able-bodied, disabled + privilege) design, we manipulated adversity perceptions by adding privilege to the target. Mturk participants ( $n = 149$ ) read a scenario about waiting in a long line at the movies and observing a consumer named Alex in line, who either had a physical disability (i.e., in a wheelchair) or not. In the disabled + privilege condition participants additionally overheard Alex say, "Here, I'll cut to the front and get our tickets – nobody ever says anything to me when I do that." Results revealed a main effect of disability condition ( $p < .001$ ) such that the moral halo effect emerged in the disabled ( $M_{\text{disabled}} = 6.56$ ) v. not disabled conditions ( $M_{\text{not disabled}} = 5.88$ ;  $p = .02$ ) but was mitigated in the disabled + privileged ( $M_{\text{disabled+privilege}} = 3.81$ ;  $p < .001$ ) condition. Process evidence showed that perceived adversity in the disabled + privilege condition was significantly lower than the disabled ( $p < .0001$ ) and not disabled ( $p < .0001$ ) conditions, together demonstrating that when a person is perceived to experience lower adversity, the morality boost from the physical disability disappears.

Study 3 examines the effects of committing a moral transgression as a boundary condition. 337 undergraduates were randomly assigned to a 2 (Disability of target: Disabled v. Not Disabled) x 2 (Moral transgression: Keep dropped \$20 v. Return dropped \$20) between-subjects experiment. As in study 2, participants imagined being in a movie theater line and observing someone drop a \$20 bill. In

the moral (immoral) condition, Alex returns the \$20 bill to the person who dropped it (puts the \$20 bill in his pocket). A 2 x 2 ANOVA on perceived moral character revealed a marginal two-way interaction ( $p = .062$ ). Alex was perceived as more moral if he had a physical disability (vs. not) when he returned the money ( $M_{\text{disabled}} = 5.69$ ,  $M_{\text{not disabled}} = 5.18$ ;  $p < .01$ ), yet no such differences emerged when he kept the money for himself—both conditions revealed a significant drop in morality ( $M_{\text{disabled}} = 2.42$ ,  $M_{\text{not disabled}} = 2.62$ ;  $p = .98$ ).

Study 4 examines how people interact with disabled individuals in a retail context, particularly when persuasion knowledge is made salient. This study used a 2 (disabled, not disabled) x 2 (persuasion knowledge: high (clothing irrelevant), low (clothing relevant)) design. Undergraduates ( $n=305$ ) read a guided visualization in which they interacted with Gina, a female salesperson (disabled vs. not), and told her they were shopping for a shirt for work. In selecting items to try, Gina offered either a dress shirt (relevant to need) or a pair of jeans (irrelevant). Upon completion, participants indicated their willingness to accept the salesperson's clothing suggestion. (We had pretested this scenario to confirm that Gina was seen as moral in the disabled (v. not disabled) condition and that provision of the irrelevant clothing item increased persuasion knowledge activation (Kristofferson, Lambertson, and Dahl 2018)). Results revealed a significant disability x persuasion knowledge interaction ( $p = .01$ ). When the clothing item was relevant, there was no significant difference in salesperson compliance, regardless of disability. However, when the clothing suggestion was irrelevant (persuasion knowledge was activated), participants were significantly more compliant to the salesperson's suggestion when she was disabled versus not ( $M_{\text{disabled}} = 4.37$ ,  $M_{\text{not disabled}} = 3.39$ ;  $p = .002$ ). We also measured salesperson and retail experience satisfaction and the results show the same pattern. Thus, consumers were more compliant and satisfied with the explicit sales attempt even when it was irrelevant to what their purchase goal.

Together, these studies provide the first investigation into the psychological and persuasive consequences of persons with disabilities in a consumption context. We find that consumers perceive those with disabilities as having elevated moral character due to the perception of their having overcome adversity. Further, the presented evidence suggests that heightened moral character is associated with persuasion such that the moral halo may activate persuasion knowledge that strengthens credibility, not suspicion.

### When People Stop Being Nice and Start Getting “Real”: Use of Identity Labels for Stigmatized Groups

#### EXTENDED ABSTRACT

No systematic research exists that has explored the impact of using identity labels to describe stigmatized groups. Yet, regulatory agencies are making suggestions about which labels should and should not be used. Ironically, these conditions are often associated with stigmatized groups. More importantly, these are “identity labels” that have implications for the person *doing* the labeling and the person *being* labeled. This is the first research, to our knowledge, that systematically explores perceptions in using *person first* in the description (e.g., person with obesity) or describing the *condition first* (e.g., obese person) in the description.

Across four studies, we first examine the frequency of person-first versus condition-first language in scholarly articles using Google Search. We find that more stigmatized medical disorders were more likely to contain condition-first language (Study 1). Next, we find that the less offensive way to address stigmatized groups is using person-first language, but the actual language used depends on the specific disorder (Study 2). Also, when people perceive a stigmatized

disorder to be controllable (not controllable), they use condition-first (person-first) language (Study 3). In study 4, when people perceive an individual is (not) willing to change in order to improve their condition, they use (condition-first) person-first language.

Growing interest surrounding how we address disabilities stems from concern over the victimization and stigmatization of these conditions. Previous research has focused on language differences to describe stigmatized groups and the need to use person-first language (Blaska 1993; Dietz 2015; Jensen et al. 2013). Researchers argue that the person-first approach presents conditions as just one part of the individual and distances the individual from their condition: a perspective that creates a more holistic view of the person being described (Dunn and Andrews 2015). However, condition-first language advocates argue that this language portrays disability as a distinct experience and brings its unique attributes to the forefront of discussion of stigmatized groups (Altman 2001).

Our findings indicate that language choices may have an important impact on how we view and interact with stigmatized groups. This research is a preliminary attempt to uncover when and why people use certain language, which can inform how they are judging others and the consequences of doing so.

In study 1, in order to shed light on language choice preferences, we conducted a Google Scholar search for scholarly articles published after 2013 containing person-first and condition-first language for six common disorders (Table 1):

Results show a clear pattern of language choices, with not all disorders following the person-first language guidelines. As an initial gauge of label usage, at least for these six conditions, it appears that condition first language is “preferred” for more stigmatized conditions and person-first language is used for less stigmatized medical conditions.

In study 2, we examine people's overall beliefs on identity labels used for stigmatized groups. We asked 215 MTurk participants what phrases, either person-first or condition-first, they believed were *least offensive*, as well as which they *preferred to use* for nine common diseases and disorders: obesity, alcohol addiction, drug addiction, anorexia, bulimia, dyslexia, schizophrenia, disability, and autism. People were significantly more likely to choose person-first language as the *less offensive* term for all nine disorders (all percentages > 85%,  $p < .001$ ). However, the phrase *actually used* varied based on the disorder, with people more likely to use condition-first language for obesity, alcohol addiction, and drug addiction than for the other disorders.

The variation in use of person-first language may be linked to perceived controllability of the disorder. Previous research indicates that the degree of perceived controllability affects the blame attributed to stigmatized groups (Weiner 1993, 1995, 1996). In study 3, we examine how controllability affects language choice. We found that people preferred person-first language when there was low perceived controllability and condition-first language for high perceived controllability situations. We used four disorders that varied on stigmatization: obesity and alcoholism (high stigmatization) and dyslexia and autism (lower stigmatization). We asked 301 MTurk participants to choose which phrasing, person-first or condition-first, they would prefer to use for each disorder under either high controllability, low controllability, or the controllability was not described. We manipulated the level of controllability for each disorder in a between-subjects experiment. In the high controllability condition, participants were told that the disorder was worsened by factors dealing with the person's lifestyle. In the low controllability condition, participants were informed that the disorder was worsened by the person's genet-

ics. If controllability was not described, participants were only told the disorder the individual was diagnosed with.

While there were no significant differences in dyslexia and autism manipulations, for both obesity and alcoholism, people were significantly more likely to choose person-first language when the condition was not in the person's control and were as likely to use condition-first language if the condition was in a person's control or not described at all. This suggests that people use condition-first language for stigmatized groups in order to convey the perceived controllability of the disorder by the person.

In study 4, we examine the impact of a person's willingness to change on the identity labels used. We ask participants which identity label they would use to refer to someone else for the four medical conditions used in study 3. The between-subject manipulation was willingness to change of the individual. Participants were told that the individual was either willing to change in order to improve their condition, not willing change, or willingness to change was not described.

For both obesity and alcoholism, people were more likely to use person-first language when an individual was willing to change versus when they were not willing to change or when willingness to change was not described. There were no statistically significant differences within dyslexia and autism manipulations. These results suggest that people use person-first language to convey an individual's willingness to change and that for highly stigmatized groups when willingness to change is not described, it is implied they are not willing to change.

### **SESSION OVERVIEW**

Decades of research suggests that attitudes serve important functions for consumers. However, much of past work has examined attitude functions in contexts where external factors (e.g., norms) play a minimal role. How do attitude functions change when different external factors are more directly considered? In this session, four papers demonstrate novel ways in which the context matters when determining the functional value of attitudes. The first paper explores how situational relevance (Paper 1) alters the function of attitude ambivalence. The last two papers investigate the roles of embodied states (Paper 2) and norm focus (Paper 3) affect the functions of attitude strength and accessibility, respectively.

Paper #1 (Singh and Unnava) explores the mental storage structure and retrieval of ambivalent product beliefs. Earlier work has demonstrated that the simultaneous accessibility of both positive and negative product beliefs often generates the experience of ambivalence and the associated discomfort. Yet, a series of studies show that, although positive and negative product information are stored together, situational relevance reduces the importance of non-applicable conflicting thoughts. Hence, the consumption context can moderate feelings of ambivalence and the associated discomfort toward an object.

Paper #2 (Shrivastava, Jain, Kwon, and Nayakankuppam) looks at the role of embodied states on attitude strength. Traditionally, it has been held that strong attitudes towards a target are a result of the conscious cognitive process of elaboration, where individuals engage in effortful issue relevant thinking. However, the authors posit that attitude strength can come about from non-elaborative processes as well, depending on certain embodied states. Four studies show that incidental bodily experiences that influence one's perceptions of 'information quality' (e.g. 'hard vs soft' data) affect the strength of one's attitude towards a target object.

Paper #3 (Barnes and Shavitt) examines a cost to attitude accessibility in contexts where fitting in is important. Prior literature suggests that having accessible preferences puts one at ease and consequently, are beneficial for coping with decision demands. The authors refine this conclusion by demonstrating that accessible attitudes have drawbacks when others' attitudes are unknown or conflict with personal preferences. The results show that, when normative consid-

erations are important, having accessible attitudes can get in the way of feeling at ease and responding positively to consumption-related decision demands.

## **Felt Ambivalence: Exploring the Storage Structure and Role of Situational Relevance on the Accessibility of Dominant and Conflicting Reactions**

### **EXTENDED ABSTRACT**

Feeling both positive and negative about a product is referred to as ambivalence (Zemboiran and Johar 2007). The Gradual Threshold Model (GTM) of ambivalence (Priester and Petty 1996) distinguishes between latent (the existence of conflicting thoughts in mind) and felt ambivalence (the discomfort felt by an individual because of the conflicting thoughts). GTM shows individuals possess dominant and conflicting reactions simultaneously but may not feel ambivalent. The model suggests that felt ambivalence and its intensity depend on the rate at which conflicting reactions are accessed. The number of conflicting reactions activated from memory should reach a threshold for an individual to feel the discomfort due to ambivalence. Thus, GTM elegantly reduces the notion of felt ambivalence to one of access to conflicting reactions in an individual's mind.

Since access to information in memory depends on how it is stored (or structured) in memory, this research first focuses on how individuals store ambivalent information. Are dominant and conflicting thoughts stored together in mind in an inter-connected way so they can cue each other? Or, are individuals' dominant thoughts separated from their conflicting thoughts, even though they are both connected to the object? Thus, our first objective in this research is to investigate whether dominant and conflicting reactions about an attitude object are stored together and whether they could be retrieved associatively. Past work suggests that simultaneous accessibility of dominant and conflicting reactions leads to felt ambivalence (Newby-Clark and Zanna 2002). Therefore, if dominant and conflicting reactions are stored together and retrieved associatively, activating one would simultaneously activate all leading to experienced discomfort every time the object is faced. Hence, our second objective is to investigate whether the situational relevance affects the retrieval of conflicting thoughts to minimize felt ambivalence in consumers.

If both dominant and conflicting reactions about an attitude object are stored at same location, activating one type of reaction would facilitate the activation of other stored reactions. In contrast, if dominant and conflicting reactions are separately stored, activating dominant would create facilitation only for dominant reactions and not for conflicting evaluations and vice-versa.

Study-1 used a two-cell design (Presentation order: control vs. sequential). Pre-tested, two univalent (positive-valence: Warren Buffet and negative-valence: Lance Armstrong) and two ambivalent objects (French fries, Nordstrom) were used as target stimuli, and evaluative statements were created for them. One positive (P) and one negative (N) evaluative statement for each ambivalent attitude object and two univalent evaluative statements for each univalent object were created. In sequential presentation condition, participants always saw two statements about the target object sequentially (e.g., French fries are tasty followed by French fries are fatty). Four types of sequential statements were used: French fries (P-N), Nordstrom (N-P), Warren Buffet (P-P) and Lance Armstrong (N-N). Participants were asked to express if they agreed with the statements and their re-

sponse latencies were measured. These response latencies, viewed as indicating the proximity of storage of two types of thoughts, formed the critical dependent measure for the study. In control condition, first statement from sequential condition was replaced by filler. The second statement used in the sequential presentation condition was used in the control condition and response times between control and experimental conditions were compared. In addition, multiple filler statements were used to space out the target objects.

Analysis of response times (in milli-seconds) showed that the presence of one statement about an object facilitated the speed of response to the next statement for both univalent ( $p < .05$  for all the reported means) (Warren Buffet: Mean<sub>RTControl</sub> = 1540 vs. Mean<sub>RTExperimental</sub> = 1170; Lance Armstrong: Mean<sub>RTControl</sub> = 2220 vs. Mean<sub>RTExperimental</sub> = 1950) and ambivalent objects (French-fries: Mean<sub>RTControl</sub> = 1660 vs. Mean<sub>RTExperimental</sub> = 1500; Nordstorm: Mean<sub>RTControl</sub> = 2110 vs. Mean<sub>RTExperimental</sub> = 1670). Thus, a *facilitation effect* was found and it was independent of the valence of preceding statement.

Study-2 replicated study-1 more conservatively. Evaluative statements for Chinese restaurants and Donuts were used. In the experimental condition, one negative statement was sequentially presented after three positive statements, and vice-versa (i.e. dominant followed by one conflicting thought). A *facilitation effect* was replicated. For both, the response time kept getting lower with each following statement and then continued for the fourth statement of opposite-valence (Donuts: Mean<sub>RTfirst</sub> = 1500 vs. Mean<sub>RTfourth</sub> = 970; Chinese restaurants: Mean<sub>RTfirst</sub> = 1840 vs. Mean<sub>RTfourth</sub> = 1110). Hence, results indicate that both the conflicting and dominant reactions toward an object are stored together and retrieval of one associative link (either dominant or conflicting) would lead to activation of all.

Given the structural property of ambivalence, does situational relevance affect the accessibility of conflicting reactions leading to minimization in ambivalence? If so, does the inhibition of conflicting reactions occur due to reduction in their perceived importance? Study-3 used a two-cell (primed scenario: tasty vs. healthy) between-subjects design. Three evaluative statements for French fries (they are: tasty-(P), crunchy-(P) and fatty-(N)) were used. Participants were primed using a party planning scenario. Situational relevance was manipulated by describing guests either as young-twenty to twenty-five with no health concerns or older-between twenty to fifty years with some health concerns. Results found, for health-prime condition, facilitation occurred for all the statements (Mean<sub>RTtasty</sub> = 1299.5, Mean<sub>RTcrunchy</sub> = 1129.9 and Mean<sub>RTfatty</sub> = 1032). But, when only taste was primed, accessibility of health related reactions was significantly reduced (Mean<sub>RTtasty</sub> = 1115, Mean<sub>RTcrunchy</sub> = 996.46, Mean<sub>RTfatty</sub> = 1204.12).

Further, study-4 incorporated an importance measurement task to study-3 design. Participants rated the importance of tastiness, crunchiness, and fattiness of French fries. Prior results were replicated. Critically, the importance of taste-associated attributes was significantly higher in no-health concern condition compared to health concern condition (Tastiness:  $M_{\text{no-healthprime}} = 5.77$  vs.  $M_{\text{healthprime}} = 3.12$ ; Crunchiness:  $M_{\text{no-healthprime}} = 4.10$  vs.  $M_{\text{healthprime}} = 2.34$ ). However, results flipped for health-associated attribute (Fattiness:  $M_{\text{no-healthprime}} = 2.52$  vs.  $M_{\text{healthprime}} = 5.55$ ).

Thus, dominant and conflicting reactions towards an ambivalent object are stored at same location and activating one would make both accessible. Interestingly, situational relevance reduces the importance of non-applicable conflicting thoughts, inhibiting their accessibility to minimize felt ambivalence.

## Data... the 'Hard' & 'Soft' of it: Impact of Embodied States on Attitude Strength

### EXTENDED ABSTRACT

Substantial research finds that *strong* attitudes come to mind faster, persist over time, and, guide behavior. Possessing strong attitudes increases the ease, speed, and, efficiency of decision-making; it is thus functionally beneficial for individuals to hold strong attitudes. Traditionally, it has been held that strong attitudes towards a target are a result of the conscious cognitive process of elaboration, where individuals engage in effortful issue-relevant thinking (Petty & Cacioppo 1981,1986). In our research however, we propose that attitude strength can follow from non-elaborative processes, as a function of certain embodied states. While embodiment has been found to influence one's attitudes towards target objects (e.g., Wells & Petty 1980; Strack, Martin & Stepper 1988), little attention has been paid to how specific embodied states can impact the 'strength' of one's attitude without impacting the attitude itself. In this vein, we find that incidental bodily experiences *that alter one's perceptions of information quality* affect attitude strength and lead one to have strong attitudes towards a target object.

Study 1 embodies the notion of '*hard vs soft*' data – an expression we often use in daily discourse. In first of the three stages, participants seated at their work stations read information about an attitude object with their feet placed on either a plank base or a pillow base. Participants reported their attitudes towards the target object. The second stage consisted of unrelated buffer tasks to create a time delay of 25 minutes. In the last stage, we measured attitude accessibility (measure of attitude strength) using the response latency to access participants' attitudes formed towards the target brand during stage 1. Essentially, the bodily feeling of hardness from the plank served to induce individuals to perceive the information as being 'hard' or dependable – so, one should be more inclined to form a stronger attitude based on such 'hard' information. Alternatively, when the same information is perceived as being 'soft' or fuzzy (from the pillow), one should be less inclined to form a strong attitude. We did *not* find any differences on attitudes towards the target between the plank and the pillow condition ( $M_{\text{pillow}} = 2.68$  Vs  $M_{\text{plank}} = 2.65$ ;  $F(1,155) = 0.028$ ;  $p = .868$ ;  $\eta_p^2 = .000$ ). However, true to our hypothesis, we found that participants in the plank condition had more accessible attitudes, i.e. they were quicker in accessing their attitudes formed towards the target brand in stage 1, when compared to those in the pillow condition ( $M_{\text{pillow}} = 1643.16$  msec Vs  $M_{\text{plank}} = 1391.89$  msec;  $F(1,155) = 4.378$ ;  $p = .038$ ;  $\eta_p^2 = .027$ ). To bolster the validity of our results, we pre-registered a study, identical to study 1, with a similar sample of 150 participants with Uri Simonsohn's AsPredicted (a pre-registration portal recommended by the Association for Psychological Science). We replicated study 1.

Study 2 embodies the notion of 'information converging to the same conclusions' versus 'information diverging to imply different conclusions' about the object. Eight pieces of paper containing information about the object were arranged depending on the condition on a panel board. Information was identical in both conditions. In the 'converging' condition, participants picked the pieces of paper, arranged in eight locations along the borders of the board, and pinned them together at the center of the board. Alternatively, in the 'diverging' condition, participants picked the pieces of paper, arranged in the center of the board, and pinned them separately in eight locations along the borders of the board. All participants then reported attitudes towards the object, followed by the buffer tasks. Finally, we measured attitude accessibility. Essentially, individuals should form stronger attitudes when they perceive the information

as converging as opposed to diverging. We did *not* find any differences on reported attitudes towards the target brand between the two conditions. However, as expected, participants in the converging condition had more accessible (stronger) attitudes, than those in the diverging condition ( $M_{\text{converging}}=1134.63\text{msec}$  Vs  $M_{\text{Diverging}}=1414.64\text{msec}$ ;  $F(1,98)=7.245$ ;  $p=.008$ ;  $\eta_p^2=.070$ ).

In study 3, under the pretext of simulating an exercise scenario in the lab, we made individuals strap on wrist weights on only one hand or on both hands, while they read an advertisement about an object. We found that individuals who read information about the object with weight *only* on one hand (thus leaning towards one side) -perceived the information as clearly favoring one side- and had more accessible attitudes. Alternatively, participants for whom the weight was distributed on both hands equally -perceived the information to be favoring both sides -and had less accessible attitudes. In this latter case, one might not have a strong clear opinion about the object and might actually need additional information before feeling more strongly about the object ( $M_{\text{one-hand}}=1168.78\text{msec}$  Vs  $M_{\text{both-hands}}=1448.71\text{msec}$ ;  $F(1,63)=4.283$ ;  $p=.043$ ;  $\eta_p^2=.065$ ).

In study 4, we find evidence for an *attitude-rehearsal* based mechanism to explain the observed effect of embodied states on attitude accessibility. We theorized that individuals on the plank perceive the arguments as being ‘hard’, dependable (i.e., high in quality), and, will thus rehearse their attitude based on those arguments to a larger extent than individuals on the soft pillow. Repeatedly rehearsing one’s attitude strengthens the object-evaluation association in memory, resulting in increased attitude accessibility (i.e., strength) (Powell & Fazio 1984, Fazio 1995). We conducted a 2(base: hard-plank Vs soft-pillow) x 3(rehearsal: facilitating-rehearsal vs hindering-rehearsal vs control) between-subject design and manipulated the second factor (rehearsal) similar to Kwon and Nayakankuppam 2015, study 6. For participants on the ‘plank’, the control condition was insignificantly different from the facilitating-rehearsal condition ( $M_{\text{faci}}=1099.15\text{msec}$  Vs  $M_{\text{ctrl}}=1103.44\text{msec}$ ;  $F(1,80)=.002$ ;  $p=.962$ ;  $\eta_p^2=.000$ ), but was faster than the hindering-rehearsal condition ( $M_{\text{hind}}=1331.25\text{msec}$  Vs  $M_{\text{ctrl}}=1103.44\text{msec}$ ;  $F(1,80)=3.529$ ;  $p=.064$ ;  $\eta_p^2=.042$ ). This suggests individuals on the plank in the control condition *already engage in rehearsal by themselves*. Alternatively, for participants on the ‘pillow’, the control condition was insignificantly different from the hindering-rehearsal condition ( $M_{\text{hind}}=1362.85\text{msec}$  Vs  $M_{\text{ctrl}}=1691.50\text{msec}$ ;  $F(1,80)=1.499$ ;  $p=.224$ ;  $\eta_p^2=.018$ ), but was slower than the facilitating-rehearsal condition ( $M_{\text{faci}}=1074.73\text{msec}$  Vs  $M_{\text{ctrl}}=1691.50\text{msec}$ ;  $F(1,81)=5.738$ ;  $p=.019$ ;  $\eta_p^2=.066$ ). This suggests individuals on the pillow in the control condition *don’t engage in as much rehearsal by themselves*.

Our work has implications for sensory marketing and can inform businesses to have harder surfaces in their stores. The feeling of hardness can influence consumers’ perceptions of product information and can lead to stronger attitudes. There can be many such manifestations of our work in marketing and sales.

### **Deny the Voice Inside: Are Accessible Attitudes Always Beneficial?**

#### **EXTENDED ABSTRACT**

Decades of attitudes research suggest that accessible preferences put at us ease. Specifically, studies have shown that people with accessible attitudes experienced less stress (e.g., Fazio, Blascovich, and Driscoll 1992). However, we suggest that having accessible preferences is not always beneficial. For example, although having highly accessible clothing preferences may be comforting when deciding what to wear on a casual night out, the same might not be said

for making decisions in normatively stricter contexts such as work. Our research expands upon prior work by examining when and why accessible preferences facilitate coping with decision demands, and when accessible preferences have drawbacks.

Our current understanding of attitude accessibility relies on key assumptions. First, attitudes have been assumed to primarily serve an object-appraisal function (Smith, Bruner, and White 1956). Second, past research has examined the functions of attitude accessibility in contexts in which norms may not be highly salient or strictly enforced. Yet, these assumptions may not hold in other contexts where norms are equally, or sometimes more, useful as a basis for preferences (Riemer et al. 2014). We propose that in contexts when there is high norm focus (Cialdini, Reno, and Kallgren 1990), accessible personal attitudes are less beneficial.

High norm focus prompts adaptation to others’ preferences. In contrast, accessible personal preferences increase private self-awareness rather than awareness of others, and thus, can conflict with fitting in (e.g., Goukens, Dewitte, and Warlop 2009). Therefore, when there is low norm focus, people should feel more at ease when holding highly (vs. not) accessible attitudes. Four experiments tested this prediction using dispositional and situational operationalizations of norm focus.

Study 1 provided initial evidence that having an accessible personal preference is less beneficial in a national culture where there is greater norm focus. 122 Americans and 120 Indians were randomly assigned to rehearse their preferences toward autonomous cars (focal attitude object) or brain transplants (filler object). Then, they rated their anticipated emotions when discussing autonomous cars with friends (positive: confident, prepared, intelligent,  $\alpha = .90$ ; negative: defensive, uptight, tense,  $\alpha = .75$ ). An ANCOVA revealed a marginally significant attitude accessibility  $\times$  country interaction ( $F(1, 237) = 3.29, p = .071$ ). As expected, having more accessible personal attitudes helped Americans cope with an attitude-relevant situation ( $M_{\text{High, US}} = 4.29, M_{\text{Low, US}} = 3.68, p = .012$ ). This was not the case for Indian participants ( $M_s = 5.46$  vs.  $5.46, ns$ ).

The goal of Study 2 was to demonstrate that having accessible preferences can backfire when norm focus was situationally salient. We manipulated norm focus with a validated self-construal prime (independent vs. interdependent; Brewer and Gardner 1996) and used the same attitude accessibility conditions as Study 1 (high: autonomous cars vs. low: brain transplants). 183 US participants were randomly assigned to one of four conditions and rated their anticipated emotions when discussing the focal topic. However, in this study, all subjects were told that their friends held the opposite preference. Thus, we expected that close others who opposed one’s accessible (vs. not) attitudes would only make those in the interdependent condition feel less at ease. An ANCOVA revealed the predicted attitude accessibility  $\times$  self-construal interaction ( $F(1, 178) = 4.66, p = .032$ ). In this context, high (vs. low) attitude accessibility decreased positive emotions for interdependents ( $M_{\text{High}} = 4.23, M_{\text{Low}} = 4.80, p = .017$ ; independent:  $M_s = 4.64$  vs.  $4.50, ns$ ). These results also suggest that having less accessible attitudes can facilitate adapting to norms and be more reassuring.

Study 3 built upon the previous two by using a different operationalization of attitude accessibility (measured) toward familiar attitude objects. 180 adults indicated their preferences toward several snacks (e.g., Cheez-its). Next, participants were randomly assigned to think about what snacks they would bring to a gathering with friends that the group (vs. participants themselves) would enjoy. Again, they rated the anticipated emotions from past studies. Regression analyses revealed the expected interaction ( $\beta = -6.07, se = 2.50, p = .016$ ). When the wishes of others were salient, having

more accessible personal preferences toward snacks decreased positive emotions (group:  $M_{\text{high}} = 5.15$ ,  $M_{\text{low}} = 5.74$ ,  $p = .005$ ; self:  $M_s = 5.07$  vs.  $4.91$ , *ns*).

Study 4 achieved three objectives. First, we explored whether attitude accessibility hurts coping when the salient norm was less relevant. Second, we generalized our findings to a marketing outcome that reflects the reassurance of having accessible attitudes (e.g., willingness-to-pay; Fazio, Powell, and Williams 1989). Third, we examined the mediating role of private self-awareness. Prior work suggests that people differ in the degree to which they rely on internal states to cope with decisions (Lam and Zane 2004). Moreover, private self-awareness has been associated with a greater consciousness of personal preferences (Goukens et al. 2009). Thus, we expected that increased private self-awareness would mediate the relationship between accessible preferences and positive coping outcomes under low norm relevance.

233 undergraduates participated in a 2 (attitude accessibility: high vs. low)  $\times$  2 (norm relevance: high vs. low) between-subjects design. After expressing their attitude toward an apparel item three times (vs. once), participants rated whether the item and others would be good or bad to wear in class (high norm relevance) or in a sports bar (low). Participants then rated their private self-awareness (Govern and Marsch 2001) and willingness-to-pay (WTP) for the focal item. As expected, two ANOVAs revealed that high (vs. low) attitude accessibility only increased participants' private self-awareness and WTP for the focal item when norm relevance was low, not high. Furthermore, moderated-mediation analysis showed that private self-awareness fully mediated WTP when norm relevance was low ( $\beta = .216$ , Boot SE =  $.13$ , 95% CI:  $.02$ ,  $.56$ ), not high (95% CI:  $-.19$ ,  $.13$ ).

In closing, our findings support the notion that normative factors are important when considering the functional value of attitude accessibility. Accessible attitudes may not always function to ease coping – particularly in normative contexts that heighten the importance or difficulty of fitting in with others. In such contexts, having less accessible attitudes can facilitate adaptation to norms and thus are more reassuring.

### **SESSION OVERVIEW**

We commonly find ourselves evaluating sets of options, such as when browsing retail displays, or purchasing bundled goods. Similarly, when buying gift cards, memberships, and/or vouchers, we consider the individual and joint benefits of the options that they allow us to access. Interestingly, the perceived value of such sets rarely arises from simply summing the value of their components.

Instead, prior findings suggest that the value of a set of options with comparable attributes reflects the average value of the individual items (Gaeth et al. 1991; Brough and Chernev 2011; Chernev and Gal 2010). However, not all options may contribute equally – a preferred target or item that receives initial consideration can have disproportionate influence on a set's net value (Yadav 1994; Shenhav and Buckner 2014). Furthermore, a cohesive relationship between items can create a unique superseding value for them when considered collectively as a set (Evers, Inbar and Zeelenberg 2013.)

The papers in this session examine how the value of individual options can relate to or interact with the value of a set based on inter-item relationships, set meanings and overarching decision goals. To start, Evers and Inbar consider how the values of individual items in a bundle are established in relation to each other. They find that a framing of “Option A is better than Option B” versus “Option B is worse than Option A” impacts not only the individual values of the options, but also the value of the bundle.

Shaddy and Fishbach consider bundles of options that serve distinct roles such as goals (e.g., ordering a gift) and means (e.g., paying for delivery), and find that people prefer shifting costs to goals and away from means. As a result, valuation of items within these bundles can reverse depending on the item's perceived role. Furthermore, consumers see more value in a goal item (e.g. a book), compared to a goal-means bundle (e.g., a book *and* delivery), meaning that they can be willing to pay more for less.

Spiller and Ariely similarly demonstrate ways in which adding options to a set can decrease its perceived value. They consider evaluations for a medium for exchange such as a gift card that can be applied to specific types of goods. They find that a medium for exchange that is designated for use on a single (preferred) good can be seen as more valuable than one that can be used on the preferred good as well as other categories.

Finally, Karmarkar and Shenhav examine the mechanisms involved in evaluating a set as a whole (appraisal) versus evaluating a set as a group of choice options (choice). Consistent with prior findings, they show that a set's appraisal value correlates most significantly with the average value of its component items. This overall set value is represented in neural activity during *both* appraisal and choice tasks. However, choice recruits additional areas of brain activity, possibly reflecting the comparative value of options within the set. Their findings suggest separable task-dependent mechanisms underlying set vs. option evaluations.

## **Worse is Bad: Asymmetric Inferences on Items and Assortments From Logically Equivalent Comparisons**

### **EXTENDED ABSTRACT**

When evaluating products, we usually compare these products to other products in the reference category (see for example, Tversky & Kahneman, 1981). The same relation between products in a bundle or category can usually be framed in two different ways; A is better than B, or B is worse than A. In this project we look at how these two different ways of framing affects quality inferences about the products under consideration as well as other products within the reference-category.

Based on work investigating the “leakage of information” (Sher & McKenzie, 2006), we expect that beyond the actual information in a description, consumers also draw inferences from the speaker's choice of frame. But what information do they infer, and how does this affect the consumer's judgment and choices about the focal products and the rest of the assortment? A simple prediction is that when “toaster A is better than toaster B”, consumers infer that toaster A must be really good. When “toaster B is worse than toaster A” consumers may infer that toaster B is really bad. Alternatively, instead of merely inferring the quality of A and B, consumers may infer different quality for the entire set of toasters. When  $A > B$ , all toasters must be pretty good, when  $B < A$  all toasters must be pretty bad.

In 8 studies, we consistently find an asymmetric pattern of inferences both for the focal products (A and B) as well for the entire assortment. Compared to an assortment where product A is described as being better than product B, consumers who see that B is worse than A infer only slightly lower quality for A, but infer a much lower quality for B. For example, in Study 1 ( $N = 313$ ), participants evaluated toasters in the top-10 toaster list from Consumer Reports. They read in the review that toaster A (JC Penny) is better than toaster B (KitchenAid), or that toaster B is worse than toaster A. Judgements for toaster A were slightly worse in “B is worse than A” ( $M = 2.87$ , on a -5 to +5 scale) as compared to “A is better than B” ( $M = 3.32$ ,  $p = 0.03$ ), but were much more pronounced for toaster B ( $M_{\text{Bworse}} = 0.43$ ,  $M_{\text{Abetter}} = 1.27$ ,  $p < .01$ ). We replicate these findings in Study 2 using different products.

We find similarly asymmetric inferences being drawn about the rest of the assortment. More specifically, between the different kinds of framing, participants do not infer that the quality of the average and top products in the assortment differ in quality, however we find stark differences in inferred quality for products in the lower range of the assortment. For example, in Study 5 ( $N = 400$ ), participants are asked to evaluate engineering teams. They read that their assistant has made a list of the ten teams available and read that either “team A is better than team B” or that “team B is worse than team A. Partici-

pants then judged the quality of Team A, Team B, but also the best, the average and the worst team. We replicate the previous effects with a small difference in judgments of team A ( $M_{\text{better}} = 3.3$ ,  $M_{\text{worse}} = 2.8$ ,  $p < .01$ ) and a larger difference for team B ( $M_{\text{better}} = -0.1$ ,  $M_{\text{worse}} = -1.45$ ,  $p < .001$ ). More importantly, we find a similar pattern of inferences for other objects in the category with no differences in the judgments of the best team ( $M_{\text{ABetter}} = 4.25$  vs  $M_{\text{BWorse}} = 4.27$ ), nor the average team ( $M_{\text{ABetter}} = 1.78$  vs  $M_{\text{BWorse}} = 2.06$ ), but find strong differences in the quality judgments of the worst teams ( $M_{\text{ABetter}} = -0.25$  vs  $M_{\text{BWorse}} = -0.95$ ). We replicate this finding in a different domain in Study 6 ( $N = 400$ ), and using different measures (percentile scores rather than subjective judgments) in Study 7 ( $N = 400$ ).

Beyond mere inferences, we also measure the downstream consequences on choice, both for the focal objects (A and B) as well as the rest of the set. In Studies 1 and 2, where product A and B are both in the top-10, we find that participants are more likely to buy an item ranked 11-25 rather than product B (which is in the top 10) when product B is described as worse than product A (68/156) as compared to when A is described as better than B (32/157),  $p < .001$ . We find similar effects for choice for the non-focal objects in the assortments. For example, in Study 8 ( $N = 400$ ), we give participants the opportunity to buy several unusual flavors of jellybeans. These participants are shown 5 different flavors of jellybeans ranked by average liking. Half of these participants read that "Orange crush" (#2) is judged to be better than "Jewel bubble gum" (#4), the other half of participants read that "Jewel bubble gum" is worse than "Orange crush". Then for each of the 5 flavors, participants can decide to buy a sample for \$0.25, or not buy. As in the quality judgments, we find no differences in the proportion choosing to buy the top ranked jellybeans (#1<sub>Better</sub> = 88%, #1<sub>Worse</sub> = 85%; #2<sub>Better</sub> = 83%, #2<sub>Worse</sub> = 74%), but a more substantial difference in the lower end of the distribution (#4<sub>Better</sub> = 35%, #4<sub>Worse</sub> = 23%; #5<sub>Better</sub> = 45%, #5<sub>Worse</sub> = 22%).

To summarize, we investigate how the framing of products within a category as "A is better than B" vs. "B is worse than A" affects inferences about the focal products (A & B) as well as the rest of the assortment. We find consistent asymmetric inferences such that the framing only weakly affects judgments of the higher end products in the assortment, but strongly affects judgments of the lower end of the range. These inferences affect subsequent choices, such that consumers avoid products in the lower range more when the focal products are described as "B is worse than A" as compared to "A is better than B".

### When the Ends Do Not Justify Paying for the Means: Consumers Prefer Shifting Costs from Means to Goals

#### EXTENDED ABSTRACT

Many consumption episodes conform to a goal-means structure (Etkin and Ratner 2012; Fishbach and Dhar 2005; Pieters, Baumgartner, and Allen 1995). Someone wishing to order a gift (a goal), for example, may also need to pay for shipping (the means). We investigate how the hierarchical configuration of goal systems affects preferences for resource investment in these goal-means "bundles."

Specifically, we propose that consumers are more willing to invest resources in goals than in means. Consequently, within a goal-means bundle, consumers will both pay more for the item perceived to be the goal (vs. the item perceived to be the means) and pay more for only the goal (vs. a means that is bundled with the goal). Consumers will also prefer to pay sooner for goals (vs. means), choose to use marketing promotions to reduce costs associated with means (vs. goals), and are happier when costs associated with means (vs. goals) are eliminated by such promotions.

We explain that this preference persists because in the architecture of goal systems, goals sit atop the hierarchy. Thus, investing resources in goals is perceived as direct investment in goal attainment (i.e., higher in the goal hierarchy), while investing resources in means is perceived as indirect investment (i.e., lower in the goal hierarchy). We argue that people prefer direct investment. Critically, this distinction between direct and indirect resource investment is a novel feature of our account and important because previous research has explored the allocation of resources horizontally (i.e., between various means; Kruglanski et al., 2002), but not vertically (i.e., between means and goals).

In Study 1 we manipulated, for a pair of products, which item was perceived as the goal and which item was perceived as the means. We elicited actual WTP (Vickrey 1961) for both chef's knife and a cutting board. In the *knife* condition, we framed a cutting board as a means for the goal of using a chef's knife; in the *board* condition, we framed a chef's knife as a means for the goal of using a cutting board. In the *knife* condition, participants expressed greater WTP for the chef's knife ( $M = \$17.17$ , 95% C.I. = [\$15.38, \$18.96]) than for the cutting board ( $M = \$14.43$ , 95% C.I. = [\$12.72, \$16.14];  $F(1, 408) = 29.98$ ,  $p < .001$ ). In the *board* condition, however, the pattern reversed. Participants expressed greater WTP for the cutting board ( $M = \$16.81$ , 95% C.I. = [\$14.96, \$18.67]) than for the chef's knife ( $M = \$14.04$ , 95% C.I. = [\$12.24, \$15.83];  $F(1, 408) = 28.15$ ,  $p < .001$ ).

One implication of our theory is that because people are more willing to invest resources in goals than in means, it is possible that they will express greater WTP for only a goal, compared to a means that is bundled with the goal. In Study 2, MBA students submitted bids for either a book autographed by Richard Thaler (i.e., paying for the goal) or for a tote bag in which the same autographed book would be delivered (i.e., paying for a means bundled with the goal). WTP for just the book ( $M = \$23.38$ , 95% C.I. = [\$17.24, \$29.51]) exceeded WTP for the tote bag bundled with the book ( $M = \$12.18$ , 95% C.I. = [\$7.06, \$17.31];  $t(79) = 2.84$ ,  $p = .006$ ).

In Studies 3-4, we presented participants with one of three scenarios, each of which presented a goal-means "bundle." Participants imagined that they needed to either take a prerequisite class (means) before a target class (goal), run a qualifying marathon (means) before running the Boston Marathon (goal), or cook a practice meal (means) before cooking a dinner party meal (goal). When paying for each goal and each means, participants both expressed greater desire to eliminate costs associated with means ( $F(1, 298) = 36.58$ ,  $p < .001$ ) and were happier when costs associated with means were eliminated ( $F(1, 299) = 12.91$ ,  $p < .001$ ).

In Study 5, we presented participants with items that either formed a goal-means bundle (i.e., a tote bag served as a means to acquire beach towels) or would be purchased for two different people and hence, served as unrelated goals. When given the opportunity to delay payment for each (thereby reducing costs through temporal discounting), participants preferred delaying payment for the tote bag only when it was part of a goal-means bundle ( $F(1, 197) = 9.50$ ,  $p = .002$ ).

Finally, in Studies 6-7 we measured nonmonetary forms of resource investment to offer process evidence for our account and eliminate pricing norms as an alternative explanation.

In Study 6 we presented participants with two news articles and manipulated whether the articles maintained a goal-means relationship (i.e., an article about the opioid epidemic served as the means by which participants could achieve the goal of understanding an article about falling life expectancy) or represented separate goals. In the goal-means condition, participants spent more time reading the

article presented as a goal than the article presented as a means ( $F(1, 215) = 3.99, p = .047$ ). This pattern disappeared when both articles were perceived as goals ( $F(1, 215) = 21.99, p < .001$ ).

In Study 7 we predicted that the perception of direct (rather than indirect) investment in goal attainment would mediate the effect. We framed either dieting as a means for achieving the goal of exercising or dieting and exercising as separate goals. In the goal-means condition, participants were willing to spend more time planning their exercise regimen than their diet regimen ( $F(1, 223) = 21.01, p < .001$ ). This pattern disappeared when both were perceived as goals ( $F(1, 223) = 6.19, p = .014$ ). Moreover, this effect was fully mediated by the extent to which participants perceived exercise to be a more direct investment in goal attainment (indirect effect = .168, SE = .09, 95% C.I. = [.030, .373]).

In short, our results suggest that consumers systematically prefer shifting costs from means to goals. Thus, while the ends may justify the means, the ends may not always justify *paying* for the means.

### How Does the Perceived Value of a Medium of Exchange Depend on its Set of Possible Uses?

#### EXTENDED ABSTRACT

A medium of exchange is valuable because it may be exchanged for something else that directly or indirectly provides value. Money, gift cards, concert tickets, and arcade tokens are all media of exchange that are valuable because they eventually enable consumption of something else. The normative value of a medium of exchange is based on the best set of goods and services for which it can be exchanged. Formally, the normative value of a medium of exchange is the difference between the expected utility of the best bundle of goods that can be obtained with that medium and the expected utility of the best bundle of goods that can be obtained without that medium.

Previous work on the value of media of exchange has focused on the medium itself, independent of its uses. One stream of literature has focused on how the numerosness of a currency and its nominal value influence its perceived value: Holding constant real prices and wages, people are sensitive to nominal prices and wages (Fisher 1928/2011; Shafir, Diamond, and Tversky 1997), the presence of an irrelevant medium changes consumer behavior (Hsee et al. 2003; van Osselaer, Alba, and Manchanda 2004), and people spend differently when spending more or less numerous currencies (Raghubir and Srivastava 2002; Wertenbroch, Soman, and Chattopadhyay 2007). A second stream of literature has examined the effect of the form of a medium on spending decisions, showing that the same medium, presented as cash or credit cards, leads to apparent differences in valuation (Soman 2001, 2003; Prelec and Simester 2001).

In contrast, we ask the basic question of how the perceived value of a medium is grounded in its potential uses. We propose the value of a medium of exchange can be affected in non-normative ways by its entire associated set of potential purchases.

We posit this because of the stylized fact that people evaluate sets according to their averages. When evaluating products as sets of attributes (Troutman and Shanteau 1976) and bundles as sets of products (Gaeth et al. 1991; Yadav 1994; Brough and Chernev 2012; Chernev and Gal 2010), people use a weighted average across multiple components to come to a judgment about the composite set (Anderson 1965; Nisbett, Zukier, and Lemley 1981). When evaluating sets of bets, people report higher evaluations of a single highly valued outcome than of the combination of that single highly valued outcome and a second, moderately valued outcome (Shanteau 1974; Lynch 1979).

In each of the evaluative cases above, the focal value individuals attempt to assess is a function of the *sum* of the components of the set. In contrast, the value of a set of potential purchases relevant for a medium of exchange should be a function of the *maximum* of the components of the set, not the sum. Whether this same averaging principle extends to such a “max-set” in addition to “sum-sets” remains an open question. If the averaging principles does extend to medium of exchange’s max-sets, such integration across irrelevant potential uses of a set would imply that adding less-desirable uses could decrease evaluations.

Findings from research on assortments lends suggestive support to this proposal, though whether it applies to the perceived value of media of exchange remains to be tested. The evaluation of a set of products decreases as the number of unacceptable products in the assortment increases (Kahn and Lehmann 1991) and decreasing the number of undesirable products available can increase evaluations when category salience is held constant (Broniarczyk, Hoyer, and McAlister 1998). These effects are particularly pronounced when people make direct evaluations of the set as a whole rather than actively thinking through all the stages of the decision and deriving an evaluation based on the underlying choice (Sood, Rottenstreich, and Brenner 2004).

*Studies 1A–1D.* In our first set of studies, we examine how including a less-attractive option reduces choice of a medium of exchange. Participants (total  $N = 603$ ) were less likely to choose a medium of exchange that could be used on either of two goods than they were to choose a medium of exchange that could only be used on the more-attractive good ( $ps < .01$ ). The magnitude of the effect increased with the difference in value between the more- and less-attractive goods (bigger differences led to bigger effects).

*Studies 2A–2E.* In our second set of studies, we examine perceived value as operationalized via willingness to pay. We also varied the salience of the value of the component goods and the choice between the component goods. Across studies (total  $N = 1300$ ), we again find that media of exchange are valued less when usable on two goods than just the more-attractive good ( $ps < .005$ ). The manipulations of value and choice had no consistent effects but together indicate that choice aversion, nor comparative loss aversion, nor non-consequential reasoning, nor category averaging fully accounts for the overall devaluation.

Using both measures of choice and willingness to pay, we find that adding a less-attractive alternative decreases the perceived value of the medium of exchange. These findings hint that comparing apples and oranges may not be as difficult as idioms lead us to believe; what is difficult is comparing two apples to a dollar that can be exchanged for any one of a nearly countless set of products.

### Dissociable Mechanisms for Evaluation Involved in Appraising a Set Versus Choosing From It.

#### EXTENDED ABSTRACT

People commonly encounter arrays of options that can be as varied as those in a bakery case, a course catalog or a car dealer’s lot. In these situations, there are two possible modes of engaging with such sets: “just browsing” the set (appraisal), versus making a choice from it. These modes intuitively seem to be distinguishable phenomena, but it’s less clear if they represent distinct processes and/or types of value.

Separate lines of research have shown specific mechanisms associated with appraising the value of individual stimuli/goods (Knutson et al., 2007; Plassmann et al., 2007; Lebreton et al., 2009), and with the process of choosing (Levy and Glimcher, 2012; Bartra et

al., 2013; Clithero and Rangel, 2013). However, that work does not establish whether the *overall* set value can be extrapolated from the value(s) of its individual options. It also remains unclear to what degree the mechanisms involved in appraising a set of options overlap those involved in choosing from that set of options.

Here we examine these questions by using behavioral tasks combined with functional magnetic resonance imaging (fMRI). We scanned participants while they were actively directed to appraise (e.g. report their liking for) sets of four items, or choose their preferred item from such sets. Importantly, both tasks required participants to consider the same kind of sets, and the value of each item in the set, but differed in terms of whether they require a *composite* of those values or a *comparison* between them.

For this experiment, a group of 30 individuals first rated their liking for each of a large number of consumer products. Based on these ratings, we constructed individualized four item sets of low-, medium-, and high-value options. We also created mixed-value sets by randomly sampling four products from across the participant's entire value distribution (without replacement). In the main fMRI task, participants were shown one of these sets on each trial, and were asked to either make a Like (e.g. appraisal) decision by rating their value for the set as a whole, or make a Choose decision, by indicating which of the items they preferred most. Each set was seen only once in this part of the experiment, but after exiting the scanner, participants engaged in a counterbalanced version of the task, so that we had both appraisal and choice ratings for all of the sets.

The first question was how the appraisal value of the set related to the individual option values. Preference for the set could be driven by the value of the best item in the set, the average value of items in the set, or some combination thereof. When regressing set liking on both of these variables, we found that it was most strongly associated with the average option value ( $\beta=0.59$ ,  $t(26.0)=10.1$ ,  $p<0.001$ ). The value of the best item in the set exerted a non-significant positive influence on set liking ( $t(25.6)=1.7$ ,  $p=0.10$ ).

This finding is convergent with prior studies on bundle values (Gaeth et al. 1990; Brough and Chernev 2011; Chernev and Gal 2010), but divergent from work involving choices from two-item sets (Shenhav and Buckner, 2014). This raises the issue of whether participants recognized that the set represented a grouping of possible choice options. Thus in a separate behavioral experiment, participants (N=300) were randomly assigned to one of three conditions related to evaluating a set of four bags of snack chips. One condition asked participants: Assuming that you are planning to buy one of these bags, how much do you like this display, or set of options, as a whole? The second condition asked "How much do you like this display, or set of options, as a whole?" The final condition replicated the framing of the fMRI task; participants were first informed that they might be asked to appraise the set or choose from it, and then were given the appraisal task. After rating the set, participants rated the individual snack bag options. There were no differences in liking ratings for the set ( $F(2,297)=.306$ ,  $p=.736$ ) across these conditions, and across conditions, each person's liking for the set was once again significantly predicted by the average of their ratings for the four snack bags separately ( $\beta=.589$ ,  $p<0.001$ ).

To study neural activity associated with set value during the Like and Choose tasks, the following analyses use a set of *a priori* regions of interest related to set preference and choice from functional results in Shenhav and Buckner, 2014. For completeness, we also performed a whole-brain analysis (thus avoiding assumptions about the specific areas involved) and observe similar results and distinctions to those reported here.

In line with prior work, neural activity in a Dorsal Value Network (DVN; ventral striatum, posterior cingulate cortex, and pregenual anterior cingulate cortex) increased parametrically with ratings of set liking during the Like task ( $\beta=0.09$ ,  $t(25.6)=3.3$ ,  $p=0.003$ ). Importantly, activity in the DVN also increased parametrically with ratings of set liking when participants were evaluating that set for the Choose task ( $\beta=0.08$ ,  $t(26.5)=2.5$ ,  $p=0.020$ ). Thus the set's appraisal value, best related to the average liking for each of the set options, was similarly represented in the brain regardless of task goal.

In contrast, activity in a differing set of brain regions that could be considered a Ventral Value Network (VVN, medial orbitofrontal cortex, retrosplenial cortex, and left middle frontal gyrus), was substantially greater for Choose relative to Like trials ( $\beta=0.36$ ,  $t(27.2)=7.1$ ,  $p<0.001$ ). Indeed we observed a network-by-task interaction demonstrating that the relative difference in activity for Choose versus Like was significantly greater in the VVN ( $F(1,65.7)=25.0$ ,  $p<0.001$ ).

Our findings indicate that when we encounter sets of items, we encode their value as the average value of the items that compose the set. In addition, the results suggest that there are differentiable task-specific mechanisms involved in estimating value when we are appraising a set of possible options versus considering and comparing the individual value of items within a set.

### SESSION OVERVIEW

Saving requires consumers to forego spending in the present to increase available resources for future use. It can reduce consumers' reliance on credit to fund consumption and may reduce financial stress. Despite the benefits of saving, consumers worldwide do not save enough. This symposium investigates consumers' psychological barriers toward saving, as well as steps for overcoming them, offering novel insights into the psychological and situational factors underlying saving motivation. Four papers shed light on the broad question of how current and future financial circumstances (actual and perceived) affect motivation to save. We discuss the influences of consumers' beliefs regarding future wealth, present financial identity, interaction of skills and mindset, and characteristics of their saving goals.

First, Desiraju, Urminsky, and Sussman examine how consumers' optimistic beliefs of future wealth may hamper their motivation to save. Consumers who expect increased future wealth demonstrate less patience and higher discount rates-- suggesting that consumers who anticipate a positive boost to their future resources may be less likely to save. They find the belief in a more favorable financial future is widespread-- most consumers believe they will be better off in the future, and such optimism may weaken saving rates on a large scale.

While perceptions of future financial resources impact current savings, Garbinsky and Mead explore how saving decisions are influenced by current financial behavior. They find that consumers who consider instances of spending money express greater saving intentions, whereas, considering instances of saving does not increase saving intentions. Consistent with the first paper, Garbinsky and Mead find a positive bias in financial perceptions: As American consumers are more likely to identify as savers, this mindset may prevalently dampen saving motivation.

In addition to perceptions of future and current financial circumstances, Salisbury, Nenkov, and Zhao evaluate how consumer mindset in goal-pursuit influences savings decisions. They find that consumers with low savings knowledge save less in an implementation mindset (focusing on the steps to achieve a goal), rather than a

deliberative mindset (focusing on whether one should pursue a goal). While implementation mindsets have long been hailed as a positive intervention to increase goal directed behavior, they find that such a mindset creates illusionary progress for low-knowledge consumers.

While the first three papers speak to cognitive evaluations of oneself and one's future that help and hinder saving, our final paper considers characteristics of savings goals. Donnelly, Ksendzova, and Norton find that consideration of future experiential (vs. material) purchases better motivates consumers to save. Underlying this effect is that experiential purchases better allow for anticipatory pleasure in the process of saving.

Together, the papers in this symposium identify important and previously unexamined influences on saving decisions (papers 1, 2 and 4) and uncover paradoxes in saving rates (papers 2 and 3). We present a cohesive view of how, why, and when consumers choose to spend in the present or save for future.

## The Role of Expectations about Changes in Wealth in Discounting Decisions

### EXTENDED ABSTRACT

When making intertemporal choices, people persistently demonstrate present bias, choosing "smaller sooner" options instead of "larger later" ones (O'Donoghue and Rabin, 1999). This pattern is particularly strong when individuals are making choices about money (Carvalho et al., 2016). Furthermore, these patterns (favoring having money to spend in the present over money for the future) in intertemporal choices about money can create obstacles to saving.

Existing research on intertemporal choices about money primarily focuses on how current wealth affects discounting. For example, people display less present bias on discounting tasks right after receiving a paycheck (Carvalho et al., 2016). Additionally, studies suggest that liquidity constraints influence discounting with some literature positing that present bias is observed in lab settings because people take part in experiments when they have an urgent need for money.

While research on resource slack and discounting suggests that individuals may consider beliefs about the future when making intertemporal choices (Zauberman and Lynch, 2005), the question of whether people are sensitive to changes in their wealth remains largely unanswered. We predict that expectations about changes in wealth factor into individuals' smaller sooner versus larger later decisions, representative of propensities to spend versus save. In particular, we hypothesize that those who anticipate having more money in the future *relative to the present* will choose fewer delayed outcomes when making intertemporal choices, demonstrating less propensity to save, than those who anticipate having less money in the future relative to the present. We anticipate this pattern to remain after accounting for current wealth.

In study 1 (N=363), we tested whether beliefs about changes in personal wealth related to individuals' discount factors, both spontaneously and when reminded to consider change. We randomly assigned participants to either answer questions about changes in their available wealth (money in their checking or savings accounts) or not, prior to making intertemporal choices. Those who were reminded to consider changes in personal wealth were asked to report their available wealth currently and the available wealth

they expected to have in six months before making intertemporal choices while those in the non-reminder condition completed those questions after making intertemporal choices. Instead of answering questions about wealth, the non-reminder group was asked to report how much furniture they had at home at different points in time. Then, all participants completed a discounting task. Those who were reminded to consider changes in wealth chose fewer delayed options in the discounting task than those who were not reminded ( $F(1,361)=8.009, p=0.004$ ). This pattern of results reflects individuals' beliefs about their future wealth: the majority of participants (83.47%) expected a positive change in their available wealth. As expected, those who anticipated a greater increase in wealth in the future were less patient (chose fewer delayed options and therefore had a lower discount factor) than those who expected a smaller one ( $F(1,361)=25.6, p<.001$ ). This relationship held when controlling for current income ( $F(2,351)=17.3, p<.001$ ). Furthermore, the impatience of participants who were reminded to consider changes in wealth was more sensitive to believed changes than those who were not reminded ( $F(3,359)=10.8, p=0.027$ ). However, the relationship between believed change and impatience was significant in both conditions (reminder:  $F(2,167)=6.59, p=0.01$  non-reminder:  $F(2,181)=10.8, p<.001$ ).

In study 2 ( $n=674$ ), we investigated whether reminding people to consider changes in personal wealth would affect the relationship between beliefs about income change and discounting. Participants either did a task reminding them of reasons their household income could increase or reasons why it could decrease. Those reminded of increases were asked to think of reasons such as receiving a promotion or experiencing a boost in the economy, while those reminded of decreases were asked to think about reasons such as losing a job or experiencing a downturn in the economy. Next, participants reported their available wealth currently and in 6 months. Then, all participants completed the discounting task used in study 1. People appeared to be spontaneously taking into account reasons why their wealth might increase or decrease; preferences for saving did not differ according to the type of reminder ( $F(2,671)=27.95, p=0.9333$ ), and the manipulation was not effective in changing expected beliefs about the future. As in study 1, most people (74.77%) expected a positive change in their personal wealth, irrespective of condition. However, those who anticipated a greater increase in wealth were less patient than those who expected a smaller increase ( $F(2,671)=27.95, p<.001$ ).

A study in progress seeks to explore whether individuals' expectations for the future match their actual changes in wealth. In this study, participants' predictions will be compared to their actual changes in wealth over a three-month period.

Overall, these studies suggest that people's expectations about changes in wealth, rather than current wealth alone, factor into their intertemporal choices. In two studies, those who believed they would have more in the future relative to the present were less patient, demonstrating that they may be less willing to put off spending than those who believed they would have less. Additionally, beliefs about changes in wealth were primarily positive, which may suggest that present bias observed in lab experiments may be due to participants' optimism about future finances rather than liquidity constraints. Broadly, these findings suggest that individuals' optimistic beliefs about changes in their personal wealth may be particularly persistent, hampering saving.

## When Perceiving Oneself as a Spender Increases Saving

### EXTENDED ABSTRACT

According to industry experts, half of Americans spend more than they earn without realizing it (Kavoussi 2012). Three quarters of Americans do not save enough money to cover an unexpected expense (Johnson 2013), and perhaps most troubling, the persistence of these overspending tendencies and failures to save for the future are expected to prevent approximately half of Americans from adequately supporting themselves in retirement (Bernheim et al. 2000).

Although statistics such as these suggest that Americans have difficulty saving money, it is not clear whether Americans perceive themselves the same way. We asked 202 MTurkers to categorize themselves as a saver, a spender, both, or neither. In contrast to what one may predict after consulting the above statistics, the results revealed that 77% of participants perceived themselves as a saver only or both a saver and spender. How is it that Americans can perceive themselves this way, yet fall so short when it comes to adequate saving?

We posit that when making savings decisions, a saving salience mindset is activated, such that consumers can more easily recall instances in the past where they saved instead of spent. In this paper, we focus on shifting consumers' mindset to one of spending salience, in the hope that causing consumers to recall past instances where they spent instead of saved, will encourage greater saving in the present moment.

### Study 1: Effect of Spending Salience Mindset on Saving

Three hundred and one participants from Mturk completed this study for 50 cents. They were randomly assigned to one of three conditions: 1) spender salience mindset, 2) saver salience mindset, or 3) hanging baseline. To activate the mindsets, we modified a procedure that instills self-perceptions through cuing everyday behaviors for the savings domain (Cornelissen et al. 2008). Those in the spender and saver conditions first answered five questions using the same scale (1 = once every 18 months or less (i.e., less frequent engagement); 7 = once a month or more (i.e., more frequent engagement), while those in the baseline condition did not answer any questions before proceeding to the savings dependent variable.

In the *spender* salience condition, participants first answered the following five questions. [Note: we highlight important differences between the two conditions using italics; participants did not view the italics.] How often do you...1) Choose to eat at a *more expensive* restaurant, instead of a cheaper one? 2) Buy something at *full price*, instead of waiting for it to go on sale? 3) *Buy something you want*, instead of forgoing the purchase? 4) Purchase a *more expensive* brand, instead of a cheaper one (e.g., store brand)? 5) *Go out to eat*, instead of cook at home?

In the *saver* salience condition, the questions directly mirrored those of the spender condition: How often do you...1) Choose to eat at a *cheaper* restaurant, instead of a more expensive one? 2) Wait for something to go *on sale* before buying it at full price? 3) *Forgo a purchase* you want? 4) Purchase a *less expensive* brand (e.g., store brand)? 5) *Cook at home*, instead of go out to eat? We selected these five behaviors based on pre-testing.

To assess savings intent, participants indicated their monthly income, and of this amount, how much they would be willing to put in their savings account at this moment. Consistent with prior work (e.g., Garbinsky, Klesse, and Aaker 2014), the main dependent variable was the amount of money participants indicated they would save divided by monthly income. Seventeen participants were excluded from the analysis because they either failed the attention

check, indicated they would save more money than they make, or indicated an unrealistic monthly income (e.g., \$2); this left 284 participants in the final sample.

Results revealed a main effect of mindset,  $F(2,281) = 3.88$ ,  $p = .022$ , such that those in the spender salience mindset were willing to save a significantly greater percentage of their monthly income ( $M = 30.6\%$ ) than those in the saver salience mindset ( $M = 21.9\%$ ),  $t(281) = 2.74$ ,  $p = .007$ , and a marginally greater percentage of their monthly income than those in the baseline condition ( $M = 24.8\%$ ),  $t(281) = 1.83$ ,  $p = .068$ . As expected, those in the saver salience mindset and baseline condition did not significantly differ regarding the percentage of monthly income they were willing to save,  $t(281) = .93$ ,  $p = .35$ .

## Study 2: Manipulating Mindset in the Field

One hundred and fifty-eight participants completed this study for \$1 at an outdoor concert in downtown South Bend, Indiana. They were randomly assigned to the spender or saver salience mindset conditions, using the same manipulation as Study 1. To establish the robustness of the savings effect, we relied on a different measure to assess savings intent; participants allocated a \$1,000 windfall across five categories: 1) Use it to buy something nice for someone special, 2) Invest it in a retirement fund, 3) Plan a fun and extravagant occasion, 4) Put it into a checking account, and 5) Other. Consistent with prior work, the main dependent variable was the amount of money participants indicated they would invest in a retirement fund (Her-shfield et al. 2011).

As expected, those in the spender salience mindset were willing to allocate a significantly greater portion of their \$1,000 windfall ( $M = \$192.41$ ,  $SD = 275.16$ ) than those in the saver salience mindset ( $M = \$114.68$ ,  $SD = 217.17$ ),  $t(156) = 1.97$ ,  $p = .051$ . There were no significant differences in the amount of money participants were willing to allocate across the other four categories, all  $ps > .3$ .

Two studies suggest that prompting people to see themselves as spenders rather than as savers can facilitate saving in the present moment. They also suggest that Americans may have a tendency to see themselves as savers, and that such perceptions may thwart actual savings. By understanding and changing self-perceptions of saving and spending, the current work contributes novel insight into the psychological barriers that limit saving and present new opportunities for improving financial decision-making.

## When Implementation Intentions Backfire: Illusion of Goal Progress in Financial Decisions

### EXTENDED ABSTRACT

A vast amount of research on an implemental vs. a deliberative mindset has demonstrated across various domains that an implemental mindset (which focuses on the steps to achieve a goal) leads to more successful goal attainment than a deliberative mindset (which focuses on whether one should pursue the goal; Gollwitzer 1999). However, related literature has also shown that an implemental mindset can be associated with optimistic inferences, such as illusory control over the extant environment (Gollwitzer and Kinney 1989) or illusion of higher personal capability (Taylor and Gollwitzer 1995).

How could these positive illusions triggered by an implemental mindset impact consumers' goal pursuit? Research on licensing has indicated that a prior choice that boosts a positive self-concept can subsequently license the choice of a more self-indulgent or less moral option (Effron and Monin 2010; Khan and Dhar 2006). Further, recent work on the effect of past good behavior has shown that while

abstract thinking highlights the underlying reasons for the good behavior and leads to consistent goal pursuit, concrete thinking focuses attention on the past good behavior itself and leads to a licensing effect (Conway and Peetz 2012). At the same time, prior research has suggested that people's knowledge of an event influences their thinking-- such that those with greater knowledge or experience are more able to integrate details at an abstract level, whereas those with lower knowledge focus on the concrete specifics (Vallacher and Wegner 1987). Drawing on these findings, we predict that an implemental mindset can backfire for low-knowledge consumers, reducing their goal pursuit because of the illusion of goal progress of the preceding task.

To test our hypothesis, we conducted three studies involving consumers' financial decisions. In all studies, participants first completed a priming task that induced different mindsets or goals. Following classic mindset manipulations (Gollwitzer 1999), in the implemental mindset condition, participants were asked to choose a specific goal they have decided to pursue and write down 5 steps and the details involved in implementing these steps. In the deliberative mindset condition, they were asked to indicate a specific goal they were deciding whether to pursue and write down 5 positive and 5 negative consequences of this goal. After the priming task, participants were shown a financial goal scenario and asked to indicate their decisions including saving (Study 1) and credit card debt repayment (Studies 2 and 3). Knowledge in the specific domains was measured at the end of each study.

In Study 1, student participants ( $N = 193$ ) were asked to consider the goal of saving money and were assigned to either the implemental or deliberative condition in the priming task. Afterwards they read about a special savings program from their local bank to encourage college students to save money that offered varying interest rates based on the amount of saving in the account. Participants were then told that they have just received a paycheck of \$500 and needed to decide how much to deposit in the savings account vs. to spend on other things. Consistent with our predictions, we found that an implemental mindset backfired for low-knowledge participants and led to a lower amount of saving compared with those in the deliberative mindset condition ( $M_{\text{implemental}} = \$302.37$  vs.  $M_{\text{deliberative}} = \$341.50$ ,  $t = 2.165$ ,  $p < .04$ ).

In Studies 2 and 3, we switched to another form of saving-- paying off credit card debt. In these studies, we also measured participants' perceived progress after the priming task. In Study 2, ( $N = 137$ ) participants from an online panel were randomly assigned to an implemental or a deliberative mindset condition and reported their perceived progress of the personal goal they have just considered. Subsequently, participants saw a typical credit card statement with total balance (\$1,937.28), APR (14%) and Minimum Required Amount (\$38.74), and were asked to indicate how much money they wished to allocate toward repaying this credit statement. The results confirmed our hypotheses: participants in the implemental mindset condition perceived greater progress on the personal goal they had considered in the priming task, compared with the deliberative condition ( $M_{\text{implemental}} = 3.00$  vs.  $M_{\text{deliberative}} = 2.15$ ,  $t = 5.33$ ,  $p < .001$ ). Further, we found a goal progress illusion bias for participants with low financial knowledge: Implemental mindset (and the greater perceived progress of the preceding personal goal) led to a higher proportion of participants paying the minimum required amount, which represented a lower payment commitment ( $M_{\text{implemental}} = 21.4\%$  vs.  $M_{\text{deliberative}} = 12.9\%$ ,  $z = 2.00$ ,  $p < .05$ ).

In Study 3, ( $N=128$ ) which used the same credit card debt repayment scenario as Study 2, we compared the effect of an implemental mindset induced by a goal that is consistent with paying off debt

(e.g., a repayment goal) versus a goal that conflicts with it (e.g., a spending goal). The results showed a similar licensing effect for low knowledge participants. Participants in the repayment goal condition perceived greater progress toward their financial goal compared with those in the spending condition ( $M_{\text{repayment}} = 3.45$  vs.  $M_{\text{spending}} = 2.89$ ,  $t = 3.64$ ,  $p < .001$ ). As a result, those thinking about implementing the consistent repayment goal indicated a significantly lower subsequent payment amount in the main task than those thinking about an inconsistent goal ( $M_{\text{repayment}} = \$242.28$  vs.  $M_{\text{spending}} = \$601.60$ ,  $t = -2.46$ ,  $p < .02$ ).

Taken together, these studies suggest that an implemental mindset can backfire and reduce goal pursuit for low-knowledge consumers because of illusory goal progress. These novel findings identify a new type of progress bias (see Campell and Warren 2015) and contribute to literature on goal attainment implementation intention, and the licensing effect. They also caution marketers and policy makers when applying implemental mindset in practice.

### Saving for Experiences versus Material Goods

#### EXTENDED ABSTRACT

Saving money involves a trade-off between present and total utility: consumers forego spending in the present to increase available resources for future use. This practice reduces consumers' reliance on credit to fund consumption, as well as their financial stress (Ksendzova, Donnelly, and Howell 2017; Xiao, Sorhaindo, and Garman 2006). Despite these benefits, household savings rates are relatively low worldwide (OECD 2014).

Thus, researchers and practitioners face an important question of how to encourage consumers to save. The answer offers value for marketers, as saving is multiply determined: while recognizing that saving money is important for its mere availability (e.g., to spend in emergencies), consumers also acknowledge more hedonic motivations to save, such as future discretionary purchases (Canova, Rattazzi, and Webley 2005; Xiao and Noring 1994).

In the current research, we explore what characteristics of discretionary purchases can motivate saving behavior. We compare consumers' interest in saving money for material and experiential purchases. On one hand, the time-sensitive nature of experiences (vs. material goods) more often leads consumers to take on debt in order not to delay or forego the purchase (Tully and Sharma, 2018). On the other hand, consumers find more pleasure in waiting for experiential (vs. material) purchases (Kumar, Gilovich, and Killingsworth 2014) and see experiential purchases as less comparable (Carter and Gilovich 2010). Thus, they may save for the experience they wish to afford in the future instead of spending money on an affordable substitute in the present.

To answer this question, we examine the influence of experiential versus material consumption on consumers' interest in saving, as expressed in scenario-based studies and revealed in a field experiment.

In Experiment 1 ( $N=261$ ), we prompted all participants to name one desired but currently unaffordable purchase that would increase their happiness. We randomly assigned participants to prompts specifying this aspirational purchase as experiential or material (i.e., "an event or series of events that you personally encounter or live through" or "a tangible object that you obtain and keep in your possession"). Subsequently, participants decided how much they would allocate to savings from a \$100 windfall. Even though purchases did not significantly differ in desirability and estimated cost (med. \$1200) by condition, participants chose a greater saving allocation after considering an experiential purchase than a material one (med.

\$60 vs. \$50;  $t=2.17$ ,  $p=.031$ ). Further, purchase type predicted saving allocation beyond the effects of annual income and general saving tendency (ratio of money available in one's savings vs. checking accounts).

In Experiment 2 ( $N=18,542$ ), we partnered with a financial service company to encourage their customers to create savings goals, using either experiential or material-purchase motivation. Prior to New Year's Eve (a popular time for goal-setting; Dai, Milkman and Riis 2014), customers received an e-mail encouraging them to create a savings goal for the new year, with an emphasis on later spending the saved money on desired but costly purchases that improve happiness. We randomly assigned customers to a message emphasizing experiential or material consumption (textually and graphically). This message concluded with a link to the service's website, urging customers to create a new year's goal. We treated a customer's clicking on the link as a binary proxy for interest in saving. We found that the encouragement of saving for experiences (compared to material goods) increased click likelihood (1.2% vs. 0.9%;  $B=.31$ ,  $p=.036$ ).

Next, we explored the explanations for why experiential consumption may better motivate saving. In Experiment 3 ( $N=242$ ), we again asked participants to name a single aspirational purchase (experience vs. material good; similar in desirability and cost [med. \$2,000]). As in Experiment 1, participants chose a greater saving allocation when considering a desired but unaffordable experience, compared to a material good (med. \$75/100 vs. \$51/100;  $t=2.00$ ,  $p=.047$ ). Further, this relationship between purchase type and intended savings was not explained by importance of purchase timing or likelihood of sharing one's purchase with others. Instead, this exploration provided evidence for mediation via pre-purchase savoring - the pleasant overlap consumers perceived between anticipation and consumption (i.e., extent to which waiting feels like already experiencing/owning, weighed by enjoyment).

In sum, we find that consumers feel more encouraged to save for future experiential (vs. material) consumption, reflected in either a single aspirational good (Experiments 1 and 3) or a broader notion of discretionary spending for happiness (Experiment 2). Relative to material goods, experiential purchases connote greater pre-purchase savoring, which helps explain why they foster a stronger interest in saving. With consumers' personal savings rate on the decline, our research suggests that saving may increase when closer coupled with consumption. If the saving process better allows consumers to affectively "preview" purchases they can enjoy in the future, they may allocate more money toward saving in the present.

### SESSION OVERVIEW

Understanding consumers' valuation of goods and services is an integral part of marketing and pricing strategy. It is therefore critical for researchers and practitioners to gain insight into how value is constructed and what contextual factors affect its construction. The four papers in this session offer new perspectives on this topic: they examine novel contextual influences on consumers' valuation of goods and present a new contextualized methodology to measure willingness-to-pay (WTP). Together, these papers offer convergent support that comparative processes underlie how consumers construct value.

The first two papers examine how marketers can influence context with different strategies to elicit WTP and to present prices. **Thomas and Kyung** assess two methods that online firms commonly use to elicit WTP from consumers: textboxes versus slider scales. The authors find response format is an important contextual factor that affects WTP—slider scales systematically elicit more extreme WTP responses. This phenomenon is due to consumers' representation of magnitudes on a mental number line. A slider scale makes both endpoints of the line salient, which influences accessible comparisons and thus consumers' judgment of magnitude. **Allard, Hardisty, and Griffin** examine the impact of two different pricing strategies for premium options: additional price framing (e.g., “for \$20 more”) and inclusive price framing (e.g., “for \$60 total”). The authors find that such contextual framing alters choice—additional price framing significantly increases the choice share of the premium option, implying a shift in consumers' valuation. The additional price framing strategy focuses consumers' attention on the price difference compared to the standard option, which increases the perceived value of the premium option.

The third paper turns to examine failure of a transaction as a contextual influence on consumers' WTP. Specifically, **Ksendzova, Morewedge, and Ariely** show that, when consumers fail to acquire a product, their WTP for the product increases substantially. The authors demonstrate that WTP increases only for the same product and not for other products and suggest that, in hindsight, consumers reconsider and update their valuation of the good.

The first three papers suggest that consumers' valuation is highly constructive in nature. The fourth paper in this session (**He, Anderson, and Rucker**) formalizes a conceptualization of WTP as a metric constructed based on the consumer, comparison, and situation. This work introduces a new methodology to measure WTP that captures these factors. In accounting for comparisons underlying the construction of WTP, this methodology can specify two pathways, direct and indirect, through which situational factors affect valuation.

Collectively, these papers advance the field's conceptual understanding of how consumers construct value and offer practical insights for pricing. They also highlight the importance of comparative processes in value construction and introduce a new methodological approach. This session is expected to generate significant interest among researchers investigating WTP, pricing, and related areas.

## Visualizing Price Magnitude: How Slider Scales Change Willingness-to-Pay

### EXTENDED ABSTRACT

Many organizations allow customers to decide how much to pay for a product or a service on technology interfaces. Online retailers such as eBay allow customers to bid on the items. Priceline allows customers to name their own prices for hotels rooms. Charitable organizations allow donors to enter a donation amount of their choice. In many cases, the response format is an open-ended textbox where people have to come up with a price in their mind and enter it. With the proliferation of mobile transactions, some organizations now use slider scales instead of textboxes due to their perceived ease-of-use. This has led to their widespread use on mobile interfaces, web sites, and even by academic researchers.

Interchangeable use of textboxes and slider scales is based on the assumption that response formats do not change people's responses because their valuations are stable. While several studies suggest that this assumption might not be valid (Champ and Bishop 2006; Klien, Thomas, and Sutter 2007), surprisingly, none of the extant studies have examined whether valuations and bids elicited using a textbox would be any different from those elicited through a slider scale. This research focuses on the following questions: Do consumers respond in systematic differently ways when presented with textbox versus slider scale response formats? If so, then what is the psychological mechanism underlying this systematic difference?

Across seven experiments, we show that relative to a textbox, a slider scale elicits more extreme responses in willingness-to-pay contexts. In experiment 1a, lab participants bid on a real Japanese thermal mug and were given the retail price (\$24) and range of possible bids. They indicated their bid price using either a slider scale or textbox. Those using slider scales bid higher (\$11.40) than those using textboxes (\$8.01,  $F(1, 125) = 37.05, p < .01$ ). Experiment 1b replicates this effect in a donation context where all participants were unexpectedly given \$1 after being asked to complete a 51-cent study. The study was run on Veteran's Day, and participants using a slider scale donated significantly more of their \$1 ( $M = 37.8$  cents) than those in the textbox condition ( $M = 24.0$  cents,  $F(1, 202) = 307.29, p < .01$ ) to a charity for veterans (Intrepid Fallen Heroes Fund). Demonstrating the robustness of the effect, the following two studies use repeated measures designs in a more familiar bidding context. In experiment 2, participants were shown three products in an ascending numeric format where bids were made that were higher than the

starting point (e.g. e-Bay) and those using a slider scale (\$291) made higher bids than those using a textbox (\$280,  $F(1, 393) = 5.61, p = .02$ ). Experiment 3 examined a descending numeric format (e.g. Priceline) where the bids were made that were lower than the starting point—they were asked to indicate their bids for six items using a textbox or using a slider with an anchor on either the right or left side of the scale. Participants' average bids in both the left-to-right-slider condition (\$130 vs. \$142;  $t(1504) = -3.25, p < .01$ ) and right-to-left-slider condition (\$135 vs. \$142;  $t(1504) = -1.84, p = .07$ ) were lower than bids in the textbox condition. Thus bids are not always higher on slider scales, but more extreme depending on the type of bid.

We offer an explanation for this effect based on the numerical cognition literature in cognitive psychology (Dehaene 2001, 2003; Dehaene and Changeux 1993; Parducci 1965, 1995) and consumer psychology (Adaval 2013; Bagchi and Davis 2016; Cheng and Monroe 2013; Grewal and Marmorstein 1994; Lembrechts and Pandelaere 2013; Monroe 1973; Thomas and Morwitz 2009). We propose that the effect of response formats on valuations is caused by a change in the boundaries of mental categories—low, medium, and high—that people use to judge magnitudes. When people use a textbox to submit their bids, the category boundaries are assimilated towards the starting bid on their mental number line. With a textbox, only the starting point is salient. In contrast, when people use a slider scale to submit their bid, the category boundaries are influenced by both end-points of the scale, causing people to recalibrate their mental number line more linearly between both the starting and ending points. Therefore, the boundaries of the mental categories used to judge magnitudes can be quite different depending on whether the responses are elicited using textbox or slider scale.

We demonstrate this underlying process in several ways. (*For brevity, the remaining results are summarized in the table below.*) First, we show that the slider scale effect is stronger for extreme categories farther away from the starting point. In experiment 4, participants were asked to submit what they considered low, medium, and high bids for a product using either a textbox, slider scale, or select a bid amount from a horizontal list of bid amounts. The effect of response format increased as distance from the starting point increased, and the effect of selecting a bid amount from a horizontal list was the same as using a slider scale, providing further evidence that visualization of a number line, rather than response momentum, is important for the effect. In experiment 5, we show that employing a slider scale that is formulated to have more convex values that increase more slowly towards the starting point results in values similar to a textbox. In experiment 6, we show that increasing the range of possible input values influences only participants responding on slider scales but not those using textboxes. Together, the results of this research demonstrate a robust new effect in the highly managerially relevant domain of response format while offering new insights in theory development.

### Only “\$20 More”: Additional Price Framing Increases the Choice of Upgraded Products and Services

#### EXTENDED ABSTRACT

Consumers must often decide between standard and upgraded versions of products and services, such as indirect vs. direct flights or smaller vs. larger capacity hard drives. The price of the superior quality option can be framed using Additional Price Framing (APF) (e.g., “for \$20 more”) or Inclusive Price Framing (IPF) (e.g., “for \$60 total”). APF is often used in retail settings but, surprisingly, has not been studied in academic literature. (Note that APF is conceptually and practically distinct from price partitioning, e.g. “\$10.80

including tax” vs. “\$10.00 plus \$0.80 sales tax”, Morwitz, Greenleaf, and Johnson 1998.) Across six studies, we find that APF leads to greater choice share for the premium option. We show that the benefit of APF is driven by *pricing focalism*: APF (relative to IPF) focuses attention on the price difference which, by virtue of being smaller than the total price, leads to lower perceived expensiveness, and hence greater choice share for the superior quality option. The APF effect is robust to displaying the total cost of the purchase and to bad deals, but is eliminated when participants are instructed to take their time and decide slowly.

Study 1 demonstrates that the APF effect occurs even when the total cost of the upgraded product is made salient (thus ruling out that the effect is driven by confusion or deception). 546 undergrad students were randomly assigned to either the IPF, APF, or APF + total condition. They chose between a 23-inch television for \$199.99 or a 27-inch version for “\$259.99” [“\$60.00 more”] [“\$60.00 more (\$259.99 total)”. The proportion of participants selecting the upgraded option in the APF condition ( $P=58%$ ) was significantly higher than in the IPF condition ( $P=42%, p < .01$ ). Likewise, the APF+total price condition was also higher than in the IPF condition ( $P=53%, p < .05$ ). Furthermore, there was no difference between the APF and the APF + total price conditions ( $p > .75$ ). According to our pricing focalism account, consumers are naturally interested in the price difference and base their judgments of expensiveness on that (rather than the total price). Thus, adding the total price to APF framing has little effect.

Study 2a shows that the effect is unique to price, and does not work when applied to other product dimensions such as quality. 235 undergraduate students chose between a smaller, cheaper hard drive (“2 TB storage capacity for \$119.99 total.”) and a larger, more expensive hard drive, which was framed with IPF (“3 TB storage capacity for \$169.99 total.”), APF (“3 TB storage capacity for \$50.00 more.”), or an Additional Quality Frame (AQF, “1 TB additional storage capacity for \$169.99 total.”). The proportion of participants selecting the upgraded option in the APF condition ( $P=48%$ ) was significantly higher than in the IPF condition ( $P=33%$ ),  $p=.05$ , replicating previous results, and also higher than the AQF condition ( $P=29%$ ),  $p < .05$ . There was no difference between the IPF and AQF conditions,  $p=.85$ . Study 2b (Prolific Academic,  $N=600$ ) found similar results using flights (framing the price or the travel time). Studies 2a-2b provide support for the pricing focalism mechanism underlying the APF effect and cast doubt on other explanations such as anchoring and adjustment or a trade-off mindset model.

Study 3 provides mediational support for the proposed mechanism by showing that APF influences consumer choice by reducing the perceived expensiveness of the upgraded option and also tests the robustness of the effect across increasingly bad deals. 404 MTurkers were instructed to imagine themselves shopping for a new computer monitor and shown two different monitor options (23-inch vs. 27-inch), where the 23-inch version retailed at \$199.99. In the IPF conditions, the upgraded 27-inch monitor was available for either “\$259.99,” “\$319.99,” or “\$379.99” depending on the price condition (for “\$60.00 more,” “\$120.00 more,” or “\$180.00 more” in the APF conditions). Participants then answered, “Compared to the 23-inch version, how much more expensive is the 27-inch version?” (1:No more expensive-7:Very much more expensive.) Replicating previous results, a higher proportion of people selected the upgraded option in the APF condition ( $P=37%$ ) compared to the IPF condition ( $P=22%$ ),  $p < .001$ . There was also no significant interaction between that APF and IPF conditions and price level in predicting the choice of the upgraded option ( $p=.20$ ). In other words, the effect of APF on choices was the same across different price levels. Moreover, judgments of expensiveness mediated the effect of AP framing on

choices. Studies 3 provide mediational evidence that APF increases the choice of upgraded options over IPF because of a shift in the perceived expensiveness of the product. Importantly, the effect appears robust across “good” and “bad” deals, further differentiating the APF effect from a price partitioning effect.

In Study 4, 221 undergraduates took the role of buyer or seller of used bicycles, using APF or IPF. The “buyer” condition replicated previous results ( $P=70\%$  vs.  $P=50\%$ ,  $p<.05$ ), while the seller condition showed the opposite pattern ( $P=26\%$  vs.  $P=46\%$ ,  $p<.05$ ), a significant interaction,  $p<.01$ . This reversal happens because the offer price in the APF appears cheaper. Therefore the seller prefers to sell the upgraded product in the IPF condition (vs the APF condition). Indeed, judgments of expensiveness mediated the choice results, replicating and extending the results of Study 3.

In Study 5, before participants ( $N=571$  MTurkers) chose between a standard and upgraded set of wine glasses, they were told to respond quickly, or slowly, or no instruction control. The main effect of AP framing replicated previous studies,  $p<.03$ , but this was qualified by a significant interaction between AP framing and decision speed,  $p=.02$ . Specifically, the effect of AP framing was eliminated when participants were instructed to take their time and choose slowly and deliberately. APF (vs. IPF) also did not affect total purchase price recall ( $Z<1$ ).

Across all studies, we find support for the hypothesized link between APF, expensiveness judgments, and product choice and show that this is not driven by confusion. Thus, we contribute a new branch of inquiry to a substantial literature examining the effect of price formats on consumer judgments while offering important and straightforward implications for effective pricing practices.

### **Hindsight Value: Failed Transactions Inform Willingness to Pay**

#### **EXTENDED ABSTRACT**

Despite a well-documented gap between buyers’ and owners’ valuation of goods, markets work: buyers buy, owners sell, and the endowment effect no longer persists once actors in both roles gain market experience (List 2003). Focusing on one component of market experience, the present research examines failed transactions – buyers’ failure to acquire a good and owners’ failure to sell it. We ask, do failed transactions inform consumers’ valuation of goods?

For example, buyers may fail to acquire a good when its price exceeds their maximum willingness to pay (WTP) for it. Such failure may decrease buyers’ WTP via cognitive dissonance or, in other situations, prompt greater spending without increased valuation (e.g., bidding frenzy, Ariely and Simonson 2003; jilting effect, Litt, Khan, and Shiv 2010). However, we propose that failure to acquire can also increase consumers’ WTP as an update in true valuation rather than an instance of regrettable overspending.

Our studies utilize the Becker-DeGroot-Marschak “BDM” (1964) mechanism, which elicits a person’s maximum WTP for a good in the form of a bid. That bid is then compared to a randomly-selected price  $P$ . If  $WTP \geq P$ , one must purchase the good for  $P$ ; in contrast, if  $WTP < P$ , one must forego the purchase. This binding resolution should reveal people’s true preferences, incentivizing them not to bid above their true maximum WTP, as well as not to bid below it.

We first examined the effect of acquisition failure on WTP in incentive-compatible designs. In Study 1A ( $N = 101$ ), participants first selected a song they wished to own in their iTunes library. All participants were endowed with \$2 and could use any portion of this experimental budget to purchase their desired song via BDM, keep-

ing any money they did not spend. We adapted the classic BDM procedure in two ways. First, we made failure systematic: after bidding their maximum WTP ( $M_{bid} = \$30$ ), participants reached the “no purchase” outcome as the undisclosed random price supposedly exceeded their bids. Second, we offered participants an unexpected opportunity to submit new bids for comparison to a new random price. In turn, 41% stated a higher maximum WTP. Overall, maximum WTP significantly increased in final bids (revised in the second round or unchanged from the first) relative to initial bids (+\$.07, 95% CI [+0.03, +.11]).

For a conceptual replication in Study 1B ( $N = 102$ ), we endowed participants with \$0.50, any of which they could bid to purchase a novel gamble for a randomly-selected entry price. This purchase would grant them access to a virtual “Money Tree” with a 33% chance of “growing” a dollar on its branches ( $M_{bid} = \$23$ ). As in Study 1A, participants stated a significantly higher WTP for the gamble after failing to acquire it (+\$.07, 95% CI [+0.05, +0.09]). Next, we examined whether the hindsight value effect extends beyond songs and small-stake gambles. In Study 2 ( $N = 250$ ), we engaged participants in a hypothetical BDM procedure and randomly assigned them to bid on one of five products (Snickers bar, bottle of Trader Joe’s wine, FitBit fitness tracker, MacBook Air laptop, or used Honda Accord car). After bidding their maximum WTP and failing to acquire the target good, 54.9% of participants subsequently chose to bid greater amounts. Overall, final bids increased by 7.7%-20.7% of the initially-stated maximum WTP.

We further characterize the hindsight-value effect in Study 3 ( $N = 202$ ). In a 2x2 between-subjects design, we varied the target good and outcome of a hypothetical BDM: participants imagined first bidding on a travel mug (vs. clock) and then failing to acquire (vs. successfully acquiring) it. Next, participants unexpectedly entered a second BDM round in which they all bid on the travel mug. We compared WTP stated in these new bids by experimental condition. First, our results suggest that failure to acquire informs valuation of the target good in particular, instead of creating a general desire to win after losing: participants bid more on the mug after failing to acquire that mug than after failing to acquire the clock (\$25 vs. \$19). Second, we found that WTP increases in hindsight of acquisition failure, rather than from repeated bidding on a good: When bidding twice on the mug, participants increased their bids after imagining a failure to acquire (+\$7.70, 95% CI [+5.25, +10.24]) but did not significantly revise their bids after imagining a successful acquisition (-\$1.15, 95% CI [-3.23, +.93]).

Finally, we propose that failed transactions help bridge the WTP-WTA gap. In Study 4 ( $N = 202$ ), we randomly assigned participants to either buyer or seller roles. As in Study 1B, we endowed buyers with \$.50, any portion of which they could bid to purchase the Money Tree gamble. Conversely, we endowed sellers with the Money Tree gamble and prompted them to bid a minimum WTA, between \$.00 and \$0.50, for selling their Money Tree. Reverse BDM rules bound owners to sell the gamble, if stated  $WTA \leq P$ , or forego the sale if  $WTA > P$ . Participants in both roles encountered transaction failure after bidding (failure to buy or to sell) and, then, an unexpected second bidding opportunity. Initially, WTP fell short of WTA (\$.24 vs. \$.30). However, subsequent transaction failure eliminated the endowment effect: buyers and owners resembled each other in valuation as WTP increased (+\$.08, 95% CI [+0.05, +.10]) and WTA decreased (-\$.07, 95% CI [-.09, -.04]).

Our findings contribute to an understanding of how markets work despite the endowment effect, as well as how consumers decide on their reservation prices. While market experience provides consumers with various cues of how much others value a good, we

propose that it may also inform consumers' own valuation through failed transactions. If consumers better recognize surplus utility in hindsight, such initial failures may foster successful and mutually-beneficial exchanges in the future.

## Willingness to Pay: A Contextualized Method of Valuation

### EXTENDED ABSTRACT

WTP is commonly defined as the maximum amount a consumer will spend to obtain a product or service. Despite decades of research on this apparently simple metric, theory and empirical approaches on the study of WTP remain somewhat underdeveloped. This talk seeks to offer two contributions. First, we develop a more cohesive conceptualization of the WTP construct based on a review of the literature. Second, we introduce and validate a new methodology to assess WTP, the Contextualized Method of Valuation (CMV).

*Conceptualization.* The common definition of WTP is ambiguous, and existing measures of WTP reflect this conceptual ambiguity. We clarify that the WTP of a given *consumer* is the result of a specific *comparison* in a specific *situation*. That is, WTP reflects a given consumer's valuation for a product compared to an alternative option (Nagle 1987), and this relative valuation depends on the situation the consumer is in (Voelckner 2006). To illustrate, suppose a consumer is choosing amongst an array of chocolates and her WTP for a Lindt bar is of interest. Our conceptualization suggests that to fully understand her WTP for Lindt, we must know what her comparative option is (e.g., a Hershey's bar) and the situation in which she compares Lindt to Hershey's. Importantly, WTP is not a well-defined metric when the comparison or situation is unspecified.

This conceptualization suggests that situational factors (e.g., marketing activity, psychological states) can affect WTP through two pathways, direct and indirect. Continuing our example, suppose the situational factor is purchase goal (personal-consumption vs. gift-giving). The *direct pathway* refers to how purchase goal changes the valuation of Lindt relative to Hershey's (the comparative option, Hershey's, is held constant), and thus WTP for Lindt. The *indirect pathway* refers to how purchase goal changes the comparative option, e.g., in a gift-giving context, the relevant comparative option might be Godiva rather than Hershey's.

*CMV Methodology.* We introduce CMV, a new methodology to measure WTP that captures both the direct and indirect pathways. CMV is a powerful generalization of the BDM (Becker-DeGroot-Marschak 1964) procedure. The respondent views a choice set, specifies the comparative option, and states a WTP for the target product that equates preference for the target and the comparative option (i.e., relative valuation). A truth-telling lottery mechanism is employed: if  $WTP \geq R$ , a randomly drawn number ( $R$ ), the participant buys the target product; if  $WTP < R$ , the participant buys the comparative option at its stated price. Because the comparative option is clearly specified *and* free to vary, CMV can specify both the direct and indirect pathways through which a given situational factor affects WTP. Existing methods (e.g., open-ended response, BDM) lack these capabilities, which means that while they undoubtedly measure some aspect of preference, they may yield poorly-defined or inaccurate estimates of WTP per se.

Across six sets of experiments, we demonstrate that CMV is sensitive to situational factors present in common consumer purchase situations and, moreover, captures the comparative mechanisms through which situational factors operate.

In Experiments 1 and 2, we compared CMV and BDM, the best current method of measuring WTP (Miller et al. 2011; Wert-

broch and Skiera 2002). Experiment 1 implemented three conditions: CMV, BDM, and BDM with the same choice set as in CMV shown. CMV yielded a different WTP estimate compared to BDM ( $p < .001$ ). Showing participants the choice set in BDM partly but not fully closed the gap to CMV ( $p < .08$ ). This experiment also found evidence that because the BDM method does not specify comparative options, participants overlooked comparisons or had different ones in mind, rendering the WTP estimates ambiguous. Experiments 2a-2c demonstrated, across three different product categories, that CMV can offer opposite implications for WTP compared to BDM, i.e., preference reversals resulted due to a lack of a clear comparative option in BDM.

Experiments 3-6 demonstrate the ability of the CMV methodology to capture the effects of the situation through direct and indirect pathways. Experiments 3a-3b provided a demonstration of the direct pathway: CMV was sensitive to contextual information affecting preference for the target, which changed its valuation relative to a comparative option. Experiments 4a-4b illustrated the indirect pathway: CMV was sensitive to changes in the price of the comparative option. In experiment 4a, participants saw a choice set of wines in which the price of one wine (La Crema) was manipulated between participants to be either low or high. CMV revealed that WTP differed across conditions *only* for participants who specified La Crema as their comparative option ( $p = .004$ ); no differences in WTP were found for participants selecting other comparative options, whose prices did not change ( $ps > .30$ ). This experiment highlights the importance of knowing participants' comparative option when measuring WTP. Existing methods could not reveal these findings. Experiment 4b provided a conceptual replication of 4a, demonstrating that in a market where the same comparative options were priced high (vs. lower), WTP accordingly increased (decreased).

The direct and indirect pathways of context were jointly examined in experiments 5 and 6. For brevity, only experiment 6 is described here. The effect of the situational factor of purchase goal (personal-use vs. gift-giving) on WTP for a Parker fountain pen was examined. A gift-giving goal might affect WTP for the target by changing its valuation relative to a comparative option (direct) and by changing what the relevant comparative option is (indirect). The choice set consisted of two comparative options, a regular pen and a Waterman fountain pen. WTP was substantially greater under a gift-giving goal ( $p < .001$ ). This occurred because a gift-giving goal drastically shifted participants' comparative option to the expensive Waterman pen ( $p < .001$ ). Existing methods would not be able to capture this mechanism.

In sum, this paper offers two important contributions. First, we clarify that consumers' WTP is situation-specific, and that situational factors can operate through direct and indirect pathways. Second, we introduce and validate a new methodology to measure WTP that reflects this conceptualization and addresses the shortcomings of existing methods.

### **SESSION OVERVIEW**

In this session, we consider myth – one of the most fundamental and pervasive ways that consumers make sense of the market and the world. Our understanding of the role of myth in consumption dates to the earliest days of what later came to be known as consumer culture theory (Levy 1981), and has spawned a substantial stream of research on myth in consumption and markets (e.g., Arsel and Thompson 2011; Brown et. al 2013; Brunk, Giesler & Hartmann 2018; Giesler and Veresiu 2014; Holt 2004; Luedicke, Thompson and Giesler 2010; Thompson 2004). Questions remain about the complexities, evolution, uses, and influences of myth in the marketplace. In this session, we aim to offer deeper, nuanced insight into ways that myth impacts, is used by, and is influenced by a diversity of agents in the marketplace. Overarching questions include: *How do myths evolve as they are appropriated and reconfigured by consumers and brands over time? How do myths and the resources needed for myth making influence the evolution of markets and socio-market systems? And, how can new research make novel, substantive contributions to this domain of consumer culture?*

The first presentation in our session examines the ways a marginalized and stigmatized consumer group enacts devaluing marketplace myths about themselves to increase their capital. While previous studies have demonstrated that devaluing marketplace myths disparage and degrade some groups, and that consumers can demythologize and de-stigmatize negative stereotypes, this research investigates the ways that consumers can actually use such myths to their benefit. This study of Roma gypsies illuminates the market-mediated race reiterations through which Roma further commercialize “Gypsy” devaluing marketplace myths.

In the next presentation, the authors investigate myth as an evolving salve for cultural anxieties and identity tensions and as an agent in the reshaping of cultural meanings. The study examines how the CrossFit brand fine-tunes established cultural discourses and ideals in its formative brand myth to alleviate identity tensions in the post-9/11 era. In contrast to previous research which has focused on the ways that consumers and brands draw from established cultural meanings in mythmaking, this research explicates the ways that established cultural meanings and ideals are transformed as they are retextualized in a brand myth.

In the third presentation, the authors unpack the role of myth in the evolution of the American firearms market system by investigating the ways that myths contribute to the (de)legitimation of products, services, and practices with potentially deadly consequences.

The final presentation extends the discussion by considering the ways that a resource for myth making—marketplace memory—is created and maintained to ensure the continuity of a market over time. This research “points to the long-lasting value of discursive acts, and how their accumulation, archival, and retrieval can, over time, shape market evolution.”

## **Consumer Enactment of Devaluing Marketplace Myths: Insights from a Multi-sited Ethnography of “Gypsies”**

### **EXTENDED ABSTRACT**

*Stay, sit down, relax, and discover the Gabor Roma tribe and true Roma culture from inside at the Gypsy House Hostel. [...] There is an interesting little activity we [Roma community] developed with our Gabor Girls where guests dress-up in the skin of the Gypsy, Gabor-Roma style head to toe. But more than that, it is an important lesson in Gabor etiquette. Being Gabor-Roma is not only about the clothing but an attitude, a walk, a presentation, etc. Our most recent actor was Loli, her baptized Gypsy name that means red. Loli toured the city with the Gabor Girls dressed in the skin of the Roma and experienced the world through their eyes and that includes the stares, comments, closed-door-receptions, and confrontation. It's an adventure that we call The Experiment. In addition, it's about experiencing the double discrimination Roma women endure. Discrimination outside the community for being Gypsy and inside for their second-class status for being female. It's interesting, a new experience. It's adventurous, you never know what's going to happen, and it's fun!*

*(Constantin, Gabor Roma, AirBnB Host, Romania)*

Constantin's creative marketplace offerings, self-branded as the *Gypsy House Hostel* and the *Experiment*, hint at a new way through which stigmatized groups approach devaluing marketplace myths – mainstream trivializations of consumers' social networks and interests rather than commercial sources of identity value (Arsel and Thompson 2011). Prior consumer research has investigated in great detail the various strategies and practices different stigmatized groups, including hipsters (Arsel and Thompson 2011), at-home fathers (Coskuner-Balli and Thompson 2013), black middle-class Americans (Crockett 2017), Asian immigrants (Hu, Whittler and Tian 2013), gay consumers (Kates 2002), Trekkies (Kozinets 2001), Apple Newton fans (Muniz and Schau 2005), veiled women (Sandkci and Ger 2010), and plus-size women (Scaraboto and Fischer 2013) utilize in order to challenge commercial stories or stereotypes circulating throughout popular culture caricaturing their communities. Together, these studies demonstrate how devaluing marketplace myths disparage and degrade individuals and their social groups, which in turn, lead consumers to defend, demythologize, and de-stigmatize themselves. However, do cases exist where stigmatized groups also benefit from marketplace stigma?

In this article, we depart from this standard view by uncovering a phenomenon where arguably the poorest and most stigmatized (im)migrant community worldwide, derogatorily referred to as “Gypsies”

but self-denominated as Roma (Simpson 2013), actively enact rather than challenge devaluing marketplace “Gypsy” myths to ensure their visible minority’s economic survival, as Constantin’s opening quote illustrates. Building on Veresiu and Giesler’s (2018) recent call “to not treat the experiences of the acculturating consumer as an essentialized point of departure but to instead pay more critical attention to the different ideological and socio-economic contexts that condition this consumer’s behaviour and the institutional frameworks that blanket uneven power relations between immigrant-sending and immigrant-receiving cultures in a seemingly inclusive marketplace,” we focus on one particular institutional variable that has only recently attracted consumer culture researchers’ attention: devaluing marketplace myths of “racialized otherness” found in mainstream media and advertising (Bonsu 2009; Hu, Whittler and Tian 2013).

To further understand this phenomenon we turn to the theory of racial performativity (Inda 2000; Miron and Inda 2000). Following Butler’s (1993, xii) seminal notion of gender performativity as the “reiterative power of discourse to produce the phenomena [gendered self or subject] that it regulates and constrains,” Inda (2000) defines racial performativity as the power of discourse to bring about what it names through the citing or repetition of racial norms. Accordingly, a series of traits linked to the whiteness of one’s skin (e.g., civilized, intelligent, moral, hardworking, clean, etc.) and non-whiteness (e.g., savage, emotional, licentious, lazy, dirty, etc) have been naturalized in service of specific social hierarchies and unequal power relationships between different racialized groups. Building on this notion of racial performativity as the “ways in which race is always actively constructed” (Inda 2000, 97), we not only argue that marketplace myths of racialized otherness are another powerful naturalizing discursive tool, but also theorize that stigmatized groups may engage in market-mediated race reiterations, which may provide short-term economic gains, but ultimately maintain the group’s unequal power position.

To investigate our theoretical proposition, we focused on dominant devaluing “Gypsy” marketplace myths and the accompanying Roma groups’ responses. Specifically, we first trace the history of the traditionally nomadic Roma race in Europe to understand how socio-political clashes with sedentary populations influence contemporary marketplace myths. Second, we uncover how a host of mainstream brands and entertainment products use these historically situated myths to enhance their contemporary marketing efforts. Based on this analysis, we extract three prominent devaluing marketplace myths about “Gypsies”: the free-spirit, the mystic, and the troubadour. Third, we unpack the market-mediated race reiterations through which Roma groups across Central Europe further commercialize these dominant devaluing marketplace myths for personal financial gain, as the opening quote summarizes, and reveal the accompanying mainstream consumers’ responses. We conceptualize this as a racialized myth market, which we define as an experiential market organized around culturally resonant stories stemming from non-white communities and sustained through marketplace performances. We then explore the visible minority group’s grass-roots race resignification attempt through the creation of the Roma denomination. This “Gypsy” racialized myth market was selected, not only because it represents a multi-million-dollar entertainment industry in Europe (Aniko 2009), but also because there are currently over 12 million individuals derogatorily referred to as “Gypsies” (European Commission 2016).

Methodologically, we adopted a historical approach in combination with an ethnographic approach to data collection (Karababa and Ger 2011; Giesler and Veresiu 2014). This entailed collecting and analyzing past historical materials, policy documents, mass media reports, as well as advertising campaigns, brand logos, and other

marketing promotional materials about “Gypsies” and the Roma ethnicity, focusing on the European continent as the bastion of Roma migration, struggle, and stigmatization. The ethnographic component involved (1) five data collection visits to Roma communities in Romania, Germany and Italy from 2009 to 2017 for triangulation purposes of different European nations, (2) photography and videography, and (3) in-depth, semi-structured interviews with Roma individuals. A hermeneutical approach (Thompson 1997) was employed to analyze the complete data set.

Overall, by critically interrogating how poor stigmatized (im)migrant individuals enact devaluing marketplace myths for economic gains, we contribute to the literatures on marketplace myths (Arsel and Thompson 2011), marketplace performances (Thompson and Üstüner 2015), and consumer acculturation (Veresiu and Giesler 2018).

### **“For the Unknown and the Unknowable”: The Rise and Reconfiguration of the CrossFit Brand as a Post-9/11 Mythos**

#### **EXTENDED ABSTRACT**

*We sought to build a program that would best prepare trainees for any physical contingency—prepare them not only for the unknown but for the unknowable as well.*

<http://journal.crossfit.com/2007/04/understanding-crossfit-by-greg.tpl>

Numerous studies have shown that significant socio-cultural disruptions—either due to natural disasters, economic crises, or major socio-political upheavals—destabilize consumers’ conventional cultural frames-of-references and sense making practices (Brunk, Giesler, and Hartmann 2017; Humphreys and Thompson 2014; Kravets 2012; Marcoux 2017; Phipps and Ozanne 2017; Weinberger and Wallendorf 2012; Zhao and Belk 2008). Such unsettled periods can engender a heightened state of reflexivity as individuals confront the socio-culturally contingent nature of formerly naturalized meanings and routines (Giddens 1991; Swidler 1986). The cultural branding paradigm (Holt 2004; Holt and Cameron 2010) similarly argues that social disruptions create a “cultural chasm” that enjoins a reflexive awareness of formerly naturalized ideological meanings. As consumers seek to negotiate the tumult of disruptive socio-economic changes, they become sensitized to the inadequacies of the ideological order that had formerly governed their identity practices. In response, they look to popular culture—movies, television, celebrities, and brands—to find new ideological meanings that can assuage the resulting identity tensions and provide a normative guide for orienting in these reconfigured socio-cultural fields.

Our analysis of the CrossFit brand as a post-9/11 mythos extends these prior analyses in two ways. First, the precedent works tend to focus on cases where emergent meanings precipitated by social disruptions necessarily manifest a historical continuity with the pre-disruption state as consumers and brands draw from the established stock of cultural meanings in their reflexive sense-making or mythmaking activities. Our analysis explicates these genealogical threads by focusing on how they are retextualized in the CrossFit brand myth. That is, established cultural discourses and ideals—such as the neoliberal self-optimizer; the Ayn Randian celebration of self-interested action; and the neo-authoritarian ethos of self-discipline—are transformed by their relation to the prevailing cultural anxieties and the mythic composition they collectively form. We argue that consumers are not so much looking for meanings that can restore a sense of lost order; but, instead, are transformed by the disruption in ways that lead them to re-evaluate the discourses that constitute their

cultural stock of knowledge. Resonant brand myths crystallize their reconfigured understanding and transposed identity projects.

Second, we explore how brand myths function as ideological performative scripts (Swidler 1986; Thompson and Ustuner 2015) that organize a range of individual and collective actions, such as CrossFit's totemic Workout of the Day (WOD). We discuss how these performative scripts once established in the context of the formative brand myth can be recontextualized by consumers whose world-views are not as strongly shaped by the disruptive events that trigger the emergence of these myths. Although consumers can rework the myth in relation to different identity goals and class and gender significations, the ideological structuring of the performative script constrains the extent of these modifications and produces modes of governmentality (Foucault 1991; Ygnfalk 2015) that may contradict consumers' reflexive understanding of the practice.

Founded in 2000, CrossFit stands out as a rebuke to specialized training regimes, opting for a more all-round mode of fitness that enables one to meet physical challenges across a broad range of functional situations. While it has rather expectedly analyzed as yet another form of neoliberal governmentality (James and Gill 2017), we suggest that its explosive growth amidst the post-9/11 socio-cultural transformations necessitates a consideration of the aspects of its brand myth that align with the post-9/11 authoritarian ethos.

Numerous studies have documented the profound shift in social attitudes and values among the American citizenry in the post-9/11 era (Perrin 2005; Woods and Arthur 2014). Prominent among these changes were amplified cultural concerns over security and a heightened favorability toward authoritarian values and ideals. During this crisis period, cultural figures associated with safety and security enjoyed a heightened state of cultural popularity, such as first responders (firefighters and paramedics) and the military (Faludi 2007). Popular media offered a steady flow of mythic representations that resonated with the post-9/11 zeitgeist and its need for affirming morality tales of strength and willpower conquering unanticipated threats (e.g. movies and TV shows such as *American Sniper*, *the Bourne trilogy*, *24*, and *Homeland*) (see McSweeney 2014).

The CrossFit brand myth's resonance with the post 9-11 ethos is readily discernible in its representations of physical preparedness and reliance on high intensity drills, which simulate the stress-inducing conditions characteristic of military combat or emergency rescue situations. Importantly, the early adopters of CrossFit were police and fire departments and military personnel as the training program aligned with the situational challenges that confronted these occupational groups. As the company opted for a comprehensive definition of fitness combining features of skill-related and health-related fitness and successfully branded itself as the "sport of fitness" (Dawson 2015), it has been appropriated by heterogeneous groups of consumers hailing from backgrounds dissimilar to that of the early adopters over the years.

In our analysis of the CrossFit brand myth, we draw on multiple data sources including online and offline branded content, news articles in popular press, interviews with CrossFitters and trainers, and a participant observation of this fitness regime, online forums, and the CrossFit Games. With this comprehensive analysis, our aims are threefold. First, we strive to illuminate how established cultural discourses and ideals are fine-tuned for CrossFit's formative brand myth with the purpose of alleviating identity tensions apropos of the post-9/11 cultural anxieties. Second, we aim to trace the reconfiguration of the formative mythos over time, brought about by CrossFit's adoption by consumers across different class and gender lines and with distinct identity goals. Third, given that the motivations and identity goals of the late adopters primarily hail from the health and well-being discourses; we seek to tap into this broader cultural space

and unravel the relations between CrossFit and similar lifestyle practices such as the paleo diet. This will allow us to make further sense of the evolution of the original myth and situate the trajectory of CrossFit within broader ideological and cultural currents.

## Negotiating the Legitimacy of an American Icon: Myth and the U.S. Gun Market

### EXTENDED ABSTRACT

Previous research has revealed how characteristics of myth, such as plot and ambiguity, restore trust in industry experts following a catastrophe (Humphreys and Thompson 2014), propel brands to iconic status (Holt 2004), and sustain a brand over time (Brown et al. 2013). Other work has investigated the legitimation of markets (Humphreys 2010), brands (Giesler 2012), practices (Ozlem and Ger 2010), and products (Wilner and Huff 2017). In this research, we consider the ways that characteristics of myth influence legitimacy of products and practices in a market system (Thornton, Ocasio, and Lounsbury 2012) by investigating these relationships in the context of the American firearms market.

In America, firearms are consumer products readily available at specialty shops, mass retailers, gun shows, and private sellers. American consumers possess over 300 million firearms (Cook and Goss 2014), which are the only consumer product whose possession is specifically protected in the U.S. Constitution. Guns are also unusual in that they are designed specifically to kill. Accordingly, gun rights have been coupled with gun control throughout the nation's history (Winkler 2011).

Debate over the appropriate balance between gun rights and gun control has loomed large in recent decades as death and injury rates have increased. Firearms were involved in the death or injury of more than 120,000 Americans in 2016, and the rate of death has increased 15.5% over the past ten years (U.S. Centers for Disease Control and Prevention). Public concern is heightened by mass shootings. While outrage over high-profile tragedies predictably manifests as alarm over related legislation – that is, the regulative legitimacy of various products and practices – the outrage also predictably wanes (Humphreys and Thompson 2014). Faced with repeated mass shootings during the last 20 years, on the whole, Americans have expanded regulative legitimacy to a broader range of firearms products and practices rather than restricting it (Waldman 2014). Seeing no federal legislative action and intensified cultural debate following Sandy Hook, Orlando, Las Vegas, and others, many Americans and the media have often lamented that "nothing will ever change."

However, on March 1, 2018, two weeks after a high-profile school shooting in Parkland, Florida, *The New Yorker* ran a piece entitled, "Something new on gun control: a glimmer of hope" (Casidy 2018). Other mainstream news outlets echoed the cautious yet optimistic twist to the typical narrative that follows mass shootings. Less than a month after the shooting, a previously staunchly pro-gun Florida legislature passed several gun control measures opposed by the powerful gun lobby. We seek to understand how this "something new" seems to be happening.

We draw from previous work on myth in the marketplace and institutional theory to examine this phenomenon. Institutional theory scholarship outlines three types of legitimacy – regulative, cultural-cognitive, and normative (Scott 2008). Previous research has revealed the ways that actors in a market system work to change regulative legitimacy of products and practices through lobbying and pressure from voters (Huff et al. 2017). We investigate changes in cultural-cognitive and normative legitimacy. Myth naturalizes ideology, practices, and socially constructed meanings, and gives legiti-

macy to social facts (Barthes 1957). In addition, marketplace myths can advance ideological agendas (Thompson 2004). In contrast to work showing the ways that the plot of a myth can restore the status quo of a market system following catastrophe (Humphreys and Thompson 2014), we investigate the role of characteristics of myth in the evolution of a market system with tragic consequences. Specifically, we aim to understand the ways that various characteristics of myths influence the cultural-cognitive and normative legitimacy of products and practices in the American gun market system.

Our methodological approach is an ongoing, multi-sited ethnography (Kjeldgaard, Csaba, and Ger 2006) begun in early 2015. We sought to understand the specifics of how market actors physically and discursively engage (or not) with firearms and in firearm practices at micro, meso, and macro levels. At the micro level, we interviewed and observed individual gun owners, non-owners, activists, and legislators, gathered public opinion data from Pew and Quinnipiac polls, and gathered posts to discussion forums related to firearms use. At the meso level, we observed and conducted field interviews at gun shows, the NRA annual convention, and gun control rallies. At the macro level, we conducted a textual analysis of mainstream media coverage and public communications from the NRA and the gun violence prevention group (GVPG) Everytown from Oct. 1, 2017 through March 15, 2018.

We analyzed the textual data iteratively over three years, moving between data, literature, and coding, and then collecting additional data and repeating the process. Our analytical approach was informed by Charmaz (2006) and followed protocol outlined by recent consumer research on market systems (Ertimur and Coskuner-Balli 2015; Martin and Schouten 2014) and automated textual analysis (Humphreys and Wang 2017).

Preliminary findings suggest that cultural myths influence the cultural-cognitive and normative legitimacy of firearms-related phenomena, and this occurs when myths have four characteristics: they serve as a framework that supports relevant facts and data; are manifest at both the individual and societal levels; are disseminated passionately; and effectively employ materiality. We find that the NRA has been relatively effective at influencing the legitimacy of firearms products, services, and practices through the use of these four myth characteristics. In contrast, GVPGs have been less effective at influencing legitimacy because their myths lack a hero character and justice for a villain, do not incorporate materiality, and have not served as an effective framework for the abundance of data that GVPGs believed would sway legislators and the public. Our data indicate that this has evolved subsequent to the 2018 shooting in Parkland, Florida.

This research will make theoretical contributions to literature on the relationship between myth and markets (Humphreys and Thompson 2014; Luedicke, Thompson, and Giesler 2010), legitimacy in market systems (Humphreys 2010), and consumer movements (Weijo, Martin, and Arnould 2018) by illuminating the ways that characteristics of myths influence legitimacy. In so doing, this study will also contribute a substantive link between marketing research and the nascent scholarly domain of gun studies (Huff and Barnhart 2019).

### **Erasure as Institutional Maintenance**

#### **EXTENDED ABSTRACT**

*“Halston’s name came to mean everything in fashion and then nothing”  
Kirby, in New York Times 1998*

Roy Halston Frowick—commonly known as Halston—was perhaps the most famous designer of the 1970s. Dubbed by Balen-

ciaga as “the greatest couturier in the world” (Gaines 1991), he was “America’s first internationally renowned designer” (Sporkin et al. 1990). Within a span of 10 years, he won four Coty awards and was inducted to the Coty Fashion Hall of Fame, a feat not repeated since. Apart from designing Jackie Kennedy’s pillbox hat, he was also the first designer to collaborate with a department store, predating collaborations such as Karl Lagerfeld & H&M. He was a fixture at Studio 54, and introduced numerous fashion innovations. Then, he disappeared into oblivion.

What can the rise and fall of Halston tell us about markets? How does remembering shape a market? Previous research has seldom examined market processes underlying the accumulation of market memories and how this affects the evolution of markets. Instead, it has thus far concentrated on micro-level, consumer-centric processes (e.g. Jiang et al. 2015), meso-level firm practices (Mena et al. 2016), and on how the interactions between a market and other types of memories, such as popular memories (Thompson and Tian 2008), nationalistic memories (Brunk, Giesler, and Hartmann. forthcoming), and memories associated to specific brands (Brown, Kozinets, and Sherry 2003), can inform myth making, branding, and marketization.

A market memory is the active past of a market, formed by the collection of archived documents referencing market occurrences (Halbwachs 1992; Olick 1999; Ocasio, Mauskopf, and Steele 2015). Occurrences, such as a fashion show or a faux-pas from a market actor, are turned into documents which are then archived. For example, the coverage of a fashion show by Vogue is transformed in an article which is archived on Vogue.com. The retrieval, re-activation, and re-interpretation of occurrences allow for their transformation into historical events and further transformation into documents. The documentation and historicization of occurrences around a market ultimately leads to the creation of a market memory (Ocasio et al. 2015). For example, the retrieval of a Vogue article to discuss a certain fashion show can lead to the creation of new documents, which over time turns the show into a historical event.

Understanding how a market memory evolves is important because such a collectively shared and commemorated past influences present events by “providing people with understandings and symbolic frameworks that enable them to make sense of the world” as we “rely on memory for the provision of symbolic representations and frames which can influence and organize ... our actions” (Miszta 2003, 13) and, we argue, markets. We propose that memory work, i.e. work upon market memory, is a type of institutional work: it helps create, maintain, or disrupt the understanding, practices, and rules that govern a market (Dolbec and Fischer 2015). We concentrate on erasure as a type of memory work that serves to maintain a market. This study asks two questions: How is a market actor erased from a market memory, and how does erasure maintain an institution?

Findings are based on an extensive archival dataset around the 1970s designer Halston from the *Women’s Wear Daily*, *New York Times*, and *Vogue*, covering the 1960s to the 2010s, and totaling 5546 pages. The analysis was performed by manually coding a subset of the data and creating dictionaries around dramatized identities of Halston, analyzing the evolution of these dramatized identities over time through automated coding (Humphreys and Wang forthcoming), and creating links with institutional and memory work. We concentrate on the dramatized identities of a market actor as they have been shown to affect institutional-level sensemaking (Giesler 2008).

Halston’s numerous identities (e.g. Halston the milliner, Halston the socialite, Halston the Halston the enfant terrible) all played mar-

ket-level roles and helped constitute the fashion market memory. We map the evolution of these identities together with the evolution of Halston within the fashion market memory. For example, positive identities helped maintain or foster aspects of the market. Mentions of how “Halston the milliner” created Jackie Kennedy’s pillbox hat helped maintain the status of hats within American society, while the numerous innovations and awards of “Halston the designer” helped promote American fashion. It also made Halston a celebrity both within and outside the world of fashion. As a celebrity, he became an important focal point for journalists to discuss the evolution of American fashion, its rules, norms, and conventions, and how it transformed from an industry that copied French design to one fueled by its own, homegrown designers. Halston helped create a “dramatized reality” of the American fashion market (see Rindova et al. 2006). In contrast, the negative identities of Halston, such as “Halston the failed businessman” and “Halston the enfant terrible”, contributed to delegitimize certain market practices (e.g. collaborations with department stores) and helped push Halston out of the fashion market memory altogether. We show how these identities are associated with processes of institutional and memory work (legitimization and celebrification; delegitimization and silencing following his breach of institutional norms; and re-integration of his legacy once the norms he once breached had changed enough that his actions, once transgressive, were now considered normal).

The findings have multiple implications: first, market memory processes can explain market maintenance and changes through memory contests. This points to the long-lasting value of discursive acts, and how their accumulation, archival, and retrieval can, over time, shape market evolution. Second, erasure contributes to institutional maintenance as it contains potential destabilization that can happen through non-exceptional events. This extends the work of Humphreys and Thompson (2014) to normal market events. Institutional maintenance thus entails a constant staging of memories to insure an alignment between occurrences, historical events, and the governing assumptions, beliefs, and norms of a market.

### **SESSION OVERVIEW**

What sorts of information and cues do people mostly care about when forming brand evaluations? For over three decades, branding scholars have informed consumer research about various factors that shape consumer responses to brands. In the wake of a *recent* string of corporate *scandals* (United's passenger-dragging and dog death incidents, Volkswagen's "dieselgate", Uber's series of scandals) and a surge of academic interest in morality in the marketplace (Campbell and Winterich 2018), researchers have brought moral attitudes, judgments, and behaviors back to the forefront in understanding consumer reactions to brands. Capitalizing on this tradition, our session puts forward cutting-edge research into the interplay between branding and morality. Each of the four papers included in this session address the following research question: how can research on marketplace morality and immorality inform the study of brands in general and consumer evaluations of and reactions to brands in particular?

The first two papers focus on the interplay between branding and morality by exploring the role of moral character and moral identity in consumer responses to brands. The authors of the first paper examine how and why brand's moral character impacts brand perception and evaluation. They find that brand's moral character dominates in evaluation formation and is more important than brand's warmth. The second group of researchers explore the impact of moral identity in predicting rejection of moralized products and brands. They document that marketing/brand labels that signal moralized values trigger reactance among consumers high, but not low in moral identity, that leads them to reject such brands.

The second two papers provide new perspectives on the intersection between branding and immorality by investigating consumer reactions to brands in the context of moral transgressions. The authors of the third paper investigate whether a brand's moral reputation is a buffer or a liability when facing later accusations of cor-

porate ethical transgressions. They show that while a positive CSR reputation can act as a buffer against negative reactions to unethical corporate/brand behavior, it can also backfire when a brand transgression directly contradicts its reputation. The authors of the last paper look at whether and how political orientation moderates desire for punishment toward users of ethical (vs. conventional) brands committing moral transgressions. Their work indicates that liberals (conservatives) punish ethical brand users committing moral transgressions *less (more)* than conventional brands users, and that stereotyping of the transgressor drives such reactions.

By bringing to the fore four novel theoretical accounts, these papers advance our understanding of the complex interplay between branding and morality. From a theory standpoint, then, this session should interest branding, morality, trust, and consumer ethics researchers who examine morality and ethics in the marketplace. Moreover, as exemplified by a series of recent brand and corporate scandals such as the infamous Volkswagen emissions (Rhodes 2016) or the Ashley Madison data breach scandals (Rotman et al. 2018), the effects uncovered here can inform managerial decision-making. Accordingly, this session may also appeal to consumer research practitioners that want to apply academic insights to the practice of branding and marketing.

## **Brand's Moral Character Predominates in Brand Perception and Evaluation**

### **EXTENDED ABSTRACT**

What sorts of trait information do people most care about when forming brand evaluations? Recent research on brand relationships (Kervyn et al. 2012) suggests "warmth" should be of prime importance in evaluation formation. Yet, some psychological research on morality (Goodwin 2015) suggests information about brands' specifically moral traits—their moral "character"—may be a primary dimension. Although warmth and character are sometimes construed interchangeably in the interpersonal domain (Cuddy et al. 2008), we argue they are separable in the consumption domain. More importantly, we posit that across a wide variety of contexts, character is likely more important than warmth in brand evaluation formation.

Study 1 recruited 193 undergraduate students in exchange for course credit. Participants were asked to rate seven different brand targets in a random order that varied in both valence and closeness: "a brand you admire a great deal"; "a brand like a close friend of yours whom you like very much"; "a brand in your life you grew up with"; "Labbatt, Canadian brand"; "Molson, former Canadian brand between 1786-2005"; "a brand that you dislike, or that irritates you"; and "a brand you despise, or have no respect for." Participants then rated these seven target brands with respect to how much they possessed each of 30 different traits (1 Not at all - 9 Extremely) that were carefully preselected from four different categories, so that the dimensions of moral character and warmth (as developed and validated by Goodwin et al. 2014) would be fully crossed. Following the trait ratings, for each target, participants responded to the primary dependent measure, which asked them to indicate how positive or negative their evaluation of the brand was (1 Very negative - 9 Very positive). In general, all four of the trait indices correlated strongly with evaluations, with the moral character—warmth, and moral character trait indices having the strongest relation with evaluations. Compar-

ing the raw correlations for all seven target brands, evaluations were more strongly associated with the pure moral character traits than to the pure warmth traits. Regression analyses revealed that as predicted, it was the moral character traits, along with the moral character–warmth traits, that best predicted variance in evaluations. Either one of these trait categories best predicted variance in evaluations for all seven target brands. In contrast, the warmth traits did not best predict evaluations for any of the target brands. Moreover, the moral character traits independently predicted variance in evaluations for all seven target brands controlling for other three trait categories.

Study 2 examined whether brand moral character information exerts a greater causal impact on brand evaluations than does warmth information. Participants were 384 U.S. adults recruited via Mturk. Brand’s moral character (good vs. bad) and warmth (warm vs. cold) were crossed in a 2 x 2 within-subjects design. An example description of a target brand was: “The brand has good moral character but is interpersonally cold.” The order of the moral character and warmth information in each description was randomized at the level of descriptions. Following manipulations, participants were asked to indicate their “overall evaluation” of each target brand on a scale from 1 (very negative, unfavorable, bad) to 9 (very positive, favorable, good). Within-subjects ANOVA revealed large main effects of both moral character and warmth on evaluations in the predicted direction. However, the overall main effect of moral character was larger than the main effect of warmth. And, of critical interest, the target brand that was of good character but cold was rated significantly more positively than was the target brand that was of bad character but warm. There was also an interaction between moral character and warmth, reflecting that the effect of warmth was larger for good than for bad targets.

Study 3 sought to extend findings of study 2 using a between-subjects design and employing behavioral intention measures in addition to the attitudinal one. 223 undergraduate students were recruited in exchange for course credit. Moral character and warmth manipulations mirrored those in study 2. Following manipulations, participants filled out the same composite measure of brand evaluations as in study 2 as well as measures of purchase intentions (MacKenzie et al. 1986), word-of-mouth intentions (Fedorikhin et al. 2008), and a single item capturing their willingness to pay in dollars. Our findings reveal a significant multivariate main effect of both moral character and warmth on brand-related dependent measures. Follow-up univariate ANOVAs revealed that the main effect of moral character was significant across all four dependent variables. The main effect of brand’s warmth was also significant across all four dependent variables. However, the overall main effects of moral character were larger than the main effect of warmth. Importantly, compared to the target brand that was of bad character but warm, the target brand that was of good character but cold was evaluated more positively, yielded higher purchase intentions, greater WOM intentions, and stronger willingness to pay. The significant multivariate interaction suggested the effect of warmth was again larger for good than for bad targets.

Theoretically, we contribute to the literature in at least several ways. Our first contribution to brand relationships research (Alvarez and Fournier 2016; Fournier 1998) lies in bringing a new trait (moral character) from research on social cognition and psychology of morality into the branding domain while showing it really matters in the consumption context. To this effect, showing that the influence of brand’s moral character holds while controlling for brand’s warmth and competence that are already explored in the branding domain (Ivens et al. 2015; Kervyn et al. 2012) represents a particularly intriguing finding that can boost future research in the domain. Importantly,

although warmth and character are sometimes conceived of as interchangeable in the context of interpersonal relationships (Cuddy et al. 2008), our findings suggest they are separable in the consumption domain. Finally, our results also give back to psychology of morality and social cognition literatures (Goodwin 2015; Goodwin et al. 2014) by establishing that influence of moral character extends to consumption/branding domain.

### Rejecting Moralized Products: Moral Identity as a Predictor of Reactance to “Vegetarian” and “Sustainable” Labels

#### EXTENDED ABSTRACT

Morality is a distinct domain of social knowledge, separate from conventional and preference domains (Turiel 1983). Behaviors, concepts, or ideas can shift from the conventional to the moral domain as individuals mature and through social and cultural changes in attitudes and values, a process referred to as moralization (Rozin 1999). Once moralized, the failure to display these behaviors or endorse certain ideas can make a person subject to sanctions. Two behaviors that have possibly become moralized are sustainability (Feinberg and Willer 2013) and vegetarianism (Rozin, Markwith, and Stoess 1997).

Sustainable goals of conserving natural resources and maintaining an ecological balance can be achieved by reducing meat consumption or reducing one’s carbon dioxide emissions through travel mode choices. While eating (or not eating) meat or travelling (or not travelling) by car and airplane might be perceived as matters of preference or convention, we argue that moralization has turned these conventions into moral values (Rozin 1999; Rozin et al. 1997). Because of their implied social pressure, moral behaviors can reduce the freedom to choose (Kouchaki, Smith, and Savani 2018) showing that morality serves as a constraint on people’s perceptions of choice. Across eight studies (N = 2,217). For instance, being exposed to people who refuse to eat meat or actively seek out ethical products can cause others to feel morally reproached (Minson and Monin 2012) and experience self-threat as a result of negative social comparison (Zane, Irwin, and Reczek 2016) more ethical consumers who seek out and use this information in making purchase decisions. Across three studies, willfully ignorant consumers negatively judge ethical others they have never met across various disparate personality traits (e.g., fashionable, boring. Although the pressure to conform to certain socially desirable norms can lead some individuals to conform, others might actively resist that pressure - a phenomenon known as psychological reactance (Brehm 1966; Brehm and Brehm 2013) - and reject the desired behavior.

We propose that if sustainability and vegetarianism have become moralized, then marketing labels that signal these values can be interpreted as a moral pressure to conform, triggering psychological reactance among certain consumers. In particular, non-vegetarian consumers should be more likely to reject vegetarian dishes labelled “Suitable for Vegetarians” and global warming skeptics should be more likely to reject a flight ticket when it signals a “Contribution to Sustainable Travel”. More importantly, to demonstrate that these effects are driven by reactance to moral demands, we show that they are moderated by the self-importance of moral identity, the extent to which consumers consider “being a moral person” a key characteristic of their self-concept (Aquino and Reed 2002). We test these predictions both by measuring and manipulating the self-importance of moral identity.

The first study tested the hypothesis that non-vegetarians with a higher (vs. lower) moral identity will be more likely to reject a dish

labelled “Suitable for Vegetarians”. 184 undergraduate students were presented with a restaurant menu that contained three non-vegetarian dishes, and three vegetarian dishes. There were two between-subject conditions: the vegetarian dishes were either labelled “Suitable for Vegetarians” or not. Participants rated the likelihood of ordering each dish and taste perceptions, completed the moral identity scale (Aquino and Reed 2002) and then indicated whether they were vegetarians or not.

There were very few vegetarians among the participants, so we only analyzed non-vegetarians’ responses. There was no difference in taste ratings between the label conditions. Overall, non-vegetarian participants were significantly less likely to choose the vegetarian dishes when they were labeled (vs. not labelled) “Suitable for Vegetarians”,  $F(1, 164)=4.48, p=.036$ . More importantly, we found a two-way interaction between moral identity and label on preference for vegetarian dishes,  $t(164)=2.77, p<.01$ . As predicted, the rejection of the vegetarian-labelled dishes was significantly stronger among non-vegetarians with a higher (vs. lower) moral identity.

In the second study, we manipulated moral identity in 239 undergraduate students by asking them to write a story about themselves using moral (vs neutral) words (Reed, Aquino, and Levy 2007). As in study 1, participants saw menus either with or without “Suitable for Vegetarians” labels and rated their likelihood of ordering the dishes. We found a marginally significant two-way interaction between the “Suitable for Vegetarians” label and the moral identity prime on the preference for vegetarian dishes,  $F(1,211)=3.32, p=.07$ . Follow-up contrast analyses showed that non-vegetarians exposed to the “Suitable for Vegetarians” label were significantly less likely to choose the vegetarian dishes in the moral identity condition than in the control condition,  $F(1,211)=5.99, p=.02$ .

The third study investigated moral reactance against flight tickets that signal a “donation to Sustainable Travel”. A pretest of 2634 workers on Amazon Mechanical Turk measured participants’ attitudes towards climate change. Participants had to self-categorize as global warming “skeptics” (global warming is not happening), “neutrals” (global warming is happening but may be a natural phenomenon), and “non-skeptics” (global warming is due to human activity). Then, we re-contacted 245 skeptics, 269 neutrals, and 201 non-skeptics for a second study. All participants were asked to choose between two flight tickets with the same date, origin and destination, but a slightly different price and time; one flight departed an hour later in the morning but was \$5 more expensive. A pretest showed that participants were indifferent between the two options. There were two between-subject conditions: the more expensive flight either had a label “includes a \$5 contribution to Sustainable Travel”, or had no such label. Participants indicated their choice, and completed the moral identity scale.

Global warming skeptics, neutrals, and non-skeptics had similar moral identity scores. Not surprisingly, global warming skeptics were less likely than the other two groups to select the more expensive flight when it had (versus did not have) the “sustainable travel” label. More importantly, we found a significant three-way interaction between the belief in climate change, the label manipulation, and moral identity on the choice of flight ticket,  $t(421) = 2.54, p = .01$ . Among global warming skeptics, there was a significant two-way interaction between the Sustainable label manipulation and moral identity,  $t(186)=-2.79, p<.01$ . As predicted, global warming skeptics with higher (vs. lower) moral identity were significantly more likely to reject the flight with the “Sustainable Travel” label.

The three studies together provide converging evidence for our predictions; that sustainability labels cause certain consumers with high self-importance of moral identity to reject the product and shift

their preferences to another one. The findings add to research on morality, and caution marketers against the excessive use of labels that can trigger moral reactance.

### **When Buffers Backfire: Corporate Social Responsibility Reputation and Consumer Response to Corporate Ethical Transgressions**

#### **EXTENDED ABSTRACT**

This research contributes to the inconclusive debate in the field of corporate social responsibility (CSR) on whether a brand’s favorable CSR reputation helps or hurts brands when facing later accusations of corporate ethical transgressions. For instance, car manufacturer Volkswagen had trumpeted low emissions of their diesel cars in marketing campaigns, followed by the well-known emissions scandal in 2015 (Federal Trade Commission 2016). In this research, we explore the influence of mixed (i.e. moral *and* immoral) brand behaviors on consumer attitudes towards the brand by investigating how a brand’s prior CSR reputation affects consumer responses to evidence of corporate ethical transgressions. We find that a positive CSR reputation can act as a buffer against negative reactions to unethical behavior—but it can also backfire, causing a precipitous fall from grace when a brand transgression directly contradicts its reputation.

Our research reconciles contradictory theories and findings on this topic from past studies within a theoretical framework based on the principles of expectancy-disconfirmation in comparative judgments (e.g., Oliver 1977, 1980) and the weighting of extreme values in information integration models (e.g., Anderson 1974; Fiske 1980). We propose two causes for the mixed evidence regarding the effect of prior CSR reputation on consumer responses to corporate ethical transgressions: (1) illusory differences caused by varying cross-study operationalizations of the consequences of transgressions (i.e. outcome variables used), and (2) true differences explained by a previously unexamined moderator—the relatedness of the brand’s transgression domain to its domain of CSR reputation. First, we note that extant studies supporting a buffering effect of a positive (CSR) reputation largely focus on differences between brands in final outcomes, comparing post-transgression attitudes towards brands with positive (prior) reputations versus those with no or negative (prior) reputations (cf. Coombs and Holladay 2006; Eisingerich et al. 2010). However, studies suggesting that a positive CSR reputation can turn into a liability largely focus on change in attitude or behavior after a transgression, relative to a brand’s pre-transgression state (cf. Helm and Tolsdorf 2014; Vanhamme et al. 2015). In our research, we measure both pre- and post-transgression attitudes for brands with positive, negative, and no CSR reputations. We hypothesize that a positive CSR reputation can provide a buffer in terms of final (post-transgression) outcomes, while backfiring in terms of pre- versus post-transgression attitude change. These effects will depend, however, on whether the transgression domain is similar to the domain of the CSR reputation.

Second, because expectations set a reference point for evaluating outcomes (e.g., Oliver 1977, 1980; Skowronski and Carlston 1989), and more unexpected or extreme information is weighted more heavily in information integration processes (e.g., Anderson 1971, 1974; Feldman and Lynch 1988; Fiske 1980), we expect that the ‘relatedness’ of an ethical transgression to a brand’s domain of CSR reputation will interact with the valence of this reputation to influence consumer attitudes. Evidence of transgressions in the same domain as the brand’s positive CSR reputation directly contradicts the brand’s reputation, thereby violating expectations

(Afifi and Metts 1998), and hence gaining in diagnosticity. Unrelated transgressions are likely to be less surprising because they do not contradict consumers' existing beliefs and, additionally, consumers may expect that brands cannot perform well in all domains simultaneously. For brands with positive CSR reputations in a given domain (e.g., voluntarily paying a "living wage"), we expect stronger negative responses to transgressions in a related domain (i.e. sweatshop labor), relative to an unrelated domain (e.g. pollution).

We used a 3 (CSR reputation: positive, negative, no)  $\times$  3 (transgression domain: no transgression, same domain, unrelated domain) between-subjects design. 443 U.S. participants (56.7% male) were randomly assigned to one of the three CSR reputation conditions in the domain of 'paying (un)fair wages', and to one of three ethical transgressions (sweatshop scandal – related domain; pollution scandal – unrelated domain; no transgression). Our dependent variable was attitude towards the brand (Wagner et al. 2009).

A 3  $\times$  3 omnibus ANOVA revealed significant main effects of CSR reputation ( $F(2,434) = 111.38, p < .001$ ) and transgression condition ( $F(2,434) = 275.54, p < .001$ ) on consumer attitudes, as well as a significant interaction ( $F(4,434) = 42.58, p < .001$ ). See table for means and standard deviations. We conducted pairwise comparisons of final, post-transgression attitudes across the three CSR reputation conditions (positive, negative, no CSR): for unrelated transgressions, attitudes were significantly higher for a brand with positive CSR reputation, compared to a brand without CSR reputation ( $p < .001$ ), suggesting a buffer effect. No significant difference ( $p = .43$ ) between positive and no CSR was found for related transgressions. Moreover, post-transgression attitudes towards brands with positive CSR reputations were significantly lower following transgressions in a related domain relative to an unrelated domain ( $p < .001$ ).

To test the second operationalization of transgression consequences, we conducted a series of interaction contrasts. Although the drop from pre- to post-transgression attitude was significant for unrelated transgressions for both, positive and no CSR reputations, the mean differences for attitude change were similar, hence non-significant, across positive and no CSR reputation conditions ( $F(1,434) = 0.10, p = .76$ ). However, for related transgressions, the mean difference was significantly higher for a brand with positive CSR reputation compared to a brand without CSR reputation ( $F(1,434) = 8.64, p = .003$ ), indicating a backfire effect.

Concluding, when comparing brands with positive and no CSR reputations in terms of final, post-transgression outcomes, a positive CSR reputation can buffer brands from negative responses, but only if transgressions are unrelated from the domain of the reputation. This buffer effect is in line with expectancy confirmation perspectives, which suggest that individuals resist negative information when they have learned favorable information about a person or entity before (Coombs and Holladay 2006; Darley and Fazio 1980). On the downside, however, we show that the buffer effect disappears – and even backfires – after a transgression when considering the change in attitude, and when the transgression domain is in the same domain as the CSR reputation.

### Crime and Punishment through the Political Lens: How Liberals Forgive, and Conservatives Punish Ethical Brand Users

#### EXTENDED ABSTRACT

We live in a politically polarized world, and a crucial decision for brands is whether they should take a stance on controversial issues. However, and importantly, even if brands choose not to have a position on any issue, they cannot control their consumers, and these

consumers' actions can shape third-party responses toward the brand (Goh, Heng, and Lin 2013). That is, the same target consumer action can be viewed differently by third parties depending on characteristics of the brands (s)he uses (Olson et al. 2016). This research improves our understanding of factors influencing marketplace moral judgments by examining characteristics of both the target (brand usage) and characteristics of the third party (political orientation) on judgments of consumers performing moral transgressions.

Recent research has dedicated increasing attention to understanding factors that influence judgment and responses to moral transgressions. For example, research has generally focused on how the nature of the transgression—e.g., cleaning toilets with a flag (Haidt, Koller, and Dias 1993)—rather than the person involved (i.e., transgressor) affects moral judgments (Haidt 2001, 2007). Alternatively, observers can make different judgments depending on the target of a given action. For example, most people answer the trolley dilemma differently depending on whether the victim is an in-group member (Swann Jr. et al. 2014). Moral judgments are also colored by the observer's characteristics, for instance, and central to this work, by political orientation (Graham, Haidt, and Nosek 2009). Drawing on motivated reasoning (Kunda 1990), we suggest that characteristics of both the actor and observer interact to predict punitive judgments (i.e., forgiveness and punishment). Importantly, we focus on more ordinary, everyday behaviors (ethical consumption) than those typically examined in moral psychology.

Extending work to looking at negative downstream consequences of judgments about consumers' ethical choices (Olson et al. 2016) and desire for punishment in consumption contexts (Lin et al. 2013), we propose that political orientation moderates the desire for punishment toward users of ethical (vs. conventional) brands committing moral transgressions. Specifically, we show that more liberal (conservative) participants punish less (more) those committing a moral transgression when they are users of ethical (vs. conventional) brands. We also show that perceptions of the transgressor's ethical values mediate this effect. Importantly, we focus on moral transgressions unrelated to the ethical properties of the brand—such as social transgressions committed by environmentally-friendly brand users.

Study 1 demonstrates our basic interaction between brand type and political orientation on punishment intensity. Participants read a scenario where "someone has irresponsibly parked their Toyota [Prius Hybrid (ethical) vs. Camry (conventional) brand] near the store entrance, occupying the last two parking spots available." Participants indicated which fine amount would be appropriate for that person and rated their political orientation (-5=extremely liberal; +5=extremely conservative scale). We found a two-way interaction between brand and political orientation on punishment intensity ( $t(137)=3.01, p < .01; CI_{95}[11.47, 55.37]$ ). Liberal participants (13<sup>th</sup> percentile) punished the Prius user ( $\hat{y}=\$98.45$ ) less than the Camry user ( $\hat{y}=\$189.29$ ), whereas conservative participants (74<sup>th</sup> percentile) punished the Prius user ( $\hat{y}=\$224.28$ ) more than the Camry user ( $\hat{y}=\$151.02$ ).

Study 2 suggests that this effect occurs because of a shift in the perception of the transgressor ethical values, and uses an alternative measure of political orientation. Using the same design and scenario as in study 1, participants were asked to rate the transgressor's ethicality as a potential mediator (e.g., immoral/moral, unethical/ethical; Olson et al. 2016) and answered the same punishment measure. Participants also completed the 7-item Conservatism-Liberal Scale (Mehrabian 1996). We found an interaction between brand and political orientation on punishment intensity ( $t(227)=2.58, p = .01; CI_{95}[6.57, 48.75]$ ). Liberal participants (31<sup>st</sup> percentile) punished the Prius user ( $\hat{y}=\$139.69$ ) less than the Camry user

( $\hat{y}=\$186.66$ ), and conservative participants (95<sup>th</sup> percentile) punished the Prius user ( $\hat{y}=\$182.29$ ) more than the Camry user ( $\hat{y}=\$90.99$ ). Perceptions of the transgressor ethical values mediated this effect  $CI_{95}[2.48,17.03]$ .

Study 3 supports that decision-making biases stemming from marketplace stereotyping explain our effects and tests our framework in a context where the brand is incidental to the transgression. First, we manipulated participants' accountability for either the decision-making *process* leading their punishment decisions (assumed unbiased), or for the *outcome* of their decision (assumed biased; Pitesa and Thau 2013). Participants then imagined they were at a doctor's office. "One of the other people in the waiting room is a lady with a giant [Whole Foods Market (ethical) vs. Kroger (conventional) brand]." The lady had arrived after you did, had been shouting on her cell phone, and was "complaining how she *just can't believe that it's taking this long to see someone!* She says she *wants* to see a physician *NOW!*" Participants answered the same measures as in Study 1. Following a significant 3-way interaction ( $t(431)=3.37$ ,  $p<.001$ ;  $CI_{95}[-75.17,-19.79]$ ), our key effect replicated in the outcome-accountable condition (2-way:  $t(431)=2.79$ ,  $p=.01$ ;  $CI_{95}[8.46,48.66]$ ), but disappeared—and reversed—in the process-accountable condition ( $t(431)=1.95$ ,  $p=.05$ ;  $CI_{95}[-37.97,13]$ ), consistent with a (over) compensating behavior, biased judgment, and motivated reasoning.

Study 4 tests a managerial intervention using branding (i.e., around core performance vs. around ethical attributes) to minimize political biases when promoting ethical brands. Participants read a scenario where someone "has carelessly tossed a [Roaster Blend Ethical Coffee-"More Ethical Beans = Better Coffee" (Ethical) vs. Roaster Blend Coffee-"Better Tasting Beans = Better Coffee" (Conventional) vs. Roaster's Ethical Coffee-"Better Tasting Beans = Better Coffee" (Ethical brand+conventional branding)] cup on the lawn, despite numerous trash cans in sight." Participants answered a measure of punishment from Lin et al. (2013). We replicated our political orientation interaction between the conventional vs. ethical brand conditions (2-way:  $t(180)=-3.66$ ,  $p<.001$ ;  $CI_{95}[-.65,-.20]$ ), but not vs. the ethical brand+conventional branding (2-way:  $t(180)<1$ ;  $CI_{95}[-.27,.17]$ ), suggesting that promoting ethical brands with a focus on core performance (vs. ethical) attributes reduces stereotyping.

This paper makes two primary theoretical contributions to the growing literature examining the downstream consequences of moral judgments in consumption. We i) highlight the interplay between characteristics of the viewer and the target on moral judgments and their consequences and ii) show how relatively trivial consumption decisions can have important consequences for consumers, due to their effect on third-party judgments. Our findings offer important implications for a better understanding of marketplace stereotyping, attribution formation, and ethical branding.

## **SESSION OVERVIEW**

Close relationships with romantic partners, family, and friends are central to happiness: previous research has documented a robust link between having close, secure, and supportive relationships and happiness in life (Lyubomirsky, Tkach, and DiMatteo 2006). Similarly, close relationships influence daily consumption decisions—given that we are often making decisions with the people that we love and care about in mind (Cavanaugh 2016). This session contributes to our understanding of the critical question of how consumers engage with products and experiences to foster love and trust in their relationships with spouses and families (Gorlin and Dhar 2012; Simpson, Griskevicius, and Rothman 2012). Specifically, the papers in this session discuss four consumption behaviors that impact close others: caregiving (Garcia-Rada, Steffel, Williams, and Norton), gift-giving (Vu, Olson, Paolacci, and Rick), acquiring time-saving purchases (Whillans, Pow, and Norton), and managing shared finances (Garbinsky, Gladstone, Nikolova, and Olson).

The first paper focuses on how consumers feel when they use products and technologies that simplify their caregiving tasks. Garcia-Rada, Steffel, Williams, and Norton show that consumers feel less dedicated and guiltier when they use products and technologies that simplify tasks like caring for their sick spouse or feeding their child because they feel they are taking the “easy way out” rather than being good spouses or parents.

The second paper focuses on gift-giving within married couples. Vu, Olson, Paolacci, and Rick examine how individuals react when they receive a lavish gift from a partner who is otherwise a frequent source of financial distress. Specifically, they find that spendthrifts are most satisfied when receiving a lavish gift from a tightwad spouse, and tightwads are most satisfied when receiving a lavish gift from a spendthrift spouse.

The third paper studies how making time saving purchases together with one’s partner (e.g., hiring a housecleaner) can impact relationship quality. Whillans, Pow, and Norton show that buying time promotes relationship satisfaction because these purchases protect couples from the negative impact of stress, and enable couples to spend more quality time together.

Finally, the fourth paper examines financial infidelity in the context of romantic relationships. Gladstone, Garbinsky, Nikolova, and Olson further understanding of situations in which partners are dishonest about financial decisions. In this paper, the authors develop a scale to measure consumers’ propensity to engage in financial infidelity.

Understanding how consumers make decisions for their loved ones is essential to discovering how to help individuals have better relationships and lead happier lives. This session sheds new light on how consumers use products and experiences to foster and maintain close relationships. All four projects are working papers with at least two studies completed and involve different methodologies (e.g., scale construction, experiments, large-scale surveys) and populations (approximately 9,000 subjects, including college students and working adults). Given the widespread applicability of the issues discussed, we expect this session to attract researchers interested in close relationships, gift-giving, experiential consumption, and financial decision-making. Finally, we hope that these diverse approaches to studying consumer behavior in the context of close relationships will generate a fruitful discussion.

## **A Preference for Effort when Caring for Close Others**

### **EXTENDED ABSTRACT**

New products and services designed to streamline consumers’ lives have made life easier on many dimensions – including making it easier to care for close others. Consumers can now send ecards and egifts to their friends, buy pre-made meals to feed their families, and purchase countless devices that simplify parenting. Yet new products that make caregiving easier come with a cost: when consumers take the “easy way out” when caring for close others, that very ease can signal that consumers are failing to be good friends, spouses, or parents.

Take for example the case of the SNOO Smart Sleeper, a crib that helps infants sleep more through the night by automatically responding to babies’ cries and rocking them gently to sleep. We retrieved social media posts of two articles describing the SNOO Smart Sleeper. Although people acknowledged that this new technology makes parenting easier, several posts included negative judgments such as: “a mom or dad rocking their baby is invaluable bonding” or “more lazy parenting products.” Clearly in some cases, making caregiving tasks easier, more convenient, and less effortful can backfire when consumers feel they have not put ample time, thought, and effort into caregiving.

In the present work, we investigate the emotional consequences of using products that simplify caregiving. Building on work showing that people value effort (Buell and Norton 2011; Cutright and Samper 2014; Olivola and Shafir 2013), we argue that when taking care of close others, consumers will choose more effortful alternatives to signal love and care. In addition, we assess the emotional consequences of using these products, focusing not on how effort impacts valuation of the outcome or object (Norton, Mochon, and

Ariely 2012) but on how it influences consumers' self-evaluations as caregivers. Across several experiments, consumers feel less dedicated and guiltier when they use products that simplify caregiving. This relationship is mediated by symbolic meaning: choosing easier caregiving makes consumers feel that they are doing a worse job of signaling that they care about the recipient.

In Study 1, undergraduates ( $N = 251$ ; 68.5% male;  $M_{\text{age}} = 20.76$ ,  $SD = 1.89$ ) were randomly assigned to make cards themselves or choose a premade card to take care of an elderly relative. Participants who made the card felt more dedicated ( $M_{\text{made}} = 5.28$ ,  $SD = 1.22$ ;  $M_{\text{chose}} = 3.93$ ,  $SD = 1.28$ ;  $t(249) = -8.57$ ,  $p < .001$ ), like they took better care of their relative ( $M_{\text{made}} = 5.17$ ,  $SD = 1.24$ ;  $M_{\text{chose}} = 3.90$ ,  $SD = 1.46$ ;  $t(249) = -7.41$ ,  $p < .001$ ), and less guilty ( $M_{\text{made}} = 2.05$ ,  $SD = 1.23$ ;  $M_{\text{chose}} = 2.78$ ,  $SD = 1.52$ ;  $t(238.22) = 4.22$ ,  $p < .001$ ) than those who chose a premade card.

In Study 2, we provide evidence for our psychological mechanism: symbolic meaning. Participants recruited through Mturk ( $N = 201$ ; 48.8% male;  $M_{\text{age}} = 38.16$ ,  $SD = 11.63$ ) imagined that their romantic partner was sick and was craving a specific soup. Participants were randomly assigned to imagine that they cooked the soup themselves or bought the soup from a store, and answered the same measures as in Study 1. Then, participants answered two items about the functional meaning of the gesture ( $\alpha = 0.86$ ): "To what extent do you think that your gesture achieves the goal of satisfying your partner's hunger," and "To what extent do you think that your gesture achieves the goal of satisfying your partner's craving?" and two questions about the symbolic meaning of the gesture ( $\alpha = 0.84$ ): "To what extent do you think that your gesture achieves the goal making your partner feel cared for?" and "To what extent do you think that your gesture achieves the goal of signaling love to your partner?" Replicating results from Study 1, participants felt as more dedicated, better caregivers, and less guilty when they cooked rather than bought the soup (all  $ps < .001$ ). The effect of effort on emotional consequences was mediated by symbolic meaning. We tested the significance of this indirect effect using PROCESS MACRO (Hayes 2012), 5,000 bootstrapped samples and 95% confidence interval, and entering both symbolic and functional meaning as mediators (symbolic meaning:  $ab = .20$ ,  $SE = .07$ ,  $CI [.09, .35]$ ; functional meaning:  $ab = .04$ ,  $SE = .03$ ,  $CI [.00, .12]$ ).

In Studies 3A-3C, we demonstrate that our effect is unique to caregiving situations that involve close others. In Study 3A, more participants reported they would make a pie from scratch instead of heating a premade pie to cheer up their roommate (46%) than themselves (21%,  $\chi^2(1, N = 199) = 13.69$ ,  $p < .001$ ), even when controlling for quality and price. In Study 3B, more participants reported they would bake cookies instead of buying them from a store for a close friend who was recovering at the hospital (66%) than for a distant friend (34%,  $\chi^2(1, N = 200) = 20.48$ ,  $p < .001$ ). And in Study 3C, more participants reported they would dry their baby manually instead of using an automatic dryer (59%) compared to participants drying their dog (33%) or their car (17%;  $\chi^2(1, N = 301) = 39.01$ ,  $p < .001$ ), even when the automatic dryer was more effective.

In follow-up studies, we addressed alternative explanations and support a self-signaling account. We show that caregivers feel more dedicated when they invest effort even if the recipient is not aware of the effort they invested ( $N = 509$ ). Additionally, we find that the effect of effort on emotional consequences is primarily driven by doing the task oneself and not by investing more time ( $N = 404$ ), and that it holds in both joint and single evaluation ( $N = 282$ ).

Taken together, these studies show that caregivers feel worse when using products that simplify caregiving because these gestures lose symbolic meaning. We provide evidence to support the idea that

products that make things easier for consumers backfire when caring for close others because consumers feel like they are taking the easy way out instead of being good parents, spouses, and friends.

## Lavish Gifts are Most Satisfying When Given by Your Financial Opposite

### EXTENDED ABSTRACT

When are lavish gifts appreciated by recipients? The right amount to spend on a gift is a frequent source of anxiety for givers (Wooten 2000). Unfortunately, the relationship between the amount spent on a gift and recipients' appreciation of the gift is not as straightforward as givers anticipate (Flynn and Adams 2009). Disappointment can be unexpectedly common.

The potential for disappointing gift exchanges seems especially high within married couples, as prior work suggests that financial opposites attract: "tightwads" tend to marry "spendthrifts" (Rick, Small, and Finkel 2011). Tightwads generally find the prospect of spending money painful, and therefore tend to spend less than they would ideally like to spend. Spendthrifts, by contrast, do not experience enough pain when considering spending, and therefore spend more than they would ideally like to spend (Rick, Cryder, and Loewenstein 2008). These common differences within couples raise the question of how spouses' assortment on spending affects how partners respond to the gifts they receive. Tightwads and spendthrifts likely buy different types of gifts, but would partners experience a particular gift differently based on whether it was given by a tightwad or a spendthrift?

Consider a desirable, lavish gift. One possibility is that the identity of the giver is not relevant to the gift recipient's satisfaction. If the little pain experienced by spendthrifts when contemplating purchases is a result of simply enjoying products more intensely, then spendthrift recipients may be more likely to enjoy the lavish gift than tightwad recipients. But there are reasons why the opposite might be true. After all, spendthrifts are often buying lavish goods for themselves, so a lavish gift from a spendthrift spouse may be less special relative to what is already owned. By contrast, tightwad recipients may be more likely to enjoy a lavish gift that they themselves would not buy.

However, previous research indicates that reactions to gifts can be influenced by the identity of the giver (e.g., Paolacci, Straeter, and Hooe 2015), and gift appreciation patterns may be more complex. It is possible that whether one's partner is a spendthrift or a tightwad affects how lavish gifts are perceived. Based on the giver's past buying behavior and/or typical financial tendencies, a partner may infer that a tightwad giver endured a lot of distress to make such a large purchase, and find the psychological sacrifice flattering. Alternatively, financial opposites, who are married to someone with opposing feelings toward spending, may be particularly appreciative of lavish gifts. Given the frequent arguments that occur when tightwads marry spendthrifts (Rick et al. 2011), it is possible that a lavish gift is most appreciated (and perhaps most needed) when it comes from a partner who is otherwise a frequent source of financial distress.

We examined the viability of these different accounts in two studies. In Study 1, conducted three weeks after Christmas, we asked 267 married adults who received holiday gift(s) from their spouse to recall what those gift(s) were and to guess the total amount of money their spouse spent on the gift(s). Participants then indicated how satisfied they were with those gift(s). Finally, participants completed the Tightwad-Spendthrift scale (TW-ST) once for themselves and then again as they think their spouse would respond (as in Rick et al. 2011). We regressed gift satisfaction on the total amount spent by the giver (guessed by the recipient), the recipient's TW-ST score,

the giver's TW-ST score (as perceived by the recipient), and their interactions. In addition to a significant main effect of amount spent (i.e., more expensive gifts were more satisfying), there was a significant three-way interaction. Spendthrifts were most satisfied when receiving a lavish gift from a tightwad spouse, and tightwads were most satisfied when receiving a lavish gift from a spendthrift spouse. In other words, people on the far ends of the TW-ST continuum were happiest when receiving more expensive gift(s) from a spouse on the opposite end of the continuum. (By contrast, participants were least happy when receiving an inexpensive gift from a spouse on the opposite end of the TW-ST continuum.)

Study 2 was designed to address two limitations of Study 1. Study 1 relied on participants' perceptions of their spouse's TW-ST status and their guesses about how much their spouse spent on their gift(s). Study 2 therefore included both spouses (81 couples), so that each spouse could complete the TW-ST scale for themselves. In addition, we asked all participants to imagine receiving the same lavish gift from their spouse. Specifically, we asked participants to imagine that, for their next birthday, their "romantic partner buys you a very nice bottle of wine. Your partner pays about \$100 for the bottle." We asked participants to indicate how happy they would be with their partner after receiving this gift. Using multi-level modeling to account for nesting within couples, we regressed happiness with partner on the participant's TW-ST score (actor effect), their spouse's TW-ST score (partner effect), and their interaction. The results revealed a significant interaction. Consistent with Study 1, spendthrift actors were happiest when imagining receiving a lavish gift from a tightwad spouse, and tightwads were happiest when imagining receiving a lavish gift from a spendthrift spouse.

Thus, two studies suggest that people on the far ends of the TW-ST continuum are happiest when receiving an expensive gift from a spouse on the opposite end of the continuum. This is consistent with the notion that lavish gifts are most impactful when they come from a partner who is otherwise a frequent source of distress (cf. Saad and Gill 2003). Our ongoing research is further examining how lavish gifts are experienced based on the TW-ST status of romantic partners.

### Time-Saving Purchases Promote Relationship Satisfaction

#### EXTENDED ABSTRACT

A persistent source of frustration in romantic relationships stems from household chores. In one nationally representative study of new divorcees, 25% of respondents cited "disagreements about housework" as the number one reason for their divorce; a close third after "infidelity" (40%) and "drifting apart" (35%). New technology offers a potential solution to these conflicts. Companies such as *TaskRabbit* have made it increasingly possible for consumers to out-source any household chore. Recent research suggests that time-saving purchases, such as hiring a housecleaner, can improve personal happiness and reduce stress (Whillans et al. 2017). Yet, nothing is known about whether, when, and why making time-saving purchases together with our romantic partners may promote relationship satisfaction. To explore these questions, we conducted seven studies with employed adults in committed romantic relationships ( $N=3,409$ ).

*Hypothesis 1 Do Time-Saving Purchases Promote Relationship Satisfaction and Why?*

First, we examined whether couples who spent money on time-saving purchases were more satisfied with their relationships. In Study 1a&b ( $N=1,048$ ), respondents reported higher relationship satisfaction if they spent money on time-saving purchases together with their

partner in a typical month,  $d=0.23$ ,  $Z=3.53$ ,  $p<0.01$ , 95%[0.10, 0.36]. These results held controlling for relevant demographics including relationship length, age, number of hours worked/week, number of kids at home, and income,  $B=0.26$ ,  $Z=2.89$ ,  $p=0.004$ , 95%[0.08, 0.43].

In Studies 1a&b, we also examined *why* time-saving purchases promoted relationship satisfaction. Based on prior research (Cohen and Wills 1985; Whillans et al. 2017), we proposed that the benefits of time-saving purchases would emerge because these purchases would 1) enable couples to spend more quality time together, and 2) protect couples from the negative impact of work/life stress on relationship satisfaction. Consistent with the first hypothesis, respondents who spent money on time-saving purchases in a typical month reported spending more quality time together with their partners, which in turn predicted greater relationship satisfaction, *Indirect Effect*=0.21(0.05), 95%[0.12, 0.33]. Consistent with the second hypothesis, we observed a significant interaction between time-saving purchases and work/life stress,  $B=0.19$  (0.06),  $Z=3.22$ ,  $p<0.001$ , 95%CI [0.07, 0.30]. Among respondents who did not spend any money on time-saving purchases ( $N=655$ ), greater work/life stress was associated with lower relationship satisfaction,  $B=-0.14$  (0.04),  $Z=3.16$ ,  $p<0.001$ , 95%[-0.22, -0.05]. For respondents who spent money on time-saving purchases ( $N=389$ ), this relationship was significantly attenuated,  $B=-0.01$  (0.04),  $Z=0.51$ ,  $p=0.610$ , 95%[-0.10, 0.06]. A Fisher *r*-to-*z* transformation confirmed that these beta-coefficients were significantly different from each other,  $Z=2.89$ ,  $p=0.004$ , 95%[0.08,0.43]. These studies suggest that time-saving purchases promote relationship satisfaction by protecting couples from the negative impact of work/life stress on relationship satisfaction and enabling couples to spend happier time together.

In Study 2, we replicated these results with  $N=193$  dyads; there was 84% cross-partner agreement on whether they made time-saving purchases,  $Kappa=0.54(0.07)$ ,  $p<0.001$ . Couples who spent money on time-saving purchases reported greater relationship satisfaction (couple composite time-saving variable:  $\beta=0.17$ ,  $p=0.002$ ; female report:  $\beta=0.19$ ,  $p=0.001$ ; male report:  $\beta=0.11$ ,  $p=0.073$ ). These results held controlling for the demographic covariates described above, and when controlling for the amount of social support that each partner received and provided to one another,  $\beta=0.18$ ,  $p=0.003$ ). Of note, making time-saving purchases was as positively impactful for relationship satisfaction as receiving quality social support from one's partner ( $\beta=0.12$ ,  $p=0.050$ ). Again, these benefits emerged because time-saving purchases enabled couples to spend more time together and protected against stress.

Studies 1a-2 cannot rule out the possibility that happier couples might be more likely to make time-saving purchases. Consequently, in Studies 3a&b ( $N=899$ ), we used a validated recollection paradigm to provide causal evidence that time-saving purchases facilitate feelings of relationship closeness (Chan and Mogilner 2017). In these experiments, participants were randomly assigned to reflect on the last time they had spent \$40 together on a time-saving purchase or to reflect on the last time that they had spent \$40 on a material purchase. Consistent with our correlational data, participants reported greater post-purchase closeness with their partners after reflecting on the last time that they had spent \$40 to save time ( $ps<0.001$ ).

*Hypothesis 2 When Do Time-Saving Purchases Promote Relationship Satisfaction?*

In Studies 4a&b ( $N=1,076$ ), we examined *when* time-saving purchases would be most likely to promote relationship satisfaction. We proposed that time-saving purchases are a form of problem-focused vs. emotion-focused coping—a way of dealing with stress-

ful events that focuses on altering the stressful situation rather than regulating negative emotions associated with the stressful event. Consistent with the Goodness-of-Fit Hypothesis (Folkman, Schaefer and Lazarus 1979), we predicted that time-saving purchases would promote relationship satisfaction when couples were faced with controllable stressors, such as having too many tasks at home and not enough time, whereas experiential purchases would promote relationship satisfaction when couples were faced with uncontrollable stressors, such as an unexpected family emergency.

Participants were randomly assigned to reflect on the last time that they had spent \$40 together with their partner on a time-saving vs. experiential purchase (VanBoven and Gilovich 2003). Participants were asked to report their post-purchase closeness with their partner, and to report on the stressors they had faced seven days prior to making the purchase. Consistent with our predictions, there was a significant purchase-type by stressor interaction,  $B=0.22(0.09)$ ,  $t(1,065)=4.38$ ,  $p<0.001$ . Upon decomposing this interaction, time-saving (vs. experiential purchases) were significantly more likely to promote post purchase relationship satisfaction when couples were faced with controllable vs. uncontrollable stressors ( $p<0.001$ ). In an additional study ( $N=593$ ), we compared time-saving, experiential, and material purchases. Following past research (Whillans et al., 2017; VanBoven & Gilovich, 2003); reflecting on time-saving and experiential purchases promoted greater post-purchase closeness than reflecting on material purchases—yet, once again, time-saving purchases were more effective at promoting relationship closeness when couples were faced with controllable (vs. uncontrollable) stressors.

## Conclusion

Together, these results suggest that the daily purchases couples make together have critical implications for relationship satisfaction. Drawing on research from the social support literature, these findings show that happy couples support each other not just through their actions or words, but also through the purchases that they make together. To best promote happiness, couples should consider making purchases that best fit their daily demands.

## Love, Lies, and Money: Financial Infidelity within Romantic Couples

### EXTENDED ABSTRACT

When it comes to money, romantic partners are not always honest with each other, with couple members often hiding spending, debts, and even savings from their loved one. This form of infidelity is theoretically important to understand, given that both infidelity and financial behavior playing a central role in the health of romantic relationships (Dew, Britt, and Huston 2012; Shackelford and Buss 1997).

The first step to developing an understanding of consumer financial infidelity is to establish a measure that captures consumers' tendency to engage in financial infidelity behaviors at an individual level. Therefore, in this work, we develop and validate a scale (the FI-Scale) to measure financial infidelity within romantic relationships. We demonstrate that the FI-Scale is distinct from related scales and predicts real financial infidelity above and beyond other individual-level measures, including dishonesty and consumers' propensity to engage in sexual and emotional infidelity.

### Pilot, Study 1 and Study 2: Item Generation, Purification and Test-Retest Reliability

We identified archetypical behaviors that represent the financial infidelity construct by asking open-ended questions to 150 married individuals (52.7% male,  $M_{age} = 39$  years). We identified six main

types: (1) hiding or lying about spending; (2) hiding or lying about savings; (3) creating debt without telling spouse; (4) giving money to others; (5) gambling without telling spouse; (6) hiding or lying about income.

We used these categories to generate 30 items to measure financial infidelity, and these were administered to a sample of 857 married participants via MTurk. After performing a series of item purification analyses, we found a 12-item the scale to have the strongest psychometric properties, and a Confirmatory Factor Analysis (CFA) revealed that the 12-item model ( $RMSEA = .077$ ;  $SRMR = .039$ ;  $CFI = .939$ ) had acceptable model fit. We then examined the test-retest reliability of the FI-Scale by recruiting a new set of participants ( $N=968$ ; 33.1% male,  $M_{age} = 40.6$  years,  $SD = 11.56$ ) and followed-up with them six weeks later. With a 51% response rate, the intraclass correlation coefficient (ICC) of .72 suggested an acceptable level of stability over time.

### Study 3: Relationships Between the FI Scale and Related Constructs

We examine the relationship between the FI-Scale and 29 potentially related scales. To assess the FI-Scale's nomological validity, we included scales that were conceptually similar, such as general intentions toward infidelity and secrecy (Jones et al. 2011; Slepian, Chun, and Mason 2017). Across two samples of participants ( $N=619$ ), the results reveal correlation coefficients ranging in strength between .01 (i.e., extraversion and relative power within the relationship) and .61 (i.e., financial harmony). We demonstrate that the FI-Scale is empirically distinct from Rick et al's (2011) measure of financial harmony, the most similar scale, by using a confirmatory factor analysis on all the financial infidelity and financial harmony items together. This revealed a substantially better fit for a two-factor model than for a one-factor model ( $\Delta\chi^2 = 671.59$ ,  $p < .001$ ).

Across the correlations with the 29 scales, we identify three different "clusters" of interest. First, the FI-Scale is positively associated with measures of primary psychopathy (Levenson, Kiehl, and Fitzpatrick 1995), machiavellianism (Christie and Geis 2013), and psychological entitlement (Campbell et al. 2004), which all capture a willingness to deceive others for personal gain. Second, responses to the FI-Scale were positively associated with self-concealment (Larson and Chastain 1990), or the active concealment of personal information that one finds distressing. Third, the results reveal a negative association between the FI-Scale and general self-control (Tangney, Baumeister, and Boone 2004). These findings are consistent with previous research; for example, those low in self-control engage in more inappropriate or undesirable sexual behavior (Gailliot and Baumeister 2007).

### Study 4: Predictive Validity in the Field

To examine whether the scale is predictive of actual behavior, in study 4 we use real, consequential decisions, to demonstrate that participants' FI-Scale scores predicted their decision to hide information about gambling-and-losing money from their spouse. We designed a field study that presented married couples with an opportunity to gamble shared resources and ultimately withhold that information from each other. We recruited a total of 65 married couples ( $N=130$ , 50% male,  $M_{age} = 51.9$  years,  $SD = 38.34$ ), with each spouse completing a few personality measures (including the FI-Scale) privately before being "randomly selected" for a seemingly unrelated task. Importantly, each spouse had the opportunity to receive the bonus directly or try quadrupling the amount with a new random number generator, which was rigged to lose. Among spouses who chose to gamble shared resources, we predicted and found evidence that

participants with higher FI-Scale scores should be associated with a greater likelihood of withholding financial information from their partner. The higher their FI-Scale score, the greater the likelihood of hiding the gambling-and-losing outcome from their spouse ( $b = 4.59$ ,  $t(60) = 2.03$ ,  $p = .0046$ ).

### Study 5: Criterion Validity of Financial Versus Romantic Infidelity

Study 5 demonstrated that the FI-Scale can predict actual behaviors constituting financial infidelity above and beyond other individual difference measures of (i) romantic infidelity in relationships or (ii) general unethical tendencies. We recruited 232 married participants on MTurk (54.7% female,  $M_{age} = 35.85$ ), who were asked questions on whether they had engaged in a series of romantic and financial infidelity behaviors **without telling their spouse**. As expected, the FI-Scale was a significant predictor of financial infidelity behaviors ( $\beta = 0.62$ ,  $t(217) = 10.68$ ,  $p < .001$ ), while neither participant's intentions to engage in romantic infidelity nor a measure of their general dishonesty were significant predictors ( $p > .05$ ) when entered simultaneously into a regression model.

### Discussion

Our research provides several contributions, including: 1) introducing and defining the construct of financial infidelity in the consumer behavior literature; 2) identifying a specific set of behaviors that constitute financial infidelity and 3) developing a reliable instrument to measure consumers' propensity to engage in financial infidelity. It is our hope that these insights can be used to identify the reasons for engaging in such behaviors, with the goal of reducing their occurrence in marriage and increasing financial harmony and happiness among couples.

### **SESSION OVERVIEW**

Technological advancements, such as the emergence of social media networks, and new ways of life and consumption have fundamentally altered the way consumers relate to brands. Consumer-brand relationships have been found to be increasingly ephemeral (Bardhi and Eckhardt, 2017), and to be less tight than prior research suggested (Arvidsson and Caliandro, 2016). Consumers use brands as attention attractors in a growing culture of consumer ‘micro-celebrities’, or as elements of assemblages of branded consumer selves (e.g. Marwick 2015; Rokka and Canniford 2016) in other words, brands seem to partly lose their cultural authority (e.g. Holt, 2002). In a networked world, brands develop new social functions, such as mediating online publics (Arvidsson and Caliandro, 2016), enabling meaningful or discursive connections with and among consumers (e.g. Schöps, Wegerer and Hemetsberger, 2017). These developments render traditional perspectives of consumer-brand relationships problematic, and raise the question: What is the social function of brands in our contemporary, networked consumer society?

This special session combines four research projects that theorize on brands as mediators among different entities, that is, people, meaning, and tangible forms of the reified brand. The contributions are interested in two aspects: (1) gaining further understanding of/ to theorize on mediation as a social process that characterizes contemporary brand relations, (2) as well as describe various forms and specificities of brand mediation (processes) among a variety of stakeholders. The four contributions are united by an understanding of brand as mediators of social, organizational and managerial processes, which sets the focus of inquiry on interactions as the ultimate sources of value creation. This implies a view of branding as facilitating, structuring or constraining the interaction between two or more parties. The term mediation has been used in a variety of studies on brands and branding processes (e.g. Mumby, 2016; Kornberger, 2010; Arvidsson and Caliandro, 2016; Luedicke, Thompson & Giesler, 2010), and is generally used as a term whose meaning is self-evident, i.e. a term that explains, rather than a concept that is to be explained. This special session takes an in-depth look on mediation and provides empirical and conceptual contributions that develop mediation into an analytical concept that can be used to understand a broad variety of branding processes.

The session consists of four presentations. The first presentation takes an in-depth look at the term mediation itself and develops three

analytical directions for studying brand-mediation processes. The second paper is also of conceptual nature and develops the notion of brands as complex social representations and mediations. The third study is empirical in nature and explores how new technological devices alter the way consumers relate to brands. The fourth study contributes to the overall theme by conceptualizing mediation as a multi-dimensional process of brand-related interaction and analysing it via socio-material artefacts.

### **Brands as mediators: A research agenda**

#### **EXTENDED ABSTRACT**

This research project intends to contribute to our understanding of how brands and branding processes unfold in organizational, managerial and social contexts. Traditionally, branding is seen as a one-directional communication process, e.g. a sign attached to an entity that signifies some sort of meaning. This paper suggests that brands and branding processes mediate the interactions between different entities. Understanding branding as a mediation process extends the traditional, semiotic perspective by highlighting that branding can be understood as a multi-directional interaction process that unfolds between multiple entities. The analytical benefit of understanding branding processes in terms of mediation is, that it sheds light onto the interactions that are facilitated through branding. This implies a view of branding as being an important facilitator, that structures or constrains the interaction between two or more parties.

Brands are in between. Brands connect organizations with consumers, products with meanings, employees with their employer (Land and Taylor, 2016; Wegerer and Munro, 2018, Wegerer, 2018), and consumers with each other (Muniz and O’Guinn, 2001, Arvidsson and Caliandro, 2016). The increasing social significance of brands has generated a growing body of contributions in a diversity of fields including Marketing, Strategy, Consumer Research, Semiotics and Organization Theory. Each discipline studies particular branding processes, applies different analytical tools and uses different theoretical approaches. This conceptual paper takes the plurality of brand research as a starting point and suggests that at the very heart of branding is a process that mediates the interactions between different entities. It suggests an understanding of the term mediation that focuses on the role of the brand as the third party in enabling or structuring the interaction of two other parties. First and foremost, brands are a sign attached to an entity, created for the purpose of generating value and distinction for products, companies or any other entity they are attached to. Branding can also be understood as a set of activities, mainly executed by managers, but can also comprise activities from other stakeholders such as employees and consumers (Hemetsberger and Mühlbacher, 2014). The result of branding practices are brands, which can be understood as “a constellation of signs through which processes of social interaction and communication are mediated and captured and hence transformed into economic value” (Mumby 2016, 6).

The term mediation has been used in a variety of studies on brands and branding processes (e.g. Mumby, 2016; Kornberger, 2010; Arvidsson and Caliandro, 2016; Luedicke, Thompson & Giesler, 2010), and is generally used as a term whose meaning is self-evident, i.e. a term that explains, rather than a concept that needs to be explained. This paper takes an in-depth look at the term mediation itself, and develops it into a concept that can be used to understand

a broad variety of branding processes. What exactly is mediation? Mediation can be understood as a social process in which a third party (the brand) structures the interaction between two other parties. That there is some manner of interaction is inherent to the notion of mediation. The interaction can take on different qualities, such as being positive (Kozinets, 2001), neutral, or can have a tension (Thompson and Arsel, 2004, Wegerer and Munro, 2018), or conflict situation (Luedicke, Thompson and Giesler, 2010). This study finds that in the case of branding, there is mainly an interaction between two parties, or a conflict that is more or less latent in nature.

The mediation perspective suggests to explore how brands mediate (mediation processes), what brands mediate (the nature of interaction), and between whom they mediate (parties, stakeholders, entities). The how perspective implies to identify, explore and explain specific brand-mediation process at work. Mediation processes are highly dependent on the parties between which brands are mediating. The parties between whom brands mediate can have different ontological qualities. Brands can mediate between very real existing stakeholders, such as consumers (Schöps, Wegerer and Hemetsberger, 2017), employees (Hatch and Schultz 2003, Wegerer and Munro, 2018; Wegerer 2018), NGOs and organizations, but brands can also mediate between more abstract concepts such as values, ethics, ideas or social conflicts and categories (Wegerer and Munro, 2018). Brand mediation can happen between an organization and any internal or external stakeholder, such as management, management and consumers, management and employees (Botschen and Wegerer, 2017) or between two external stakeholders such as when a brand provides a mediation platform for the social interaction between consumers (Schöps, Wegerer and Hemetsberger, 2017). A third possibility would be when a brand mediates between a stakeholder, such as a consumer, and a more abstract sphere, such as a contradiction in the consumers' life or a certain discourse in society (Wegerer and Munro, 2018). This leaves us with the last dimension of what is mediated, i.e. the nature of interaction that is mediated. The interaction is of course linked to the ontological quality of the parties between whom the brand mediates. The what refers to any issue that is capable of creating an interaction between two parties. Looking at the management as a possible party, we will see that the interactions are related to managerial tasks, such as the management of organizational identity, the communication with organizational members, or how to govern organizational change projects (Botschen and Wegerer, 2017). Employees' questions tend to resonate around issues such as meaning, coping with contradictions, and motivation. Finally, looking at the stakeholder groups of consumers and society, conflicts that emerge include: responsible consumption, ethical buying decisions.

### Brands as social mediations

#### EXTENDED ABSTRACT

Branding has grown out of the business domain and firm authority (El-Amir and Burt 2010) and become a ubiquitous practice in contemporary networked society. Consumers not only engage in symbolic work and co-create brand meaning and value (Hatch and Schultz 2010); digital networks enable consumers to co-design; co-develop; individualize; personalize, link to, and hashtag brands for their own purposes of self-branding, publicity and identity construction (Arvidsson and Caliandro 2016; Marwick 2015; Rokka and Canniford 2016). In a networked world brands have become mediators of relationships among people, providing meaningful genres of content manifested in objects, experiences, people, places, and networks. Building on the premise that brands *mediate* interactions among different entities, this paper reviews extant literature in di-

verse fields and provides a detailed and comprehensive process perspective on brands. We introduce social mediation theory as theoretical lens to capture and extend existing theorizations of branding, and inform future branding research.

Scholars in branding and consumer research make several implicit suggestions how 'branding' occurs in several contexts and complex social brand arrangements. As brands find more public and varied expressions, consumer research and branding literature suggest more encompassing and agency-based theories to account for these complexities and new functionalities of brands in a technology-determined society. Recent conceptualizations include multiple, networked, human and non-human actors in branding (Jones 2005; Diamond, Sherry, Muñiz, McGrath, Kozinets and Borghini 2009; Merz, He and Vargo 2009; Onyas and Ryan 2015), emphasizing the sociomateriality character of brand constellations (Lucarelli and Hallin 2015; von Wallpach, Hemetsberger and Espersen 2017). Assemblage theoretic perspectives consider brands as loose assemblages of heterogeneous elements, including people, things, material and expressive elements, all of which contribute to an understanding of the mechanisms and logics of brands in a networked world (DeLanda 2006; Lury 2009; Onyas and Ryan 2015; Parmentier and Fischer 2015). Drawing on these perspectives, we understand brand mediation as processes that occur among brand elements in the broadest sense, which are people (multiple actors), objects (manifestations of sociomateriality), and its expressions (captured in brand meaning). We apply social mediation theory to understand the dynamics among these elements.

As suggested by Jovchelovitch (1995a, 1995b), social mediation constitutes the bridge between individual and social activity. Defined as process of communication or vivid experience mediating between the individual and the public sphere, social mediation comprises all discursive interactions among social actors, such as public dialogue, rituals, art, and patterns of work and production. Acknowledging that manifestations, meanings and brand interested actors are interrelated on an individual and social level, this study is interested in concrete processes that mediate the individual and social sphere, and contribute to an understanding of how social interaction forms individual thought and action and vice versa; how, for instance, brand fans create desire in individual consumers; how consumption in the private domain creates and alters brand objects and ideas; how consumers' ideas become public or how public brand articulations become anchored in individuals' everyday thinking. Drawing on Jovchelovitch's mediation perspective and including contemporary views of branding, we assume that the individual and the social sphere interrelate in a non-hierarchical manner, that individuals, objects, the social—all together build socio-material spheres of branding.

Our literature review results in a comprehensive set of mediations, categorized and integrated in a social mediations framework of brand. We find practices of individual and collective *engagement* through documentation and negotiation of meaning, as well as in processes of familiarization and figuration as a means to translate brands into a reified nucleus or image. *Impression management* contributes to the continuous creation of brand meaning amongst a network of a brand interested collective through forms of advocacy, persuasion but also through antagonistic practices. Brand manifestations result from various *collaborative* and *collective co-production* practices, and *brand use* in private and public domains. Mediating practices, for example, include several forms of ritualization, personalization, brand emplacement in several media and (sub-)cultures as forms of brand use, as well as concrete productive work, and all genres of brand communication. Social actors interested in a brand

apply *self-affiliation*, *co-member identification* and *social networking* practices, including identification, socializing, mobilization, recruitment, education, socializing and brand governance to negotiate legitimate participation in brand interactions. Overall, we find that brands processes comprise various forms of socially mediated *narrations* of brand meaning that *translate* into and gain momentum in their manifested form as organizations, objects, ideas, or people, and that *connect* brands and their public. We illustrate these mediation processes with real branding cases.

The paper makes several contributions to branding theory and consumer research. First, it includes consumers and other publics, brand meaning and manifestations in a comprehensive view of brand (assemblages). Second, it draws attention to the innate nature of new media where both, the individual and the networked public, are visible and in permanent exchange in that it integrates individual and social levels, and describes how these levels are socially mediated. Third, the paper is first to provide a catalogue of social mediations, which form and transform brands, and conceptualize brands as processes that connect objects, ideas, meaning, consumers and the interested public. In doing that, we propose a new perspective on branding as mediation among people, objects and meaning that prioritizes the facilitating role of brand management much more than the managerial one. Our view also acknowledges the increase in access-based, ephemeral, dematerialized, and more fluid nature of consumption (Bardhi and Eckhardt 2017) and puts emphasis on social mediations that *connect* brand and users network as, for example in the case of Uber; that *translate* consumer needs into concrete action and orders, as for example via Amazon Echo and Google Home, and that produce brand *narratives* that become meaningful to an interested public. In other words, brands as mediators are meaningful narrations translated into branded offers that are characterized by the capability to connect heterogeneous brand elements.

### The re-mediation of consumer/ brand relationships through voice shopping: The case of amazon echo

#### EXTENDED ABSTRACT

Brands help consumers to make sense out of products in purchasing decisions (e.g., Keller 1993; McCracken 1986). Brands mediate between products and consumers especially in industries where products are perceived as alike and/or almost interchangeably. Take for instance Fast-Moving-Consumer-Goods (FMCG), where toothpaste or shampoo are barely differentiable except for their brand. Visual clues such as packaging and brand logos help consumers to navigate through the jungle of choice (Ampuero & Vila 2006; Underwood 2003).

The rise of voice shopping (for instance Amazon Echo or Google Home) harbors two major changes: First, consumers cannot rely on visual clues for their sensemaking in purchasing decisions. Second, agency is shifted from consumers to voice assistants, i.e. voice assistants take a more proactive role (Rijsdijk and Hultink 2003; Rijsdijk and Hultink 2009) in considering and selecting products. For instance: When asking Amazon Echo to buy some batteries, Alexa will suggest some batteries of her choice and ask the consumer whether s/he wants to purchase them. This fundamentally questions the role of FMCG brands in voice shopping. This paper is interested in exploring the role of FMCG brands in voice shopping. By taking a consumer-centric perspective it asks the following research question: *How do consumers employ brands in voice shopping for FMCG products?*

As the technology is only emerging, this paper relies on an explorative approach that allows for adductive theory building (based

on interviews and netnographic data). FMCG products were chosen as they rely on strong visual clues in the shopping process. Data analysis followed an iterative coding process (Spiggle 1994). Preliminary insights show that consumers use three tactics in voice shopping: (1) habitualization, (2) commodification and (3) delegation. Those tactics help consumer to make shopping decisions based on vocal clues.

Consumers engage in habitualization when naming the name of the brand that comes first to their mind when thinking about a specific product category. For instance: They ask Alexa to order Pampers or Duracell instead of batteries or diapers. Informants mentioned that this simplifies sensemaking in the “competitive product jungle” (Quote from Lucia) that is perceived as far more complex as visual clues are absent. As voiced by Andreas:

*“It is really difficult to imagine how a product looks like and what the actual product. So I just go for the brands where I know how they look like. I can visualize the packaging in my mind. And then I order this brand.”*

Habitualization favors strong and well-established brands in voice shopping and limits browsing. Commodification focuses consumer attention on price considerations. Data collection shows that consumers often go for the cheapest and not for branded products. As expressed by Sabrina:

*“I always used to buy Pantene shampoo. But with Alexa I order a different shampoo. I also do not really know why. I think I just listen to the prices that Alexa tells me. And then I go for the cheapest one. Is there any difference between shampoos?”*

This quote illustrates how voice shopping diffuses consumer prior brand preferences and puts more emphasizes on price considerations.

Delegation refers to attributing more agency to the voice assistant in the purchase decision. Says Michael:

*“Alexa learns from algorithms. So she kind of brings an objective assessment to the purchase decision. So why shouldn't be the bestseller on Amazon also not be best for me? I basically almost every time take the first product that is suggested by Alexa.”*

Michael delegates the sensemaking in purchase decisions to Alexa based on his rationalization that such assistants yield superior decision making processes and outcomes.

Those three tactics allow consumers to engage in sensemaking in purchasing decisions without visual clues. The tactics work as a form of simplification heuristics that harness complexity in sensemaking by drawing on prior brand knowledge, focusing on price considerations and delegating control and agency to voice assistants. This consumer perspective yields interesting insights for brand management in the vocal age: Based on the preliminary results it is expected that consumers will browse less when voice shopping for FMCG goods. Further, strong brands at the top of the mind will reap the majority of the market and Amazon – through its humanized retail brand of Alexa – will have the power to mediate between FMCG brands and consumers.

## Mediation as a multi-dimensional process of brand-related interaction

### EXTENDED ABSTRACT

The paper departs from a view of brand as processual spatio-temporal constructions (Lucarelli and Hallin, 2015; Mühlbacher and Hemetsberger, 2008; Vallaster and von Wallpach, 2013; von Wallpach, Hemetsberger and Espersen, 2017). These constructions are continuously manifested, interpreted and re-interpreted via brand-related socio-material artefacts (e.g., brand-related images and text), in dynamic interactive assemblages (von Wallpach et al., 2017; Lury, 2004). Socio-material artefacts materialize, and perform, what is called the brand form. A form is the material of social interaction (e.g., websites, images, texts). Forms also have content (i.e., they manifest cognitive-symbolic representations; see Reckwitz, 2002). It follows that the form consists of materialized social interaction, which at a metaphysical level represents a processual social abstraction of shared meaning, involving shared world-views, realities and culture (Simmel, 2009). In its materialized manifestations, the brand form mediates brand-related social interaction by providing temporarily shared objectified and collective ways of seeing the world that continuously structure and re-structure the socio-material performing of brands (e.g., Laltheide and Snow, 1988).

The present paper thus proposes that mediation occurs dynamically as a multi-dimensional process of interaction. Brand form is identified as the locus of mediation. Socio-material artefacts perform shared cognitive-symbolic realities of brand form. The brand form, in turn, “directs and informs social activity” (Laltheide and Snow, 1988, p.194) in interrelated and dynamic brand assemblages, hence mediating brand-related social interaction. Manifesting as brand-related socio-material artefacts, brand-related interaction feeds back to the shared cognitive-symbolic realities of this brand form, shaping the shared meaning that underlies and further mediates the continuous social interactive processes constituting the brand.

To illustrate this theoretical conceptualization the authors discuss a case based on the branding of the city of Stockholm. Building on the work of Rose and Tolia-Kelly (2012) on visibility/materiality, the authors analyze socio-material artefacts as performances of cognitive-symbolic constitutions of multiple stakeholders’ shared realities. These cognitive-symbolic constitutions are materialized (i.e., objectified) in brand forms (i.e., brand-related socio-material artefacts), which are in turn interpreted and re-interpreted by others who interact in these brand forms (Rose and Tolia-Kelly, 2012). These multiple performances both constitute and represent the brand form, consciously or unconsciously.

The analysis proposed by Rose and Tolia-Kelly (2012) is appropriate for understanding how the brand form functions as locus of mediation in a multi-dimensional process of interaction, since it considers materialized social interaction (i.e., forms) and the shared cognitive-symbolic realities that comprise these materializations (i.e., socially shared and implicit ways of understanding; Reckwitz, 2002). First and foremost, by its cognitive-symbolic incorporation of brand-related socio-material artefacts, the authors engaged in a reflexive analysis of the co-constitution of continual dialogue; that is, based on multiplicity (e.g., parallel observations and performances among selected stakeholder groups), rather than singularity (sequential observations). Multiple parallel performances reveal an aggregation of shared brand-related cognitive-symbolic realities that may or may not be part of major clusters of aggregative experiences (e.g., the representational) (cf. Rose and Tolia-Kelly, 2012).

The analysis focuses on 183 brand-related socio-material artefacts of the city of Stockholm, comprising of images and text avail-

able across 108 web-pages accessed via the search engine Google (cf. Rose and Tolia-Kelly, 2012). Based on the empirical material, the authors propose that brand-related socio-material artefacts are a cognitive-symbolic articulation of performances of this brand form. The collective aggregation of these cognitive-symbolic performances materializing in socio-material artefacts dynamically expresses and constructs the brand form at a metaphysical level. The brand form, materialized in website design, images and text is loaded with shared cognitive-symbolic realities that are typically shared among the same stakeholder groups (e.g., municipalities, tourist agencies, consumers). These cognitive symbolic realities in turn mediate brand-related interaction, and constitute the continual becoming of brands.

Examples of mediation through the Stockholm brand form are related to language (Swedish vs. English), ideology (capitalism vs. Marxism), and geography (Copenhagen vs. Stockholm). Socio-material artefacts are loaded with brand-related elements in images and text expressing cognitive-symbolic realities, such as ironic, political, ideological and personal. In all of these brand forms or materializations (e.g., Stockholm as the capital of Scandinavia) the brand form acts as the locus of mediation in a multi-dimensional process of interaction. Importantly, the Stockholm brand form is not only mediating brand-related interaction in a positive way (e.g., Stockholm as the capital of Scandinavia), but also fosters rather negative performances, contributing to a view of the Stockholm brand as not being the true capital of Scandinavia. These negative socio-material performances often entail an element of influence and aim to pursue the intent of de-stabilizing an overall representational view of the brand. These views are also manifested in socio-material performances expressing cognitive-symbolic idiosyncrasies related to stakeholders’ perceptions of themselves (in relation to the brand) as being ‘open-minded’ and ‘progressive’, as opposed to what they expect Stockholm to be like. Even in these socio-material performances, the brand form of Stockholm as being the capital of Scandinavia still mediates idiosyncrasies of those who oppose to this representational view. That is, stakeholders make efforts to distance themselves from the representational brand form by resisting to what this representational form represents.

In conclusion, this paper proposes and empirically illustrates a conceptualization of mediation as multi-dimensional process of brand-related interaction. The findings suggest that the brand form, continuously preformed (e.g., materialized) via brand-related socio-material artefacts, mediates brand-related social interaction; which in turn feeds back into the the shared cognitive-symbolic realities of this brand form. This multi-dimensional process thus constitutes the continuous becoming of brands.

## SESSION OVERVIEW

Given consumers' limited attentional resources, the spotlight of attention must be directed toward a subset of information (Cherry 1953). While prior work has examined how attention toward certain pieces of information may amplify its weight or importance (Towal, Mormann, and Koch 2013), or may affect consumer choice (Atalay et al. 2012), it has been relatively mute in regard to whether this may be a good or bad thing. However, it is possible that the specific subsets of information on which people focus are not always optimal. The goal of this session is to explore whether the information to which people attend optimizes their satisfaction with the decisions they make, the social norms they deduce, and the products they choose.

More precisely, when does concentrating attention on specific information work to consumers' benefit or detriment in purchasing decisions and social scenarios? Why do consumers focus on certain information in purchase and social contexts, and when and why is focusing on that information an aid or a hindrance? These questions serve as the cornerstone to this session. The first two papers in this session concentrate on cases in which consumers focus on specific information that is either uninformative or even detrimental to their happiness and satisfaction. Papers two and three explore how relative attention plays a role in happiness or decision satisfaction, in the cases of both product choice and experiences. Papers three and four transition into considering social contexts, as paper three examines social versus non-social counterfactuals, while paper four extends the consequences of attention to perception of social norms and subsequent behavior.

Specifically, **Weingarten, Barasch, and Davidai** present work suggesting that despite their equivalent diagnosticity, people overly focus on higher ranked competitors instead of lower ranked competitors. This asymmetry influences their choices about how to allocate resources and their overall happiness. Next, **DePaoli** showcases studies in which deliberative consideration of options leads people to attend to and overweight good reasons to make a purchase even if they don't like the choice. This decision process boosts commit-

ment to that choice while also reducing satisfaction with it. Third, **Morewedge, Zhu, and Buechel** present findings in which hedonic contrasts for an experience compared to its alternative may be larger in the case of social counterfactuals (i.e., another person experienced the alternative) versus not (i.e., a foregone alternative). The salience of focal experience moderates this effect, suggesting that greater attention to social comparisons drives the differences in hedonic contrasts. Fourth, **Lieberman, Duke, and Amir** highlight findings that drawing attention to an incentive for a behavior framed as a cost (versus a discount) leads people to perceive that behavior as more normative and to engage in healthier and more environmentally-conscious behaviors (e.g., using hand sanitizer, bringing a reusable shopping bag).

Overall, these papers demonstrate various ways in which biased attention processes can affect consumer happiness and choice in product choice, social, and environmental contexts. This session should therefore be of interest to those studying attention, judgment and decision-making, hedonics, social comparisons and counterfactuals, and retailing.

## Looking to the Front of the Pack: Perceptions of Ranked Lists

### EXTENDED ABSTRACT

Imagine participating in a spin class in which your class ranking is displayed on a large television in the front of the room. You spend thirty minutes in third place, eagerly trying to pass the person in second. But, just as the class approaches its ending, out of nowhere the person in fourth overtakes you, leaving you bewildered, and wondering how you didn't see it coming.

Many areas of life involve rankings or ordered lists—colleges and graduate schools, professional sports and fantasy sport leagues, wealthiest and most successful individuals, and so on. Knowing one's place in a ranking is important both for evaluating one's performance and informing future decisions, and individuals may look to higher and lower ranked others to get an accurate sense of how well they are doing. Of course, both pieces of information are important, with higher ranked competitors providing information about how to improve one's standing and lower ranked competitors providing information about how to avoid falling behind (Locke and Latham 1990).

But are lower ranked competitors given the same consideration as higher ranked competitors? People typically desire to advance towards something desirable such as the top of a ranking (Higgins 1987), believe that rising up in rankings is more likely than descending (Davidai and Gilovich 2015), and perceive changes in their abilities in terms of improvements rather than declines (Molouki and Bartels 2017; O'Brien and Kardas 2016). Similarly, we argue that people may focus disproportionately more on higher ranked competitors than lower ranked competitors, even when that is not necessarily more diagnostic. And, given that unfavorable comparisons can be detrimental to one's well-being (Lockwood and Kunda 1997; Rogers and Feller 2016), we argue that this asymmetry in attention can lead people to feel worse off about themselves. In nine studies (N = 1498), we demonstrate that this asymmetry in attention drives people's choices in what information to acquire, how happy they feel about their relative performance, and how they choose to invest their efforts to improve.

First, we demonstrate that participants are more interested in learning about the performance of higher ranked others than lower ranked others. In Studies 1a-1c ( $N_{1a} = 131$ ;  $N_{1b} = 142$ ;  $N_{1c} = 100$ ), participants completed four *Where's Waldo* search tasks as quickly as they could. Following, participants learned their own score and were informed that they had placed fifth out of nine participants but were not provided information about other participants' scores. They were then given the opportunity to learn how other competitors scored in the task and were asked to indicate their preference for which players' scores to reveal—the score of higher ranked participants or the score of lower ranked ones (e.g., do you prefer to learn the score of the 4<sup>th</sup> ranked participant or the 6<sup>th</sup> ranked participant?). In the first study, a vast majority of participants preferred to see information about the scores of higher ranked participants (i.e., 1<sup>st</sup>-4<sup>th</sup>) compared to lower ranked participants (i.e., 6<sup>th</sup>-9<sup>th</sup>; 87%;  $\chi^2(1, N = 131) = 71.82, p < .001$ ). We replicate this result in a second study (93%;  $\chi^2(1, N = 142) = 104.82, p < .001$ ) and conceptually replicate it with a different measure in which participants indicated their most to least preferred scores to reveal (85%,  $\chi^2(1, N = 100) = 49, p < .001$ ).

Studies 2a-2c show the negative effect of this upward focus on well-being. We show that participants' happiness was more affected by the performance of higher ranked others than lower ranked others. In three studies using both hypothetical (within-subjects; spin class scores or fantasy football league scores) and real (between-subjects; completing Jumbles) tasks ( $N_{2a} = 92$ ;  $N_{2b} = 84$ ;  $N_{2c} = 139$ ), participants were given feedback about their performance placing them in fifth place out of nine participants. We then manipulated how the scores of higher- and lower-ranked competitors were distributed and examined participants' happiness with their own performance. In all three studies, we find that the performance of higher-ranked others had a greater impact on participants' happiness compared to the performance of lower-ranked others ( $F(2, 91) = 4.91, p = .0095$ ;  $F(2, 83) = 7.95, p = .0007$ ;  $F(2, 136) = 3.18, p = .045$ ). That is, relative to a baseline set of scores and ranks, shifting the scores of higher ranked competitors upwards by 500 points had a greater (negative) impact on participants' happiness relative to a condition where the scores of lower ranked competitors were shifted downwards by the same amount.

Finally, Studies 3a-3c demonstrate an important implication of this upward focus. We find that people put more effort into surpassing higher ranked others (rather than ensuring they are not surpassed by lower ranked others), and therefore invest in categories that can achieve this goal. In three studies with binary choice tasks ( $N_{3a} = 99$ ;  $N_{3b} = 262$ ;  $N_{3c} = 449$ ) using multiple contexts (e.g., a Theme Park Simulator, Sim City), participants put more resources into improving themselves on categories (e.g., roller coasters or water parks) in which they were outperformed by higher-ranked others compared to categories in which they were outperformed by lower-ranked others (61.6%,  $\chi^2(1, N = 99) = 5.34, p = .021$ ; 64.9%,  $\chi^2(1, N = 262) = 23.22, p < .001$ ; 65.3%,  $\chi^2(1, N = 449) = 41.80, p < .001$ ). We show that these effort investment decisions may not be optimal for actual advancement in the ranking, and therefore reflect a sub-optimal distribution of resources.

Ultimately, nine studies provide evidence that people disproportionately attend to those above them in ranked lists compared to those below them, and that this difference affects both well-being and actual decisions about where to invest one's resources. These results suggest that there may be limitations to the practice of motivating competitors by focusing them on "stars" in the ranking: such upward comparisons may not always make people happier and may lead to non-optimal investments. The results also suggest a reason why individuals do not recognize the plight of worse-performing others: by focusing on climbing the social ladder, people may ignore the struggles of those lower-stats others.

## The Pros and Cons of Pros and Cons: Consumer Deliberation has Opposite Implications for Post-Choice Satisfaction and Consistency

### EXTENDED ABSTRACT

Deliberative pre-decisional reasoning about a choice set (i.e., thinking about or articulating arguments for or against each option) leads consumers to attend to reasons which help them to make more justifiable decisions, thus leading to choices they may not have otherwise selected (e.g., Shafir, Simonson, and Tversky 1993; Wilson et al. 1993). The current research proposes that these resulting choices are subject to paradoxical post-decisional outcomes. In keeping with literature that finds reasoning leads to lower satisfaction (Wilson et al. 1993), consumers will evaluate and rate their choices as less satisfying. Conversely, consistent with literature suggesting that effortful decisions increase product liking (e.g., Brehm 1956), consumers will tend to make subsequent choices consistent with their initial choice. In other words, reasoning will lead consumers to be simultaneously less satisfied with but more committed to their choices.

To test this, study 1 participants ( $N=424$ ) choose between two novelty coffee mugs either by first writing their reasons for or against choosing each one (Reasoning condition) or by making their decision normally (Control condition). After their choice, participants were assigned to either a Satisfaction or a Consistency condition. Satisfaction participants rated their post-decisional satisfaction on a series of five 0-100 point scales (Cronbach's alpha = .86). Meanwhile, Consistency participants made a second choice between their chosen mug and a third mug (presentation order of the three total mugs was randomized). As predicted, satisfaction ratings were lower in the Reasoning ( $M=81.86, SE=1.53$ ) than Control condition ( $M=86.37, SE=1.22$ ;  $b=4.51, t(214)=2.32, p<.022$ ) but choice commitment increased in Reasoning ( $M=77.78\%, SE=4.41\%$ ) versus Control ( $M=64.41\%, SE=4.43\%$ ;  $b=0.66, z(207)=2.07, p<.039$ ). Thus, there is an apparent preference reversal between satisfaction ratings and choice consistency.

Study 2a examined whether reasoning may decrease satisfaction while increasing choice consistency within the same consumer. Participants ( $N=215$ ) either reasoned or not in an incentive compatible choice between gift cards. They then completed both post-decision tasks: they rated satisfaction (as in study 1) and had the option to switch to a different gift card (from the original set of four). Reasoning led to lower satisfaction ratings ( $M=77.36, SE=1.74$ ) than control ( $M=83.75, SE=1.71$ ;  $b=-6.39, t(212)=-2.61, p<.010$ ), but increased commitment ( $M=97.22\%, SE=1.59\%$  for reasoning vs.  $M=88.79\%, SE=3.06\%$  for control;  $b=1.52, z(214)=2.29, p<.023$ ). Thus, the same participants were both less satisfied with and more committed to their choice after reasoning. This finding was replicated in study 2b using the mug stimuli from study 1 ( $N=341$ ).

I propose that this phenomenon is driven by the reasons and information to which consumers attend during the reasoning process. While these reasons determine what consumers choose, they are not informative when the chosen product is subsequently evaluated by itself (only the chosen product itself is). However, such reasons are both highly relevant and highly accessible in any subsequent choice involving the product. In this sense, the relationship of reasons to post-decisional judgments may be viewed in terms of evaluability or task compatibility (Hsee 1996; Nowlis and Simonson 1997): reasons generated in the context of choice are not diagnostic in the context of rating satisfaction, but are diagnostic in subsequent choice contexts. This was tested by manipulating reason types.

Research suggests that negative effects of reasoning on satisfaction may be attenuated by attending to "compatible" information

and arguments during reasoning, which leads to the same options being chosen as without reasoning (DePaoli, Khan, and Simonson 2017). For the hedonic novelty mugs and gift cards used here, this means attending to affective or feelings-based arguments rather than to the logic and justifiability-driven arguments elicited by a standard reasoning manipulation (Wilson et al. 1989). Compatible reasoning should lead to no differences in choice behaviors (vs. control), thus attenuating the effect of reasoning on satisfaction. However, compatible reasons remain diagnostic for choice, so the manipulation should still increase choice consistency. Study 3 participants ( $N=508$ ) were assigned to one of three conditions: Control (no reasoning), Reasoning (as in the above studies), and Compatible Reasoning (wherein they attended to their feelings for or against each option). Participants chose between two novelty mugs, then rated their satisfaction before making a choice between their chosen mug, a relatively more hedonic mug, and a relatively more utilitarian/justifiable mug. Replicating studies 1-2, Reasoning led participants to make different choices than Control ( $b=0.22$ ,  $z(450)=1.88$ ,  $p<.060$ ), leading to less satisfaction ( $b=-8.44$ ,  $t(506)=-7.95$ ,  $p<.001$ ) but more commitment ( $b=0.23$ ,  $z(506)=2.06$ ,  $p<.040$ ). Conversely, Compatible Reasoning and Control made the same choices ( $b=0.10$ ,  $z(450)=0.90$ ,  $p=.368$ ) leading to no drop in satisfaction ( $b=-0.04$ ,  $t(506)=-0.04$ ,  $p=.972$ ), but Compatible Reasoning still led to greater commitment ( $b=0.25$ ,  $z(506)=2.23$ ,  $p<.026$ ). This is consistent with the proposal that ratings depend on the chosen option while consistency depends on pre-existing reasons. Further evidence is suggested by participants who switched: if initial reasons inform subsequent choice, then participants should switch to alternatives favored by their initial reasons type. I.e., because they have constructed arguments favoring justifiability (Reasoning condition) or hedonicity (Compatible condition), they should tend to switch to products which meet these criteria. As predicted, Reasoning switchers tended to choose the utilitarian/justifiable alternative while Compatible Reasoning switchers preferred the hedonic alternative ( $b=0.24$ ,  $t(111)=2.19$ ,  $p<.026$ ).

A number of alternative explanations may exist for the finding, many of which propose some form of System 1 interference on either the ratings or choice consistency tasks (e.g., Kahneman and Frederick 2002). Study 4 aimed to rule these out broadly by having participants ( $N=361$ ) replicate study 2b with the addition of instructions to deliberate during the post-decisional tasks. This manipulation should generally drown-out System 1 interference, but should not impact the difference in diagnosticity of reasons in choice versus ratings. The findings replicate for both satisfaction ratings ( $b=-15.93$ ,  $t(359)=-6.82$ ,  $p<.001$ ) and choice consistency ( $b=0.11$ ,  $z(359)=2.17$ ,  $p<.04$ ), thus rejecting System 1 explanations.

Reasoning leads to both less satisfaction with and more commitment to choices. While paradoxical, this is parsimoniously explained by the differing diagnosticity of initial reasons in post-decisional ratings versus choice. The result has important implications both for the study of deliberative decision-making, as well as for marketers determining whether to emphasize evaluative (e.g., reviews) or behavioral (e.g., repurchase) post-purchase outcomes.

### Social Attention Increases the Hedonic Impact of (Social) Comparison

#### EXTENDED ABSTRACT

One dark side of variety is foregoing alternatives to our experiences. Choosing a job, marrying a spouse, or ordering a salad usually precludes us from having other jobs, spouses, and entrées. Comparing our experiences to these foregone counterfactual alternatives—experiences we could have had, but didn't—sometimes produces a

hedonic contrast effect. The comparison makes our experience subjectively better or worse (e.g., Cooke, Meyvis, and Schwartz 2001; Novemsky and Ratner 2003; Tversky and Griffin 1991). However, many alternatives to our experiences are not simply foregone. Another person experiences them. Another person is working in Barcelona, married our crush, or is eating the burger. These counterfactual alternatives are social comparison standards (Festinger 1954).

We suggest that when a standard of comparison is social, it induces a more potent hedonic contrast effect than if it is purely counterfactual (i.e., if no other person experiences it). We report the result of six experiments comparing similar social and counterfactual comparisons that find social comparisons induce larger hedonic contrast effects. Furthermore, process evidence via mediation and moderation by distraction, cognitive salience and perceptual salience support a social attention account of this difference. Social comparisons are more potent because people are more likely to attend to and consider an alternative when another person experiences it. This increased attention, in turn, magnifies their impact relative to similar counterfactual alternatives.

More formally:

*Hypothesis 1 A comparison standard induces a larger hedonic contrast effect on a focal experience when it is social (i.e., when consumers believe another person experiences it) than when it is merely counterfactual (i.e., when it is not experienced by another person).*

*Hypothesis 2 Social comparison standards induce larger hedonic contrast effects than similar counterfactual standards because consumers are more likely to orient attention and cognitive resources to social comparison standards than to counterfactual comparison standards.*

We report six experiments testing our two hypotheses. In Experiments 1 and 2, we tested H1 by examining whether happiness with a food or wage would be more affected by social than counterfactual comparisons. In Experiment 1, relative to controls who were provided with no standard of comparison, both counterfactual and social induced hedonic contrast effects. But the hedonic contrast effects induced by social comparisons were larger. Participants were less happy winning a smaller amount of chocolate if another person won the larger amount than if no other person won the larger amount. In Experiment 2, hedonic contrast effects influenced happiness with a wage more when alternative wages were social than counterfactual comparison standards. People were happier with the larger of two wages if the smaller wage was paid to someone else. This was true whether wages paid were contingent on or independent of each other.

In Experiments 3 - 6 we tested our proposed social attention mechanism (H2). Experiment 3 found that consumers allocate more attention to social than counterfactual comparison standards, and this difference in the orientation of attention mediated the larger hedonic contrast effects induced by social comparison standards. Experiment 4 manipulated attentional capacity by imposing an easy or demanding cognitive load on participants. According to H2, the demanding load should enact a larger reduction in the hedonic contrast effect for social than counterfactual comparison standards. Occupying participants' attention with a taxing cognitive load did more to reduce the hedonic contrast effects induced by social than counterfactual standards.

In Experiments 5 and 6, we further tested the attentional portion of our account by manipulating the relative cognitive and perceptual salience of the focal experience and comparison standards. Found that explicitly drawing attention to comparison standards in Experiment 5 had a larger effect on counterfactual than social comparison standards (to which participants should already have attended). Finally, we found that reducing the perceptual salience of both the target and comparison standard in Experiment 6 reduced the difference in contrast effects induced by social and counterfactual standards.

Consistent with our theory, a single-paper meta-analysis (SPM; McShane and Bockenholt 2017) of our studies estimated the interaction effect of comparison standard (social vs. counterfactual) and standard value (inferior vs. superior) at 1.14 (95% CI = 0.50, 1.78), suggesting that social standards induced larger hedonic contrast effects than did counterfactual standards across all experiments. Specifically, the same focal experience was more pleasurable when its alternative was an inferior than a superior social standard (simple effect estimated at 2.43, 95% CI = 1.96, 2.91), and when its alternative was an inferior than superior counterfactual standard (simple effect estimated at 1.29, 95% CI = .81, 1.77).

Comparison is a ubiquitous feature of social life, and social standards provide a rich source of information by which to calibrate judgment (Festinger 1954; Suls and Wheeler 2000). People deliberately and spontaneously seek out social standards to assess themselves (Dahl et al. 2012; Feinberg et al. 2002; Klein 1997; McFerran et al. 2010), even when those standards provide them with little diagnostic information (Gilbert et al. 1995; Mussweiler et al. 2004). The cognitive processes that underlie social comparisons are similar to those that underlie comparisons in other domains (De Brigard et al. 2015; Mussweiler 2003; Olson et al. 2000). Yet, we found that social attention, the propensity to orient the mind toward the experiences of others (Langton, Roger, Watt, and Bruce 2000), leads people to attend more readily to social standards and infuses them with a more potent impact.

### How Incentive Framing Can Harness the Power of Social Norms

#### EXTENDED ABSTRACT

How consumers behave is strongly influenced by what they perceive as the social norm (Ajzen and Fishbein 1980; Asch 1951). Accordingly, behavior change interventions often attempt to shift normative perceptions by offering explicit information about the normative behaviors of consumers' reference groups (e.g., 75% of guests in this hotel reuse their towels; Goldstein, Cialdini, and Griskevicius 2008). The current research offers a novel method of influencing perceived norms and, ultimately, behavior. Rather than directly stating the norm, we suggest that norms can be signaled indirectly by guiding consumers' attention to a common marketing tool: monetary incentives. Specifically, we propose that drawing attention to an incentive framed as a surcharge (vs. a discount) will lead consumers to perceive the incentivized behavior as more of an injunctive norm—what people ought to do—and more of a descriptive norm—what most people do (Cialdini, Reno, and Kallgren 1990, 1991). In response, we find that consumers display emotions consistent with a desire to conform, and, in turn, are more likely to engage in the incentivized behavior. This effect is especially pronounced among individuals with a greater sensitivity to social influence. Importantly, directing consumer focus toward these invoked norms has the power to influence behavior even after the incentive is removed.

In Study 1, participants considered whether to bring a reusable mug to a coffee shop, a behavior incentivized with either a surcharge

or a discount. Participants who read about a surcharge (vs. a discount) more strongly believed that customers at this shop should bring their own mug, an injunctive norm ( $M_{\text{surcharge}} = 5.73$ ,  $SD = 1.26$  vs.  $M_{\text{discount}} = 5.01$ ,  $SD = 1.44$ ;  $t(300) = 4.65$ ,  $p < .001$ ), and thought that significantly more customers would bring their own mugs, a descriptive norm ( $M_{\text{surcharge}} = 60.66$ ,  $SD = 21.72$  vs.  $M_{\text{discount}} = 49.53$ ,  $SD = 23.40$ ;  $t(300) = 4.28$ ,  $p < .001$ ). Participants who read about a surcharge (vs. discount) also anticipated feeling guiltier ( $M_{\text{surcharge}} = 3.20$ ,  $SD = 1.71$  vs.  $M_{\text{discount}} = 2.66$ ,  $SD = 1.75$ ;  $t(300) = 2.70$ ,  $p = .007$ ) and more embarrassed ( $M_{\text{surcharge}} = 3.631$ ,  $SD = 1.75$  vs.  $M_{\text{discount}} = 2.76$ ,  $SD = 1.75$ ;  $t(300) = 4.32$ ,  $p < .001$ ) for failing to bring their own mug. Importantly, participants who read about a surcharge indicated significantly higher intention to bring their own mug ( $M_{\text{surcharge}} = 5.44$ ,  $SD = 1.45$  vs.  $M_{\text{discount}} = 4.80$ ,  $SD = 1.68$ ;  $t(300) = 3.57$ ,  $p < .001$ ).

Study 2 tested whether exposure to a surcharge at one location increased intention to carry out the encouraged behavior at a nearby location with the same reference group, sans an incentive. Participants considered bringing a reusable bag to the grocery store, incentivized by either a surcharge or discount. As predicted, surcharge (vs. discount) participants perceived stronger injunctive and descriptive norms surrounding the incentivized behavior ( $ps < .001$ ) and anticipated feeling more embarrassed and guiltier ( $ps < .01$ ) for failing to bring a bag. Most critically, reading about a surcharge at the first shop influenced perceptions and behavioral intentions for a second local shop, where there was no incentive: significantly more surcharge participants believed that it was “the norm” for customers to bring a reusable bag to the second shop ( $M_{\text{surcharge}} = 47.83\%$  vs.  $M_{\text{discount}} = 32.34\%$ ;  $\chi^2(1, N = 602) = 15.03$ ,  $p < .001$ ) and reported significantly higher intention to bring a reusable bag themselves ( $t(600) = 2.26$ ,  $p = .02$ ), an outcome mediated by perceived norms and norm-related emotions.

Study 3 provides further support for our proposed norms-based mechanism by demonstrating that compliance under a surcharge is moderated by an individual's tendency to conform to peer norms. Study 3 also tests whether the effects remain different between conditions even when the incentives are roughly loss-equated (i.e., the discount is twice that of the surcharge; Abdellaoui, Bleichrodt, and Paraschiv 2005; Camerer 2005). Participants read about an incentive (surcharge vs. discount) to dress up for a themed race, after which they reported their intention to dress-up and completed a norm-conformity scale. Indeed, participants who read about the surcharge perceived greater injunctive and descriptive norms and anticipated stronger emotional reactions for not dressing up, relative to participants who read about a discount twice as large ( $ps < .01$ ). As predicted, there was also a significant interaction between condition and individual differences in norm-conformity ( $\beta = .18$ ,  $t(795) = 2.47$ ,  $p = .01$ ), such that participants' tendency to focus on social expectations significantly moderated the effect of incentive frame on their likelihood to conform.

Study 4 used a consequential, real-stakes design to assess whether exposure to a surcharge incentivizing a behavior at one point in time increased individuals' likelihood of carrying out that behavior after the incentive was removed. At the start of a laboratory session, participants were invited to purchase gum. They received a discount (vs. paid a surcharge) on the gum's price if they used (vs. did not use) hand sanitizer before purchasing. Thirty minutes later, upon exit, participants were invited to take a cookie from a table next to the hand sanitizer. With the incentive no longer in place, significantly more surcharge (vs. discount) participants spontaneously used the hand sanitizer (19.7% vs. 10.2%;  $\chi^2(1, N = 294) = 5.24$ ,  $p = .02$ ), even among participants who had not purchased gum in phase 1 and

thus merely observed the incentive but were not financially affected by it ( $p = .01$ ). This suggests that merely attending to a surcharge can influence social perceptions and significantly alter behavior thereafter.

In sum, merely drawing attention to differently framed incentives significantly changed social norm perceptions and consequential behaviors, even among individuals who were not financially impacted by the incentives. These findings suggest powerful implications in how simple incentive framing can effectively encourage behaviors, with important implications for academics, policymakers, and practitioners.

### SESSION OVERVIEW

Consumers often engage in prosocial behaviors such as making monetary donations, tipping generously, purchasing environmental-friendly products, and resisting counterfeits. One type of situational antecedents involves people-related influences: who one is and what others do. Despite decades of work exploring how the presence of others (e.g. bystander effect, Darley and Latané 1968), considerations of the self (e.g. Aaker and Akutsu 2009, Brown and Smart 1991), and salience of groups and norms (Cialdini 2009) influence prosocial behavior, some fundamental questions remain open: How do people's self and other perceptions affect prosocial behavior? What are the roles of self, others, groups and norms in affecting their readiness of act prosocially and reactions toward help?

This session brings together four papers that explore people-related situational determinants of prosocial behavior. They each ask an interesting question, take a unique approach, and provide exciting findings.

*How is prosocial behavior mediated by the need to express one's self-identity?* The first paper, by Rifkin, Crain and Berger, demonstrates that framing prosocial behavior as an opportunity to express their identity can significantly boost people's tipping and donation amounts. In a novel setting, they frame the act of giving as a choice between two identity-relevant categories (e.g., cat vs dog person) and examine the effect of a dueling preferences approach.

*How does others' identity affect the effectiveness of prosocial behavior?* The second paper, by Chen and Gao, shows that revealing the identity, specifically, the name of the donor can lead to greater recipients' likelihood of making good use of the money received and working harder. We name it the identifiable donor effect.

*Which is a more important driver of prosocial behavior, maintaining a positive self-image or social-image?* The third paper, by Jung, Saccardo, Gneezy, and Nelson, compares the relative importance of self-signaling and other-signaling in driving prosocial behavior. Across nine studies, they demonstrate that neither self- or social-signaling has a single uniform influence on generosity. They suggest that self- and social-signaling may operate in the same direction to influence prosocial behavior instead of competing with each other.

*What are the differential effects of social norm and individual exemplar on people's selfish and unselfish behaviors?* The last paper, by Yang and Zhang, examines how prosocial versus selfish actions are influenced by others. They compare the effects of social norms and individual examples and show that while one individual example is less influential than a social norm in inducing prosocial behaviors, it is as influential as norm in inducing selfish behavior.

Taken together, the session examines situational antecedents of prosocial behavior. The findings of the four papers suggest that people's motivations to maintain a positive image to the self and to others, reciprocate the kindness of a specific individual, and interpretations of how others behave in similar situations have significant impacts on their prosocial behavior and reactions toward help. The session should be of great interest not only to those interested in help, altruism, moral behaviors and charitable donations, but also to anyone who is interested in self-perception, motivation, and decision-making.

## **Penny for Your Preferences: Leveraging Self-Expression to Increase Prosocial Giving**

### EXTENDED ABSTRACT

How can marketers motivate prosocial giving? Recently, scientists and practitioners have begun leveraging identity to motivate prosocial behavior (e.g., Aaker and Akutsu 2009; Gneezy et al. 2012). For example, organizations can increase prosocial giving by appealing to people who strongly identify with the organization (i.e., donated to them previously, Kessler and Milkman 2016) or by growing the set of people that view an organization as linked with their identity (Arnett, German, and Hunt 2003; O'Reilly and Chatman 1986). However, these approaches can suffer from constraints of scope (i.e., few people may strongly identify with an organization) and implementation (i.e., shifting identities can be challenging and costly).

We examine a novel approach that is increasingly popular among charitable and service organizations that leverages peoples' drive to express their identity while resolving some challenges and costs with prior identity-based appeals. Rather than simply asking people to tip or donate (i.e., a standard giving appeal), the *dueling preferences* approach frames the act of giving as a choice between two categories (e.g., cats vs. dogs; [imgur.com/a/tMDYU](http://imgur.com/a/tMDYU)).

People value and will pay for the opportunity to express their identities through their choices (Berger and Heath 2008; Escalas and Bettman 2003; Levy 1959; Tamir and Mitchell 2012; White and Dahl 2006, 2007). As such, we suggest that framing the act of giving as an opportunity to express one's self will enhance prosocial giving. Thus, while giving (e.g., tipping, donating) may already be somewhat self-expressive, we suggest that the dueling preferences approach provides an even greater opportunity to self-express, and, consequently, leads to more frequent and greater acts of prosocial giving. Four studies in the laboratory and field test this theory.

Study 1 ( $N = 88$ ) was a field experiment conducted at a local café. We varied whether cash-paying patrons encountered a tip jar (standard appeal condition; Figure 1) or a cats-versus-dogs duel (Figure 2) and observed tipping behavior. As predicted, compared to a standard tip jar, dueling preferences nearly doubled the number of customers who tipped ( $P_{\text{Duel}} = 77.3\%$  vs.  $P_{\text{Standard}} = 40.9\%$ ,  $p = .014$ ).

Study 2 tests the dueling preferences approach with a real donation opportunity. Online participants ( $N = 203$ ) were given an opportunity to donate to the American Red Cross, and we varied whether they were shown a standard appeal labeled “donations” or a chocolate-versus-vanilla ice cream duel. Participants then indicated how much of a \$0.10 bonus they wanted to donate. Consistent with Study 1, compared to the standard appeal (37.3%), dueling preferences (57.4%) led more participants to donate ( $p = .004$ ) and increased how much they donated ( $M_{\text{Standard}} = \$0.03$  vs.  $M_{\text{Duel}} = \$0.04$ ,  $p = .032$ ), ultimately raising 30% more money for the Red Cross.

If our theory is correct, duels should only increase prosocial giving when they provide a greater opportunity for self-expression. Study 3 tests this prediction by including a non-self-expressive duel. Participants ( $N = 172$ ) imagined ordering a beverage at a café. While at the register, they imagined viewing a standard appeal (single tip jar), a pre-tested expressive duel (Duke vs. UNC), or a pre-tested non-expressive duel (Hate vs. Love Licorice), depending on condition. Consistent with prior studies, compared to the standard appeal ( $M = 3.61$ ), the expressive duel ( $M = 4.51$ ) made people more likely to tip ( $p = .017$ ). Importantly, the non-expressive duel ( $M = 3.92$ ) did not boost tip likelihood relative to the standard appeal ( $p > .25$ ). Thus, in addition to supporting our theory about the role of self-expressiveness, this study also casts doubt on concerns that some other aspect of the duel format (e.g., novelty, attention-grabbing, or competition) drove the key effects.

Study 4 provides additional process evidence through both mediation and moderation. If our theorized mechanism (self-expression) is correct, duels should only change behavior among those who find it personally relevant. To test this, participants ( $N = 136$ ) imagined ordering a beverage at a café. While at the register, they imagined viewing a standard appeal (single tip jar) or a cats-versus-dogs duel. After indicating their tipping decision (yes, no), they rated how self-expressive the tipping opportunity was (3 items) and the extent to which pets are personally relevant to them. Supporting our prediction, in addition to a simple effect of appeal type ( $b = .93$ ,  $p = .016$ ), we found the predicted appeal type  $\times$  personal relevance interaction ( $b = .89$ ,  $p < .001$ ). As with prior studies, the duel increased tipping among people who rated pets as personally relevant (+1 SD;  $P_{\text{Duel}} = 78.8\%$  vs.  $P_{\text{Standard}} = 23.1\%$ ,  $p < .001$ ); however, this effect disappeared among people for whom pets were personally irrelevant (-1 SD;  $P_{\text{Duel}} = 27.5\%$  vs.  $P_{\text{Standard}} = 42.4\%$ ,  $p = .241$ ).

We also found the predicted appeal type  $\times$  personal relevance interaction on the mediator, self-expressiveness of the tip opportunity ( $b = .45$ ,  $p = .017$ ), and moderated mediation analysis indicated that the effects on tipping were mediated by self-expressiveness and moderated by personal relevance (index of moderated mediation = .20, 95% CI [.01, .51]). When pets were personally relevant (+1 SD), the duel made the tipping opportunity a greater opportunity for self-expression, which enhanced tipping ( $ab = .75$ , 95% CI [.28, 1.59]). When pets were personally irrelevant (-1 SD), however, these effects disappeared ( $ab = .02$ , 95% CI [-.48, .48]) because the duel no longer provided greater opportunity for self-expression and thus did not increase tipping.

Across a range of identities, duels, and giving contexts, these studies demonstrate that dueling preferences boosts prosocial giving by providing an opportunity for self-expression. This work also reveals a new, flexible, and easy-to-implement identity-based appeal. Rather than being restricted to the set of people that already hold a strong, relevant identity or exerting resources to grow that set, this approach can leverage *any* valued identity to motivate behavior. This research contributes to the literatures on self-expression and identity factors that influence prosocial behavior.

## The Identifiable Donor Effect

### EXTENDED ABSTRACT

Extant research has identified multiple situational factors that motivate people to donate money and provide help to those in need, such as physical appearance of recipients (Small & Verrochi, 2009), similarity to recipients (Small & Simonsohn, 2007), and number of bystanders (Darley & Latané, 1968). However, very little attention has been paid to situational factors that influence how people react to help provided by others (Fisher, Nadler, & Whitcher-Alagna, 1982). The present research explores the mere revelation of the help provider’s name as a situational factor that has significant impact on people’s reactions toward help. Specifically, we show that compared to an unidentified individual donor, merely revealing the individual donor’s name can lead to greater recipients’ likelihood to make good use of the money received and to work harder. We also show that the identifiable donor effect is driven by a greater sense of obligation activated by the donor specificity.

Research on reciprocation has established considerable evidence that people are motivated to repay in kind what others has done for them (Cialdini, Green, & Rusch, 1992; Cialdini et al., 1975). The norm of reciprocation is widely applied to different human behaviors and governs all human societies (Cialdini, 2009). Thus, people expect reciprocity in interpersonal relationships and a lack of reciprocity is often accompanied by negative affect (Cialdini, 2009). From an evolutionary perspective, reciprocal altruism is adaptive and contributive to collective survival and well-being (Ridley, 1997). As a result, the motivation to reciprocate is deeply rooted in our human nature; most people have an instinct tendency to reciprocate after receiving help, accompanied by a sense of obligation (Cialdini, 2009). However, for reciprocity to occur, it is important that the person who receives the benefit actually knows who the provider is (Whatley et al., 1999). If the helper is unidentified, it remains an unspecified target which is less likely to elicit the recipient’s sense of obligation to reciprocate. In our case, merely revealing the name of the donor (without providing any other information) can serve to increase target specificity and elicit the recipient’s sense of obligation. In our case where direct reciprocation is unlikely (e.g. a student receiving scholarship from a donor), we propose that the recipient is more likely to internalize the sense of obligation and adjust his/her decisions and behaviors in a positive direction to be a worthy person.

Four studies examined above propositions. In all studies, we manipulated whether the donor’s name was revealed to the help recipient while keeping all other information constant. Study 1 ( $N = 109$ ) provided an initial support for the identifiable donor effect. Participants were asked to imagine receiving a scholarship either from Prof. Elliot or a professor from their university (no name). Compared with those who received scholarship from an unidentified professor, participants who received scholarship from Prof. Elliot felt more obligated ( $p = .019$ ), and indicated that they would spend more money on study-related items ( $p = .041$ ). Besides, perceived obligation mediated the relationship between identification and money allocation (95% CI = [1.50, 12.24]). Alternative explanations based on perceived supervision, perceived generosity of the donor, psychological distance, and self-esteem were ruled out.

Study 2 ( $N = 530$ ) generalized the above findings to a situation with multiple donors. Besides the donor identified manipulation, we told participants that the scholarship was contributed by either one or five professors. We also included a condition where the participants were told that the scholarship was contributed by an organization, i.e., the faculty association of their university. Finally, to test if the effect was affected by the differential perceived cost to the donor

(relative to the total wealth of the donor), we told half of the participants that over the years the donor had contributed 10% of the personal wealth / total asset to the scholarship. The design was a 2 (control the cost vs. not)  $\times$  5 (one identified professor, one unidentified professor, five identified professors, five unidentified professors, the faculty association) between-subject design. Since the cost of total wealth had no effect, the data were combined and analyzed among the five conditions. As predicted, participants in the identified donor conditions (one and five identified donors) indicated that they would spend more money on study-related items than when the donor was unidentified or when the donor was an organization ( $p = .015$ ). Again, the effect on money allocation was mediated by perceived obligation.

Study 3 ( $N = 205$ ) tested donor specificity as the driver of the identifiable donor effect. We predicted that if the donor remains un-specific, even revealing the potential donors' names will not elicit a sense of obligation. Participants were instructed to imagine receiving scholarship from one of five professors. In addition to manipulating donor name revelation, we manipulated whether the participants knew which one out of five professors contributed money to their scholarship. As predicted, when participants didn't know which specific professor provided the scholarship, revealing the names of the professors no longer created a sense of obligation ( $p = .019$ ), nor made them allocate more money on study-related items ( $p = .011$ ).

Study 4 ( $N = 126$ ) examined the proposition in a different context with real behavioral data. Undergraduate students were recruited by a marketing professor (name either revealed or not) to participate in an extraordinarily well-paid lab study. Although in both conditions the participants were told that their identity would remain anonymous to the researchers, they worked harder (indicated by the number of words they wrote) when the professor's name was revealed than not ( $p = .018$ ).

Four studies consistently show that money recipients will respond more positively to aid from an identified (vs. unidentified) donor, even when all other information is kept constant. This research is among the first to examine prosocial behavior from the perspective of help recipients. Our findings advance current understanding of situational influence on prosocial behavior, and provide important real-world implication on increasing the effectiveness of prosocial behavior.

## Burnishing Prosocial Image to Self vs. Others

### EXTENDED ABSTRACT

Prior research has shown that people's kindness and generosity can be explained, at least partially, by image concerns; people want to signal to themselves that they are kind, in order to preserve a positive identity. Likewise, they want to signal their kindness to others, to maintain a positive social-image (e.g., Andreoni & Bernheim, 2009; Ariely, Bracha, & Meier, 2009; Dana et al., 2007).

Whereas there are situations where the two signaling motivations might operate in the same direction, self and social image concerns might also compete with each other. Gneezy, Gneezy, Reiner, and Nelson (2012), for example, has looked at how self-image concerns influenced economic behavior under pay-what-you-want. In one field study at a restaurant, people paid more when their payments were anonymous (vs. observed), suggesting that self-signaling motives are stronger when behavior is not observed. Other work shows that social signaling can backfire when people's generosity toward others directly benefit their own self-interest (Newman & Cain, 2014). We conducted eight field and one lab experiments in both for-profit and non-profit settings to investigate the dynamics of con-

sumers' self- vs. social-image motives under pay-what-you-want. Furthermore, we used these studies to examine potentially meaningful moderators.

In Study 1, visitors to an art museum paid what they wanted for their admission; contrary to the self-image signal hypothesis, payments were higher when done in public, versus anonymously. Perhaps visitors believed that, unlike in a buffet restaurant, admitting an additional person did not cost the museum more, and therefore paid less in the absence of social pressure. In Study 2 we used a product with a clear marginal unit cost to test image concerns in a lab setting. We also examined whether positive social interaction influenced the type and magnitude of image signaling; some participants had a pleasant conversation with an experimenter and were later asked to pay-what-they-wanted for a mug. Neither the social interaction or anonymity manipulation significantly influenced payments.

Studies 1 and 2 showed no evidence of self-signaling. In fact, the overall direction of the results was supportive of social-signaling; people paid more when their payment was observed by others. In Studies 3 and 4, we investigated consumers' signaling motives in a charitable giving context in which consumers are likely to be more sensitive to social-signaling. In both studies, we manipulated anonymity as well as the presence of an explicit charitable signal; customers saw products either with a commercial or charitable logo imprinted on it. We predicted that if self-signaling influenced behavior, customers would pay more for products with a commercial logo and when paying anonymously.

We conducted Study 3 at a local flea market. Customers saw reusable bags with a charity logo, the same logo with the charity name removed, or a commercial logo. Customers paid similar amounts whether their payments were observed or anonymous across the two charity logo conditions. But customers paid more paying anonymously in the commercial logo condition, showing evidence of self-signaling motivations. In Study 4, we tried to replicate the results of Study 3 with a larger sample size, selling coffee in a local farmers' market. Customers saw our coffee cups with either a charity or the coffee shop logo. Payments were higher in the charity logo condition. Payments in both logo conditions were not influenced by the payment anonymity manipulation.

The results of Studies 3 and 4 could have been driven by selection bias. Knowing that 50% of their payment going to charity attracted a particular type of customers that were less influenced by anonymity. To test this possibility, in Study 5 we removed the pricing information from our signs and randomly assigned customers to the conditions *after* they decided to purchase. We sold donuts at a campus location. Once customers decided to buy a donut, they were asked to select a piece of paper from a box that contained our pricing manipulation. Even in the absence of selection, customers paid similar amounts whether their payments were observed or anonymous.

The results in Studies 3-5 support neither the self- or social-signaling hypothesis. It is possible that our anonymity manipulation had an additional influence on customers' payments beyond simply allowing the "anonymity" of payments. For example, an envelope itself could have pressured people to put a generous amount. In Study 6, we tested signaling using a different social-signaling manipulation. We conducted Study 6 at a children's museum in the Bay Area. Visitors were asked to fill out a card to indicate their donation amount. Some visitors were asked to write their initials on their cards. Our results showed that payments were not influenced by the signaling manipulation. Study 7 replicated these results at the same museum.

In Studies 8 and 9, we tested how a signal of prosocial identity influenced payments with a different manipulation than the one used in Studies 3-5. In Study 8, we manipulated the signal of prosocial

identity by providing visitors an art museum an admission badge that said, "I am a supporter of [museum name]" before or after their payment. If visitors received a badge before their payment for admission, they have an opportunity to signal their prosocial identity consistent with the identity signal on the badge by paying more. But visitors who received the badge after their payment did not have the same opportunity. Visitors paid similar amounts regardless of paying before or after receiving a badge. Study 9 followed the same design, in addition to a manipulation of payment anonymity. Again, visitors paid more when their payment was observed but people paid similar amount before and after receiving a badge.

The results from nine experiments show neither self- or social-image signaling has a single uniform influence on payment. Across these experiments we occasionally see evidence for one, occasionally for the other, and frequently for neither. We observe slightly more evidence for social signaling, but the effect is not robust across the experiments. It is possible that self- and social-signaling may not necessarily compete to influence consumers' social preferences, but operate in the same direction.

### **Easy To Be Selfish: Comparing the Influence of a Social Norm and an Individual Example**

#### **EXTENDED ABSTRACT**

As social animals, we are inevitably influenced by others. Consider the following scenario: if you are told that most people have downloaded pirated music, would you do so as well? How about if you are told that a classmate has downloaded pirated music? In this research, we compare the strength of impact from two types of social influences: social norms and individual examples. The social impact theory proposes that  $N$  people are more influential than  $N-1$  people (Latané 1981), and this argument has been supported by much research (Babić Rosario et al. 2016). In our case, the social impact theory would predict that a social norm should be more influential than one individual example. However, we think that this can be an overly simplified view about the impact of social influences. We suggest that the impact of the two types of social influences may depend on whether these two social influences promote selfish or unselfish behavior.

Intuitively, a social norm telling people that many others have done something is more influential than a single social example. A social norm implies the legitimacy of a behavior and thus is usually more influential than one individual example (Cialdini 2009). However, this may be only true for behaviors that are not selfish. When facing the opportunity to reap benefits by behaving selfishly, people tend to find self-serving reasons to justify the behavior (Gino and Ariely 2012; Schweitzer and Hsee 2002). Interestingly, the justification can be easily found when people want to, and research finds that one bad apple can be rather contaminating (Gino, Gu, and Zhong 2009). Thus, a single example is sufficient to offer an excuse for the selfish behavior, making an individual example as influential as a social norm.

We tested these predictions in four experiments. Experiment 1 followed a 2(valence: unselfish vs. selfish) x 2(type of influences: social norm vs. individual example) between-participants design. Participants imagined that they liked a luxury wallet but found out that it was a counterfeit. Participants in the individual example conditions were told that a shopper claimed that (s)he would (selfish condition) or would not (unselfish condition) buy counterfeits. Participants in the social norm conditions were told that a survey found that 72% of local people would or would not buy counterfeits. Participants indicated how likely they would buy the wallet and the extent to

which they were willing to buy it on 1(not at all) to 9(very much) scales. Note that the impact of a social norm or an individual example should be calculated differently depending on the valence of the social influence. A higher purchase likelihood of the counterfeit implies a higher impact of the selfish influence, whereas a higher purchase likelihood of the counterfeit implies a lower impact of the unselfish influence. Therefore, we reverse coded the purchase likelihood to get the impact score for the unselfish conditions, so that a higher impact score implies a greater influence in all conditions. The analysis on the impact score showed a significant interaction between valence and type of influences,  $F(1, 208) = 5.94, p = .016$ . The unselfish social norm were significantly more influential ( $M = 7.94$ ) than the unselfish individual example ( $M = 7.18$ ),  $F(1, 208) = 4.04, p = .046$ . However, this difference was insignificant for selfish behaviors ( $M_{\text{norm}} = 2.33$  vs.  $M_{\text{individual example}} = 2.85$ ),  $F(1, 208) = 2.06, p = .153$ . If anything, the individual example seemed to be slightly more influential.

Experiment 2 replicated the results of Experiment 1 in the context of whether to download pirated music. The results showed a similar significant interaction between valence and type of influences,  $F(1, 261) = 4.38, p = .037$ . Participants in the unselfish conditions were influenced to a greater extent by the norm ( $M = 2.74$ ) than by the individual example ( $M = 2.19$ ),  $F(1, 261) = 4.54, p = .034$ , and this difference diminished in the selfish conditions ( $M_{\text{norm}} = 5.65$  vs.  $M_{\text{individual example}} = 5.86$ ),  $F(1, 261) = .67, p = .414$ .

One potential concern was that we asked participants' intention to commit selfish behaviors, and asking about their intention to commit unselfish behaviors might produce different results. Experiment 3 and 4 addressed this issue. Experiment 3 adopted a 2(valence: unselfish vs. selfish) x 2(type of influences: social norm vs. individual example) between-participants design, plus one control condition in which no social information was provided. Participants allocated \$20 between their partners and themselves. Thus, we didn't ask them whether to be selfish or unselfish. Since past research shows that most people tend to allocate 40% of the total money (\$8 in our case) to others (Piff et al. 2010), we choose \$10 as the unselfish behavior and \$6 as the selfish behavior. Participants in the individual example conditions were told that one previous participant allocated either \$10 or \$6 to the partner. Those in the social norm conditions were told that most participants who had finished this game allocated either \$10 or \$6 to their partners. We found that the unselfish social norm led to a higher allocation to the partner ( $M = 9.60$ ) than the individual example ( $M = 8.72$ ),  $F(1, 147) = 4.97, p = .027$ , but the selfish norm produced an allocation ( $M = 7.96$ ) similar to the individual example ( $M = 7.70$ ),  $F(1, 147) = .38, p = .538$ . Consistent with past findings, people in the control condition allocated \$7.81 to their partners.

Because the allocations in the control condition were close to those in the selfish conditions, it is not clear whether the selfish norm/example was effective at all. Experiment 4 lowered the selfish norm/example to \$3. We replicated the results from Experiment 3 (see the figure below). In all studies, the extent to which the norm was believable did not affect the results.

Taken together, four experiments provide corroborative evidence that while the impact of an unselfish social norm is much stronger than that of one unselfish individual example, one individual selfish example is almost as influential as a selfish social norm.

## A Journey with no Return into the Animal Kingdom: The Role of Tattooing in the Construction of the Collective Identity of the Vegan and Vegetarian Movement

Renata Andreoni Barboza, IBMEC-Instituto Brasileiro de Mercados e Capitais e FGV EAESP - Escola de Administração de Empresas de São Paulo da Fundação Getulio Vargas, Brazil

Tânia Veludo-de-Oliveira, FGV EAESP - Escola de Administração de Empresas de São Paulo da Fundação Getulio Vargas, Brazil

### ABSTRACT

The purpose of this study is to understand how tattooing consumption shapes the formation of the collective identity of the vegan and vegetarian social movement. Tattooing is used as an instrument of social interaction and to establish and exhibit the ideological position that reflects the movement's collective identity.

### INTRODUCTION

One form of permanent voluntary body alteration is tattooing (Watson 1998). It is a radical consumption choice inspired by the desire to define and reconstruct one's identity (Langman 1991; Schouten 1991). Although Bengtsson, Ostberg, and Kjeldgaard (2005) observe that tattooing has gone mainstream, "the emergence of tattooing as a mass consumer phenomenon has received scant attention in consumer research" (Kjeldgaard and Bengtsson 2005, 172).

To the best of our knowledge, no previous study has been devoted specifically to explore jointly both tattooing and social movements' collective identity. This is surprising as the departure from the usual standards relates to both themes. While tattooing has long been associated with social deviation (Bjerrisgaard, Kjeldgaard, and Bengtsson 2013), the concept of collective identity "implies direct opposition to the dominant order" (Taylor and Whittier 1992, 110). In this study, we delve deep into the existing literature to understand how tattoo consumption shapes the formation of the collective identity of the vegan and vegetarian social movement.

Our study seeks to give continuity to the work of Patterson (2017) that sketches out "the process of tattoo in respect of wounding, healing, and the procurement of a mark" (p. 2), which implies the traditional "functions of tattoo in terms of decoration, ritual, identification, and protection" (p. 1). In our study, we address specifically the issue of identification, however our focus is not the tattooed individual per se, but the tattooed group, who, by sharing the same symbols on their skin, establish connections among themselves. The choice of deliberately not consuming animal products flies in the face of the mainstream practice of cultures with a strong meat-mindset, which is the context of the empirical fieldwork reported here.

### LABELED ON THE SKIN:

#### AN OVERVIEW OF TATTOO CONSUMPTION

For a long time in the Western culture, "tattoos have been considered socially marginal and risky consumption choice" (Watson 1998, 543). Nonetheless, tattoos became "fashionable" and thus mainstream from the 1980s onwards (Shelton and Peters 2006). "Having a tattoo has gradually become a mainstream consumption practice that can be found among people from all walks of life" (Kjeldgaard and Bengtsson 2005, 172). Today the artistic universe recognizes the art of tattoo artists (Kjeldgaard and Bengtsson 2005) so that many of the tattoos created are deemed pieces of art of high commercial value (Kjeldgaard and Bengtsson 2005; Sanders 2009).

"Irreversible forms of body decoration are used as a vehicle for human expression [...] and tattoos may signify a wide array of

meanings" (Velliquete, Murray and Creyer 1998, 461). The body, as something malleable, offers opportunities for modification and improvement (Kjeldgaard and Bengtsson 2005). The phenomenon of tattoo consumption is an example of the collapse of the mind-body duality (Firat and Venkatesh 1995), which alludes to the role of the body customization in the construction of stories, biographies, and identity (Kjeldgaard and Bengtsson 2005).

### METHOD

The empirical study was undertaken in Brazil, the third largest consumer market of beef in the world, with an average of 25.7 kilos per capita per year (OECD 2017). Our study started by exploring vegans and vegetarians and by doing so we noticed the significance of tattoos for them. We took part in 18 vegetarian events and made regular visits to five different vegan restaurants, in which we met people with tattoos related to veganism or vegetarianism who were invited to take part in the interviews. We conducted long interviews with six tattooed ovo-lacto vegetarians and 10 tattooed vegans (about 2 hours each, to a total of 30 hours). The interviews were filmed, audio recorded, and transcribed (totaling 475 pages). We took photos (327 in all) and field notes (302 pages) right after the interviews and during the observations of the events and in the restaurants. All of the interviewees had chosen to be vegetarian/vegan because of their love for animals and a desire to fight for animal rights. For the analysis we undertook a process of constant and systematic coding, categorizing, and abstracting the data, as indicated by McCracken (1988). The keywords and phrases with some thematic similarities were highlighted throughout the content of the interviews and field diary.

### MAIN FINDINGS

Tattooees often use their tattoos as a means of informing and transmitting a message about their uniqueness to the external world (Watson 1988). In the interviews and informal conversations at events and restaurants, the informants reported that their tattoos demonstrated their connection with the irrational animals, something that from their point of view sets them apart from most other people, making them unique. The narrative that best explains the connection of vegans and vegetarians with the animal kingdom is Alana's, by virtue of its singularity. Alana appropriated the zoomorphism, "the attribution of animal traits to human beings, deities, or inanimate objects" (VandenBos 2007, 1171) in choosing each of her 15 tattoos related to veganism. In the interview, Alana confided that she has two identities, because she secretly also considers herself a mermaid. In explaining the symbolism of her tattoo, Alana makes her alternative identity clear as the result of an extreme connection with irrational animals:

This is the most beautiful [tattoo]. It's a rhino-mermaid! I love mermaids! And I love rhinoceroses, I love all animals! I would not tattoo a mermaid, because I think I'm a mermaid. Would I then tattoo another mermaid? I will not tattoo myself! They [the

tattoos] are animals that I love, that represent me and they [the tattoos] are my connection with animals.

Due to her passion for irrational animals Alana appropriates the identity of the mythical animal “mermaid”, which is half human (rational) and half fish (irrational). Her identity is not just vegan; it is an animal identity, with the plural features of these two distinct animals’ worlds.

Besides the animal affiliation, the interviews make it clear that tattoos foster the connection of the tattooed with other people, whether they are known, unknown but who share common interests, or totally foreign to them. The decision of Nicole and her friends to tattoo exactly the same drawing (i.e., various animals and the word “vegan”) on their bodies shows the strong connection between themselves. Nicole describes her tattoos: “Each letter of the tattoo is an animal. If you take a look, the ‘v’ is a rabbit, the ‘e’ is a pig, and so on [...]. The tattooist did it on me, on my friend, and everyone in my group did this very same tattoo as well. We’re a group of vegan friends!”. They were acquaintances who became “a group of vegan friends” due to their shared tattoo, establishing a timeless and iconic representation on their bodies forever. For Blanchard (1991), there is a belief that the image of a tattoo is eternal. It seems that the pact of faithfulness to the animal kingdom is forever sealed when people decide to tattoo their own bodies to pay homage to the animals. In celebration of her three years as a vegetarian, Grace decided to tattoo the photo of the cow that, according to her, had persuaded her to become a vegetarian. She still visits the cow every year on her friends’ farm, and says that she expects to continue to do so in the long future.

People unknown to each other are able to recognize one another as members of the vegan and vegetarian movement because of the tattooed symbols. “I’m a vegan too!” is the common phrase used when vegans identify each other by looking at each others’ tattoos. Emily told us about her participation in what she calls the green blood donation campaign, a social campaign for blood donation by vegans. When the group that organized the campaign came across someone with the symbolic tattoo of veganism, who had come to the hospital to donate blood, it was a cause for rejoicing. In Emily’s words:

[The tattoo] is a way of identifying a vegan. When we were involved in the green blood donation campaign, we came across many people who had the vegan symbol, and when we saw the symbol everyone got happy and excited [...]. It’s a way to identify yourself in this world of so many people.

Symbols act as an important part of the discourse for communicating the identity of the individuals and their group (Velliquette, Murray, and Creyer 1998). Emily demonstrates, by what she says, how the tattoo is used by members of the vegan social movement, unknown to each other, for collective identification. The vegan symbol tattoo is not one that non-vegans would necessarily know, but a kind of ‘secret handshake’. Choup (2008) highlights the importance of the solidarity between members of the group (e.g., all for the sake of vegan blood donation) for establishing the collective identity and how this collective identity helps to bring together these members by indicating shared issues and the need for collective action. Thus tattooing can be seen as a manifestation of collective identity and becomes a tool that ratifies the communal goals of group members – in the case of a green blood donation campaign, the goal was to show that vegans are healthy and can donate blood as well.

Vegans and vegetarians use their tattoos as a collective opportunity to talk about veganism and vegetarianism, within or outside the social movement. The vegan tattoo was not an accidental choice for Olivia, it was rather a conscious choice to promote a social and collective interaction. Olivia chose to tattoo the word “vegan” in a conspicuous place (i.e., on her right arm) with the aim of demonstrating the identity of the group to which she belongs, to “outsiders”, which means people who consume products of animal origin. Olivia explains:

I did this tattoo when I was already vegan [...]; for this tattoo I chose three animals, I wanted a totem of animals, and I wanted the word vegan underneath, and why? Because it [the right arm] is a region that is clearly visible to other people. Many people have stopped me on the street asking what vegan means, if it is the name of someone in my family, or if it is my husband’s name, so it’s really cool because you can explain the meaning of vegan to them. It’s a way of making people curious and encouraging them to discover the meaning of “vegan”.

Olivia’s journey shows that tattooing “reflects our dynamic navigation of self and its society, of personal identity projects and commitments to the social” (Patterson 2017, 5), but also shows the utilitarian function of tattooing in drawing attention to the cause of animals’ rights, which is done by constant (re)negotiation with others (Sullivan 2001). Her tattoo acts as a collective identity’s political symbol for recruiting “outsiders” for her cause (Jasper and McGarry 2015). The same thing is true of Sara, an actress, who knew that her tattoo would be seen by many people when she performed on the stage. After going through the process of transformation into the vegan life, Sara felt she needed to externalize her story on her body (“[my tattoo] speaks of my soul, talks about my struggle in this life”) as this could influence a lot of people.

All the interviewees reported that they had transformed their bodies through tattooing into “living records of their life histories and consumption habits [...] situated in a field of historical and social relationships” (Thompson and Hirschman 1995, 151). Our conclusion is that tattooing has acted as a very important tool in shaping the collective identity of the vegan and vegetarian social movement. Reviewing the work of Taylor and Whittier (1992), Touraine (1985), and Melucci (1989) it can be seen that one essential element of the collective identity is that individuals see themselves as part of a group for which some shared characteristic becomes prominent, as creating a sense of solidarity and membership termed “we-ness”. The sense of “we-ness” is noticeable when vegans who have never met before say to each other after seeing their tattoos: “I am [a vegan] too!” It is further demonstrated by Nicole and her friends who chose to be tattooed with exactly the same symbol. Alana also highlights the sense of “we-ness” when she considers herself as half irrational animal, and half human. Her “we-ness” goes beyond the members of the vegan and vegetarian movement, whether they are your friends, acquaintances, or completely unknown people, to include the irrational animals themselves as part of her membership group. Another key component of collective identity, as pointed out by Taylor and Whittier (1992), is what Cohen (1985) denominates “consciousness”, something that members of the vegan social moment wanted to show when they honor the green blood donation campaign to create the awareness that vegans and vegetarians also can donate blood because they are healthy. Melucci (1989, 35) holds that “movements build submerged networks of political culture that are interwoven with everyday life and provide new expressions of identity that challenge dominant representations”, which is what both Olivia and Sara try to do when they deliberately leave their tattoos exposed to the outside world in order to attract attention to the animal cause they

**Figure 1: Pictures of the interviewees' tattoos**

The top left drawing is Emily's, the vegan symbol in a mandala. The bottom left drawing is the same vegan symbol but is Sara's. The image in the center of the figure is the cow tattooed on Grace with the words "vegetarian pro-life". The top right drawing represents the five animals that compose the vegan word tattooed on Nicole and a group of friends. The bottom right drawing is Olivia's and has the totem with three animals and the word vegan below it.

defend, or to show off their "struggle in life" as regards their vegan journeys. A tattoo is an extreme form of pre-commitment; there is no turning back. A vegetarian can change back to omnivore, but someone with a tattoo would have difficulty changing. Maybe tattooed vegans and vegetarians also get the tattoo to make sure that they could not change their minds.

### CONCLUSIONS

Collective identities continue to play a central role in the development of social movements (Klandermans 2014). In this study, tattooing is seen as a way to establish and present an ideological

position that goes against the prevailing cultural pattern and by doing so, goes beyond the function of aesthetic beauty to include not only the identification of an entire group with a cause (i.e., social identity), but also fulfills the function of the fellowship's credentials. We argue that when the symbol of a social movement is stamped on the body of its members, the movement is not only collectively passing on a message by means of that symbol; we argue that the collective body-stamped message serves as an "identity card" for its members, and therefore shapes the collective identity of the group.

One means by which vegans and vegetarians present to the outside world the personal transformation that they have undergone

when they said no to the consumption of animal products are the tattoos on their physical bodies. The tattoo can be used as an instrument of social interaction and as a political manifestation, which expresses an irreversibly strong connection with the animal kingdom. Being and “surviving” as a vegan or a vegetarian within a meat culture is a message that many vegans and vegetarians like to embrace as part of their individual, social and collective identities. In this study, we find that the tattoo functions as a means of communication of a whole community’s way of life. We, therefore, argue that the establishment of the collective identity is another function of the tattoo consumption, thus complementing Patterson’s discussion (2017).

**Table 1: Summarizing the empirical results**

Coding Categories	Main findings
Connection with the animal kingdom	Vegans and vegetarians feel they have a strong connection with irrational animals, so that they put themselves on the same level of importance as them. Their tattoos symbolize this connection, intended to last forever.
Symbols of the collective identity	Unknown people are able to recognize each other as members of the vegan and vegetarian movement because of the tattooed symbols. To position a tattoo on a conspicuous part of the body calls for a deliberate decision that serves to identify their ideological position to others.
Activating relationships and promoting social interaction	Vegans and vegetarians use their tattoos as a collective opportunity to talk about veganism and vegetarianism, whether within or outside the social movement. It is, therefore, a tool for social interaction.
The sense of “we-ness”	The tattoo represents the unity of the social movement and intensifies the sense of belonging to it. Vegans and vegetarians not only use their tattoos to identify themselves to others both within and outside the movement, they also use them as a symbol of their unity. Vegans, specifically, further enhance the sense of “we-ness” among the members of the vegan group by tattooing the official vegan symbol on their bodies.
Emotional investment	The tattoo acts as a historical landmark of the time when present vegans and vegetarians stopped being meat eaters or consumers of animal-derived products to start a new way of life anchored in their respect for animals. They invest in their tattoos emotions resulting from this process of transformation. The tattoo is then revealed as a means of transformation to a new identity.

## ABSTRACT

Given the lack of public trust in opinion polls, we propose novel approaches to supplement existing methods of predicting political outcomes. Neural similarity and recall of candidates in a televised presidential primary debate accurately forecasted election results. Additionally, the neural data predicted changes in the opinion polls following the debate.

## INTRODUCTION

Even though most voters do not trust public opinion polling (Jackson & Sparks 2017), what alternatives do we have? For most of human history, we could only know what others were thinking by asking them to report it. This subjective account, even when given in earnest, suffers from many shortcomings and biases (Nisbett & Wilson 1977, Griffin & Hauser 1993), and these issues recently gained notoriety as political opinion polls predominantly failed to foresee the United Kingdom's vote to leave the European Union (the "Brexit") and the election of Donald Trump as President of the United States. Complicating matters further, scholars have linked political preferences to irrelevant events occurring close to election day (Healy et al. 2010), unconscious feelings about the physical appearance of the candidate (Todorov et al. 2005), and even our genetics (Fowler & Dawes 2008). Thus, decoding political preferences is a challenging task requiring further research (Mauser & Kopel 1992, Bartels 2002, Lakoff 2008, Hall et al. 2013).

Consumer research, neuroscience, and other fields have provided many methods to passively assess preferences, emotions, and decision-making processes (Berka et al. 2007, Levy et al. 2011, Jost & Amodio 2012, Ely et al. 2015). Given that political campaigns spend billions of dollars on messaging, there is growing interest among practitioners in measuring the effectiveness of these techniques (Aron 2007). Recent work on attention and mind-wandering (Mason et al. 2007) has shown that content that can recruit similar brain activity (e.g., activate the same regions or circuits simultaneously) is associated with engagement (Barnett & Cerf 2015, Hasson et al. 2008). Simply put, a measure of engagement can be derived by assessing the similarity between multiple brains (Hasson et al. 2004).

We measured responses to a live televised presidential primary debate in a natural environment (i.e., a large auditorium, as opposed to a traditional laboratory setting). Unlike prior studies on engagement that focused on neutral or positive stimuli (Hasson et al. 2008, Boksem & Smidts 2015, Barnett & Cerf 2017), we studied reactions to candidates with whom the participants generally disagreed. Also, in general, politics can be controversial, generating strong emotional responses among individuals (Haidt 2012). We theorize that elevated neural similarity will reflect collective, engaged disagreement with the content. When participants already predisposed to opposing the candidates exhibit especially strong, aversive engagement, we hypothesize that the population that prefers those candidates will also be more engaged in voting for them. For example, if Trump makes Democrats' brains more alike—perhaps driven by shared aversion—

our hypothesis suggests that Trump will also be more memorable to Republican brains and ultimately increase his likelihood of earning their votes.

We test neural similarity, survey recall and its sentiment, and continuous ratings of subjective agreement as predictors of both public polling changes and population-level voting results. Unlike polls, which typically interview over a thousand individuals, we present these refined techniques that accurately extrapolate from just dozens to predict the behavior of tens of millions. We report the strength of these predictions and also combine the neural and subjective data to form multivariate model estimates.

## METHODS

### Participants

Twenty-nine participants (7 female) viewed the January 14, 2016 Republican presidential primary debate in a large auditorium. Participants were asked to refrain from talking and excessive movement during the viewing and were paid \$60 for their time.

To select participants who would likely disagree with some or all of the presented content, we screened for candidate preference with a pre-survey. Immediately prior to the debate, the three leading Republican presidential candidates, according to opinion polls, were (in descending poll rank) Trump, Cruz, and Rubio, collectively representing nearly two thirds (65.7%) of the sample population; thus, we only accepted participants that preferred other candidates (i.e., not Trump, Cruz, or Rubio).

### Subjective and Neural Data Collection

On the day of the debate, the participants answered a pre-debate survey regarding demographic information as well as their detailed opinions on each individual candidate and a variety of selected topics (e.g., abortion, gun control, taxes).

Eleven participants were fitted with high performance EEG systems (BrainVision, Morrisville, NC) to measure their neural activity. Sampling was performed at a rate of 250 Hz from sixteen channels, high-pass filtered at 1 Hz, low-pass filtered at 50 Hz, and processed via Independent Component Analysis (ICA) (Delorme et al. 2007, Hyvärinen & Oja 2000) using EEGLAB in MATLAB (Delorme & Makeig 2004). Additionally, for redundancy, headband EEG systems (Muse, Toronto, Canada) with a lower sampling rate and fewer channels were assigned to ten additional participants; however, none of the main acquisition systems failed, so only the BrainVision data were ultimately used.

All of the participants used an online application to continuously report their agreement/disagreement with the content throughout the debate ("How much do you agree with what is being said?" presented on a sliding scale as in many focus groups; cf., Kamberelis & Dimitriadis 2005). Immediately following the debate, a post-debate survey was administered, which assessed political views and candidate recall. Two research assistants independently coded the recall sentiments for each candidate (e.g., favorable/unfavorable).

**Calculation of Neural Similarity**

We calculated neural similarity across every pairwise combination of participants as performed in related techniques with both fMRI (Hasson et al. 2004, 2008) and EEG data (Dmochowski et al. 2012, 2015; Barnett & Cerf 2015, 2017). We used a Fast Fourier Transform (FFT) to select neural data in the alpha frequency spectrum (7.5-12.5 Hz), which has been linked to attentional modulation and engagement (Barnett & Cerf 2015, Boksem & Smitsds 2015, Falk et al. 2012, Ki et al. 2016). We determined the maximally correlated pair of components for each pair of participants (Dmochowski et al. 2012, 2015), and then averaged the correlation levels across all participant pairs to obtain a single value for a 30-second window. We repeated the process for each successive second (i.e., rolling 30-second windows) to obtain a time series of neural similarity throughout the debate.

An underlying assumption with measures of neural similarity is that the relevant correlations are due the simultaneous exposure of a stimulus to multiple brains. If the assumption holds, then data correctly synchronized across subjects would be statistically different than randomly aligned data. We tested this assumption with bootstrapping; we correlated 100-second segments of raw EEG data, again pairwise across participants, but with a random starting point for each subject (i.e., misaligning the data). We found that indeed the assumption holds: the real neural similarity value was significantly higher (1.2 standard deviations, SDs; Z-test:  $p < .01$ ) than the mean of the values computed for 1,000 randomly shuffled segments.

The neural similarity that we attribute to a given candidate (or the moderators or commercials) is assessed in a related way. We compared the correctly aligned data with 1,000 random shuffles (matched in duration); higher z-scores reflected greater neural similarity generated by that candidate.

**RESULTS**

Subjective and neural responses varied significantly over the course of the debate (144 minutes). We analyzed moment-to-moment responses to each of the seven candidates, the two moderators grouped together, and the television commercials. We also studied survey data before and after the debate as well as public opinion polling (aggregated by HuffPost Pollster, 2016 National Republican Primary) and population-level vote totals in the primary elections.

**Engagement with Candidates vs. Other Stimuli**

Since a political debate centers around the candidates, we expected that they would induce greater engagement than the neutral moderators. Indeed, each of the candidates generated higher neural similarity (by .15-2.54 SDs) than the moderators. However, the candidates produced significantly less neural similarity (by 2.42-4.81 SDs) than the comparatively non-controversial and widely engaging television commercials, which were 4.96 SDs more engaging than the moderators.

**Forecasting Changes in Public Opinion Polls**

From the day before the debate (January 13) through the first primary contest (February 1), three of the seven candidates rose in the public polls ( $1.57\% \pm 1.42\%$ ), while the other four fell slightly ( $-.65\% \pm .44\%$ ). On average, a candidate’s poll support changed  $0.30\% \pm 1.47\%$ .

Neural similarity during each candidate’s debate answers forecasted these changes in popular opinion levels ( $r = .67, p = .10$ ). Additionally, the two candidates yielding the highest neural similarity (Rubio and Cruz) showed greatest improvement in public support (3.20% and 0.70%, respectively). However, unlike neural similarity, none of the subjective responses were correlated with with subsequent changes in the candidates’ poll standings ( $p > .70$ ; see Table 1).

**Forecasting Election Outcomes**

Over the course of the Republican presidential primaries (February-May 2016), over 30 million votes were cast for the seven candidates analyzed in this study. Trump’s rival candidates suspended their campaigns (effectively dropping out of the race) at various times. To normalize by campaign length, we divided a candidate’s total votes received by the number of days after the debate (January 14) to the date he suspended his bid for the nomination (or, in Trump’s case, when he had no more rivals after Kasich suspended his campaign on May 4). Christie received the fewest average votes per day of active campaigning (2,135) whereas Trump received the most (126,270). The typical candidate received  $45,813 \pm 43,748$  votes per active campaign day.

*Neural Similarity and Voting Results*

Neural similarity during the debate was strongly predictive ( $r = .79, p = .03$ ; see Table 1) of votes received in the first primary contest (Iowa caucuses, February 1). Additionally, neural similarity was positively linked to candidates’ overall future campaign performance ( $r = .37, p = .41$ ). Statistical significance was reduced by Trump’s vote total being a distinct outlier. Excluding Trump, neural similarity was highly correlated with average votes per active campaign day ( $r = .78, p = .07$ ; see Table 1) over the entire primary season.

*Subjective Responses and Voting Results*

Participant recall of candidates following the debate was closely linked ( $r = .83, p = .02$ ) with eventual voting results throughout the primary campaign. Partitioning the recall data by subjective valence, we observe that this result is predominantly driven by unfavorable recall ( $r = .91, p < .01$ ; see Table 1) as opposed to favorable memory of the candidates ( $r = -.09, p > .80$ ; see Table 1). To wit, aversive memorability among participants who oppose the candidates reliably forecasts population-level voting outcomes.

Furthermore, recall was positively correlated with votes received in the first primary contest ( $r = .69, p = .08$ ), albeit to a lesser degree than its correlation with the aggregate results over all pri-

**Table 1: Correlations of Various Predictors and Political Outcomes.**

Significant predictions were asterisked: \*, \*\*, and \*\*\* denote  $p$  less than .10, .05, and .01, respectively. Trump’s data point was removed as an outlier in one correlation analysis (†).

Predictor	Collection Period	Correlations with Predictor		
		Change in Poll Standings	Results of Iowa Caucuses	Votes Per Active Campaign Day
Neural Similarity	During Debate	.67*	.79**	.78*†
Subjective Disapproval		.06	.60	.44
Total Recall	Following Debate	.00	.69*	.83**
Favorable Recall		.17	-.23	.03
Unfavorable Recall		-.13	.87**	.91***

maries. Again, we attribute this finding to the level of unfavorable recall ( $r = .87, p = .01$ ; see Table 1) versus favorable recall, which was not correlated ( $r = -.23, p > .60$ ; see Table 1) with the results of the Iowa caucuses. Similarly, real-time subjective disapproval of the candidates was associated with higher vote totals on February 1 ( $r = .60, p = .15$ ; see Table 1) and on average throughout the campaign ( $r = .44, p = .33$ ; see Table 1).

**Combining Metrics for Improved Forecasts**

Multivariate models achieved even greater predictive power over voting outcomes (see Figure 1). We performed linear regressions of this form:

$$[Expected\ Votes] = \beta_0 + \beta_1 \times [Unfavorable\ Recall\ (\%)] \dots + \beta_2 \times [Relative\ Neural\ Similarity\ vs.\ Moderators\ (SDs)]$$

This model, which combines subjective and neural data, predicted the results of the Iowa caucuses with notable accuracy ( $r = .98, p < .01$ ;  $\beta_0 \approx 18,388, \beta_1 \approx 1,706, \beta_2 \approx 11,364$ ; see red circles in Figure 1). The regression of the same form was also predictive of votes per day during the primary season ( $r = .91, p < .01$ ;  $\beta_0 \approx 5,425, \beta_1 \approx 4,896, \beta_2 \approx -1,490$ ; see blue diamonds in Figure 1). Note that the model for the Iowa caucuses is weighted heavily by neural similarity whereas the model for the full primary season is more dependent on unfavorable recall.

**DISCUSSION**

We found alternative predictors of three examples of political outcomes: (1) changes in poll standings following the debate, (2) votes received in the Iowa caucuses, and (3) average votes received per active campaign day, which each had a different time scale (on the order of days, weeks, and months, respectively). The recall measures, in particular, improved with longer time; aggregate recall was not at all correlated ( $r = .00, p \approx 1.00$ ) with poll changes, positively associated ( $r = .69, p = .08$ ) with Iowa results, and highly predictive of daily votes over months ( $r = .83, p = .02$ ). Since neural similarity was closely linked ( $r > .67, p < .10$ ; see Table 1) with all three of the political outcomes, its relative effectiveness over the self-report data was greatest in predictions immediately following the debate (e.g., the changes in public opinion polls).

Most of our analysis focuses on candidate-versus-candidate election predictions, but the observation that commercials generated significantly higher neural similarity (more than 2 SDs above the candidates and moderators) is worthy of future study. Of course, commercials are designed to appeal to common denominators and promote consensus around an advertised product, whereas a debate, by definition, presents conflicting viewpoints.

Additionally, in prior studies, neural similarity was linked to collective engagement with neutral or pleasing stimuli, such as movies and advertisements, but our results with contentious content suggest that, regardless of valence, neural similarity is a meaningful measure of engagement. In particular, strong, shared brain responses and self-reported feelings on one side of the political spectrum corresponded with similarly strong behavioral responses on the other side in the form of polling support and votes.

**Limitations**

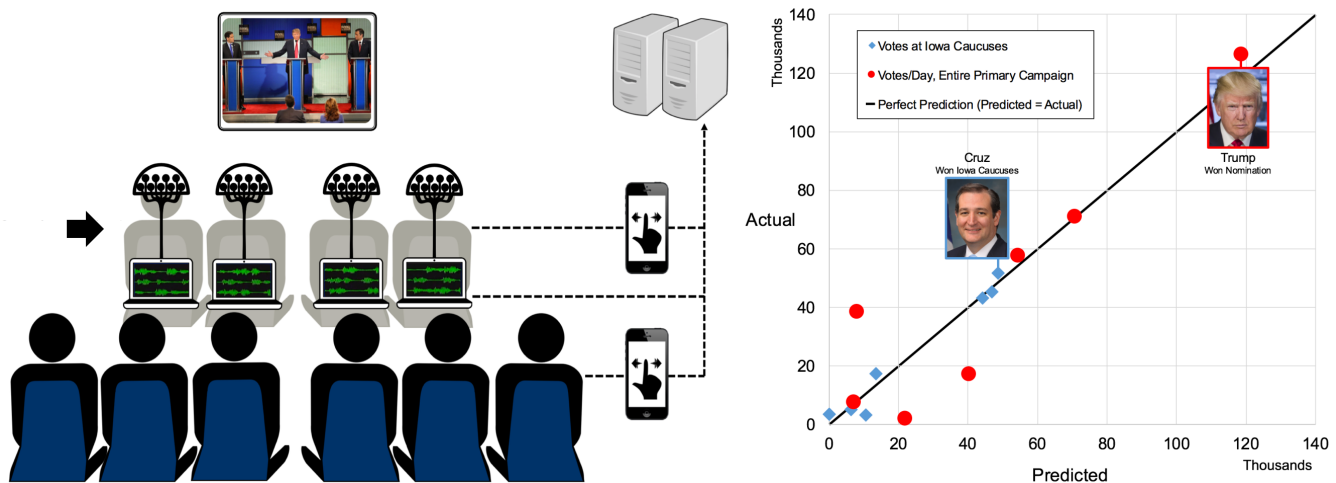

Our use of a live debate enhanced the naturalistic aspects of the participants' experience, but it also meant that we had no control of the stimulus. While seven candidates in a primary debate is a large number in its political context, it is a small number of data points. Similarly, free recall responses are true-to-life, but vary with effort and memory abilities. Furthermore, these responses required manual coding, and although this was performed independently by two individuals, the process introduces subjectivity.

**CONCLUSION**

Elections impact us profoundly, which is why we still pay attention to opinion polls despite not trusting their predictive power. This work demonstrates that certain neural and recall responses can serve as additional predictors of political outcomes. Voters, candidates, policymakers, and consumer researchers all stand to benefit from an increasingly robust set of election forecasting tools, and our proposed techniques contribute to that end.

# The Effects of Subjective Knowledge and Naïve Theory on Consumers' Inference of Missing Information

Lien-Ti Bei, National Chengchi University, Taiwan  
Li-Keng Cheng, National Chengchi University, Taiwan

## ABSTRACT

Consumers form inferences to estimate the missing product information. Three experiments are conducted to investigate how consumers' subjective knowledge influence the inference base used to make an inference and to reveal the correction effects of their naïve theory on the inferred results. The correction effect is noticeable on knowledgeable consumers.

## INTRODUCTION

Consumers are constantly faced with missing product information in advertisements or labels, so they tend to rely on experience or simple cues to infer the quality of the missing attributes of the product in order to decide on a purchase. Past research on this process of inference is mostly focused on the determinants of the results of inferences, but few studies have concentrated on the basis of consumers' inferences, such as a category base or a correlation base. Because consumer's subjective knowledge of products (hereafter referred to as knowledge) affects their belief and decision-making confidence, knowledge may also influence the bases of their inferences. This paper explores how consumers' knowledge affects their bases of inference and subsequent decisions. In addition, when consumers' knowledge level is high, they have confidence in their personal experiences and decision-making; consequently, they may tend to use their naïve theory—that is, people's belief and common sense—to correct their estimation of missing information.

## LITERATURE REVIEW

### Inference and inference basis

Inferences are people's beliefs which are generated through elaboration when they are unfamiliar with or lack information of a product's attributes (Fishbein and Ajzen, 1975). Jaccard and Wood (1988) found that people replaced missing values with the average value of an already known product, and then integrated the known information with the inference to make an overall assessment. However, because of the uncertainty of missing values, this assessment also tended to be adjusted negatively.

Ross and Creyer (1992) proposed that consumers inferred missing product attributes through two approaches. First, consumers estimated the quality or value of the missing attributes by assuming the same attributes as other brands. Second, consumers inferred missing attributes by using other known information of this product. Pechmann and Ratneshwar (1991) proposed that the basis of consumer's inferences for the unknown attribute of a product in comparative advertising were as follows: 1) brand-based inferences, where consumers made inferences based on their beliefs about a particular brand; 2) category-based inferences, where consumers made inferences based on their beliefs about the category of product; and 3) correlation-based inference, where consumers used two relevant attributes to make an inference. Ross and Creyer (1992) further indicated that consumers generally preferred to estimate the missing attribute by using the same attribute of other brands. When the perceived variation of one attribute among different brands was small, consumers believed that their estimation based on the same attribute of other brands was accurate. However, when consumers perceived a high variation on the same attribute of other brands, they had less confi-

dence about their inferences based on other brands. To avoid the risk of inaccurate estimation, they might estimate the missing attribute by using other information known about the focal product—which is a correlation-based inference. Furthermore, some studies found inferences over missing attributes decreased the tendency to choose none of the options and increased purchase intentions (Gunasti and Ross, 2008, Gunasti and Ross, 2015). Based on the above literature, this study proposes the replicated following:

*Hypothesis 1 Consumers tend to use category-based inferences more with missing attributes when the perceived variation of the attribute among other brands is small than when the perceived variation is large.*

### Subjective product knowledge

Consumers used information gleaned from memory and experience when they tried to infer some quality regarding a missing attribute; thus inference was related to a consumer's product knowledge (Brucks, 1985; Park and Lessig, 1981). Brucks (1985) compared consumers' subjective and objective product knowledge and found that subjective knowledge corresponded to a consumer's consciousness about their own product knowledge level, which in turn was related to confidence and the inhibition of seeking other opinions.

Because consumers with low product familiarity considered external cues as easy to understand and use, they preferred to apply external cues for inferences regarding a product's missing attribute. However, consumers with a high degree of familiarity of a product are more confident using internal cues to infer the missing attribute of a product (Park and Lessig, 1981). Rao and Monroe (1988) further found that consumers with high product familiarity have more confidence in using internal cues to draw inferences and they also assume they are able to distinguish the diagnostic value of external cues for their inference. Therefore, consumers with a high product familiarity not only use internal cues to estimate inferences on quality, but also use external clues to make inferences. Based on the above mentioned, this study proposes the following:

*Hypothesis 2 Consumers with high subjective product knowledge use more types of bases for their inferences to estimate missing attributes than consumers with low subjective product knowledge.*

### Subjective product knowledge and naïve theory

When consumers used their beliefs or a known relation between two attributes, they had to rely on their naïve theories. Deval, Mantel, Kardes, and Posavac (2013) define naïve theory as the belief and common sense that exists in people's minds, which is then used to explain and infer events that occur in their daily lives. Therefore, this naïve theory could affect people's judgments and decision-making. For example, one naïve theory could be that "a valuable product is superior in quality to one with a low price" or the opposite one that "quality goods should be expensive."

Petty, Wegener, and White (1998) and Deval, Mantel, Kardes, and Posavac (2013) found that people used their naïve theory as the correcting basis for judgments. Consumers with high levels of subjective knowledge of a product had strong confidence, so they could

use their naïve theory based to correct their inferences (Deval, Mantel, Kardes, and Posavac, 2013; Handley et al., 2009; Petty, Wegener, and White, 1998). As Ross and Creyer (1992) suggested, consumers tend to use correlation-based inferences to estimate a missing attribute when they perceived a high variation on the same attribute of other brands. Thus, when attribute variation is large, both consumers with high or low subjective knowledge will use correlation-based inference to the estimate missing attribute. But consumers with high subjective knowledge also adopt naïve theory to correct the result of inferences.

*Hypothesis 3* When consumers perceive the attribute variation as large, consumers with high subjective knowledge are more likely to use naïve theory to correct the results of their inferences regarding the missing attributes than consumers with low subjective knowledge.

## STUDY 1

### Method

A total of 87 undergraduate students participated in Study 1. Contact lenses were selected as the focal product. The students were randomly assigned to one of four conditions in a 2 (subjective knowledge: high or low)  $\times$  2 (attribute variation: large or small) factorial experiment. Knowledge was measured on a four-item four-point scale. Participants were divided into high and low knowledge groups based on median split. Attribute variation was manipulated by varying oxygen permeability from 149 to 155 DK/t and maximum continuous wearing days from 10 to 18 days.

All participants received an experimental booklet in which the first page provided an article about disposable contact lenses by *Consumer Reports*. The manipulation was presented in an information table with five brands and five product attributes, including product type, continuous wearing days, oxygen permeability, water content, and price. Among these attributes, oxygen permeability affects maximum wearing days; therefore, the positive relationship between these two attributes was designed for the correlation-based inference.

After participants read the article, they were asked to estimate the maximum wearing days of a new disposable contact lens that Johnson & Johnson recently launched. This new product had all other attribute information except the wearing days. Then, participants were requested to write down their reasons for their estimation concerning this missing attribute. Finally, participants answered a series of questions that measured subjective knowledge and manipulation checks.

### Results

Based on the inference classification by Pechmann and Ratneshwar (1991), plus the price-based inference that commonly existed in people's naïve theory, the participants' inference reasons were classified into four inference bases: brand-based inferences, category-based inferences, correlation-based inferences, and price-based inferences. Then, participants' inference reasons were coded, and calculated the total number of inference bases used.

When attribute variation was small, 43% of participants used a category-based inference to estimate the missing attribute. When attribute variation was large, only 23% of participants used a category-based inference (see Table 1). The result of a Chi-square analysis indicated that participants preferred to use a category-based inference on the missing attribute more when the attribute variation was small as opposed to high ( $\chi^2_{(1)}=3.89, p=.049$ ).  $H_1$  was supported.

There was no significant difference on the average amount of inference bases used between high and low knowledge participants ( $M_{\text{High Knowledge}}=1.43$  vs.  $M_{\text{Low Knowledge}}=1.30, t_{(85)}=1.14, p=.258$ ). Hypothesis 2 was not supported.

### Discussion

Study 1 supported the expectation that consumers prefer to use category-based inferences on missing attributes when they perceive the attribute variation in the market is small rather than large. However, the influence of consumers' subjective knowledge on the inference basis was not verified. There were two possible explanations for this unexpected result. First, the brand of the newly launched product was Johnson & Johnson, which is famous and participants with high product knowledge tend to use more brand-based inferences, which interfered with the results. Second, the relation between oxygen permeability and maximum wearing days in the manipulation was too strong to be ignored. So, even participants without knowledge could use it to infer the missing value.

## STUDY 2

### Method

Study 2 was similar to Study 1, with some alterations to overcome previous weakness. In the product information table, the correlation coefficient between the oxygen permeability and maximum wearing days was reduced from .94 to .68, and Johnson & Johnson was replaced with a fictional new brand.

Furthermore, the estimated wearing days was designed to signal the inference bases. When participants inferred the maximum wearing days was 18 days or more, it implied they might use the correlation between oxygen permeability and the maximum wearing days to draw their inference. When participants estimated the maximum wearing days were 14 days, it was likely that they would use the average maximum wearing days of the product category, which is category-based inference.

### Results and discussions

Participants were comprised of 107 undergraduate students. The proportion of participants using category-based inferences was higher when the attribute variation was small rather than large ( $M_{\text{Small Variation}}=35\%$  vs.  $M_{\text{Large Variation}}=14\%, \chi^2_{(1)}=7.06, p=.008$ , see Table 1). In addition, the amount of inference bases used by participants with knowledge was significantly higher than those without knowledge ( $M_{\text{High Knowledge}}=1.38$  vs.  $M_{\text{Low Knowledge}}=1.16, t_{(105)}=2.27, p=.025$ ). Both  $H_1$  and  $H_2$  were supported.

When the attribute variation in the market was large, participants with a low knowledge level inferred more wearing days than those with a high knowledge level ( $M_{\text{Low Knowledge}}=17.03$  (sd=2.04)  $>$   $M_{\text{High Knowledge}}=15.20$  (sd=2.02)) significantly ( $t_{(57)}=3.464, p=.001$ ). Further analyses revealed that less knowledgeable consumers used more correlation-based inferences (66%) than other bases. High subjective knowledge consumers not only used correlation-based inferences to estimate the missing value (60%), but also they used price-based inferences to correct the estimation ( $M_{\text{High Knowledge}}=53\%$  vs.  $M_{\text{Low Knowledge}}=21\%$ ).  $H_3$  is supported.

In sum, Study 2 reconfirmed  $H_1$  and  $H_2$ . It also found that consumers who had a high level of subjective product knowledge and more confidence used more correlation-based inferences. They also used their naïve theory to correct the inference for the missing attribute. However, Study 2 did not provide the correction effect of consumers' naïve theory directly. Consequently, Study 3 manipulated

**Table 1: The frequency of inference bases used by different levels of subjective product knowledge and attribute variation in three Studies**

	Inference Base	Attribute Variation			Inference Base	Attribute Variation

the naïve theory directly and revealed the correction effect of naïve theory explicitly.

### STUDY 3

#### Method

In Study 3, the naïve theory “quality goods should be expensive” was activated in participants to reveal the stronger correc-

tion effect by consumers with a high knowledge level versus a low knowledge level. The activation of the common naïve theory “quality goods should be expensive” could make it more accessible and applicable on inference correction. A total of 172 undergraduate students participated in Study 3. The students were randomly assigned to one condition of a 2 (Knowledge: high or low) × 2 (Variation: large or small) × 2 (Naïve theory: yes or no) factorial experimental setting. Naïve theory was activated by a short passage. Also, the new

focal product with a low-profile brand, Hydron, was given a relatively low price, so the correction effect of the naïve theory could be revealed on the fewer wearing days attribute.

Participants were invited to participate in two unrelated experiments. First, participants read a passage about travel and then completed a reading test. The passage had two versions: one was about how travelers might encounter many problems if they sought a cheap travel package; this was done in order to activate the naïve theory, “quality goods should be expensive.” The other passage was an article about travel with neutral attitudes. After completing the reading test, participants were invited to continue the second experiment which was the same as Study 2.

## Results and discussions

This study supported  $H_1$  and  $H_2$  again. Participants used more category-based inferences when the attribute variation was small ( $M_{\text{Small Variation}} = 52\%$  vs.  $M_{\text{Large Variation}} = 29\%$ ,  $\chi^2_{(1)} = 8.87$ ,  $p = .003$ , see Table 1). Furthermore, knowledgeable participants used more inference bases than novice participants ( $M_{\text{High Knowledge}} = 1.43$  vs.  $M_{\text{Low Knowledge}} = 1.22$ ,  $t_{(170)} = 2.00$ ,  $p = .047$ ).

A three-way ANOVA indicated a significant interaction effect among participants' subjective product knowledge, attribute variation, and naïve theory on the estimation of maximum wearing days ( $F_{(1, 164)} = 4.133$ ,  $p = .044$ ). In the group without naïve theory activation, participants inferred more wearing days when the attribute variation was large rather than small ( $M_{\text{Large Variation}} = 16.74$  ( $sd = 2.31$ ) vs.  $M_{\text{Small Variation}} = 14.05$  ( $sd = 1.36$ )). This difference suggested that participants used more correlation-based inferences when attribute variation was large ( $M_{\text{Large Variation}} = 76\%$  vs.  $M_{\text{Small Variation}} = 30\%$ ). Conversely, participants used more category-based inferences when attribute variation was small rather than large ( $M_{\text{Small Variation}} = 48\%$  vs.  $M_{\text{Large Variation}} = 26\%$ ).

When participants' naïve theory was activated and faced a small attribute variation, they estimated the maximum wearing days was 13.98 ( $sd = 1.03$ ), almost equal to 14, whether they were knowledgeable or novices. This estimation implied that participants tended to use category-based inferences (56%). When the attribute variation was large, knowledgeable participants inferred less wearing days than novice ones ( $M_{\text{High Knowledge}} = 14.75$  ( $sd = 2.20$ ) vs.  $M_{\text{Low Knowledge}} = 16.70$  ( $sd = 1.74$ )). Since knowledgeable and novice participants both used correlation-based inferences more than other bases, 30 and 23 counts respectively, the estimated fewer wearing days made no sense unless it was due to the correction effect of their naïve theory.

## GENERAL DISCUSSIONS AND IMPLICATIONS

The contributions of this paper are twofold. First, when consumers noticed a small attribute variation in the market, they preferred to use category-based inferences to estimate the missing attribute. On the contrary, when consumers perceived a large attribute variation, they tended to use correlation-based inferences to form the estimation. The current results coincided with Ross and Creyer (1992) and further found that knowledgeable consumers used more types of inference bases to estimate the missing value.

Second, this paper disclosed the correction effect of naïve theory on inferences. When the naïve theory, “quality goods should be expensive,” was activated in knowledgeable consumers, they used it to correct the inference of missing attribute. Conversely, the correction effect was not observable on less knowledgeable consumers because their naïve theory was not strong enough. Future research may try to use other products requiring different levels of product knowledge to make a purchase decision to confirm the effect of naïve theory on inference.

# How Regional Diasporic Consumer Experiences Produce Transnational Imaginary

Mark Buschgens, RMIT University, Australia  
Bernardo Figueiredo, RMIT University, Australia  
Kaleel Rahman, RMIT University, Australia

*“Because we are people from the same region,  
we are from the same country,  
we do share the same mentality as a Middle Easterner”  
Informant #024*

## ABSTRACT

This paper examines individual experiences of regional diaspora consumers and how they combine to produce a transnational consciousness and belongingness in the marketplace. In-depth interviews with Middle Eastern diaspora identify five emotions to construct a transnational imagined Middle Eastern world through three elements of re-enactment. Implications for marketing are discussed.

## INTRODUCTION

In the wake of globalization migration has risen sharply, resulting in large diasporic consumer groups who possess cultural identities distinct from their host country and maintain powerful attachments to their home culture (Fernandez et al., 2011; Takhar et al., 2012). As the quote above indicates, individuals can imagine themselves as belonging to a transnational community and home culture that extends beyond their national origin. For example, Maha may originate from Yemen, yet living in Australia can connect to a sense of imagined home through media from the greater Middle East region. Her consumption of television programs from Egypt, foods from Lebanon, and imported brands from Turkey all serve as mediators of a shared consciousness and belongingness to a transnational Middle Eastern world. Understanding the consciousness and belonging of growing diasporic communities like in Maha's case is important because these connections are a known determinant of consumer's lifestyle and consumption practices (Vadakepat, 2015; Figueiredo, 2015; Cappellinim and Yen, 2016).

However, while a growing body of marketing and consumer research examines the nature of individuals originating from a national homeland, to migrate and settle in another location (Mehta and Belk, 1991; Kumar and Steenkamp, 2013), the specific ways through which consumers engage with these experiences to construct their transnational experience have not been directly studied. As such this research adopts a transnational view of regional diaspora consumers and how their experiences combine transnationally (Figueiredo and Uncles, 2015; Chelekis and Figueiredo, 2015). That is, how individuals from separate national homelands enact strong connections to an imagined community of people who feel belonging to the same region, despite not being born in the same country. Understanding transnational communities such as the Middle Eastern diaspora is important in marketing because they reflect large consumer segments that need to go beyond an emotional connection to their national homeland to cultivate a sense of shared consciousness and belonging at a higher, transnational, level (Craig and Douglas, 2006; Cayla and Eckhardt, 2008).

## THEORETICAL BACKGROUND

In this paper we draw from Appadurai's (1990; 1996) theoretical insights on globalization, transnational identity and self-imagining to better understand the sense of consciousness and belonging of regional diaspora and how their individual experiences combine to construct transnational connections. This corresponds with Ander-

son's (2006) concept of 'imagined communities', whereby various commercial mediums (i.e. books, cinema, brands) allow individuals who may never meet to 'imagine' themselves as being part of the same group. Prior literature in consumer research has highlighted the importance of imagined communities for transnational brands and those targeting ethnic markets (Cayla & Eckhardt, 2008; Wu et al., 2013), but has not discussed how consumers create and maintain emotional bonds with these imagined communities. Adopting the Australian-Middle Eastern community as a research context, our aim is to understand *how the sense of consciousness and belonging of Middle Eastern diaspora's help foster a Middle Eastern imaginary.*

Prior research in consumer research has recently taken increased interest in diasporic communities as consumers (Takhar et al., 2012; Dey et al., 2017). Many of these studies focus on how forms of media can speak to a diaspora by conveying a sense of national imagined community. For example, Takhar et al., (2012) examined how Bollywood films from India conveyed a sense of Indianness to Indian diaspora in the UK, including reaffirming pride in Indian heritage and reinforcing family values. From an acculturation standpoint, Dey et al., (2017) investigated the lifestyle and cultural identity of South Asian diaspora communities in Brittan and ways individuals exhibit multiple cultural identities between their respective national origin and place of living. However, these existing studies are inadequate for understanding how individual experiences of a regional diaspora combine to establish a sense of shared consciousness and belonging to a transnational community. Cayla and Eckhardt (2008) come close, having explored how brand managers contribute to creating a shared belonging and consciousness in the Asian region by placing emphasis on the globalization of Asia and market-mediation work performed by brands. But, their study focuses on the material produced by brands, and therefore does not provide insight into how the transnational imagination is emotionally experienced, which is surprising given the amount of work relating emotional experience with a sense of belonging and collective consciousness (Cova and Cova, 2002; Gentile et al., 2007). Hence, this paper builds on these prior constructs by focusing specifically on how the emotional experiences of a diverse Middle Eastern diaspora helps create a sense of transnational belonging and consciousness to a Middle Eastern imaginary.

## METHODOLOGY

Our study took a phenomenological approach (Moustakas, 1994) to understand the individual experiences of Middle Eastern diaspora and how they combine as a transnational imagined community. We conducted semi-structured in-depth interviews (Belk et al., 2012) ranging from 35 to 95 minutes with 30 individuals (12 female) from diverse countries in the Middle East living in Melbourne, Australia. Informants were selected based on being first generation migrants that self-professed to maintain connection with their home culture at some level. Informants originated from various homelands in the Middle East, including Iran, Saudi Arabia, Jordan, Yemen, United Arab Emirates, Lebanon, Egypt, Turkey, Iraq and Morocco and had lived in Australia for less than 10 years. Prior to each interview, informants were asked to take photographs of items in their possession from their homeland that held particular significance to them. During interviews, questions were asked regarding the informant's experiences with the stimuli depicted in the photos. Data

analysis involved an iterative reading strategy to develop a holistic understanding of each interview transcript (Thompson et al., 1989). The first author identified significant statements yielding insight into how the sense of consciousness and belonging of each individual's experience combined as transnational. Statements were then triangulated with the second and third authors and subsequently categorized into themes (Spiggle, 1994).

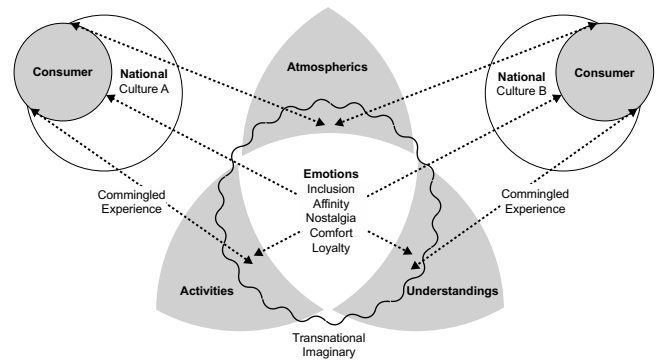

## FINDINGS AND DISCUSSION

From our interviews with Middle Eastern diaspora, we found the transnational experience manifests as a double consciousness (Du Bois, 1903) in reverse, which we call 'commingled-experience'. Double consciousness is an established concept in social philosophy that refers to the inward "twoness" experienced by African-Americans because of their racialized oppression and devaluation in a white-dominated society. In the commingled-experience, the twoness is not necessarily oppressive; instead it expresses itself as a capacity to be aligned both with a national culture and a transnational imaginary. In this sense, the term 'commingled' functions as a metaphor for describing how the individual experience of a diverse regional diaspora blends as Middle Eastern consciousness. Having an understanding of the role of emotions in fostering these commingled-experiences is important as it can help brands serve as an emotional and experiential platform for diverse diaspora groups to maintain transnational ties to an imagined regional homeland. Thus, we shift the focus of the analysis to emotions constituting the commingled-experience of a transnational imaginary, and the specific re-enactment components by which they exist.

The data analysis revealed five emotions that help create a sense of transnational belonging and consciousness to a Middle Eastern imaginary. The emotions were identified as: 1) *inclusion* (belonging and kinship); 2) *affinity* (rapport and like-mindedness); 3) *nostalgia* (longing for what was lost); 4) *comfort* (contentment and eased tension) and 5) *loyalty* (commitment and support). Each emotion does not follow any ordered hierarchy and thus may at times overlap and intertwine. In their experiences, these emotions emerge through three elements. The first element, *atmospherics*, performs emotions of the transnational imaginary via sensory representations. The second element, *understandings*, performs emotions of the transnational imaginary by re-enacting social comprehension and cultural values. The third element, *activities*, performs emotions of a transnational imaginary through the re-enactment of behaviours and everyday tasks. Since the Middle East takes imaginary form and is not a given, these elements of re-enactment become necessary, as Sökefeld (2006) points out that people need to be mobilized through certain events and practices to construct these imaginings (See Figure 1).

### Atmospherics

The first element to re-enact the transnational imaginary is *atmospherics*, which have previously been discussed as representational 'cues' composed of "any component within an individual's perceptual field that stimulates one's senses" (Milliman and Fugate, 1993, p.68). These cues may include temperature, noise, decoration, and scent, to name a few. *Atmospherics* are important in consumer research for creating value perceptions (Schmitt, 1999), and operationalizing pleasure and arousal (Babin and Dardin, 1995). In our interviews, informants described experiencing different emotions toward the Middle Eastern imaginary, such as *inclusion*, through sensory forms of representation. For instance, a female respondent from Saudi Arabia felt personal sense of belonging and kinship to patterns and other design elements embedded in the visual aesthetics of an Australian fashion brand (Table 1, Quote A). Note she describes her

**Figure 1: Framework for how regional diaspora consumer experiences produce transnational imaginary**

experience with the brand's visual aesthetics as representative of the person she is and her own life story. While she had previous experience with the designs from Saudi Arabia, their material presence on the brand mobilized a sense of kinship to a transnational identity beyond her national origins, such as the greater 'Arab' community. In addition to fostering *inclusion*, several informants expressed emotions of *loyalty* to a transnational imaginary through re-enacted experiences with atmospheric representations in diaspora. For example, an Iraqi man shared his experience visiting a Turkish mosque in Australia (Table 1, Quote B). Observe how the mosque's unique architecture and design creates a strong sense of commitment and *loyalty* to return there even though it is not convenient, due to certain *atmospherics* from another nation helping to mobilize a transnational connection akin to his homeland. These findings on *atmospherics* help contribute to our understanding of sensory consumer experiences (Gentile et al., 2007; Schmitt, 1999) by showing how different national forms of representation can use material similitude to leverage emotions associated with the transnational imaginary.

### Understandings

The second element to re-enact a sense of Middle Easternness is *understandings*, which have been described as "discourses, cultural tropes, or value systems" (Woermann and Rokka, 2015, p.1498) comprehended through social interaction. *Understandings* are important for activating shared knowledge (Gupta, 2008) and reflecting cultural values of intended audiences (Zubcevic and Luxton, 2011). Our informants described experiencing emotions such as *comfort* within the Middle Eastern imaginary as emerging from re-enacted ways of comprehending their commingled-experience. For example, a Yemeni informant describes how being in the company of others from the Middle East community makes living in diaspora easier (Table 1, Quote C). Notice here that he was able to experience a sense of *comfort* and eased tension through having common *understanding* through his interactions with other Middle Eastern nationalities such as Iran and Kuwait. Informants also experienced emotions of *affinity* to the transnational imaginary as re-enacted through shared *understandings*. For example, a Moroccan informant spoke about the 'Angry Arab' persona, saying it helped him connect and build a sense of rapport and like-mindedness with an Iraqi friend living in Australia (Table 1, Quote D). Here we see the 'Angry Arab' persona extends beyond any one specific nation, being transnationally acknowledged and understood. There is a level of comprehension and 'getting one another' that mobilizes this sense of *affinity* to an imagined community that goes beyond his own country. While *atmospherics* provide sensory experiences through material forms of representation, *understandings* are more phenomenologically experienced being intellectually and socially transmitted through interaction. Hence, *understandings*

Table 1: Findings

		Elements of Re-enactment		
		Atmospherics	Understandings	Activities
Emotions	<b>Inclusion</b> Emotion of belonging and kinship	<b>QUOTE A.</b> Informant #021: "This is the shop that it's left me that, they have a Arab design. It reminds me that this is me, this is my life. This is where I grow up and I'm proud of that. When you see something that reminds you of this places, you feel like 'this is me' more than anything else."	Informant #006: "There are a lot of things that are similar actually, it is important for me, because it is my branding at first, also I think that if I live without my culture, you can't live...if you live without your culture you live without branding, so you will live without anything. But Islamic culture, Middle east culture...that's the main thing, my culture is important for me."	Informant #23 "...Once I was even at a barber shop, I just remember this, and the guy was Iraqi, and he was using a gel that is manufactured in Lebanon. I was like, "Do you know if that is made in Lebanon?" He was like, "Oh, is it?" I was like, "Yeah, I used to use that product on my hair."
	<b>Affinity</b> Emotion of rapport and like-mindedness	Informant #010: "Sitting in there, the scenario, the decoration and the atmosphere there, just prompts you to bring up memories and remember and tell about your life (homeland)... the other person is the same. So everyone, it brings up memories."	<b>QUOTE D.</b> Informant #016: "You know there is this very funny stereotype that Arab men are angry. I don't have to be politically correct because I am one of them, so you know, it kind of takes the edge off me. ...he (Iraqi friend) showed up late one time, we were having lunch with him, and I pretended to be angry at one point, looking at my watch in a demonstrative Arab guy kind of way, and that goes by easily because he knows where I am coming from."	Informant #015: "I usually call my friend over and we have dinner together, or sometimes we go out together to eat, and we go to a Middle Eastern place, like on Sydney road there are a lot of Middle Eastern places".
	<b>Nostalgia</b> Emotion of longing for what was lost	Informant #005: "Being in Australia right, it's nice to see something like that, and they also made it axiomatizing, or a Middle Eastern thing where it was like a tent kind of thing..."	Informant #004: "I saw a mother and her little son, when I saw that woman I remember my mother, and I saw a family...they were together and the father played with his little girl. And their connection was similar."	<b>QUOTE F.</b> Informant #027: "There is a "Best Foods" in Brunswick... I love going there, because not only Turkish things, they have all Middle Eastern ingredients and things and cultural things, for example coffee cups. I love them".
	<b>Comfort</b> Emotion of contentment and eased tension	Informant #003: "It makes me feel comfortable, it makes me feel calm...it feels like I am there. We are not Muslims actually, but mosques, for us...because they are common in that culture, I remember when I was young I went with my grandfather there...and it feels very comfortable there".	<b>QUOTE C.</b> Informant #008: "I am actually living with Iran and Kuwait guys, so yeah, we do totally feel connected to that... we can find it much easier to interact with people from the same cultural background, yeah its much easier...majority I think, like almost 90% of things we have in common, its just a little bit of differences, which is unnoticeable".	Informant #17 "...the things that are handmade in Iran, like, we got these, you might have seen it in the Middle East, we have these tiny cups that they drink tea in it. I asked my parents to bring it for me but they forgot, but I really want to have one in here."
	<b>Loyalty</b> Emotion of commitment and support	<b>QUOTE B.</b> Informant #012: "I go to the Turkish mosque I see more and feel like my country more... I am back in my home country. It is strong feelings to remember my country. But the places here in the city that are close, they don't have this. But the Turkish mosque...similar to my country, they have this kind of architecture or design...the first time I was crying to be honest."	Informant #024: "The music I think its the Middle Eastern, could be music almost the same... especially in Iraq, most of Iran music came from Turkey and beyond. When we meet people from the same region, we are friends from the same country because we are from the same region. We do share the same mentality as a Middle Easterner."	<b>QUOTE E.</b> Informant #018: "I can't drink any other type of coffee in the morning, it has to be this coffee, it is Turkish in origin, but we get 'home'. It comes in small cups of powder and you boil it. It has to be my morning coffee".

help contribute to furthering Gentiles et al. (2007) cognitive and relational components of consumer experience concerned with thinking process and social relationships (Woermann and Rokka, 2015) by demonstrating how shared forms of comprehension can help re-enact commingled-experiences of a transnational imaginary.

**Activities**

The third element to re-enact the emotions of a Middle Eastern imaginary is *activities*, made up of actual behaviours such as tasks performed by someone like preparing dinner or putting on clothes (Dayal et al., 2013). In consumer research, such *activities* are described as practical acts of doing things, and are known to be important for enhancing user experiences (Gentile et al., 2007) and better understanding behavior (Brakus et al., 2009). In our interviews, informants described experiencing commingled emotions such as *loyalty* to Middle Easternness through the re-enactment of particular tasks from their homeland. For example, an informant from Jordan detailed his morning ritual (Table 1, Quote E). Here the informant expresses loyalty to Turkish coffee, discussing it as giving a feeling of 'home' despite his homeland being Jordan. Many of our informants from around the region described similar situations where they prepared things like coffee in similar way. Informants also discussed experiencing emotions of *nostalgia* to a transnational imaginary (Rahman and Cherrier, 2010). For example, a Turkish informant talked about her love for visiting stores that allow her to cook familiar foods and purchase items from the greater Middle East region (Table 1, Quote F). You will notice here that items such as ingredients and cups allow her recreate a sense of home that was lost in diaspora that extend

beyond her home nation. While *atmospherics* provide sensory experiences through ways of representing and *understandings* provide phenomenological experiences through ways of comprehending, *activities* tend to be more practical and based on everyday tasks and behaviors (Gentile et al., 2007, Brakus et al., 2009). *Activities* help contribute to understanding of the pragmatic and lifestyle components of consumer experiences by showing how the Middle Eastern imaginary can be mobilized through shared behaviors.

**IMPLICATIONS AND CONCLUSION**

Two significant implications stand out. First, our findings extend current knowledge of diaspora marketing by explaining commingled-experience, a concept specific for helping cultivate the double consciousness of the transnational imagination. For example, the experiences of individuals from diverse nations in the Middle East may be able to combine to produce a sense of belonging and kinship (*inclusion*) to a larger Middle Eastern community through elements of re-enactment such as certain decorations and other *atmospherics* used in store environments. Second, by examining how the individual experiences of regional diaspora allow them to think beyond their own nation, without rejecting their national cultures, this research contributes toward a better understanding of diasporic consumer experiences in the global marketplace. Even more specifically, understanding the transnational imagination of migrant consumers like the Middle Eastern diaspora helps advance prior work on transnational consumption (Bardhi et al., 2012), because it reveals the role of shared material designs, understandings and activities in helping instil emotions that support the transnational imaginary. Ad-

ditionally, this study can also contribute to the literature in customer experience (Lemon and Verhoef, 2016) by adding extra layers of understanding to the creation of transnational experience of diaspora consumers. However, due to limited space we could not develop this line of research further.

This paper has investigated how the consciousness and belongingness of individuals from a Middle Eastern diaspora can connect to produce commingled-experiences of Middle Easternness outside the Middle East. We identified five distinct emotions in the commingled-experiences of a transnational imagined Middle Eastern world that are performed through three elements of re-enactment. Explanations of each finding helps to benefit prior work in diaspora marketing (Kumar and Steenkamp, 2013) and transnational consumption (Bardhi et al., 2012) by showing how the commingled-experiences of diaspora co-create the transnational imagination.

# A Beautiful MIN(D): The Multiple-Identity Network as a Framework for Integrating Identity-Based Consumer Behavior

Julian K Saint Clair, Loyola Marymount University, USA

## ABSTRACT

It is now established that individual consumers have multiple identities that drive consumption behavior. Although multiple-identity research is growing, it has yet to adopt an integrative framework. Drawing on classic social-cognitive theories, the present research offers a simple, unifying model: the Multiple-Identity Network. Extant and future research are discussed.

## KEYWORDS

Identity, Self, Self-Concept, Cognition, Association, Categorization

## INTRODUCTION

Consumer self-concept has a profound impact as a driver of consumption behavior (Belk, 1988). Recent marketing research has begun to systematically review the work on consumer identity. This work reveals two main bases for identity-based consumer behavior: identity-congruent consumption (A. Reed, Forehand, Puntoni, & Warlop, 2012) and compensatory consumption (Mandel, Rucker, Levav, & Galinsky, 2017). Importantly, identity research has also acknowledged that consumer self-concept is comprised of multiple distinct identities (for a review see Kang & Bodenhausen, 2015). For example, a consumer may have a gender identity (e.g., female), a national identity (e.g., American), a cultural identity (e.g., Asian), and occupational identity (e.g., Mathematician), or a lifestyle identity (e.g., Athlete; see figure 1). An important question looms large following the recent reviews of consumer identity research: How do consumers manage the complex processes required for both congruent and compensatory consumption behaviors across their multitude of identities? Answering this question calls for identification of a framework in which to synthesize consumer identity research, going beyond the taxonomic approach used in prior literature. Such a framework allows for more systematic advancement of the literature. This is the primary focus of the present research.

## IDENTITIES AND THE MULTIPLE IDENTITY NETWORK

What is an identity? Reed et al. (2012) suggest a definition of identity that is inclusive enough to consolidate streams of literature conducted in different domains, but also distinguishes an identity from other concepts such as a simple self-view or a self-association. They define identity as “any category label to which a consumer self-associates, either by choice or endowment” (A. Reed, et al., 2012, p. 312).

Reed and colleagues go on to say that a category label evokes a clear mental representation of the prototypical category member: their appearance, attitudes, behaviors, etc. Thus, each self-associated category label, or identity, has its own subset of associations that includes behaviors, attitudes, beliefs, norms, goals, and other associated concepts (Coleman & Williams, 2013; Oyserman, 2009). Following this, one can say that at the fundamental level, identities are groupings or collections of self-associated concepts<sup>1</sup> (McConnell, 2011; A. Reed, et al., 2012).

<sup>1</sup> To be clear, an identity is not a single self-association, but a collection of self-associations. It is similar to the concept of a “social category.” However, social categories imply that identifying a group of similar individuals is requisite for category formation, and this assumption is not present in the current paper’s conceptualization of identity.

**Definition 1: Identity.** A collection of self-associated concepts.

Focusing on identities as collections of self-associated concepts allows us to more clearly draw comparisons between identities and other theoretical constructs in the study of social cognition. For example, consumers store collections of concepts (i.e., categories) like “dogs,” “chairs,” “Apple users,” or “Nike products” in memory in associative networks (Bagga, Noseworthy, & Dawar, 2016; Lajos, Katona, Chattopadhyay, & Sarvary, 2009; Noseworthy & Goode, 2011; Noseworthy, Wang, & Islam, 2012; Rosch, Mervis, Gray, Johnson, & Boyesbraem, 1976). If identities are also collections of self-associations, then it follows that *identities are also cognitively stored within an associative network* (Greenwald et al. 2002; McConnell 2011). We refer to the associative network of consumer identities as the Multiple-Identity Network.

**Definition 2: Multiple-Identity Network.** The associative memory network that contains a consumer’s multiple identities.

**Figure 1: Multiple-Identity Network of a Hypothetical Consumer**

Note: Dashed lines represent negative associative relationships

Below, we integrate consumer identity research within this framework, describing how identity congruence, discrepancy, and resolution can be represented in the MIN. We also identify areas for future research.

## MULTIPLE-IDENTITY CONGRUENCE

### Bipolar Identity Paradigms

Investigating identity-relevant behavior in multiple-identity paradigms is an area in need of further research (Kang & Bodenhausen, 2015). Current work in the area shows that consumers generally behave congruently with an active identity despite the existence of an alternate identity with a different pattern of consumption behavior (Coleman & Williams, 2013; LeBoeuf, Shafir, & Bayuk, 2010; Luna, Ringberg, & Peracchio, 2008; Mercurio & Forehand, 2011; Zhang & Khare, 2009).

These paradigms often use the context of bicultural identity (e.g., Asian vs. American identity), and they generally use bipolar opposition to assess outcomes following identity activation (Briley, Morris, & Simonson, 2005; Lau-Gesk, 2003; Mok & Morris, 2013). For example, purchasing an interdependent product that signals group membership is behaving congruent with Asian-identity priming. This is inherently avoidance of an independent product that signals distinctiveness, congruent with the alternate (non-primed) American identity. Given the notion of the MIN, these bipolar paradigms may be masking a richer pattern of effects.

### Future Directions: Alternate-Identity Effects

Following a basic tenet of associative network theory (Collins & Loftus, 1975; Dimofte & Yalch, 2011; Lei, Dawar, & Lemmink, 2008; Morrin, Lee, & Allenby, 2006), identities within the MIN may be positively or negatively associated with one another (or not associated at all: “dissociated”).

Let us suppose that our Asian-American consumer’s Asian identity is positively associated with her Female identity because both are associated with the traits of interpersonal warmth (Fiske, Cuddy, Glick, & Xu, 2002; Fournier & Alvarez, 2012). Spreading activation (e.g., Dimofte & Yalch, 2011) would predict that activation of the Asian identity would also activate the Female identity because the two are positively associated. Therefore, the consumer may have increased likelihood to purchase products from Asian brands as well as products targeted toward females. In other words, a consumer primed with identity A might also approach identity B. This dual-approach effect is underexplored in identity priming research, and would be obscured by a bipolar paradigm.

Let us also suppose that the consumer’s identity as an Athlete is associated with the trait of aggression (Coleman & Williams, 2013). Aggression may be considered a bipolar opposite to warmth. The athlete-aggressive association may thus be negatively associated with the female-warm association. Activating the Female identity may therefore lead consumers to avoid Athlete-targeted products. This type of downstream consequence is also underexplored in identity research.

Taken together, it becomes clear that future work should explore alternate-identity effects of identity priming given the existence of inter-identity relationships within the MIN.

## MULTIPLE-IDENTITY DISCREPANCY

### Self-Discrepancy

Mandel and colleagues (2017) describe six types of self-discrepancy in their review: intelligence, personal freedom, power, social exclusion (i.e., belongingness), system threat (i.e., control), and group exclusion. These self-discrepancies can be readily integrated into the MIN to situate the current work and identify areas for future research.

Group exclusion may be conceptualized as discrepancy between one’s actual and desired level of group affiliation (Mandel, et al., 2017). Group exclusion may thus be represented in the MIN by a salient negative association between the self and a group-identity.

In the present definition of identity, identity content can include attributes. Each of the remaining forms of self-discrepancy can therefore be conceptualized in the MIN as negative associations between the self and the desired attributes. Seminal conceptualizations of self-discrepancy (Higgins, 1987) describe these collections of desired attributes as “ideal self” (i.e., the attributes one ideally would like to have) and “ought self” (i.e., the attributes one ought to have). Within the MIN, we can refer to these as “ideal identity” and “ought identity.” Taken together, ideal identity, ought identity, group identities, and their subassociations are sufficient to integrate the extant self-discrepancy work within the MIN. This allows us to more readily proceed to exploring areas of future research.

### Future Directions: From Discrepancy to Inconsistency

Per Higgins (1987) seminal research, the notion of discrepancy within the self was initially described by prior work that was largely focused on cognitive inconsistency, such as cognitive dissonance (Festinger, 1957) and imbalance (Heider, 1958). The MIN allows us to reconsider self-discrepancy more broadly, beyond the level of at-

tributes or subassociations. Instead, we can consider inconsistencies between the identities themselves.

Consider our hypothetical consumer in a department store: the athletic department may activate her aggressive-athlete identity, and the women’s department may activate her warm-female identity. Which identity will her behavior follow? By defining identities as collections of self-associated concepts, one can clearly see that this represents a consumer simultaneously holding two inconsistent associations. In this instance, there is no discrepancy between the self and a desired attribute (i.e., self-discrepancy). Rather, there is *inconsistency* between the two identities themselves following from their oppositional identity content (aggressive vs. caring). This is referred to in prior literature as *identity conflict*, and researchers have called for additional work that explores its antecedents and consequences (Hirsh & Kang, 2016; Hollenbeck & Kaikati, 2012; Horton, Bayerl, & Jacobs, 2014; LeBoeuf, et al., 2010; A. Reed, et al., 2012).

Two more identity inconsistencies need additional consumer research. First, inconsistency can occur between two group identities (group-group inconsistency). For example, membership in one group (e.g., Females) may be negatively associated with membership in another group (e.g., Mathematicians) following from a negative stereotype about women and mathematics (for reviews see Pennington, Heim, Levy, & Larkin, 2016; Spencer, Logel, & Davies, 2016). Indeed, consumer research on stereotypes is an area in need of further exploration (Grau & Zotos, 2016; Mirabito, et al., 2016). Second, inconsistency can also occur between a group identity and an attribute (e.g., University students are not good at recycling; White, Simpson, & Argo, 2014). Few studies in consumer research have investigated this topic (White, Argo, & Sengupta, 2012).

In sum, self-discrepancies can be represented in the MIN as negative associations between the self and an attribute or between the self and an identity. Additionally, we propose that further identity inconsistencies may be described in the MIN as occurring between an identity and an attribute (e.g., group-identity threat), between two identities’ attributes (e.g., identity conflict), or between two identities themselves (e.g., stereotypes). These latter three are relatively understudied in consumer research.

## MULTIPLE IDENTITY RESOLUTION

### Compensatory Consumption

In their review of self-discrepancy, Mandel and colleagues (2017) also identified methods of resolving inconsistencies. The MIN can describe these in terms of associations.

Take for example a consumer feeling “unathletic” after skipping a workout. She may compensate for this discrepancy symbolically by purchasing athletic apparel (Shalev & Morwitz, 2012; Ward & Broniarczyk, 2011), or directly with a longer workout on her next gym visit (Soo & Gal, 2014). Both of these behaviors would help reinforce a positive association between the self and the identity.

Rather than approaching a positive self-association, the consumer may also respond by reinforcing a negative self-association with the identity (Dalton & Huang, 2014; White & Argo, 2009). For example, if feeling unathletic, the consumer may respond by disidentifying with the athlete identity by avoiding athlete-congruent behavior below baseline. This effect may be more prominent for consumers lower in collective self-esteem (White & Argo, 2009) and also when approaching the identity seems less feasible (Dimofte, Goodstein, & Brumbaugh, 2015).

Rather than positive or negative reinforcement of a given association, the consumer may seek a different, “neutral” route. For example, the consumer may engage in escapism (Kim & Rucker,

2012), where they intentionally focus on domains that are irrelevant to the discrepancy (Mandel, et al., 2017). Alternatively, the consumer may instead reinforce a different, unrelated identity. This type of fluid compensation may manifest as the consumer reinforcing her Asian identity after feeling “unathletic.”

In sum, the five compensatory consumption strategies discussed by Mandel et al. (2017)

– symbolic and direct resolution, dissociation, escapism, and fluid compensation – can be parsimoniously described by the MIN: reinforcing a positive self-association, reinforcing a negative self-association, or engaging in “neutral” behaviors that reduce the salience of the discrepancy.

### Future Directions: Principles of Multiple-Identity Management

While a taxonomic approach to cataloging the various sources of identity inconsistency and resolution provides an important contribution to consumer research (and Mandel, et al., 2017; e.g., So, et al., 2015), a critical question arises: *when* will consumers engage in the different behaviors? We argue that an important next step toward contributing to this literature lies in arriving at common processes, or principles, that guide multiple-identity management. Below, we offer an initial set of three such principles.

**Principle 1: Identity Maintenance.** Consumers want to maintain associations with their identities.

Models of self-evaluation maintenance (Tesser & Campbell, 1982), self-verification (e.g., vanDellen, Campbell, Hoyle, & Bradfield, 2011), coping (e.g., So, et al., 2015), and self-affirmation (Steele & Liu, 1983) all contend that a fundamental human motivation is to maintain a favorable self-view. This suggests that consumers’ first response is to approach the identity inconsistency in order to reinforce a positive association with the desired identity (i.e., identity-reinforcement; Americus Reed & Forehand, 2016). This notion is augmented by the next principle.

**Principle 2: Inconsistency Evaluation.** Consumers seek to identify the specific nature of an inconsistency.

When University students were told that their student body was bad at recycling, they engaged in sustainability behavior that reflected well upon the group, but not behavior that only reflected well upon themselves individually (White, et al., 2014). Consumers also responded to a self-status threat by reinforcing their personal status (Lee & Shrum, 2012), a self-group (exclusion) threat by reinforcing their group membership (Mead, Baumeister, Stillman, Rawn, & Vohs, 2011), and a threat to their personal control by seeking products that reinforce boundaries (Cutright, 2012). These findings suggest that consumers examine the exact nature of the threat to focus their behavior on addressing the specific inconsistency (So, et al., 2015). The MIN becomes particularly useful given this principle. Articulating threats in terms of inconsistencies between different identities or different subassociations very clearly suggests that consumers will respond by reinforcing the associations in question. The foregoing two principles are balanced by the next principle.

**Principle 3: Behavioral Evaluation.** Consumers engage in a means-end assessment of available identity-relevant behaviors.

When consumers have less self-regulatory resources, consumers engage in less identity-reinforcement (Steele, Spencer, & Lynch, 1993; White & Argo, 2009). The same occurs when identity-rein-

forcement appears unapproachable (Dimofte, et al., 2015). Similar resource-based effects play out with general self-verification as well, where self-reinforcing behavior may be less prominent when resources are low (Park & Maner, 2009; vanDellen, et al., 2011). Each of these effects suggests that consumers must be engaging in some expected value assessment of the available identity-relevant behaviors, where lower expected value begets behavioral avoidance. This principle is useful in that it helps identify which resolution strategy consumers might utilize for a given inconsistency. Taken together, these three principles begin to answer the question of when consumers might engage in the different identity-relevant behaviors.

### CONCLUSION

Using a social-cognitive approach, the present research moves the literature on consumer identity forward by offering a parsimonious framework in which to integrate extant and future work. We delineate how identity-congruent and compensatory consumption are described within the MIN as self-associations. We also identify three broad areas for future research: 1) alternate-identity effects of identity-congruent priming, 2) consequences of multi-level identity inconsistencies, and 3) principles of multiple-identity management. We offer initial suggestions of new theoretical propositions that may guide this future work, as well as suggesting some novel, unexpected results that this work might uncover. In sum, the MIN provides a practical tool for advancing consumer identity research within the burgeoning paradigm of multiple consumer identities.

# 'But Screw the Little People, Right?'

## Case of the Commercialization of Reward-Based Crowdfunding

Natalia Drozdova, NHH Norwegian School of Economics, Norway

### ABSTRACT

This paper contributes to the research on hybrid economy as we study how tensions resulting from co-existence of commercial and social systems of exchange and blurred boundaries between actors are formulated and reinforced. Study illustrates how actors are trying to make sense of the hybrid context by splitting into subgroups.

### INTRODUCTION

A number of studies focused on the development of collaborative (or sharing) economy (Belk, 2014; Scaraboto 2015; Bardhi & Eckhardt, 2012, etc.) Consumer research in particular suggests distinctions between such forms of exchange as sharing, access, renting, borrowing, gift-giving, and commercial exchange (Belk, 2014; Belk, 2010; Eckhardt and Bardhi, 2012). Many companies operating under the umbrella of the collaborative economy meet challenges when social and commercial motivations of actors co-exist. However, there is lack of understanding of what is happening when actors fail to negotiate contradictions caused by co-existence of various forms of exchange. In this paper, we explore case where co-existence of two systems of exchange cause conflicts and disharmony.

In the reward-based crowdfunding, funders provide financial support for commercially oriented projects without getting any equity rights or monetary rewards in return. Thus, reward-based crowdfunding creates a special context where social and commercial motivations of actors co-exist.

The research question we address in this paper is 'How tensions are formed and reinforced when social and commercial modes of exchange co-exist in reward-based crowdfunding?'

We illustrate how tensions are formed by inherent structural contradictions and mixed messages and how they are reinforced by reaction formation and splitting.

### METHOD – CASE STUDY

We conduct an in-depth case study of a seminal crowdfunding project - the case of Oculus Rift. We used qualitative analysis and followed case's development from August 2012 until August 2017. We analyzed 2617 funders' comments from Kickstarter commentary as well as 7 publicly available founder's interviews, and number of funders' blogposts and tweets.

In this study, we focus specifically on tensions and reinforcing cycles signified by contradictory definitions of success and purpose of the project as well as by blurring boundaries between funders and founders' roles.

### FINDINGS

'Join the revolution, make a pledge, and help us change gaming forever' – declares the closing of Oculus' promotion video on Kickstarter. This message appealed to funders, resulting in the massive support of the project. The project – Oculus Rift – was funded on Kickstarter in August 2012, receiving 2 million USD from 9522 funders. Few days after the end of the crowdfunding campaign, Palmer – Oculus' founder – thanked funders and claimed that 'we would not be able to do it without the community, it always been a community project from the start' (electricity, 2014). Funders, on the other hand, endorsed this community feeling and felt proud to 'be part of the gaming history' and to 'contribute to something big'.

After the launch, project went through few difficult periods. The most disturbing event happened in September 2014, when project was acquired by Facebook for 2 BN dollars.

Commercialization of the project revealed tensions and contradictions in actors' perception of the mutual rights and obligations towards each other. Many funders considered this commercialization of the project as the betrayal of the community and break of unwritten crowdfunding contract ('Facebook is not evil, it's a company. A company that invested 2 billion dollars in Oculus. Don't fool us. Even if you don't admit it today, you've lost your freedom. You've lost your soul. You annihilated every single beautiful ideas your project carried. But you're rich now').

In this paper, we focused particularly on how tensions are formed and reinforced. As the formal contract between funders and founders is rather ambiguous, funders make sense of their rights and expectations based on the messages received from founders. Mixed messages denote inconsistencies between statements or between verbal and nonverbal responses that appear during social interactions. Mixed messages communicated by founders provoke mistrust and feeling of betrayal. At the same time, crowdfunding platform does not provide necessary regulations or mechanisms of conflict's resolution. We identify inherent structural contradictions built into the system of reward-based crowdfunding. Therefore, we observe tensions caused by the inherent structural contradictions and mixed messages.

We also identify reinforcing cycles such as reaction formation and splitting. When the conflict arises, actors are trying to make sense of the context by placing themselves into more familiar and clearly defined roles. In the focal case, funders start to identify themselves as customers, investors, or philanthropists in order to justify arising demands and perceived rights in the ambiguous context of the hybrid economy.

# Trust in the Holy or the Material: The Combined Impact of Religiousness and Materialism on Life Satisfaction

Kelly Gabriel, Villanova University, USA  
Aronté Marie Bennett, Villanova University, USA

## ABSTRACT

The current research examines relationships between life satisfaction trust placed in religious beliefs and that placed in material possessions. Findings indicate that the impact of materialism and religiousness on life satisfaction is qualified by an interaction evidencing circumstances in which religiousness and materialism combine for counterintuitive outcomes.

## INTRODUCTION

Religious and material values are deeply embedded in many cultures worldwide. Though seemingly antithetical on the surface, these values have long been argued to be mutually constitutive. Max Weber (1905) most notably argued a strong connection between Protestantism and the “spirit” of capitalism whereby the pursuit of profit is virtuous in itself, and scholars have made similar claims from Judaism (Sombart 1911) to Islam (Rodinson 1966). Further, individuals are capable of exhibiting both values, leading lifestyles reflective of their religious beliefs while also “treating” themselves to the latest goods.

Literatures in consumer behavior, religion, and psychology have examined the individual influences of religiousness and materialism on life satisfaction (Hackney and Sanders 2003, Dittmar *et al.* 2014). Although both religious and materialist values seek to improve life in the long term, albeit, in vastly diverse ways, there have been limited examinations in the literature on the relationships among materialism, religiousness, and life satisfaction. Exceptions can be found in Baker *et al.* (2013) and Rakrachakarn *et al.* (2015); however, these studies focused more on differences among religions than on different dimensions of religiousness. This study seeks to fill that gap, offering a substantial contribution to the religiousness-materialism-well-being literature through exploration of the impact that materialism has on the relationship between life satisfaction and religiousness by deconstructing religiousness into intrinsic and extrinsic factors, permitting for investigation of complement between distinct facets of religious values and materialism.

## Life Satisfaction

Life satisfaction, a component of well-being, captures long-term levels of contentment, opposed to short-term happiness. Subjective well-being is typically conceptualized as a function of two components: a state factor, or short-term emotional reactions to present circumstances, and a long-term trait factor, or enduring and comprehensive evaluations of life (Diener 2000). Well-being scholars distinguish between happiness as the more dynamic state and life satisfaction as the relatively stable evaluation (Diener *et al.* 2003).

Life satisfaction is related to behaviors, attitudes, and myriad other person-specific concepts. Life satisfaction has been found to be influenced by personal goals (Palys and Little 1983, Emmons 1986, Brunstein 1993) and essential to the achievement of such goals are resources (e.g., money, social skills, physical attractiveness). Having resources needed for goal attainment is an accurate predictor of life quality (Diener and Fujita 1995); specifically, with financial resources, one can fulfill basic human needs while also directing resources to more advanced desires. Additionally, social support, the feeling that one is cared for and valued within a social network, is associated with life satisfaction (Diener and Oishi 2005).

## Religiousness

Although there is not a universally accepted definition, it is agreed that religion is a multidimensional construct (Spilka *et al.* 1985) that impacts multiple aspects of life, at the individual and societal level (Hill 2002, Mittelstaedt 2002, Prati *et al.* 2007, Vitell 2009, Jamali and Sdiani 2013). Modern scholars agree that religiousness is distinct from being religiously affiliated in that religiousness includes a level of commitment to religious beliefs and values whereas affiliation does not (Worthington *et al.* 2003). Further, though often conflated, contemporary understandings of spirituality and religiousness are viewed as related though distinct concepts (Zinnbauer *et al.* 1999), with religiousness relating to institutions and rituals and spirituality relating to personal experiences and finding purpose (Kapusinski and Masters 2010).

The current investigation adopts Pargament’s (1997, p. 32) conceptualization of religion as “a search for significance in ways related to the sacred.” Thusly, religiousness is the degree to which one holds this search central to one’s life. This conceptualization removes restrictions affiliated with specific religious dominations and permits for consideration of diverse faiths and pathways to the numinous, including ways of thinking, behaving relating, and feeling (Pargament 2002).

Gordon Allport’s operationalization of religiousness represents the backbone of modern empirical research on the psychology of religion (Wenger and Yarbrough 2005, Piedmont and Friedman 2012) and is the most widely used measure of religiousness in consumer behavior literature (Vitell 2009). Allport and Ross (1967) posited that religiousness is composed of two dimensions: an extrinsic dimension that is externally focused, and an intrinsic dimension that is internally focused. People with a dominant extrinsic orientation value religious belief for its associated personal benefits (e.g., comfort and protection), or its associated social rewards (e.g., friendship and status). People with a dominant intrinsic dimension value religion as a method to achieve spiritual objectives, leading to the internalization of religious prescriptions that ultimately serve others. This orientation approaches religious belief not as a means to an end, but as an end in itself. Flexible in its design, the original Allport and Ross (1967) scale of religiousness permits the dimensions to be examined as a single measure or two orthogonal ones.

## Religiousness and Life Satisfaction

Religiousness has been consistently found to be correlated with higher life satisfaction (Mathras *et al.* 2016), with some suggesting that the relationship stems from the positive social and personal contributions religiousness can impart. Findings in settings that parse religiousness into its two dimensions reveal distinct and oftentimes contradictory outcomes for life satisfaction (Swinyard *et al.* 2001). Intrinsic religiousness has been related to greater subjective well-being, happiness, and life satisfaction (Maltby and Day 2004), while extrinsic religiousness has been related to lower levels of those outcomes (Maltby and Day 2000). Higher levels of extrinsic religiousness may also be related to greater insecurity and a resulting need to use religion as a substitute for relationships or to bolster social successes and standing (Allport and Ross 1967). Thus, the best evidence and logic suggest:

*Hypothesis 1A* Intrinsic religiousness will have a positive association with life satisfaction.

*Hypothesis 1B* Extrinsic religiousness will have a negative association with life satisfaction.

## Materialism

Materialism has multiple dimensions, including achievement of happiness through acquiring possessions. Richins and Dawson (1992, p. 307) assert that materialism “reflects the importance a person places on possessions and their acquisition as a necessary or desirable form of conduct to reach desired end states, including happiness.” Sirgy *et al.* (2013) posit materialism has positive and negative consequences and clarify that they are the result of the nature of aspirations and motivations.

People turn to materialism to cope with uncertainty about their identities; they display status through material objects to project desirable self-images, to conform to groups, and to maintain positive selves (Chang and Arkin 2002, Kasser 2002). Low self-esteem has consistently been found as an antecedent to materialism (Chaplin and John 2007). “Materialists” are in a search for happiness and are hoping to achieve peace and compensate for feelings of insecurity by owning, consuming, and displaying (Richins 2017).

## Materialism and Life Satisfaction

The nature of the relationship between materialism and life satisfaction is actively debated. Although some researchers have shown that satisfaction with material life is positively related to overall life satisfaction (Diener and Fujita 1995, Diener *et al.* 2010), others have shown materialism and the belief that acquiring possessions leads to fulfillment are linked to negative consequences such as lower well-being (Wright and Larsen 1993). Extant results have shown negative consequences of inordinate value placed on possessions to individual subjective evaluations of well-being (Burroughs and Rindfleisch 2002). Consistently, findings in consumer behavior research suggest material values or “materialism” as a guiding force for life satisfaction will fail to meet this important human need.

Although we acknowledge evidence of instances in which materialism has a positive impact on life satisfaction, these instantiations often rely upon intervening factors. When considered in isolation, placing inordinate value on acquisition of possessions is consistently found to have negative impact. Thus, we posit:

*Hypothesis 2* Materialism will have a negative association with life satisfaction.

## Materialism, Religiousness, and Life Satisfaction

While to our knowledge there has not been an explicit examination in the literature on how materialism impacts the relationship between intrinsic and extrinsic religiousness and life satisfaction, researchers have looked at relationships among similar variables. As mentioned, these examinations have produced disparate results. Many studies have found a positive association between religiousness and well-being and a negative association between materialism and well-being (Swinyard *et al.* 2001, Baker *et al.* 2013, Rakrachakarn *et al.* 2013). This coincides with Burroughs’ and Rindfleisch’s (2002) conflicting values perspective: people who hold opposing values, such as materialism and religiousness, experience psychological unease and decreased well-being. While the two previous investigations of these relationships operationalized religiousness as a

unidimensional construct, we deconstruct religiousness into intrinsic and extrinsic factors to account for possible synergies with materialism, allowing for the possibility of complementary or contradictory values.

The conflicting values perspective (Burroughs and Rindfleisch 2002) suggests that the coexistence of the opposing values of intrinsic religiousness and materialism should bring about psychological unease and decreased life satisfaction. Intrinsically religious people internalize religious values as a framework to live life by and strive to “transcend all self-centered needs,” (Allport 1966, p. 455). Materialistic individuals embrace material values as a framework to project a desirable self-image, to advance the self socially, and to maintain a secure identity.

Conversely, the conflicting values perspective suggests that the shared external aspects of materialism and extrinsic religiousness should have a synergistic positive influence on life satisfaction. Those who are extrinsically religious use religion for its personal (e.g., protection, solace) and social (e.g., gain status, community) benefits. Similarly, materialistic people have an external focus, believing the route to happiness is through acquiring possessions, and making continuous social comparisons of standards of living. Based on our previous discussion of relevant literature we posit:

*Hypothesis 3A* Materialism will moderate the relationship between intrinsic religiousness and life satisfaction such that when combined with high levels of religiousness, higher levels of materialism will attenuate perceptions of life satisfaction.

*Hypothesis 3B* Materialism will moderate the relationship between extrinsic religiousness and life satisfaction such that when combined with high levels of religiousness, higher levels of materialism will augment perceptions of life satisfaction.

## METHOD

Three hundred and fifty-seven residents of the United States completed an online questionnaire in exchange for small financial rewards. U.S. population statistics were used to guide the collection of a nationally representative sample. The order of presentation of scales, as well as the items within each scale, was randomized.

Respondents completed scales that measured religiousness, materialism and life satisfaction. Religiousness was measured using Allport and Ross’s (1967) Religious Orientation Scale (ROS). Twenty statements measured on 5-point Likert scales were presented; 11 of which comprise the original extrinsic subscale, and 9 of which comprised the original intrinsic subscale.

Materialism was measured using the abbreviated version of the Material Values Scale (Richins and Dawson 1992) validated by Richins (2004). Five-point Likert scales were used to measure agreement with each of the 9 items on the scale.

Life Satisfaction was measured using Diener’s (1985) Satisfaction with Life Scale (SWLS). The SWLS is a 5-item, 5-point Likert scaled instrument used to assess global life satisfaction.

## Results

A multiple moderation model conducted with the PROCESS procedure (Hayes 2013) was used to test the presented hypotheses. Age, gender, education level and household income were included as covariates.

The moderation model is significant (adj.  $R^2=.18$ ,  $F_{(9, 347)}=8.33$ ,  $p<.001$ ). There are marginal direct effects of both religiousness orientations on life satisfaction. Substantiating hypothesis 1A, respondents who reported higher levels of intrinsic religiousness also reported higher levels of life satisfaction ( $\beta=.09$ ,  $t_{(1,347)}=1.69$ ,  $p=.09$ ). Respondents who reported higher levels of extrinsic religiousness also reported higher levels of life satisfaction ( $\beta=.13$ ,  $t_{(1,347)}=1.64$ ,  $p=.10$ ); these results fail to provide support for hypothesis 1B. Results also fail to support hypothesis 2. In isolation, there is no significant, direct effect of materialism on life satisfaction beyond that of religiousness ( $\beta=-.07$ ,  $t_{(1,347)}=-.94$ ,  $p=.34$ ).

Central to the current investigation is the interaction between religiousness and materialism. There is no evidence in support of hypothesis 3A; rather than working in opposition, there is no interaction between intrinsic religiousness and materialism ( $\beta=-.01$ ,  $t_{(1,347)}=-.22$ ,  $p=.83$ ; See Figure 1). Conversely, there is evidence to support hypothesis 3B. The direct effect of extrinsic religiousness is qualified by an interaction with materialism ( $\beta=.16$ ,  $t_{(1,347)}=2.03$ ,  $<.05$ ; see Figure 1). More specifically, life satisfaction is bolstered when respondents have an external religious orientation AND value material possessions.

The Johnson-Neyman technique (Hayes 2013) identified a response of 2.96 on the 5-point materialism scale as the turning point in the interaction (Krishna 2016). At values of materialism below this point, there are no differences reported life satisfaction, without regard to level of extrinsic religiousness. At values of materialism above this point, reported life satisfaction increases as extrinsic religiousness increases.

Results suggest that covariates household income and education impact life satisfaction ( $\beta=.08$ ,  $t_{(1,347)}=5.09$ ,  $p<.01$ ;  $\beta=.05$ ,  $t_{(1,347)}=1.92$ ,  $p=.06$ ). Other demographic covariates, age and gender, did not.

**DISCUSSION**

The current investigation revisits the religiousness-materialism-life satisfaction relationship. We demonstrate that contrary to most perceptions of religious teaching, materialism and religiousness are not antithetical. In fact, they can work in complement to provide feelings of a satisfied life. Moreover, there does not seem to be combinations in which the coexistence of both values is a detriment.

Without regard to the specific motivation, we found that those who value religious practice experience greater life satisfaction. As expected, the intrinsically religious, those who place more value on religious practice as a method to achieve spiritual objectives, report increased levels of life satisfaction. Surprisingly, the extrinsically religious, those who value religious practice for its associated benefits and social rewards, also enjoy increased levels of life satisfaction. Materialism seems to have no direct effect, neither positive nor negative, on life satisfaction.

Results indicate that the relationship between materialism can be a beneficial addition to the religiousness-life satisfaction relationship. As predicted, materialism has a decidedly positive influence on life satisfaction for those who have an extrinsic religious orientation, which suggests that valuing material possessions as a way to lead a fulfilling life can also lead to a satisfying life if this behavior is in alignment with closely held personal values. Yet, counter to the conflicting values perspective (Burroughs and Rindfleisch 2002), when materialism is not aligned with other closely held personal values, it does not have a deleterious impact on life satisfaction.

**Limitations and Future Research**

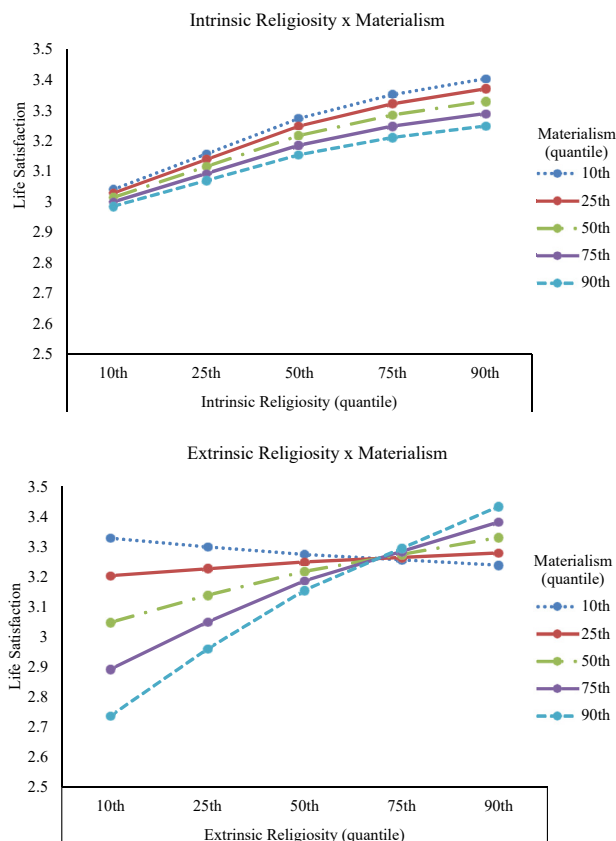

Ultimately, living in a consumer culture unconsciously and strongly impacts our development of identity, values, and search for life purpose, and the constructs religiousness, materialism, and life satisfaction offer fertile ground for continuing research in the consumer culture domain. Consideration of macro-level variables related to cultural context would permit for a more complete understanding of the role of religiousness in determining life satisfaction. A similarly sophisticated approach may be called for when researchers examine the role of micro-level variables, including materialism and personality. Like religiousness, the underlying dimensions of materialism need to be examined in effort to shed light on when it can be advantageous versus deleterious. Further, introducing the Five-Factor Model (FFM) of personality in future studies might yield new insights. Lastly, in effort to address some of the limitations of the current work, future research should endeavor to more closely map onto the contemporary Universal Intrinsic/Extrinsic scale, (Chen and Tang 2013, Gorsch and Venable 1983).

**CONCLUSION**

The current work contributes to a body of literature that is concerned with consumers' well-being and intervening factors. Our results show that relationships across materialism, religiousness, and life satisfaction are not as simple as previously thought, offering new ways of viewing their individual and combined influences on consumption behaviors.

# From Country-of-Origin (COO) to Country-of-Consumption (COC): The Institutional Journey of Consumer Trust in Food

Caixia Gan, University of Auckland, New Zealand  
Denise M Conroy, University of Auckland, New Zealand  
Michael SW Lee, University of Auckland, New Zealand

## ABSTRACT

This study finds that multiple Country-of-origin cues collectively contribute to building trust in food through institutional food regulation of each country involved in the globalised food provisioning. Country-of-consumption is newly identified as equally important in trust building while a gap of trust may exist between countries of different food regulations.

## INTRODUCTION

Previous studies reveal that Country-of-origin (COO) could be influential to trust in products and services (Jiménez & San Martín, 2010; Michaelis, Woisetschläger, Backhaus, & Ahlert, 2008). However, these studies treated COO as one of the variables to impact trust and little is known about the relationship between COO and trust (Michaelis et al., 2008). In the context of food consumption, intensive work has studied how COO may impact food preference and purchase intention (Dinnie, 2004) while little research has linked COO with consumer trust in food. Furthermore, although the importance of institutional and social structures is noted respectively in research on COO (e.g., Jiménez & San Martín, 2014) and on trust in food (e.g., Kjærnes, Harvey, & Warde, 2007), little work has been done to particularly investigate the institutional processes and mechanisms by which COO may impact trust in food. Given that multiple countries may involve in food production in the globalisation era, further exploration on how food-related institutional structures associated with different COO may impact the dynamics of trust in food is worthy of scholarly and practical attention.

This work aims to explore how COO may influence consumer trust in food in the globalisation era by investigating the role of institutional food regulation of multiple countries. To avoid the common methodological concerns in previous research regarding the manipulation of COO stimuli in experimental settings (Usunier, 2011; Verlegh & Steenkamp, 1999), an actual consumption scenario, i.e., infant formula consumption in China, was selected as the context of this study. Being in the world's largest and fastest-growing market of formula milk (Euromonitor, 2015), Chinese parents consume a wide range of infant formula products sourced from, manufactured in, and sold in different countries. They are exposed to various COO cues in decision-making, and trust is essential in this process due to previous food safety incidents such as the 2008 Melamine Scandal which killed six and sickened 300,000 babies (BBC, 2010). Therefore, infant formula consumption in China is a suitable context to reflect the globalisation of food and a sensitive context to examine the relationship between COO and trust in food.

This study may contribute to a further understanding of the COO effect on trust in food by addressing the impact of institutional food regulation of different countries involved, and shed lights on building consumer trust in the international food production and consumption practice.

## THEORETICAL BACKGROUND

### Trust

In social science trust is generally accepted as one's positive expectations of the ability and goodwill of the trusted individual or

institution in the face of risk (Barber, 1983; Hart & Saunders, 1997; Rousseau, Sitkin, Burt, & Camerer, 1998). There are two distinctive types of trust, namely, interpersonal trust which is based on familiarity and emotional bonds between the two parties (Lewis & Weigert, 1985; Misztal, 1996), and institutional trust which requires necessary impersonal social institutions and structures to enable one to act in anticipation of a successful outcome (McKnight & Chervany, 2001; Zucker, 1986).

### Trust in food

Consumer trust in food has been studied from both interpersonal and institutional approaches (Zhang, Xu, Oosterveer, & Mol, 2015). Interpersonal approach emphasises the intimacy and familiarity between individuals and food chain actors, while institutional approach centres the institutional operation of food provisioning in trust-building. For example, comparatively studied across six European countries, Kjærnes et al. (2007) argue that consumer trust in food varies significantly across countries due to institutional and structural differences. However, little is known about how institutional food regulation of the home country as well as other countries may influence consumers' trust in food, when more than one country is involved in food provisioning.

### Country-of-origin (COO)

COO, usually recognised as the "made-in" or "manufactured-in" labels, functions as an extrinsic cue for consumers to evaluate products (Bilkey & Nes, 1982; Hong & Wyer, 1989). Since the 1960s, intensive work has been conducted to measure the occurrence, magnitude and significance of COO effects on product evaluation across various categories (Verlegh & Steenkamp, 1999). The emergence of multinational companies and hybrid products have resulted in a wide range of COO cues such as country-of-design, -manufacture, -assembly, and brand origin (BO), etc., as well as debates regarding the relevance and accuracy of the effects of these COO cues on consumer behaviours (Josiassen & Harzing, 2008; Samiee, Shimp, & Sharma, 2005; Usunier, 2006). As such, COO "remains a fuzzy, contingent, and evasive international marketing concept" and more in-depth investigation is necessary (Usunier, 2011, p. 486).

### Theoretical approach

Viewing COO effect as an outcome of cognitive processing, plenty research has engaged in identifying antecedents and mediators that might affect such processing of COO effect, for example, ethnocentrism and animosity (Jiménez & San Martín, 2010; Kaynak & Kara, 2002). Nevertheless, cognitive approaches are insufficient for the holistic understanding of the relationship between COO and trust because they neglect the power of social and institutional structures in shaping the way how consumers may make sense of the reality in which they live. According to Giddens (1990), in modern societies where interactions are commonly mediated through institutions and organisations, institutional trust has to be the predominant type of trust in social life. Therefore, this work adopts an institutional approach to investigate the impact of COO on trust in food by looking into how consumers associate the institutional assurance of food with different COO cues.

## RESEARCH METHOD AND DATA COLLECTION

Prior COO research is considered to insufficiently reflect the nature of consumer intention and behaviour by manipulating selected stimuli in experiments rather than observing in the actual consumption (Dinnie, 2004). Qualitative in-depth interviews are particularly suitable when one is interested in complexity or process, or where an issue is controversial or personal (Smith, 1995), thus is adopted by this study. Twenty-eight prospective mothers living in urban China were recruited by snowballing. In contrast to Western mothers who seldom buy infant formula until necessary, all participants of this study had bought, or were planning to buy, infant formula when interviewed. These participants, 25 of whom were in their first pregnancy, were mostly inexperienced mothers with no direct experience of any infant formula brand at the time of interview, making trust even more important for their purchasing decisions. Their detailed experience of choosing and purchasing infant formula, and how they developed trust in any brands or products was documented. All interviews lasted for 45-90 minutes, were audio-taped, and translated from Chinese into English. Inductive thematic analysis (Boyatzis, 1998) was conducted to identify and categorise key themes from empirical data.

## FINDINGS

In interviews, participants acknowledged that they felt secure, although to different extents, to feed their babies with the infant formula they had bought or planned to buy, and held positive expectations regarding the products' future performance. A certain level of trust has therefore been demonstrated even before gaining any actual feeding experience with these products. Participants frequently referred to various COO cues as their trust was developing in specific infant formula brands and products. Three themes have emerged from data analysis.

### COO effects on trust: from production to consumption

Many agreed that ingredients (raw milk) matter to the quality of infant formula and more trust was placed in products sourced from "better" country-of-ingredients. Country-of-manufacture also played a critical role as *"it's not the place of milk source that determines the processing line and the final products, any mistake in processing may lead to non-qualified products at the end"* (MENG). Participants believed that products manufactured in different countries may be different in quality. More noteworthy, when products are manufactured then transmitted to target markets for sale, country-of-consumption (COC) becomes relevant to trust. COC, seldom studied in previous research, here refers to the country where the products are sold and consumed. Many participants preferred infant formula sold in overseas markets to domestic or imported products sold in China, as they believed the former is safer than the latter. For example, one claimed that *"the most secure way is that I can see my friend buying this infant formula from a supermarket in Holland and mailing it to me. This is the most secure way to me, and I don't really trust any others"* (PENNY). So it is evident that, from ingredients to manufacturing and consumption, all COO cues relating to countries involved in the food provisioning process collectively contributed to the establishment of participants' trust in infant formula products.

### Institutional structures behind COO

More trust was found in infant formula from developed western countries than from participants' home country due to institutional reasons. For instance, one participant stated that *"New Zealand has very strict requirements of baby formula. It has been doing well in protecting its babies and women. So I trust the policy of this coun-*

*try, and trust that the policy will regulate companies. ... In foreign countries, the policy would be enforced and implemented, and it can make the company close down if the company doesn't comply.... Therefore, trusting this company may be mainly because of trusting in the policy of this country, as it indeed pays attention to protecting its babies"* (PING). This comment, together with other similar articulations, highlights the institutional mechanism behind COO cues through which participants' trust is built. The institutional food regulation, including the establishment and enforcement of food-related rules and laws, and the punishment of non-compliance, was accounted by participants to evaluate the safety and quality of infant formula at each stage from ingredients to consumption relating to all countries that have involved in such process. Therefore, the institutional structures of food regulation at a country level are the foundation for COO to impact participants' trust in infant formula.

### The "gap of trust"

In the journey from the farm to the consumer, infant formula moves from regulation of one country to another as the product crosses the border between countries. A gap of trust was found when the institutional food regulation in one country was not perceived to be as sound as another in this journey. This gap of trust was most significantly observed if participants held less positive or even negative perceptions of the food regulation of their home country as the country-of-consumption. For example, participants worried that *"after entering into China, no matter what the brands are, they might lower the requirement of themselves (SKY)"*, because the food standard in China was considered lower than western countries. Some even felt that *"as long as China is involved in any part of the process, there might be some danger"* (ENYA). Food products, despite their origins, are supposed to reach the threshold set by the food regulation system of a country in order to be sold in that country. So many participants believed that *"some domestically manufactured products which are to export to Europe may be subject to a higher standard than those for domestic markets"* (SUNNY). Therefore, this gap of trust is actually the gap of perceived soundness of the institutional food regulation between countries. COC accounts for the overall level of trust in food as it informs the level of soundness of the institutional food regulation which is the ultimate safeguard before the food products are consumed by consumers of this country. Participants might draw on other resources to fill this gap and obtain trusted infant formula, such as asking a trusted overseas contact to buy and send the product back directly from foreign countries.

## DISCUSSION AND CONCLUSION

This study reveals the institutional mechanism of COO effect on trust in food through the experience of Chinese mothers with infant formula. When multiple countries are involved in the journey from ingredient sourcing to food processing and the destination of consumption, COO cues of these countries collectively provide institutional safeguards for consumers to develop trust in food, through the food regulation of each country. While there are arguments that some COO cues, such as manufacturing origin, have become largely irrelevant to product evaluation (e.g., Pharr, 2005; Samiec, 2010; Usunier, 2006), this study demonstrates that in food evaluation, all COO cues could be relevant and collectively impact on consumer trust and food choice. The reliance on institutional and structural assurances to build trust in food is also in line with Zucker's (1986) observation that people were enabled to trust by regulations and institutions which were in place to make sure the other was either afraid of, or punished for, doing harm to the trustor.

In particular, the newly identified COO cue, COC, significantly impacts trust in food when consumers have access to food products sold in other countries via cross-border businesses. As contemporary consumers are greatly detached from farming and food processing (Meijboom, Visak, & Brom, 2006), they have little control over food provisioning and have to rely on institutional food regulation to ensure food safety and quality. The food regulation of the country where the food products are sold and consumed functions as the final safeguard to stop the unsafe or unqualified food from entering the market, so that consumers' interests are secured. Therefore, COC is an essential cue for consumers to develop trust in food given that food provisioning and consumption is increasingly globalised.

Although COO cues collectively contribute to trust in food, the soundness of food regulation of each country may be perceived differently by consumers. Consequently a gap of trust may be generated between countries due to the differences in perceived-soundness of food regulation. Especially at the stage of consumption, when consumers' home country is perceived as weak in food regulation, food products sold and consumed in other countries with stronger food regulation may gain more trust from consumers.

This study concludes that multiple COO cues, especially COC, are important for consumers to develop trust in food based on institutional and structural assurances. Behind the COO cues, institutional food regulation of multiple countries collectively contributes to building consumer trust in food in the globalisation age.

### CONTRIBUTIONS AND IMPLICATIONS

This empirical work provides an institutional explanation of COO effect on consumer trust in food and reveals that COC may play a particularly important role when consumers are seeking institutional assurance in food. The identification of COC broadens current COO knowledge by extending the discussion on the origin of product design or manufacture to the destination of product consumption in the rise of cross-border business. For policymakers, attention shall not only be paid to food regulation system of their home country, but also to the collaboration with other countries so that the international institutional assurance network can be advanced to facilitate trust in food globally. For food brands and food producers, attention needs to be paid to minimise the "gap of trust" and maximise overall consumer trust in food by synthesising the institutional food regulation of multiple countries which are involved in food provisioning.

### LIMITATION AND FUTURE RESEARCH

As an exploratory work, this study discussed the relationship between COO and trust in food only within the context of one product category in one country. This may compromise the generalisability of the role of COC in other settings. Thus, it is suggested that future research may test how COC may work in other product categories across countries and cultures.

# The Production and Consumption of Retro Brands Beyond Meaning Revival

Benjamin Julien Hartmann, University of Gothenburg, Sweden

Katja H. Brunk, European University Viadrina, Germany

Markus Giesler, York University, Canada

## ABSTRACT

While past research articulates retro branding predominantly as brand meaning revival, our findings from a historical analysis of the production and consumption of retro brands in Germany reveal how these commercialized representations of the past operate also via brand meaning inversion (retroversion) and brand meaning invention (retrovention).

## INTRODUCTION AND CONCEPTUAL BACKGROUND

Previous consumer research highlights the ideological functions served by commercialized representations of the past, how consumers and producers frequently expropriate them for competitive or ideological gains, and the moral conflicts that are variously negotiated through them (e.g., Brunk, Giesler, and Hartmann 2018; Brown, Hirschman, and Maclaran 2000; Brown, McDonagh, and Shultz 2013; Luedicke, Thompson, and Giesler 2010; Penalzoza 2000; Press and Arnould 2011; Thompson and Tian 2008). One vital market resource for the negotiation of commercialized representations of the past is given by retro brands, or “relaunched historical brands with updated features” (Brown, Kozinets, and Sherry 2003).

However, while recent research highlights the importance of politicized memory-making that undergirds the negotiation of commercialized representations of a past (Brunk et al. 2018), existing research on retrobranding still frames this process purely in terms of *revival* of past meaning (Brown et al. 2003; Cattaneo and Guerini 2012). Consequently, important cultural, historical, political, and ideological dimensions are currently not sufficiently considered in Western retro-branding processes.

In this article, we explore the production and consumption of retro brands, which we call brand retrofication, as a cultural branding practice orchestrated by consumers, commercial actors, and other important cultural actors. When we analyzed retro brands in Germany over time, we found evidence for Brown et al.’s (2003) brand meaning revival. However, our longitudinal approach with emphasis on popular memory dynamics and conflicts also revealed that retro brands are much more politicized than previously acknowledged. Once the political dimension is considered, it becomes evident that retrofication can go beyond reviving prior brand meanings (i.e. *retrorevival*). Instead, it is a more complex cultural process, whereby commercialized representations of the past also are negotiated and enacted through *retroversion* (retro brand meaning inversion) and *retrovention* (retro brand meaning invention).

To conceptualize these types of retrofication strategies alongside Brown et al.’s (2003) meaning revival operating via ‘aura’, ‘allegory’, ‘arcadia’, and ‘antinomy’, we bring to bear a cultural branding perspective (Holt 2002; 2004; 2005) on the negotiation of commercialized representations of a past via retro brands. Consequently, we suggest that retrofication operates through allegorizing, articulating, assembling, and antinomizing. *Allegorizing* refers to reconstructing the past by rendering a brand as a locus of virtuous feelings and traditions that can serve as a powerful anodyne for the cultural anxieties facing consumers who are ambivalent about their position in the present. *Articulating* denotes the enunciation of compelling historical identity dramas and narratives presented to enact and verify the narrative claim of revitalized utopian past (community). The brand

articulates a specific ideological memory conflict and gains meaning only through politicized popular memory-counter-memory dynamics. *Assembling* describes how brand owners assemble and animate their brands and its core values in such a way as to offer a (unique) aura instrumental to resolving a moral contradiction highlighted by a given popular memory tension. Through assembling, a brand can act as an authentic identity salve by offering an indexical and/or iconic link to an (imagined) past. *Antinomizing* entails the systematic contradiction of the proposed past to old products’ concrete material qualities and attributes such as form, function, or flavor by negotiating how a brand builds its enchanting paradox that manifests at consumption-level.

## METHODOLOGICAL APPROACH

### Analytical approach

Our research approach was two-fold. Following calls for the increasing need to historicize (Brown, Hirschman, and Maclaran 2001) and to attend to the context of context (Askegaard and Linnet 2011), our first analytical step *zooms out* from our research phenomenon to contextualize the nature of retro brand emergence. Here we take advantage of the power of unique contexts to generate theoretical insights (Arnould and Thompson 2005; Arnould, Price, and Moiso 2006) and contextualize retro brand emergence in East Germany against the backdrop of the socio-historic and cultural changes surrounding the German reunification. In our second analytical step we then *zoom into* our research phenomenon to analyze two cases of negotiating a commercialized representation of a past via retro brands previously left untouched (Brown et al. 2003). In doing so, our approach leverages macro, micro and individual levels of observations to expose the production and consumption of retro brands beyond meaning revival, whereby contributing to existing literatures on retro branding.

### Data collection

We explore the meaning making process central to retrofication in its empirical context and collected a combination of qualitative empirical material: (1) historical data including statistics, documentaries and other culturally relevant material from mass media; (2) 15 one-on-one interviews with consumers; (3) visits to and observations in retailscapes; (4) netnography including consumer and interactive brand sites (Brown et al. 2003; Kozinets 2002; 2010).

### Data analysis

To analyze our data, we opted for a hermeneutic approach (Thompson 1997), including coding and recoding, constant comparison, and iterative inter-researcher discussions. Coding and analysis became increasingly specific as the analysis progressed. We started with a general focus on the meaning making processes surrounding retro brands in East Germany against the backdrop of our socio-historic context data. This was followed by comparing and contrasting these emerging processes with those identified by Brown et al. (2003).

## HISTORICIZING RETRO BRAND EMERGENCE IN EAST GERMANY

The fall of the Berlin Wall in 1989 finally opened the gates to Western prosperity and a consumer society of material wellbeing

that had always served as a contrasting point of comparison to the East (Landsman 2005; Merkel 2006). Continuous exposure to—although forbidden—West German TV and advertising as well as social contacts with relatives and their care packages sent from the West established a perception of Western brands as *echt* (the real thing) and East German products as *ersatz* (inferior surrogate) (Bach 2002; Veenis 1999). Because of their poor quality and inferiority, frequently reaffirmed by West German market research and corporate discourse, East German products were ridiculed as symbols of antiquated socialist economies, inefficiency, and backwardness (Berdahl 1999; Boyer 2001; Merkel 2006). The overall aesthetics, packaging, and product design was highly simplistic and reflected the GDR's struggle with production. Due to a lack of access to Western currency and the subsequent challenges to import the necessary raw materials and resources for production, essential product ingredients had to be replaced with low-grade substitutes, impairing product quality and taste. For example, chocolates were filled with a mixture of peas, sugar and aroma; candied lemon peel was replaced by green tomato; and the national car Trabant was manufactured out of recycled cotton waste (Der Spiegel 1991).

While in the West the range of shiny and attractive brands promising a happy life in prosperity was continuously increasing, East German consumers became progressively frustrated with their own reality of empty shelves and subordinate brands and products. Thus, when the German reunification finally facilitated the long-desired access to Western brands, instantly discarding the *ersatz* for the *echt* was the norm for East Germans. In the years that followed, East Germans engaged in historically unparalleled hyper-consumption of Western brands. Not only did East Germans no longer purchase East German products, they moreover purged their houses and exchanged entire interiors to rid themselves of any reminders of their previous supposedly primitive life (Berdahl 1999; Merkel 2006; Veenis 1999).

Given their historically rooted aura of inferiority and related consumer rejection of anything East German, East German products were destined for the necropolis and entirely disappeared from the retail landscape. Yet, contrary to conventional retro-branding wisdom (Brown et al. 2003), which implies that reviving such negative brand meanings is destined for failure, we witness the emergence of previously disliked and discarded East German retro brands not as revivals, but as inversions of their former selves (retroversion) and newly invented 'past' East German brands that never existed as brands back then (retrovention). How do these types of retrofication work and why?

## RETROFICATION ANALYSIS

Our retrofication analysis reveals how commercialized representations of the past are negotiated and enacted through retroversion and retrovention using two illustrative cases (see table 1).

### Retroversion and the relaunch of the 'Simson Schwalbe'

One prominent relaunched historical brand of East German origin that has undergone an inversion of original brand meaning is the recently relaunched moped brand 'Simson Schwalbe'. While 'Simson' began making bicycles in 1896, it became a household name for mopeds made in the GDR. To respond to increasing mobility needs, the GDR regime introduced the moped 'Schwalbe' (German for swallow) in 1964 and sold over a million exemplars until its termination in 1986 (VDI 2015). Consumers in the GDR valorized the Schwalbe as an old-fashioned, raw, smelly, loud, unpretentious, simple, aesthetically displeasing, and purely functional, easy-to-repair, inexpensive, and ordinary means of transportation—a prototypical socialist, standardized, and rationalized *ersatz* mass-product.

In 2016, the Schwalbe was re-launched by GOVECS as an e-scooter, a progressive lifestyle brand located in West-German Munich. While back then in the GDR, even its designers had stark reservations about the aesthetics of the original Schwalbe, the brand caters now to individualist urbanist identity myths and hedonic consumption desires with slogans like: "The Schwalbe makes you smile. Not only because she looks good and makes you look good on her. The cult e-scooter also sweeps you away with its outstanding performance [and is] quiet, clean and sustainable" (myschwalbe.com). Statements like these represent an attempt of inverting the Schwalbe's original brand meanings as an ordinary and ugly *ersatz* mass-product, now rendering it as an extraordinary and good-looking individualized identity salve in Germany's post-reunification capitalist consumer culture. This inversion on the level of brand meaning goes beyond the naturalized updating processes retro brands undergo: Brown et al.'s (2003) old and new Beetle share personality, values, and cultural narrative forming a moral and functional allegory. However, the new Schwalbe is the antitheses of the moral qualities, values, and cultural narrative of the original brand. Through this *allegorizing*, the Schwalbe and its East German heritage are rendered as a locus of virtuous feelings which serves to resolve identity stigma by inverting West-German stereotypes of the East as backwards, displeasing hinterland (Brunk et al. 2018). Through *articulating* this popular memory conflict, the new Schwalbe brand romanticizes and proclaims an idealized (national) western consumer culture through inverted brand meanings which gain their value only from the context of this conflict. Through *assembling* these (inverted) core values, the new Schwalbe brand presents an iconic-authentic identity salve rather than an indexical-authentic link to a past. Thus, through *antinomizing*, producers and consumers render the brand into a systematic contradiction in itself, in moral and functional terms, which becomes an enchanting paradox that can manifest on a consumption level.

### Retrovention and the launch of the 'Ampelmann'

One prominent case of a commercialized representation of the past that is negotiated and enacted through retrovention is the Ampelmann brand. Retrovention refers to the invention of retro brand meanings, whereby a cultural, originally non-commercial and public token of the past then becomes commercialized, marketed and consumed as a 'born retro' brand: while the Ampelmännchen originally referred to the distinctive little man displayed in the pedestrian traffic lights all across the GDR, it was commercialized and launched as a 'neo-retro' (Fort-Rioche and Ackermann 2013) design brand by Markus Heckhausen in the mid 1990s. The inception of the Ampelmann brand was built on critiquing the replacement and devaluation of East German Culture by West German Culture, rendering the Ampelmann a symbol of political resistance, endurance and continuity.

Refashioning the Ampelmännchen from an ordinary and public traffic sign to a cult brand universe including flagship stores, cafés, children traffic safety and regular fashion, tech products (speakers, headphones), food (chocolate, coffee) and other accessories (golf balls, umbrellas, bags, home-décor) extends Brown et al.'s (2003) scope of brand meaning revival and updating. Through *allegorizing*, the brand draws on larger already existing memory narratives of everyday life in GDR's cityscapes to form an iconic parable that can soothe present-day cultural anxieties of consumers. Here, by *articulating* a memory conflict in the moralistic nostalgia frame (Brunk et al. 2018), the Ampelmann brand universe presents a compelling identity drama of saving and savoring a cultural icon as a place-holder for many East German life trajectories to enact and verify the narrative claim of a revitalized utopian past (Duckenfield and Calhoun 1997). When it comes to *assembling*, brand managers can

**Table 1: Summary of illustrative empirical material for Retroversion (Simson Schwalbe) and Retrovention (Ampelmann) strategies**

	Illustrative Data	Analytical category
<b>Retroversion</b> (Simson Schwalbe)	“I remember the old Schwalbe well. My grandpa drove one. Every day, rain, snow, no matter what weather, he drove it 20 km to work, sometimes breaking down because the spark plug got soaked or other issues. I remember mostly older people driving them. We (younger people) actually looked at this thing and made fun of it. It just looked so old-fashioned and primitive, like from another time, the shape (leg protection!), the horrible colors, the clunky shape. We all wanted to drive something more sportive and most of us actually got a S51, which in comparison to western mopeds still looked bad but not as bad as the Schwalbe. I remember my best friend was forced to drive a Schwalbe, because her father considered it more safe, I felt so sorry for her. She was so embarrassed! We were even joking that she would never find a boyfriend driving around in this thing! So she would try to ride with me whenever there was a chance in order to not be labelled as backwards and old-fashioned.” (Interview)	Historicization (inferiority; negative brand meanings)
<b>Retroversion</b> (Simson Schwalbe)	“The Simson bird series and especially the swallow I associate very much with my father and my grandfathers. They all drove Schwalbe. This makes it part of my own family history. The Schwalbe also fascinates me as a strong relic of the Iron Curtain and because of its presence in the present as a vehicle with a high degree of customization on our roads. [...] In times of global merchandise trade and completely anonymous products, a large group of people is growing up, consciously seeking clear contrasts. In addition, I am personally always pleased when a discarded object is transformed by my work into a desirable object.” (netnography)	Articulating Allegorizing Assembling Antimonizing
<b>Retrovention</b> (Ampelmann)	“AMPELMANN products are reminders of their varied history and their triumphal procession from the eastern part of the city through the whole of Berlin. The Ampelmännchen are one of the very few relics of the former GDR to have survived, with our help!” (Ampelmann website)	Allegorizing
<b>Retrovention</b> (Ampelmann)	“To some, the lamp man is a symbol of a simpler, happier past. He is a relic from an inhumane regime that in retrospect seems in some ways more human than the capitalist regime East Germans have joined.” “The Ampelmännchen [...] are an example of Berliners’ ability to recognize the good parts of their past—amid all of the atrocities—and to preserve them.” (popular media)	Articulating
<b>Retrovention</b> (Ampelmann)	Heckhausen holds the copyright to the iconic Ampelmann design alongside its original creator, Karl Peglau, who was sceptical of Heckhausen’s project at first. But after getting to know the artist he was soon on-board, becoming not only a shareholder, but also a father figure in the company until his death in 2009. Together they (...) made the Ampelmann into something East Germans could be proud of. Ossi, a term for people living in the GDR, “was such an insult. But the Ampelmann started to change that as it was something more positive,” the father-of-three said. As interest grew, Heckhausen said that he began to realize the green man was “a symbol that the GDR was more than just the Stasi.” (popular media)	Assembling
<b>Retrovention</b> (Ampelmann)	“(The Ampelmann) Brings out a unique part of East Berlin that is both historic and current. A great shop for souvenirs.” (netnography) “The conflict between Euro and regional is part of the wider conflict between global and local. The lamp man alternately blinks ‘stop’ and ‘go,’ and thus may be a modern symbol of our ambivalence about progress.” (popular media)	Antimonizing

thus not build on existing brand-level aura, core values, brand essence as suggested by Brown et al. (2003). Rather, assembling in the case of retrovention includes a collective effort by various actors in consumer culture who animate the brand and its core values in the light of a given counter-memory to act as an iconic-authentic identity salve. Consequently, in the case of Ampelmann, *antinomizing* refers predominantly to the systematic contradiction of the brand existing simultaneously as both, a public good (traffic light) and a commercialized representation of a past.

### CONCLUDING DISCUSSION

By using a cultural branding perspective on the emergence of retro brands in East Germany, we demonstrate how the production and consumption of commercialized representations of the past via retro brands can only partly be explained with the revival of brand

meaning but includes also the inversion of past brand meanings (retroversion) and invention of retro brand meanings of born retro brands (retrovention). Our development of these two types of consumer brand retrofication by tailoring Brown et al.’s (2003) four As of retro brand qualities into processes of allegorizing, articulating, assembling, and antinomizing has the following implications.

Our work is formulaic about the importance of commemorative culture and its various participants as the larger social setting for the production and consumption of retro brands via retro-revival, retroversion, or retrovention. Commercialized tokens of the past produce and reproduce specific commemorative templates that are joined and enacted by historians, journalists, celebrities, artists, musicians, entrepreneurs, marketers, and consumers who act as co-creators of a specific past, themselves selectively crafting, consuming, and variously interpreting commercialized representations

of the past. The marketplace mythology of commemorative culture postulates a balanced image of the GDR past but does not determine where the truth ends and the revisionism begins. Consequently, retro brands are far more political and collective entities than previously acknowledged and should not only be seen primarily as devices for consumer enchantment as past research suggests but must also be understood as market-mediated ideological resources in popular memory conflicts as well as collective and individual identity dramas.

Moreover, Brown et al. (2003) argue that retro brands reanimate a powerful sense of authenticity. From this perspective, retro brands such as Star Wars sequels or Volkswagen's "New Beetle" draw on a fundamental brand essence from an earlier epoch that is revitalized by marketers by "piecing it together from pop culture and retro references." In contrast, we propose that, if a brand's allegory or quality of resolving a specific moral contradiction is never a given, neither can be its authenticity in doing so (Brown, McDonagh, and Shultz 2013). While this applies also to retrorevival and retroversion, it is particularly pertinent in the case of retrovention where no commercial track record of the brand's past exists, because it never existed as a brand. Instead, its meanings are entirely culture-based. Commercializing tokens of a culture's past might ultimately be seen as a consumer-cultural mechanism of the survival of culture (Firat 1995).

# How Employees Relate to Their Brand Online: A Critical Visual Analysis of Hollister

Stephanie Kogler, University of Innsbruck, Austria

## ABSTRACT

This study aims to investigate the role of employees as co-creators of brand meaning on social networking sites. Analysis focuses on the fashion brand Hollister and their employees' visual practices. In particular the findings shed light on visual practices of employees that intersect with identity assemblages of the company.

## INTRODUCTION

Every single day, 95 million pictures are uploaded and shared on Instagram (Aslam 2018). Due to the visual nature of Instagram (Marwick 2015) and its continuous growth, novel visual practices within this social network where various actors constantly interact, negotiate and exchange meanings become particularly important for brands (e.g. Kedzior et al. 2016; Rokka and Canniford 2016). While contemporary consumer research provides valuable knowledge on how consumers visually perform brands on Instagram, for example via "brand selfies" – i.e. consumer images featuring and tagging brands (Presi, Maehle, and Kleppe 2016; Rokka and Canniford 2016) –, the role of other important stakeholders for brand building, such as employees, has thus far received limited attention. To address this theoretical gap, this study investigates how employees relate to their brand online, and more specifically, how employees co-create brand meaning via new forms of visual practices.

Prior research has emphasized that employees take an important role as meaning-makers as they constantly produce and project brand meanings towards customers, colleagues, and friends (Kärreman and Rylander 2008; Rokka, Karlsson, and Tienari 2014; Schultz and de Chernatony 2002). The digital age has further accelerated employees' meaning co-creation. Employees' online engagement has the potential to be useful but also damaging for the brand (Fournier and Avery 2011; Rokka et al. 2014). Due to multiple or shifting roles employees can adopt and embody online (Vallaster and von Wallpach 2013), we currently lack theoretical understanding about which roles they take, and how they contribute to brand co-creation online. Additionally, most research on online brand co-creation or electronic word of mouth has been textually, rather than visually based (Rokka and Canniford 2016). This is striking given that Instagram – one of the leading online branding platforms –, for example, is above all a visual communication platform.

Prior research recognizes that in social media environments such as Instagram, consumers use brands in multiple ways, and especially as an instrument for self-presentation and accumulation of attentional capital, "instafame", and in attempts to becoming micro-celebrities (Arvidsson and Caliandro 2016; Marwick 2015), even to an extent that it has the potential to destabilize brands (Presi, Maehle, and Kleppe 2016; Rokka and Canniford 2016). How employees re-assemble images and expressions of their employer brand as part of their own identity assemblages remains unknown, so far.

Taking the perspective of internal/employer brand members, we theorize the role of employees as co-creators of brand meaning on social networking sites. Our empirical analysis focuses on the fashion brand Hollister and their employees' visual practices. In particular, the findings shed light on visual practices of employees that intersect with identity assemblages of the company. We describe and discuss how employees mimic, pick and neglect assemblages of their brand in online environments, point out limitations of the study and offer future research possibilities.

## ASSEMBLAGE THEORY

Drawing on assemblage theory (Canniford and Bajde 2016; Rokka and Canniford 2016), we build up on the assumption that brands are composed of mobile and dynamic arrangements of heterogeneous elements (DeLanda 2006), including expressive and material, rather than being comprised of stable or standardized constituents. Multitude of elements including people, but also physical, narrative, and visual elements, as well as digital technologies allow access to and constantly perform a brand (Parmentier and Fischer 2015). The concept of socio-materiality assumes that material and social elements are inseparable, which means that brands are being constructed by and realized through social interactions of various people that comprise material artefacts. These theoretical underpinnings shape our understanding of brands. Brands cannot be understood from choosing or looking at one single stakeholder, brands derive from complex networking dynamics among all actors.

Assemblage theory allows to explore the complex cultural understandings of brands by considering the material and expressive components of visuals (Presi, Maehle, and Kleppe 2016; Rokka and Canniford 2016). Material elements are tangible elements, such as physical objects including consumers, physical products, retail spaces, and media spaces (Lury 2009; Parmentier and Fischer 2015). Expressive components refer to communicative elements, such as brand narratives, mythologies, consumer's gestures that signal class, gender and heritage (Alexander 2009; Beverland 2005; Rokka and Canniford 2016). A further advantage of assemblage theory is its sensitivity towards processes of stabilization and destabilization processes of brands (Parmentier and Fischer 2015; Presi, Maehle, and Kleppe 2016; Rokka and Canniford 2016).

This study is grounded on assemblage theory's dual interest in the material and the expressive in brand elements to investigate visual brand meaning co-creation processes of a brand and its employees online. Assemblage theory also draws attention to territorial boundaries, or the degree to which the elements of an assemblage draw on a homogeneous repertoire. We, therefore, sample employer as well as employee visuals, in order to analyze how brand visuals resonate with the visual identity assemblages of employees.

## METHODOLOGY

This study builds upon data retrieved from Instagram, as it is the fastest growing platform in terms of numbers and importance (Tidénberg and Gómez Cruz 2015). For our analysis, we investigated the official brand account of Hollister (@hollisterco) and 12 accounts of its employees. In total, we collected 1480 brand images and 616 Hollister employee posts, covering a time frame from May 2015–May 2016. Because of the first author's professional background, we were able to identify employees' Instagram accounts. After randomly sampling the visuals, the final sample comprised 100 Instagram posts of the brand Hollister and 200 Instagram posts of employees of the brand, which were further analyzed in detail. Using critical visual content analysis techniques (Humphreys and Thompson 2014; Rose 2012), the Instagram posts were analyzed and coded for their material and expressive components as well as patterns of similarities and differences (Canniford and Bajde 2016; Rokka and Canniford 2016).

Our context is the international retailing brand Hollister, which is a subsidiary of Abercrombie & Fitch. In order to be able to juxtapose the constituents of the brand with the material and expressive visual elements of employee's posts, we draw on the published com-

pany vision. In line with the vision of the company, employees at Abercrombie & Fitch must have “the ability to be extroverted, fun, friendly, active and social. This includes projecting an energetic, vigorous and lively personality, and actively seeking out interaction with others, liveliness and enthusiasm, having a positive demeanor, and displaying a passion and enjoyment for life”. The following section illustrates how the brand’s Instagram account as well as its employees’ accounts draw on these components that constitute the brand.

**FINDINGS**

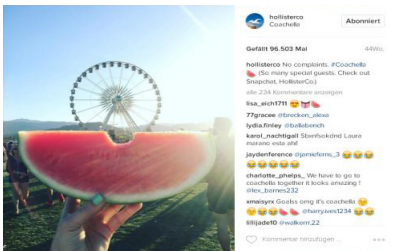

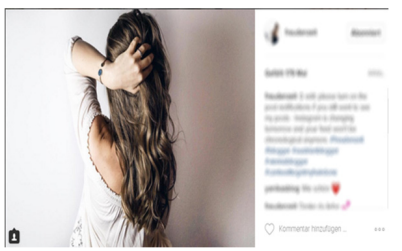

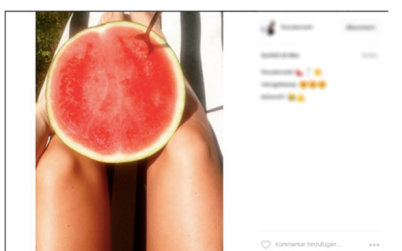

The findings of the study reveal how employees relate to their brand in online environments through practices of *mimicking*, *focusing* and *neglecting* elements of their brand. In the discussion, we further outline how these assemblages affect the brand as a whole. In the following we provide a detailed description of these practices.

**Mimicking the brand**

The analysis reveals that the images of employees share important characteristics with the images of the brand account. Employees strongly express the brand image, mimic and imitate the brand’s visual rhetoric in relevance of material elements as well as expressive elements as described in the following.

Common material elements in the brand account and the employee accounts are beaches, the sea, rocks or surf boards. Clothes are an important material element in both accounts. “*Hollister is the fantasy of southern California. Inspired by beautiful beaches, open blue skies, and sunshine, Hollister lives the dream of an endless summer*” (Hollisterco.com). While, as one might anticipate, all humans in the brand posts, wear Hollister clothes, employees are wearing a similar style of clothes, but without visible reference to the brand Hollister. It is a striking finding that the brand’s fashion and life-

**Table 1: Summary of the Findings**

	<p align="center"><b>Official Brand Account Hollister</b></p>	<p align="center"><b>Employee Account Hollister</b></p>
<p><b>Mimicking the brand</b>                      Employees embed their brand into their personal lives and normalize brand meaning                      -mimic clothing style                      -snapshot-like imaginary                      -same gestures and postures                      -live the California lifestyle</p>	   	   

style is clearly visible in the employees' posts. Employees remarkably reproduce the style of the brand, depicting the same clothes and combine them in the same way, yet they do so in an inconspicuous manner and never use the Hollister brand logo.

The brand and the employee's posts use snapshot-like imaginary. Humans on the images are active, full of energy and having fun; products are shown in motion. While brand images are mostly placed in a natural environment, showing beaches, the sea, gardens, streets or landscapes, the location of employee's visuals is mostly inside, taking the brand into their everyday context, like for example at the gym, in the bedroom, living room or kitchen. Snapshots are a powerful tool to create authenticity and demonstrate how the brand might fit into the consumer's or employee's lifestyle (Schröder 2013). Employees posts reveal the tendency to mimic the brand not

only in terms of material elements, postures and gestures but even in terms of authenticity in that they choose their own authentic places.

Turning towards the expressive components within the visuals, the Californian lifestyle the brand stands for, is strongly expressed within the brand account as well as the employees' accounts through living the good life, having fun with friends, enjoying time together, spending time at the beach. Employee visuals also mimic expressive brand elements. The most frequent expressive categories such as happiness, inspiring others, positivity and coolness are not only aligned with the brand image but also found to a great extent within the employee's visuals. Interestingly, employees do not only mimic the lifestyle, but even reinforce it.

The findings illustrate how employees emplace the brand into their personal lives. Life world emplacement is an important technique to make brands culturally relevant (Holt 2002). In times of

social media, employees take over emplacement work by translating brands into their everyday life context. By doing that, employees provide valuable proof for consumers that the brand reflects a valuable cultural meaning. Employees do not only help authenticate the brand by integrating it into their lives, but also visually normalize its cultural message. The inconspicuous emplacement of the brand in the real-life context of employees, and the snapshot composition of the picture itself, legitimates and authenticates the brand, which potentially stabilizes the brand assemblage as a whole.

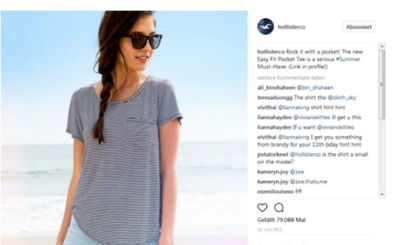

**Picking central brand elements**

Employees pick or take out a central element of the brand assemblage and give priority to this component by focusing on it and amplifying it. The brand Hollister is known for putting high body-related aesthetic standards on employees willing to work in their

stores. The aesthetic standards emphasized by the brand resembles the current preoccupation with fitness in contemporary society (Bauman 2005). Unsurprisingly, the body becomes a central visual element of Hollister, which is eagerly reproduced by its employees. We identify identical body types in brand and employees' visuals: skinny females and muscular and well-trained males. Material elements play a crucial role. Employees like to present their body and put it in the center of attention, posting selfies how they work out in the gym. Shirtless torsos and other body parts are exhibited, expressing strong motivation and dedication for aestheticizing their own body.

Interestingly, pictures focusing on the employees' bodies are often taken as selfies. Selfies are a popular mode of visual self-presentation acting as a nodal point where official brand assemblages and microcelebrity assemblages intersect (Rokka and Canniford 2016). Employees posts liken consumers attention seeking posts. The selfies

<p><b>Neglecting commercial elements</b> Employees represent the brand and use the brand's visual rhetoric, but they do not actively promote the brand and do not participate in the marketplace Instagram -other brands visible -employees are assemblages</p>	   	   

shared by employees show a visual rhetoric that is different from the brand, shifting attention towards their bodies rather than towards the brand. Two mechanisms might be at play here. Employees strongly focus on the brand promise and legitimize and demonstrate that they suit the brand by presenting their “perfect” bodies. At the same time, having a perfect body might also serve as an ego enhancement for employees and cultural capital in liquid modernity where being fit is a “certificate of ‘being in’, of belonging, of inclusion, of the right of residence” (Bauman 2005). We argue that employees use and amplify the visual rhetoric of the brand in an attempt to legitimize their role of being an employee of the brand and at the same time make it self-relevant.

### Neglecting commercial elements

Employees’ visuals also reveal brand elements to which employees do not refer to at all. Employees strictly avoid any sales attitude. In the brand account, Hollister products appear frequently, trying to evoke the desire to go shopping. Brand visuals share product information about Hollister fashion with the intention to give outfit inspirations, mainly through the presence of Hollister clothes on the visuals or expressed through the caption.

Contrary to the brand, employees neither show the brand logo of Hollister in the visuals nor do they share product information about Hollister. Interestingly, employees even post a few other brands, most commonly Apple, Nike and Starbucks, but also other fashion brands such as Zara, H&M, and luxury brands such as Louis Vuitton or Michael Kors. This illustrates how employees actually create assemblages of various brands. These trendy brands reoccur in all employee accounts strengthening employees’ aspiration to be “in” and to belong to the “cool” crowd.

Employees do not express their love towards the brand. Contrary to other actors such as bloggers or influencer who get paid for promoting the brand, employees neither cite, nor promote or sell the brand and do not become part of the Instagram marketplace. They represent the brand and use the brand’s visual rhetoric, but they do not actively promote the brand by referring to the products or tagging the brand. As employees represent but do not sell the brand, the brand appears more integrated in their lives, making it even more authentic and credible.

### DISCUSSION

This paper contributes to our knowledge how employees relate to their brand in online environments and emphasizes the significant role of employees’ visual communications in the construction of brand assemblages. Our findings reveal three important practices how employees add to visual brand rhetoric and stabilize visual brand assemblage—mimicking brand elements and style, picking central brand elements, and neglecting commercial content. In our study, we find that employees confirm and reinforce brand meaning through mimicking and providing coherent visual interpretations of the brand, through extracting and amplifying central brand elements, and through authenticating acts of neglecting commercial content. We find that employees visual brand expressions and authentic self-presentations fulfill an important bridging function between the brand and its consumers. On the one hand, employees serve as representatives and brand ambassadors, who credibly convey brand meaning and visually communicate these to consumers. On the other hand, similar to consumers in online environments, they perform micro-celebrity and attention-seeking practices (Rokka and Canniford 2016) and refuse any commercial logic in their visual brand rhetoric, which renders the brand more authentic among consumers. Stabilization of brand assemblages is not only a matter of the degree

to which the elements of an assemblage draw on a homogeneous repertoire, which we massively find in mimicked material and expressive visual elements, but also through authentic, self-relevant articulations that become nodes in a network (DeLanda 2016)—or relations to consumers.

The study has two main limitations. First, our study focuses on one brand and one digital platform. Second, findings should be contrasted with other important stakeholders of a brand. Further research should therefore investigate the visual online behavior of consumers in contrast to employee’s visual rhetoric, but also include other brands outside the fashion industry.

# Faster Than Fact: Consuming in Post-Truth Society

Robert Kozinets, University of Southern California, USA  
Rossella Gambetti, Università Cattolica del Sacro Cuore, Italy  
Silvia Biraghi, Università Cattolica del Sacro Cuore, Italy

## ABSTRACT

Technocapitalism a potent combination of information technology and capitalism is the fundamental industrial force of our time. Technocapitalism affects consumers' communication power consumer culture's acceleration speed de-temporalization and counter-narratives. This paper uses social assemblage dynamics to explain how technocapitalism produces some of the most vivid digital manifestations of post-truth society.

## INTRODUCTION

The time people spend online browsing, creating, sharing, and commenting contents is increasing. According to the American Press Institute the 88% of young people use Facebook as their main source for information (<https://www.americanpressinstitute.org/publications/reports/survey-research/millennials-social-media/>). In general, online users decide if news is truth or fiction based on who shared it (<https://www.americanpressinstitute.org/publications/reports/survey-research/trust-social-media/>). Is truth getting lost in the algorithms of social media? In this paper we address this research question and investigate how people build narratives and counter-narratives that are perceived as truthful in social media conversations. In addition, we investigate how speed may shape people's formation of truth.

To address these questions, we ground our study in the frame of assemblage theory (i.e. the intersectional nature of social assemblages), social media literature on counter-narratives, and technocapitalism-related theories of speed, acceleration and de-temporalization. These are the conceptual underpinnings of what nowadays has been called post-fact society. Our study is set in the dog breeding context, an online field site where multiple beliefs and truths are constantly generated and disputed in controversial narratives and counter-narratives.

## THE DYNAMICS OF INTERSECTING SOCIAL ASSEMBLAGES

Consumers are commonly enrolled in intersecting social assemblages (i.e. a fan of a specific TV show who is enrolled also in discussion boards about TV shows in general or more broadly fan communities which intersect with media companies). These assemblages may be complementary but also problematic in their intersections, like in the case of counter-assemblages (see Canniford and Shankar 2013; Giesler 2012; Parmentier and Fisher 2015; Scaraboto and Fisher, 2016; Thompson and Coskuner-Balli 2007). According to Deleuze and Guattari (1987) assemblages are made of discontinuous and different components: some of them are rigid with high territorialization degree, while others are supple with low territorialization degree, and some of these components can mark the directions along which an assemblage gets deterritorialized (DeLanda 2016). Deterritorialization in the assemblage can occur at different rates of flow in terms of slowness and viscosity or acceleration and rupture. In fact, social assemblages may operate at different temporal scales that are relative to the duration and stability (or instability) of the events and interactions capable of building and changing them (DeLanda 2006).

Extant marketing and consumption literature has recognized the communal and commercial tensions that may arise from these intersections (McQuarries et al. 2013; Kozinets et al. 2010) and analyzed how consumers try to navigate and resolve these tensions (Par-

mentier and Fisher 2015), as in the case of consumers who work to stabilize fields, networks, communities, markets and industries (Scaraboto and Fisher 2016: 172) when tensions occur in social assemblages. However, we currently know very little about how the speed of territorialization and deterritorialization of social assemblages shape consumers' formation of truth.

Dynamism characterizes the discontinuous changes of contemporary consumer culture (McCracken, 2006: 3-4) and dromology, or the logic of speed, emerges as the foundation of contemporary technocapitalist society and the ultimate agent of progress (Virilio, 1977 [2006]: 69). Technology speeds social change and makes it largely computational (Bratton, 2006: 13). Yet, the impact of the current speed of the discursive and expressive practices through which assemblages are produced, contested, and re-stabilized in the social construction of truth in social media has largely remained unexplored. Because speed characterizes social change in contemporary consumer culture, a deeper understanding of this gap may advance consumer culture knowledge.

## THE SPEED OF COUNTER-NARRATIVES IN POST-FACT SOCIETY

Social media are connective platforms where the democratized communication power of consumers and their networked activism (Helman and Wagnsson 2015; Ray et al. 2017; Williams 2017) facilitate the outbreak and the circulation of counter-narratives (Cheong and Lundry 2012: 489). These alternative narratives compete with those of official sources of information as well between each other. Beyond the use of words, the visual rhetoric characterizing social media discourse forms a dynamic visual lexicon that articulates a multilayered counter-narrative that openly contrasts with mainstream discourses (Clancy and Clancy 2016: 282).

The multiplicity of competing narratives that characterizes social media discourse (Page, 2014) finds a fertile territory of expression in the current *post-fact society* (Manjoo 2008; Mihailidis and Viotty 2017). Post-fact society is the result of the fracturing of common institutional sources of information, the lack of common trust in avenues for information, and the massive spread of content creation and dissemination practices that have collectively led to a society in which citizens are less frequently exposed to similar sets of facts (Mihailidis and Viotty 2017: 447) that may allow for a shared perception of objective truth.

Additionally, crystallizing shared truths requires a time frame that is no longer compatible with the pace of contemporary economy. In this new economic reality, speed and its concentration have actualized the centralization and the acceleration of the technocapitalist powers of media, industry, and war-making (Virilio, 2006: 11). Rosa, Dörre and Lessenich (2017: 58) contend that modern societies are characterized by three processes of acceleration that mutually reinforce each other: 1) the technical acceleration of transport, communication and production; 2) the acceleration of socio-cultural change; and 3) the acceleration of the speed of life, social interaction, and consumption. Moreover, social media communications have made it possible to "detemporalize" consumers' connections and reactivate them at will at points in time and in sequences of consumers' own choosing (Rosa, 2013: 103). As Castells (2013: 34) argues with the concept of "timeless time" and Bauman (2000: 117-118) postulates

in his notion of “no time”, the relentless effort to annihilate time by negating formal sequencing has ended up compressing and hyper-accelerating time (Tomlinson, 2007: 10). Social media is marked by the rapid-fire development of content and its spread. This speeding of textual and imagistic content and its destructured sequentialization nurture narratives and competing counter-narratives in amplified profusion. As we have learned with the intrigue of recent events occurring across social media, this multitudinous profusion of narrative magnifies the formation of post-truths.

### THE POWER OF NEGATIVE DISCOURSE IN SHAPING POST-TRUTHS

Social media have created liquid spaces of interaction where post-fact truths are boosted by misinformation and populist discourses that are easy to distribute but difficult to refute (Bode and Vraga 2015; Dalrymple, Young and Tully 2016; Lewansowski et al. 2012; Speed and Mannion 2017; Vraga and Bode 2017). As well, harsh disputes, incivility and sarcasm arouse and polarize opinions and beliefs (Anderson and Huntington 2017), continuously destabilizing and reconfiguring existing social assemblages.

In fact, despite the recent trend that depicts individuals turning to online sources to seek out, understand, and discuss scientific issues more broadly (Su et al. 2015; Uldam and Askanius 2013), contemporary portrayals of online discussions often see them as harbors of conflict, uncertainty, and personal attack (Anderson and Huntington 2017: 599; Dalrymple et al. 2016). The negative discourse of social media shapes public perceptions of and engagement with science (Hwang, Kim and Huh 2014), while triggering contrasting debates that variously empower and disempower competing statements. With so many competing sources of truth, trust and reliability in the veracity of statements depends increasingly on the persuasive rhetoric ability of people to assemble, affiliate, territorialize and deterritorialize social consensus (Zappavigna 2012).

In this investigation, we aim to unpack how post-truths are built in the context of connective social media platforms and also map how the speed of territorialization and deterritorialization of assemblages and counter-assemblages shapes the social construction of those truths in the social media era.

### METHOD

We sought a methodological lens that could help us focus on the narratives and counter-narratives present in social media. We opted for a netnographic research approach, focusing on the plethora of discursive and expressive practices and interactions flowing through a Facebook’s social networking site. Netnography opens a window on the rich cultural and symbolic world of people and groups as they use social media (Kozinets, 2015: 80). The netnographic field site we chose was a pet-related site devoted to topics relevant to purebred dog breeds.

Pets have been treated both as consumption objects, ornaments, things that we own (Hirschman 1994), aspects of our self-concept (Belk 1988), and members of our families (Downey and Ellis 2008; Greenebaum 2004; Hirschman 1994; Hollbrook and Woodside 2008; Sanders 1990). They are fellow beings with whom we establish an intersubjective connection and share our lives (Sanders 2003). In social media, the relationship between pets and their human partners represents a prolific arena for the formation of narratives and counter-narratives. These narratives are particularly powerful when it comes to discussing about scientific issues related to dogs’ accurate selection, care, and health. In this case, dog breeders, owners and lovers form social assemblages to disseminate their post-truths.

In this paper we specifically focus on the context of purebred dog breeding and care and their public construction and representation in social media discourses. Pet breeding entails the controlled propagation of domestic animals to improve desirable qualities (Freeman 1998). The links between pet ownership and modern science run deep. No less than Charles Darwin described the connection between domestication, selection and evolution, demonstrating how domestication and selective breeding are a science that had produced significant changes over time in a range of animals, including dogs (Darwin 1868). Deliberate selective dog breeding has been used to create desired changes in dogs to adapt them to perform tasks necessary for human survival. Today some of these tasks are performed in other ways, yet dogs still have fundamental specialized uses for search and rescue, narcotics and other kinds of detection, along with other skills such as therapy (Cooper 2016). Additionally, today dog breeding follows scientific principles to refine dogs’ appearance, boost their athletic ability or improve their temperament both for personal pleasure and for increased market opportunities.

The modern-day science of dog breeding offers a fertile territory for generating strong common links between people. But it also generates equally harsh debates, disagreements and conflicts. The aim of our study is to contribute to a general understanding of the assemblage dynamics through which post-truths are socially constructed by studying how they operate and are configured in social media discourses related to dog breeding and care.

As initial sites for data collection, we followed netnographic procedures and selected three public Facebook pages. These pages were dedicated to breeders, owners and lovers of three dog breeds that are particularly sought-after in the market for the established purebred qualities and, as a result of this purity, members of these breeds are subject to specific health problems. The dog breeds are Black Pugs, Welsh Pembroke Corgi and Boxers. These Facebook spaces, named “*Welsh Pembroke Corgi*” (2013, 11,037 members), “*Black Pugs*” (2007, 11,587 members), and “*Everyday Boxer*” (2016, 35,140 members) deal with controversial and largely disputed topics of dog breeding. We collected in total 163 posts including 7,660 comments (49 posts and 2849 comments for “*Everyday Boxer*”, 48 posts and 2095 comments for “*Black Pugs*”, 66 posts and 2716 comments for “*Welsh Pembroke Corgi*”). Data collection was conducted between June and October 2017.

We conducted a hermeneutic interpretation of this qualitative dataset to identify the discursive and visual rhetoric patterns that consumers build when producing and sharing their narratives and counter-narratives on selected purebred dog care issues. We observed a variety of patterns among which we selected the most substantial (dense in meanings and actions) and the most dynamic (frequently updated). Each pattern was subsequently analyzed in-depth following Kozinets’s (2015) netnographic guidelines, generating a corpus of field notes, transcriptions, archived texts, and images constituting the entire dataset. The overall corpus of fieldnotes and transcriptions included more than 745 pages of visual and textual narratives that provided the basis for our hermeneutic interpretive work.

### PRELIMINARY FINDINGS

In table 1 we briefly show some of the key discursive dynamics that consumers use to build counter-assemblages that lead to post-truths related to vaccines, pet food, and purebred selection. Figure 1 specifically focuses on two topics, vaccines and pet food, to illustrate the different temporal scales through which post-truths are assembled.

These two topics act as *catalytic triggers* of social assemblages and counter-assemblages that get territorialized and deterritorial-

ized in post-fact truths. In the three Facebook pages analyzed, users tend to share a strong anti-vaccination ethos that builds a solid *echo chamber* (Gilbert, Bergstrom and Karahalios 2009; Pariser 2011), where common negative beliefs about vaccines are shared—in both the social media, as well as the cultural sense of that word. These shared beliefs establish a social assemblage which is reinforced by similar expressions. These expressions become enduring post-truths in which extreme, and also populist positions are held by users (see table 1: 1) anti #overvaccination). Research shows that the Internet plays a large role in disseminating and sensationalizing vaccine objections. Such objections are part of the “anti-vaccination movement” (Poland and Jacobson 2001), which involves counter-debate about potential vaccination risks that social media amplify via a rhetoric of doubt (Kata 2010: 1709). This rhetoric increases vaccination decisions based on misleading information and post-truth claims that are propagated in social media around cogent socio-cultural issues (e.g. safety, civil liberties, natural well-being, morality, ideology, conspiracy and emotional appeals) (Kata 2012; Nicholson and Leask 2012).

In the case of #diet, users tend to be united in opposing the dominant narrative spread by the pet food industry about their product quality with counter-narratives. However, while being anti-vaccine necessarily means avoiding vaccination, being anti-pet food industry does not leave pet owners with a lack of alternative options. In fact, multiple intersecting and competing counter-assemblages are territorialized and deterritorialized to support the validity of different dieting choices (see *Everyday Boxer*) where no dieting narrative emerges as dominant (see table 1: 2) multiple dieting options).

Stable echo-chambers are actualized by strong catalytic triggers, (i.e. #anti-vaccination) that territorialize widely shared ideological movements of protest which oppose institutional forces (i.e. veterinary science). These eco-chambers generate forms of speed resistance to post-truth because the crystallized beliefs constituting the eco-chamber are so strongly defended that they end up annihilating divergent opinions, while neutralizing the speed of counter-narrative generation (see table 1: 2) anti #vaccination).

In contrast, unstable territorialization and deterritorialization generated by weak catalytic triggers (e.g. multiple dieting options) are governed by high speed of post-truth. In this case different claims are confronted in a rapid flow of intersecting narratives and counter-narratives that confer dynamism and speed to the discourse (see table 1: 2) multiple dieting options). That rapid flow shapes and reconfigures the liquid boundaries of social assemblages.

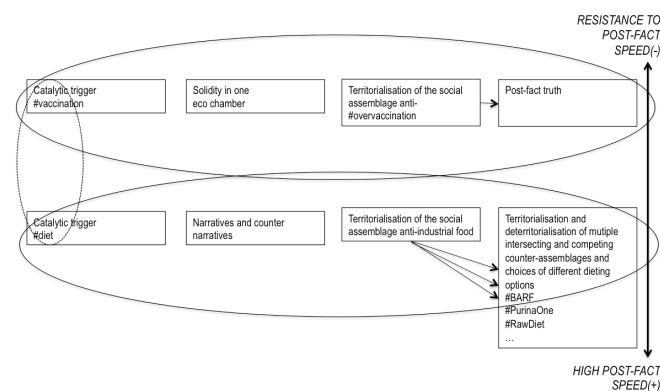

Figure 1: Speed of Social Assemblages and Counter-Assemblages in Building Post-Truths

## DISCUSSION AND CONTRIBUTION

The intensifying connectivity between networked humans and technological agents drives new influence mechanisms. These interconnected actors activate triggers that catalyze temporary investments in configurations which gather multiple truths in numerous social assemblages. Consequently, consumers make decisions based upon what they believe momentarily to be the most credible social assemblage, rather than what they might feel, in that moment, or universally, to be true.

These insights, although preliminary, offer novel insight towards understanding the complex social dynamics of contemporary consumer behavior in the social media age. As consumers such as dog breed enthusiasts encounter one another on Facebook, they also encounter contemporary technocapitalist forces related to their communicative empowerment and disempowerment, consumer culture’s acceleration, speed and detemporalization, and polarizing and reactivity-inducing counter-narratives.

**Table 1: Catalytic triggers generating tensions in social assemblages leading to post-truths**

Catalytic triggers	Example of evidence that generates tensions in a social assemblage	Eco-chamber and Counter-assemblage	Example of evidence through which post-facts are built as truth
<p>#vaccination and sub-related topics such as pharmaceutical industry and products (i.e. #benadryl; #apoquel) and vet allopathic standards</p>	<p><i>Sandra Brush to Everyday Boxer: to counteract a corrupt Veterinarian practice of over-vaccinating - I stopped going to VCA (Mars Candy Bar company) clinics who are pushing me to repeatedly vaccinate my dogs on a 3 year rotation and not offering me titer testing... When I asked what they charge for a rabies titer (a blood test that checks for antibodies and proves immunity) they gave me "deer in the headlights" reaction and then quoted me \$449 for one titer! I took my boys to a different independent vet yesterday who agreed to draw blood samples and provide to me... I contacted Dr. John Robb in CT and he gave me instructions on how to ship -- I drove across the border to avoid having them held up in customs and shipped to Kansas State University Rabies Laboratory and paid \$54 US for Rabies / Parvo / Distemper titer testing... if the tests prove immunity for the next 8 yrs I am done and no more vaccines ever for my dogs. I have joined the movement to have the current antiquated rabies law amended. #ProtectThePets</i></p> <p><i>Tiffnie Greer Don't listen to your vet. Sounds so much like over vaccinating for cash. In 3 years, my Boxer has been vaccinated, once. He's beautiful and healthy.</i></p>	<p><b>1) anti-#overvaccination:</b> consumers' posts and related comments get crystallized in an eco-chamber that opposes the scientific standards of pharmaceutical industry and vets. Posts - like the one shown in the next column - consistently build post-facts, which assemble support from consumers.</p> <p><b>2) anti-#vaccination and resistance to speed:</b> The powerful populist claims of the anti-vaccination eco-chamber generate post-truths that are discursively built and perpetuated to isolate the divergent opinions and exclude the persons who expressed them from the social assemblage. The eco-chamber is so strongly asserted that the people whose beliefs do not conform to the dominant positions perceive themselves as victims of bullying inside the social assemblage and may consequently abandon it. Additionally, the strength of this crystallized anti-vaccine eco-chamber slows down the conversation and brings it to stop, making any opposing or competing truth surrender. That neutralizes the speed of generation and propagation of counter-narrative discourse.</p>	<p><i>Syni Brent: Jill Jenkins, look up titer testing and you will understand that what I am suggesting is not NOT VACCINATING, it's NOT OVER VACCINATING. And vaccinating on a schedule where their nervous systems are developed enough to withstand it. There's a huge difference. And I'm not just some backyard breeder who doesn't want to do right by the puppies in order to save a buck. I work closely with holistic vets, chiropractors, acupuncturists and even animal communicators regarding all my animals. They are the top priority and I look out for their best interest &amp; optimal health. Do some research and you will see that over vaccinating is a top trigger for DM&amp; kidney issues in dogs. Both issues are prevalent in the corgi breed already. It breaks down their nervous system by over-vaccinating, or giving too many at once or too early or too closely together. Taking the easy route by just letting some pharmaceutically backed vet give them an entire series of vaccinations when they don't need it can shorten their lifespan tremendously. So I refuse to follow blindly any lazy veterinarian that won't collaborate. I know my stuff. It's my job to advocate for my animals and my kids and my loved ones. That's what we do for those who can't speak for themselves.</i></p> <p><i>Candace Muenzner: I agree with the census. I hate to over vaccinate however vets just don't trust people to do their own. Good or bad you must really trust the person regarding vaccine dates or proper shipping care etc.</i></p> <p><i>Sandra Brush: the laws are wrong and not based on science at all Catarina Schwahn: Honestly, Tina Crabtree, is there any way this could be taken down? This is illegal and dangerous information she is putting out. I am a Veterinary technician and we are not even allowed to touch an animal without it's vaccination UTD in my clinic until the doctor comes in. Especially since the patient I had last year was positive for rabies at 6 months of age. This, to me, is reckless. I'm sorry</i></p> <p><i>Tina Crabtree: I understand your position Catarina, truly I do. In truth, I'm a believer in vaccines. With that being said, Sandra has the right to her belief.</i></p> <p><i>Catarina Schwahn: That, I understand, and am all for. The major issue is that what she is pushing here is illegal and people that are reading this and do as she says because she seems so full of knowledge, will end up in legal trouble and possibly having their dog's head cut off because they are not UTD. Plus, the bullying of people that don't agree with her is down right rude.</i></p> <p><i>Sandra Brush: ummm ok and your point ? my post is simply about SCIENCE and sharing information from a board certified VETERINARIAN on correct dosing of vaccines by body weight and to titer test to avoid killing your dog with over-vaccination if he already has immunity (circulating antibodies).</i></p> <p><i>Sandra Brush: I will not allow any vet to inject a vaccine into a living being (my dogs) that already has proven immunity -- it's criminal.</i></p> <p><i>Catarina Schwahn: Sandra Brush, I have noticed over the weeks that I have been on this page that you are a serious bully and anyone that doesn't agree with you, you bash and make them out as animal abusers for simple things such as vaccinations. You are basically telling us to break the law because of YOUR beliefs, which is reckless. Not only for us, but our dogs. Where did YOU get your veterinary experience from? Did YOU go to veterinary school? Have your veterinary science degree or Veterinary Technician degree? Have you seen, like I have, a six month old puppy that has rabies? That was twisting his body? It nipped me while I was triaging it last year, luckily, I am vaccinated so I was safe. But that six month old puppy was not vaccinated at all. I assisted in euthanizing and severing it's head and putting it into a cooler for Animal Control to take to state just for a confirmation of rabies. You need to stop bullying people in this group for not sharing your views. Please! You make everyone seem so hostile just because not in line with YOUR views. I had enough, I quit!</i></p>
<p>#diet and sub-related topics such as ingredients (i.e. #grainfree; #coconutoil; #feed); allergies to food; industrialization of pet-food; different dieting choices (i.e. BARF, vegan food, raw diets, natural home-made diet)</p>	<p>I don't mean to start a war or controversy, but so saddened to see all the onset of diseases in our precious companions. I was doing some research on GMO's (Genetically Modified Organisms) that plague our food supply as well as pets and wondered if this plays a part (as well as some vaccines) that are hurting our pets (allergies, kidney disease, tumors, other organ diseases, etc). This is just for information. I know its expensive to feed higher end food and organic raw and vaccines are always going to stir up fighting sides. I don't do raw, but here is a link I read about GMO's and dog foods. Wishing well to everyone of you out there because I know how much you love your fuzzy butts out there! I just wanted to share information. Please don't fight over this or add comments that are condescending to others, but just read for your own information. I think this can effect some dogs but not others just like vaccines.</p> <div data-bbox="375 1629 781 1766">  <p><b>The Dangers of Genetically Modified Ingredients in Pet Food</b> Recent research shows that genetically modified (GM) corn causes kidney and liver disease in rats. HEALTHYPETS.MERCOOLA.COM</p> </div>	<p><b>1) Natural, anti-industrial pet food:</b> To contrast food allergies, consumers publicly craft their scientific expertise by showcasing a plethora of dieting options that build a chain of alternative post-fact truths which territorialize social consensus on natural diets over industrial food and remedies (i.e. #grain free food, # coconut oil, #home-made salmon and sweet potatoes)</p>	<p><i>Tori Ann: Ok. Anyone have a pug with allergies? She takes a cocktail of Benedryl and Clairitan regularly. Seems like Lulu has chronic earaches. I think I clean her ears ok...</i></p> <p><i>Julie Dominick: Try adding organic unrefined coconut oil</i></p> <p><i>Tori Ann: She eats a salmon and sweet potato diet. It's a limited ingredient diet. I went thru many different diets. I believe it's an environmental issue. The vet couldn't find anything that caused the scratching and earaches...</i></p> <p><i>Tori Ann: What would you recommend for her to eat? I like the ear cleaning idea... oh my Baby. I just love the daylight out of her. It pains me to watch her scratch herself and to see her ears all pink... sigh.</i></p> <p><i>Sheryl Zaiko: I feed my girls grain free...allergies have definitely improved, plus Benadryl and Hydroxyzine (from vet), expensive, but definitely helps).</i></p> <p><i>Susan Mckinnon: grain free dog food helps</i></p> <p><i>Jill Sterling Pratt: Elroy my pug/chin mix is allergic to corn and chicken he eats a limited fish diet and salmon treats his ears and butt get itchy from snacks with corn and throws up chicken</i></p> <p><i>Ashen Louise Frana: My pug is allergic to most grain products. So she eats Taste of the Wild food and that seems to have cleared up most of the problems. I also got some young living oils from a friend that i use.</i></p> <p><i>Jeanne Hemer Johnson: My kids eat Orijen Six Fish, have a teaspoon of unrefined coconut oil and a teaspoon of nonfat plain yogurt. Lily still complains of allergies once in a while. We live in the woods in an old house. So who knows.</i></p> <p><i>Colleen Wincentsen: Grain free Tori. Heart healthy oil supplements, and sweet oil or olive oil in the ears would be good.</i></p>

Table 1: Catalytic triggers generating tensions in social assemblages leading to post-truths (continued)

Catalytic triggers	Example of evidence that generates tensions in a social assemblage	Eco-chamber and Counter-assemblage	Example of evidence through which post-facts are built as truth
	<p><i>Earl Schiller to Everyday Boxer: So as many of you know Ocean had puppies, today marking 10 weeks, and one of the new owner of a pups that they bought from us, would like to start the puppy direct on a vegan diet kibble...I would like to add that we as humans can change our diet and make our own decisions and that's fine, But animals CAN NOT change their diets by themselves, it is built into their brain what they eat and dogs canines wolfs diet is MEAT. I think this is a bit selfish of her to wanting to do that because as I said animals cannot change their diet, if the owner wants a vegan animal she should buy a rabbit or something, I also feel that if she does this she is not respecting nature... anyway, just my thoughts, I would like your guys opinions about this please and thanks. Has anyone else come across this kind of thing before???? — feeling confused.</i></p>	<p><b>2) Multiple dieting options:</b> Catalytic triggers that do not create solid eco-chambers generate a confrontation of multiple options where no narrative emerges as really dominant (e.g. vegan, protein-based diet; BARF, raw diet, natural home-made diet). Confrontation then gets actualized in a rapid flow of intersecting narratives and counter-narratives that confer dynamism to the conversation, materializing acceleration and speed in the formation of different post-truth claims</p>	<p><i>Just don't overdo it because it can trap bacteria as well. And I agree with your friend who said is there a pug without allergies? Mr. Clyde has them as well. He's not related to Lulu he's one of my new ones. Absolutely no porn in their food if they smell like Fritos it's a yeast thing on the skin and you have to control the yeast in their bodies and their diet. The coconut oil works great for all of them except Clyde. He is allergic to it and gets bumps on his belly from it. Wrong I have to give him Benadryl pills and Benadryl cream to get rid of it. So I cut the coconut oil out of his diet. The bumps have cleared up.</i> <i>Colleen Wincentsen: Porn lol??? That might be tough in Vegas lol! I meant corn!!</i> <i>Dusty Herbert Tori: my pug Moe had the same issue. He is now on salmon and sweet potato as well, natural balance I think the brand is? We switched his diet because he was biting his inner thighs and they were badly irritated. He is okay now, after food change and daily prednisone and Benadryl. However, the vet also said he could have a pollen allergy. Maybe yours does too?</i></p> <p><i>Angel Warren I know many raw feeders, lots are breeders. 50% believe in whole prey raw diets (meats and proteins only) Others believe in omnivore diets or BARF which incorporates veggies, meats, grains and fruits. The argument between them (those who believe all dogs are carnivores, and the rest being those who believe all dogs are omnivores) rages on daily. BUT, never in ALL of my years and years of raw feeding, and being a raw feeding advocate have I heard of anyone making a dog a vegan fed animal. I personally believe dogs NEED protein for proper muscle/bone growth and development. My personal opinion is, that I wouldn't sell a puppy to anyone that believes that's ok. As you said, maybe a gerbil, or a bunny would be a better suited pet.</i> <i>Earl Schiller I totally agree, I thank you very much for your opinion.</i> <i>Ginger Hays Ray I have actually seen a dog the owners put on vegan diet and it looked horrible and was not healthy at all. If they truly want the puppy then they need to research the needs of a canine. We use a sweet potato and green bean diet very short term to pull weight off dogs but never long.</i> <i>Ashley Russell Kegley Amen Angel!!</i> <i>Melissa McGuire Dogs and cats should NEVER be on a vegan diet!</i> <i>Stephen McClure I thought you were joking, I'm sorry it appears your not</i> <i>Earl Schiller ya sadly I'm not.... but our decision is a no anyway.</i> <i>Stephen McClure At the very least you have been fair</i> <i>Earl Schiller So far our decision is a no to this person, that she can't have the pup, I mean yes every dog is different and what works for some dogs don't work for others, BUT iam NOT willing to take that chance that one of our pups will have health problems because a Vegan lady is forcing a helpless puppy to eat vegan kibble, I almost find that as animal cruelty to an extent even though she might have good intentions ? I think she is just a little out of touch with reality because of her veganism.....</i> <i>Hugh Oneill The Owners can choose what they want to eat but to enforce this on a Dog is WRONG WRONG WRONG. Dogs are Carnivores and thus derives its energy and nutrient requirements from a diet consisting mainly or exclusively of animal tissue. Dogs are not humans and cannot change their diet on a whim like us!!!! The puppy could grow up malnourished.</i> <i>Misty Strauser My puppies eat home-made vegan and they have never had any problem...I'm a caring mum and I give them only what is best for them to grow healthy.</i> <i>Earl Schiller exactly my thoughts also !!, thanks for the comment !!</i> <i>Angel Warren Yes, I forgot that in my list, malnourished, very much so! Which would lead to weakness, unhealthy bones, the list is crazy long of "what could be"</i> <i>Earl Schiller ya and I am definitely not will to take that chance.</i> <i>Hugh Oneill Good to hear Earl, puppy's especially need the best food content to grow strong and healthy. If i was a Vegan or Vegetarian i wouldn't impose my eating on my dog or my friends and family. the Dog doesn't have a choice! Some people just beggar belief!!!!</i> <i>....</i> <i>Brandi Rogers Can they have sardines in sunflower oil???</i> <i>Jill Vargas No, water</i> <i>Melinda Kreissler Boeh Once a month I throw whatever meat is on sale in a crockpot with brown rice, lentils, sweet potatoes, and lots of veggies and cook it until mushy. Then I freeze in small containers and add some to his kibble. He loves it. Warning: it's stinky while cooking, but he knows it's for him. Chicken livers are a special treat.</i> <i>JJ Page Kefir, raw eggs, sardines</i> <i>Chris Stypinski Couple teaspoons of coconut oil.</i> <i>Alex Kuretech Freeze dried raw food! It's incredibly healthy, and completely balanced so you won't have to feed as much kibble! Never met a dog who turned it down!</i> <i>Christina Dodge I used to do sweet potatoes green beans hamburger and chicken I would sometimes add raw egg or would even cook her scrambled eggs lol sometimes id even do plain oatmeal with a little chicken broth my pup was so underweight i did that for the first year and it helped a lot now she's 3 and will not eat without all that.</i> <i>Rafael Perez Salmon an egg left over rice chicken skin. Liver, leftover vegetables (no onion)</i></p>

Table 1: Catalytic triggers generating tensions in social assemblages leading to post-truths (continued)

Catalytic triggers	Example of evidence that generates tensions in a social assemblage	Eco-chamber and Counter-assemblage	Example of evidence through which post-facts are built as truth
			<p><i>Sherri Wickersham Tucker Ground flax seed, coconut oil, baked sweet potato, avocado, carrots, plain yogurt scrambled eggs or hard boiled, rice, cottage cheese, peanut butter...</i></p> <p><i>Chere Tait We add a little coconut oil.</i></p> <p><i>Louise Fienemann I started adding a "meat" day in once a week. Wednesdays were meat days. I gave my two a portion of raw green tripe in the morning and raw meat (lamb, beef or chicken) in the evening. They loved it! Then I did this on Saturdays too.... Now they are completely raw fed (BARF)</i></p> <p><i>Linda LaFluer Kaczor Plain can pumpkin. I add a heaping tablespoon to their dry food. Great source of fiber and they love it.</i></p> <p><i>Jill Vargas Meat, fish or eggs.....I wouldn't add more carbs on top of what the dogfood already has</i></p> <p><i>Misty Strauser Pumpkin or green beans</i></p> <p><i>Lis Hennesay 100 % pumpkin</i></p>
<p>#purebred (i.e. #genetic; #gene)</p>		<p><b>Anti-gene alterations:</b> in these threads of posts, consumers negotiate post-fact truths through which the concept of purebred selection liquefies in multiple narratives supporting different "acceptable" (or "non-acceptable") practices</p>	<p><i>[...] Melanie Allen: The dogs fur is not super "bad genes" unless it was for show. I see nothing wrong with that beautiful coat. To each their own &amp; someone will love the fact that this one came out different</i></p> <p><i>Jon Shelley: Pugs Come in fawn and black. Genetically a fawn is always fawn/fawn. Blacks can be black/ black or black/ fawn. I don't know what other mix gives you the white but probably fawn/x. So, black/ fawn x fawn/fawn could produce fawn/fawn or black/fawn. Likewise, a fawn/x with black/fawn could produce x/fawn or x/black or fawn/fawn. These pups look fawn/fawn, fawn/fawn and either fawn/x or black/x.</i></p> <p><i>[...] Denise Caceres: Wow, I didn't know that could happen. Sure she didn't cheat on him? Jk. I think you should keep him/her so we can see how they turn out</i></p> <p><i>Bev Bev Moore: and no she didn't cheat thanks I dont interbreed and only have pugs in my home</i></p> <p><i>[...] Bev Bev Moore: rose u mean someone was naughty i only have pugs in my home and don't inter bred thanks</i></p> <p><i>[...] Paula Edwards: I would dna test all the pups, but especially the black and white one as its just not in the genes to get pied markings. Maybe a cheeky suitor managed to get to your girl without noticing? :)</i></p> <p><i>Bev Bev Moore: paul your comment is very rude as i watch my girl at all times thank u so much</i></p> <p><i>Paula Edwards: If there wasn't a possible 'extra baby daddy' then I would look at the parents pedigrees, one or both sides must have Frenchie or some other breed in the mix. Lots of false papers around these days and unscrupulous breeders turning out 'pugs' with papers but non standard colors. Possible that yours have non standard colors in the past and this has caused this pup to be produced. Same with the other lady on her with her fawn pied pug.</i></p> <p><i>Tammy Gabb: It could have been generations ago that a pug got together with another breed and t not show up in pup's till many years later</i></p> <p><i>Tammy Gabb: Happens in humans all the time</i></p> <p><i>Paula Edwards: Not being offensive, but as a pug breeder of many years and knowing many more breeders who have been in it for decades more than I have, no other color that black or fawn have ever been produced. Just saying it might be worth dna testing to check for what in the bloodlines.</i></p> <p><i>Bev Bev Moore: WELL I KNOW FOR A FACT THAT MY MALE WAS THE ONLY ONE NEAR HER AND HE IS A PURE Pug AS BOTH PARENTS ARE FROM BREEDERS ALSO SHE IS NOT OUT OF MY SITE SO YOUR COMMENTS ARE RUDE AND I DO NOT BELIEVE IN ANY WAY WAT SO EVER OF INTER Breeding</i></p>

# Consumers' Response to Branded Longevity

Anthony Moussa, Paris School of Business, France  
Virginie de Barnier, IAE Aix-Marseille Université, France

## ABSTRACT

This research draws on fluency theory to uncover consumers' response to branded longevity. It employs experimental methodology. Results demonstrate that branded longevity positively impacts processing fluency as well as brand familiarity under low involvement conditions. Contribution and future results are also discussed.

## INTRODUCTION

We've all been previously exposed to the words "Since" or "established in" followed by a date while shopping for everyday items in large-scale retail outlets. The practice of communicating founding dates is trending nowadays with brands such as Lacoste (2017) and Heineken (2017) are emphasizing founding dates in their recent ad campaigns. Founding dates can be communicated on different communication mediums (food trucks, packages, ads, price tags...) thus can become very costly to companies.

The explicit communication of founding dates results in what we label as: branded longevity. The studies that investigated consumers' response to branded longevity mostly focused on its effect on other marketing variables such as brand trust and perceived risk (Rose et al., 2016; Desai et al., 2008). Surprisingly, literature did not examine the psychological mechanism that can explain its effect. This research draws on processing fluency (Lee & Labroo, 2004) to explain this effect and determine under which condition branded longevity has an effect on consumers' evaluation of the brand (Beck et al., 2016; Desai et al., 2008).

## BRANDED LONGEVITY - PROCESSING FLUENCY - BRAND FAMILIARITY

We assume that consumers are exposed to multiple accounts of branded longevity in everyday environments (e.g. product packages & ads). Berger and Fitzsimons (2008) found that frequent incidental exposure to stimuli in everyday life can influence product evaluation and choice. This is because some stimuli, such as branded longevity, has meaning for the consumer and can trigger automatically representations in memory, rendering them more accessible (Higgins, Rholes and Jones, 1977). Meaning that memory associations can be activated automatically by corresponding stimuli. Moreover, other associations that are part of the associative network of the consumers' memory can be activated automatically (Anderson, 1983; Collins & Loftus, 1975). This activation leads to an increase in processing fluency, as in render the processing of information easier, upon subsequent exposure as long as the consumer is not able to attribute the source of fluency (Berger & Fitzsimons, 2008). Indeed, features that facilitate processing fluency may also enhance consumers' evaluation of the brand (Chang, 2014) such as its familiarity. This is because an unfamiliar brand with previously encountered similarities to another brand can create an illusion of brand familiarity (Brown & Marsh, 2009). Product involvement is considered as moderator because it can moderate how labels can influence consumers' evaluation for low involvement products because it can be viewed as a peripheral cue, while for high involvement products it can also influence consumers' evaluation of the product because the label can act as a central cue (Atkinson & Rosenthal, 2014; Beltramini & Stafford, 1993; Liu & Shrum, 2009).

*Hypothesis 1* Branded longevity influences processing fluency only when consumers are not able to attribute the source of their fluency experience.

*Hypothesis 2* Processing fluency mediates Branded longevity's effect on brand familiarity.

*Hypothesis 3* Product involvement negatively moderates the influence of branded longevity on processing fluency, the higher (lower) consumers' involvement with the product the less (more) that branded longevity has an influence on processing fluency.

## STUDY 1

262 participants were randomly assigned to one of four groups following a 2 (branded longevity vs no-branded longevity) \* 2 (product involvement: high product involvement vs low product involvement) between subject design. Branded longevity was manipulated by altering the brand's founding date (e.g., Since 1952) near the logo similar to previous studies (Zhang et al., 2017; Beck et al., 2016). We measured consumers' initial evaluations of the brand, including brand familiarity (1 item from Simonin & Ruth, 1998) and processing fluency (6 items from Kidwell et al., 2013). Second the involvement of the consumers with the brand was measured using a 2 item 7-point Likert scale adopted from Berens et al. (2013). All scales were back translated following Douglas and Craig (2007).

## RESULTS

Manipulation checks proved that participants did perceive the brand's founding date and that there is a significant difference between product category involvement (see Table 1). Regarding hypothesis 1, results of a two-way ANOVA demonstrate that in both high and low product involvement conditions, a statistically significant difference is found between means of processing fluency in branded longevity and non-branded longevity conditions ( $M_{\text{branded\_longevity}} = 5.04$  vs.  $M_{\text{non\_branded\_longevity}} = 4.47$ ;  $F(2,260) = 20.69$ ;  $P = .00$ ). This means that branded longevity leads to greater processing fluency and thus H1 is corroborated. We perform a bootstrap analysis to further test significance of our results following Hayes (2014). The bootstrap was set to generate 5000 samples. Regarding the effect of branded longevity on brand familiarity, results demonstrate a partially significant effect:  $F(1,260) = 2.78$ ;  $P = .09 < .1$ . Regarding the effect of branded longevity on processing fluency, results demonstrate a significant effect with  $F(2,260) = 17.17$ ;  $P = .00$ . Regarding the effect of branded longevity and processing fluency on brand familiarity, results are significant  $F(2,260) = 9.15$ ;  $P = .00$  for processing fluency. While branded longevity is no longer partially significant  $\beta = 0.42$   $P = .49$ , processing fluency has a significant effect on brand familiarity  $\beta = .244$   $P = .00$ . This leads us to conclude that processing fluency totally mediates the effect of branded longevity on brand familiarity. Hence hypothesis 2 is corroborated. Regarding hypothesis 3, results demonstrate that there is a statistically significant effect of product involvement on processing fluency ( $M_{\text{high\_product\_involvement}} = 4.88$  vs.  $M_{\text{low\_product\_involvement}} = 4.62$ ;  $F(2,260) = 4.33$ ;  $P = .038$ ). Moreover, results indi-

cate a significant interaction effect between branded longevity and product involvement on processing fluency,  $F(2;260) = 9.22$ ,  $P = .003$ . In low-product involvement conditions, processing fluency is higher in the branded longevity groups ( $M_{Processing\_fluency}=5.09$ ,  $SD=0.72$ ) than in the non-branded longevity groups ( $M_{Processing\_fluency}=4.15$ ,  $SD=1.12$ ). This allows us to corroborate hypothesis 3.

This research provides insights regarding consumers' response to branded longevity. In particular, it identifies processing fluency as the psychological mechanisms that can explain consumers' response to branded longevity. It demonstrates a counter-intuitive conclusion demonstrating that more information (e.g. branded longevity) can lead to less neural effort (Reber et al., 2004). Finally, it proposes that the communication of the chronological age of the brand on products in low involvement categories can provide them with false familiarity (Holden & Vanhuele, 1999).

**Table 1: Significant difference between the product involvement of the two groups**

Product involvement	
Beer Steigal	Shoes Kurton
N=122	N=140
M=3.36 (SD= 2.77)	M=3.90 (SD=2.94)
F (2,260)=6.51 P=0.011

# How Discourse Theory Exposed Fraud in a Digital Hypertext Campaign and Proved Trademark Infringement on the Playboy Brand Name

Laura R. Oswald, Marketing Semiotics, USA

## ABSTRACT

The paper develops a theory of meaning production in digital marketing based in discourse theory. Focusing on the interface between digital roadmaps and user agency, a discourse analysis of meaning and inter-subjectivity in a digital hypertext proved trademark infringement in the keying process linking the Playboy trademark to unsponsored content.

## INTRODUCTION

Considering the arbitrary association of signs and meanings in language, Umberto Eco (1978) claimed that, "semiotics is in principle the study of everything that can be used in order to lie." Questions of trust and distrust are thus inscribed in meaning production and the conventions binding speakers in community. They take on even greater importance on the Internet, because the digital hypertext frees discourse from its anchor in the context and the inter-subjective contract joining I/you in the space-time of ordinary discourse, increasing the vulnerability of digital marketing to ambiguity, confusion, and fraud.

The paper develops a theory of meaning production on the Internet based in discourse theory, a development in post-structural semiotics that moves the focus of analysis from signs and meanings to the implication of meaning and reference in semiotic performance (for example Benveniste 1967, 1971; Austin 1962; and Eco 1976). Theory is supported by a case analysis that demonstrates how the author applied discourse theory to a trademark infringement case and uncovered evidence of fraud that led to a successful outcome for the Plaintiff.

## DISCOURSE THEORY

The notion of semiotic performance not only places meaning in context but also accounts for the inter-subjective contract joining speakers and interlocutors in the communication event (see Oswald 1989). Indexical markers such as personal pronouns (I/you), demonstrative pronouns (this/that), and adverbs (here/there, now/then) trace subjectivity in discourse and orient semiotic performance to the space-time of the speaking event (Benveniste 1971).

Writing from the perspective of speech act theory, Austin (1962) reflects on the implicit difficulty of assessing the veracity of performative statements because the burden of authenticity rests not with the statement itself but with the referential context. He uses the example a vow to wed spoken by actors in the course of a theatrical performance. The actor is not held to the vow because theatrical convention suspends audience disbelief and reframes the actors' statements in a fictional context. Likewise, ironic statements can be confused with lies because they are built upon a contradiction between a statement and its referent. Thus the statement, "Great weather we're having!" spoken in the midst of a blizzard is not a lie, but an indirect way of stating the speaker's displeasure with the weather.

In summary, the paper applies four semiotic principles to the case analysis.

1. Taken out of context, the arbitrariness of the signifier/signified relationship exposes signs and meaning to confusion, ambiguity, and distrust.
2. The precise meaning of words depends upon the relationship between statements and reference to a context.

3. The authenticity of the message and the intentions of the messenger build upon the inter-subjective relationship between speaker and interlocutor in the communication event.
4. Digital media increase the vulnerability of discourse to ambiguity, confusion, and fraud.

## DISCOURSE THEORY AND THE DIGITAL HYPERTEXT

The digitalization of mass marketing exposes brand communication to the potential for fraud and copyright infringement because the marketing hypertext draws from multiple Internet platforms discourses, and contexts (Neumüller 2000) in a single space-time. Thus the digital hypertext breaks down the traditionally stable play between meaning and reference to the context and disrupts the inter-subjective contract binding speakers and users in the brand discourse.

Hypertext marketing has important implications for consumer trust by exposing brands on the Internet to the effects of ambiguity, copyright infringement, and even fraud. In the following case analysis, I show how discourse theory can introduce trust to a culture of distrust by clarifying the context and subject address of a marketing campaign designed to mislead consumers, steal a brand name, and tarnish the reputation of an iconic brand.

The case study below is drawn from the author's report as an expert witness in copyright infringement litigation before the Appellate Court of the Ninth Circuit in California for the plaintiff, Playboy Enterprises International a/k/a PEI.<sup>1</sup> The case demonstrates how semiotics, and discourse theory in particular, provided insights that supported the plaintiff's claims regarding fair use of the Playboy brand name. The research proved that the search engines, Excite and Netscape, committed trademark infringement when they keyed the search terms "playboy" and "playmate" to unsponsored adult entertainment sites.

## CASE STUDY: TRADEMARK INFRINGEMENT: WHO OWNS THE TERM "PLAYBOY" ON THE INTERNET?

Trademark ownership contributes to brand equity because it protects companies' most valuable assets - the meanings and reputation consumers associate with the logo and brand name. On the Internet, competitors may violate trademark regulations by linking brand names to content and contexts unintended by the owner of the trademark. The issue of infringement is particularly tricky in cases, such as Playboy, where the brand name is the same as a common noun.

Principle: Taken out of context, the search term "playboy" became vulnerable to ambiguity and confusion, allowing defendants to key the term to unsponsored content.

The Playboy (PEI) litigation focused on the practice of "keying" or linking the search terms consumers type into the search box to advertising on a webpage. Defendants claimed that the word "playboy" and "playmate" were common words that can be found in the dictionary. Playboy claimed that the terms acquired their specific trademark meanings in the course of branding activities by PEI.

<sup>1</sup> U.S. District Court Case No. CV 90-320 AHS EE. Related case: Sa CV99-321 ahs (eex)

**Fair Use**

The International Trademark Association (1999) defines the scope of fair use on the Internet.

“The proper trademark analysis in a ‘keyword’ case, just as in any infringement case, should begin with an examination of whether the defendant’s use is a use of the plaintiff’s mark in its secondary or trademark sense. If not, then the word is being used in its dictionary sense and is a descriptive fair use. ... If, however, the word is used in its secondary, trademark sense, then the inquiry turns to: (1) whether the direct or indirect use is likely to cause confusion, and (2) where appropriate, defenses such as nominative fair use or non-confusing comparative advertising.”

Advertisers can purchase the right to appear on the results page above or below the search term. There is trademark infringement if search engines deliberately key (“link”) search terms for brand names to competing web sites. For example, if consumer types the word, “Harvard MBA” in the search box, a competing university may legitimately purchase advertising space on the results page to attract users to their sites. However, if advertisers deliberately confuse consumers by keying branded search terms, such as “Harvard,” to a less renowned brand, such as a school in Harvard, Texas, they could be accused of pilfering Harvard University’s brand equity and even diluting the Harvard brand by association with a less prestigious school.

The next section summarizes how Excite and Netscape misled consumers by linking the term playboy to unsponsored adult entertainment sites by blurring historical differences between the trademark and common uses of term “playboy.”

The judge summarized PEI’s complaint as follows.

“Plaintiff has a trademark on “Playboy®” and “Playmate®.” Plaintiff contends that defendants are infringing and diluting its trademarks (1) by marketing and selling the group of over 450 words, including “playboy” and “playmate,” to advertisers, (2) by programming the banner ads to run in response to the search terms “playboy” and “playmate” (i.e., “keying”), and (3) by actually displaying the banner ad on the search results page. As a result, plaintiff contends, Internet users are diverted from plaintiff’s official web site and web sites sponsored or approved by plaintiff, which generally will be listed as search results, to other adult entertainment web sites. Plaintiff further argues that defendants intend to divert the users to the non-PEI sites.”<sup>2</sup>

**Implications for the Playboy Brand**

Plaintiffs argued that Excite and Netscape’s infringements caused harm to the Playboy brand by fostering confusion, blurring, brand dilution, and tarnishment.

*Confusion*

Excite and Netscape confused consumers by blurring distinctions between the common and trademarked meaning of the term “playboy.” Lawyers for the defense claimed that Playboy Enterprises did not own the terms “playboy” and “playmate” on the Internet because they could be found in the dictionary. They claimed that these terms have always been associated with erotic meanings.

Principle: By anchoring the term “playboy” in historical context, semiotic research identified clear differences in the meaning and reference of the term “playboy” before and after the creation of Playboy Enterprises in 1954.

Semiotic research restored the semantic context of “playboy” and “Playboy” by tracking the use of the common noun “playboy” in dictionaries, songs, literature, and popular culture going back to the 17th century.

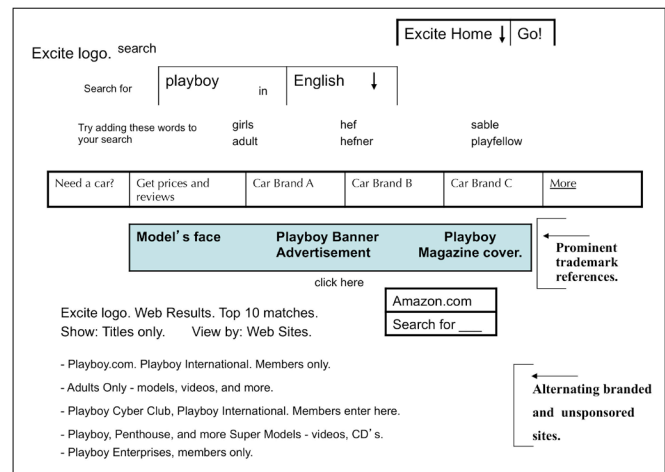

- A companion in play; a good time girl, a funny gentleman; blatantly silly
- Playboys are impractical; couldn’t do a man’s job. A player, reveler.
- Hilarious, gay, rowdy, outspoken.
- Lives a life devoted chiefly to the pursuit of pleasure.

Research revealed that the term “playboy,” along with “playmate,” had indeed acquired its specific, trademark meanings beginning in 1954 and the creation of Playboy Enterprises. They include:

- Erotic, voyeuristic, recreational sex, pleasure doll, sex kitten,
- Concubine, playmate, free, openness, Casanova, nudity
- Pin-up, centerfold girl, bunny.
- Upscale, glamorous, sophisticated, featured in mainstream press

**Implications for the Playboy Brand**

Analysis of one of the search pages used as evidence in the case reveals how Excite and Netscape confused consumers, blurred and depleted the Playboy trademark, and tarnished the brand in consumers’ minds. Excite and Netscape keyed links between the “playboy” search term and unsponsored content to confuse users and blur distinctions between the Playboy trademark and unsponsored content.

**Figure 1: Excite Web Page Analysis**

Defendants also exploited spatial connections between competitors’ content and the Playboy trademark on the search page to implicate Playboy in unsponsored content. They juxtapose the PLAYBOY key word with a menu of Playboy Related Searches, such as Hefner and *Playboy Magazine*. On some of the search pages the Playboy Related Search menu is juxtaposed with a banner ad for unsponsored adult entertainment. By inferring a connection to Playboy, these kinds of associations prompt users to click on the banner ad and visit the site. This inference is reinforced when the banner ad is juxtaposed with a “Top 10” list on which Playboy Enterprises is prominently featured. These kinds of associations tarnished Playboy’s commitment to high quality, “soft” adult entertainment.

Principle: Netscape and Excite created consumer distrust by violating the inter-subjective contract between users and the site.

<sup>2</sup> U.S. District Court Case No. CV 90-320 AHS EE. Related case: Sa CV99-321 ahs (eex)

### Blurring

A semiotic analysis of the Excite webpage shows that Excite and Netscape reinforced the branded meaning of “playboy” and “playmate” by associating these key words with the Playboy trademark through juxtapositions and analogies. In this way, defendants blurred Playboy’s hard-fought distinctiveness in the competitive environment and sent consumers to sites that had not developed a brand identity.

### Dilution

Brands rely on a coherent message. When Netscape and Excite rerouted the links between the Playboy trademark and unsponsored adult sites they diluted the brand’s strength and integrity.

On the original site, the organization of the various elements of the page takes on a rhetorical dimension that suggests associations between Playboy and unsponsored adult sites. Throughout the original web page, the juxtaposition of the keywords ‘playboy,’ or ‘playmate’ in the “Try These First” lists, site directories and search results reference Playboy International and draw from Playboy’s secondary, trademarked use of the words PLAYBOY and PLAYMATE.

Looking once more at the Search Results page [Figure 1], the alternating juxtaposition [A/B/A/B] of the sites for PEI [A] with the unsponsored adult sites [B], implicates Playboy Enterprises in an undifferentiated list of sites for unsponsored adult entertainment. This rhetorical device effectively blurs distinctions in consumers’ minds between the Playboy trademark and the unsponsored sites.

### Tarnishment

Lawyers for PEI claimed that Excite and Netscape degraded its equity by linking the keyword “playboy” to an array of hard core web sites other than Playboy Enterprises. That is, when a user typed the word “playboy” into the search box, the Excite search engine produced a list of links to unsponsored pornographic sites.

Looking again at the Search Results Page [Figure 1], Playboy Enterprises positioned the brand as “soft” adult entertainment, having avoided association with “hard core” adult entertainment such as *Hustler* and *Penthouse*. In their corporate report, management claims that the Playboy trademark references a world of ideas, culture and politics, not only the magazine centerfold. On page 4 of the 10-K form is a list of American Presidents, prominent writers, artists and celebrities interviewed in the magazine, as well as special features on cultural trends, politics and art. Moreover, Playboy Enterprises is associated with a mainstream, upscale market, as proven by the choice of advertisers in *Playboy Magazine*. Netscape also tarnished the Playboy brand by positioning Playboy banner ads next to links keyed to unsponsored pornographic sites.

## CONCLUSIONS

The Circuit Court of Southern California ruled against Playboy, but the decision was overturned on appeal. The judgment from the 9th Circuit Court of Appeals in California agreed with our argument that Playboy Enterprises (PEI) had created a new, proprietary meaning for the nouns “playboy” and “playmate” by means of advertising and marketing activities over a long period of time. The Court agreed that by creating Internet links and rhetorical associations between Playboy trademarks for “playboy” and “playmate” and X-Rated sites, Excite and Netscape confused consumers, blurred hard-fought distinctions between Playboy trademarks and unsponsored adult entertainment, diluted the Playboy brand equity, and tarnished the Playboy brand name.<sup>3</sup>

The case study illustrates the role semiotics can play in teasing out truth from fiction, restoring consumer trust, and protecting brand equities on the Internet. Future research would draw from semiotics’ untapped potential to understand dynamic and performative aspects of digital media that pose urgent questions about the nature of meaning and subjectivity in the digitalized world.

# Enhancing the Effectiveness of Narratives Among Vaccine-Skeptical Parents

Sandra Praxmarer-Carus, Universität der Bundeswehr München, Germany

Stefan Wolkenstoerfer, Universität der Bundeswehr München, Germany

## ABSTRACT

Vaccine skeptics do not trust immunization recommendations and cause problems for public health. Using negatively framed anecdotal messages, we test how adding information about the protagonists' vaccine skepticism affects message effectiveness. Among skeptics, a narrative that portrayed vaccine-skeptical protagonists in a positive way proved most effective. Our findings are easy to implement.

## INTRODUCTION

In many countries, vaccine-preventable diseases, for example, measles, cause a significant number of unnecessary deaths because immunization levels in the population remain lower than required (Kabra and Lodhra 2013). While immunization programs successfully reach the majority of the population, some parents are concerned about potential adverse effects of vaccines for children and decide against immunization (Nyhan et al. 2014). Such parents do not trust the immunization recommendations provided by public authorities (Gershoff and Koehler 2011; Healy 2009).

Because immunization levels are lower than required, measles outbreaks have recurred in many western countries, for instance, the US, Great Britain, and Germany (e.g., Centers for Disease Control and Prevention, 2018). Outbreaks of the disease inevitably place others (who are innocent because they did not decide against the vaccine) at risk because infants younger than 12 months cannot be vaccinated and are most likely to experience severe complications when infected. Thus, vaccine-skeptical parents may cause a problem for public health, and persuading them to have their children vaccinated is a relevant public health issue (Nyhan et al. 2014; Horne et al. 2015).

Research suggests that providing vaccine-skeptical parents with information that directly addresses their concerns about the potential adverse effects of the vaccine by explaining the lack of evidence for such effects is less effective than drawing parents' attention to the negative consequences of not vaccinating their child (Horne et al. 2015). One problem with directly addressing the existing concerns is that the message repeats them, thereby potentially strengthening recipients' associations between the concern and the vaccine (Lewandowsky et al. 2012; see also the study on rumors by Tybout et al. 1981). Another problem is that it seems impossible to provide evidence for a complete absence of risk (Gershoff and Koehler 2011; Popper 2014). In regard to the question of how to draw parents' attention to the negative consequences of not vaccinating their child, previous research demonstrates that statistical evidence, for example, information about how many deaths a disease causes (ideally graphically displayed; Gershoff and Koehler 2011), works for the general public (Slater and Rouner 1996). However, skeptical recipients tend to counterargue when provided with such facts (Slater and Rouner 1996; Nyhan and Reifler 2015). Thus, when targeting skeptical recipients, Slater and Rouner (1996, 229) recommend the use of anecdotal evidence because "the processing of narrative does circumvent the tendency to counterargue." Among alternative medical students who tend to have skeptical views of vaccinations, Wilson et al. (2004, 3012) report a small (insignificant) advantage of an anecdotal intervention compared to a presentation of facts with regard to message recipients' intention to vaccinate their own child. However, Nyhan et al. (2014) report that their anecdotal message

(providing evidence of the negative consequences of not vaccinating a child against measles) did not increase skeptical parents' intent to vaccinate future children (neither did any of the other messages that the authors tested).

Because vaccine skeptics are a highly relevant target group for public health, and the literature suggests that anecdotal evidence is the most effective tool when targeting such audiences, we use the narrative by Nyhan et al. (2014) and test how information provided about the protagonists may increase its effectiveness. Previous research suggests that increasing the similarity between the recipient and the protagonist may be a way to improve message effectiveness (De Graaf 2014). This research focuses on similarity with regard to the recipient's skeptical mind-set and adds information about the protagonists' vaccine skepticism to the narrative. We are not aware of other studies that address recipients' skeptical mind-set by portraying a skeptical protagonist in a narrative.

## THEORY

In the narrative by Nyhan et al. (2014), a mother tells about her and her partner's dramatic experience when their infant almost died of measles and how they suffered at the bedside of their child with fear of losing him. Furthermore, the narrative asks the target audience to have their children vaccinated. The narrative does not provide information about the parents' attitude towards the vaccine, nor does the target audience learn whether the parents decided for or against the vaccination.

For message recipients, the parents described in the narrative (protagonists) may represent potential identification figures, and the extent of identification with a protagonist affects message effectiveness (Slater and Rouner 2002; Igartua 2010). Thus, we attempt to increase message effectiveness among vaccine skeptics by stimulating their identification with the protagonists portrayed in the narrative. Identification is related to perceived similarity (Cohen 2001, De Graaf 2014) as well as to aspirational similarity, that is, the perceived valence of the information provided about the protagonist (Tal-Or and Cohen 2010).

*Perceived similarity.* Studies demonstrate that similarity between the recipient and the protagonist with regard to relevant characteristics increases the self-relevance of the message (McKeever 2015; Raghubir and Menon 1998) and message effectiveness (De Graf et al. 2012; Hoeken and Fikkers 2014). Construal level theory provides an explanation for the effects: Liviatan and Liberman (2008) demonstrate that interpersonal similarity reduces the social distance between individuals, and less social distance leads to more concrete thinking about the other person's experiences (Trope and Liberman 2010). Concrete thinking about potential negative life events leads to higher perceived risk (Wakslak and Trope 2009). Thus, if the protagonist is similar to the message recipients, the message recipients should perceive the negative event described in the narrative as more likely to happen and as more severe, thereby increasing message effectiveness (Murdock and Rajagopal 2017). Parents who are vaccine skeptics should perceive a protagonist who mentions that he/she had the same skeptical attitude and decided against the vaccine to be similar to themselves. Vaccine skeptics may recognize their own decision in the narrative, and the negative consequences described in the narrative may become more self-relevant to them thereby increasing message effectiveness.

*Aspirational similarity.* However, the target audience is more likely to identify with protagonists whom they see in a positive light (Tal-Or and Cohen 2010). Because this research uses negatively framed narratives (as recommended by Cox and Cox 2001), the narrative highlights the negative consequences of not getting the vaccine. Thus, message recipients may assign responsibility for the dramatic situation to the protagonists, and protagonists whom the message plainly describes as vaccine opponents may appear irresponsible or stubborn. Thus, even though a skeptical protagonist may be similar to the skeptical message recipient, aspirational similarity may be low.

Taken together, we argue that to increase message effectiveness among skeptics, the narrative should provide information about the protagonists' skepticism and, at the same time, should portray the skeptical protagonists in a positive way, for instance, by mentioning how hard they thought about their decision to not have their child vaccinated. In other words, vaccine-skeptical message recipients should be more likely to identify with a thoughtful, responsible vaccine skeptic than with a seemingly stubborn vaccine opponent. Thus, the former message should be more effective than the latter; that is, it should lead to higher perceived severity of the disease, more positive attitudes towards having children vaccinated, and a higher level of intention to have a future child vaccinated. We propose the following hypotheses:

*Hypothesis 1a* Among skeptical recipients: compared to the narrative by Nyhan et al. (2014), which does not provide information about the protagonists, the same narrative is more effective when it portrays the protagonists as thoughtful vaccine skeptics.

*Hypothesis 1b* Among skeptical recipients: Compared to the narrative that portrays the protagonists as thoughtful vaccine skeptics (see hypothesis 1a), a narrative that portrays the protagonists as vaccine opponents is less effective.

## STUDY

### Participants

We conducted the study in Germany and translated all items to German. Because our aim was to reach vaccine-skeptical parents, we collected our data on internet platforms on which parents discuss relevant health issues of their children, such as immunizations. We posted the invitation to participate in our study and the link to our online survey on the internet platform "Eltern.de" (a platform for parents) and on Facebook pages linked to alternative medicine. The sample consists of 370 respondents (who responded to all relevant questions); 95% were female, the mean age was 39 and 95% had children (respondents who neither had children nor planned to have children in the future were excluded). The very high proportion of females did not cause a problem for our sample because mothers usually make health care decisions for their children (Matoff-Stepp et al. 2014).

### Measures and Procedure

We measured skepticism levels before the respondents observed the message. We used one item on immunizations in general and one addressing the specific vaccine ("I am concerned about serious adverse effects of vaccines" and "The risk for adverse effects from this vaccine is too great" 1 = fully disagree; 7 = fully agree, Freed et al.

2009). After the respondents had seen one of the messages (to which they were randomly assigned), we measured future intentions with the item (Nyhan et al. 2014) "If you had another child, how likely is it that you would give the child the MMR vaccine?" (1 = very unlikely, 7 = very likely). We measured respondents' attitude towards having children vaccinated against MMR with the item "Please indicate how reasonable you think it is to have children vaccinated against measles, mumps, and rubella" (1 = not reasonable, 7 = very reasonable). We measured the perceived severity of the disease with the item "How severe do you perceive an infection with the MMR diseases to be if a child did not get the vaccine?" (1 = very low severity, 7 = very high severity). Furthermore, we measured perceived similarity to and identification with the protagonists ("I think the parents in the narrative are similar to me" and "I could identify with the parents in the narrative", 1 = fully disagree, 7 = fully agree).

### Stimuli

Participants observed one of the following messages:

- Ad 1: the narrative by Nyhan et al. (2014) was presented with two minor adaptations. First, the narrator in the original narrative was a mother (Megan Campbell) telling about her and her partner's dramatic experience when their infant almost died of measles. We used a couple (parents) as narrators because we wanted to provide an identification figure for both female and male respondents. Second, instead of "Megan," we used names that are common in Germany (Anja and Christian).
- Ad 2: the same narrative was presented but with the additional information that before the dramatic event, the parents were vaccine opponents and had deliberately decided against the immunization ("Protagonists: vaccine opponents"),
- Ad 3: the narrative of group 1 was presented but with the additional information that before the dramatic event, the parents were vaccine skeptics who had thought very hard about their decision and had then decided against the immunization ("Protagonists: thoughtful vaccine skeptics").

All three narratives included the same appeal that parents should have their children vaccinated to avoid the severe disease.

### Data Analyses and Findings

*Vaccine skepticism in the sample.* The immunization levels of approximately 80%-90% in most western countries demonstrate that the vast majority of the population holds positive attitudes toward vaccinations, and vaccine skeptics represent a minority. Thus, in our sample, only relatively few respondents were skeptical. We aggregated the two skepticism variables ( $r = .59$ ), and the mean values represent respondents' vaccine skepticism in this study. Figure 1 shows the frequency distribution of the aggregated variable.

We split the sample into three skepticism-groups: "no skepticism" (variable vaccination skepticism = 1,  $N = 102$ ); "slight skepticism" ( $1 < \text{vaccination skepticism} \leq 2.5$ ,  $N = 178$ ); "skepticism" (vaccination skepticism  $\geq 3$ ,  $N = 90$ ). Nyhan et al. (2014) split their groups by tercile. We did the same for "no skepticism" and "slight skepticism." However, we assigned respondents with vaccination skepticism  $\geq 3$  to the skeptical group (the tercile was 2.5) because on the 7-point scale, 2.5 is still very low.

*Test of the hypotheses.* Table 1 shows the mean values of the three dependent variables across the different messages and across the three skepticism groups. We tested hypotheses 1a and 1b with pairwise t-tests among the skeptical respondents. Table 1 also reports

**Figure 1: Frequency distribution of the aggregated variable “vaccination skepticism” in the sample**

the t-test results. The findings support hypothesis 1a for each of the dependent variables (attitude  $t = -3.07, p < .01$ ; severity  $t = -1.71, p < .05$ ; intention  $t = -1.61, p < .10$ ). Among vaccine skeptics, the narrative portraying skeptical but thoughtful protagonists (Ad 3) proved to be more effective than the narrative by Nyhan et al. (Ad 1).

The findings also support hypothesis 1b for the dependent variables attitude ( $t = -2.64, p < .01$ ) and the intention to have a future child vaccinated ( $t = -1.41, p < .10$ ). Among vaccine skeptics, Ad 3 proved to be more effective than the narrative that merely described the protagonists as vaccine-opponents (Ad 2). With regard to the perceived severity of the disease, Ad 2 and Ad 3 did not differ significantly ( $p > .10$ ).

Among nonskeptical respondents, the effectiveness of the three messages did not differ. This finding makes sense because Slater and Rouner (1996) argue that value-affirmative recipients employ a central-processing strategy. Thus, the additional information about the protagonists should not affect their attitudes and intentions. Among respondents who were slightly skeptical, only two pairs of mean values differed significantly. Perceived severity was higher when slightly skeptical respondents had seen Ad 3 compared to Ad 1 ( $t = -1.51, p < .10$ ) and when they had seen Ad 3 compared to Ad 2 ( $t = -1.46, p < .10$ ).

**Additional Analyses.** To test the robustness of our findings, we estimated PROCESS model 1 (Hayes 2018), including recipient skepticism as a metric moderator variable. Ads (Ad 1, Ad 2, and Ad 3) was the multicategorical independent variable of the model (with indicator coding), and message effectiveness was the dependent variable (Hayes and Montoya 2017). Because Cronbach Alpha of the three effectiveness measures (intention, attitude, and perceived severity) was .70, we used an aggregated message effectiveness index for this analysis.

While recipient skepticism has a negative main effect on the dependent variable, ad type has no main effect. Thus, overall, the effects of the three ads do not differ. However, as expected, with increasing recipient skepticism, Ad 3 is more effective than Ad 1 (coefficient of Ad 3 x skepticism interaction: .28,  $t = 2.52, p < .05$ ). In line with the mean values of Table 1, the conditional effects of Ad 3 at increasing values of the moderator that PROCESS estimates demonstrate that among nonskeptical and slightly skeptical respondents, ad

type does not affect message effectiveness. However, among skeptical respondents (the moderator value that PROCESS uses is the 84th percentile: 3.5), Ad 3 is significantly more effective than Ad 1 (coefficient: .63,  $t = 3.04, p < .01$ ). This finding is in line with the above t-test findings among skeptical respondents and again provides support for H 1a. Among skeptical respondents, Ad 2 also proves more effective than Ad 1 (coefficient: .27,  $t = 1.85, p < .10$ ), but we did not propose a hypothesis for this comparison.

When we conduct the same analysis separately for the three dependent variables, the effect of the skepticism x Ad 3 interaction is significant at 1% on attitude and at 10% on perceived severity but insignificant ( $p > 10\%$ ) on intention. However, the t-test findings (Table 1) support hypothesis 1a across the three dependent variables.

**Perceived similarity and identification.** Interestingly, the vaccine-skeptical respondents also perceived the protagonists of Ad 1 to be more similar to themselves than the protagonists described as vaccine opponents (Ad 2) and the protagonists described as thoughtful vaccine skeptics (Ad 3). Among skeptics, the mean values of perceived similarity with the protagonists were  $M_{Ad1} = 3.8$ ,  $M_{Ad2} = 2.8$ , and  $M_{Ad3} = 2.5$  (the difference between  $M_{Ad1}$  and  $M_{Ad2}$  is significant at  $p < .10$ ; the difference between  $M_{Ad1}$  and  $M_{Ad3}$  is significant at  $p < .05$ ). With regard to identification, no significant differences showed, but again, skeptics tended to identify less with the skeptical protagonists (the mean values among skeptics were  $M_{Ad1} = 3.4$ ,  $M_{Ad2} = 2.7$ , and  $M_{Ad3} = 2.6$ ). Thus, our data cannot show that perceived similarity or identification mediate the effect of the information provided about the protagonists' vaccine skepticism on message effectiveness among skeptical message recipients.

This finding poses the interesting question of why among vaccine skeptics, the message effectiveness of Ad 3 was higher than that of Ad 1 and Ad 2, but perceived similarity and identification were not. In contrast, the weakest message with regard to message effectiveness among skeptical respondents (Ad 1) was the strongest with regard to (reported) similarity and identification. The most likely explanation for this finding is our explicit measurement of similarity and identification. Research suggests that evaluations of risks rely on an automatic and quick process (Gershoff and Koehler 2011; Slovic and Peters 2006). We assume that the messages that mentioned the protagonists' skeptical mind-sets increased self-relevance and perceived risk among skeptical recipients (subconsciously), thereby increasing message effectiveness. However, when the questionnaire later asked respondents to express how similar they were to the protagonists and how strongly they identified with the protagonists, respondents might have wanted to differentiate themselves from the dramatic event and from protagonists whose decision almost caused their child to die. In line with this assumption, the mean values (see above) demonstrate relatively low levels of perceived similarity and identification (measured on 7-point scales). Implicit similarity and identification measures (instead of the explicit measures that we used) might be able to demonstrate the expected mediating effect.

## DISCUSSION

### Implications

In line with previous research, our study demonstrates that the effectiveness of narratives may depend on the information that the message provides about the protagonists (De Graaf 2014; Dillard and Maine 2012; Mc Keever 2015). We recommend that narratives addressing vaccine skeptics should present a protagonist who held similar skeptical views (before he/she experienced the negative consequences). In addition, the message should present the protagonist in a positive way, for example, as a thoughtful individual with

**Table 1: Mean values of attitude toward the vaccination, severity of the disease, and intentions dependent on: Ad type (Ad 1, Ad 2, Ad 3) and recipients' vaccine skepticisms (no skepticism, slight skepticism, skepticism)**

**Legend:**

- Ad 1: like Nyhan et al.
- Ad 2: Protagonists are vaccine opponents
- Ad 3: Protagonists are thoughtful vacc. skeptics

Ad 2	N = 40																								
Ad 3	N = 21																								

Note: all reported *p*-values in Table 1 are one-tailed

a strong sense of responsibility. Our findings are useful for practice because providing information about the protagonists is easy to implement.

**Limitations and Future Research**

Based on the limitations of our study and on our findings, we make the following suggestions for future research. First, because vaccine skeptics are a minority, our skeptical message recipient group was relatively small. Future studies may test the effects with a larger sample. Second, because we aimed to compare different nar-

ratives, we did not include a control group in our study. This absence is a limitation because we are unable to demonstrate whether the narrative that we identified as superior (Ad 3) also worked in absolute terms. Future studies should test this issue. Third, our explicit similarity/identification measure was unable to demonstrate the expected mediating effect. Future studies may use implicit identification measures, particularly when the message framing is negative and the message recipients may wish to differentiate themselves from the protagonist. Fourth, we did not repeat the measurement of the dependent variables at a later point in time. Therefore, we do not

know how robust the advantage of Ad 3 over the two other messages is over time. Future studies may repeat the measurement of the dependent variables at a later point in time, as, for instance, did Frank et al. (2015).

# Effects of Brand Knowledge, Motivations, and Trust on Consumption Experience among Millennial Consumers

Ananya Rajagopal, Tecnológico de Monterrey, Mexico City

## ABSTRACT

This is an empirical study conducted in Mexico City among millennial consumers who use vogue brands. The study addresses the effect of knowledge motivations and trust dimensions on consumption experiences analyzing the self-congruity theory. The study reveals that brand knowledge self-congruence peer motivations and brand experience influence consumption behavior.

## INTRODUCTION

Most consumers exhibit satisfaction as a materialistic output based on self-congruity, motivation, and consumption experience, instead of the perceptual value gained. (Schmitt et al., 2015). The experimentation attitude towards vogue brands is a cognitive phase, which is overridden by many consumers possessing utilitarian attitude. Millennial consumers exhibit consumption behavior within the domains of materialism (Rindfleisch et al., 1997) and experientialism (Rahinel and Redden, 2013; Giesler and Veresiu, 2014), which distinguish them as pro-vogue verses utilitarian consumers. Conventionally, consumers tend to be more responsible towards acquiring comprehensive information about brands to update their existing knowledge. Consumers evaluate extrinsic motivations for developing trust prior to making consumption decisions in reference to perceived satisfaction and societal values in general. Brand trust influences purchase intentions, consumption experience, and positive referrals (Becerra and Badrinarayanan, 2013). However, millennial consumers exhibit subjectivity in adapting to vogue brands and transformative consumption experience (Giesler and Veresiu, 2014).

Most millennials seek to establish their identities in convergence with social self-concept and the social trends. Such self-concepts develop self-image congruence through using and exhibiting the vogue brands (Chaplin and John, 2005). The vogue brands create high consumer involvement, and develop emotional attachments when consumers find the brand attributes matching with self-image congruence (Malar et al., 2011; Rhee and Johnson, 2012). Consumers express their self-image through the brand personality, which attributes to emotions and perceived satisfaction of fashion brands. Therefore, brand manifestation plays key role in driving consumer cognition towards trendy and unfamiliar brands (Su and Reynolds, 2017).

The buying behavior of millennial consumers is widely motivated by self-perceived expectations, psychodynamics, vogue, and socio-personal interactions. Vogue brands are generally positioned as high-end products, which motivate and induce young consumers for experimentation, and a social pattern-based consumption spread across spatial and temporal dimension (Gofman et al., 2010). Brand communication using rich conceptual and application driven vocabulary, which distinguishes the brand meaning and associated relationships, motivates consumers. Consumers explore brands, and analyze social relationships with brands to validate self-congruity and brand experience (Fournier, 1998). The extrinsic values motivated by peer consumption experiences build self-congruence among the potential consumers of the vogue brands in the market place. Therefore, consumers tend to explore motivations to derive new consumption experiences to support their self-congruence (Plewa and Palmer, 2014).

This study addresses the effects of knowledge, motivations, and trust (KMT) dimensions of vogue brands on consumption experiences among millennial consumers, analyzing the self-congruity theory.

It focuses on exploring the consumption behavior among millennials in reference to self-congruence, consumption motivations, and consumption experience. This study explores two fundamental research questions in reference to the hypotheses structured in this study, as given below:

- How do the interactions of millennial consumers on social media update their brand knowledge and influence their consumption experience?
- How do brand promise and brand experience develop brand trust among consumers?

The rationale of this study is built around the psychological domains of materialism and experientialism. The principal research objective embedded in this research is to explore the impact of intrinsic and extrinsic knowledge on brands, the associated motivational factors, and brand trust. These dimensions help in building consumption experience among millennials. This study contributes to the existing literature by revisiting the self-congruity theory in explaining consumer behavior among millennial consumers in reference to materialism and experientialism towards adapting vogue brands.

## LITERATURE REVIEW AND FRAMEWORK OF HYPOTHESES

Brand knowledge among millennial consumers is disseminated through the interactive platforms on the digital space. Implicit spatiality of social media has contributed in developing explicit knowledge on brands among young consumers through consumption experience sharing. The social media interactions through consumer-generated contents serve as knowledge building blocks on vogue and brand associations (Laurell, 2017). Customer engagement in brand communities on the social media causes fast updates on brand knowledge with the changes in fashion trends among the millennial consumers, which alters the consumer perceptions on brands (Gummerus et al., 2012). The millennial consumer segments exhibit differing behavioral and attitudinal brand response in reference to dynamic brand knowledge patterns. Consumers with updated knowledge and high brand response intensity elicit favorable brand associations, and show stronger affinity when stimulated with the brand name (Koll and von Wallpach, 2009). In view of the above-mentioned studies, the hypothesis has been constructed as:

*Hypothesis 1 Social media interactions help millennial consumers towards updating their brand knowledge*

Intrinsic and extrinsic motivations also affect the cognitive process of developing self-congruence and perceptions on the vogue brands and the market trends. Social media, consumer generated contents, and experience sharing on the digital media have emerged as major extrinsic motivational factors in developing self-congruence on the brands among millennials (Geri et al., 2017). Information acquired from extrinsic sources builds sustainable perceptions and strong ties with vogue brands among millennial consumers. However, image-impairment concern makes a difference with negative psychodynamics spread through the negative word-of-mouth, regardless of whether or not they are concerned about their self-image (Zhang et al., 2014).

Millennial consumers develop self-congruence on brands in view of the peer-culture and contemporary social values. The peer

motivation drives them to assimilate to their social group by conforming on identity-signaling attributes such as premium brands, uniqueness attributes such as color, and the price-affordability ratio (Chan et al., 2012). Consumption among millennials signifies symbolism, which can be explained as exhibition of personal attributes motivated by vogue. Consumers live at par with the contemporary social patterns today. Symbolic consumption reflects the personality and lifestyle of consumers, expressing social distinctions (Hosany and Martin, 2012). Consumers symbolize consumption in reference to self-congruity and brand personality. Symbolic consumption is experienced by anthropomorphizing with social endorsements and brand attributes (Fournier, 1998; Brown 1991). Upon reviewing the literature on consumer motivation as stated above, the hypothesis has been formulated as:

*Hypothesis 2 Consumers acquire motivations from social media and peer influences towards developing self-image congruity.*

Brand trust demonstrates the robustness in making purchase decision, and develops behavioral intentions towards vogue brands in a cross-cultural context. Brand trust exhibits confidence of consumer in the attributes of a brand and its social equity (Li et al., 2015). Consumers recognize strong cues from trustworthiness in advertisements, which develops self-congruence, brand image, and purchase intentions. Brand trust as consumers' confidence that the brand, product, or service firm is dependable and competent. Trust predicts perceptions of brand credibility. Brand trust builds consumers' confidence that the brand, product, or service firm is dependable and competent. Trust predicts perceptions of brand credibility and brand commitment (Herbst, et al., 2012). Consumers understand brand commitment as brand promise, which is conveyed by the companies through various advertisements and campaigns. Brand trust as consumers' confidence that the brand, product, or service firm is dependable and competent. Trust predicts perceptions of brand credibility. Brand trust as consumers' confidence that the brand, product, or service firm is dependable and competent. Trust predicts perceptions of brand credibility. Young consumers evaluate brand promise encompassing social, economic, and personal advantages as manifested in the brand communications in reference to their brand experience, and reinforce trust on the brands (Hoppe, 2017). Millennials commonly exhibit placebo effect with vogue brands in reference to their personality augmentation. Brand promise builds such placebo notion, and the consumers perceive brand benefits towards objective performance outcomes, trust, and loyalty (Garvey et al., 2016). By critically reviewing the research contributions in the context of brand trust, the following hypothesis has been developed:

*Hypothesis 3 The brand promise and brand experience contribute significantly in developing brand trust among consumers.*

Buying decisions to gain consumption experiences close to the perceived values of the consumers endure happiness, and enhance customer value. Self-congruence leads to satisfaction by developing consumer values in reference to the attributes of products and services comprising referred experience, image, and brand reputation. The value-brand congruency tends to deliver satisfaction, and inculcates a favorable attitude and buying intention (Allen et al., 2008). Millennial consumers also tend to share their consumption experience with peers to boost their self-image, and maximize satisfaction upon matching the experience with self-congruence. They desire to communicate their social identity as the lead consumers, and con-

form to choices that are strongly associated with their group and the market vogue. Identity-relevant consumer categories such as clothing and fashion accessories reinforce their social identity (Chan et al., 2012; Dalton and Huang, 2014). Self-congruity theory belongs in an outgrowth of cognitive-consistency theories (Rojas-Mendez et al., 2015), which suggest that people strive for consistency in their beliefs and behaviors to achieve satisfaction. Self-congruity theory assumes that self-concept, socio-cultural values, and market trend determine the brand choice (Allen et al., 2008).

## STUDY DESIGN

In order to measure the consumption experience of vogue brands, and the effects of brand attributes on decision making among millennial consumers, 114 respondents including both men and women between the age group of 18-30 years were selected in Mexico City. The study was conducted at the shopping malls having exclusive stores of vogue brands such as Victoria Beckham, Manolo Blahnik, H&M, Louis Vuitton, and Calvin Klein. The study was conducted during the festive shopping months of September-November, when most stores offer season's promotions in Mexico attracting large number of consumers. The data were collected on 18 variables related to the brand knowledge, motivation, brand attributes, and decision-making segments. Relevant variables within the above variable segments were chosen during the focus group session conducted prior to the development of research instrument, in which nine young consumers participated. Respondents were asked to indicate on a five-point Likert scale (1-Totally agree; 5-Totally disagree) when they make a purchase decision. In all, five vogue brand categories in the fashion apparel, fashion accessories, computer electronics, diet beverages, and mobile phones were selected for the study.

## ANALYSIS AND FINDINGS

The data was pooled variable-segment wise, and was used to analyze the 'goodness-of-fit index', which revealed that chi-square statistics (6.82), root mean square error of approximation (0.471), Tucker-Lewis fit index (0.492), comparative fit index (0.406) and incremental fit index (0.518) had an appropriate fit in the model used for analysis in the study. The results of the Table 1 have been obtained using OLS method. The following OLS equation has been used to determine the  $\beta$  values.

$$C_{exp}^{ij} = \alpha + \beta_1 B_{kno} + \beta_2 U_{gc} + \beta_3 P_{mot} + \beta_4 S_{inf} + \beta_5 B_{prom} + \beta_6 S_{cgr} + \beta_7 B_{exp} + \beta_8 B_{att} + \beta_9 P_{anth} + \epsilon$$

In the above equation, the dependent and independent variables are explained as below:

Dependent variable is Consumption experience ( $C_{exp}^{ij}$ ), whereas independent variables include brand knowledge ( $B_{kno}$ ), user generated contents ( $U_{gc}$ ), peer motivations ( $P_{mot}$ ), social influence ( $S_{inf}$ ), brand promise ( $B_{prom}$ ), self-congruence ( $S_{cgr}$ ), brand experience ( $B_{exp}$ ), brand attributes ( $B_{att}$ ), anthropomorphic perception ( $P_{anth}$ ).

Consumers update their brand knowledge ( $\beta=0.641$ ,  $p<0.01$ ) through advertising and communication, social media interactions, and peer reviews. Companies marketing vogue brands develop awareness by engaging consumers in sharing user-generated contents ( $\beta=0.527$ ,  $p<0.01$ ) on social media channels. Consumers also share brand experience among peers on the digital space. Accordingly, the results of the data analysis are consistent with hypothesis H<sub>1</sub>. Higher brand awareness, peer motivation ( $\beta=0.583$ ,  $p<0.01$ ), and wider social influence ( $\beta=0.425$ ,  $p<0.05$ ) drive positive brand perceptions and brand attachment, which prompt consumers to make purchase decision in favor of vogue brands. Millennial consumers evaluate brand promise ( $\beta=0.635$ ,  $p<0.01$ ), develop self-congruence ( $\beta=0.577$ ,  $p<0.01$ ), and tend to gain brand experience ( $\beta=0.539$ ,

$p < 0.01$ ) while motivated by the peers. Accordingly, the results validate the hypotheses  $H_2$  and  $H_3$ .

It was observed during the study that millennial consumers have pre-conceived notions on vogue brands and their effect of personality. Thus, they evaluate brands in reference to brand attributes ( $\beta = 0.471, p < 0.05$ ), anthropomorphic leverage ( $\beta = 0.541, p < 0.01$ ) and perceived social values. The study revealed that buying decisions of consumers are also motivated significantly by the brand knowledge and brand campaigns. Hence, the results of the study reveal that hypotheses  $H_1$  and  $H_2$  can be accepted. The correlations among the variables of the study have been exhibited in Table 1.

The key variables of the study were subjected to correlation matrix, which indicated that all the variables were significantly correlated with each other. Additionally, anthropomorphic perception was found to be highly correlated to social influence, self-congruence, and brand experience. Similarly, the correlation results reveal that positive brand experience reinforces self-congruence for vogue brands among millennial consumers.

**MANAGERIAL IMPLICATIONS AND CONCLUSION**

Companies engaged in promoting vogue brands can improve the brand manifestation to develop brand awareness by extensively using the consumer interactions through the social media. Vogue brands need to carry verbal and non-verbal endorsements in brand advertising to drive anthropomorphic motivations among consumers. The social media led motivations, and knowledge augmentation approaches help in disseminating a holistic view of vogue brands among consumers in the marketplace by synchronizing knowledge-motivation-trust (KMT) effects on brand experience. The KMT dimensions influence the contemporary buying decisions, and consumption experience build consumer behavior towards the vogue brands over time.

The effective verbal and nonverbal communications, brand events, and dissemination of vogue culture through digital space motivate millennial consumers. Prior awareness of fashion trends helps consumers develop appropriate self-image congruity, social self-concept, and anthropomorphic expressions on the brands.

This study reveals that millennial consumers continuously update their brand knowledge through social media interactions and brand advertisements. Consumers acquire extrinsic motivations from social media and peer influences to develop brand attachment and loyalty over time. The results of the data analysis endorsed that convergence of brand promise and brand experience develops brand trust among consumers. Millennial consumers appraise commitment of the vogue brands, and develop self-congruence accordingly to experience the brands. The peer motivation also drives consumers to anthropomorphize the effects of vogue brands on their personality. Consumers tend to explore new shopping styles. Therefore, the vogue brands should be able to provide recreational shopping infrastructure, and scope for self-revelation in the trial rooms. Such strategy would encourage consumers to anthropomorphize their personality with the vogue brands.

# Consuming Commodified Selves – Accelerated Identity Co-Construction Dynamics Through Fashion Performances on Instagram

Jonathan D. Schöps, University of Innsbruck, Austria

## ABSTRACT

This paper enhances the understanding of the bi-directional relationship between performers as commodified selves and consumers in digital environments. Drawing on performativity theory this study illuminates accelerated identity co-construction dynamics through visual fashion performances on Instagram. Analysis of interview data identifies three such dynamics: affirming emulating and immersing in dreams.

## INTRODUCTION

Contemporary consumer culture has increasingly transformed from a linguistic to an overall visual culture (Schroeder 2002). This visual turn also manifests in increasing popularity of visual photo-sharing platforms like Instagram, which is the fastest growing social media platform with currently over 800 million monthly active users (Begu 2018; Instagram 2018). The nature of the digital environment of Instagram accelerates visual consumption by “pointing, tapping, swiping, and glancing” (Carah and Shaul 2016, 83) – in other words, scrolling quickly through the flow of images, tapping to stop the flow, taking a quick glance at an image, and continue swiping. But, how does this accelerated consumption affect consumers’ daily lives? How does acceleration manifest in the construction of consumers’ selves?

Prior research on visual performances mainly focused on the site of production – the consumed, performers respectively (Kerrigan and Hart 2016). These studies investigated digital identity formation using dramaturgical approaches of impression management and self-presentation techniques (Jensen Schau and Gilly 2003; Kerrigan and Hart 2016), micro-celebrity practices (Marwick 2015), and blogging (McQuarrie, Miller, and Phillips 2013; Scaraboto and Fischer 2013). Yet, scholars increasingly argue that the most important site of an image’s meaning is the audience referring to the “death of the author” (Barthes 1977, 145; Rose 2012). However, research on identity co-construction dynamics through visual consumption with a focus on the site of the audience – the consumers – is scarce.

This study aims to investigate the bi-directional relationship between performers as commodified selves and consumers, that is, identity co-construction dynamics through fashion performances on Instagram. Analysis focuses on in-depth narrative interviews supplemented with auto-driven photo elicitation (Heisley and Levy 1991) to investigate consumers’ meanings ascribed to the visual consumption of fashion and commodified selves on Instagram. Findings reveal consumers’ desired content, requirements for consumption, and accelerated identity co-construction dynamics. Accelerated identity co-construction dynamics encompass affirming, emulating, and immersing in dreams. This study closes with discussing findings, and pointing out limitations and future research possibilities.

## THEORY

### Consumers as commodities in postmodern society

Postmodern society manifests as “a society of consumers meant for and made for their consumption” (Bauman 2005, 35). Accordingly, consumer society embodies a process of commodification, that is, consumers crafting themselves to become sellable and valuable objects within the market. Consumers increasingly consider “being a consumer commodity that makes them bona fide members of that

society” a desirable quality (Bauman 2007, 57). The rise of social media further accelerated this process of commodification (Schwarz 2010). Influencers deploy manifold marketing practices to become and remain sellable commodities – constantly trying to increase their market value by “staying ahead of the style-pack” (Abidin 2016; Bauman 2007, 99). Consequently, commodified consumers are always on the move, searching for something desirable and attention-grabbing.

Yet, postmodern consumers are governed by the constant pressure to reinvent themselves, refresh their offers, and change identities. Thus, contemporary consumerist culture prioritizes “parts” over the “whole,” “short term” over “long term” respectively (Bardhi and Eckhardt 2017; Bauman 2007, 69). Digital environments foster this urge for self-endorsement. Instagram characterizes such a visual digital environment where consumers may frame digital commodified selves for the consumption of others that do not necessarily reflect “real life” identities (Marwick 2015; McQuarrie et al. 2013; Presi et al. 2016; Rokka and Canniford 2016).

### Performing and co-constructing identities in postmodern society

Postmodern consumers experience an intertwined struggle between conformity and individualization – a so-called “hybridization” demanding conformity to individualization (Bauman 2005, 28). Thus, identity formation is an ongoing process where consumers compose, decompose and recompose their identities by means of repetitive social interactions (Howarth 2002). Social media further reinforces repetitive social interactions on a daily basis (Larsen 2007). Digital performances not only inspire, but also encourage the audience to replicate (Khamis, Ang, and Welling 2017). Accordingly, consumers not only seek constant change in material objects, but also in their identities (Bauman 2005; Shankar, Elliott, and Fitchett 2009). They quickly discard and adjust their online identities if rejected by others. Consequently, consumption-oriented performative acts on social media enable co-construction of ‘identity-in-practice’, which is of short timespans, situation dependent, and thus temporal, dynamic and fluid (Kerrigan and Hart 2016; Larsen 2007).

### Performativity theory

This study draws on performativity theory (Austin 1975; Butler 1990, 2010) in order to investigate how individuals consume visual fashion performances on Instagram, and how this consumption relates to co-construction of consumers’ identities. The central idea of performativity theory is that repetitive acts construct and form identities (Butler 1990). Accordingly, a performance comprises the relationship between performers, their actions and the audience (Butler 1990). Language, practices, and visuals frame performances of identities that, in turn, shape reality through the exertion of intentional (illocutionary) forces and related intentional or unintentional effects (perlocutionary acts) (Austin 1975; Schechner 2006). Thus, performances reinforce and communicate identities within society – both verbally and bodily (Austin 1975; Butler 1990, 2010).

In the context of this study, this implies that visual fashion performances on Instagram as intentional (illocutionary) acts have a related and potentially unintended (perlocutionary) effect on consumers’ identity formation. This study focuses on consumers’ narratives related to visual consumption of fashion performances on Instagram.

Applying this performative view onto identity co-construction dynamics provides an increased understanding of the entangled dynamic relationship between performers as commodified selves and consumers in digital environments like Instagram.

**METHODOLOGY**

This study uses in-depth narrative interviews supplemented by auto-driven photo elicitation to investigate consumers’ visual consumption of fashion performances on Instagram (Harper 2002; Heisley and Levy 1991). Criteria for the applied purposive sample implied that respondents, first, had an own Instagram account, second, actively engage with Instagram, and, third, belonged to the most prevalent user group on Instagram – Millennials. Prior to the interview, respondents were asked to select three fashion-related persona brand accounts, which they frequently consume on Instagram. This projective material was then integrated in the interviews generating in-depth insights into respondents’ meanings ascribed to visual fashion performances on Instagram, and related identity co-construction dynamics.

The sample comprised 11 German-speaking respondents (age range: 20–30; mean = 26; profession: student (6); nurse (2); manager (2); doctor (1)) – ensuring a gender distribution congruent with Instagram’s user statistics – 68% female and 32% male (Aslam 2018). Interviews lasted from 55 minutes up to 1.5 hours resulting in 161 pages verbatim transcripts. Data analysis involved an iterative process of inductive categorization (Kreiner, Hollensbe, and Sheep 2006; Spiggle 1994) and abstraction to derive major themes arising throughout respondents’ narratives.

**FINDINGS**

Narrative interviews brought forward insights into the multi-faceted visual consumption of fashion performances on Instagram. The following section entails a detailed account of desired content, requirements for consumption, and performatively accelerated identity co-construction dynamics (Figure 1).

**Desired content and requirements for consumption**

Respondents frequently stated that they seek foremost variety in content, that is, lifestyle performances related to fashion, travel, food, sports, interior design, nature, photography, and even politics / activism. Fashion is rather an integral part within these thematic categories and rarely consumed as stand-alone category. However, respondents consider fashion a tool to express these lifestyle-related themes. Compositional aesthetics and consistency of visuals have to be visually appealing – yet, regarding photography itself, not regarding display of fashion taste per se (Dolbec and Fischer 2015).

“For me it is very important with respect to Instagram accounts in general that the quality of photography is good. I don’t like accounts that are arranged unprofessionally. That is why I also don’t follow some of my friends, because I am not interested in that. I select very carefully, because it has to be visually appealing to me. That is extremely important to me. I am interested in certain things, which may be the person itself, lifestyle, interior design, fashion, or food.”(R5, female, 27)

Respondents additionally argued that representing naturalness fosters repetitive consumption (Butler 1990). Contrary, respondents do not value excessively staged unnatural performances as they consider these as ‘calls for attention.’ Consumers prefer performances they can relate to – ‘torn from real life’ and filled with emotions – as R2 refers to a plus-size model account:

“It seems very likeable to me that she shows herself as she is. That she is simply posting images of herself without using Photoshop or anything else, simply showing that every woman has problems with her body in a certain way and that you can regardless like yourself as you are and that makes her very much likeable as a person to me.” (R2, female, 26)

Moreover, respondents stated that they immediately discard persons who post too often, that is, multiple times a day, and replace them by other accounts – “I like what you are doing, but don’t impose on me” (R5, female, 27) – illustrating the accelerated consumption dynamics in postmodern consumer culture (Baumann 2007).

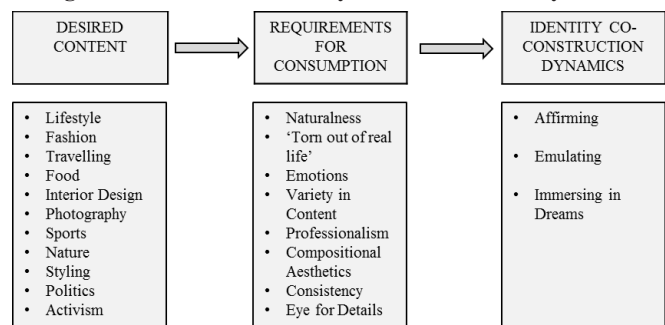

**Accelerated identity co-construction dynamics**

Consumers explained their frequent usage of Instagram by referring to the ever-changing, constantly renewing nature of home feed content. Relating to consumers’ urge for fast consumption, Instagram offers a visual environment enabling such accelerated consumption:

“[...] and when I push the ‘follow’ button, then the recommendations pop up. These are similar feeds, related types of bloggers respectively. And due to that you delve into the whole thing quite fast, because you have a multitude of such persons very fast.” (R1, female, 20)

Respondents further claimed that they prefer consuming images over text – first, due to faster consumption, and, second, due to the myriad of meanings images can convey (Schroeder 2002). However, consumers’ narratives not only addressed accelerated dynamics of the digital environment per se, but also accelerated identity co-construction dynamics (Figure 1).

**Figure 1: Accelerated Identity Co-Construction Dynamics**

First, this study finds that the consumption of commodified selves accelerates *affirmation* of purchases that cause internal struggle within consumers’ conscience, that is, respondents reported cases of uncertainty and twinges of conscience with respect to prior or upcoming purchases.

“I set myself the goal to purchase an expensive watch when I am done with my apprenticeship. I already decided for a specific Rolex, however it is a huge investment. But then I saw this photo and experienced affirmation. I thought to myself, if Roger Federer is wearing this watch it must be really beautiful.”(R6, male, 27)

This quote emphasizes that consuming Roger Federer affirmed R6’s decision already made of purchasing a Rolex – solving his internal struggle of desire vs. costs (Kozinets, Patterson, and Ashman 2017). Accordingly, consuming commodified selves accelerated

the **affirmation** to purchase this watch without having to look for alternative sources of affirmation. Similarly, this study finds that performative acts of commodified selves unintentionally affect post-purchase **affirmation** in terms of uncertainty, and even motivation for work out (Austin 1975) (Table 1).

Second, this study finds that consumers **emulate** consumed visual performances in terms of places. Respondents predominantly associate fashion with travelling. *“I really like that I can see different kinds of fashion in different countries and that is why I associate it [fashion] with travelling”* (R5, female, 27). However, fashion only plays a minor role in this case. Consumers rather engage in lifestyle-oriented place co-branding (Sevin 2014). Performative acts of commodified selves travelling the world accelerate consumers’ quests for adequate motives when visiting similar places:

*“[...] The funny thing is when I was on my way to London I quickly browsed through Instagram, and then remembered his account [iamgalla], and there is this photo of him. There I saw,*

*for instance, this place – this arc from which you can see Big Ben. And then this photo came out in the end.”* (R9, male, 25)

Accordingly, this quote illustrates the accelerated **emulation** enabled through the consumption of commodified selves on Instagram (Table 1). Thus, the performer’s intention of depicting a jet set lifestyle unintentionally results in visual networked co-branding of specific places (Austin 1975) – visual performances of places that a lot of consumers would like to have on their own accounts. Respondents frequently stated that they reminisce about their own travelling experiences when they see a similar photo.

Third, this study finds that consumers **immerse in dreams** when consuming commodified selves on Instagram. Consuming commodified selves elicits wanderlust and longing within consumers. Most respondents state that they do not have the financial means to live the lifestyle of Instagram performers – yet, Instagram offers a possibility to delve into virtual journeys:

**Table 1: Findings**

	<b>Examples of Interview Data</b>
<b>Affirming</b>	<p><i>“I set myself the goal to purchase an expensive watch when I am done with my apprenticeship. I already decided for a specific Rolex, however it is a huge investment. But then I saw this photo and experienced affirmation. I thought to myself, if Roger Federer is wearing this watch it must be really beautiful.”</i> (R6, male, 27)</p> <p><i>“I have this light pink blouse with birds on it. I always thought to myself that it looks really shitty, but then I repeatedly saw it on Instagram and it changed my perception of this blouse. So in the end I thought to myself that it cannot look that bad and now I am wearing it.”</i> (R3, female, 24)</p> <p><i>“Well, every now and then I am quite lazy when it comes to running, especially when it rains. Then I shrink away from running. But then I look on Instagram and see these people working out and think for myself, “alright, let’s go for working out.””</i> (R3, female, 24)</p>
<b>Emulating</b>	<p><i>“If I know that I am travelling somewhere soon, then I explicitly look for other people’s content of these places. I go to the browse bar, put in the place first, i.e. London, and then set the location to London, and then I immediately get the “most popular posts” of London. Similarly, I check for hotels or restaurants, i.e. London, there is this famous restaurant that I saw on Instagram. And then I check hashtags in similar vein. The funny thing is when I was on my way to London I quickly browsed through Instagram, and then remembered his account [iamgalla], and there is this photo of him. There I saw, for instance, this place – this arc from which you can see Big Ben. And then this photo came out in the end.”</i> (R9, male, 25)</p> <p><i>“For instance, I am planning to go on vacation this summer, this means that I followed a multitude of travel accounts to seek inspiration in what I like and where I think to myself, “wow, I would really love to take this photo, too” or food, if I don’t know what to I should cook, I might find something on Instagram that appeals to me, where I say to myself, “ok I’m cooking this for myself now.”</i> (R5, female, 27)</p>
<b>Immersing in Dreams</b>	<p><i>“Just as I said, Instagram is such a small separate world and I think it is a beautiful place where you can submerge and say “okay now I am not the person who has to get up early in the morning for work or such things,” but on Instagram I am a person who can also show other people due to likes, that I really appreciate what they do. It is a community and I am a part of it. I may become in some way another person on Instagram.”</i> (R5, female, 27)</p> <p><i>“What I like so much about this account is the fact that she posts a lot of pictures where I think: “Ahhh this could be me!” because you don’t see her on the pictures. [...] you don’t see her face, and when I look at these photos, I think for myself: “Ahhh I’d love to sit there right now.” Somehow this makes me identify myself stronger with these pictures.”</i> (R1, female, 20)</p> <p><i>“What animates me to consume Instagram is that it isn’t so stressful, that it is a distraction, and that you can delve into a different little world, which sets itself apart from everyday life, and which is a little bit dreamy. [...] These are feelings where I say to myself, “wow just live your life! Just do it! I really would like to do it the way these people do.”</i> (R5, female, 27)</p>

	Examples of Projective Visual Data
<p><b>Affirming</b></p>	 <div data-bbox="1084 226 1435 693"> <p><b>rogerfederer</b> • Abonniert</p> <p>rogerfederer Welcome to Instagram @Rolex #101031</p> <p>Weitere Kommentare laden</p> <p>instagmuser Obviously, lucky watch for you Sir 🤩</p> <p>pgro2345 @rogerfederer : that's a cool shot</p> <p>perrymarco @alessandra.rezzola .. Le' ura de na per me ..</p> <p>blomeuhren 🍷</p> <p>♥️ 💬 📌</p> <p>Gefällt 81.466 Mal</p> <p>28. NOVEMBER 2015</p> <p>Kommentar hinzufügen ...</p> </div>

“Well, unfortunately I don’t have the financial means for travelling. I think that you can’t have it all, but maybe it animates me to take charge of my own life and pursue my dream of travelling. This means that I travel virtually as I look at all these things. As I said, I associate fashion very much with travelling. So in a way, I definitely travel virtually.” (R4, female, 28)

Correspondingly, *immersing in dreams* also triggers a ‘just do it – live your life!’ mentality within consumers. Even though momentarily not within reach, visual performances exhibiting close external focalization, that is, the audience can see the same things in the same way as the performer (Rose 2012), align the consumer with the consumed – identities the consumer might never be able to achieve (Table 1). Thus, performers’ intentional depiction of travel lifestyle unintentionally leads to consumers’ *immersion in dreams* about possible future selves (Austin 1975).

## DISCUSSION

The empirical investigation illustrates how the digital environment of Instagram enables accelerated identity co-construction dynamics between performers as commodified selves and consumers. Interestingly, this study finds a discrepancy between the intended commercial force of visual Influencer-driven advertorials, namely promoting products, and unintended related effects in consumers’ identity formation (Abidin 2016; Austin 1975). Thus, this study sheds light on the complexity of meanings consumers ascribe to digital consumption of fashion – protruding far over the classical realm of fashion.

Consumers in this study predominantly do not buy the advertised products, but rather take ‘bits and pieces’ out of the sandbox of consumed commodified selves and performatively fashion their selves through repetitive visual consumption on Instagram (Butler 1990). Consumers seek affirmation of decisions already made that yet cause internal struggle. Furthermore, under the arising duality between consumers and commodities, individuals become both object and subject (Bauman 2007) – especially when emulating. Metaphorically speaking, consumers delve into the digital environment of Instagram immersing themselves into different possible selves and worlds. Consequently, the dynamics of Instagram allow for instant accelerated identity co-construction dynamics related to multiple temporal selves – past, present, and future (Kerrigan and Hart 2016). Past in the sense of solving a post-purchase dissonance or reminiscing about visited places. Present in terms of impromptu consultation on popular photo locations or best restaurants in town. Future in regard to taking charge of one’s own life and dream about possible future selves. Consuming commodified selves on Instagram thus potentially accelerates co-construction of consumers’ multiple, fluid and temporal identities.

This study has two main limitations. First, this study focuses on the site of the audience. Second, findings are still exploratory. Future studies could take into account both performers and their consumers, confronting both with ascribed meanings vis-à-vis, namely intention and reception of specific posts – in other words, connecting the consumed and the consumer. Visual analysis of projective material could further illuminate identity co-construction dynamics (Rokka and Canniford 2016).

# The Effects of Breadth of Product Categories on Budgeting

An Tran, University of La Verne, USA

John G. Lynch Jr., University of Colorado at Boulder, USA

## ABSTRACT

Individuals plan for the use of their resources daily. We explore how the level of details of one's budget affects the budget's predictive power. We find evidence that more detailed budgets predict spending less accurately. This phenomenon is mediated by one's liking for the products budgeted and perceived financial constraint.

## KEYWORDS

Budgeting, Category Size, Breadth of Category, Overspending, Planning.

## INTRODUCTION

Individuals have to plan for the use of their resources (e.g., time, money, etc.) daily.<sup>1</sup> Factors that affect how individuals plan and the accuracy of their plans have attracted much interest from researchers. Recent research suggests that one such factor is how much one plans. Interestingly, some evidence suggests that the more one plans, the less accurately one predicts one's use of resources. This area of research has focused on demonstrating this tendency when one plans for and uses one's time. We explore this tendency in the financial domain by studying the relations between how detailed one's budget is, operationalized as how narrow or broad the product categories that one plans for are, and how well one's budget predicts one's spending. For example, one's total, broad budget for remodeling one's house could be broken into narrower sub-components, such as one for flooring, one for lighting, and one for landscaping. Existing literature suggests that how detailed one's budget is affects how well that budget predicts one's spending. Research on planning for time suggests that budgeting for narrower product categories could lead to less accurate predictions of one's spending.

## THEORETICAL BACKGROUND

Considerable research has shown that individuals maintain mental budgets for different categories of spending (e.g., Thaler 1999). Consumers' spending and consumption behaviors are affected by how mental accounts are formed and how expenses are assigned into them. The more spending is recorded in one account, the less likely consumers will spend from that account (Soman and Lam 2002). Consumers are also motivated to post ambiguous expenses (e.g., a dinner with friends at a concert) into the accounts perceived to have more funds available (Cheema and Soman 2006). Assigning a resource to an account associated with "specialness" makes consumers less likely to use it because they keep waiting for the perfect occasion to use it, which often comes after resources, such as wine or coupons, have expired (Shu 2011). More generally, mental budgets have been implicated in under-consumption in some categories and over-consumption in others (Heath and Soll 1996).

The breadth of product categories has been shown to affect one's willingness to spend resources. Spiller (2011) shows that individuals become less willing to spend resources when they are thinking of spending on/from narrow product categories (e.g., Starbucks gift cards) than when they are thinking of broad categories (e.g., Visa gift cards). This is because narrow categories evoke a sense of resource constraint, which makes one consider opportunity costs more.

Another line of research by Malkoc and Zauberan (2006) show that willingness to pay increases with concreteness of mental representations of outcomes. Concreteness is driven by both category size and psychological distance. Narrower categories (e.g., strawberry cheesecakes) should evoke more concrete mental representations than do broad categories (e.g., desserts) (i.e., the fan effect, Anderson and Redder 1999). Additionally, concreteness of representations may also differ between budgeting and shopping. According to construal level theory (CLT, e.g., Trope and Liberman 2010), temporal distance is one determinant of the level of concreteness of representations. Relative to shopping, budgeting or planning is more temporally distant from consuming the product, and thus, should evoke less concrete representations. We therefore expect category size to have differential effects when individuals budget than when they shop.

How much individuals like certain products is another factor underlying how individuals budget and shop. Narrow categories are more likely to recruit specific exemplars of that category to one's mind than do broad categories (Anderson and Redder 1999). And specific exemplars evoke more affectively charged responses, which are more likely to affect people's behavior, such as donating to a cause (e.g., Small, Lowenstein and Slovic, 2007). Similarly, narrow categories should make people more willing to spend on positively valued products than do broad categories because they evoke more intense affective responses. This effect should also be differential between budgeting and shopping because of differential temporal distances from consuming the products. Budgeting should evoke less affect intensity than shopping does due to greater temporal distance from consuming the products (e.g., Trope and Liberman 2010).

These factors drive one's willingness to spend in different directions. In this paper, we explore how these conflicting forces combine to affect one's budget and spending. The literature reviewed suggests that category size should differentially affect budgeting and shopping.

My research helps deepen a body of literature on the planning fallacy (Kahneman and Tversky 1979), and the "irony of planning" (Buehler and Griffin 2003; Spiller and Lynch - working paper). Considerable research has studied the "planning fallacy", which shows that people underestimate how much time they need to complete tasks. Most of this research focuses on individuals' planning for time. But a smaller set of papers studies the "budget fallacy", defined as individuals' tendency to underestimate their future spending (Peetz and Buehler 2009, Peetz and Buehler 2012).

Despite the vast amount of research on the planning fallacy for time, there is a paucity of research on the planning fallacy for money, i.e., the budget fallacy. We broaden this body of literature by focusing on the budget fallacy. Additionally, we explore the breadth of product category as a new operationalization of the extent of planning. We consider budgeting for one broad product category to be less extensive than budgeting for many narrower sub-categories of that broad category.

Some research shows an ironic effect of planning in that individuals who plan for time more exhibit the planning fallacy more (Buehler and Griffin 2003; Spiller and Lynch - working paper). Individuals commit the planning fallacy for time less if they are induced into an abstract mindset, which involves less concrete details (Peetz and Buehler 2012, Peetz, Buehler and Wilson 2010). Consistent with

---

<sup>1</sup> This article was developed based on the first author's Ph.D. dissertation.

this literature, we predict that the budget fallacy is exacerbated when consumers plan for narrower product categories.

*Hypothesis 1* Individuals exhibit the budget fallacy more as they budget and shop for narrower product categories.

Based on the literature reviewed, we also expect individuals' liking for products and perceived financial constraint to mediate this exacerbated budget fallacy.

*Hypothesis 2* The phenomenon predicted in hypothesis 1 is mediated by individuals' liking for the products.

*Hypothesis 3* The phenomenon predicted in hypothesis 1 is mediated by individuals' perceived financial constraint.

The following two experiments were designed to test these hypotheses.

## METHOD

### Study 1: Budgeting and Shopping Experience to Test Hypothesis 1

#### Study Overview

350 MTurk participants participated in an online study to be paid \$1.40. Participants were randomly assigned to one of three conditions (Category Size: Broad vs. Narrow vs. Very Narrow). Participants budgeted and shopped online for a provided list of grocery products for enough consumption over one week.

#### Procedure

All participants were first given a list of 20 grocery products, including 10 food and 10 beverage products (e.g., Nestle instant coffee, Safeway instant coffee, Welch's grape juice, etc.) that they would budget and then shop for.

#### Manipulation of category size

In the Broad category condition, participants sorted this list of 20 products into 2 categories with fixed, provided labels, "Food" and "Beverages". In the Narrow category condition, participants sorted the list of 20 products into 10 narrow categories with fixed, provided labels, which are sub-categories of the broad categories "Food" and "Beverages", (e.g., instant coffee, grape juice, etc.). There were two brands in each narrow category, one more expensive and high-quality than the other (e.g., in the narrow category "instant coffee", there were two products "Nestle instant coffee" and "Safeway instant coffee"). In the Very Narrow category condition, participants were asked to take several minutes to carefully read through the list of 20 products. Each "very narrow category" was operationalized as a product with a brand (e.g., Welch's grape juice). Thus, in the Very Narrow category condition, it was not possible to ask participants to sort the 20 branded products into any categories other than the branded products themselves, a task that would likely not induce any additional effects.

The 20 very narrow categories were sub-categories of the 10 narrow categories, which in turns were sub-categories of the 2 broad categories.

Participants were told that their grocery consumption totaled typically about \$50 per week; but they could budget and spend as much as they wanted.

Besides the sorting task, a second part of the category size manipulation was presented in the budgeting task. In all conditions, participants were shown the same list of all 10 grocery products that they would shop for (e.g., tomatoes, orange juice). But below this list, participants were presented with either the 2 broad categories, 10 narrow categories, or 20 very narrow categories, depending on their condition, and then asked to budget for their consumption over one week by typing in a budget amount, in dollars, for each of the [2/10/20] categories presented to them. A field that automatically calculated the total budget was presented below the categories.

After budgeting, participants shopped for the groceries they budgeted for. All participants were presented with the same list of 10 products that they saw when budgeting and were asked to shop for these 10 products for enough consumption over one week using the budget they just created. When shopping for each product, participants saw two brands with their prices, one more expensive and high quality than the other. Participants typed into two text boxes how much of each option they would buy, in pounds for foods and ounces for beverages. The shopping list of 10 unbranded products was always presented to participants throughout the shopping task.

A third part of the category size manipulation was presented in the shopping task. While shopping, participants saw feedback of how much they had spent in each of either 2 broad categories, 10 narrow categories, or 20 very narrow categories, depending on their condition. All participants also saw how much they had spent in total.

After shopping, participants filled out the covariates, including the Tightwad-Spendthrift scale (Rick, Cryder, Loewenstein, 2008), adapted scales measuring Propensity to Plan for Money in the next 1-2 weeks (Lynch, Netemeyer, Spiller and Zammit, 2010), and demographic variables.

The dependent variable was the total amount of money that participants budgeted and spent.

#### Results

We first calculated how much money participants overspent relative to their budget:

$$\text{Over-Spending} = \text{Total Dollar Spent} - \text{Total Dollar Budgeted}$$

An ANCOVA testing for the main effect of Category Size on Over-Spending showed a significant main effect of category size ( $F(2, 329) = 11.56, p < .001$ ). Participants over-spent less in the Broad condition ( $M_{\text{Broad}} = -7.28$ ) than in the Narrow ( $M_{\text{Narrow}} = 6.00$ ;  $F(1, 329) = 8.99, p = .003$ ) and Very Narrow ( $M_{\text{Very Narrow}} = 13.16$ ;  $F(1, 329) = 22.39, p < .001$ ) conditions. Narrow and Very Narrow conditions differed marginally ( $p = .099$ ). The covariates did not have any significant effects (all  $p > .191$ ).

Participants spent significantly less than they budgeted in the Broad condition ( $t = -4.58, p < .001$ ). The mean Over-spending was marginally larger than 0 in the Narrow condition ( $t = 1.51, p = .133$ ), and significantly larger than 0 in the Very Narrow condition ( $t = 3.83, p < .001$ ). That is, participants increasingly spent significantly more than they had budgeted as the category size gets narrower.

In summary, the results of this experiment support hypothesis 1. In the next experiment, we aim to uncover the mediators underlying this phenomenon by exploring the mediators Liking for products and Perceived Financial Constraint. Additionally, in study 2, we informed participants of relevant prices of all products before beginning the budgeting task.

**Study 2: Budgeting and Shopping Experience to Test Hypotheses 2 and 3**

*Method*

300 participants from mTurk were recruited for this study. Study 2 had similar paradigm, procedure and manipulation with study 1. The only changes from study 1 were:

1. When products were presented to participants in the sorting and budgeting tasks, the product prices were also presented.
2. Study 2 has two conditions instead of three. These two conditions were similar to the “Broad” and “Narrow” conditions in study 1.
3. Two mediators were measured after the sorting task, but before the budgeting and shopping tasks:
  - Perceived Financial Constraint: On the same page, participants were presented with the list of products, with their prices, that they would budget and shop for, for enough consumption over one week; they were told that their grocery consumption over one week was typically about \$50 dollars; participants then rated how constrained they felt their financial situation would be for those budgeting and shopping tasks on three 11-point scales adapted from Spiller (2011).
  - Liking: Participants in both conditions were presented with the same list of all the products they would budget and shop for. But below this list, participants in the “Broad” condition were presented with two scales, for “Food” and “Beverages”, and rated their liking for the products they were presented with on these two scales. Participants in the “Narrow” condition were presented with ten scales, each for a narrow product category that

they would encounter in this experiment, and rated their liking for the products on these ten scales. The liking score was the average of these either two or ten scales.

*Results*

The findings in study 1 were replicated. Participants over-spent more when category size was narrow ( $M_{\text{Narrow}} = 10.95$ ) than when it was broad ( $M_{\text{Broad}} = -2.48$ ;  $F(1, 293) = 7.03, p = .008$ ). The mean over-spending was significantly greater than 0 in the Narrow condition ( $t = 2.61, p = .010$ ), but not in the Broad condition ( $t = -.86, p = .392$ ).

We then conducted mediation tests with the two mediators Liking for products and Perceived Financial Constraint, with the bootstrapping technique discussed by Zhao, Lynch and Chen (2010), using Preacher and Hayes’ (2008) SPSS script. The independent variable is Category Size. The dependent variable is Over-Spending. The effect of Category Size on Overspending through both mediators are significant (CI Constraint = .025: 4.064; CI Liking = .095: 4.452). These results support hypotheses 2 and 3.

\*\* IV Category Size: Narrow coded as 1 and Broad coded as 2  
Constraint: Higher score means higher constraint  
Liking: Higher score means higher liking

## DISCUSSION

These two experiments are among the few examining a budget fallacy. As a new operationalization of the extent of planning for money, product category size has high ecological relevance to the domain of budgeting. We found that individuals' over-spending increases as they budgeted and shopped for narrower categories, which was mediated by how much individuals liked the products, and how financially constrained individuals felt.

This research does not suggest that no planning is better than planning. Rather, it points to an avenue to further explore how consumers can plan to maximize their well-being.

## CONCLUSIONS

In this research, we explored a consequence of category size on budgeting by manipulating category size. However, we expect that there are endogenous factors that determine which level of categorization individuals assign products or activities into. An avenue for future research is to explore determinants of category size. What long-lasting individual tendencies affect one's level of categorization? Cheema and Soman's work (2006) suggests that situational factors affect categorization. But do situational factors affect certain individuals more than others? It would also be interesting to explore how these questions generalize to the domain of planning for time.

# It's About Trust: The Diffusion of Deviant Consumer Behavior

Peter Voyer, University of Windsor, Canada

## ABSTRACT

When does deviant consumer behavior become accepted as non-deviant? Addressing this, a social diffusion process is modeled, which starts with individual adoptions, builds critical mass to where the behavior once labelled as deviant, becomes mainstream, resulting in a new emergent norm. Propositions are developed, supported by a comprehensive conceptual framework.

## INTRODUCTION

Deviant consumer behavior (DCB) is ubiquitous; some legal, some illegal. Pornography is edging its way into the mainstream: it is a \$97 billion global industry (CNBC 2014) with 40 million Americans regularly visiting porn sites (Webroot 2014); and in 2017 (alone) a major porn site, Pornhub, got 28.5 billion visits (Silver 2018). Once flaunted by the “deviant” minority, seemingly most people now have tattoos – 40% of US adults aged 26-40 (Pew Research 2013). Illegal software downloading is pervasive – 57% of computer users, worldwide, admit they pirate software (BSA 2012). In 2001, two years after Napster’s creator gave the first version of the music sharing software to 15 friends, it had been downloaded 57 million times, equipping 200 million PCs worldwide, and established the basis for illegal music downloading (Fattah 2002) – this rapid diffusion through society revolutionized the music recording industry.

As some DCB spreads through society, when does it stop being deviant and become non-deviant or “normal?” The extant CB literature does not address this research question, nor does it give sufficient attention to the pervasive subject of deviance (Dootson et al. 2016). This is not surprising given the inherent challenges in studying this diverse topic. Conceptual boundaries vary, as does the nature of deviance itself; what is deviant to one person might not be to another, and what was deviant many years ago might not be today (Voyer 2014). The dark side of CB, deviance was recognized as being difficult and troubling (Hirschman 1991), while also being one of the most important new areas of CB research (Mick 1996). Notwithstanding, since Wells’ (1993) call for greater research into the dark side of CB, substantial advancement remains to be made.

This conceptual research is positioned within the limited CB literature on deviant consumption and adheres to Debbie MacInnis’ perspective on conceptual research (MacInnis 2017). Several key contributions are made: our understanding of DCB is enhanced, and the CB literature is enriched as theory from other disciplines (marketing, sociology, and criminology) informs this work. Although some individual factors are considered (initially), I focus on society as the level of analysis.

## DEFINING DEVIANT CONSUMER BEHAVIOR

In this research, I am not concerned with the origins of *why* consumers pursue deviant behavior. Instead, using society as the level of analysis, I focus on *how* DCB spreads through society, and its resultant social normative effects resulting in “acceptance.” Integrating social learning theory with marketing diffusion theory, I explore the dissemination of DCB to when it ceases being considered as deviant and becomes commonly accepted as non-deviant.

Deviance is embedded in a social environment, and a particular behavior can be deemed deviant upon evaluation against the norms of a reference group (i.e., society). Norms are rules in the minds of group members that stipulate expected behavior. Here, the usual pejorative sense of deviance is not assumed. Instead, I emphasize the

notion of “departure.” Merton (1961, 723) emphasized that, “deviant behavior cannot be described in the abstract but must be related to the norms that are socially defined as appropriate and morally binding.” Adopting this argument, I define deviance as: a socially-based notion, which reflects willful normative violation as defined by the members of a reference group. DCB is formally defined as, a consumption experience that is related to an idea, practice or object of consumption, which is in contravention of normative standards as defined by the members of a reference group (society).

## THE CONCEPTUAL FRAMEWORK OF DCB DIFFUSION

The process-oriented framework at figure 1 conceptually traces the diffusion of DCB starting with individual adoption, and spreads to the collective level at which point, the formerly DCB, having attained mass adoptions, has entered mainstream society and has become non-deviant. The process is described under three major rubrics: (1) adoption – how individual consumers adopt the DCB; (2) diffusion – how a critical mass of adopters occurs; and (3) attainment of non-deviant status – as it is accepted by society. An emergent norm in support of the behavior ultimately results.

### Adoption Process

Social cognitive theory distinguishes between two separable processes in the social diffusion of innovations: the acquisition of knowledge via social learning (regarding the innovation), and the adoption of it (Bandura 1986). Social learning is assumed to be the main process that links social structure to individual behavior – DCB (Akers 1998). Adoptive behavior is best analyzed in terms of psycho-social determinants rather than types of people (Bandura 1986). Moreover, social contextual factors can serve to greatly influence individual adoption decisions (Fisher and Price 1992). I propose:

**PI:** in table 1

*Social Structure.* Prominent sociologists (e.g., Durkheim, Merton, Blau) contend that society cannot be adequately understood by solely observing individual behavior; people are enmeshed in relationships that are hinged on communications networks (Bandura 1986). These networks are, “the regular patterns of person-to-person contacts that can be identified as people exchange information in a human social system” (Monge 1987, 243). Social structures are comprised of these networks, which are based on ties. Granovetter’s (1983) analysis of ties suggested that weak ties, which serve a bridging role between network clusters, are the primary types of relationships that facilitate entry of new information into the cluster; strong ties hold the clusters together but allow limited transmission of new information – members hold similar views. Consumers with weak ties are likely to travel in diverse social circles where they learn new behavior like DCB.

In uncertain situations, people turn to those who they believe are knowledgeable for guidance (Bandura 1986). I surmise that to mitigate uncertainty, DCB occurs in the presence of those with whom trust has been secured. Trust would likely be facilitated in a strong-tie situation. Also, consumers’ adoption of DCB would act to reduce uncertainty by activating a strong tie relation by turning to those who they know and perceive to be knowledgeable and trustworthy.

Acquaintances who interact with members of other groups act to broaden diffusion paths. Weak ties could enhance access to diversity; however, it is the strong-tie network that greatly influences

INDIVIDUAL

COLLECTIVE

“DEVILANT”

“NON-DEVILANT”

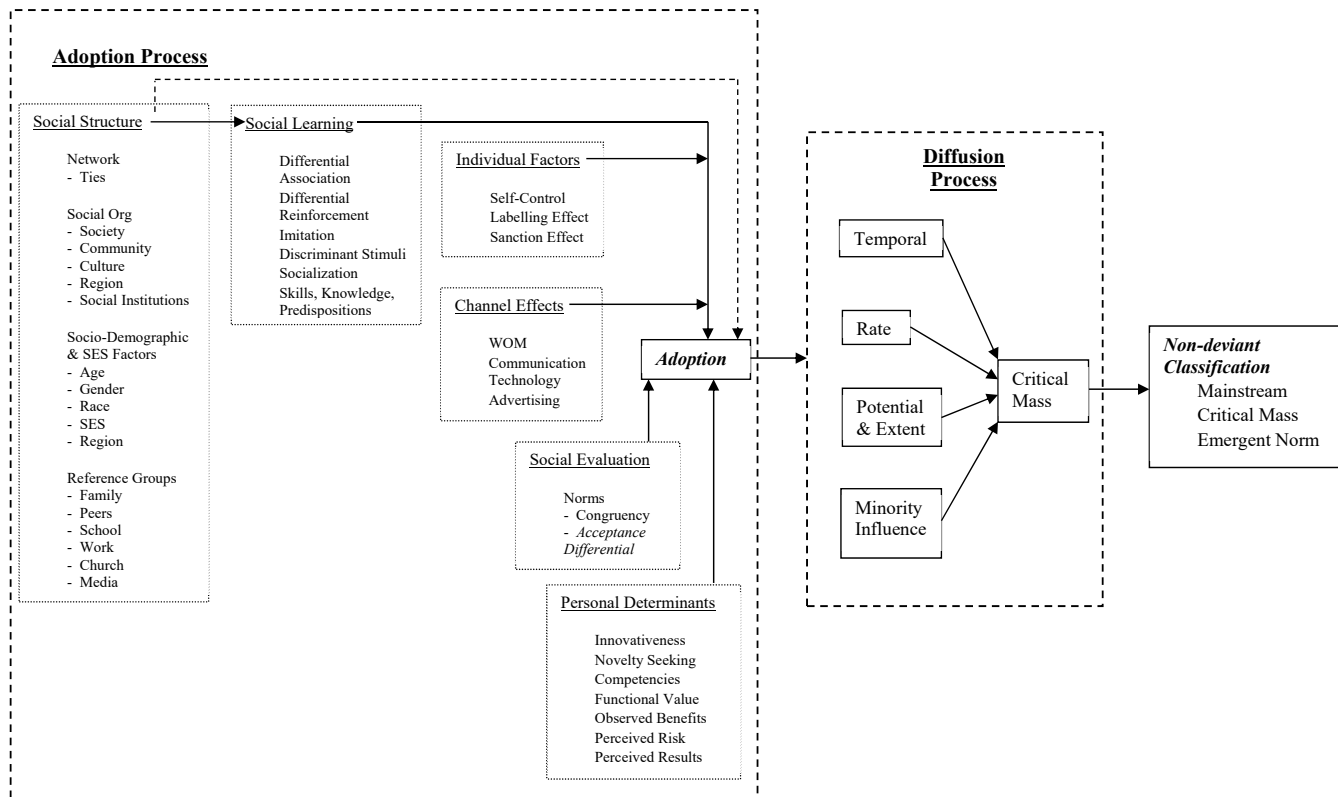

Figure 1: A Conceptual Framework: The Process of Deviance to Non-Deviance

what actually gets adopted from the diversity (Bandura 1986). New information from weak ties would serve to expose new clusters to DCB. I propose:

**P2, P3, P4:** in table 1

Social structure variables contained in a deviance-facilitating environment can impact adoptive behavior, via learning mechanisms (Akers 1998). Social structure facilitates social learning. I propose:

**P5:** in table 1

*Social Learning.* Social learning theory (Bandura 1986) holds that a learner can acquire new responses by solely observing the behavior of a model, which explains learning of many social responses (DeLamater and Myers 2011). Whether the learner will perform the behavior is influenced by its consequences. People can differentially associate with those who model particular behaviors, and through successive exposures to stimuli (DCB), differential reinforcement of the behavior occurs (Birenbaum and Sagarin 1976). These behaviors can be imitated, facilitating social learning, and supporting socialization (DeLamater and Myers 2011). I propose:

**P6, P7, P8:** in table 1

Socialization refers to: instrumental learning (rewards and punishments); observational learning (modeled behaviors); and internalization (making behavioral standards part of the self) (DeLamater and Myers 2011). Via socialization, social norms are learned from others – socializing agents. Learned early in life, conformity to norms facilitates social interaction. Learning plays a key role in acquiring some DCB but not others e.g., skills needed to pirate software, but not compulsive shopping. I propose:

**P9:** in table 1

*Individual Factors.* Theoretically grounded in internalization (described above), self-control is the struggle between the two psychological states: desire and willpower (Hoch and Loewenstein 1991; Baumeister 2002). Internalized standards guide behavior when a consumer behaves without considering possible rewards or punishments, even without surveillance by others. She might feel morally obliged to perform a behavior, or she might experience a strong internal feeling that a behavior is wrong (experiencing guilt if these moral prohibitions are violated). The pejorative label, “deviant” serves to stigmatize the holder, making her less worthy than others (Becker 1963; Birenbaum and Sagarin, 1976). Most consumers wish to avoid this – its threat would reduce the likelihood of DCB adoption, but once bestowed, secondary deviance may serve to enhance potential adoption (Becker 1963). Sanction is a negative occurrence (legal implications, ostracizing, ridicule from others, etc.) that consumers try to avoid. Potentially powerful, consumers will likely consider its consequential effects when processing learned information. The effect of learning on DCB adoption is expected to be moderated by the aforementioned individual factors. I propose:

**P10, P10a, P10b, P10c:** in table 1

*Channel Effects.* WOM is one of the most influential forces in the marketplace (Kozinets et al., 2010). Arndt (1967, 1) stated that WOM is, “informal conversation [that] is probably the oldest mechanism by which opinions on products and brands are developed, expressed, and spread.” It is likely one of the most prevalent means of DCB-information transmission. Social information transmission is enhanced by communications technologies (Bandura 1986); video games and TV can portray norm-violating behavior as interesting,

fun, and exciting. Due to advertising's pervasiveness, repetitiveness, sophistication, and effective delivery (Pollay 1986), its role is highly salient and could lead to DCB. I propose:

**P11, P11a, P11b, P11c:** in table 1

*Social Evaluations.* Norms serve to: (1) foster coordination among members in pursuit of social goals by providing a cognitive frame of reference through which group members interpret and judge their environment, and thus, provide a basis for distinguishing good from bad, and important from unimportant; (2) act as pointers on how to behave in novel/ambiguous situations; and (3) define common identity (DeLamater and Myers 2011). Norms evolve over the "diffusion time horizon" (Gatignon and Robertson 1985) and can aid or hinder DCB diffusion. The interplay between the individual and existing social norms is important; self-evaluative reactions to one's own behavior governs DCB adoption (Bandura 1986). The social normative context in which behavior occurs is instrumental in DCB adoption (Gatignon and Robertson 1985). Adoptability of DCB (taken as an innovation) can be enhanced when it is compatible with prevailing social norms and value systems (Rogers and Shoemaker 1971). An evaluative comparison between norms and DCB (congruency) will affect adoption. I propose:

**P12, P13:** in table 1

*Personal Determinants.* Highly impactful in CB, innovativeness is "the degree to which an individual is receptive to new ideas and makes innovation decisions independently of the communicated experience of others" (Midgley and Dowling 1978, 236). A consumer who possesses a high level of innovativeness is more likely to adopt a DCB. Novelty-seeking is a motivating force that drives a consumer to seek out new and potentially discrepant information (Hirschman 1980). Some consumers will seek novel stimulation by adopting DCB (Hirschman 1984). Personal adopter competencies affect the adoption of DCB; requisite knowledge and skills could be required, e.g., software piracy requires computer skills. The rate at which innovations are adopted in society varies, because they differ in the skills and resources required for successful adoption (Bandura 1986). Experienced functional value, i.e. desired goals can be determinants of adoption (Betman, Luce and Payne 1998). DCB's functional value addresses the purpose of adoption by classifying it as either intrinsic, instrumental. Intrinsic purpose implies adoption that is inwardly focused, whereas, instrumental implies external outcomes. Conspicuous consumption (e.g., fashion, body modification, etc.) can be expected to be subject to greater social influence versus those consumed privately (Bandura 1986). Adopters of DCB who view observed benefits of adoption from others would be expected to be positively influenced by observation. Perceived risk is a formidable force (Murray and Schlacter 1990). Consumers who perceive an innovation (DCB) as risky are more likely to seek the advice of opinion leaders (Arndt 1967). I propose:

**P14:** in table 1

### Diffusion Process

Diffusion is the spread of DCB through society. When a critical number of adopters is attained, the label of "deviant" ceases to be applied, and the behavior has "entered mainstream." I apply diffusion theory to understand the spread of DCB: "the process by which alteration occurs in the structure and function of a social system. When new ideas are invented, diffused, and adopted ... social change occurs" (Rogers 1995, 6). Temporal considerations involve: the process by which an individual transitions from first knowledge to adoption; the earliness/lateness of adoption in relation to other members of the system; and the rate of adoption (adoptions per time period). Rate is linked to critical mass – the number of adoptions (a threshold level) – required for social normative change by stimulat-

ing the emergence of a new social norm supportive of the behavior. Norms and values are determinants of the rate of diffusion (Gatignon and Robertson 1985). Since DCB initially contravenes norms, temporal effects become important since time lags would slow the adoption process (Rogers 1995). Dissocial behaviors (vs. prosocial) are slower in stimulating widespread diffusion (Bandura 1986). Differential consequences and social inducements associated with the DCB likely account for the variation in time between initial awareness and subsequent adoptions. Early adoptions that are socially valued can gain benefits for the user; however, some DCB carries the risk of punishment and requires the impact of "striking examples to reduce restraints sufficiently to initiate a substantial rise in the modeled behavior" (Bandura 1986, 174). Strong inducements are likely needed for adoption of DCB. I propose:

**P15, P16, P17, P18, P19,** in table 1

The potential and extent to which DCB is diffused depends on numerous factors: interpersonal communication, and the nature and utility of the DCB itself. If something is intriguing or useful, it would spread quickly (e.g., Napster). Interpersonal communication is impactful as opinion leaders (innovators) transmit DCB (Stuterville and Roberts 1975). Highly innovative, opinion leaders are often seen as deviant and are therefore, accorded questionable credibility by average members; their role in diffusion is likely to be limited since all members can serve as opinion leaders by spreading information about DCB (Rogers 1995). Hence, diffusion of DCB relies on adopters more so than opinion leaders. I propose:

**P20, P21, P22:** in table 1

Interpersonal influence has many forms: normative (members conforms to others' expectations); majority (pressure from a group's majority over individuals); and minority (a few members can exert pressure on the majority). Often a dissenting minority, holding different viewpoints from the majority, can be impactful. A minority coalition may attempt influence if it wants to change a judgment by the majority, and/or norms or procedures (DeLamater and Myers 2011). Several conditions could serve to enhance attempts by a minority coalition. Moscovici (1980) advanced the conversion theory of minority influence, which suggests that to attain compliance, the minority coalition will usually seek to use persuasive means to affect change by taking a distinctive position (may be deviant) and holding it consistently in the face of pressure to demonstrate commitment. The size of the minority affects the coalition's capacity to influence others; many members can exert more influence than just a few (DeLamater and Myers 2011). I propose:

**P23, P24, P25:** in table 1

### The Tipping Point

Originating in scholarly research, in the area of social movements, the notion of critical mass has gained prominence, as well as popular notoriety in Malcom Gladwell's, "The Tipping Point." Rogers (1995, 313) describes critical mass as, "the point at which enough individuals have adopted an innovation so that the innovation's further rate of adoption becomes self-sustaining." It is the cumulative result of progressively attaining subsequent individual thresholds that ultimately leads to the point of critical mass (Granovetter 1978). I consider it to be a "tipping point" – the point at which the DCB ceases to be "deviant" and has been effectively diffused through society. Associated with this adoption by the majority of society's individuals, is the normative change that takes place; from being largely negative (rejecting the DCB) to acceptance. I propose:

**P26, P27:** in table 1

*Emergence of New Social Norms* as described by Coleman (1990) is the prototypical micro-to-macro transition that arises from

individual actions leading to the formation of a norm. In turn, the process ends at the micro level again with individual conformity to the norm. Over time there is a tendency for conceptions of rights (underlying norms) to converge and ultimately attain an agreement among members (Wallace and Wolf 1999). Supporting this, Blau (1964) proposed an “emergent process” whereby shared experiences can serve to produce norms and values. The mechanism is not direct

exchange, but rather people’s dislike for the psychological state of cognitive dissonance, as they seek to avoid it; individual rationalizations can be strengthened and transformed into norms. Normative change is the ultimate outcome of DCB’s diffusion through society. Members receive social approval in exchange for conformity (Blau 1964). I propose:

**P28, P29, P30, P31:** in Table 1

**Table 1: Propositions and Related Descriptions**

Proposition	Description
<b>P1</b>	The adoption process of DCB (and in turn the resultant diffusion process) will be expected to be facilitated and enhanced under positive conditions of: <ul style="list-style-type: none"> <li>• A supportive social structure to support learning to sustain the adoptive behavior;</li> <li>• Optimal conditions for social learning;</li> <li>• Positive social evaluations with respect to normative standards; and</li> <li>• Personal determinants related to perceived factors associated with adoption.</li> </ul>
<b>P2</b>	Network structures will affect individual adoption, leading to the diffusion of DCB where: <ul style="list-style-type: none"> <li>• Weak ties will be expected to enhance diffusion of DCB;</li> <li>• Strong ties will be expected to have a limited effect on the diffusion of DCB but will influence adoption of the DCB; and</li> <li>• The greater the tie strength, the greater the likelihood of adoption of DCB.</li> </ul>
<b>P3</b>	Initial knowledge acquisition regarding the DCB will be affected by tie strength where weak ties will be more likely to convey “new” information. The source of the DCB will likely originate from a weak tie relationship.
<b>P4</b>	DCB is diffused to a larger number of individuals and traverses a greater social distance when passed through weak ties rather than strong ties.
<b>P5</b>	The effects of social structure on DCB adoption are expected to be mediated by the social learning process.
<b>P6</b>	Differential association – by associating with those persons partaking in the DCB, those not engaged in the DCB are likely to adopt it via this contact.
<b>P7</b>	Observational learning (imitation) is a key mechanism by which many DCB are acquired.
<b>P8</b>	Differential reinforcement – the greater the number of exposures (stimuli) to DCB, the higher the likelihood of adoption.
<b>P9</b>	Some forms of DCB require skills, knowledge, and predisposition in order for adoption to occur.
<b>P10</b>	The adoption of DCB can be expected to be influenced by the level of social learning. However, the effect can be expected to be moderated by some individual factors: <ul style="list-style-type: none"> <li><b>P10a</b> At higher levels of self-control, the influence of social learning on adoption will be expected to be negligibly related to adoption. Conversely, at lower levels of self-control, the influence of social learning on adoption can be expected to be positively related to adoption.</li> <li><b>P10b</b> At higher levels of the labelling effect, the influence of social learning on adoption will be expected to be negligibly related to adoption. Conversely, at lower levels of the labelling effect, the influence of social learning on adoption can be expected to be positively related to adoption.</li> <li><b>P10c</b> At higher levels of the sanction effect, the influence of social learning on adoption will be expected to be negligibly related to adoption. Conversely, at lower levels of the sanction effect, the influence of social learning on adoption can be expected to be positively related to adoption.</li> </ul>
<b>P11</b>	The adoption of DCB can be expected to be influenced by the level of social learning. However, the effect can be expected to be moderated by the channel effects: <ul style="list-style-type: none"> <li><b>P11a</b> At lower levels of transmission of DCB via <i>WOM</i>, the influence of social learning on adoption will be expected to be negligibly related to adoption. Conversely, at higher levels of <i>WOM</i>, the influence of social learning on adoption can be expected to be positively related to adoption.</li> <li><b>P11b</b> At lower levels of <i>communication technology</i>, the influence of social learning on adoption will be expected to be negligibly related to adoption. Conversely, at higher levels of communication technology, the influence of social learning on adoption can be expected to be positively related to adoption.</li> <li><b>P11c</b> At lower levels of the <i>advertising</i>, the influence of social learning on adoption will be expected to be negligibly related to adoption. Conversely, at higher levels of the advertising, the influence of social learning on adoption can be expected to be positively related to adoption.</li> </ul>
<b>P12</b>	The greater the congruency between existing social norms and the DCB, the higher the likelihood of adoption.

Proposition	Description
P13	The greater the congruency between existing social norms and the DCB, the higher the rate of adoption.
P14	The primary personal determinants of adoptive behavior will be expected to be influenced by the following adopter-oriented factors: <ul style="list-style-type: none"> <li>• Innovativeness (+);</li> <li>• Novelty seeking (+);</li> <li>• Adopter competencies (required skills and knowledge) (+);</li> <li>• Experienced functional value (intrinsic or instrumental) (+);</li> <li>• Observed benefits (from others) (+);</li> <li>• Perceived risk (-); and</li> <li>• Perceived results (outcomes) (+).</li> </ul>
P15	Temporal lags in diffusion of DCB will be expected due primarily to: <ul style="list-style-type: none"> <li>• Reluctance to undertake an activity or behavior that might result in sanction (be punished) from society; and</li> <li>• Discrepancy between anticipated and actual experience.</li> </ul>
P16	DCB will spread at different rates and patterns because they differ in the skill and resources they require for successful adoption.
P17	The more compatible the DCB is with existing social norms and values, the greater the rate of diffusion.
P18	The more homogeneous the social system, the faster the diffusion rate.
P19	A time delay between DCB practise and its benefits will be expected to reduce willingness to try new DCB practices.
P20	The greater the influence of interpersonal communications in society, the greater the likelihood of diffusion. Specifically, the following factors will be expected to have a positive relationship with the likelihood of diffusion: <ul style="list-style-type: none"> <li>• Information sharing;</li> <li>• Give meaning by mutual feedback to the information they exchange;</li> <li>• Gain understanding of each other's views and influence each other's views; and</li> <li>• Mutual influence.</li> </ul>
P21	If a DCB is highly functional, has high utility value, and does not require unavailable resources, it will be expected to be widely diffused through a large number of networks.
P22	DCB diffusion through a social system will be expected to be reduced, the greater the discordance with prevailing values and practices.
P23	The greater the extent to which the DCB is idiosyncratic, the lesser the extent to which it will be diffused through society due to the reduced likelihood of sequential adoption.
P24	If the DCB is presented/displayed in a non-conciliatory fashion (unwilling to make concessions) it is likely to cause others to perceive it as being dogmatic and therefore idiosyncratic and therefore, reduce its likelihood of adoption.
P25	The greater the number of persons forming the initial coalition, the greater the likelihood of the DCB being adopted by the majority.
P26	Once a critical mass is attained, the formerly DCB, loses its deviant status resulting in the emergence of a supportive social norm.
P27	Once a new supportive emergent social norm arises, the behavior can be considered to have entered mainstream.
P28	As progressively greater numbers of individuals adopt the DCB, the higher the likelihood that social attitudes will be accepting (or positive) of the DCB.
P29	As progressively greater numbers of individuals adopt the DCB, the higher the likelihood that an emergent social norm will develop that is accepting of the DCB.
P30	The (original) DCB will be considered to be "mainstream" (i.e., having diffused through society) when it is supported by an emergent and underlying social norm.
P31	Sustainability of the DCB will be expected to be enhanced as: <ul style="list-style-type: none"> <li>• Personal and collective attitudes and behavior must be changed for sustainability; and</li> <li>• Benefits must be produced and perceived to gain wide acceptance.</li> </ul>

## CONCLUSIONS AND IMPLICATIONS

In this conceptual research, I have sought to understand how DCB becomes mainstream by presenting a comprehensive process-oriented model. In so doing, I have adhered to Debbie MacInnis' perspective on conceptual research (MacInnis 2017). Notably, I have answered calls from Mick and Hirschman for research into the area of deviance, and I have heeded Rogers' (1976, 1995) suggestions for

integrating social structure into diffusion theory. This has served to address a void in the CB literature on consumption. I have enriched the CB literature by importing theory from other disciplines. Importantly, theoretical contributions have been made: this research represents an initial attempt to understand DCB diffusion; and a platform for subsequent empirical research into DCB has been established.

## On Politics, Morality, and Consumer Response to Negative Publicity

Chethana Achar, University of Washington, USA

Nidhi Agrawal, University of Washington, USA

### EXTENDED ABSTRACT

Events of negative publicity around brands often invoke widespread responses from consumers who observe the event. Interestingly, these observing consumers diverge quite drastically in their responses to the brand. Consider a widely publicized event about the US-based airline carrier United Airlines. In early April 2017, the airline's employees forcibly removed a boarded passenger after he refused to give up his seat. In response to this event, one Twitter user said, "*Video of man being violently dragged off a plane is disgusting @united should be boycotted. You treat people with respect not like animals.*". However, opinions were not entirely one-sided; many people felt the outrage was not justified and defended United Airlines, arguing that airlines were within legal bounds to overbook and re-accommodate passengers, and that the customer was disruptive to the entire flight. One such Twitter user said, "*Let's not all blame @united—you're legally required to follow crew instructions when you're on a plane, even when they tell you to get off.*"

For the same negative publicity event, what leads some consumers to be outraged at the brand while others defend it? What are the determinants of such divergent consumer responses? Past research suggests that brand and relationship-related variables (e.g., brand commitment; Ahluwalia, Burnkrant, and Unnava 2000, and loyalty status; Steinhoff and Palmatier 2016) moderate consumer responses to negative publicity. Current research shows that political ideology could be one predictor of consumer responses to negative publicity event – even if the event is non-political in nature.

We posit that political ideology plays a significant role in influencing consumers' diverging responses (condemnation vs. defense) of brands in such scenarios. Research in consumer behavior has examined how individuals' political ideologies drive complaining behavior (Jung et al. 2017) and responses to various persuasive appeals aimed at them (e.g., Winterich, Zhang, and Mittal 2012; Kidwell, Farmer, and Hardesty 2013; Kaikati et al. 2017). We theorize that consumers' political ideology shapes their responses to events involving *others* via broad beliefs about what is right vs. wrong.

Specifically, we suggest that opposing political ideologies give rise to moral pluralism among consumers, which leads to varying concepts of acceptable behaviors by brands in the marketplace. Moral pluralism is the idea that several conflicting conceptions of morality may all be equally correct and fundamental. Morality is the set of principles concerning the distinction between right and wrong or good and bad behavior. However, what individuals consider to be "moral" varies widely both in nature and strength. In the current literature, we draw from Dworkin (1978) and Chiu, Hong and Dweck (1997), who theorize that individuals tend to hold one of two main classes of moral beliefs in which either upholding *duties* within a given system is fundamental (duty-based belief) or upholding human *rights* is fundamental (rights-based belief). Following norms, laws, and role expectations are at the core of a duty-based conceptualization of morality. In contrast, protecting individuals' rights, providing equal opportunity, and upholding fairness are fundamental to rights-based morality.

During negative-publicity events those involving service failure, consumers' moral beliefs are pitted against each other in their responses to the event. We demonstrate that liberal (vs. conservative) consumers are more likely to condemn a brand and defend the customer in such a scenario, and that this response is mediated by rights (vs. duty)-based moral beliefs. A liberal consumer, due to his or her rights-based moral beliefs, will likely view the denial of a customer's rights as a fundamental moral violation. Conversely, a conservative consumer who holds duty-based moral beliefs is likely to view the customer's refusal to comply with norms and authority as a fundamental moral violation. Thus, political ideology indirectly influences consumer responses to publicized brand events, even when there is no explicit political partisanship associated with the event.

We use a multi-method approach to test our theory. For study 1, we gathered a large dataset of tweets ( $n = 219,070$ ) from Twitter in a quasi-experimental field study using consumers' actual social media activity surrounding the United Airlines incident mentioned above as a behavioral outcome variable. We estimated users' political orientation using a ranking algorithm and conducted sentiment analysis of tweets utilizing two approaches (a machine learning-based Naïve Bayes classifier and a dictionary-based text analyzer). Analyses show that immediately after the negative-publicity incident, liberal (vs. conservative) Twitter users were more likely to express negative sentiments, especially anger and anxiety, against United Airlines. A control sample of tweets from immediately before the event showed a null effect of political ideology on negative sentiment.

In study 2, we surveyed a national panel of U.S. adults following the United Airlines incident. Participants' self-identified political ideology (liberal vs. conservative) predicted higher rights- vs. duty-based moral beliefs, respectively, which jointly mediated their attitudes toward both United and the affected customer. Using binary party identification as IV, analysis show that participants identifying as Democrats expressed more negative attitudes toward the airline brand ( $M_{\text{dem}} = 1.61$ ,  $SD_{\text{dem}} = .99$ ) than did Republicans ( $M_{\text{rep}} = 2.06$ ,  $SD_{\text{rep}} = 1.49$ ;  $t = 2.27$ ,  $p = .009$ ). Additionally, Democrats expressed more positive attitudes toward the affected customer ( $M_{\text{dem}} = 4.95$ ,  $SD_{\text{dem}} = 1.57$ ) than did Republicans ( $M_{\text{rep}} = 4.27$ ,  $SD_{\text{rep}} = 1.76$ ;  $t = -2.87$ ,  $p = .004$ ).

Finally, in study 3 we manipulated moral pluralism among participants in order to test our theory in an experimental setting. Manipulated Rights vs. Duty mindsets significantly predicted the variance in brand attitudes ( $F(2, 403) = 5.02$ ,  $p = .007$ ), with a significant main effect of priming condition ( $F(1, 403) = 4.31$ ,  $p = .038$ ) and a significant main effect of political ideology ( $F(1, 403) = 6.124$ ,  $p = .014$ ). As predicted, participants primed with a rights-based moral view of self expressed more negative attitudes toward the fictitious brand ( $M_{\text{rights-based}} = 3.50$ ,  $SD_{\text{rights-based}} = 2.23$ ) than did those primed with a duty-based moral view of self ( $M_{\text{duty-based}} = 3.97$ ,  $SD_{\text{duty-based}} = 2.54$ ). These findings demonstrate the causal relationship between rights (vs. duty)-based moral beliefs and consumer attitude toward brands in a negative publicity scenarios.

# The Influence of Conflicting and Complementary Benefit Goals on the Execution of Accuracy and Effort Process Goals

Felipe Marinelli Affonso, University of Florida, USA

Chris Janiszewski, University of Florida, USA

## EXTENDED ABSTRACT

Goals influence consumer choices not only by setting outcome priorities, but also by managing the approach to goal pursuit. We will refer to the first class of goals as benefit goals and to the second class of goals as decision process goals. There are two perspectives on the relationship between benefit goals and decision process goals.

The first perspective assumes that benefit goals determine the nature of the decision process goals. When benefit goals represent important outcomes, conflicting objectives, or high-effort pursuits, people are more likely to invoke a *maximize accuracy* process goal (Beach and Mitchell 1978; Johnson 1984; Luce 1998). When benefit goals represent trivial outcomes, oft-pursued objectives, or low-effort pursuits, people are more likely to invoke a *minimize effort* process goal (Harris and Blair 2006; Hoyer 1984; Hoyer and Brown 1990; Moore and Lehmann 1980). The second perspective assumes that characteristics of the decision context itself can activate decision process goals, independent of the nature of the benefit goals. Decision contexts that have an extensive information load, high level of complexity, or significant degree of accountability are more likely to invoke a maximize accuracy goal (Bettman, Luce, and Payne 1998; Griffin and Broniarczyk 2010; Lee et al. 1999; Payne, Bettman, and Johnson 1993; Tetlock 1992; Wright 1975). Decision contexts that create time constraints, ease information assimilation, or create “lock-in” (e.g., stickiness) are more likely to invoke a minimize effort goal (Bettman and Kakkar 1977; Dhar and Nowlis 1999; Häubl and Trifts 2000; Lurie and Mason 2007; Moore and Lehmann 1980; Zauberger 2003).

This research proposes a third perspective on the relationship between benefit goals and decision process goals. We explore the possibility that the characteristics of benefit goals can moderate the execution of decision process goals. We find that conflicting benefit goals interfere with the pursuit of both a maximize decision accuracy goal and a minimize decision effort goal. This interference effect is a consequence of decision difficulty leading to ambiguity about how to execute the decision process goals. Furthermore, we show that complementary benefit goals facilitate the pursuit of both a maximize accuracy goal and a minimize effort goal. This facilitation effect is a consequence of decision ease leading to clarity about how to execute the decision process goals.

We find support for our proposed theoretical framework in six experiments using a sequential, stimulus-based choice paradigm in which people consider alternatives until they find an acceptable option (Wald 1947). In all experiments, the procedure involved choosing a vacation package (replicate 1) and a car (replicate 2). We directly manipulated the decision process goals because indirect manipulations (e.g., varying time pressure, varying involvement, varying product category) are less precise. The conflicting benefit goals (thrift and prestige) and complementary benefit goals (prestige and have fun) were chosen based on a pretest designed to find benefit goals relevant to the choice context.

Experiment 1 shows that conflicting benefit goals interfere with the decision process goal execution by activating (vs. not) conflicting goals (e.g., thrift and prestige) and assessing whether consumers consider more (or less) options before making a decision. When participants did not have active benefit goals, they were able to pursue both the maximize accuracy and minimize effort decision process

goals. When participants had two conflicting benefit goals active, there was an interference effect: participants with a maximize accuracy goal considered fewer options and participants with a minimize effort goal considered more options than their control condition counterparts.

Experiment 2 shows that complementary benefit goals facilitate the pursuit of both a maximize accuracy and a minimize effort decision process goal. When participants with a maximize accuracy goal had two complementary benefit goals, they considered significantly more options than participants who had no active benefit goals because it was easier to make additional comparisons. When participants with a minimize effort goal had two complementary benefit goals, they considered significantly less options than participants who had no active benefit goals because it was easier to be confident an adequate option had been found.

Experiments 3a and 3b provide evidence for the interference effect proposed underlying mechanisms. We found that the effect of conflicting goals on the number of options considered is serially mediated by decision difficulty → decision ambiguity both for a maximize accuracy (experiment 3a) and a minimize effort (experiment 3b) decision process goal. Further, we also investigated four alternative explanations for the effect: process accountability, outcome accountability, decision importance, and involvement with the choice task, as each of these processes have been shown to influence pursuit of a decision process goal (Bettman et al. 1998; McAllister, Mitchell, and Beach 1979; Tyszka 1998; Zhang and Mittal 2005). None of these explanations accounted for the interference effect.

Experiments 4a and 4b provide evidence for the facilitation effect proposed underlying mechanisms. We found that the effect of complementary goals on the number of options considered is serially mediated by decision ease → decision clarity both for a maximize accuracy (experiment 4a) and a minimize effort (experiment 4b) decision process goal. As in experiments 3a and 3b, none of the alternative explanations accounted for the facilitation effect.

Overall, our findings demonstrate that the relationships between benefit goals can influence a person’s ability to execute a decision process goal and extend the adaptive decision-making literature by identifying factors unrelated to choice characteristics influencing the execution of a decision process goal. The implication is that decision process goals can be conceptualized similarly to benefit goals, in that the goals get activated, goals are pursued using means, and sustained goal pursuit depends on the effectiveness of that pursuit. Consequently, the results will encourage research into how a variety of yet-to-be considered factors (e.g., commitment, progress, equifinality) encourage the pursuit of decision process goals.

# Communicate Healthiness Through Indirect Measures: The Effect of Food in Motion Figure on the Perceived Healthiness of Food

Moty Amar, Ono Academic College (OAC), Israel  
Yaniv Gvili, Ono Academic College (OAC), Israel  
Aner Tal, Ono Academic College (OAC), Israel

## INTRODUCTION

The use of health claims in food advertising over the past few decades is widespread and well documented (e.g., Chandon & Wansink, 2007). Advertisements tend to employ direct health claims or use cues that have clear associations with health (e.g., Batra & Ray, 1986; Chowdhury, Olsen, & Pracejus, 2008; Edell & Burke, 1987; Olney, Holbrook, & Batra, 1991; Reichert, LaTour, & Kim, 2007; e.g., Snyder & DeBono, 1985).

Numerous studies have examined the effectiveness of marketing communication that directly argues product healthiness (Kozup, Creyer, & Burton, 2003; Lähteenmäki, 2013; Nocella & Kennedy, 2012). The findings suggest that in general, health claims effectively increase perceived product health (e.g., Dean et al., 2007; Lyly, Roininen, Honkapää, Poutanen, & Lähteenmäki, 2007). Claims that foods can prevent illness also influence on perceived healthiness (Saba et al., 2010). In addition, mentioning healthy ingredients improves perceived healthiness (Hasler, 2008; Jesionkowska, Sijtsema, Konopacka, & Symoneaux, 2009; Aschemann-Witzel & Hamm, 2010; Lalor, Madden, McKenzie, & Wall, 2011).

In the current work we show that cues that do not directly tied to healthiness can also serve to communicate healthiness. Specifically, we show that presenting food in motion in advertisements can improve perceived healthiness. We believe that this occurs by means of *visual rhetoric*, which is defined as “an artful deviation in form that adheres to an identifiable template”. Visual rhetoric entails three key elements: an image deviating from reality, repeated encounters of consumers with the same template, and an identifiable pattern (McQuarrie & Mick, 1996). Consumers become used to the irregular presentation of the product through repeated exposure to the pattern. This normalization of an unusual pattern in turn serves to increase persuasion.

In the food domain, advertisements frequently display food in motion (Gvili et al., 2015; Gvili, Tal, Amar, & Wansink, 2017), even though when consumed in real life foods are motionless and cannot move. Individuals who are exposed to such ads perceive food in motion as deviating from reality, but do not interpret this deviation as an error due to their repeated encounters with food in motion in advertisements. Hence, food in motion advertisements entail all the key elements of *visual rhetoric*. Accordingly:

*Hypothesis 1*    *Advertisements presenting food in motion constitute a visual rhetorical device through their irregular imagery template*

As stated above, our underlying argument is that ads presenting food in motion may lead to better perceived healthiness compared to those displaying static food. But, why should a visual rhetoric presentation of food in motion signal healthiness? We argue that food motion enhances perceived healthiness because both motion and healthiness are associated with freshness. More specifically, (Gvili et al., 2015) reported an association between motion and freshness by showing that food products were rated as fresher when presented in motion. They posited that this relationship is rooted in the relationship between motion and life (see also Goldman, Krider, & Ramaswami, 1999; Péneau, Brockhoff, Escher, & Nuessli, 2007).

Increased judgments of freshness should in turn increase judgments of healthiness. Extensive research confirms that freshness significantly increases judgments of health (see also a review article by Paquette, 2005). Evidence concerning the strong positive linkage between perceived freshness and perceived healthiness also derives from governmental agencies dealing with food health related issues (e.g., U.S. Department of Agriculture, 2011). Accordingly, exposing consumers to food in motion is likely to increase its perceived freshness, which should in turn lead to enhanced perceptions of healthiness. Formally:

*Hypothesis 2*    *Food products that are presented as moving in ads will be rated as healthier than food that is presented still.*

*Hypothesis 3*    *Evaluation of food product freshness will mediate the positive effects of motion on perceived healthiness.*

## EXPERIMENT 1

Due to the essential role of freshness in our argument we decided to first replicate the findings reported by Gvili et al. (2015), who found that exposure to food in motion appears to generate a sense of freshness.

### Method

Seventy undergraduate students (44% females, mean age of 26) were presented with a printed advertisement, ostensibly from a newspaper. The brand name and other identifying cues were removed from the advertisement.

Participants were randomly divided into two experimental conditions: motion and no motion. Both conditions were identical except that the ad in the motionless condition included an image of a still fish, whereas the ad in the motion condition presented the very same image of a fish but depicted as leaping out of the water.

After viewing the advertisement, participants were asked to evaluate the freshness of the fish shown in the advertisement on a scale of 1 (not fresh at all) to 9 (very fresh).

### Results

A one-way ANOVA revealed a significant main effect of motion on freshness. Specifically, participants rated the fish as fresher when it was presented in motion ( $M = 6.23$ ,  $SD = 1.88$ ) rather than motionless ( $M = 4.86$ ,  $SD = 2.22$ ;  $F(1, 68) = 7.77$ ,  $p < .01$ .) This result suggests that visual presentation of food in motion enhances consumer judgments of freshness.

The next experiments sought to explore the connection between this effect and perceived food healthiness, demonstrating that motion leads to enhanced judgments of healthiness through its enhancement of judgments of freshness.

## EXPERIMENT 2

Experiment 2 examined whether the visual rhetoric of food in motion would enhance judgments of health, and tested whether this effect would be mediated by the consumers' sense of freshness.

### Method

Sixty undergraduate students (55% female, mean age 26) were sampled from the same population pool as in Experiment 1 for course credit. Through computerized monitoring of participants across all our experiments, we ensured that they did not participate in more than one experiment.

The same method as in Experiment 1 was applied with two main changes. First, we measured perceived health on a scale of 1 (= not healthy at all) to 9 (= very healthy). Second, to further extend the generalizability of our findings to another food product, we used a different food: yogurt.

### Results and Discussion

As predicted, a one-way ANOVA revealed that participants rated the yogurt as healthier when presented in motion ( $M = 6.03$ ,  $SD = 1.97$ ) rather than motionless ( $M = 5.00$ ,  $SD = 1.86$ ;  $F(1, 58) = 4.36$ ,  $p < .05$ ). In addition, and consistent with the previous results, the yogurt was perceived as fresher when depicted in motion ( $M = 6.20$ ,  $SD = 1.42$ ) rather than still ( $M = 5.31$ ,  $SD = 1.02$ ),  $F(1, 58) = 7.75$ ,  $p < .01$ .

A mediation analysis indicated that perceived food freshness mediated the relationship between the motion condition and judged food health. The indirect effect of motion on judged food healthiness through judged freshness was positive and significant ( $a b = 1.04$ ,  $z = 2.68$ ,  $p < .01$ ). Presenting food in motion had a significant effect on perceived freshness ( $a = .89$ ,  $t = 2.78$ ,  $p < .01$ ). This, in turn, significantly increased anticipated healthiness ( $b = 1.18$ ,  $t = 8.79$ ,  $p < .001$ ). In addition, the direct effect of food in motion on perceived food healthiness was positive and significant ( $c = 1.03$ ,  $t = 2.09$ ,  $p < .05$ ). However, when the indirect effect was accounted for, this direct effect became non-significant ( $c' = -.01$ ,  $t = -.03$ ,  $p > .05$ ). A bootstrap analysis with 5,000 resamples revealed that the 95% confidence intervals for the significant indirect effect excluded zero (from .33 to 1.85). These results provide support for the argument that perceived freshness mediates the effects of motion on healthiness, supporting  $H_2$ . That is, food motion increases participants' perceptions of freshness. This increase in perceived freshness due to motion is what in turn increased perceived health.

The final experiment was intended to rule out a halo effect as a potential alternative explanation for these findings.

## EXPERIMENT 3

Halo effects can provide an alternative explanation for the relationship between motion and health. That is, motion may create an overall positive halo, which would in turn positively influence judgment of all product attributes, rather than affecting freshness and health specifically. However, our explanation as to the link between motion and healthiness argues for a specific link between motion and healthiness, such that not all attributes should be affected.

The objective of Experiment 3 was to rule out a halo effect as an alternative explanation for the effect of the visual rhetoric of food in motion on health. An additional objective was to obtain a more ecologically valid effect. Accordingly, we used a realistic newspaper advertisement as our stimulus for this experiment. We expected that the results would hold in a real life setting, enhancing the ecological validity of the findings (Bateson & Hui, 1992; McKechnie, 1977).

### Method

Fifty undergraduate students (42% female, mean age of 26) were sampled from the same population pool as in Experiment 1, and participated in this experiment in exchange for course credit.

Participants were randomly divided into two experimental conditions: motion and motionless. They were then presented with a newspaper that included an advertisement for fish. In the motion condition the visual ad depicted the fish in motion, leaping out of the water, whereas in the motionless condition the fish was depicted still. The actual image of the fish itself was identical in both conditions.

After viewing the advertisement, participants were asked to evaluate four properties of the fish in addition to its freshness and healthiness. Two measures of food attributes aside from health and freshness were added to rule out halo effects as a potential explanation. Specifically, participants evaluated the following food attributes: appearance (the fish does not look good at all / looks very good), and heaviness (not heavy at all / very heavy), all rated on 9-point Likert scales. They then rated how interesting the ad was (not interesting at all / very interesting) and how suitable the ad was for the newspaper (not suitable at all / very suitable).

Together, these four new measures were used to rule out halo effects. If halo effects are responsible for the effect of motion on food judgment, other favorable product properties should also be enhanced by motion. However, if the effect is unique to the inferences of freshness (and consequently health), motion should be unrelated to participants' judgment of other food properties.

### Results and Discussion

The results of Experiment 3 showed a similar effect of motion in food advertisements as found in Experiment 2. A one-way ANOVA indicated that participants rated the fish as more fresh when it was presented in motion ( $M = 6.76$ ,  $SD = 1.71$ ) rather than motionless ( $M = 3.52$ ,  $SD = 1.94$ ;  $F(1, 48) = 39.17$ ,  $p < .001$ ). In line with the results of the previous experiments, this result suggests that food movement enhances the perception of freshness, providing further support for the visual rhetoric effect of food in motion ( $H_1$ ). In addition, although participants in both conditions saw the same picture with the same fish, those in the motion condition rated the fish as healthier when they saw it in motion ( $M = 5.28$ ,  $SD = 1.84$ ) rather than motionless ( $M = 3.52$ ,  $SD = 1.61$ ;  $F(1, 48) = 12.97$ ,  $p < .001$ ), supporting  $H_2$ .

Next, we tested the mediation of these effects by freshness judgments. The mediation analysis showed that perceived freshness mediated the relationship between motion and anticipated food health. The indirect effect of motion on anticipated health through perceived freshness was positive and significant ( $a b = 1.17$ ,  $z = 2.63$ ,  $p < .01$ ). Exposure to food in motion had a significant effect on perceived freshness ( $a = 3.24$ ,  $t = 6.26$ ,  $p < .01$ ). This, in turn, significantly increased expected health ( $b = .36$ ,  $t = 2.86$ ,  $p < .01$ ). Further, the direct effect of food in motion on health was positive and significant ( $c = 1.76$ ,  $t = 3.60$ ,  $p < .001$ ). However, when the indirect effect was accounted for, this direct effect became non-significant ( $c' = .59$ ,  $t = .96$ ,  $p > .05$ ). A bootstrap analysis with 5,000 resamples revealed that the 95% confidence intervals for the significant indirect effect excluded zero (from .36 to 2.27). As in Experiment 2, these results provide support for the claim that perceived freshness mediates the effects of motion on health, supporting  $H_2$ .

More importantly, the results help rule out halo effects by showing that the visual rhetoric effect of food in motion did not influence the judgment of any other favorable food attributes. Namely, the appearance of the fish was not perceived more favorably when it was presented in motion ( $M = 4.08$ ,  $SD = 2.18$ ) rather than motionless ( $M = 4.32$ ,  $SD = 2.29$ ;  $F(1, 48) = .144$ ,  $p > .05$ ). Likewise, the portion

of fish was not perceived as larger (heavier) when it was presented in motion ( $M = 510.00$ ,  $SD = 331.66$ ) rather than motionless ( $M = 544.00$ ,  $SD = 273.98$ ;  $F(1, 48) = .156$ ,  $p > .05$ ). Similarly, the ad was not perceived as more suitable for the newspaper when the fish were presented in motion ( $M = 4.00$ ,  $SD = 1.87$ ) rather than motionless ( $M = 3.72$ ,  $SD = 2.57$ ;  $F(1, 48) = .19$ ,  $p > .05$ ). Finally, the ads were not evaluated as more interesting in the motion condition ( $M = 4.80$ ,  $SD = 1.63$ ) than in the motionless condition ( $M = 4.84$ ,  $SD = 1.60$ ),  $F(1, 48) = .01$ ,  $p > .05$ ).

If a halo effect was indeed responsible for the effect of the food in motion visual rhetoric on food product evaluation, motion should also have affected the consumer judgment of other favorable attributes, which did not occur. Consequently, food motion uniquely influenced judgments of freshness, which in turn raised the ratings of perceived health.

### GENERAL DISCUSSION

The display of moving food in advertising can and is exploited by advertisers as a form of visual rhetoric to promote positive product evaluation. The widespread use of the visual rhetoric of food in motion is supported by the significant effects of this technique on consumer judgments of these foods. Motion specifically appears to increase anticipated food healthiness, which may impact overall product evaluations and, consequently, choice.

Motion influences judgments of healthiness through its association with freshness, despite its ostensible irrelevance for judgments of product health. Such implicit messages may prove effective in enhancing product evaluations. Further, implicit cues of healthiness such as motion may avoid the negative relationship between healthiness and tastiness. This would allow advertisers to communicate both enhanced healthiness and taste together, despite the persistent and well-documented negative association between healthiness and tastiness.

# Self-Producer's Journey: Identity Construction and Transformation in Self-Production

S. Sinem Atakan, Ozyegin University, Turkey

Mina Seraj Aksit, Ozyegin University, Turkey

## EXTENDED ABSTRACT

Identity is dynamic and shaped by the experiences within the environment in a reflexive interaction (Cherrier and Murray, 2007). Production of a good or service for one's own consumption, that is self-production (Troye and Suphellen, 2012), creates a reflexive milieu. Even a seemingly mundane self-production experience, such as cooking for yourself, may have extensive consequences on self-producing consumer's sense of who s/he is.

The current research examines the act of food preparation and the journey of self that transpires through the self-production act and the social dynamics that shape individual self-producers. We expand the theorization of identity formation and transformation around self-production activities that have been studied within do-it-yourself (Wolf and McQuitty, 2011), craft consumption (Campbell, 2005), productive consumption (Press and Arnould, 2011), and prosumption (Toffler, 1980) literatures.

In order to explore the topic, we conducted a multi-sited netnography (Kozinets, 2010) on six forums consisting of 4000 consumer posts. The sites were chosen due to their high circulation rate and diversity of posts. We coded and analyzed the data set with our research goals in mind; first independently, then together by comparing and contrasting emerging themes. Data analysis followed an iterative process and was in constant dialogue with the literature.

Analyses reveal bi-directional relationships among self-production, identity, and community. Here, we discuss two main themes: the loop between identity and self-production, and the community around the self-production act.

### *Identity-Self-Production Loop*

Self-producers' motivations, emerging from their identities, define the meaning of the self-production act. Furthermore, identities shape the production process including production methods (e.g., baking, grilling) and styles (planning, execution). Production styles, for instance being a planner or an improviser, affect how people cook. A planner likes organizing and values precision. Instead, an improviser is a "free-spirit" who decides on the spot, works with whatever ingredients are available in the pantry, and favors rules of thumb over scales and measurement cups.

Identity shapes the production activity and outputs that, in turn, shape several identity layers. Engagement in the production process (experimenting, learning, using the tools) triggers a self-awareness and reflection process:

*Rita: Food is a direct channel to someone's mind and culture. and through cooking different foods, I can learn more about myself, test my limits and broaden my horizon.*

Furthermore, in time, the self-production act nourishes the self-producer's confidence and pride through a sense of mastery and control over the process and outputs:

*Erica: What I like best about cooking is the sense of getting my stuff together....Imposing order and control over life and its circumstances may be beyond my ability. But planning, preparing and executing a dish or even a meal is possible. Mind you, it is a challenge, but none the less, sometimes I pull it off. And that is very, very rewarding.*

The sense of control and confidence felt through the production process is an internal appraisal by and for the self-producing consumer. The production experience enables the journey of transformation from actual to desired (e.g., confident, highly-esteemed

cook) identity. Through repeated exposure to continuous self- or other-evaluated success (or failure) episodes during or as a result of the self-production process, individuals repeatedly access various identities (e.g., successful person). These identities may become part of the stable self, eventually independent of the context (cooking).

Outputs and community dynamics also enable the self-reflexive processes. Self is assessed, evaluated, and re-directed through social comparisons. The individual finds a place within one's own social relationships as well as the larger community by exchanging recipes and presenting outputs. On these occasions, contrasting the self with others has identity consequences since the assessments may lead to more or less favorable self-evaluations.

Furthermore, food preparation helps individuals demarcate their identities from the crowd while forming social bonds. Through experimentation, self-producers create a unique identity, and by sharing their experiences, they become part of the larger community. Via dissemination of self-producers' unique practices and acknowledgments of success, identities of self-producers are validated within the community. Once individual experimentation outputs are validated, one's personal practice becomes part of the community's journey. The individual shapes the norms and the community too.

### *Self-Production Community Defined*

Given our findings and the lack of emphasis in the literature, we propose a distinctive definition of self-production community and highlight its unique properties of practice and learning orientations. We define 'self-production community' as a social community structure that consists of members who engage in the design and/or the physical production processes of outputs for personal consumption. Unlike craft communities (Campbell, 2005), self-production communities do not require output personalization or high standards for the production process. Craftsmanship emerges as a specific subset of self-production activities (e.g., gourmet cooking).

Within brand communities, identities are formed in the image of the brand. The brand acts as an anchor that defines the meanings and the associated identities within the community. Even in the cases of anti-brand or anti-consumption groups (Thompson and Arsel, 2004), brand identity shapes the ethos of these groups. As opposed to the pre-defined meanings of a brand, self-production acts may mean different things (e.g., self-esteem, socialization) to different self-producers. Self-producers choose the meaning of their own act. Without the borders of a brand, self-production offers flexibility in defining and expressing the self-identities around it, and the self-production community assists (not regulates or structures) the creation of the self by the self. The acceptance of prescribed meaning structures versus creating your own meaning structures is in line with Cherrier and Murray's (2007) discussion of 'having' versus 'being' lifestyles.

Self-production holds the potential for symbolic representation and meaningful enactment of actual or desired identities. Hence, it is a venue of identity transformation. It provides a symbolic sphere in which self-producers can gradually rehearse and finally release themselves into new identities by using the reflections from the process, output(s), and/or community. The findings, in line with Oyserman et al. (2012)'s conceptualization of the identity and self, insinuate that the content of the self is dynamic. The reciprocal relationships that are pinpointed in our study support processual theorization of identity (Cherrier and Murray, 2007) and underscore a self-reflexive process.

# Divorcing the Market

Deniz Atik, University of Texas Rio Grande Valley, USA  
A. Fuat Firat, University of Texas Rio Grande Valley, USA  
Ebru Uzunoğlu, Izmir University of Economics, Turkey

## EXTENDED ABSTRACT

Missing from the recent interest in consumer research literature in consumers organizing and creating new markets (e.g. Bardhi and Eckhardt 2012; Dolbec and Fischer 2015; Firat 1991; Karababa and Ger 2011; Martin and Schouten 2014) is the phenomenon where people detach themselves from market society and the 'high life' they have achieved well before retirement age to construct alternative modes of living. The purpose of this paper is to close this gap.

We study this phenomenon in Turkey because as a relatively recent and fast growing market society Turkey presents a fresh insight into a phenomenon that occurred earlier in market societies such as the United States. The back-to-land movements of the 1950s and 1960s in the United States (Jacob 1997), for example, present similar motivations, but, as we find in this study, the resulting actions and purposes have changed significantly.

We had long interviews with ten informants who, after having successful, high income lives in large cities, chose to abandon market society and began to experiment with new modes of life. They were selected through purposeful snowball sampling. An extensive search of news items about such people and their experiences was executed and information was collected from print and video sources, as well as from the Internet blogs and other records. Moreover, we benefited from 8 short interviews conducted by a group of cinema and digital media students for a video documentary project, supervised by Özgün (2014), who investigated the dynamics behind the life change of a group of friends who decided to form a community close to nature, trying to construct a sustainable life. We followed the guidelines provided by Spiggle (1994) and Kvale (1996) for the analysis and interpretation of the qualitative data.

Our informants' discourses exhibit that they are moved by tensions between substance they seek in life and an emptiness they experience in market society as well as the tension between maintaining and sustaining this substantive life versus the destructive impulses they observe in market society, which they perceive as inviting death. This quest for substance and life leads to a recognition that sharing with and helping others, doing something genuinely good for society, and emphasizing substance in social interactions in general is required for the quest to be realized. This sentiment finds expression in moral and spiritual (albeit not religious) fulfillment rather than material gratification. Happiness is then linked to meaningful contribution to lives beyond one's own. This is significant because this concern guides much of how the people who abandon the market centered life (re-)organize their lives. For example, one of our participants moved from Turkey to Cambodia to help children and started a soup kitchen. Two of them started a little café in a small remote village also as a center for helping children with their education. Another outcome of the quest, also emphasized in extant work, is being close to nature, establishing a sustainable way of life. According to our participants, since the existing system gives way to exploitation and waste, there will soon be a lack of fresh air to breathe and fresh water to drink, not to mention proper food. Some have built small communes for sustainable lifestyles, producing their own food and energy. On the other hand, starting new lives is not without challenges. One needs to be determined to survive in nature, away from the comforts of the city. Our participants also recognize the allure of consumption that is difficult to resist once one becomes part of consumer culture. Con-

sequently, rather than completely abandon the market, they utilize it infrequently and only as a means of accessing dire necessities otherwise impossible to obtain. Other challenges relate to adapting to the new social environment.

The meaninglessness of modern life, especially when market driven, was foreseen and observed by several key scholars who have influenced contemporary thinking (e.g., Durkheim 1964/1893; Rousseau 1984/1762; Weber 1958/1905), and its effects as consumer culture also discussed by more recent others (e.g., Ewen 1988; McCracken 1988; Slater 1997). These observations indeed were realized for our informants. Thus, they chose to disassociate themselves from market society. The key difference, however, from early back-to-landers is that our informants today do not exhibit a desire to create a new mode of living to completely limit themselves to. Instead, they wish to experiment with their visions of modes of life that are not dominated by market society, yet willing to navigate among different orders, including occasional marketplace exchanges. This is what some have called a postmodern tendency (Firat and Dholakia 1998). This willingness to exist with and navigate multiple orders of life, even if preference for the one experimented with is strong, is a novel phenomenon. Earlier movements were built on intentions to replace one order with another to which people would have total loyalty. Also, our participants see resistance from within the culture largely ineffective, therefore opting to construct and create alternative modes of living. Our participants' foremost concern is to live a mode of life they envision without imposing it upon others; if others like it, they can join in.

Studying consumer culture and how consumers integrate into and even construct markets is, indeed, informative to understand the nature of the contemporary human condition and how it developed. Yet, just as ardently, we also need to study people's attempts to find alternative modes of life if we are to explore and find the potentials for change that many recognize to be imperative if humanity is to escape from the evidently critical and possibly devastating consequences of continuing on a path that an order guided solely by the market logic will produce.

## EXTENDED ABSTRACT

Trust is a central concept undergirding economic exchanges and can impede or promote the welfare of consumers and organizations. We investigate how trust arises in decision-making by examining a genetic factor (the catechol-O-methyltransferase gene; *COMT*) and an environmental variable (touch) to reveal a process explaining how and when people trust each other in economic exchanges.

### Trust

Trust is often studied via economic games (e.g. Berg, Dickhaut, and McCabe 1995; Bohnet and Zeckhauser 2004; Camerer 2003; Camerer and Weigelt 1988). We use the multi-move centipede game to examine determinants of behavioral trust. In this game, participants are provided with a monetary allotment divided into larger and smaller piles. Participants can take the larger pile or pass control to their partner. After each pass, both piles double. Standard assumptions of self-interest suggest that rational players should take immediately to maximize winnings. However, players frequently pass control, even late in a game (e.g. Colman et al. 2017; Levitt, List, and Sadoff 2011; McKelvey and Palfrey 1992). Such behaviors imply that players who trust their opponents will pass reciprocally to increase collective winnings.

We propose that a basis for trust lies in the human wanting system (e.g. Anselme and Robinson 2016; Berridge and Robinson 2003), and that polymorphisms of the *COMT* gene drive trusting behavior. We investigate two questions: *How* and *when* (i.e., under what conditions) does *COMT* influence trusting behaviors? To answer “how,” we hypothesize that empathy and psychological trust serially mediate the effects of *COMT* on passing versus taking. To answer “when,” we hypothesize that incidental touch moderates the effects of *COMT*.

### COMT and the Genetic Basis of Trust

The wanting system underlies reward pursuit and particular genes regulate motivation therein (e.g. Berridge and Kringelbach 2015; Pool et al. 2016). In the wanting neural network, unconditioned and conditioned stimuli are paired to form learned internal expectations and unconscious motivation for rewards (e.g. Schultz 2015). Both winning and monetary outcomes in the centipede game can be considered as salient rewards in this context.

*COMT* is especially crucial in the wanting system (e.g., Camara et al. 2010; Marco-Pallarés et al. 2010). For example, people with the met/met *COMT* polymorphism show greater reward responsiveness than met/val and val/val carriers (Lancaster, Linden and Heery 2012). The former experience rewards as more pleasant (evoking a greater wanting response; Wichers et al. 2008; see also Lancaster et al. 2015).

Further, *COMT* is particularly relevant to choice contexts (Lancaster et al. 2012), executive processing and short-term memory (Goldberg et al. 2003), and positive emotionality and reward-seeking (Wacker et al. 2012). In such cases, the met/met allele increases dopaminergic activity at synapses related to information processing,

decision-making, and fear reduction (Lachman et al. 1996), all central processes in economic exchanges.

### Regulating the Effects of COMT in a Trusting Way

Extant research shows that touch leads to emotions (e.g., Hertenstein et al. 2006, 2009), and emotions in the form of feelings of security drive the effects of touch on money invested in an allocation game (Levav and Argo 2010). Further, touch as an extended massage facilitates social bonding (Morhenn, Beavin and Zak 2012) and monetary sacrifice (Morhenn et al. 2008) via oxytocin. We argue that the activation of empathy is another outcome of incidental touch occurring in everyday situations.

### Empathy, Perspective-Taking, and Trust

Empathy is often construed as an affective trait/state where a person feels empathetic concern for others (Batson 2011). Similarly, perspective-taking - one's ability to understand others' points of view and feelings - is sometimes considered a cognitive component of empathy (e.g., Davis 1996). Empathy prompts prosocial behavior to gain rational benefits (e.g., reciprocity, morality, optimizing resources, etc.; Eisenberg, Eggum and Di Giunta 2010) or for purely altruistic reasons (e.g., Batson and Shaw 1991).

In summary, we posit that incidental touch will open participants to social facilitation and interact with *COMT*. For *COMT* met/met carriers, touch should lead to greater stimulation of natural inclinations to both feel empathetic concern and engage in perspective-taking. In turn, these affective and cognitive empathy responses should guide state trust and trusting choice behavior.

### Method

Participants played ten centipede games using directions and stimuli adapted from McKelvey and Palfrey (1992) and were assigned to a touch or no-touch condition. In the touch condition, a female experimenter verbally told each participant whether they would make the first/second move in the centipede games and surreptitiously applied a 1-second open-palm touch to the back of the shoulder blade. In the no-touch condition, this instruction was delivered without a touch. Participants then played the centipede games. Subsequently, we measured affective/cognitive empathy, psychological trust, and socio-demographic variables. Finally, participants donated a saliva sample and were paid their earned game proceeds.

We coded *COMT* (rs 4680) as met/met = 1 and (met/val and val/val) = -1. For behavioral (revealed) trust, we examined the proportion of times participants passed out of their total opportunities and applied a logit transformation.

### Results

We used Hayes' (2013, 2015) PROCESS macro to test two conditional serial mediation models with *COMT* as the independent variable, empathetic concern/perspective-taking as the first mediators, state trust as the second mediator, and revealed trust (propensity of passing) as the dependent variable. Touch moderated the relationship

between *COMT* and both types of empathy. Gender, time spent in the USA, race, game format, and game order (first/second choice) were controls.

Empathetic concern and perspective-taking yielded similar results when entered as the first-stage mediator, as predicted. *COMT* and touch interacted to influence both types of empathy. For the touch condition, met/met carriers had greater empathetic concern and perspective-taking than met/val and val/val carriers. Empathy, in turn, positively influenced psychological trust. Finally, psychological trust positively influenced revealed trust. The index of moderated mediation was significant in both cases, indicating the presence of the hypothesized path.

Thus, both sources of empathy and psychological trust mediate the effects of *COMT* on passing, and incidental touch moderates the effects of *COMT*.

## Conclusion

Our findings contribute to a better understanding of the psychological and biological mechanisms underlying trust and conditions when trust is likely to arise.

# Dancing with Commercialism: Emphasizing Dramatism to Persuade

Yuxin Bai, Lancaster University, UK  
Xin Zhao, Lancaster University, UK  
Hayley Cocker, Lancaster University, UK

## EXTENDED ABSTRACT

Prior research has noted that people dislike commercial content and try to avoid online advertising (e.g., Cho 2004). Trust is difficult to establish between brands and audience on social media. Tensions arise when commercial activity is discerned in blogs (Kozinets et al. 2010; McQuarrie, Miller and Phillips 2013; Dolbec and Fisher 2015). Understanding how to create engaging commercial content online is an important issue for many global firms (Holt 2016; Kozinets et al. 2010, Kozinets, Patterson, and Ashman 2017). Through the theoretical lens of performance theory, we examine how bloggers ease the tension between commercial content and audience distrust.

Performance theory has its origins in sociology (e.g., Goffman 1959), anthropology (e.g., Turner 1986), and theater studies (e.g., Schechner 1988). It has also been utilized to study a variety of consumption phenomenon (Grove and Fisk, 1992; Grove and John, 2000). Service encounters have long been conceptualized as a performance co-produced by both consumers and providers (e.g., Sherry and McGrath, 1989; McAlexander and Schouten, 1998; Kozinets et al., 2002; Tucker, 2007; Tumbat and Belk 2013) and market evolution has long been conceptualized as a drama (Giesler 2008). This stream of research adopts the dramaturgical perspective (Goffman 1959, 1961, 1967; Turner 1986) and focuses on the role of consumers in the co-construction of performance. In these studies, performance is conceptualized as “a witnessed event, whose audience perceives it to happen in relation to an obligation and who holds it to a standard” (Deighton 1992, p.363). Social media is a space to observe consumer performances (Papacharissi 2012) and self-presentation (Arsel and Zhao 2010; Schau and Gill 2003). We examine how successful bloggers engage in dramaturgical performance to ease communal-commercial tensions and at the same time maintain their popularity.

Extant research has examined consumer responses to the commercialization of online blogs as well as the strategies used by bloggers to alleviate the tensions that have emerged as a result of such commercialization. Kozinets et al. (2010) suggested that the commercial content on blogs ought to be relevant to the blog’s subject and not violate communal norms. McQuarrie, Miller and Phillips (2013) found that consumers tend to accept the commercialization of fashion blogs, interpreting this as evidence of the bloggers’ taste leadership. Dolbec and Fisher (2015) highlighted the tension between the logic of art and the logic of commerce in fashion blogs. However, the bloggers in these studies are all focused on a particular field (e.g., fashion). In this paper, we emphasize dramatism as a key strategy in a variety of commercial blogs to reduce the communal commercial tension.

The essence of dramatism is to produce transformation (Schechner 1988). Theatrical transformation takes place at three levels: in drama, in the performers, and in the audience. Schechner (1988) differentiates two types of spectators, accidental audience and integral audience. Deighton (1992) extended these ideas and differentiated between consumers attending a performance or consumers participating in a performance. By bridging Schechner’s (1988) focus on audience and Deighton’s (1988) emphasis on performance, we seek to extend our understandings of the tensions between commercial content and communal ideals in social media and examine the transformation of the audience from accidental to integral through dramaturgical performance on blogs.

We adopted netnography (Kozinets 2002; Kozinets 2015; Kozinets 2010) and in-depth interviews (McCracken 1988) in data collection. The first author followed more than 50 most active WeChat bloggers from December 2015 to March 2018. An aggregate online news feed site (<http://www.newrank.cn/>) was used to identify blogs for this analysis. This news feed has more than 10 million WeChat blogs and publishes daily reports. We analyzed 10 popular WeChat blogs. The selection of WeChat blogs was based on the blog entry’s reading rate and ranking. We chose WeChat bloggers that represented a variety of different writing styles, but they all heavily relied on commercially oriented cooperation in blogs (e.g. with WOMM messages integrated in entries). 28 in-depth interviews were conducted with 16 popular bloggers and 12 marketers in China. Our data analysis was based on several iterative movements (Spiggle 1994; Kozinets 2015).

Based on our data analysis, we found three transformation processes in blogging performance. Similar to Schechner’s (1988) notion of theatrical transformation in drama, in the performers, and in the audience, we found that transformation occurs in relation to the blogger and the audience as a result of the blogging performance. Successful bloggers facilitate the transformation of commercial content to consumer desire through dramaturgical performance (skill, show, thrill, festival, and hybrid performance) and through these performances they are able to transform an accidental audience into an integral audience. We found that WeChat bloggers can use dramaturgical performance to produce a multitude of different engaging brand-related content for the audience. Blogging performance can produce transformation at different levels, such as transforming content into consumer desire, brand indifference into brand interest, and accidental audience into integral audience.

## EXTENDED ABSTRACT

A handful of recent studies show that nostalgia – a bittersweet mindset of returning to one’s earlier days, characterized by associations of warmth, familiarity, trust, safety, belonging and a sense of protection (Hepper et al. 2012; Holak and Havlena 1998; Stern 1992) – is a valuable inner resource that can be accessed in times of distress and discomfort (Sedikides et al. 2015; Sedikides and Wildschut 2017) and can provide a coping value for consumers experiencing aversive states. For example, during cold days or in cold rooms, people use nostalgia to literally feel warmer (Zhou et al. 2012) or experiencing nostalgia acts as a response to self-threat (Sedikides et al. 2015). One such aversive and discomforting state that people confront every day is experiencing disease threat.

Given the particular qualities of nostalgia as capturing safety, comfort, and self-protection, it makes sense to propose that nostalgia may be particularly suitable as a psychological resource under conditions where these specific qualities are likely to be under threat, i.e., when one is confronted with the threat of illness and disease. We suggest a novel approach that when facing a disease threat, consumers will experience higher levels of nostalgia and demonstrate increased preferences for nostalgic products. More importantly, this paper is the first to propose that not only disease threat triggers the need for nostalgia and increases consumer nostalgic preferences, but in turn nostalgia may be harnessed to buffer and mitigate the threat and itself act as a coping mechanism, successfully psychologically substituting other coping behaviors (i.e., washing one’s hands). We show that experiencing nostalgia through product choice or advertising cues may be a positive psychological coping mechanism to maintain comfort and handle the threat of disease. Hence, our research suggests that triggering nostalgia in the marketplace might have notable and unexpected downstream consequences for consumer welfare and well-being. In contrast to the previous research showing that general feelings of disease threat increase the likelihood of reactive behavior and avoidance (Schaller 2014), we suggest that this aversive state may actually trigger a proactive response, i.e., the choice of nostalgic products.

In addition, we suggest that these nostalgic preferences form while experiencing the emotion of disgust which is a typical response when facing a threat of disease and which allows us to detect and avoid the potential threat. When experiencing such an aversive and unpleasant state as disgust, people will aim for comforting and soothing cues and thus show an increased receptivity towards nostalgic stimuli. However, people respond differently towards disgust and their response depends on individual sensitivity levels. We approach this in our research by employing experienced disgust as a mediator and one’s sensitivity to disgust as a moderator of the proposed relationship.

Four experiments tested our hypotheses. First, we predicted that disease threat would trigger higher levels of experienced nostalgia (experiment 1, N=302). This study used a single factor between-subjects design and experienced nostalgia as the main dependent variable. When disease threat was made salient (vs. absent), participants engaged in a word stem completion task and we measured how many nostalgia-related words they wrote in each condition. Next, we proposed that disease threat, but not actual disease experience, would elicit consumer nostalgic preferences (experiment 2, N=296),

and this effect would be mediated by the emotion of disgust (experiment 3, N=77). The second experiment used a single factor between-subjects design and willingness to buy nostalgic products as the main dependent variable. Experiment 3 used the same manipulation procedure and additionally tested whether experienced disgust mediates the impact of disease threat on consumer nostalgic preferences. Finally, the last experiment tested our notion that experienced nostalgia would have the capacity to compensate the protective behavior and act as a psychological coping mechanism (experiment 4, N=238). This study used a 2 (disease threat vs. control) x 2 (nostalgic vs. non-nostalgic advertisement) between-subjects factorial design with individual difference in disgust sensitivity as a measured independent variable and hand cleaning as the main dependent variable.

Across four experiments, we found consistent support for our hypotheses that consumers may seek nostalgic products to buffer and mitigate the threat of disease. Experiment 1 showed the initial evidence that disease threat leads to higher levels of experienced nostalgia. The results of experiment 2 extended this finding and demonstrated that disease threat, and not actual disease experience, motivates consumers to choose nostalgic products. In experiment 3, we replicated the results of experiment 2 and provided further evidence for the underlying processes by revealing the mediating role of disgust. Finally, experiment 4 demonstrated that nostalgia functions as a psychological resource with buffering qualities and is used as a coping mechanism to maintain comfort when experiencing disease threat.

Our point of theoretical departure was that nostalgia is a valuable psychological resource that can be accessed in times of distress and discomfort (Sedikides et al. 2015; Sedikides and Wildschut 2017). The present research contributes to this literature in several ways. First, it documents a novel factor influencing nostalgic consumer choices – disease threat. Next, the present research uncovers unexpected downstream consequences of nostalgia in the consumer domain by revealing its buffering qualities when the disease threat is salient. The current findings are in line with the research by Zhou et al. (2012) which showed that nostalgia can assist in regulating not only psychological self-threats, but more physical threats as well. In addition, although much of the prior research (Argo, Dahl, and Morales 2006; Huang et al. 2017; Mortensen et al. 2010) has shown that disease threat leads to avoidant behavior and withdrawal, we demonstrate that it may not always be the case and in certain situations it might result in increased preferences for products.

## EXTENDED ABSTRACT

### Purpose of this paper

For most humans, the local environment can have a major influence on their attitudes and behaviors. Whether it is the ambient smells (Mitchell, Kahn, & Knasko, 1995), sounds (Spangenberg, Grohmann, & Sprott, 2005), color (Bellizzi & Hite, 1992) or warmth (Huang, Zhang, Hui, & Wyer, 2014), the immediate surrounds play a part in how we feel and the decisions we make.

It is no surprise, then, that weather also has the ability to shape what we think, feel and do. For example, research has shown weather can influence stock returns (Goetzmann & Zhu, 2005; Jacobsen & Marquering, 2008), retail sales (Starr-McCluer, 2000; Steele, 1951), food consumption (Bruno, Melnyk, & Völckner, 2017; Lucht & Kasper, 1999), helping behaviors (Cunningham, 1979; Rind, 1996) and willingness to pay (Murray, Di Muro, Finn, & Leszczyc, 2010). Importantly, most of the existing research has typically examined the effects of actual weather (Bruno et al., 2017; Goetzmann & Zhu, 2005) and ambient temperature (Bruno et al., 2017; Murray et al., 2010). Given that anchoring serves as a heuristic in a cognitive process (Tversky & Kahneman, 1974), it is proposed that psychological traits, such as impulsivity, can influence anchoring effects. This is because impulsivity is associated with how an individual seems to react without an objective reasoning (Dickman, 1990). That is, consumers with high levels of impulsivity are more likely to use such heuristics in making decisions (Cheung, Kroese, Fennis, & De Ridder, 2017; Salmon, Fennis, de Ridder, Adriaanse, & De Vet, 2014).

The current research aims to extend the findings in this area by testing a novel prediction that weather and temperature cues can lead to anchoring effects, thus influencing consumer behavior in a subtle and indirect manner. Specifically, it is proposed that high (vs. low) temperature cues will increase higher levels of price valuations for a given product or service. However, this anchoring effect will be moderated by impulsivity. Further, positive affect will mediate the relationship.

### Design/methodology/approach

The research consisted of two studies. Study 1 was a one-factor, six-level (temperature: 31, 32, 39, 81, 83, 89) between-subject design. Guests at a hotel in the United States participated in exchange for a chance to win an additional free night of accommodation. Study 2 was a one-factor, two-level (temperature: 35, 85) between-subject design, conducted to replicate the results of Study 1, test the condition under which the predicted effect might be attenuated (H2) and examine the underlying causal mechanism in the process (H3). That is, increasing temperature influences positive affect and leads to higher perceived valuation. However, this indirect effect should only occur among those with high levels of impulsivity.

### Findings

Findings demonstrate participants viewing high temperature cues ( $M=110.96$ ,  $SD=8.96$ ) reported higher levels of price valuations than did those viewing low temperature cues. In addition, a significant interaction between temperature and impulsivity was

observed. Specifically, there were positive effects of temperature on price valuations at moderate and high levels of impulsivity. Similarly, moderated mediation analysis examined the indirect effect of temperature (high vs. low) on choice price, via positive affect, and moderated by impulsivity. Results revealed the indirect effect was significant at moderate (3.82) and high levels of impulsivity (5.82).

### Originality and contribution of this paper

The findings of this current research provide three important implications, theoretically and practically. First, this research contributes to the literature on weather and anchoring effects by testing a novel perspective that demonstrates how simple visual (temperature) cues, rather than ambient weather and temperature, can lead to anchoring effects. Second, the findings of this research identify theoretically grounded moderator (impulsivity) and mediator (positive affect) variables within the research context. This is significant because there is little understanding on how psychological traits and individual differences can influence anchoring effects (Furnham & Boo, 2011). Moreover, most studies which examine the underlying mechanism of anchoring effects have focused on cognitive factors, including anchoring-and-adjustment (Tversky & Kahneman, 1974), selective accessibility (Chapman & Johnson, 1999), and attitude change (Blankenship, Wegener, Petty, Detweiler-Bedell, & Macy, 2008)2008. Thus, the current study contributes to the literature on anchoring effects by identifying the impact of psychological traits (impulsivity) and examining the underlying process from an affective perspective (positive affect). Third, the findings of this research are beneficial to marketers by highlighting the importance of simple, environmental cues to increase positive consumer evaluations.

# What Converts Webpage Visits into Crowdfunding Contributions: Assessing the Role of Circumstantial Information

Lucia S. G. Barros, Universidade Federal de São Paulo, Brazil

César Zucco Jr, FGV/EBAPE, Brazil

Eduardo B. Andrade, FGV/EBAPE, Brazil

Marcelo Salhab Brogliato, FGV/EBAPE, Brazil

## EXTENDED ABSTRACT

The information displayed on a crowdfunding project webpage can be divided into two broad categories: *core* and *circumstantial*. Whereas the former reflects relatively stable information about the project, its purpose, and its characteristics, the latter refers to the information that is continuously updated because of the circumstances.

Given the ubiquity and visual salience of circumstantial information in crowdfunding platforms, it is fair to assume that companies and consumers believe it influences funders' decision-making processes. To assess this assumption, we conducted a survey of 113 Brazilians ( $M_{\text{age}} = 23.11$ ,  $SD=6.65$ , female = 53%). They were introduced to a hypothetical project purportedly hosted on an all-or-nothing crowdfunding platform. We then told them that the project had information about (a) the number of people who had already funded the project, (b) the amount raised so far relative to the funding target, and (c) the number of days left in the campaign. Participants were asked whether they believed one or more of these three pieces of information would influence their decision. Sixty-six percent said they might be influenced by this circumstantial information and 23.9% said they were sure that they would be influenced by it. They were also asked which of the three pieces of information they would most and least like to have access to before making their funding decision: 60% responded that the most valuable piece of information was the amount raised relative to the target, and about half (48.7%) answered that the least valuable information was the time left in the campaign.

This suggests that consumers believe circumstantial information could indeed influence their funding decisions, but their perception of the relative importance of each piece of information seems to vary. However, whether their beliefs and answers reflect reality is an open question. As we shall see, a careful reading of the literature reveals that it is still unclear whether and/or how this kind of circumstantial information influences the effectiveness of projects in converting webpage visits into actual contributions. We seek to fill this gap by analyzing a unique dataset of about 3.5 million web page visits and 79,600 contributions for 934 different projects displayed on the largest Brazilian crowdfunding platform. Precisely, this paper systematically assesses the extent to which information about the number of past contributions of a given project (NPC), the relative amount raised (RAR), and time left in the campaign (TLC) influence the funding rate (FR), which we define as the ratio of the number of contributions to the number of web page visits on a given day.

Crowdfunding studies usually rely on the number of contribution pledges as the main outcome measure (Kuppaswamy and Bayus, 2017; Lu et al., 2014; Thies et al., 2016). While it is useful in many situations, this metric may capture not only the influence of core and circumstantial information about the project on subsequent contributions, but also the effort of the project owner, which is unlikely to remain constant overtime. Given that our interest is in whether circumstantial information influences the effectiveness of projects in converting webpage visits into actual contributions, a more compelling outcome measure is needed: funding rate (FR). This measure represents the ratio of the number of contributions to the number of webpage visits on a given day. This departure from the previous literature is significant as it captures the behavior of people who have

a minimum interest in the project (i.e., have decided to visit its page), but who have probably not yet made their funding decision and may therefore use the salient circumstantial information on the page to help make their decision.

We obtained data from Catarse, the largest non-investment crowdfunding platform in Brazil. During the period for which we obtained data from the company, all the projects followed the all-or-nothing rule and ran on a pre-defined time frame. Approximately 80% of the projects available were related to arts (music, film, theater, etc.), which suggests that most funders were motivated to be part of an artistic project or to help the project owners achieve a personal goal. Although the project owners could decide on the duration of their project's funding campaign, 77% of them had a funding period of two months. We obtained data on all the projects between 2011 and 2013 and adopted the following inclusion criteria: (1) having a (termination) deadline prior to October 2013; (2) not having a "second chance" (a few projects, which we removed from our dataset, were allowed to receive funds after their stated deadline); and (3) having a duration of two months (60 to 62 days). The daily number of visits to each project was collected from Google Analytics in collaboration with Catarse. Our empirical analysis employs project fixed effects to analyze our panel data set of daily observations for all projects.

There are theoretical reasons to suggest that past contributions could influence a prospective funder's funding decisions. People rely on others' behavior to infer quality as well as social norms. Hypothesis 1 claims a positive association between NPC and funding rate. Despite the theoretical possibility that NPC may increase perceived quality or trigger social norms, H1 is not supported.

Adopting the rationale of perceived usefulness (Dawes et al., 1986; Kuppaswamy and Bayus's, 2017), it is reasonable to speculate that the greater the amount of funds raised relative to the funding target, the higher the funding rate will be. Hypothesis 2 posits that RAR will positively associate with the funding rate, but the strength of the association will be significantly reduced once the target fund is reached. It is supported.

It is reasonable to suspect that procrastination may also take place among potential funders in crowdfunding settings, such as committing to support a friend's social project next week rather than now. Thus, the funding rate should increase as the perceived opportunity to put off making a contribution (i.e., the time left in the campaign) declines. However, this should only be true up to a point. If the perceived usefulness of the contribution also plays a dominant role, as argued in H2, then the impact of TLC on the funding rate should become much weaker once the target has been reached. Hypothesis 3 suggests that TLC will negatively associate with the funding rate, but the strength of the association will be significantly reduced once the target fund is reached. It is supported.

In summary, the results show that RAR and TLC are powerful pieces of circumstantial information, but only until the funding target is reached. After that, their influence declines significantly. NPC has little influence on funding decisions, possibly due to the overwhelming impact of the other two pieces of information.

Consistent with Kuppuswamy and Bayus's (2017, 2018) studies using Kickstarter data, our results suggest that funding in Catarse has an asymmetric U-shape: projects attract more funders in their first days than in the middle of the funding period, and then the number of funders increases again towards the end. Interestingly (although yet to be documented), part of the phenomenon is likely a function of visibility (e.g., promotional efforts). Once controlled for the number of visits on every given day, the U-shape gives way to an upward trending line: the funding rate increases throughout the funding period. For this reason, our first contribution is to show that variations in visits over the life of a project account for a substantial part of the variations in contributions over time, suggesting that funding decisions start before the platform is assessed. Using the funding rate (i.e., the ratio of the number of contributions to the number of web page visits on a given day) as our outcome measure allowed us to disentangle the influence of a project's visibility from the decision a funder makes after accessing the project's page on the platform.

Our second contribution is to provide evidence for the positive effect that past funding has on the funding rate. We show that the amount already raised is a much better predictor than the number of past funders, suggesting that what matters is not the size of the crowd, but how close a project is to achieving success. We also show evidence for the effect of time on funding decisions. Simply put, when there is less time left to fund a project, the funding rate increases.

More interestingly, our third contribution is to show that the perceived usefulness of a contribution plays a dominant role. We found that when a project reaches its funding target, the impact of

both the amount already raised and time becomes much weaker. Disentangling these possibilities helps give a better understanding of the motivations behind funding in all-or-nothing non-investment crowdfunding projects. Prospective funders seem concerned about the usefulness of their funds: they are willing to help project owners, but mainly when "their help really matters" (i.e., before the target is reached).

# Product Ethicality Dilemma: Consumer Reactions to ‘Disgusting’ Recycled Products

Berna Basar and Sankar Sen, Baruch College, CUNY, USA

## EXTENDED ABSTRACT

As the increasing attention to environmental issues led companies to introduce sustainable brands and products to the market (Mazar and Zhong 2010), the gap between consumers’ explicit attitudes toward sustainable products and their consumption behavior has been a major concern (Luchs et al. 2010). Although extensive research has focused on potential reasons for the relatively low market share of sustainable products (Newman, Gorlin, and Dhar 2014), very limited research has examined the obstacles specific to recycled products (Linton and Hamzaoui 2013). As green products, recycled products are made in whole or in part from a wide range of materials recovered from the waste stream (EPA 2016). This study examines the effect of feelings of disgust associated with recycled products on product ethicality perceptions and product attitudes. Given that consumers usually buy recycled products mostly for social and ethical considerations, it is especially important to examine how factors unique to those products affect ethicality perceptions and product evaluations.

Moral judgments are founded upon approximately five moral domains, which involve discrete sets of interrelated values and rules of how people ought to behave and what warrants punishment or sanctions (Haidt and Graham 2007). The domain of purity involves principles directed at protecting the sanctity of the body and soul. These values are originally related to the evolutionary challenges of avoiding the consumption of toxins, parasites, or bacteria. From a purity standpoint, it is immoral to behave in a way that is self-polluting, filthy, or profane (Rozin et al. 1999). The morality literature has conceptualized disgust as a moral emotion defined by appraisals of purity and contamination (Haidt 2003). Research shows that physical disgust and moral disgust activate overlapping brain regions and are linked through cognitive and behavioral processes (Eskine, Kacirik and Prinz 2011). As a consequence, feelings of disgust have been shown to increase extremity in our moral judgments (Eskine et al. 2011).

According to the consumer behavior literature, many common consumer products such as cigarettes, diapers, and trash bags elicit disgust among consumers (Morales and Fitzsimons 2007). This suggests that feelings of disgust are not a rare occurrence in the marketplace, and consumers are likely to experience them on regular shopping trips. Today, many disgust-eliciting products such as cigarette butts, marine debris, and underwear are recycled to manufacture new sustainable products (Terracycle 2017). Hence, one can expect that feelings of disgust associated with some of those recycled materials cause consumers to perceive the end product as disgusting as well. Driving from the morality literature showing the effect physical disgust on negative moral judgments (Eskine et al. 2011), this study suggests that compared to ‘non-disgusting’ recycled products, ‘disgusting’ recycled products might result in lower product ethicality perceptions, which in turn might decrease product attitudes (H1).

Moral identity represents an individual’s broad associative cognitive network of related moral traits (e.g., being kind), feelings (e.g., concern for others), and behaviors (e.g., helping others) (Aquino and Reed 2002). Within this associative network, the strength of these moral associations reflects the degree to which a person’s moral identity is chronically important (e.g., whether a person cares about being a person who has these traits, feelings, and behaviors in general). Therefore, an individual who is characterized by high moral identity would likely have more thoughts, both in quantity and speed, regard-

ing moral traits such as fairness, generosity, and helping the society. For instance, moral identity was found to be a strong predictor of charitable giving, even when the donation recipient was a member of an out-group (Reed and Aquino 2003; Winterich et al. 2009).

Given that individuals with high internalized moral identity see morality at the very core of their being, one might expect them to be more concerned about ethical situations. For instance, compared to individuals with low moral identity, individuals with high moral identity are less likely act unethically (Gino et al. 2011) and more likely to engage in prosocial behaviors (Aquino and Reed 2002). However, prior research suggests that feelings of disgust and moral judgments are interrelated through cognitive processes (Eskine et al. 2011). Therefore, this study suggests that individuals high in moral identity internalization are more likely to have higher product ethicality perceptions for non-disgust eliciting products versus disgust-eliciting products. On the other hand, given individuals low in moral identity internalization are less concerned about ethical situations, they are not expected to experience significantly different levels of product ethicality perceptions between disgust-eliciting recycled products and non-disgust eliciting recycled products (H2). The interactive effect of recycled product type and individuals’ moral identity internalization on product ethicality perceptions is expected to be reflected in product attitudes (H3).

A pilot study was conducted to test whether feelings of disgust associated with end products depend on the type of recycled materials they are made from. For this study, we recruited 199 individuals from MTurk ( $M_{age} = 33.88$ ). Participants were asked to evaluate 24 hypothetical bags, each partly made from a different type of recycled product (e.g., recycled seatbelt, plastic bottle, etc.) and displayed in random order. Each participant rated all 24 bags on a scale from 1 (“not at all disgusting”) to 7 (“very disgusting”). Hierarchical cluster analysis uncovered 3 distinct clusters: (1) extremely disgusting, (2) moderately disgusting, (3) not-disgusting. Whereas mean disgust value of the bags in the extremely disgusting cluster (e.g., a bag made from recycled underwear) were significantly higher than the scale midpoint ( $M = 5.37, t(198) = 11.87, p < .001$ ), mean disgust value of the bags in the not-disgusting cluster were significantly lower than the scale midpoint ( $M = 2.16, t(198) = -24.80, p < .001$ ). Results of this study confirmed that consumers can perceive products as disgusting depending on the type of recycled product they are made from.

Study 1 had a three-factor (disgusting recycled product, non-disgusting recycled product, recycled material) between-subjects design. For this study, 233 individuals who were recruited from MTurk ( $M_{age} = 39.12$ ), were randomly distributed to one of three product-type conditions. In all conditions, participants were asked to imagine shopping on a website that sells bags. Then, participants saw a website visual describing a bag made of recycled materials. All participants saw the same bag visual and website, but the materials the bag was made from varied depending on their assigned condition. In order to avoid any prior attitudes consumers might have, we used the brand and website design of a Canadian bag brand Mariclaro which sells recycled products online.

In the disgusting recycled product condition, the bag was made from disgust-eliciting materials (e.g., recycled cigarette butts). In the non-disgusting recycled product condition, the bag was made from non-disgust eliciting materials (e.g., recycled seatbelts). Finally, in the recycled-material condition, the bag was made from particular

fibers (e.g., polyester). According to the pilot study, mean disgust rating of the recycled products in the disgust condition ( $M_{disgusting} = 4.36$ ) were significantly higher than the mean disgusting rating of the recycled products in the non-disgusting recycled product condition ( $M_{not-disgusting} = 2.32$ ,  $t(198) = 21.43$ ,  $p < .001$ ).

We measured participants' general attitude toward the bag using five seven-point scale. The items included "dislike/like", "unfavorable/favorable", "negative/positive", "undesirable/desirable", and "bad/good" ( $\alpha = .98$ ). In order to measure perceived product ethicality, participants rated their agreements with the statements "This bag is social responsible", "This bag is produced with high ethical standards", and "This bag is sustainable" on a scale ranging from 1 ("not at all") to 7 ("very much") ( $\alpha = .84$ ). As adapted from previous literature (Argo, Dahl, and Morales 2006), we asked participants to report to what extent wearing the bag would make them feel: "disgusted", "revolted", "unclean", and "gross" ( $\alpha = .97$ ). The order of the product ethicality and disgust measures was counterbalanced.

An analysis of variance (ANOVA) using product type as the independent variable and disgust index as the dependent variable produced a significant main effect ( $F(2,230) = 19.35$ ,  $p < .001$ ). Participants perceived wearing the bag more disgusting in the disgust-eliciting recycled product condition ( $M_{disgusting} = 2.60$ ) than in the non-disgust eliciting recycled product ( $M_{not-disgusting} = 1.35$ ,  $t(230) = 5.46$ ,  $p < .001$  or recycled material conditions ( $M_{material} = 1.42$ ,  $t(230) = 5.24$ ,  $p < .001$ ). A second ANOVA using attitude index as the dependent variable produced a significant main effect ( $F(2,230) = 8.39$ ,  $p < .001$ ). Participants had lower product attitudes in the disgust-eliciting recycled product condition ( $M_{disgusting} = 4.52$ ) than in the recycled product ( $M_{not-disgusting} = 5.42$ ,  $t(230) = -3.63$ ,  $p < .001$  or recycled material conditions ( $M_{material} = 5.35$ ,  $t(230) = -3.41$ ,  $p < .001$ ). Similarly, an ANOVA using product ethicality as the dependent variable produced a significant main effect ( $F(2,230) = 4.35$ ,  $p = .014$ ). Participants had lower product ethicality perceptions in the disgust-eliciting recycled product condition ( $M_{disgusting} = 5.40$ ) than in the recycled product ( $M_{not-disgusting} = 5.93$ ,  $t(230) = -2.84$ ,  $p < .01$  or recycled material conditions ( $M_{material} = 5.78$ ,  $t(230) = -1.49$ ,  $p = .04$ ).

We conducted mediation analysis (PROCESS model 4; Hayes 2017) with product type manipulation as the categorical independent variable; product ethicality perceptions as the mediator, and product attitude as the dependent variable. The bootstrap analysis confirmed an indirect effect both for disgusting recycled vs. non-disgusting recycled product comparisons ( $\beta = .33$ , 95% CI: [.11, .60]) and disgusting recycled product vs. recycled material condition comparisons ( $\beta = .23$ , 95% CI: [.01, .50]).

Study 2 was conducted to test our findings in Study 1 with undergraduate students, to examine the effect of moral identity internalization as a moderator, and to rule out alternative explanations. Participants in the study included 139 undergraduate students ( $M_{age} = 22.03$ ). We randomly assigned them to one of the two conditions: non-disgusting recycled product condition vs. disgusting recycled product condition. Study 2 was very similar to Study 1 with some exceptions. First, in order to rule out alternative explanations, participants rated the bag on various dimensions (stylish, lightweight, multifunctional, waterproof, creative, and innovative) using scales from 1 ("not at all") to 7 ("very much"). We also asked participants how easy or difficult it is to make the bag (1 = very difficult to make, 7 = very easy to make) and how common or uncommon the bag is (1 = very uncommon, 7 = very common). Additionally, to test whether perceived fit between the identity of the bag and recycled products differ across conditions, identity overlap scale was drawn from Bergami and Bagozzi's (2000) visual scale. In a series of differentially overlapping pair of circles, participants picked the circle pair which

best reflects the overlap between the bag and each recycled product the bag was made from. Finally, participants rated how representative they found the website visual using three items ( $\alpha = .86$ ).

In this study, after evaluating the bag on provided dimensions, participants completed Aquino and Reed's (2002) moral identity internalization scale (1 = strongly disagree, 7 = strongly agree). Consistent with prior research (Aquino and Reed 2002), the five items that measure this scale were averaged to create a moral identity index ( $\alpha = .86$ ).

An analysis of variance (ANOVA) using product type as the independent variable and disgust index as the dependent variable showed that participants perceived wearing the bag more disgusting in the disgusting condition than in the non-disgusting condition ( $M_{disgusting} = 3.21$ ,  $M_{not-disgusting} = 3.21$ ;  $F(1,137) = 18.08$ ,  $p < .001$ ). A second ANOVA using attitude index as the dependent variable showed that participants had significantly lower product attitudes in the disgusting condition than in the not-disgusting condition ( $M_{disgusting} = 3.60$ ,  $M_{not-disgusting} = 4.24$ ;  $F(1,137) = 4.90$ ,  $p = .029$ ). Similarly, an ANOVA using product ethicality as the dependent variable showed that participants had significantly lower product ethicality perceptions in the disgusting condition than in the not-disgusting condition ( $M_{disgusting} = 4.75$ ,  $M_{not-disgusting} = 5.52$ ;  $F(1,137) = 4.90$ ,  $p < .01$ ). Additionally, none of the product-related measures used to test alternative explanations differed across two product-type conditions.

We conducted a moderated mediation analysis using (10,000 resamples) PROCESS (Model 8, Hayes 2017). In the model estimated by this analysis, recycled product type (disgusting = 0, not-disgusting = 1) was the manipulated independent variable, perceived product ethicality was the mediator, attitude toward the product was the dependent variable, and moral identity internalization was the measured moderator variable. Mediated moderation was supported because the indirect effect of the two-way interaction on attitude toward the product through perceived product ethicality was significant (indirect effect = .36, SE = .18; 95% CI: [.0303, .7584]). For participants with high moral identity internalization, the conditional indirect effect of product type was significant ( $\beta = .69$ , 95% CI: [.31, 1.12]) whereas for participants with low moral identity internalization, the conditional indirect effect of product type was not significant ( $\beta = -.90$ , 95% CI: [-.31, .56]).

This study reveals that recycled products can be perceived as disgusting which in turn, might decrease product ethicality perceptions and overall product evaluations. Additionally, this research shows that although individuals high in moral identity internalization perceive 'non-disgusting' recycled products as more ethical than 'disgusting' recycled products, individuals low in moral identity internalization perceive 'non-disgusting' recycled product and 'disgusting' recycled products as equally ethical.

The purchase of recycled products is one way by which consumers satisfy their desire to protect the environment. Although recent research has focused on green products, little is known about the role of recycled-product features on consumers' product attitudes and ethicality judgments. The current study contributes to the recycled product literature by showing that perceived ethicality of recycled products and their overall evaluations might vary depending on the type of recycled materials used for the manufacturing of the final product. In terms of managerial implications, this study shows that marketers need to take into account the type of feelings associated with recycled materials used in the manufacturing of new products.

# Marketing's Ethical Blind Spot: The Problem with Catering to Customer Preferences

Suncal Bedi, University of Pennsylvania, USA

## EXTENDED ABSTRACT

Whether in the context of teaching marketing classes, finding the best attributes of a product, or producing viral, revenue enhancing advertising, marketers are guided by a longstanding mantra: *Consumers preferences are king*. In many ways, to be the best marketer is to create products and services that are directly aligned with consumer preferences.

This paper focuses on the potential ethical issues associated with catering to consumer preferences. The preoccupation with consumer preferences leads marketers to prioritize them, even if the preferences are perverse. This preoccupation can trigger a kind of cultural, group based harm. Marketers and business ethicists alike have historically understood consumer harm narrowly, focusing only on how business actions can harm individuals. I argue that marketers have ethical obligations to prevent cultural harms and may even have to contribute to cultural diversity in their endeavors.

The contributions of this work are following: first, I use critical political theory to identify a harm that has gone unnoticed in the marketing ethics literature. Although marketing ethics has been sensitive to some aspects of problematic imagery including stereotypes, that work has still understood the harm of stereotypes and lack of cultural diversity narrowly. Broadening this harm to group based harms creates new sets of unethical products and practices. Second, no work has attempted to provide rationales for why problematic images and products still exist in the marketplace. By rooting this problem in catering to consumer preferences, I provide an easy and clear intervention for marketers (e.g. be skeptical of consumer preferences in some cases). Lastly, previous work on cultural diversity in marketing ethics has not provided normative justifications of why it is that firms have an obligation to prevent the sorts of harms I identify, even though those harms do not accrue to their customers. They may even benefit their customers, yet I argue marketers should not pursue actions that create cultural harms.

Traditional accounts of marketing and business ethics have used the theories of John Rawls to argue that certain practices are unethical because they harm individuals. (Rawls 1971) This harm can take multiples forms including marketing physically harmful products (smoking, guns), breaches of implicit social contracts, and violations of autonomy. This paper seeks instead to use Iris Marion Young's criticism of John Rawls to expand the scope of harms to which businesses should be attuned to. Young argues that Rawls has too narrow of a view of justice. According to her, the focus on individual level harm leaves a theory of justice blind to those kinds of harms or injustices that require appeal to group based categories such as race or gender. Her account focuses on harms that reinforce cultural norms while stereotyping minorities, females, and other under-represented cultural groups—so called “cultural imperialism.” (Young 1990)

In the first paper to analyze Young from a marketing ethics perspective, I highlight the distinctive cultural harms posed by tailoring products, services and advertising to consumer preferences. When marketers tailor their activities to majoritarian preferences they risk using predominately majoritarian models and imagery which not only further normalizes white, male, straight faces but also renders invisible their counterparts. This kind of discrimination reinforces cultural hierarchy. If images of minority and female models are primarily cast in stereotypical roles, this only validates such roles, creating a culture and set of meanings that stigmatize minorities and how they are perceived as members of a subordinated group. It is

this group harm that makes lack of cultural diversity in marketing so problematic.

Turning our attention to this kind of group-based cultural harm has two ethical implications for marketers. First, marketers should not cater to customer preferences in ways that create these harms by reinforcing social hierarchies and stereotypes. Doing so is unethical. Second, marketers may even have a positive obligation to counteract and mitigate this kind of cultural harm. Hence, managers should encourage their companies to be more culturally inclusive in their marketing strategies.

The political theorist Iris Marion Young in *Justice and the Politics of Difference* (1990) has a broad account of the scope of harm and justice that social institutions should take into consideration. The notion of marketing to consumer preferences contributes to what Young calls the harm of “cultural imperialism.” For Young, to experience cultural imperialism “means to experience how the dominant meanings of a society render the particular perspective of one's own group invisible at the same time as they stereotype one's group and mark it out as the Other.” (Young 1990: 58-59). This is a kind of group-based harm and Young makes clear that “mass entertainment media” which includes “movies, television, magazines and their advertisements” is a major producer of these dominant meanings.

Cultural imperialism occurs when a dominant group's cultures becomes the social norm which gives the dominant culture a type of power that sends a message to those groups outside of the norm. The message is that the dominant group's perspectives express the appropriate “experience, values, goals and achievements” in society (Young 1990 p. 59). Those that are labeled as “others” (not part of the dominant cultural group) suffer what Young calls “paradoxical oppression” where certain races, genders, and non-mainstream cultural groups are both stereotyped as well as “rendered invisible.” (Young 1990 p. 59).

In the U.S., the dominant cultural group has taken on the identity of the straight white male. With cultural imperialism, those not part of this cultural dominant group experience unique group harms that label those who are not white, straight, and male as deviant, unimportant, and voiceless. “As a result, the ‘privileged experience’ of white consumers stands as the ‘normal one’ against which non-whites’ experience is evaluated. In such instances, non-white communities are clustered into monolithic categories, while the oft privileged positionalities of white consumers are naturalized and normalized.” (Johnson & Grier 2017; Grier et al 2017).

Even when marketers have understood harms associated with stereotypes, they have routinely focused on the individual harms associated with problematic imagery. For example, arguments have been made that stereotypes offend people who may view them. This however, is still too narrow of a conception of harm. What if only those consumers who enjoy the stereotypes, see them? According to prevailing theory, this is not problematic. When we expand the scope of harms to group harms, we recognize that even when individuals who are presented with problematic imagery find it compelling, it still can be wrong. Understanding this kind of harm assists in broadening the scope of products and images that cause cultural harms and are hence problematic. For example, skin lightening cream creates no individual harm, in fact it is quite in demand by those individuals who use it. Yet, these lightning creams create cultural harms by promoting the idea that lighter is better and hence are problematic.

Other accounts of marketing ethics, even those that advise against stereotypes, do not encompass such problematic products.

When consumer preferences are discriminatory, tailoring products or services to consumer preferences creates these group-based cultural harms. A concrete example of tailoring to male consumer preferences that creates cultural harms includes the arguably sexist hiring practices of Hooters. (Barkacks & Barkacks 2011; Rhee 1997). Hooters is a paradigmatic case of creating a service tailored to straight male preferences for sexualized women. They routinely hire and fire women who do not satisfy the “ideal” body type of so called “Hooters Girl.” (Bedi 2016) (<http://www.originalhooters.com/careers>). This imagery is clearly geared towards men’s sexual appetite. It appeals to those exact consumers preferences that marketers care so deeply about.

Tailoring a service and product like the “Hooters Girl” to men’s preferences creates a broader cultural harm. The marketing of Hooters furthers the already problematic heteronormative perception of women in society. (Colker 1986) Hooters promotes the cultural agenda that women should be sexual entertainment for men and the agenda of what the ideal body type of a women should be.

This amounts to a hijacking of cultural norms by Hooters. By creating a product that is tailored to men’s preferences, Hooters has promoted cultural imperialism of the type that Young argues is problematic. Again, even if those who patron the store are not offended or harmed by the product, there is a broader group based cultural harm that’s at play.

In addition to cultural gender harms, race harms are also prevalent in marketing. Marketers use predominately white, male, heteronormative imagery to more effectively sell their products. Whereas studies show that diversity in the workforce may improve a business’ bottom line (e.g. Richard 2000, 2007; Carter 2010) and positively affect group dynamics and task performance (e.g. Bantel and Jackson 1989; Murray 1989;), cultural diversity in advertising may be detrimental to profitability precisely because consumers don’t prefer it. Including minorities in advertising could lower the purchase likelihood of non-minorities. (Kerin 1979; Whittler and DiMeo 1991; Grier and Deshpande 2001; Johson & Grier 2015). This fear may motivate white imagery in marketing campaigns. (Puntoni, Vanhamme, and Visscher 2011).

Even when minorities are included in advertising, they are often stereotyped. By focusing on these types of problematic representations, marketers make advertising more effective for the cultural majority because there is easy of processing. For example, the use of the Asian model minority or the perceptual foreigner image is easily processed by white consumers because these are the exact representations of Asians in the arena of the cultural majority (Taylor et al 2005; Jussim 1990). This extension of the stereotype only reinforces this cultural hierarchy and can have psychological effects on those minorities who do not fit the stereotype (Graham 1983; Taylor and Lee 1994)

This paper ultimately gives marketing managers a play book by which they can create products and advertising that do not create cultural harms even if all consumers who interact with the products and advertising prefer them.

# Conjuring Creativity: The Impact of Fear

Ilgim Dara Benoit, Appalachian State University, USA

Elizabeth G. Miller, University of Massachusetts Amherst, USA

## EXTENDED ABSTRACT

Consumer perceptions of creativity frequently drive marketing success (e.g., new products, advertisements). However, while prior research has examined factors influencing creativity *generation* (Hennessey and Amabile 2010; Burroughs et al. 2008), external factors that affect creativity *perception* have not been explored. Yet, the two are independent processes (Groborz and Necka 2003), so their drivers cannot be assumed to be the same. Given the positive consequences of perceived creativity and its subjective nature, there is value in identifying factors which could enhance perceived creativity. In this research, we identify a factor, fear, which enhances creativity perceptions, leading to more positive attitudes toward the ad and behavioral intentions. These effects are unique to fear (vs. other main negative discrete emotions (sadness, disgust, anger; Izard 2007), neutral emotion, and happiness, despite sharing similar appraisals or arousal).

Creativity incorporates two dimensions: novelty/unexpectedness and meaningfulness (appropriate/relevant to the audience and context). Thus, appreciating creativity requires the viewer to engage with the ad to connect the ad's unexpected elements in a meaningful way. Because fear increases visual attention (Dunn and Huegg 2014), supports the extra effort to decipher the environment (Smith and Ellsworth 1985), and heightens engagement with and attention to an immediate stimulus, those experiencing fear should be more likely to appreciate a creative ad's complexities. They should be more likely to connect divergent pieces of the ad and connect them together to form an overall meaning for the ad, leading to an increased appreciation of its creativity. Thus, we expect fear, but not other negative emotions, to positively impact creativity (H1). In addition, given prior work linking creativity to increased attitudes and purchase intentions, we expect fear will positively influence attitudes and behavioral intentions, and that these effects will be mediated by creativity perception (H2-H3). Four studies support these hypotheses using a variety of products and contexts and both integral and incidental manipulations of fear.

## Methods and Results

Study 1 used a 2(ad context: commercial/cookies ad, PSA) x 4(emotion: fear, sadness, disgust, neutral) between-subjects design (N=309 students). Emotion was manipulated integrally using IAPS images (with exception of sadness for which alternative image was selected). A pretest (N=56) confirmed that the advertisements induced the appropriate emotions. After viewing the ad, participants answered questions about creativity perception, attitude toward the ad ( $A_{ad}$ ), behavioral intentions, engagement, and emotions ( $\alpha's > .70$ ).

Manipulation checks were successful. Supporting H1, two-way ANOVA (IVs= ad context, emotion, their interaction) revealed a significant main effect of emotion ( $F(3,287)=6.98, p < .001$ ). Those in the fear condition perceived the ad as the most creative ( $M_{Fear}=4.51$  vs.  $M_{Neutral}=3.39, M_{Disgust}=3.89, M_{Sadness}=3.96; p's < .05$ ). The fear condition also had the greatest engagement ( $M_{Fear}=3.37$  vs.  $M_{Disgust}=2.59, M_{Sadness}=2.90, M_{Neutral}=2.71, p's < .05$ ; other  $p's > .1$ ) ( $F(3,283)=5.80, p < .001$ ). As expected, engagement mediated (5,000 bootstrapping) the effect of fear on perceived creativity ( $axb_{vs.Neutral}=.28, axb_{vs.Disgust}=.33, axb_{vs.Sadness}=.20; p's < .05$ ) (direct effect,  $p < .05$ ). Additional statistical tests supported H2-H3. Finally, a serial mediation analysis confirmed that fear had a positive effect

on behavioral intention through "engagement->creativity-> $A_{ad}$ " ( $\beta_{Neutral}=.06, \beta_{vs.Disgust}=.02, \beta_{vs.Sadness}=.03; p's < .05$ ; direct effects  $p's > .1$ ), supporting our proposed process.

In Study 2, we manipulate emotions incidentally using videos (Schaefer et al. 2010). After watching an emotion-evoking video (anger, sadness, or happiness), participants (N=258 Mturkers) saw a (print) juice ad and rated creativity perception, willingness-to-pay, and emotions. Control variables included whether participants had previously seen the film/video and time spent viewing it.

Manipulation check was successful. EFA supported the discriminant validity of our measures. Consistent with H1, a one-way ANCOVA ( $F(3,252)=2.48, p=.06$ ) showed that those in the fear condition perceived the ad as significantly more creative ( $M_{Fear}=5.99$  vs.  $M_{Anger}=5.38, M_{Sadness}=5.53, M_{Happiness}=5.56; p's < .05$ ), and reported higher willingness-to-pay ( $M_{Fear}=\$4.20, M_{Anger}=\$1.76, M_{Happiness}=\$2.66, M_{Sadness}=\$2.87; p's < .001$ ). Creativity perception mediated (5,000 bootstrapping) this relationship ( $axb_{Fearvs.Anger}=.13, axb_{Fearvs.Happiness}=.09, axb_{Fearvs.Sadness}=.10; p's < .05$ ) (direct effect  $p < .001$ ).

To further generalize our findings, Study 3 used 162 real advertisements about anti-texting and driving. 682 Mturkers viewed three advertisements and rated each on  $A_{ad}, A_{issue}$ , perceived persuasiveness, behavioral intention, creativity perception, and emotion ( $\alpha's > .93$ ). CFA supported the discriminant validity.

Using advertisements as the unit of analysis (each advertisement was evaluated by 12 people on average), a regression (DV=perceived creativity; IVs=emotions experienced (fear, disgust, sadness, anger)) revealed a positive effect of fear on perceived ad creativity ( $\beta=.45, p < .001$ ), while the other emotions had no or negative effect ( $\beta_{Sadness}=.09, \beta_{Anger}=-.08, p's > .3; \beta_{Disgust}=-.22, p < .05$ ), supporting H1. Additional analyses supported H2-H3. Path analysis also revealed that creativity perception mediated the effect of fear on attitudes, and fear positively impacted behavioral intention through serial mediation of creativity perception and attitudes.

To rule out arousal as an alternative explanation of our results, in Study 4, we used advertisements that evoked different emotions, but did not differ in uncertainty or arousal. Seventy-nine participants rated the viewed ad on creativity, emotions, uncertainty, arousal, and engagement ( $\alpha's > .8$ ).

The fearful ad was perceived as more creative ( $M_{FearCond}=4.79, M_{NeutralCond}=3.67; p < .001$ ) (H1), and induced more engagement ( $M_{FearCond}=4.80, M_{NeutralCond}=3.63; p < .001$ ) ( $F's > 11$ ). Engagement mediated (5,000 bootstrapping) fear's positive impact on creativity perception ( $\beta=.18, p < .001$ ), and a serial mediation analysis confirmed that the fearful ad positively impacted creativity perception through "self-reported fear->engagement" (partial mediation:  $\beta=.08, p < .01$ ; direct effect  $p < .07$ ). These findings replicate those of the prior studies while also suggesting it is fear (rather than mere arousal or uncertainty) that drives people to be more engaged with the ad, as the two ads did not differ in their appraisal and arousal, only in the overall emotions-induced.

While fear can trigger many responses which may not all be conducive to enhancing creativity, in our research, we do not find evidence for "flight" or "freeze" responses (cf., Blanchard et al. 2011) as response time data indicate that emotion condition does not impact amount of time spent looking at the ad. A "fight" response is consistent with increased engagement with the ad, which then leads to enhanced creativity perception.

### General Discussion

We show that fear impacts perceived creativity due to its positive impact on engagement, and this occurs in contexts where fear might be expected (Studies 1,3,4) or unexpected (Studies 1&2). This research extends the literatures on discrete emotions, incidental fear, and creativity, by exploring a new dependent variable, creativity perception (rather than generation), and a new factor (fear) that influences this construct. Further our findings suggest that the drivers of creativity generation and perception may differ since prior research shows happiness increases creativity generation, but it did not impact creativity perception (Study 2).

Practically, our findings indicate marketers can enhance ad effectiveness through perceived creativity by placing ads in fearful contexts (e.g., during a scary show/movie, at a doctor's office, during/after a haunted tour).

# Symbolic Sustainable Attributes Improve Attitude Toward Low-Quality Products: A Warm-Glow Feelings Account

Valéry Bezençon, Université de Neuchâtel, Switzerland  
Florent Girardin, Université de Neuchâtel, Switzerland  
Renaud Lunardo, KEDGE Business School, France

## EXTENDED ABSTRACT

Firms are investing considerable amounts of money to develop sustainable offerings that respond to an important global consumer trend (Olsen, Slotegraaf, and Chandukala 2014). However, sustainable attributes can have either positive, neutral or negative effects on product evaluation (e.g. Bodur, Gao, and Grohmann 2013; Luchs, Naylor, Irwin, and Raghunathan 2010). In this research, we report on three experiments to demonstrate that sustainable attributes have a positive effect on consumer attitudes for low-quality (versus medium-) products or services. We also identify the mediating role of warm-glow feelings and of the relative weight of the sustainable attribute (vs utilitarian attribute) in forming product attitude.

When external cues signal that the overall quality of a product is low, it discredits performance-related product attributes in a process of quality disconfirmation (Golder et al. 2012). Therefore, in the case of a low-quality product, attributes that do not relate to product performance are likely to gain additional weight in consumers' formation of product attitudes. Accordingly, symbolic sustainable attributes, which do not relate to product performance (vs utilitarian attributes) should improve product or service attitude when external cues signal low quality (Hypothesis 1).

Research shows that sustainable attributes induce warm-glow feelings (Chernev and Blair 2015). Given our prediction that symbolic sustainable attributes may gain additional weight when consumers evaluate low-quality products, this change in weighting should in turn lead to an increase in warm-glow feelings. Hence, we expect that warm-glow feelings mediate the effect of a symbolic sustainable attribute on product attitude when external cues signal low product quality (Hypothesis 2). We also propose that this mediating effect is explained by the relative weight of the symbolic sustainable attribute in forming an overall evaluation (i.e. there is a serial mediation; Hypothesis 3).

Study 1 used a 2 (product quality: low vs. medium)  $\times$  3 (sustainable attribute vs. utilitarian attribute vs. no attribute) between-subjects design to test H1 and H2. We manipulated product quality with *Consumer Reports* ratings of a sunscreen product, which was presented as either "EcoConscious" (sustainable attribute), "Very Water Resistant" (utilitarian attribute), or without text (no attribute). A sample of 615 US citizens (52% women) completed a survey on MTurk. An ANOVA revealed main effects of product quality ( $F(1, 615)=359.85, p<.001$ ) and sustainable attribute ( $F(2, 615)=4.15, p=.016$ ) on product attitude, as well as an interaction effect ( $F(2, 615)=3.71, p=.025$ ). Planned contrasts revealed that eco-conscious attribute induced better attitude than no attribute and water resistant attribute in the low-quality condition ( $M_{EcoConscious}=2.99$  vs.  $M_{NoAttribute}=2.33, p=.003$ ;  $M_{EcoConscious}=2.99$  vs.  $M_{WaterResistant}=2.43, p=.054$ ). When quality was medium, no significant difference appeared across conditions, supporting H1. H2 was tested with a moderated mediation analysis (PROCESS Macro Model 8, Hayes 2017). A significant moderated mediation was observed (Index=.55, 95% CI=.13 to .97), whereby the indirect effect of symbolic sustainable attribute (vs. utilitarian attribute) on product attitude was more important in the low-quality condition ( $ab_{Low-quality}=-.90, 95\% CI=-1.24$  to  $-.58$ ) than in the medium-quality condition ( $ab_{Medium-quality}=-.35, 95\% CI=-.62$  to  $-.09$ ). These results support H2.

Study 2 tests the differential effect of symbolic sustainable vs utilitarian sustainable attributes. It used a 2 (product quality: low vs. medium)  $\times$  3 (symbolic sustainable attribute [fair-trade] vs. utilitarian sustainable attribute [organic] vs. no attribute) between-subjects design. "Fair-Trade" and "Organic" were successfully pre-tested as representing respectively symbolic and utilitarian attributes. We manipulated product quality with independent experts' quality ratings. Respondents (660 US citizens, 55.8% women) were asked on MTurk to evaluate a T-shirt. A main effect of product quality ( $F(1, 660)=398.15, p=.000$ ) on product attitude was again observed but not of sustainable attribute ( $F(2, 660)=1.56, p=.211$ ). Their interaction was not significant ( $F(2, 660)=1.31, p=.270$ ). Yet, planned contrast indicated that when quality was low, attitude was more favorably rated in the symbolic sustainable attribute condition ( $M_{FairTrade}=2.75$ ) than in the no attribute condition ( $M_{NoAttribute}=2.30, F(1, 660)=6.67, p=.010$ ). All the other contrasts revealed no significant differences across conditions ( $p's>.10$ ). These results provide further support to H1 by showing that adding a symbolic sustainable attribute (but not a utilitarian sustainable attribute) increases product attitude when the product quality is low. H2 was tested using the same procedure as in study 1. As expected, a significant moderated mediation was observed (Index=.43, 95% CI=.09 to .77), whereby the indirect effect of symbolic sustainable attribute (vs. utilitarian sustainable attribute) on product attitude was significant and more important in the low-quality condition ( $ab_{Low-quality}=-.34, 95\% CI=-.60$  to  $-.07$ ) than in the medium-quality condition ( $ab_{Medium-quality}=.09, 95\% CI=-.11$  to  $.30$ ).

Study 3 used a 2 (hotel quality: low vs. medium)  $\times$  3 (attributes: symbolic sustainable first [then utilitarian] vs. utilitarian first [then symbolic sustainable] vs. utilitarian only) between-subjects design. Respondents (728 US citizens, 55.5% women) were asked on MTurk to evaluate a Hotel. Quality ( $F(1, 728)=533.65, p=.000$ ) and sustainable attributes ( $F(2, 728)=10.841, p=.000$ ) had a main effect on attitude. Their interaction was marginally significant ( $F(2, 728)=2.724, p=.066$ ). Planned contrasts indicated that when quality was low, the order of attribute presentation had no effect on attitude ( $M_{SustainableFirst}=4.02$  vs.  $M_{UtilitarianFirst}=4.32, p=.128$ ) but both conditions generated more favorable attitudes than utilitarian attributes only ( $M_{UtilitarianOnly}=3.53$  vs.  $M_{SustainableFirst}=4.02, p=.001$ ;  $M_{UtilitarianOnly}=3.53$  vs.  $M_{UtilitarianFirst}=4.32, p=.000$ ). By contrast, when quality was medium, the attitude was not different across conditions ( $p's>.10$ ). These results provide further support to H1 and show that the order of attribute presentation does not influence the hypothesized effects. To test H3, we performed a serial mediation (PROCESS Macro Model 6, Hayes 2017) with the relative weight of attributes and warm-glow feelings as mediators. Results support our hypothesis: sustainable attribute importance and warm-glow feelings had a negative sequential indirect effect on attitude (indirect effect=-.07, 95% CI=-.12 to  $-.03$ ), whereby hotel quality decreased sustainable attribute importance, which negatively influenced warm-glow feelings, resulting in a less favorable attitude.

Using different implementations of quality cues (provided by independent experts and other consumers) and sustainable attributes, this research contributes to the literature on sustainable attribute effects by showing that the presence of a symbolic sustainable attribute increases attitude when product quality is low (vs. medium). More-

over, this research shows how the attribute weight influences warm-glow feelings and attitude.

# I'm Scared, Want to Listen? Fear's Influence on Self-Disclosure

Anupama Mukund Bharadwaj, University of Washington, USA

Lea Dunn, University of Washington, USA

JoAndrea Hoegg, University of British Columbia, Canada

## EXTENDED ABSTRACT

Extant research has considered various antecedents that may influence consumers' engagement in self-disclosure (Derlega et al, 1993). For example, trust in another person can motivate an individual to self-disclose (Derlega et al, 2008). However, scant research has examined the impact of incidental emotion on self-disclosure. For example, it is common for consumers to experience fear regularly. Yet, research has not considered incidental fear's potential influence on self-disclosure motivations. In this research, we explore the impact of fear on self-disclosure and how this self-disclosure may be beneficial for brands.

Fear is a basic negative emotion elicited in response to perceived threat (Izard, 2013). Several theories examine the antecedents to and outcomes of fear. For example, cognitive appraisal theory suggests that fearful individuals are risk-averse and express pessimistic risk estimates of future events (Lerner and Keltner, 2001). Emotion regulation, however, has found that people cope with fear through affiliation with others (Schachter, 1959; Sarnoff and Zimbardo, 1961), a mechanism that has been shown to enhance brand attachment (Dunn and Hoegg, 2014).

These theories provide divergent predictions on fear's effect on behavioral outcomes. While cognitive appraisal theory would predict that fearful individuals are risk-averse, affiliation theory would predict that fearful individuals are motivated to affiliate with others. Such affiliative behavior could potentially put an individual at risk of rejection or exploitation, if it involves self-disclosure (Derlega et al, 1993). Previous literature has suggested that individuals divulge private information when it provides a "net benefit" (White 2004), and are more likely to be open and honest when they do disclose (Derlega et al. 1993). This vulnerability results in self-disclosure being an inherently risky activity. If self-disclosure can enhance affiliation, but is also perceived as risky, which motivation (risk-aversion vs. affiliation) would exert greater influence over a fearful individual?

Across five experimental studies and one field study, we observe directional and significant effects of fear on self-disclosure. Specifically, we expect affiliation (via measurement and moderated by affiliative experience) as the underlying process. We predict that individuals who experience fear alone will engage in significantly greater amounts of self-disclosure than individuals who have experienced fear in a group.

Study 1 tested whether a) self-disclosure is seen as a risky activity and b) fear leads to higher perceptions of risk. Using several measures of self-disclosure behavior [i.e., private information, personal information, use of private and personal information (Vogel and Wester 2003; Fogel and Nehmad 2009)], we find a consistent pattern for fear: those who experienced fear perceived directionally greater risk in different domains of private and personal information than those in the control group.

Study 2 was conducted as a field study. Participants at a local haunted house experienced a haunted attraction alone or in a group and then had the option to complete a short survey. Lone participants, as compared to group participants, showed significantly greater engagement in the survey and marginally greater discussion in personal regrets.

Study 3 was a 2 (emotion: fear vs. control) x 2 (experience: alone vs. with others) between-subjects design used to test the mod-

erating effect of experience on incidental fear's influence on self-disclosure. Participants were told that they would either be watching a movie clip alone or with everyone in the lab and were then randomly assigned to watch either a fear-inducing or control movie clip. All participants were told that they had been selected for a pre-screening for a future focus group conducted by a brand. Scared lone participants believed they would demonstrate significantly greater openness and honesty with the brand if they were selected for the future focus group (Figure 1).

Study 4 utilized a similar setting and design as Study 3. Scared lone participants provided significantly longer responses about what they were most guilty about in life. Additionally, these participants were directionally more likely to agree to release their photo to an unknown brand moderator than other participants.

Study 5 tested fear's impact on self-disclosure in a general perspective, rather than explicitly stating to an individual that their self-disclosed material would be shared with a specific entity, such as a brand or brand representative. Participants were randomly assigned to conditions similar to Study 3's design. Participants in the alone condition reported significantly greater amounts of needing to be with others than participants in the together condition. Scared lone participants, as compared to scared group participants, provided significantly longer responses to describe their relationships with their mothers as well as were more likely to engage in self-disclosure about their childhood and about expectations for the future.

Study 6 tested a brand's anthropomorphism level as a moderator to self-disclosure under moments of fear. Participants were randomly assigned to watch a fear or control movie clip. Individuals who experienced fear reported a significantly greater need for affiliation than control participants. Participants were then randomly assigned to read about an anthropomorphized TV or a non-anthropomorphized TV as designed by Hur and colleagues (2015). Participants were asked about their typical television and streaming habits. A marginal interaction between fear and anthropomorphism was observed for disclosure of indulgent viewing behavior. Additionally, a significant interaction was observed between fear and anthropomorphism on inappropriate viewing behavior.

Our contribution to theory is three-fold. Firstly, we present a novel consideration of cognitive appraisal theory and affiliation theory in the domain of fear. Secondly, we extend the current knowledge of incidental emotional research within marketing (Achar et al, 2016). Thirdly, we extend self-disclosure literature within marketing by offering fear as a novel antecedent. We believe brands can utilize our findings to create strategic plans for communication with their consumers after an unrelated scary event has occurred. By doing so, both parties within the relationship can benefit; consumers can have the opportunity to alleviate their fear by affiliating with the brand via self-disclosure and the brand can obtain valuable information about its consumers that it would otherwise not have access to, thereby strengthening the bond between consumer and brand. Future research will examine brand outcomes.

# When Too Much “I” is Bad for “Us”: The Detrimental Effect of Selfie on Self-Brand Connection

Mehak Bharti, Nanyang Technological University, Singapore  
Sharon, Ng Sok Ling, Nanyang Technological University, Singapore

## EXTENDED ABSTRACT

In this social media era, the growing popularity of selfie is swarming the world into becoming a selfie - obsessed generation. Selfie is the act of taking self-portraits by using one's camera (Murray 2015). The selfie fever could not even spare the astronaut, Mark Vande, who very recently clicked his own “space-selfie”, during the first spacewalk of the year (Smith 2018). Now, the marketers are also trying to capitalize on the appeal of this selfie movement to connect their brand with the consumers.

Contradicting the conventional wisdom of the marketers, this research proposes that encouraging consumers to take a selfie with a brand actually inhibits the establishment of a strong self-brand connection. It shows that the act of taking a selfie, shifts consumers' attention away from the brand to themselves (i.e., exhibits greater self-focus). In such situations, the brand becomes peripheral and the person clicking his/her own selfie becomes the focus of attention. Considerable research has shown that a strong self-brand connection leads to various positive marketing consequences like increased customer loyalty etc. (MacInnis and Folkes 2017). In contrast, sufficient literature in psychology shows that too much self-focus may reduce relationship quality between couples and friends (Campbell, Brunell and Finkel 2006; Reiss and Wright 1996). Research also shows that individuals with personality dimensions like narcissism and materialism exhibit a lack of empathy towards others and are unable to form quality interpersonal relationships because of extreme self-love (Campbell et al. 2006; Richins and Dawson, 1992). Drawing from these findings, this research proposes that at times, too much self-focus may inhibit, instead of facilitating, the building of a strong self and brand relationship.

Instead of having consumers take a selfie with the brand, a more effective strategy will be for a third party to take a picture of the consumer with the brand. For example, in some restaurants, staff are encouraged to help their customers take a picture of their time in the restaurant. In such non-selfie contexts, consumers are less likely to focus on themselves, but on their relationship with the brand, leading to a stronger self-brand connection. Thus, we propose:

*Hypothesis 1 Selfie campaign is detrimental to the establishment of self-brand connection, relative to non-selfie campaigns.*

*Hypothesis 2 The above effect is mediated by heightened self-focus in selfie (versus non-selfie) campaigns.*

Study 1 (N=90) showed that asking consumers to take a selfie with a brand indeed led to a lower self-brand connection. They were randomly assigned to one of the three between-subjects conditions (Selfie-condition, Non-selfie condition, Control condition). Across all three conditions, participants were given a Lindt Chocolate bar. In the selfie-condition, participants were asked to take a selfie with the product. In the non-selfie condition, participants were told to hold the product in any way they like, and the researcher clicked a picture of them. In the control condition, participants were simply asked to take a picture of the product (the participants were not in the picture). A one-way ANOVA on the mean of the 7-items self-brand connection scale shows a significant main effect of campaign condition on

self-brand condition ( $F(2, 86), p = .012$ ). Specifically, as predicted, participants in the selfie condition exhibited significantly lower self-brand connection. More interestingly, contrasts also showed that self-brand connection between the self and control conditions were not significantly different. More interestingly, contrasts showed that participants in the non-selfie condition exhibited significantly higher self-brand connection than those in the control condition.

Study 2 (N=105) provided evidence for the mediating role of self-focus. Participants were randomly assigned to either the selfie or the non-selfie condition. In this study, a well-known tea brand “TWG” was chosen as the focal product. After completing the study, participants completed the self-brand connection scale. In addition, they were also asked to indicate the extent to which they were focusing on themselves while the clicking campaign. ANOVA on participants' self-brand connection revealed a significant main effect of type of photography ( $F(1, 103) = 4.41, p = .03$ ). ANOVA on the self-focus measure showed that participants in the selfie-condition reported significantly higher focus on the self, relative to those in the non-selfie condition ( $M_{\text{selfie}} = 4.49, M_{\text{non-selfie}} = 3.09; F(1, 103), p < .001$ ). To test if self-focus mediated the above effect, a mediation analysis using Model 4 by Preacher & Hayes (2008) with 5000 iterations was conducted. We entered condition (selfie versus non-selfie) as the independent variable, mean self-brand connection as the dependent variable, and response on the self-focus as the mediator. Results revealed a significant mediation by self-focus ( $B = -.1950, SE = .122, 95\% \text{ CI } [-.509, -.006]$ ).

Study 3 (N= 149) manipulates the participant's focus on the self in a (Self-focus: Low versus High) X (Campaign: Selfie versus Non-Selfie) between-subjects design. To elicit self-focus, participants in the high self-focus (low self-focus) condition were told to write their names (any two words) on the electronic board before taking the pictures in both selfie and non-selfie condition. ANOVA on participants' self-brand connection ( $\alpha = .96$ ) with self-focus and campaign as independent variables showed a significant main effect of self-focus ( $F(1, 145) = 12.91, p < .001$ ) but insignificant main effect of campaign ( $F(1, 145) = 1.43, p = .23$ ). More importantly, there was a significant interaction between self-focus and campaign type  $F(1, 145) = 4.58, p = .03$ ). Contrasts showed that in the condition of low self-focus, those in the selfie condition exhibited significantly lower self-brand connection relative to those in the non-selfie condition ( $M_{\text{selfie}} = 2.25, M_{\text{non-selfie}} = 2.81; F(1, 145)$ ). However, when self-focus was heightened, the difference in self-brand connection between participants in the selfie and non-selfie condition was eliminated ( $M_{\text{selfie}} = 2.01, M_{\text{non-selfie}} = 1.85; F(1, 145)$ ).

Findings from 3 studies provide converging evidence to support our proposition that contrary to conventional wisdom, selfie campaigns are not necessarily a good tool for brands to establish a strong relationship with their customers. This research provides an interesting nuance to the general belief that selfies are good for the brand.

# Effects of Retail Food Sampling on Subsequent Purchases: Implications of Sampling Healthy versus Unhealthy Foods on Choices of Other Foods

Dipayan Biswas, University of South Florida, USA

J. Jeffrey Inman, University of Pittsburgh, USA

Johanna Held, Bayreuth University, Germany

## EXTENDED ABSTRACT

The food-and-beverage industry spends over a billion dollars annually on food samples (Biswas et al. 2014). These food samples vary considerably in terms of their healthfulness levels. In that regard, we examine how sampling healthy versus unhealthy foods might influence subsequent food purchases in terms of caloric content and healthfulness levels.

Prior studies on food sampling have mostly examined the effects of sampling a particular product on the subsequent choice of that focal product (Biswas et al. 2014; Nowlis and Shiv 2005; Shiv and Nowlis 2004). Studies have also examined the reward seeking effects of sampling (Wadhwa, Shiv, and Nowlis 2008). Similarly, prior research studies have examined several factors that influence choices between healthy and unhealthy options (Biswas et al. 2017; Shiv and Fedorikhin 1999). Research has also examined anchoring effects of sequential evaluation of vices and virtues (Chernev 2011a). However, to the best of our knowledge, no research has examined the effects of sampling healthy versus unhealthy food items on subsequent *choices* of *other* food items. We make an important step in examining how the healthfulness level of a sampled food item might influence subsequent choices when choosing from a set of healthy and unhealthy options. We also examine the effects on total calories purchased and consumed.

It should be noted that our research differs from prior research that has examined how consumers balance healthy and unhealthy meals (Chandon and Wansink 2007; Dhar and Simonson 1999). These studies show that perceived unhealthy meals are balanced by selecting relatively healthier side dishes or drinks and guilt is often the underlying factor behind this behavior (Chandon and Wansink 2007; Chernev 2011b; Okada 2005). In contrast, we are not examining effects of full meals – instead, we are focusing on the effects of bite-sized sampling on subsequent choices. The focus on bite-sized sampling is practically relevant given the widespread popularity of sampling practices at retail stores and restaurants, as outlined earlier. Along similar lines, our research differs from research by Finkelstein and Fishbach (2010). They found that when participants ate the same food sample labeled as healthy (vs. tasty), they indicated feeling hungrier. In contrast, we did not label the foods in any of our studies and instead, participants sampled different food items that were either healthy or unhealthy; moreover, we examine subsequent choice for healthy versus unhealthy foods while Finkelstein and Fishbach (2010) examined perceived hunger and consumption amount of a neutral food. Similarly, Wilcox et al. (2009) examined the mere presence of a healthy item on subsequent choice while we examine actual sampling of food items.

Finally, our work differs from work in moral licensing where people get to *choose* a virtue item, which leads to subsequent indulgence (Effron and Conway 2015; Khan and Dhar 2006). That is, in the moral licensing literature, the individual makes the “moral” *choice* to earn the “license.” In contrast, in our research context, the choice has been *made* for the consumer (e.g., by the retailer or restaurant).

We hypothesize that initial sampling of a healthy (vs. an unhealthy) item will lead to feeling good, which in turn will lead to self-rewarding indulgence, which in turn will lead to subsequent higher

choice likelihood for unhealthy options. We test our hypotheses with three field experiments and two lab studies.

Study 1a tested our main effects hypothesis via a field experiment at a restaurant. The experiment had three between-subjects manipulated conditions (sampling a healthy food vs. sampling an unhealthy food vs. control condition of no food sampling). The results show that the restaurant patrons who were given a healthy (vs. an unhealthy sample or vs. no sample) subsequently ordered unhealthy items from the menu to a greater extent. We replicated these findings in a lab setting (study 1b).

Study 2 tested the serial mediation effects whereby sampling a healthy (vs. an unhealthy) item leads to feeling good, which in turn leads to self-rewarding indulge and a higher likelihood of indulging (i.e., choose unhealthy options).

Then study 3 (a field experiment) examined the moderating effects of presence of other foods and found that when the sampled food item was displayed in the midst of healthy items, consumers sampling a healthy (vs. an unhealthy) item subsequently chose the unhealthy option to a greater extent. These effects were attenuated when the sampled item was displayed in the midst of unhealthy items.

While Studies 1a-3 examined the effects on subsequent choice of a single item, Study 4 (a field experiment conducted at a food store at a farmers’ market, in collaboration with the store management) examined the effects of sampling on subsequent purchase of total calories of a basket of items. As predicted, customers who sampled a healthy (vs. unhealthy) item right after arriving at the store ended up purchasing a higher amount of total calories.

In conclusion, five experiments (three conducted in field settings and two in the lab) demonstrate interesting results for the effects of sampling a healthy versus unhealthy food item on subsequent choices and total calorie purchases. In the absence of any moderators, sampling a healthy (vs. an unhealthy) item led to greater subsequent choice of unhealthy items and also greater amount of calories purchased.

# The Trusted Influencer: How They Do It and How Brands Can Benefit

Gillian Brooks, University of Oxford, UK

Mikolaj Piskorski, International Institute for Management Development, Switzerland

## EXTENDED ABSTRACT

Social scientists have long argued that individual's preferences and decisions are heavily influenced by opinions and actions of others (McPherson, Smith-Lovin and Cook 2001). Countless studies across numerous disciplines, including marketing, have shown that the social influence effects are large and exist in a wide variety of environments (Hartmann 2008, Nair et al. 2006, Van den Bulte and Lilien 2001, Iyengar et al 2010, Bernheim 1994, Bass 1969, Choi et al 2008, Nair et al. 2006, Godes et al. 2005). Research has further shown that while every individual can potentially influence everyone else, some people or entities have a much larger impact on others preferences or actions (Van den Bulte and Joshi 2007, Nair et al. 2006, Trammell and Keshelashvili 2005, Aral and Walker 2014). Often referred to as "influencers" or "opinion leaders", they can trigger adoption of a particular belief or practice in a large population quickly (Lazarsfeld, Berelson, and Gaudet, 1948; Watts and Dodds, 2007).

Companies recognize the power of such influencers and seek to engage with them to encourage consumers to buy a particular set of products. These influencers are paid for their endorsements and as their viewers discover the existence of such payments, they question the presumed impartiality of such broadcasters, thereby limiting their influence, or so we think. Our findings illustrate that trust and influence are still maintained between influencer and influencee, despite knowledge of the paid endorsement. Using data from a 15-month qualitative study of the industry, we identify two types of strategies: one related to the review process, and one related to community management that allow online influencers to maintain influence despite being paid. Our sample consisted of interviews with successful and unsuccessful influencers based in New York and Los Angeles, interviews with talent agencies in Los Angeles; public relations firms in Los Angeles, London, New York, Paris, San Francisco and Toronto; and international consumer goods companies (based in the United States) that had partnerships with online influencers.

Our findings revealed that the payments that influencers receive present a fundamental dilemma for the influencers themselves. On the one hand, they are an important source of influencers' revenue. On the other hand, the payments actively undermine the presupposed independence of the online influencers. Even influencers who do not explicitly talk about products are not immune to these concerns. To alleviate these concerns, we discovered that the influencers have developed two sets of practices that allow them to maintain their influence, even if their followers are fully aware of the payments they receive. The first set requires that influencers provide their followers with extensive comparisons of various products in use, as compared to examining product features, while refraining from explicitly telling the viewers what to do or buy. The second set is much more affective in nature, and requires that the influencers augment their discussions and reviews of different products while maintaining a seemingly personal relationship with their audience, often by providing extensive insights into their personal lives and personalities so that they appear loveable, entertaining and above all, aspirational.

The analysis we present has important industry implications for how to produce an effective influencer strategy; specifically, online influence is effective because it is not a controlled experience. The influencer has to be able to talk about a product freely, engage in direct comparisons with other brands, and identify flaws. These kinds of messages are key because these potentially negative messages

are critical to establishing consumer trust. This implies that engaging with online influencers will produce a somewhat uncontrolled environment, but given that the influencers have their own brand to contend with, they need to say certain things to resonate with the audience, and continue to have influence over them. This is very different from what marketing executives are used to. In fact, the kinds of skills that were really helpful in the previous era, such as tight execution, scripting, making sure that the message was always consistent, might actually work against brands in the era of influencer marketing.

Despite the apparent success of online influencer marketing strategies so far, relatively little academic work has explored who the influencers are, how they operate and how they engage with companies (for notable exceptions see Subramani and Rajagopalan 2003; Biran, Rosenthal, Andreas, and McKeown 2012; and Trammell and Keshelashvili 2005). Our paper seeks to help fill this gap as we investigate the nuances of the influencer landscape and how trust is built and maintained.

# Exploring Consumers' Technology Dreams and Nightmares: A Collage-Elicitation Study

Céline Del Bucchia, Audencia Business School, France

Caroline Lancelot, Audencia Business School, France

Cristel Antonia Russell, American University, USA

Claire Burlat, Audencia Business School, France

## EXTENDED ABSTRACT

The study adopts a holistic view of the role of technology in (post-) modern life to uncover the latent meanings behind consumers' dreams and nightmares associated with living in a techno-connected world and to uncover the dynamics of how dreams may turn into nightmares. This study builds on the extant marketing literature dealing with how consumers perceive and react to technology-based personalized interactions with brands. Technologies form ideologies that influence consumer's thoughts and narratives (Kozinets 2008). Conflicts and paradoxes are aplenty in the context of technology: for all the benefits that technology offers, it also brings different kinds of fears and concerns (Mick and Fournier 1998).

We draw on the literature on dream interpretation (Freud 1900, Lacan 1966) to explore how consumers reflect on the role of technology in their lives. The dream approach enables a deeper exploration of unconscious and irrational feelings, yielding new insights about consumers' holistic experience of their technology-mediated consumer journeys. Dreams are a 'powerful condensed metaphor for irrational beliefs' that cannot otherwise be articulated. (Barrett 2002) and psychodynamic work today still relies on dreams to access the unconscious. This 'manifest content', which we can consciously recall and articulate, is used to reveal the underlying, latent content.

Data were collected through focus group discussions, group construction of collages and collage narratives. Group collages serve as a compelling projective technique to access latent meanings without explicitly asking for them (Belk, Ger, and Askegaard 2003, Zaltman 1997). Collages provide a creative, unbounded, projective task that bypasses participants' defense mechanisms, rationalization, and social desirability biases. In the spirit of Zaltman's (1997) metaphor elicitation technique, this interpretive tool is used here to uncover deep insights into how consumers reflect on their lived experience of a techno-connected world. The use of collages in a group context facilitated the sharing of irrational thoughts among participants and the co-construction of collective narratives as participants build on others' ideas by enriching and contrasting them (Morgan 2002).

Data analysis was guided by grounded theory as advocated in Glaser and Strauss (1967) and elaborated by Strauss and Corbin (1998); verbatim data were coded and themes distilled using the constant comparative method of analysis (Spiggle 1994). We identified latent content in analyzing informants' metaphors, for example images of superheroes, desires, big brother, clones, etc. in each collage stories. The focus group discussions were used to supplement the analysis of 'surface meanings' and identify how dreams and nightmares relate to lived experiences in consumer journeys. The second level of analysis compared dream narratives to nightmare ones, to uncover the transformation of dreams into nightmares.

The analysis of focus groups, collages and collage narratives signals that dreams and nightmares are interrelated (Kramer 1991) and puts forth three mechanisms through which digital interactions can transform consumer experiences into nightmares: inaccurate personalized messages, repetition of personalized messages, and consumers' overreliance on immediacy of technology.

Dreams of an ideal day in the hyper-connected world involved metaphors of superpowers and fairytale. The services delivered by connected objects provide consumers superpowers, multiplying their

capacities, such as the capacity to anticipate, to have the immediate information, the power of ubiquity. In such a wonder world, objects and applications access data to enable personalized recommendations as well as anticipate needs and wants. Nightmares bring up themes of harassment and human objectification. Attempts of personalized notifications are viewed as creating conformism and uniformity, where individuals lose their uniqueness as illustrated by the twins in a nightmare collage. Consumers become dependent on techno-based interactions, illustrated by a man held by the tie in a nightmare collage. They become objects, harassed by a system of hyper consumption.

Although technology facilitates personalization of the interactions that underlie a world of superpowers and fairytales, deeper analysis reveals that personalization and immediacy also cause nightmares. Indeed, many nightmare collages start as dreams. We use those to analyze the shift.

Findings highlight that the promise of magic with the use of personalized and immediate notifications through digital devices contributes to a self-centered world, driven by instant and personal gratification (Lipovetsky 2006). Such promises raise consumers expectations and clash with real life contexts. The three mechanisms of inaccurate information, repetition and over-reliance on technology first interrupt the dream process, and participate to change consumers' vision of themselves: from superheroes living in a wonder world to objectified individuals living in a world of nonsense. Such findings shed light on unexpected consequences of digital personalized interactions: beyond the personalization/ intrusiveness paradox (Aguirre et al. 2015), our findings reveal that attempts to personalize can instead lead to standardization of human behavior. Findings also uncover a contrast between consumers' critical sense regarding personalized digital interaction and their credulity for blindly relying on immediate information from their digital devices. This raises the need for further research on consumer vulnerability in relation to ideologies of the techno-connected world.

From a methodological point of view, the use of both declarative insights from focus group discussions and projective data through collages enables access to a more accurate understanding of the interrelatedness of dreams and nightmares. The combination of methods enables exploration of all facets of the phenomenon, including its paradoxical aspect (McGrath, Sherry and Levy 1999). Collages enable access to latent content because the process of creation of a collage is metaphorical (Zaltman 1997). The group dynamics boosted the creativity of collages by engaging informants into magical and absurd narratives. Focus groups narratives helped connect latent meanings and consumers' lived experiences.

Of course, caution is warranted to not over interpret dreams and nightmares and to not overstate the psychiatric meanings of collages, since none of the authors are professional psychotherapists even though one of them has previously worked on applications of psychodynamics in consumer research. Notwithstanding these limitations, the dream approach offers a novel lens through which to uncover consumers' reflections of their own experience in a technology-ridden world.

# When Consumers Choose for Others, Their Preferences Diverge from Their Own Salient Goals

Olya Bullard, The University of Winnipeg, Canada

## EXTENDED ABSTRACT

People's daily lives are filled with consumption decisions, which frequently involve making choices for others. In the current research we examine how choices for others differ from choices for oneself based on one important factor—the way these choices are influenced by consumers' own salient goals.

Extant research demonstrated that consumers are motivated to fulfil goals through consumption (Yang et al., 2015), that consumers evaluations and choices of products are based on instrumentality of those products to consumer-goal fulfilment (Garbarino and Johnson, 2001; Ramirez et al., 2015), and that goals with higher levels of activation (i.e., more salient goals) have a stronger influence on product evaluation and choice (van Osselaer and Janiszewski, 2012). In other words, consumers prefer products congruent with their salient goals because consumption of these products allows them to experience (or at least perceive experiencing) progress toward these salient goals. Prior studies examined situations in which consumers make choices for themselves; how consumers' salient goals influence choices made for others, however, remains an open question.

In the current research we predict that when consumers choose for others, their preferences diverge from their own salient goals. Perception of goal progress is not only influenced by a consumer's own goal-consistent or goal-inconsistent actions, but also by social comparison (e.g., Fishbach and Dhar, 2005; Fishbach et al., 2006). Consumers perceive making more (vs. less) goal-progress if they compare themselves to a lower (vs. higher) standard (e.g., Etkin and Ratner, 2012) or if they compare themselves to a person who is making less (vs. more) goal progress or engages in less (vs. more) goal-consistent actions (e.g., Fishbach and Dhar, 2005; Fishbach et al., 2006; Park and Hedgecock, 2016).

Based on the notion that consumption of goal-consistent products creates the perception of progress toward the goal and that comparing oneself to another who is making more (vs. less) progress undermines (vs. enhances) perception of one's own progress toward the goal we predict that choosing a product for another person (vs. for oneself) increases preference for products that are incongruent with a salient consumer goal compared to products that are congruent with a salient consumer goal. We contend that this effect occurs because the perception of consumer's own goal-progress is enhanced (vs. undermined) by goal-incongruent (vs. goal-congruent) products chosen for another person (vs. oneself).

Further, we suggest that this effect only holds for salient goals construed at a personal level. Goals construed at group- or societal-level will not influence preferences in the same way. A goal is set at a group level when a specific level of performance that is to be attained is measured by collectively assessing the level of performance of all group members (Weingart and Weldon 1991; Weldon and Weingart 1988). If a salient goal is set at a group/societal level, choosing a goal-congruent (vs. goal-incongruent) product for another person should contribute to the perception of progress on the salient goal (as long as the recipient belongs to the social unit of the goal level); hence consumers should prefer goal-congruent products for others for salient goals set at group/societal level.

In Study 1 participants were primed either with a goal of healthy eating or with a goal of taking pleasure in the food they eat. After completing a filler task, participants made a choice between an apple and a Twix bar to either keep for themselves or to give to a

friend. Participants who were choosing for themselves were more likely to choose a goal-consistent option (63%), while participants choosing for a friend were more likely to choose a goal-inconsistent option (58%;  $\chi^2(1) = 5.452, p = .02$ ). In study 2 female participants were primed with a goal of being beautiful and imagined buying a beauty or wine-tasting gift card either for themselves or for a friend. We measured goal-progress perception and purchase evaluation. Participants who imagined buying for themselves evaluated a goal-consistent purchase ( $M = 5.81, SD = 1.44$ ) higher than a goal-inconsistent purchase ( $M = 4.69, SD = 1.77, F(1, 172) = 11.150, p < .001$ ). Participants who imagined buying for a friend evaluated a goal-consistent purchase ( $M = 5.15, SD = 1.68$ ) lower than a goal-inconsistent purchase ( $M = 5.84, SD = 1.28; F(1, 172) = 4.175, p = .043$ ). Participants who imagined buying for themselves perceived more goal-progress if they imagined buying a goal-consistent product ( $M = 5.01, SD = 1.20$ ) than a goal-inconsistent product ( $M = 4.40, SD = 1.40; F(1, 173) = 4.183, p = .042$ ). Participants who imagined buying for a friend perceived less goal-progress if they imagined buying a goal-consistent product ( $M = 4.37, SD = 1.66$ ) than a goal-inconsistent product ( $M = 5.03, SD = 1.29; F(1, 173) = 4.734, p = .031$ ). Perception of goal-progress mediated the effect of choice recipient on purchase evaluation of a goal-consistent versus goal-inconsistent product. In study 3 participants were primed with a health goal either on a personal or societal level and imagined shopping for themselves or for a friend. Participants expressed purchase intentions either for goal-consistent or goal-inconsistent products. Among those who were primed with a health goal on a personal level: In the buying-for-the-self condition, purchase intentions were higher for goal-consistent products ( $M = 5.67, SD = 1.41$ ) than for goal-inconsistent products ( $M = 4.58, SD = 1.65; F(1, 200) = 13.364, p < .001$ ). In the buying-for-a-friend condition, purchase intentions were higher for goal-inconsistent products ( $M = 5.49, SD = 1.15$ ), than for goal-consistent products ( $M = 4.89, SD = 1.72; F(1, 200) = 4.059, p = .045$ ). Among those who were primed with a health goal on a societal level, there was only a main effect of product so that purchase intentions were higher for goal-consistent products ( $M = 5.35, SD = 1.38$ ) than for goal-inconsistent products ( $M = 4.78, SD = 1.64; F(1, 202) = 7.113, p = .008$ ).

This research contributes to the body of research on goal-directed consumption by demonstrating that choices made for others are influenced by salient goals differently than choices made for the self.

# Can Implicit Theory Influence Construal Level?

Olya Bullard, The University of Winnipeg, Canada

Sara Penner, The University of Winnipeg, Canada

Kelley J. Main, University of Manitoba, Canada

## EXTENDED ABSTRACT

Implicit theories (Dweck, 1999) influence people's beliefs about the malleability (incremental theory) versus stability (entity theory) of human traits and world disposition and account for a variety of differences in behavior exhibited by consumers. For example, entity theorists form strong attitudes about brands faster and with less cognitive elaboration than incremental theorists (Kwon & Nayakankuppam, 2015); entity theorists also form perceptions of people based on their brand use more readily than incremental theorists do (Park & John, 2018). On the other hand, incremental theorists are more susceptible to framing effects in advertising (Jain, Mathur, & Maheswaran, 2009), and are more accepting of brand extensions compared to entity theorists (Yorkston, Nunes, & Matta, 2010).

Is it possible that the implicit theory that an individual holds influences a fundamental aspect of the cognitive process—the level of construal (Lieberman & Trope, 1998) at which information is processed and organized? The answer to this question can provide a wealth of information about implicit theorists' tendencies as consumers, as construal level has been shown to impact which product features and attributes consumers value in product-choice (Zhao, Hoeffler, & Zauberaman, 2007), how they evaluate and select financial products (Ainslie & Haslam 1992; LeBoeuf 2006), and how they mentally organize product information (Lee, Deng, Unnava, & Fujita, 2014).

Abstract representations necessitate assignment of meaning to certain stimuli, and any concrete action can lend itself to “multiple abstract representations” (Lieberman, Sagristano, & Trope, 2002, p. 524). The transition from an observed concrete event to its abstract form occurs by considering pertinent situational information to determine which of the multiple possible abstract representations is most relevant (Lieberman et al., 2002). As such, this transition requires the individuals to efficiently switch between thinking about different superordinate concepts that could potentially represent the observed concrete action—the ability captured by a construct known as cognitive flexibility (Scott, 1962). Indeed, cognitive flexibility is an integral part of an abstract mindset responsible for exploratory and creative tendencies of abstract thinking (e.g., De Dreu, Nijstad, & Baas, 2011; Jia, Hirt, & Karpen, 2009).

Holding an incremental (vs. entity) theory makes people more flexible in their interpretation of observed outcomes. Entity theorists attribute observed events to “fixed” underlying dispositions, while incremental theorists rely on pertinent situational information to arrive at an explanation (Erdley & Dweck, 1993; Hong, 1994). As such, incremental theorists acknowledge that several alternative explanations of an observed outcome are potentially plausible, demonstrating that they are aware of multiple possibilities and alternatives in a situation—consistent with Martin and Rubin's (1995) definition of cognitive flexibility. In addition, entity theorists are often reluctant to adjust their thinking based on new information (Erdley & Dweck, 1993), indicative of lower cognitive flexibility (Deak, 2003) on the part of entity theorists. Lastly, incremental theorists endorse the belief that a person's behavior is not fixed by an underlying personality trait but rather is a response to the demands of a situation (Erdley & Dweck, 1993) consistent with Martin and Rubin's (1995) behavioral efficacy component of cognitive flexibility. We propose that incremental (vs. entity) theory leads to increased (vs. decreased) cognitive

flexibility and causes individuals to adopt a more abstract (vs. concrete) level of information construal. Study 1 demonstrated that individuals' implicit theory (measured via Levy et al.'s 1998 instrument) correlates with their level of action identification (BIF—Vallacher & Wegner 1989), so that stronger incremental (vs. entity) theory is associated with action identification on a more abstract level (vs. concrete level). Study 2 primed incremental (vs. entity) theory using Chiu and colleagues (1997b) manipulation and measured cognitive flexibility (Martin & Rubin 1995) and construal level. Manipulating incremental (vs. entity) theory led to greater cognitive flexibility. Increased cognitive flexibility, in turn, led to stronger preference for desirability/feasibility in product preference indicative of abstract/concrete construal (Yan, Sengupta, & Hong, 2016; Aggarwal & Zhao, 2015). In study 3, we primed implicit theory using the same procedure as study 2 and assessed construal using two measures. The first measure was a lottery choice (Aggarwal & Zhao, 2015): Lottery A offered a 1 in 100 chance of winning \$50, with the reward available immediately (preferred by concrete thinkers); Lottery B offered a 1 in 100 chance of winning \$65, with the reward available with a time-delay of three months (preferred by abstract thinkers). The second measure involved a product grouping exercise. Participants saw 6 groups of 4 products (one group at a time). Each group consisted of two product categories with two brands within each product category. For each group, participants indicated which products belong together (belonging to the same product category or to the same brand). We argue that product categories are superordinate to brands. Since product category reflects functionality of a product, it represents a primary feature, whereas brand reflects preference within a product category—a secondary feature. Incremental (vs. entity) theorists were more likely to select a lottery option with greater pay-off available after time delay (vs. lower pay-off available immediately) indicating abstract (vs. concrete) thinking. Incremental (vs. entity) theorists were more likely to organize products by product category (vs. by brand) also reflecting a tendency to think in superordinate (vs. subordinate) terms.

The current research furthers our understanding of consumer behavior by bridging two important theoretical frameworks—implicit theory and construal level. We identify that incremental theorists think more abstractly than entity theorists and that cognitive flexibility mediates this relationship. This finding is novel and has implications for the understanding of consumer behavior. As demonstrated by the results of our studies, incremental (vs. entity) theorists value desirability (vs. feasibility) in products choice, prefer financial products with greater pay-off amounts even if it requires time delay (vs. smaller pay-off amounts without time delay) and organize products by product category (vs. by brand). Future research should examine whether construal level may explain previously observed implicit-theory effects.

# Which Healthy Eating Nudges Work Best? A Meta-Analysis of Field Experiments

Romain Cadario, IESEG School of Management, France

Pierre Chandon, INSEAD, France

## EXTENDED ABSTRACT

Healthy eating nudges have generated a lot of excitement but, disappointingly, existing meta-analyses have only found average effect sizes ranging from null to moderate. Our work contributes to the many useful existing meta-analyses in terms of (1) scale and scope, (2) method, and (3) categorization of predictors.

In terms of scale and scope, we examine more than twice as many effect sizes as the largest existing meta-analysis. This is achieved despite focusing only on field experiments involving actual food choices (vs. perception, evaluation, or choice intentions) and conducted in field settings (onsite cafeterias, offsite eateries, or grocery stores) rather than in a laboratory or online. This allows us to offer guidance to restaurants, supermarket chains, and foodservice companies who want to help their customers eat more healthily but do not know which intervention will work best in their particular context; and to provide guidance for policy makers who need to forecast the effects that these nudges would have in real-world settings.

Methodologically, our meta-analysis differs from earlier ones on three levels. First, we formulate hypotheses about which healthy eating nudges work best and about the effects of eating behavior and of population and study factors. Second, to reduce the risk of confounds from univariate analyses, we employ a multivariate model incorporating all predictors simultaneously. Third, we include a three-level analysis to take into account the hierarchical structure of our data.

Finally, Figure 1 shows that we use a more granular predictor structure compared to existing meta-analyses, which either estimated the effect size of a single type of healthy eating nudge or compared the effect of one single difference (say, descriptive vs. evaluative labeling) and which rarely incorporated behavior, population, and study characteristics.

We distinguish between seven nudge interventions classified according to whether they are 1) cognitively-oriented, such as “descriptive nutritional labeling,” “evaluative nutritional labeling,” or “visibility enhancements”; 2) affectively-oriented, such as “hedonic enhancements or “healthy eating calls”; or 3) behaviorally-oriented, such as “convenience enhancements” or “size enhancements.” Our framework also accounts for the type of eating behavior (food selection or consumption) and distinguishes between healthy eating, unhealthy eating, and total energy intake. It also considers population characteristics such as age (children vs. adults), consumption setting (onsite cafeterias vs. offsite eateries vs. grocery stores), and location of the study (USA vs. other countries), as well as characteristics such as the duration of the study and its design.

Compared with existing univariate meta-analyses, our multivariate three-level meta-analysis of 300 effect sizes controlling for

eating behavior, population, and study characteristics yields smaller effect sizes overall. The average effect size of healthy eating nudges is  $d = .24$ , with a 95% confidence interval of [.16; .32].

In order to provide a more intuitive grasp of what this means, we computed the daily energy equivalent that one would expect from such an effect size using the method described in Hollands et al. (2015). Since  $d$  is the standardized mean difference, a  $d$  of .24 means that, on average, healthy eating nudges increase healthy eating by .23 standard deviations. Assuming that the standard deviation in daily energy intake is 537 kcal for an adult (Hollands et al. 2015), the average effect size of .24 translates into a  $.24 * 537 = 129$  kcal change in daily energy intake (-7.5% of the 1,727 kcal average energy intake). Given that a teaspoon of sugar contains 16 kcal, this is equivalent to about 8 fewer teaspoons of sugar per day.

Effect sizes increase as the focus of the nudges shifts from cognition ( $d = .12$ , -64 kcal) to affect ( $d = .25$ , -134 kcal) to behavior ( $d = .40$ , -215 kcal). Analyses at the level of each intervention type show even larger differences. For example, by switching from descriptive nutrition labeling to plate and portion size changes, cafeteria managers can expect to improve the effectiveness of their intervention by a factor of 14.

We also find that behavioral interventions are more effective in reducing unhealthy eating ( $d = .36$ ) than increasing healthy eating ( $d = .27$ ) or reducing total eating ( $d = .08$ ). Effect sizes are larger in the US than in other countries, in restaurants or cafeterias than in grocery stores, and in studies including a control group. Effect sizes are similar for food selection vs. consumption, for children vs. adults, and are independent of study duration. Compared to the typical study, one testing the best nudge scenario should expect a fourfold increase in effectiveness, with half due to switching from cognitive to behavioral nudges.

Overall, our results show that healthy eating ‘nudges work, help predict the impact of a particular intervention in a given environment, and highlight areas for future research. An online tool (<http://tinyurl.com/healthy-eating-nudge>) allows researchers to correct and update our data, turning our work into a “live” meta-analysis that can be continuously updated.

# When Zero Prices Backfire: A Dual-Process Model for Understanding Consumers' Reactions to Zero Prices

Fengyan (Cindy) Cai, Shanghai Jiao Tong University, China  
Xiaomeng Fan, Northwestern University, USA  
Galen V. Bodenhausen, Northwestern University, USA

## EXTENDED ABSTRACT

Both intuition and prior research indicate that people like inexpensive products and that free products are particularly attractive. Therefore, compared to a low price, a zero price can substantially enhance consumer demand (Shampanier, Mazar, and Ariely 2007). In this research, we show that a zero price can also backfire. We argue that zero pricing produces two parallel tendencies: positive feelings resulting from not having to spend money, plus cognitive scrutiny of the offer for nonmonetary costs (e.g., time costs, worries that the product malfunctions, etc.). If the nonmonetary costs are high, a close scrutiny can lead to greater concerns, which might override the immediate positive affect elicited by the free signal. As a result, a zero (vs. low) price will decrease consumers' intentions to take the offer. But if the nonmonetary costs are low, the scrutiny may lead to a low level of negative concerns. In that case, the positive affect elicited by the zero price will still have a dominant impact. Therefore, we hypothesize that

*Hypothesis 1* When nonmonetary costs for obtaining or using a product are high, a zero (vs. low) price decreases consumers' intention to try the product.

*Hypothesis 2* When nonmonetary costs for obtaining or using a product are low, a zero (vs. low) price increases consumers' intention to try the product.

In study 1, we used a 2 (prices: zero or low)  $\times$  2 (nonmonetary costs: high or low) between-subjects design. The context is about making a decision of taking a stress management course. Participants were 205 students from a large Midwestern university in the United States. In the high nonmonetary cost conditions, we told participants that the course would be given on another campus, about a 40-minute trip from the main campus where they usually study and live. Therefore, taking the course requires them to spend a significant amount of time and effort on travel. In the low nonmonetary cost conditions, we told them that the course would be held online, so there would be no traffic hassles in these conditions. Then we told participants that they could take the trial lesson either for free (zero price) or by paying \$2 (low price). Participants indicated their willingness to attend the trial lesson (1 = not at all, 7 = very much). Then, we asked them to write down their thoughts when they made the decision. We also asked them to indicate their feelings when they saw the offer (1 = very unhappy, 7 = very happy).

Results supported our hypotheses. When nonmonetary costs were low, participants in the zero (vs. low) price condition were more inclined to attend the trial lesson (3.49 vs. 2.94,  $F(1, 201) = 3.75$ ,  $p = .054$ ,  $\eta_p^2 = .02$ ). But when nonmonetary costs were high, participants in the zero (vs. low) price condition were less inclined to attend (2.50 vs. 3.12,  $F(1, 201) = 4.81$ ,  $p = .029$ ,  $\eta_p^2 = .02$ ). A coder blind to hypotheses and experimental conditions coded participants' thoughts. We formed an index representing concerns about nonmonetary costs based on the following ratio: (number of unfavorable thoughts about

nonmonetary costs – number of favorable thoughts about nonmonetary costs)/number of all thoughts. Consistent with our prediction, we found that a zero (vs. low) price prompted more concerns about nonmonetary costs only when nonmonetary costs were high (.40 vs. 0.19,  $F(1, 192) = 10.98$ ,  $p = .001$ ,  $\eta_p^2 = .05$ ) but not when they were low (.17 vs. .24,  $F(1, 192) = 1.04$ ,  $p = .31$ ). The results of a moderated mediation analysis further showed that positive affect significantly mediated the effect of zero (vs. low) prices on intentions to attend the lesson, irrespective of nonmonetary costs,  $b_{\text{high nonmonetary cost}} = .26$ ,  $SE = .12$ ,  $BC\ 95\% \text{ CI } [.04, .53]$ ,  $b_{\text{low nonmonetary cost}} = .42$ ,  $SE = .15$ ,  $BC\ 95\% \text{ CI } [.16, .74]$ . However, the mediation effect through concerns about nonmonetary costs was significantly moderated by the level of nonmonetary costs; the mediation effect was significant only when nonmonetary costs were high,  $b = -.15$ ,  $SE = .07$ ,  $BC\ 95\% \text{ CI } [-.34, -.04]$ , but not when nonmonetary costs were low,  $b = .05$ ,  $SE = .05$ ,  $BC\ 95\% \text{ CI } [-.03, .18]$ .

In study 2, we tested our hypotheses using a secondary data from a smartphone application that provides auto repair solutions to car owners. This application allows registered users to post questions regarding problems with their cars. The auto mechanics will answer their questions. Before May-27-2017, car owners could post questions and receive answers either for free or by offering a small compensation to the mechanics. However, after May-27-2017, the free service was discontinued. All questions would then need to include a small compensation for the mechanics. The nonmonetary costs in this situation are likely to focus on the risk of getting incorrect advice and thus having a bad consumer experience. We hypothesize that these risk will loom larger to the extent that one owns an expensive car. We obtained data regarding users who registered within 30 days before the policy change (30-days-before) or within 30 days after the change (30-days-after). Based on the users' car price information, we used a median split method to classify the users into two categories: expensive-car owners (perceiving high nonmonetary costs) and cheap-car owners (perceiving low nonmonetary costs).

The usage of the service application is reflected in two behaviors: registration and question-posting. The results on both behaviors are consistent with our hypotheses. First, discontinuing the free service increased the number of registrations among expensive-car owners ( $N_{30\text{-days-before}} = 14,674$ ,  $N_{30\text{-days-after}} = 21,487$ ) but decreased the number of registrations among cheap-car owners ( $N_{30\text{-days-before}} = 27,102$ ,  $N_{30\text{-days-after}} = 18,361$ ). Second, among the newly registered members, discontinuing the free service significantly increased the proportion of expensive-car owners who posted questions (30-day-before vs. 30-day-after: 23.69% vs. 33.69%,  $\chi^2(1) = 418.34$ ,  $p < .001$ ), but the effect was reversed for cheap-car owners (30-days-before vs. 30-days-after: 55.96% vs. 16.64%,  $\chi^2(1) = 7047.82$ ,  $p < .001$ ). These results demonstrate that our hypotheses can be generalized into real-world business practices.

# Consumers' Attitudes Towards Their Rights and Responsibilities in the Sharing Economy: An Ideological Perspective

Marylouise Caldwell, University of Sydney, Australia

Steve Elliot, University of Sydney, Australia

Paul Henry, University of Sydney, Australia

Marcus O'Connor, University of Sydney, Australia

## EXTENDED ABSTRACT

Despite consumers being essential to the exponential growth of the sharing economy, knowledge of their context-specific attitudes towards their rights and responsibilities is scant. This research addresses this gap by testing a novel hypothesised model mapping how consumers' moral foundations influence their political ideologies which in turn influence their attitudes towards their rights and responsibilities. The research context consists of Uber customers in the United States.

### Consumer rights

In 1985, The United Nations adopted eight basic principles of consumer protection: the right to basic needs, safety, be informed, choice, be heard, redress, consumer education and a healthy environment (Consumers International 2017). The applicability of these well-established principles is now being tested in the sharing economy. For example, BEUC—The European Consumer Organisation—notes: “questions emerge such as how existing laws regarding information provision or the liability of each party, apply in these new business models. This is why policy makers need to have a close look at this ‘collaborative economy’ to ensure it is delivering for consumers” (2016, 1).

### Mutual self-regulation

Fitzmaurice et al. (2016) argue that the consumer attraction to the sharing economy centres on a longing for marketplace exchanges imbued by a sense of greater intimacy, community, and moral obligation. The descriptive language linked to the sharing economy reflects such aspirations: sharing rather than exchanging, collaborating rather than competing, and peer-to-peer rather than corporate-to-consumer. The peer-to-peer feature of sharing economy exchange may promote a sense of mutuality—defined as “the sharing of a feeling, action, or relationship between two or more parties” (Oxford Dictionary 2017). An important part of this mutual self-regulation involves transparency and information sharing that fosters trust that exchanges will be fair. Reflecting this idea, this research proposes that consumers in the sharing economy may perceive such mutuality as an alternative form of (self) regulation to that of (or in addition to) imposed government regulation and/or onus on individual responsibility.

### The role of political ideology

Henry (2010) in his study of consumer rights and responsibilities employed a one-dimensional approach to political ideology that ranged from libertarian (individual autonomy) through to liberalism (social equality)—a case of self-reliance versus social support. The libertarian position abhors government intervention that impinges in any way on individual autonomy (Hayek 1978; Kekes 1997; Nozick 1974). Hence, small government is good government with heavy regulation of consumer rights likely to be rejected. Liberalism is less black and white. Rather, liberals recognise that a certain amount of inequality exists in everyday sociality, being a by-product of belief in significant motivation for individual advancement. These ideas suggest that liberals are likely to support both regulatory protection and individual responsibility. In particular liberals are likely to advocate

regulation to a far greater degree than libertarians, but place comparatively lesser onus on individual responsibility.

### Moral foundations

Haidt, Graham, and Joseph (2009) argue that political ideology is underpinned by distinctive moral foundations. These foundations can be thought of as a “system that enables people to perceive actions and agents as either praiseworthy or blameworthy” (Haidt, Graham and Joseph 2009, 112). They describe five categories of moral foundations that include avoiding harm/care for others, fairness/reciprocity in equal treatment of others, in-group/loyalty to your immediate group, authority/respect for hierarchy, traditions, and purity/sanctity, which refers to sense of virtue, decency and adherence to dominant norms of behaviour. Liberals are distinguished from the other ideologies in that they display a greater emphasis on avoiding harm/care for others and fairness/reciprocity. Conservatives are distinguished by a propensity for placing the greatest emphasis on in-group/loyalty, authority/respect, and purity/sanctity. These authors found that Libertarians are the least bound by moral foundations.

### Method

Consumers in the USA, who had used Uber at least once, formed the site of study. The Uber business model is typical of the sharing economy in that the Uber Corporation does not own the vehicles or physically interact directly with either drivers or passengers. Rather it acts as a platform that connects the driver and passenger. We employed two studies. The first was designed to develop and test measures for the three political ideologies (liberalism, libertarianism, and conservatism) and the three mechanisms that consumers perceive as facilitators of fair exchange (regulation, individual responsibility and mutual self-regulation). The second study added the Moral Foundations questionnaire (Graham et al. 2011) and tested the hypothesised model that flowed from left to right with moral foundations influencing political ideology which in turn influences consumer rights and responsibilities.

In study one, we developed and assessed a pool of 32 items set up as a Likert-type survey format with seven-point scales and administered the initial questionnaire via Amazon's M-Turk survey panel in the USA. The completed sample consisted of 496 consumers who had used the Uber app. From this sample we derived a theoretically appropriate solution of twenty items (3 rights items, 4 mutual self-regulation items, 3 individual responsibility items, 4 libertarian items, 4 liberal items and 2 conservative items). We then took this 6 factor solution into the second study. In study two, we included the thirty item Moral Foundations Questionnaire (Graham et al. 2011) along with the 6 factor solution derived in study one. We then used a second sample of 769 respondents to test the model using SEM.

### Findings

Overall, the hypothesised model displayed an excellent fit with all statistics exceeding recommended cut-offs (Hu and Bentler 1999). In summary, our hypothesised structural model - where moral attitudes tend to be associated with political views, which in turn influence consumer rights and responsibilities - is substantially veri-

fied. Liberals tend to emphasise Avoiding harm/Fairness, conservatives tend to emphasise Authority, and libertarians are influenced by Loyalty and Purity to a lesser extent. In terms of Consumer Rights and Responsibilities, liberals tend to equally emphasise Consumer Rights and Mutual Self-regulation, whilst conservatives emphasise all three aspects (Consumer Rights, Mutual Self-regulation and Individual Responsibility). Libertarians, not surprisingly, tend to focus exclusively on Individual Responsibilities.

# Pro-Environmental Waste Receptacle Labeling Can Increase Recycling Contamination

Jesse R. Catlin, California State University, Sacramento, USA

Yitong Wang, University of Technology Sydney, Australia

Rommel J. Manuel, California State University, Sacramento, USA

## EXTENDED ABSTRACT

Early research has suggested that point-of-disposal signage and recycling receptacle modifications can increase recycling rates (Austin et al., 1993). However, the once steady increase in overall recycling rates over the past few decades appears to be stalling, with the most recent data showing only a 0.6% increase from four years prior (US EPA, 2014). At the same time, there has been a substantial rise in the rate of contamination from placing unrecyclable materials in recycling receptacles, which has created significant additional costs in the follow-up processing (Grodén, 2015).

In four field and online experiments, we show that point-of-disposal signage aiming to encourage recycling (such as the term “landfill” on garbage bins) could also increase recycling contamination. Prior research suggests people are generally averse to being wasteful (Bolton & Alba, 2012) and that failure to recycle could engender feelings of guilt (Viscusi et al., 2011). Therefore, we reason that labeling garbage bins with pro-environmental terms could make emotions evoked by the negative consequences of garbage more salient and thus increase the likelihood that individuals will incorrectly categorize unrecyclable items as being recyclable.

In study 1 ( $n = 259$  observations), as part of a new product sampling event by a well-known brand of coffee and related products, we offered passersby on a university campus the opportunity to sample a carbonated beverage (served in an unrecyclable foam cup). The study site featured two swing-top bins to dispose of their used sample cups. The label on one bin was experimentally manipulated to be either “Landfill” or “Trash”. The other bin was labeled as “Recycle” in both conditions. The rate of (incorrect) recycling increased to 54.5% (67 out of 123 cups) when the “Landfill” label was used compared to 25.0% (34 out of 136 cups) for the “Trash” label ( $\chi^2(1) = 23.58, p < .001$ ).

In study 2 ( $n = 122$  observations; minimum of 33 observations per condition), during a separate beverage sampling event several weeks after the study 1, using the same procedures and unrecyclable cups as study 1, we tested additional types of labels including (i) control: “Trash” and “Recycle”, (ii) avoid garbage: “Don’t Destroy the Earth, Trash Less” and “Recycle”, (iii) encourage recycling: “Trash” and “Save the Earth, Recycle More”. Compared to the control condition, the recycling rate of the foam cups significantly increased in the avoid garbage condition (19.6% vs. 60.5% respectively;  $\chi^2(1) = 15.58, p < .001$ ) and marginally significantly increased in the encourage recycling condition (19.6% vs. 39.4% respectively;  $\chi^2(1) = 3.76, p = .052$ ).

Study 3 ( $n = 225$ ; minimum of 51 participants per condition) provided some preliminary evidence of the underlying mechanism. Participants were randomly shown one pair of receptacles used in Studies 1 or 2 and an image of an empty potato chip bag. They were asked to imagine that they had disposed of the chip bag in the trash/landfill bin and to indicate how much they felt ashamed/guilty/embarrassed/bad/happy/good/proud/pleased (scale endpoints: 1 – Strongly disagree; 7 – Strongly agree; Donnelly et al. (2017) and Sun & Trudel (2017)). Participants then were asked how likely they were to retrieve the potato chip bag and instead dispose of it in the Recycling Bin (scale endpoints: 1 – Very unlikely; 7 – Very likely; Trudel et al. (2016)). We found that the mean intention to recycle of the “Saving the Earth” condition was not significantly different from the

baseline condition ( $F(1, 102) = 1.92, p = .17$ ) but the mean intention to recycle in the “Don’t Destroy the Earth” condition ( $F(1, 105) = 6.59, p = .01, \eta_p^2 = .06$ ) and the “Landfill” condition ( $F(1, 109) = 7.09, p = .01, \eta_p^2 = .06$ ) were significantly higher than the baseline condition. Similarly, the negative emotion index in the “Saving the Earth” condition was not significantly different from the baseline condition ( $F(1, 102) = 0.048, p = .83$ ) but the mean intention to recycle of the “Don’t Destroy the Earth” condition ( $F(1, 105) = 4.09, p = .046, \eta_p^2 = .04$ ) and the “Landfill” condition ( $F(1, 109) = 15.11, p < .001, \eta_p^2 = .12$ ) were significantly higher than the baseline condition. Lastly, the positive emotion in the “Saving the Earth” condition ( $F(1, 102) = .09, p = .76$ ) and the “Don’t Destroy the Earth” condition ( $F(1, 105) = .73, p = .40$ ) were not significantly different from the Baseline condition, but the mean positive emotion index of the “Landfill” condition ( $F(1, 105) = 15.49, p < .001, \eta_p^2 = .12$ ) was significantly higher than the baseline condition. We tested the mediation role of positive and negative emotions in each pairwise comparison. The results showed that across all mediation analyses, negative emotions were consistently mediating the effect while the results for positive emotions were less consistent.

Study 4 ( $n = 60$  observations; 30 per condition) explored a way to mitigate the previously observed contamination by incorrect recycling of unrecyclable items. Specifically, we conducted a before-and-after field experiment involving six different garbage/recycling bin pairs on a university campus to test the mitigating effect of a pictorial guide illustrating proper item disposal. We measured the contents of these bins in the first week as the baseline condition. In the next week, both garbage bins and recycling bins were labeled with pictorial guides featuring appropriate items to be placed in each bin. The results show that the proportion of unrecyclable items (excluding wrappers) placed in the recycle bin was marginally significantly reduced when the bins featured pictorial guides (26.7% vs. 32.5%;  $t(29) = -1.48, p = .075$  (one-tailed)). The proportion of unrecyclable wrappers placed in the recycle bin was also marginally significantly reduced when the bins featured pictorial guides (21.4% vs. 27.7%;  $t(29) = -1.54, p = .067$  (one-tailed)). And there was no statistically significant change in the proportion of recyclable items placed in the recycle bin (80.2% vs. 79.7%;  $t(29) = .09, p = .464$  (one-tailed)).

In sum, our studies suggest that if proper steps to educate people about accurate disposal are not taken common efforts to increase recycling rates through receptacle labeling (e.g., using the term “landfill” on garbage bins) could lead to higher recycling contamination because of the emotions evoked by these labels.

# Understanding Trust Formation in Peer-to-peer Social Commerce

Lena Cavusoglu, Portland State University, USA  
Deniz Atik, University of Texas Rio Grande Valley, USA

## EXTENDED ABSTRACT

Many users perform informal commercial transactions (e.g., no contracts, invoices, or official guarantees) on Instagram to sell and buy clothes, accessories, art, or even puppies. We call these informal, peer-to-peer social media markets “Insta-shops.” Insta-shop activities fit within the scope of social commerce because they comprise a commercial activity platform on one of the most popular social networking sites, Instagram, which allows for peer-to-peer interactions (Liang and Turban 2011). Insta-shops are fascinating to study because it not only contributes to the academic literature on peer-to-peer social commerce markets, but also provides significant insights on trust formation when the risk of vulnerability is involved.

Researchers have extensively discussed the issue of trust and its significance in the context of e-commerce (e.g., Morrison and Firmstone 2000). However, since social commerce is a relatively new research domain, studies on trust formation in this setting are scarce. Also, while some studies (e.g., Liang et al. 2011; Hajli et al. 2017) have investigated how peer recommendations, reviews, and ratings increase familiarity with the platform and, thus, positively influence the perceived trustworthiness of a particular social commerce site, no prior research has considered who the reviewer is and how the online identity of that reviewer affects trust formation. Within the Insta-shop context, this study attempts to analyze the links between online identities, trust formation, and purchasing behavior. For this purpose, we employ the media credibility framework, which has three theoretical dimensions: medium credibility, source credibility, and message credibility (e.g., Cosenza et al., 2015). With this study we propose a new dimension to these existing credibility evaluations: social credibility.

Since this study focuses on trust formation in social commerce by investigating the motivations and experiences of both consumers and sellers, a qualitative inquiry using semi-structured, open-ended, in-depth interviews was appropriate to provide a greater breadth of data (Fontana and Frey 2000). Seventeen semi-structured, in-depth interviews were conducted with Insta-sellers and Insta-consumers. For an overall understanding of a given phenomenon, a combination of visual and textual imagery is crucial (Highfield and Leaver 2014). Therefore, we gathered images from our informants to fully understand the influence of Instagram visuals on trust. A total of 51 images were analyzed regarding their textual and graphical components, and the results were incorporated with the textual analysis.

All transcripts were examined manually using the open-coding method by one researcher who was more familiar with the research setting. Once the labeling process was complete, the findings were grouped for each interview. Similar patterns and irregularities between transcripts were checked. As suggested by Creswell (2003), to achieve reliability in the analysis, researchers identified the core categories using selective coding. Two researchers carried out regular checks of the transcripts, codes, their self-reflectivity, and theory to achieve credibility in the findings until they came to a substantial agreement.

Our findings reveal three primary motivations of sellers and consumers to shop from and sell on Instagram: 1) social influence, 2) convenience, and 3) economic gain. There is a significant relationship between these motivations and trust formation toward the medium. Social influence is linked to the logic of “following the crowd.” Convenience is related to the platform’s ease of use. Both consumers

and sellers trust a medium that is easy, time-efficient, and does not require advanced technical knowledge. Consumers find the entire Instagram shopping journey, from search to purchase, fast and straightforward, while sellers consider Instagram to be the most interactive selling tool. Lastly, consumers choose Instagram to have a smooth shopping experience with competitive pricing, and sellers believe Instagram is a way to make money more quickly compared to using other social media platforms. The unique benefits of Instagram, its popularity, and the opportunity for economic gain positively influence trust formation towards the medium.

Since the source communicates cues that are more specific about a vendor’s trustworthiness, medium credibility is followed by source credibility (Lucassen and Schraagen 2011). On Insta-shops, consumers check cues such as product presentation; user reviews; and the number of followers, likes, and comments. After checking the shop’s background, if consumers decide to communicate with the seller, they use WhatsApp, which leads to the formation of message credibility.

Aware of the increasing number of phishing scams by fake accounts (e.g., having paid followers, likes, and comments), consumers feel the need to extend their evaluations beyond the seller and the shop and look for personal and social proof based on other users. Beyond the examples mentioned above for medium, message, and source credibility, a new dimension appears in our research. Trust is also formed by “cyberstalking” the personal Instagram accounts of strangers who are customers, fans (i.e., followers, likers, and reviewers), or sales representatives (i.e., Insta-sellers). We call this new dimension “social credibility” and define it as the influence of others’ online identities on trust formation in a social commerce environment. We found social credibility as an important characteristic of social commerce that is not seen in B2C or peer-to-peer e-commerce environments such as Amazon, E-Bay, and Etsy as these shopping sites do not allow consumers to view the social media profiles of others. Although it is possible to read third-party insights about the quality of the products and the shopping experience in the form of reviews, it is not possible to find personality clues about the owners of the reviews.

In the Insta-shop context, consumers prefer to shop from people they know, like, and trust. Instagram hosts a great amount of personal information—such as one’s hometown, living arrangements, social circles, occupation, travels, hobbies, leisure activities, family, and appearance—to allow a user to know a person. For social credibility, consumers randomly choose someone from an Insta-shop’s followers, likes, and comments and lurks about that person’s Instagram profile to collect social cues. If a consumer can identify with others based on their appearance, such as body type and size; the way they dress; the brands they use; their hobbies and lifestyle; their occupation; places they have checked in; their possessions; social circles; travels; and the way they take photographs, then trust is established.

# Magic Hands? How Hand-Holding Appeal, Food Type, and Contamination Effects Impact Food Advertising Effectiveness

Chun-Tuan Chang, National Sun Yat-sen University, Taiwan

Xing-Yu (Marcos) Chu, Nanjing University, China

Chun-Chen Tsai, National Sun Yat-sen University, Taiwan

Dickson Tok, National Sun Yat-sen University, Taiwan

## EXTENDED ABSTRACT

Hand models are prevalent in advertising where advertisers want close ups of the product being handled. Observations from massive amount of ads suggest numerous ways to present a hand. For example, a common way is to present a visual hand holding a product directly. Sometimes, advertisers present a visual hand holding a product with its package to reduce consumers' worry feelings of contamination. Instead of using a visual hand, advertisers ask consumers to imagine hand-holding through verbal description in the tagline (e.g., "Enjoy your curry with hands"). Because of the overwhelming use of hand images in food advertising and the divergence in the type of images used in practice, the current research attempts to examine how the three hand-holding appeals above (visual hand holding the product directly [VH] vs. visual hand holding the product package [VHP] vs. verbal hand [VRH]) impact consumer outcomes and responses toward the product.

Physical touch plays a double-edged sword in the evaluation of consumer products (Mooy and Robben 2002; Peck and Childers 2003). Merely touching an object increases an individual's perceived ownership of the object and such psychological ownership enhances affective response and product evaluation (Peck and Shu 2009). Negative contamination effects may result in decreasing product evaluation when a consumer aware of the product has previously touched by another consumer (Argo et al. 2006).

We propose that the choice of hand-holding appeals is subject to different types of foods. Virtue foods are purchased and used primarily to satisfy the practical or functional needs of consumers—health-oriented utilization (Rozin, Ashmore, and Markwith 1996). As people believe the source transfers a contagious essence to the target through touch, product cleanness and hygiene are closely associated with health benefits (Castro, Morales, and Nowlis 2013). People often react mindlessly to stimuli that trigger certain automated responses (Cialdini 2001). When consumers see a virtue food being held with VH in an ad, the worry of microbial contamination and negative contamination should profoundly decrease virtue food evaluation. VRH may remove such perceived risk of contamination. Furthermore, consumers can experience mental simulation (Bower and Morrow 1990). VRH is expected to work in virtue product evaluation.

Vice foods are more difficult to justify because the pleasure and enjoyment they provide come at the expense of long-term health (Okada 2005; Shiv and Fedorikhin 1999). Vice food generates positive affect (pleasure, delight and gratification) and negative cognition (harmful health-related, Kilgore et al. 2003) simultaneously. When the impact of the positive affect is greater than that of negative cognition, consumers will feel less conflict in the interplay between affect and cognition (Nowlis and Shiv 2005; Shiv and Nowlis 2004), resulting in increased taste and subsequently preference for unhealthy choices (Poor, Duhachek, and Krishnan 2013). Compared with VRH, VH indicates a stronger haptic element in advertising, strengthens indulgent feelings, and increases feelings of pleasure and reward. Visual cues of food serve as reinforcement cues that can lower self-control (Forzano and Corry 1998). VH is expected to be more persuasive than VRH in vice product evaluation.

In Study 1, we conducted a 3 (ad type: VH vs. VRH vs. no hand at all) X 2 (food type: virtue vs. vice) between-subjects experiment. The no-hand ad condition served as a baseline group. Orange juice and orange soda served as the virtue and vice food respectively. The results showed that for virtue food, VRH was more effective in generating positive attitudes toward the brand than VH. For vice food, opposite results were found.

In Study 2, we examined whether the effect of a visual hand with the product directly (VH) or indirectly (VHP) and VR on advertising persuasion is differed subject to food type. A 3 (hand-holding appeal: VH vs. VHP vs. VRH) X 2 (food type: virtue vs. vice) between-subjects design was conducted with chicken wrap as the test product. The results indicated that when facing virtue food, participants exposed to the VRH ad showed the highest purchase intention, followed by those exposed to VHP and finally the ones exposed to VH. When facing vice food, participants exposed to VH showed the highest purchase intention, followed by those exposed to VRH, and finally the ones exposed to VHP. The contamination effect was tested as the underlying mechanism.

In Study 3, the experimental design was the same as that in Study 2, but conducted in a field setting. The experiment was conducted in collaboration with a café on the campus of the university. Participants were told that a new cupcake would be launched, and they could decide the cupcake price only for these three days since the café were collecting customer feedback. Each person could purchase only one cupcake. The actual amount spent on a cupcake served as the dependent measure. For the virtue condition, participants exposed to VRH paid most, followed by the ones exposed to VHP and the counterparts exposed to VH. For the vice condition, participants viewing VH paid the most, followed by those exposed to VRH, and the ones exposed to VHP.

Our findings make several theoretical contributions. First, we examine how hand-holding appeals may serve as a heuristic cue to increase or decrease product evaluation, and such effects are subject to food type. Second, the current research contributes to this evolving research stream by adopting both objective and attitudinal measures in its examination of product evaluation behavior. Third, this investigation also contributes to food lay theories, which have received recent attention.

This research provides important practical implications. Our findings raise the issue of how marketers might leverage a hand-holding appeal to enhance product evaluation. Our research suggests that VH can be a double-edged sword. Restaurants can benefit from our study as well. Those that wish to offer virtue foods on their menus should avoid using VH in their posters. However, restaurants should show VH when promoting their vice foods. Therefore, marketers need to be judicious when using VH, VRH or VHP to make sure they take food type into consideration.

# When Negative Observations Broaden Generalization of Product Attributes to Novel Products

Rui Chen, Tarleton State University, USA  
Marcus Cunha Jr., University of Georgia, USA

## EXTENDED ABSTRACT

Consumers often face decisions involving generalizing knowledge from known to novel products. For example, consumers who plan to purchase stocks of “tow trucks” may need to generalize their knowledge from “cars” to “tow trucks” if they know that the stock prices of “cars” will drop due to new tariffs. Extensive research has focused on examining the effect of adding positive premises (i.e., those that confirm the knowledge can generalize to some specific categories) on the likelihood to generalize (e.g., Smith et al. 1993; Hayes, Heit, & Swendsen 2010; Osherson et al. 1990). However, in many situations, consumers face a mixed set of premises. Prior research about generalizing processes either was silent in the effect of negative premises or documented mixed findings (e.g., Voorspoels et al. 2015, Heussen et al. 2011).

One stream of research documented that individuals generalize knowledge as a function of the number of positive premises and how diversified the premises are. For example, monotonicity rule suggests that the likelihood to generalize tends to increase as the number of positive premises increases (Smith et al., 1993; for summaries, see Hayes, Heit, & Swendsen, 2010). Diversity principle indicates that individuals are more likely to make generalizations when the positive premises constitute a more diverse set of evidence (Lopez 1995, Osherson et al. 1990). They converge to imply that negative premises will decrease the likelihood to generalize given the symmetry between positive and negative evidence. In contrast, reasoning-based processes suggest that individuals tend to make generalizations when they can reason about generalizing in light of available premises (McDonald et al. 1996; Bruner 1957). Specifically, individuals often formalize the initial proposition about positive premises and their relation to unknown, novel stimuli, and further evaluate the proposition in light of other available premises (Medin et al. 2003). This implies that a negative premise from a distantly related product category may help consumers verify the temporarily held proposition. Since consumers often believe that dissimilar products feature the attributes different than those of similar products (Noseworthy et al. 2012), a negative premise about a product dissimilar to a novel product may increase the likelihood to generalize these attributes to the novel product.

This paper investigates an under-studied pattern of generalizing in which consumers are more likely to generalize to novel products when a negative observation from a distantly related product category was added. Results from three experiments documented this effect and shed a light on the underlying mechanism.

Study 1 supported that consumers are more likely to generalize knowledge to novel products when a negative premise from a distantly related category is added comparing to when a positive premise from a close category is presented alone. The design was a 3 premise conditions (i.e., positive premise alone vs. positive premise + a close negative premise vs. positive premise + a distant negative premise; between-subject) X 8 scenario replicates (within-subject) mixed design. In each of the eight scenarios (i.e., cheese, leisure activities, payment methods, Airbnb rates, vegetable, drink, music, sports activities), participants were presented a set of premises depending on which premise condition they were randomly assigned to. Then, they were asked to indicate the likelihood to generalize what they learned in the premises to a novel product on a 100-point sliding scale. The

analysis yielded a main effect of premise condition ( $F(2, 119) = 34.00, p < .000$ ), with participants reporting a greater likelihood to generalize to novel products when a distantly related negative premise was added comparing to presenting a positive premise alone. In contrast, an additional, closely related negative premise decreased the likelihood to generalize.

Study 2 replicated the effect in study 1 in the contexts more related to consumers and showed that the effect could carry over to influence purchase intention. The design was a 3 premise conditions (between-subject) X 3 scenario replicates (within-subject) mixed design. Different from study 1, after reporting the likelihood to generalize to novel products, the participants in study 2 also indicated their intention to purchase the novel products on a 7-point scale. The analysis revealed that the participants exposed to an additional, distantly related negative premise were more likely to make generalizations about novel products ( $F(2, 87) = 29.80, p < .000$ ) and intend to purchase the product later on ( $F(2, 87) = 14.39, p < .000$ ) and those receiving an additional, closely related negative premise indicated the otherwise.

Study 3 explored when the effect of a distantly related negative premise would be offset. In line with reasoning-based processes, we propose that the effect is offset when the initial proposition covering positive premises and unknown, novel stimuli is not utilized. Specifically, this occurs when consumers can immediately access more diagnostic information than the proposition that they need to make efforts to formalize. Thus, different from study 2, we imposed a prior belief in terms of breadth of generalizability among participants at two levels: broad versus narrow generalization. We predict that consumers imposed with a prior belief in broad generalization will be forced off the path of forming the initial proposition and further evaluating the proposition in light of negative premises, leading to a null effect of negative premises. The study was a 2 premise conditions (P1+ vs. P1+PD-; between-subject) X 2 levels of generalizability (broad vs. narrow generalization; between-subject) X 3 scenario replicates (within-subject) mixed-design. The analysis revealed a significant interaction effect of premise condition by prior belief in breadth of generalization ( $F(1, 96) = 5.30, p = .024$ ). When the participants held a prior belief in broad generalization, the effect of a distantly related negative premise was offset. In contrast, the effects observed in study 1 and 2 were replicated for the participants who held a prior belief in narrow generalization.

This paper documented a puzzling effect in which consumers broaden generalization of product attributes to novel products in presence of an additional, distantly related negative premise. We also showed that the effect only occurs when consumers hold a prior belief in narrow generalization.

# Accounting for Gains From Discounted Credit

Andong Cheng, University of Delaware, USA

Ernest Baskin, Yale University, USA

## EXTENDED ABSTRACT

Purchasing and spending “discounted credit” is becoming increasingly prevalent. Discounted credit is store credit that can be purchased at a price lower than its redeemable value, such as when a consumer pays \$80 for a \$100 restaurant voucher. When a consumer buys discounted credit and later redeems that credit for a store purchase, that purchase indirectly has a lower cost to that consumer than the purchase’s market price. Discounted credit appears on the market either through retailers and third-party businesses selling directly to consumers or through the customer-to-customer gift card resale market (Groenfeldt 2014).

This project explores the mental accounting of how consumers organize the gains derived from discounted credit. Specifically, as a consumer applies a single discounted credit to make multiple purchases across time, an open question is how do the gains derived from the credit gets divided across these perceived purchase costs. This topic pertains to mental accounting, defined as the ways consumers psychologically organize money into different accounts as an act of self-control (Heath and Soll 1996; Thaler 1999). Because mental accounting is known to be malleable (Cheema and Soman 2006), several mental accounting possibilities may occur when spending discounted credit. A first possibility is that consumers mentally decrease their perceived cost of each purchase proportional to the credit’s discount percentage (e.g. “I purchase this credit at 20% off, so all purchase made with this credit feels 20% off). However, another possibility is consumers can mentally divide their credit gains to offset subsequent purchase costs in a more disproportional manner (e.g. “Purchase 1 feels like it is \$20 cheaper, but Purchase 2 feels undiscounted”). In this paper, we find that discounted credit is frequently *disproportionally* mentally allocated to offset redeemed purchase costs and explain why this occurs.

In study 1, university student participants were randomly assigned to receive one of two promotional offers at a donut store: 1) discounted credit (pay \$12 for a 12 donut punchcard) vs 2) control discount (get \$50% off each donut). Donuts are labeled to cost \$2 each. Participants reported how much they feel like their first donut would cost upon getting the promotion. Participants in the discounted credit condition (vs control condition) reported feeling that their first donut in the store costed an average of \$2.24 (vs \$1.26);  $F(1,186)=7.19, p<.01$ . Participants in the discounted credit condition were reluctant to mentally discount the cost of their initial donut even though it was redeemed with a discounted credit. This is initial evidence that consumers do not evenly distribute savings derived from discounted credit towards redeemed purchases in equal proportions, as they did not perceive their initial purchase to be less expensive by 50%.

In study 2, we introduced all participants to the following scenario: “Imagine that you purchased a \$200 gift card from Target for \$100, a 50% discount. Later, you make four separate \$50 purchases with that gift card (in sequence Purchase 1, Purchase 2, Purchase 3, and Purchase 4). Knowing this, how much do you perceive each purchase to cost?” Participants filled in their perceived cost values for each purchase. Results suggests that 48.5% of participants wrote \$25 for each Purchase 1 to Purchase 4, but the remaining participants wrote different amounts across the four purchases. For those whose

answers differed across purchases, here are the average perceived costs for each purchase: Purchase 1=\$39.24, Purchase 2=\$24.45, Purchase 3=\$16.32, Purchase 4=\$19.98. This study exposes us to the idea that consumer don’t necessarily discount all purchases made by the same discounted credit equally; further, participants tend to feel that purchases made later in a sequence feel less expensive than purchases made earlier.

We theorize that consumers are reluctant to mentally take a consistent percentage off all purchases made by one discounted credit because they naturally weigh in, at different redemption points, the likelihood of redeeming the entire value of their credit when they estimate perceived costs of each redeemed purchase. In study 3, we track how consumers’ uncertainty of being able to redeem an entire discounted credit across multiple redemption points influences perceived costs of redeemed purchases. Participants imagined buying a new pass (pay \$48 upfront for a \$96 value pass) that can be used on four classes. Those in a certain (uncertain) condition were told they will definitely (possibly not) go to all four classes. We sequentially asked participants to report how much they perceived each class (Purchases 1-4) to cost. We ran a mixed ANOVA analysis with uncertainty as the between subjects variable, purchase number as the within subjects variable, on perceived cost and found a significant interaction effect (Wilks’ Lambda=4.05,  $p=.008$ ). Within-subject contrasts suggested that the interaction had a linear trend ( $F(1,297)=11.32, p=.001$ ), suggesting that those who were uncertain that their discounted credit would be depleted thought that their purchases felt dramatically sequentially less expensive as they depleted more of the credit while those who were certain that their discounted credit would be depleted more frequently recorded that each of their purchases’ costs felt equally discounted.

We found initial evidence that under a range of contexts, consumers who pay for purchases using a single discounted credit do not mentally distribute their derived gains to offset the perceived cost of multiple purchases by a consistent proportion. Initial purchases made by a discounted credit feels more expensive than last purchases (when the credit is about to be depleted), suggesting that sequence of purchase when redeeming discounted credit impacts perceived costs consumers are paying. This finding suggests that consumers using discounted credit can dramatically alter how they perceive present purchase costs depending on their assessment of the likelihood of future decisions and makes an addition to mental accounting theory.

# Stigma at Every Turn: Exploring Bi+ Consumer Experiences

Abigail Nappier Cherup, University of Nebraska-Lincoln, USA

Andre F. Maciel, University of Nebraska-Lincoln, USA

## EXTENDED ABSTRACT

The lesbian, gay, bisexual, transgender, and queer (LGBTQ) community has commonly been considered a 'Dream Market' segment for mainstream marketers in the United States (Peñaloza 1996), with a purchasing power nearing \$1 trillion (Green 2016). Within this community bi+ consumers make up the largest segment: about 40% (Pew Research Center 2013). Bi+ individuals are those that experience attraction to more than one gender (Burchard 2006). Despite being the largest group within the LGBTQ community, this social category remains understudied in consumer research. In response to this oversight, this study explores the consumer behavior of bi+ individuals, with an emphasis on how they interact with marketing communications and servicescapes.

Given the scant academic knowledge of this social category, we employ a grounded-theory approach (Charmaz 2014; Glaser and Strauss 1967). We sampled twenty-two consumers who self-identify as bi+. They were recruited through LGBT Resource Centers on two different college campuses, one city Pride Center, informal networks, and snowball sampling. Informants' ages ranged from 19 to 48, with interviews lasting between 25 and 95 minutes.

Interviews covered informants' generic experiences in the marketplace. They also included a projective section (Heisley and Levy 1991), in which the first author used mainstream LGBTQ-themed ads to further probe participants to share their experiences as consumers. Interviews were tape recorded and transcribed. Analysis relied on data-driven coding, the constant comparison method, memoing, and an iterative engagement with the literature on representation and stigma (Charmaz 2014; Spiggle 1994). We developed themes to represent informants' distinctive consumer experiences.

Bi+ individuals are the largest group in the LGBTQ community. Whereas one may think that this leads to them being well accepted, instead we find that they experience stigma both inside and outside the community. This dual stigma is shaped by two gender normative discourses. One is heteronormativity, a long-standing notion that prescribes as normal people who have sexual interest in what is culturally construed as the opposite sex (Meyer 2010). The other is homonormativity, a more recent expectation that emerged with the gay rights movement and further marginalizes queer identities that do not fit into traditional gender norms (Ng 2013). Bi+ identities are not visible in either heteronormative or homonormative representations. Bi+ individuals cope with this multi-layered stigmatization in two main ways, by seeking representation and confronting representation in the marketplace.

Bi+ consumers look for representation of their identity in marketing communications. For example, Eleanor seeks out media that she feels offer positive representations of lesbian women. This tangential identification offers bi+ individuals the ability to feel a sense of belonging in the LGBTQ community. Bi+ consumers also actively search for representation. For example, Suzanne has started a LGBTQ book club. According to her, bi+ literary representations are not as vivid as visual depictions, or as easy to find as a bestseller, but they help individuals find some way of seeing their identity represented. In seeking representation, bi+ consumers find a sense of self that is often invisible in mainstream marketing communications.

When confronting negative representations or invisibility, bi+ consumers are critical when interpreting ads and in their purchase behavior. Cherrie notes that anytime two women are pictured together

er they are assumed to be representing lesbianism, not bisexuality, and are hypersexualized. Jess recalls an experience when she and her partner attended a Pride event in the downtown part of their city and needed a place to stay overnight. Seeing the rainbow colors that signify Pride on the Marriott hotel, Jess felt secure in staying there. By using community signifiers, Marriott signaled that it is a legitimate brand of the LGBTQ community (Kates 2004), or a company that offers services to the community such as a sense of safety. Informants educate themselves about legitimate brands by paying attention to marketing communications, community initiatives, and how the brand ranks on workplace equality. These efforts help bi+ consumers avoid stigma and vulnerability (Rowe and Rowe 2015).

In short, bi+ individuals hold a unique position, at the boundary between straight society and the LGBTQ community. Goffman (1963) discusses the ways in which members of a subordinate group face stigma at the hands of the dominant group. However, bi+ individuals make up a stigmatized identity status between the dominant (straight) and subordinate (LGBTQ) groups. They must cling to the closest representations they can find of bisexuality in mass media and patronize places that only occasionally embrace their marginalized identities.

These findings offer insights for marketing academics and practitioners. First, businesses that wish to cater to the LGBTQ community may be unaware that the largest portion of the community feels unwelcome and unsafe in their establishments. Informants shared experiences of violence in mainstream establishments as well as those that serve the LGBTQ community. This work shines a light on a unique type of dual stigma that has implications for all service providers, especially those in the LGBTQ community.

Second, consumers with bi+ identities challenge representational norms as they interpret advertising messages and firm motives. Informants are critical of negative representations and erasure of their identities (Bennett et al. 2016). Bi+ identities have been stereotyped as sexually greedy and non-monogamous (Meyer 2010). Therefore, an advertising norm, sex, does not sell within this demographic. Advertisers seeking to tap into this segment of consumers should educate themselves on community values and incorporate them into their marketing communications.

While this project explores the consumption behavior of individuals with bi+ identities, further work must examine the consumption of other "in-between identities," such as biracial and bicultural consumers. Bi+ individuals find themselves walking a tightrope at the boundary between two communities to which they should belong yet experience stigma at the hands of each. Additionally, bi+ individuals make up a distinct market segment, yet experience either negative, stereotypical portrayals or all out erasure in the marketplace. Similarly, biracial consumers live in two social worlds, experience invisibility of their unique identity, and make up a viable market segment (Harrison, Thomas, and Cross 2015). Future work must explore the similarities and differences between these multiple identities and further develop the notion of dual stigma.

# Potions and Antidotes for Jekyll: What Summons Moral Identity in Product Choices

Young Joo Cho, Korea University Business School, Republic of Korea

Y. Rin Yoon, Korea University Business School, Republic of Korea

Jongwon Park, Korea University Business School, Republic of Korea

## EXTENDED ABSTRACT

Many consumers identify themselves as advocates of human rights and environmental sustainability. Does this mean they are also loyal customers of sweatshop-free garments and compostable bags of chips? Prior findings suggest this is often not the case. Rather, the effect of moral identity seems particularly weaker in product choice domain. The “30:3 phenomenon,” coined by Cowe and Williams (2000), refers that while about 30% of consumers claim their moral intention when asked, only 3% of consumption choices represent such intention. Studies have shown that though consumers maintain product morality is an important purchasing factor, it does not portend actual choices (e.g., Aaker, Vohs, and Mogilner 2010; Obermiller et al. 2009; Auger et al. 2008). One line of reasoning suggests that this is because products with moral traits are perceived to have inferior qualities in comparison to those without (Aaker, Vohs, and Mogilner 2010; Obermiller et al. 2009), and also because most consumers choose functionality over morality in a tradeoff between moral and functional product attributes (Auger et al. 2008).

Understanding why such attitude-behavior gap is observed irrespective of the strength one’s moral identity, and how this partiality can be attenuated is of both theoretical and practical importance. The present research provides insights into this matter. As will be elaborated next, we expect that the impact of moral identity diminishes under consumption context, as the moral relevance of decision is obscured by the prevailing commercial, self-benefit focused mindset.

Research has shown that moral identity increases a wide range of moral behaviors (e.g., Aquino and Reed 2002; Frimer and Walker 2009; Hardy 2006). Unlike charity donation and volunteering that are typically used in the moral identity research, consumption is not socially defined as a moral behavior. Rather, a traditional code of conduct in consumption is to make an economic and self-beneficial decision. We assume that unless the imminent choice act in the domain of consumption is perceived to be highly related to morality, moral identity may be overridden by another identity, thus decreasing the likelihood of making moral choices. Consistent to the identity-based-motivation model (Oyserman 2009), we further predict that contextual factors that make the consumption choice task deem more morally relevant can increase the impact of moral identity. We suggest simply informing consumers about ethical attributes is not enough, because consumers will process the information after having already been subjugated to the norm of consumption context: that one should opt for the most self-benefitting alternative. For a consumption choice task to be deemed morally relevant, we propose that cues need to alter the framing of the choice act. Five experiments provide consistent support for this theorization.

Study 1 (N=109) provide evidence that the effect of moral identity decreases in consumption purchase context, such that moral behavioral intention reduces. In particular, the effect of moral identity on moral behavioral intention was lower when participants were asked to decide whether to choose a morally superior product over a functionally superior alternative, versus when they were asked to make a donation to a charity ( $b = 3.39, t(107) = 2.84, p < .01$ ).

Studies 2 and 3 provide further evidence that the impact of moral identity on moral consumption choice is augmented when the choice context becomes more morally relevant. In study 2 (N=93), a same choice act between a more environmentally friendly and a more

powerful detergent was framed as related to either moral context (donation) or non-moral consumption context (personal shopping). We found that participants’ moral identity increases the ethical choice of in the moral context, but not in the consumption context ( $b = -.56, z = -2.08, p < .04$ ). Study 3 (N=252) varied the perceived relevance of a choice task to morality by manipulating the presentation order of product information. Presenting the ethical attribute first versus last made the product choice task more ethically relevant, thus making the effect of moral identity more pronounced ( $b = -0.23, t(250) = -2.16, p = .03$ ). These results together suggest that the factors which induces people to attend and process the difference along ethical attribute in details can increase the perceived moral relevance of the choice task and thus the impact of moral identity on choice.

Based on this inference, the following studies investigated the role of moral thinking style (deontological vs. consequential thinking) as a moderator for the impact of moral identity. To elaborate, Tanner and his colleagues (Tanner & Medin, 2004; Tanner, Medin, & Iliev, 2008) found that consequential thinkers are more concerned about losses and gains in outcome, while deontological thinkers simply focus more on an action itself, whether the action abides by rules. Their findings suggest that individuals with outcome-based thinking style are more capable of thinking beyond the mere act of decision-making, which requires one to employ more deliberate information processing procedures (Eyal et al. 2008, Körner & Volk 2014). We conjecture that individuals with rule-based thinking style will adhere more to the rule of the confronted consumption situation, which is to select the most self-beneficial choice. In contrast, individuals with outcome-based thinking style will be more capable of assessing the outcome of a choice from various angles and will therefore be more likely to draw their decisions from their moral identities. The following two final studies test this hypothesis.

In study 4 (N=128), participants were first asked to perform either a moral priming task or a control priming task, based on the procedure used by Aquino and Reed (2002). They then rated their preferences between the two detergents same as in study 2. Consistent with our predictions, participants in moral priming conditions rated moral identity as more important than those in control conditions ( $t(126)=2.49, p = .01$ ). We also expected that the preference for the ethical product was greater in moral priming (vs. control) conditions among participants with consequentialist thinking style, whereas the difference was not significant among relatively more deontological thinkers. Indeed, the result was consistent to this assumption ( $b = -.44, t(126) = -2.44, p < .02$ ).

Study 5 (N=263) replicated the results of study 4 while experimentally manipulating the moral thinking style and measuring individuals’ moral identity. Participants were asked to write either about a time when they made a choice based on its positive consequences (consequentialist thinking style), or about an example of actions that someone can do to strictly follow rules or guidelines (deontologist thinking style). Following this priming task, participants were given a product choice task after which their moral thinking style was measured. While the scores of a thinking style scale (Lammers and Stapel 2009) from a subset of the sample (N=171) indicated that the manipulation was successful ( $t(169) = 2.69, p < .01$ ), we found the hypothesized interaction of thinking-mode priming and moral identity scores ( $b = 0.51, z = -2.50, p = .01$ ) in which participants’ moral

identity significantly increases ethical choice under consequentialist-thinking priming, whereas the impact of moral identity was negligible under rule-based thinking priming, replicating the results of study 4.

In the present research, we theorize that it is the consumption itself that bars consumers from accessing their moral values and thus their moral identity from having an influence. Consistent with this assumption, our five studies show that introducing the factors that can increase the perceived moral relevance of the product choice tasks also increases the impact of moral identity in ethical choice. Thus, the present investigation not only delineates why the effect of moral identity diminishes in consumption decisions, but also shows how consumers' moral values to be impactful in consumption decisions, thereby making both theoretical and practical contributions. Nevertheless, our studies are all scenario-based. Therefore, future research that replicates our findings in real choices is awaited.

# Consuming Products with Experiences: Why and When Consumers Want Mementos

Charlene Chu, Chapman University, USA

Suzanne Shu, University of California, Los Angeles, USA

## EXTENDED ABSTRACT

While recent research has advanced our understanding of the differences between experiences and material goods, experiences are often accompanied by the consumption of material goods, most notably in the form of mementos. The prevailing account for why consumers desire mementos of experiences is that mementos provide memory-related benefits (Belk, Wallendorf, & Sherry, 1989). In this research, we propose further understanding mementos as a way for consumers to alleviate sadness that arises from the end of positive experiences. Based on this understanding of mementos, we further propose that the desire for mementos is additionally prompted by the end of a positive experience and the heightened sadness associated with that ending.

*Hypothesis 1* Having a memento of an experience lessens sadness arising from the end of the experience.

*Hypothesis 2* Consumers are more likely to keep mementos when the end of an experience is approaching or salient.

In Study 1, we build on existing research showing that endings of meaningful positive experiences, such as graduating from college or visiting a meaningful location for the last time, leads to heightened sadness (Ersner-Hershfield, Mikels, Sullivan, & Carstensen, 2008). We used a 2 (regular visit vs. last visit) x 2 (memento vs. no memento) between subjects design. Graduating undergraduates at a west coast university either imagined visiting a meaningful campus location on a regular visit or for the last time as an undergraduate at the university. Those in the memento conditions were additionally prompted to think about college mementos that they owned. Participants then rated various positive and negative emotions. A two-way ANOVA revealed a significant main effect of last visit ( $F = 6.361$ ,  $p < .02$ ) on sadness, thus replicating increased sadness when facing an ending. Importantly, we find a significant last visit x memento interaction ( $F = 7.159$ ,  $p < .01$ ), such that the rise in sadness among those visiting for the last time was significantly lower among those thinking of mementos compared to those who were not thinking of mementos, supporting hypothesis 1.

In Study 2, we replicate our findings for a different experience and also examine appraisal theory, which holds that sadness arises from appraisals centered on irrevocable loss (Smith & Lazarus, 1993). Participants rated their emotions and appraisals during a recent vacation and toward the end of their vacation. Half of the participants were additionally asked to think about mementos from their vacation. A two-way ANOVA revealed a statistically significant time x memento interaction ( $F(1, 150) = 4.259$ ),  $p = .041$  such that the increase in sadness was smaller in the memento condition than in the no memento condition. We further find that changes in appraisals of loss mediate the effect of mementos on sadness ( $a \times b = .4256$  with a 95% confidence interval excluding zero (.0410, .8750)). This suggests that mementos alleviate sadness at the end of an experience by reducing appraisals of loss.

In Study 3, we test hypothesis 2 by tracking photo-taking behavior, a form of memento-keeping, among graduating undergraduates

facing the end of their college experience via their Instagram posts. We manipulated the salience of the end of college using surveys that students completed over a two-week period and examined Instagram photos that they posted over the same two-week period. While all participants were graduating undergraduates, only half received salient reminders about their upcoming graduation (salient condition). As predicted, photos posted by participants in the salient condition were more related to the university compared to photos in the non-salient condition as rated on a university relatedness scale ( $t(169) = 2.092$ ,  $p < .04$ ) and were more likely to be taken at the university ( $\chi^2 = 5.798$ ,  $p < .02$ ).

In Study 4, we further test hypothesis 2. Graduating university students either wrote about the most interesting class taken during college (control condition), or were reminded about the upcoming end of their college experience and asked to write about their college experience (salient end condition). Participants then chose between a pack of chocolates featuring the university logo on each wrapper (a memento item) or a variety pack of chocolates (a non-memento item). To test whether the likelihood of keeping mementos when facing an ending increases apart from memory considerations, we intentionally selected consumable material items that would be unlikely to provide future memory benefits and pretested these items. As predicted, participants in the salient end condition were significantly more likely to choose the memento chocolates than those in the control condition (29% vs. 51%,  $\chi^2 = 3.921$ ,  $p = .048$ ).

In Study 5, we provide additional process evidence for the effect demonstrated in Studies 3-4. Tourists visiting a famous beach location completed a brief survey asking how close the end of their trip felt and rated their emotions. They then imagined choosing between two different mugs to receive that day: a Starbucks mug (non-memento) and a mug depicting an image of the beach location (memento). Using a bootstrap analysis to test for mediation, we find that the mean indirect effect of the closeness of the end on choice of memento through sadness was positive and significant ( $a \times b = .2084$ ) with a 95% confidence interval excluding zero (.0399, 1.5278), providing evidence for sadness mediating the effect of perceived closeness of the end on preference for mementos. In contrast, neither memory concerns nor the value of the experience mediated the effect of the perceived closeness of the end on preference for the memento mug.

While the existing literature often contrasts experiences with material goods, this research studies both types of consumption together in a broader context to yield novel insights.

# Powerful Buy Time: Why Social Power Leads to Prioritizing Time over Money

Myungjin Chung, University of Texas at Arlington, USA

Ritesh Saini, University of Texas at Arlington, USA

## EXTENDED ABSTRACT

In this paper we examine how social power influences a consumer's willingness to buy time-saving options.

Both money and time are valued resources but their relative value may vary amongst different individuals and different contexts. Money is a familiar, fungible, and unambiguous resource. In contrast time is difficult to account and more ambiguous (Soman 2001; Okada and Hoch 2004; Saini and Monga 2008). Given such difference between perceptions of temporal and monetary resources, we argue that spending time to save money can be viewed as a conservative investment where one is exchanging an ambiguous currency (time) for a relatively stable, fungible one (money). In contrast, spending money to buy additional time is a relatively audacious move because the returns on such an exchange are uncertain.

Power is defined as asymmetric control over valued resources in social relations (Rucker, Galinsky and Dubois 2012). Power has been associated with risk taking capacity (Anderson and Galinsky 2006), increase approach- and action-tendencies (Smith and Bargh 2008) and invoke optimism and confidence (Fast, Gruenfeld, Sivanathan, and Galinsky 2009). Therefore, social power, by making a person more risk tolerant and action-oriented, leads people to save time by spending money. In a series of studies we examine how and why the state of felt social power influences people's decision to exchange money for time.

In study 1a, participants ( $n = 150$  undergraduates) made two hypothetical decisions involving trade-offs between time and money. Alongside, the Sense of Power scale (Anderson and Galinsky 2006) was administered. We averaged the responses to the time-saving option in the two scenarios. A linear regression with measured power as an independent variable revealed that greater willingness to spend money to save time was associated with a greater power of participants ( $b = 13.38, t = 3.15, p < .01$ ). In study 1b, participants ( $n = 155$ ) read the scenario that involves time-money trade-offs, and answered if they would buy a time-saving option. Participant's chronic sense of power was measured using the same scale. Study 1b included a gender, age, subjective economic status questions, and a "frugality" measure to control for possible confounds. As predicted, a logistic regression revealed that participants with higher power chose time-saving option more ( $\beta = .37, \chi^2 = 4.51, p < .05$ ), and this relationship persisted even after controlling for all other measured variables ( $p = .02$ ). In study 2 ( $n = 160$  undergraduates), participants were randomly assigned to either high-power or low-power conditions. We manipulated power using a recall task (Galinsky, Gruenfeld and Magee, 2003). Next, participants read three scenarios where they were asked to make time-money trades-offs (Whillans, Weidman and Dunn 2016). We summed the number of time-saving decisions that participants made in response to the three scenarios. Comparison across high and low-power conditions revealed a main effect of power ( $\beta = 1.81, t = 2.15, p < .05$ .) As predicted, participants who were primed to have high power chose to have purchase more time-saving options.

Thus far we have demonstrated that power leads people to prioritize time over money. However, there is one prominent context where powerless people prioritize time over money. Recently, Bellezza, Paharia and Keinan (2016) demonstrated that displaying busyness and time scarcity can be status enhancing. Separately Rucker and Galinsky (2009) and several others have demonstrated that powerless people are highly motivated to convey positive social

signals engaging in conspicuous consumption. Therefore, we suggest that social visibility will enhance the powerless to exchange money for time. This will lead to a reversal of our core result that power leads to greater preference for time (vs. money).

In study 3 ( $n = 310$  mTurkers), participants were randomly assigned to high- or low-power conditions where social power was manipulated with a role-playing task (Rucker, et al., 2012). Then, participants were assigned to one of the four conditions in a 2 (power: low vs high)  $\times$  2 (social visibility: high vs low) design. Both high (diner with friends and picking up relatives) and low social visibility scenarios (doctoral visit and post office) involved a binary choice decision between valet parking (time-saving option) and garage parking (money saving option).

Confirming our hypothesis, a logistic regression confirmed that the interaction effect of power and social-visibility was significant ( $\beta = -1.147, \chi^2 = 5.75, p < .05$ ). In the low-social visibility conditions, powerful consumers chose time-saving option more, replicating our previous results ( $M_{hi-power} = 38.0\%; M_{lo-power} = 20.2\%; \chi^2 = 25.51, p < 0.0001$ ). In the high-social visibility conditions, powerful and powerless consumers did not vary significantly in their time buying tendency ( $M_{hi-power} = 40.0\%; M_{lo-power} = 47.1\%;$  Pearson's  $\chi^2 = 0.80, p > 0.30$ ). More pertinent to our moderation hypothesis, while the powerful consumers remained entirely uninfluenced by social visibility, powerless consumers were more likely to engage in time-buying in high- (vs. low-) social visibility conditions (Powerless:  $M_{hi-visib} = 47.1\%; M_{lo-visib} = 20.2\%;$  Pearson's  $\chi^2 = 12.06, p < 0.0001$ ).

In multiple studies we amassed converging evidence that power leads people to prioritize time over money (studies 1a, 1b and 2). However, powerless consumer's stronger social signaling motives reverse this tendency (study 3). Give our results, companies selling time-saving products and services should appeal to the consumer by showing them as more dominant and powerful entities. Alongside, low-power consumers can also be targeted to buy such time-saving products and services if their positive social signaling externalities are highlighted.

# Doing Good by Buying from a Peer: When and Why Consumers Prefer Peer Economy Purchases

John P. Costello, The Ohio State University, USA  
Rebecca Walker Reczek, The Ohio State University, USA

## EXTENDED ABSTRACT

The term “peer economy” has been used to describe organizations that facilitate market-based transactions between private individuals (Sundararajan, 2016). Implicit in the peer-to-peer business model is the notion of connecting with other individuals (i.e., one’s peers) directly rather than making a purchase from a business. Based on this distinction, we propose that rather than focusing on the firm, as they would in a traditional economy purchase, in a peer economy purchase, consumers focus relatively more on the peer providing a good or service rather than on the underlying firm facilitating the peer-to-peer transaction. As a result, consumers perceive peer-to-peer purchases as inherently more prosocial than purchases from traditional economy firms because these purchases are seen as helping another individual (vs. simply providing profits for a firm). Hence we predict:

*Hypothesis 1 Purchases from peer-to-peer economy firms are perceived as more prosocial than purchases from traditional economy firms.*

*Hypothesis 2 Consumers’ perceptions of peer-to-peer providers as more prosocial will drive greater purchase likelihood for peer economy options as compared to traditional economy options.*

We argue that the default in a peer economy transaction is to focus on the individual, but external factors may shift the consumer to focus more on the for-profit firm facilitating the transaction. This shift decreases perceptions of prosociality and preference for peer-to-peer options since consumers no longer see their purchase as benefiting an individual.

*Hypothesis 3 When consumers focus on the underlying for-profit organization facilitating a peer to peer purchase rather than on the individual peer provider, the effect proposed in hypothesis 2 will be attenuated.*

We argue that the underlying process driving increased preference for peer-to-peer purchases is caused by the belief that these purchases are more prosocial. Therefore, any marketing action that changes consumers’ perceptions of purchases from traditional economy firms to be more prosocial, such as cause marketing (Krishna and Rajan 2009), should attenuate this difference in preferences. Because peer-to-peer economy firms are already seen as prosocial, they are less likely to benefit from such an action.

*Hypothesis 4 When traditional economy firms link consumer purchases to charitable donations via cause marketing, the effect proposed in hypothesis 2 will be attenuated.*

In study 1 (three conditions) participants were asked to imagine taking a trip where the only option available in their desired location was a hotel or an apartment on Airbnb. In the Airbnb individual condition, the person renting the apartment lived there. In the Airbnb

agent condition, the person renting the apartment “works as an agent for a property owner who is renting out multiple properties on Airbnb’s website as a business.” Next, participants rated how prosocial they felt this purchase was with four statements ( $\alpha = 0.82$ ). Because the Airbnb agent should not be seen as a true “peer” in the sense that he/she is someone working on behalf of a business, we did not expect perceptions of prosociality to differ across these conditions. Analysis using Bonferroni-adjusted contrasts revealed that there was no significant difference in the perceived prosociality of the purchase in the Airbnb agent ( $M = 4.26$ ) versus hotel condition ( $M = 4.02$ ). Supporting H1, however, the purchase in the Airbnb individual condition was seen as significantly more prosocial ( $M = 4.80$ ) than the Airbnb agent ( $p = .01$ ) and hotel conditions ( $p < .0001$ ).

In study 2 we test H2 and H3 by showing participants an advertisement for Lyft (a peer-to-peer rideshare company) or Yellow Cab (a traditional alternative) that featured photos of three individuals, either identified as drivers or corporate employees (e.g., VP of Partnerships) in a 2 (Company: Lyft vs. Yellow Cab) x 2 (Advertisement Focus: Drivers vs. Corporate employees) design. An ANOVA analysis of purchase likelihood revealed a significant interaction ( $p = .027$ ) with simple effects showing a significant difference between the Lyft ad focus conditions ( $M_{\text{driver}} = 5.70$ ,  $M_{\text{corporate}} = 4.91$ ,  $p = .036$ ) but not the cab conditions ( $M_{\text{driver}} = 3.18$ ,  $M_{\text{corporate}} = 3.58$ ). To test H2 and H3, we conducted a moderated mediation analysis using PROCESS model 7 (Hayes 2013) with company as the IV, ad focus as the moderator, prosociality as the mediator, and purchase likelihood as the DV. Supporting our predictions, this analysis indicated significant moderated mediation.

In study 3a we partnered with a real peer economy firm to conduct a field study. We manipulated the platform’s promotional materials (e.g., download cards) with one condition focusing on the individual provider and the other focusing on the company itself. We predicted that the individual provider-focused condition will be more effective, with number of download cards taken serving as our dependent variable. As predicted more cards were taken in the individual provider condition (379) than the company condition (281,  $p = .001$ ). A follow up lab study (study 3b) was conducted with the same stimuli. The results showed that promotions focusing on an individual provider led to higher download likelihood as mediated by prosociality perceptions.

In study 4 we test H4 using a 2 (Company: Lyft vs. Yellow Cab) x 2 (Cause Marketing: Cause Marketing vs. Control) design. Participants see a billboard for Lyft/Yellow Cab and are either told that a portion of their purchase will be donated to the United Way (CM condition) or not given additional information. Analysis of purchase likelihood revealed a significant interaction ( $p = .046$ ). Further analysis of this interaction’s simple effects revealed that while tying a purchase to a cause made individuals in the Yellow Cab condition significantly more likely to make a purchase ( $M_{\text{Control}} = 4.38$ ,  $M_{\text{Cause}} = 5.04$ ,  $p = .024$ ), that cause marketing made no significant difference in the Lyft conditions ( $M_{\text{Control}} = 5.54$ ,  $M_{\text{Cause}} = 5.37$ ). We conducted another moderated mediation analysis to test H4. Supporting our prediction, this analysis indicates significant moderated mediation.

In this research we demonstrate that consumers perceive peer-to-peer purchases as more prosocial than purchases from traditional economy firms and express greater purchase intentions for peer

economy firms compared to traditional economy firms. This work contributes to the literatures on non-traditional business models, pro-social consumer behavior, and cause marketing.

# Hedonic Consumption Fosters Prosocial Behavior

Daniela Cristian, BI Norwegian Business School, Norway

Bob Fennis, University of Groningen, The Netherlands

Luk Warlop, BI Norwegian Business School, Norway

## EXTENDED ABSTRACT

Hedonic experiences abound. Despite their universal appeal, a common intuition is that besides enjoyment, hedonics elicit guilt or regret (Okada 2005). Hence, pursuing pleasure has been considered generally suboptimal (Keinan and Kivetz 2008). To redress this misconception, we contend that under particular conditions hedonic consumption fosters prosociality.

Hedonic experiences are sought for their inherent affective and sensory attributes, and the enjoyment they provide (Holbrook and Hirschman 1982). When pursuing pleasure, consumers escape functional goals and derive satisfaction from hedonic consumption per se without further goals (Botti and McGill 2011). Based on this, we propose that when deliberately engaging in hedonic experiences, consumers break free from other endeavors. Because hedonics are highly immersive, they prompt a higher focus on the consumption experience and render consumers more impulsive and less inhibited. On these premise, we argue that freely engaging in hedonic consumption induces behavioral disinhibition.

Extant research suggests that disinhibition is a direct precursor of prosociality (Rand, Kraft-Todd, and Gruber 2015; Van den Bos et al. 2009). Within moral psychology, the social intuitionist model stipulates that moral judgments (i.e., favoring cooperation over defection) ensue from relatively automatic intuitive processes (Haidt 2001). Building on this and on the notion that most people adhere to prosocial values (Van Lange et al. 2011) recent studies propose that our innate impulses are geared towards cooperation and that such predispositions are often overshadowed by deliberation (Rand 2016).

Prior research has suggested competing antecedents of prosociality such as positive mood (Isen and Levin 1972) and guilt-induced helping (Strahilevitz and Myers 1998; Zemack-Rugar et al. 2016). However, hedonic episodes do not unequivocally trigger positive affect or guilt, but concurrent positive and negative responses (Ramanathan and Williams 2007). Thus, we extend existing work by documenting a qualitatively different relationship between hedonics and prosociality. Specifically, we propose that following free hedonic consumption, prosociality ensues as an intuitive response, and that disinhibition underlies this effect.

Results from four experiments using real hedonic food consumption lend support to these hypotheses. To exclude the possibility that the effect is due to potential physiological correlates of food consumption (i.e., glucose), we utilized a yoked between-participants design across all studies, where hedonic consumption (free vs. instructed) was the manipulated factor. In the instructed condition, each participant consumed the same food amount as another participant consumed in the free condition. Therefore, the intake was identical across conditions. We systematically ruled out mood by measuring it before and right after the eating task in all studies.

Study 1 tested whether free hedonic consumption fosters behavioral helping. Hedonic consumption (free vs. instructed) was manipulated. We measured behavioral prosociality by asking participants to help checking written exams for the Exam Office. A Poisson regression revealed that free hedonic consumption had a positive effect on helping ( $\beta = 0.44$ ;  $\chi^2(1) = 25.69$ ;  $p < .001$ ) (12.6% refusals coded as zero). Participants who experienced free chocolate consumption voluntarily checked 55.3% more exams than those who consumed

the same chocolate amount instructed. Besides mood, we also ruled out post-consumption conflict.

To test whether the effect is germane to hedonic consumption, Study 2 employed a 2 (consumption: free vs. instructed) x 2 (food: hedonic vs. non-hedonic) between-subjects design. A control condition void of consumption was included to capture baseline prosociality. After consuming either chocolate truffles (hedonic) or rice crackers (non-hedonic), participants were asked how much of their experimental payment they wanted to donate to a charity of their own choice. Participants in the control condition proceeded directly to the prosociality measure.

A 2 (consumption: free vs. instructed) x 2 (food type: hedonic vs. non-hedonic) ANOVA on charitable donations revealed a main effect of consumption ( $F(1, 157) = 4.48$ ;  $p = .03$ ) and a main effect of food type ( $F(1, 157) = 13.52$ ;  $p < .001$ ). As predicted, free hedonic consumption led to more generous donations relative to instructed hedonic consumption. This was not the case for non-hedonic consumption. In the two non-hedonic conditions, the donation level did not differ regardless of consumption being free or instructed. Donations in the control condition ( $M = 22.58$ ) were lower than donations in the free hedonic consumption condition ( $p < .001$ ), but did not differ from the two non-hedonic conditions. Thus, non-hedonic consumption was analogous to no consumption. As predicted, the effect was not driven by consumption per se, but germane to hedonic consumption. Additionally, we tested whether psychological reactance alters prosociality. Results disconfirmed this potential explanation.

So far, we ascribed the differences in prosociality to disinhibition induced by free hedonic consumption. To test this hypothesis, Study 3 measured consumers' chronic predispositions to disinhibit. We utilized the same design (free vs. instructed hedonic consumption). Prosociality was measured as in Study 2. Following the donation task, participants completed the Behavioral Inhibition System (BIS) scale where lower scores reflect higher disinhibition. Results indicated a significant main effect of hedonic consumption on donations ( $F(1, 97) = 6.62$ ;  $p = .01$ ) qualified by an interaction with BIS ( $b = 28.21$ ;  $t(95) = 2.74$ ;  $p = .007$ ). Thus, Study 3 showed that disinhibition measured as the chronic tendency to "let go" underlied the effect.

Study 4 provided additional process evidence by directly measuring disinhibition. We used a consequential prosociality measure: real donations. Each participant had the payment in an envelope next to the computer. The hedonic eating task (free vs. instructed) was followed by an ad for Save the Children. Participants were asked to leave the desired donation amount (if any) in the envelope. Results indicated a significant main effect of hedonic consumption on real donations ( $F(1, 83) = 7.21$ ;  $p < .01$ ). Importantly, the direct effect was not significant when including disinhibition in the model ( $p > .09$ ; 95% CI [.577; 7.93]; Hayes 2009) indicating full mediation.

Considered jointly, the current studies support our central hypothesis that free hedonic consumption promotes spontaneous non-monetary helping, hypothetical and real charitable donations. We augment the current understanding of hedonics and contribute to the prosociality literature. Besides providing actionable insights for marketers that offer hedonic products and experiences, this work is highly beneficial for charity organizations.

# Globalizing from the Periphery: The Role of Consumer Paratextual Translation

Angela Gracia B. Cruz, Monash University, Australia

Yuri Seo, University of Auckland, New Zealand

Itir Binay, Monash University, Australia

## EXTENDED ABSTRACT

Much of the debate on the assimilation of global cultural products has focused on how Western cultural products and brands are adopted, resisted, and hybridized in other 'foreign' regions and countries (Alden, Steenkamp, and Batra 1999; Izberk-Bilgin 2012; Kjeldgaard and Askegaard 2006; Thompson and Arsel 2004). Yet, globalization is becoming increasingly dislocated from Western centers due to the rise of cultural, economic, and political institutions within different regions of the world (Bhambra and Santos 2017; Ger 1999; Goldstein-Gidoni 2005; Iwabuchi 2002) – what Ger (1999, 66) refers to as the “peripheries talking back.” Some popular materializations include the worldwide popularity of Indian Yoga (Askegaard and Eckhardt 2012), Manga comic books from Japan (Iwabuchi 2002) and, more recently, the international expansion of K-pop from South Korea (Shin 2009).

Despite the growing popularity of cultural products originating from the 'periphery', there are limited insights about how their meanings become globally accepted. Scholars seem to agree that peripheral cultural products face higher barriers to internationalization compared to their established American counterparts (Cayla and Arnould 2008; Eckhardt 2005; Iwabuchi 2002) due to 'cultural discounting', whereby “a particular [cultural product] rooted in one culture and thus attractive in that environment will have a diminished appeal elsewhere as viewers find it difficult to identify with the style, values, beliefs, institutions and behavioural patterns of the material” (Hoskins and Mirus 1988, 500). Peripheral cultural products thus lack transcultural intelligibility because they are less aligned with the established global cultural models (Thompson and Arsel 2004); consequently, international consumers may lack the necessary interpretive frames of reference to make sense of, activate, and negotiate their meanings. Given these theoretical asymmetries, we ask: what sociocultural and consumption processes enable peripheral cultural products to become transculturally intelligible?

Our answer to this question is informed by the interdisciplinary field of cultural translation studies (Cain 2001; Chidlow, Plakoyianaki, and Welch 2014; Freeman 2009; Gal 2015; Wolf 2007) and Genette's (1997) concept of paratextual translation. Beyond processes of interlingual transfer, translation more broadly refers to the “expression in one semiotic system of what has been said, written, or done in another” (Gal 2015, 227). Scholars of translation theory point toward two key 'problems of translation' relevant to the challenges of cultural globalization from the periphery. The first problem is cross-cultural incommensurability, where the meanings of cultural products posed within a culture of origin may not convey the same resonance in the context of another foreign culture (Chidlow et al. 2014; Freeman 2009; Reiss and Vermeer 1984), making translated cultural products feel somehow inferior or not original. The second problem is asymmetrical global power relations which implicitly favor Western cultural meanings, resulting in the erasure of difference on its own terms (Venuti 2008). Even as translation bridges intercultural differences, it is at the same time a “practice which in fact produces the 'Other'” (Wolf 2002, 180). That is, peripheral cultural products face implicit disadvantages because they must foster transcultural intelligibility in the context of asymmetrical power relations within which such cultural products are, by default, framed as 'foreign' (Cayla and Arnould 2008).

The concept of paratextual translation helps develop insights about how peripheral cultural products can become globally accepted despite these problems of translation. A paratext is defined as any written, audiovisual, or mediated content which enables the reading of a focal text (Cain 2001; Genette 1997). Paratextual translation can help potential international consumers map routes to intelligibility by expanding the repertoire of cultural images available to these consumers, or by crafting links between previously disparate cultural frames of reference.

Our analysis focuses on the paratextual translation practices of English-speaking consumers of K-pop, a cultural product described as “South Korea's greatest export” (Mahr 2012). Our findings show how three consumer paratextual translation practices help international K-pop consumers to locate this 'foreign' cultural product in relation to their existing cultural frames of reference. These extend beyond linguistic intelligibility to involve the translation of embodied practices, as well as complex negotiations in relation to local cultural identities and geopolitical positionalities. Even though K-pop contains a host of unfamiliar cultural elements, consumer-generated translation practices help craft connections between the familiar and the unfamiliar, thereby building the frameworks of intelligibility required to consume its multi-layered meanings.

This study helps advance our understanding of cultural globalization processes in two ways. First, beyond the well-documented ideological tensions between the 'global' and the 'local' which erupt in the consumption of global cultural products (Dong and Tian 2009; Izberk-Bilgin 2012; Thompson and Arsel 2004), our findings show the emergence of a quasi-nationalistic geopolitics within the transnational consumption field of K-pop; identity politics now plays out on a transnational scale, intriguingly inverting traditional Western center-periphery dynamics. Second, our analysis underscores the rise of the consumer-mediator as a key agent in processes of cultural globalization. Even though studies of market-mediated globalization processes have previously framed consumers as active *readers* and *appropriators* of plurivocal cultural product meanings (Dong and Tian 2009; Kjeldgaard and Askegaard 2006; Thompson and Arsel 2004), this study extends this perspective by showing how consumers are also productive *intercultural translators* of interpretive frames for globalizing cultural products. Consumers do not only *draw on* culturally specific interpretive frames to interpret the plurivocal meanings of a global cultural product, but also *shape, modify, and expand* these interpretive frames. Overall, the transcultural paratextual field of K-pop emerges as a key node, a productive site of translation which facilitates the globalization of this peripheral cultural product.

# Consumer Attachment Styles and Preference for Sharing Products

Kivilcim Dogerlioglu Demir, Sabanci University, Turkey

Ezgi Akpinar, Koc University, Turkey

Mehmet Okan, ITU, Turkey

## EXTENDED ABSTRACT

Sharing in its pure form has innate developmental attributions (e.g. caring, giving, interdependence, non-reciprocity) (Belk 2010; Belk 2014b; John 2012). These attributions are typical features of interpersonal attachment bonds (Bowlby 1973; Hazan and Shaver 1987; Park et al. 2006) that are often based on mother-child relationships (Belk 2010). In this research, we suggest that consumers' likelihood to participate in different types of sharing systems should be influenced by their attachment styles, which is a reflection of their relationship tendencies. We expect that consumers will perceive non-commercial sharing (non-market mediated sharing forms) without monetary exchange and commercial sharing facilities with monetary exchange (Belk (2010; 2014a) differently based on their attachment styles. First, we anticipate that as the sharing systems become commercial, they lose their collective nature, thus core aspects of pure sharing such as caring, giving, interdependence and non-reciprocity no longer play a role. Further, we propose that consumers with anxious attachment style compared to avoidant attachment style, would be more willing to use non-commercial shared resources.

Study 1 investigates the effect of attachment styles (anxious vs. avoidant) and type of sharing systems (commercial vs. non-commercial) on willingness to use home sharing facilities. This study employed 2 (attachment style: anxious vs. avoidant) x 2 (type of sharing facility: non-commercial vs. commercial) between subjects' design (N=140). For manipulating attachment styles, participants were asked to think about a relationship that fits the description provided to them and to picture in their mind a person whom they had this type of a relationship (Bartz and Lyndon 2004; Swaminathan et al. 2008). After attachment style priming, individuals were randomly assigned to a hypothetical scenario about an either commercial or non-commercial house sharing situation. Finally, participants indicated their likelihood to stay in such a house sharing facility. As hypothesized, our results showed that, for non-commercial sharing facilities, participants in the anxious condition were more likely to use others' facilities, compared to participants in the avoidant condition. On the other hand, there was no difference in likelihood to use shared housing facilities at different conditions of attachment style for commercial facilities.

Study 2 investigates the effect of chronic attachment styles and type of sharing systems (commercial vs. non-commercial) on willingness to use home and bag sharing facilities. This study employed a between subject design (type of sharing facility: non-commercial vs. commercial) between subjects' design (N= 220). Chronic attachment styles (avoidant and anxious) was measured (Thomson, Whelan and Johnson 2012). After filler items, individuals were randomly assigned to two hypothetical scenarios about either commercial or non-commercial sharing facilities (both home and bag). Finally, participants indicated their likelihood to stay in a house from a sharing facility and use a bag from a sharing site. We also controlled for the effect of acquisition centrality. Higher levels of anxious attachment style had a positive effect on willingness to share non-commercial housing, yet there was no significant effect of avoidant attachment style on non-commercial housing. Further, as shown in Study 1, the effect of anxious attachment style on sharing non-commercial housing was higher than avoidant attachment style. In addition, our results showed that the effect of anxious attachment style on staying in

non-commercial shared housing facilities persists controlling for the effect of acquisition centrality. For commercial house sharing facilities, the effect of attachment styles was not significant on willingness to stay. Yet, there was a positive effect of acquisition centrality on willingness to stay in the house from a commercial sharing facility. This effect was not significant for non-commercial house sharing facility. The results for bag sharing were the same as house sharing, providing robustness for our findings.

Another important aspect of sharing goods is that they include some form of previous contact of another user. As sharing includes use of the same object by many others (simultaneous use or taking turns), each time there is a new user, an essential residue of previous users is transferred to the new ones (Bloom, 2010). Sharing possessions is also seen as a tool for achieving intangible assets such as establishing intimacy and solidarity in groups (Appadurai, 1981) and feeling of connection among members of communities (Mauss 1972). We predict that contagion aspect of shared products might help individuals with high levels of anxiety to feel connected to others through use of the products. Contagion could fulfill their drive for forming relationship with others. Since commercial reasons for sharing housing suggest, to the anxious individual, a lack of personal interest, non-commercial reasons indicate a deeper commitment (Feeney and Noller, 1990). Thus, we predict that higher levels of contagion in shared goods would increase willingness to use shared products among individuals with higher levels of anxiety. Given that we have not found the effect of avoidant style on willingness to share resources, in the next study, we have explored the effect of anxious compared to secure attachment styles.

Study 3 investigates the moderating role of contagion on using non-commercial sharing facilities under different levels of attachment styles. In this study, 2 (attachment styles: anxious vs. secure) x 2 (contagion level: high vs. low) between subject design was employed (N=155). For manipulating attachment styles, the same method in Study 1 was used. After the attachment style manipulation, participants were asked to imagine themselves in a scenario that describes a story about searching a suit for a job interview from a non-commercial sharing community. In the high contagion condition, participants saw a suit worn by a man (face not shown) and asked to imagine the person with this suit (i.e., visualizing him in an interview). In the low contagion condition, participants saw only a suit. Next, participants in both conditions were asked to rate the "likelihood to wear" item on a 7-point scale (not at all likely/very much likely). As hypothesized, we found a significant interaction between attachment style and contagion level. While there is no difference in likelihood to wear the suit at different levels of contagion for participants under secure attachment condition, there is a significant difference in likelihood to wear the suit at different levels of contagion for participants under anxious attachment condition. Taken together, the results show that for consumers with anxious attachment styles, contagion is one of the factors that drive willingness to use non-commercial sharing.

Taken together, the results demonstrate that attachment styles determine consumers' willing to use shared facilities. Most importantly, in non-commercial systems, consumers with anxious attachment styles are more likely to use shared goods or services, and this effect is moderated by the level of contagion.

# Intentionally “Biased”: People Purposely Use To-Be-Ignored Information, But Can Be Persuaded Not To

Berkeley J. Dietvorst, University of Chicago, USA

Uri Simonsohn, Ramon Llull University, Spain

## EXTENDED ABSTRACT:

Research has repeatedly shown that people make judgments based on information they should ignore: jurors don't disregard inadmissible evidence (Stebly, Hosch, Culhane & McWethy, 2006), people exaggerate how predictable outcomes are after they have occurred (Fischhoff, 1975), people use private information when estimating other's valuations (Camerer, Loewenstein & Weber, 1989), participants continue to believe information provided during a study after it has been discredited (Anderson, Lepper, Ross, 1980), etc. We refer to this behavior as “use of to-be-ignored information”. Research demonstrating use of to-be-ignored information has contributed to the popular notion that once people learn information, they are unable to ignore it. In this paper we revisit this proposition. In a nutshell, we will argue and provide evidence that very often the problem is not that people cannot ignore information. But rather, that people do not want to ignore information. People often pay attention to information they shouldn't, not because they are unable to ignore it, but because they (sometimes fallaciously, sometimes defensibly) believe they are better off using it.

Many papers have investigated different types of use of to-be-ignored information (e.g. Camerer et al., 1989; Fischhoff, 1975; Steblay, Hosch, Culhane & McWethy, 2006), mechanisms for use of to-be-ignored information (for a review of many see Hawkins & Hastie, 1990), and moderators of use of to-be-ignored information (e.g. Arkes, Faust, Guilmette, & Hart, 1988). However, this research was not designed to investigate whether or not use of to-be-ignored information is intentional; it often used experiments designed to maximize the number of participants who intend to ignore the to-be-ignored information, but didn't check to see if participants actually intended to ignore it. Past research has attempted to persuade participants to disregard to-be-ignored information by explicitly instructing participants to ignore the to-be-ignored information (see Fischhoff, 1975), by giving participants incentives for accuracy (see e.g., Hell et al., 1998), and by constructing scenarios in such a way that they believe participants would necessarily try to ignore the answer (e.g. Fischhoff (1975) asking participants to predict the responses of uninformed others). However, it would be inaccurate to assume that all participants in these experiments intended to ignore the to-be-ignored information without checking. For example, if participants don't believe that ignoring the to-be-ignored information is beneficial (a premise supported by Studies 1-2 in this paper) these instructions and incentives are likely to fail (and potentially backfire).

There are many reasons why people may use to-be-ignored information intentionally. First, people may believe that using to-be-ignored information improves their accuracy, and in some cases they may be right. For example, imagine a participant who reads a multiple choice question that she does not know the answer to, learns the correct answer, and is then asked how others would answer the question. One option that she has is attempting to completely ignore the correct answer, and answer as she would have if she hadn't learned it. Alternatively, if she believes that some uninformed others would know the correct answer to the question (presumably *some* people know the answer), she could shade her answer towards the correct answer and ostensibly increase her accuracy. Additionally, people may use to-be-ignored information: in an attempt to “appear intelligent, knowledgeable, or perspicacious” (see Hawkins & Has-

tie 1990 p.316; see also Campbell & Tesser, 1983), as a shortcut if they believe that they would have figured out the correct answer with enough effort, because relying on the to-be-ignored information requires lower effort than generating an independent answer, because they misunderstood or chose not to follow the instructions, or for other reasons that we have not considered. Given that people have many compelling reasons to use to-be-ignored information, we propose that people often use of to-be-ignored information intentionally.

From the premise that use of to-be-ignored information may be intentional we arrive at several predictions that we test in studies reported here. First, we predict that when asked whether or not they want to ignore to-be-ignored information, a substantial share of people will indicate they do not want to ignore it. As predicted, across Studies 1-3, only 34% of participants in classic paradigms from past research agree that to-be-ignored information should actually be ignored. Second, we predict that people who desire to ignore the information do so, and that the previously documented biases are driven by the (majority) of participants who want to use the information. As predicted, in Studies 3 and 4 we do not find that obtaining to-be-ignored information has a significant effect on participants' estimates, *after accounting for their plan to use that information*. Third, we predict that giving people persuasive arguments about the importance of disregarding information will increase the degree to which such information is in fact disregarded. As predicted, in Study 4 we find that such arguments reduce people's plan to ignore the to-be-ignored information, and their use of that information as a result. We conclude that when people use to-be-ignored information, they may not be acting rationally, but they are often acting intentionally.

These findings not only suggest revising our understanding of the psychology behind use of to-be-ignored information, but also revisiting the implications of this body of research. For example, our findings suggest that we can sort people based on their use of to-be-ignored information. As an illustration, a judge could ask jurors whether or not they are attending to inadmissible evidence, trust that jurors have the ability to accurately report the truth, and dismiss jurors who report that they are using such information. Our findings also suggest methods for de-biasing individual decision makers: persuade decision makers to ignore information that needs to be ignored. For example, our research suggests that consumers can ignore fallacious negative information about a product if they are given a persuasive reason to do so. An interesting demonstration of this idea comes from a natural experiment - In 2007 the trusted magazine Consumer Reports publically retracted a botched safety-ranking of infant car seats and demand for the affected car seat models returned to baseline almost immediately (see Simonsohn, 2011).

# How Materialism Shapes Spending on Friends

William Ding, Washington State University, USA

David Sprott, Washington State University, USA

Andrew Perkins, Washington State University, USA

## EXTENDED ABSTRACT

Materialism is a set of centrally held beliefs about the importance of possessions in one's life and is a pervasive value in the United States and other developed nations (Richins and Dawson 1992). While researchers have provided numerous insights into decision making by materialists (vs. nonmaterialists), not much is understood regarding the influence of materialism on social life spending (i.e., spending on friends). The idea that materialism should influence how consumers spend on others has been raised in the literature, but prior theories and initial findings are inconclusive and sometimes even contradictory.

On the one hand, previous studies suggest that materialists are asocial, finding that materialists lack feelings of community (Kasser and Ryan 1993) using a heterogeneous noncollege sample, extends these findings by showing that a high centrality of aspirations for financial success is associated with interview ratings of lower global adjustment and social productivity and more behavioral disorders. Discussion is focused on the deleterious consequences of materialistic world views and the need to examine differential aspects of content regarding goals and values. (PsycINFO Database Record (c and exhibit low social engagement (Bauer et al. 2012). Based on these findings, one might reasonably expect materialists to spend less than nonmaterialists on others. In contrast, other research suggests that materialists might not cut off social connections entirely. In particular, Richins and Dawson (1992) reported that materialists scored fairly high on the need for warm personal relationships. These results suggest an apparently contradictory view of the social lives of materialists, and thus further investigation is warranted.

We contend that the differences observed in the literature may be due to a subtle but important balance between being removed from social life (Kasser and Ryan 1993) using a heterogeneous noncollege sample, extends these findings by showing that a high centrality of aspirations for financial success is associated with interview ratings of lower global adjustment and social productivity and more behavioral disorders. Discussion is focused on the deleterious consequences of materialistic world views and the need to examine differential aspects of content regarding goals and values. (PsycINFO Database Record (c while still maintaining social connections (Richins and Dawson 1992). Our premise is that while materialists may not be overly successful in terms of their social lives (vs. nonmaterialists), they may still want to maintain some level of social connectedness. This expectation is built on a fundamental motivation for human beings, the *need to belong* (Baumeister and Leary 1995) stable interpersonal relationships is evaluated in light of the empirical literature. The need is for frequent, nonaversive interactions within an ongoing relational bond. Consistent with the belongingness hypothesis, people form social attachments readily under most conditions and resist the dissolution of existing bonds. Belongingness appears to have multiple and strong effects on emotional patterns and on cognitive processes. Lack of attachments is linked to a variety of ill effects on health, adjustment, and well-being. Other evidence, such as that concerning satiation, substitution, and behavioral consequences, is likewise consistent with the hypothesized motivation. Several seeming counterexamples turned out not to disconfirm the hypothesis. Existing evidence supports the hypothesis that the need to belong is a powerful, fundamental, and extremely pervasive

motivation. (PsycINFO Database Record (c. Importantly, materialism is positively associated with attachment anxiety (Norris et al. 2012). While materialists tend to experience higher anxiety related to relationships, they do not give up those social connections (Hazan and Shaver 1994). Relatedly, materialists have strong beliefs in the transformative powers of acquisition and are more likely than others to manage unpleasant psychological states through consumption (Richins 2017). Therefore, we propose that materialists are likely to perceive that spending on an important other will be interpreted more positively, and thereby enhance the connections with the other person. Materialists' willingness to spend more on others is motivated by a perceived obligation to spend a greater amount of money, in order to develop and strengthen a friendship.

Study 1 was designed to provide evidence of the relationship between materialism and consumers' spending on friends. We predicted that materialists would likely spend more on friends than nonmaterialists. This spending tendency, we propose, is more likely to occur in new friendships than in established ones, because of high uncertainty in new relationships. Moreover, another objective was to provide evidence for our process claim that materialists spend more because of perceived obligation. Participants were randomly assigned to 2 experimental conditions (Friendship stage: New vs. Established); materialism was a measured variable using the Material Value Scale (Richins 2004). As expected, the findings suggested that when friendships were relatively new, materialists spent more than nonmaterialists. For established friendships, in contrast, materialists did not differ from nonmaterialists. Moderated mediation analysis confirmed the proposed mediator of perceived obligation.

Study 2 had two purposes. The main purpose was to further test our theorizing by using manipulation approaches (Spencer, Zanna, and Fong 2005). Specifically, given that materialists spend more on friends to secure a friendship, it may be the case that, in certain circumstances, the tendency for materialists to spend more might also occur within established friendships. For example, when a good friend moves to another city, the greater spatial distance might increase the uncertainty of the friendship, motivating the materialist to attempt to secure the friendship by spending more on the friend. Thus, study 2 manipulated spatial distance (far vs. close) as a proxy for friendship certainty. Second, the present study aimed to identify boundary conditions for the effect of spending more in new friendships. Given that the main purpose for such spending is to build the new friendship, we would expect this effect to be attenuated when the friendship objectively can no longer continue to develop in the future (e.g., the new friend is moving to another city). As expected, our results suggested that (1) materialists would spend more than nonmaterialists even in an established friendship when uncertainty was present; (2) materialists would not spend more than nonmaterialists in a new friendship when the friendship could not grow in the future.

## CONCLUSION

Decades of research on materialism, based largely on seminal works from Belk (1985) and Richins and Dawson (1992), offers consumer researchers and marketing practitioners a better understanding of both antecedents and consequences of this fundamental construct in marketing. Adding to this stream of literature, the findings of study 1 indicate materialists spend more on new friends compared

to nonmaterialists. To back up our explanation of perceived obligation, we also provide direct evidence for the proposed underlying mechanism. Study 2 further tests our theorizing using a moderation approach to show that willingness to spend more occurs in not only new friendships, but also established friendships.

# Can Fear Be Eaten? Emotional and Behavioral Consequences of Intake of Fear-inducing Food or Drink

Jiangang Du, Nankai University, China  
Qiuying Zheng, Beijing University of Chinese Medicine, China  
Miachel K. Hui, Chinese University of Hong Kong, China  
Xiucheng Fan, Fudan University, China

## EXTENDED ABSTRACT

While past studies focused on food consumption as a means to meet people's physiological and hedonic needs, this paper ventures into another psychological driver and consequence of food consumption – a sense of mastery over what is being eaten. We predict that the intake of fear-inducing food will not only reduce (rather than increase) people's fear arising from a prior threatening activity(H1), but will also increase people's tolerance of a prospective threatening activity(H2), and self-confidence is a mediator to explain the above effects(H3).

Study 1 is a 2 (movie clip color: red vs. green) x 2 (drink color: red vs. green) experiment (N=67). Red horror movie clip feature red blood splashing from the body whereas the green one featured green fluid pouring out of the body. We manipulated the color of drinks with red or green grape juice (red vs. green) with the same taste. After viewing the movie clips, participants were asked to report their fear level and drink a cup of grape juice. For those who had viewed the red movie clip, the red grape juice was the fear-inducing drink and the green grape juice was the non-fear-inducing drink, vice visa. Fear level was measured again, as well as self-confidence.

In study 1, we found support for H1 and H3. An ANOVA analysis revealed that the interaction between the movie clip and drink colors was significant ( $F(1, 63) = 6.81, p = .01$ ). After watching the red movie clip, the participants experienced a greater drop in fear after drinking the red grape juice than the participants who drank the green juice. Furthermore, the participants who had watched the green movie clip reported a more substantial decline in fear after drinking the green (vs. the red) grape juice. The indirect effect of the interaction of the movie clip and drink colors through self-confidence was found to be significant, with a point estimate of .96 and a 95% confidence interval (CI) excluding 0 (.30 to 1.94).

Study 2 was designed to test whether the intake of fear-inducing food would increase or decrease people's tolerance of a prospective threatening activity (N=59). The fear-inducing cookies resembled human fingers and were presented in the shape of hands, in sharp contrast with the appearance of the non-fear-inducing cookies. Two sets of cookies were identical in terms of ingredients, size and taste. Participants were asked to indicate their preferred horror level for the movie clip for the next stage (it is a disguised question. No more movie at all) after being served with the cookies. Self-confidence was measured.

Results of study 2 supported H2 and H3. ANOVA revealed that the participants who ate the fear-inducing cookies chose movie clips with significantly higher preferred horror levels than those who ate the non-fear-inducing cookies ( $F(1,57) = 12.89, p = .001$ ). These results indicated that the intake of fear-inducing food increases people's tolerance of a prospective threatening activity. Moreover, self-confidence was proved to be the significant mediator for such a relationship.

Study 3 predicted that the participants with high regulatory-emotional self-efficacy (RESE) would possess greater self-confidence in dealing with threatening activities than those with low RESE. A 2 (RESE: high vs. low) x 2 (food type: fear-inducing vs. non-fear-inducing) factorial design experiment was conducted (N=115). We manipulate RESE by a sentence-unscrambling task in which the participants had to construct four-word sentences from five-word jumbles containing adjectival terms representing high ("calm") or low ("impulsive") levels of RESE. We manipulated food type using the same cookie as in Study 2. Participants were asked to watch a horror movie clip before completing the sentence-unscrambling task, and then answered questions about their fear level and preferred level of horror for another movie clip to be watched before the end of the experiment. Subsequently, Participants were served with the cookies and reported their fear level and preferred horror level again.

ANOVA revealed that the interactive effects of food type and RESE on both fear reduction and the change in preferred horror level were also significant, fear reduction ( $F(1, 111) = 7.48, p < .01$ ); change in preferred horror level ( $F(1, 111) = 14.93, p < .001$ ). The intake of fear-inducing (vs. non-fear-reducing) cookies significantly reduced fear and increased preferred horror level for the participants in the low-RESE group, fear reduction ( $F(1, 111) = 22.09, p < .001$ ); change in preferred horror level ( $F(1, 111) = 32.35, p < .001$ ). Results showed that self-confidence played a mediating role in fear reduction and increased preferred horror level only for the participants in the low-RESE group.

Our research contributes to food consumption research by finding another psychological driver. Ample evidence has shown that there are two types of needs of food consumption: homeostatic needs and hedonic needs (Witt *et al.* 2014; Wansink and Chandon, 2014). While homeostatic needs arises from energy deprivation, hedonic needs is a function of people emotional state (e.g., feeling of stress and exhausted), exposure to palatable food (e.g., a chocolate bar) and social occasions (e.g., eating out with family and friends) (Haedt-Matt and Keel 2011). Our study finds that beyond hedonic needs, gaining self-confidence to cope with fear emotion is another important driver in food consumption.

# When do More Options Produce Worse Choice?

Shannon Duncan, Columbia University, USA

Ulf Bockenholt, Northwestern University, USA

Eric J. Johnson, Columbia University, USA

## EXTENDED ABSTRACT

A major difference between economic and psychological analysis of choice concerns the effect of having more options. Economic theory postulates that more choices should result in better outcomes because there will be a better match between the goals of the decision maker and the selected product. However, much work in psychology and consumer research has questioned this assumption (e.g., Iyengar and Lepper, 2000; Reibstein, Youngblood, and Fromkin, 1975; Schwartz, 2004), suggesting that choice overload occurs. This theory suggests that people have difficulty making choices when presented with larger choice sets in comparison to smaller sets, with choice set being defined as the number of alternatives in a choice set. Several studies have found that consumers have poorer subjective feelings regarding their choices when presented with larger choice sets (for a different perspective, see Scheibehenne, Todd and Greifeneder, 2010). Chernev, Bockenholt and Goodman (2014) recently conducted a large meta-analysis on the existing literature on choice overload. They looked at four subjective measures of choice: satisfaction/confidence, regret, choice deferral, and switching likelihood. With 99 meta-analytic observations ( $N = 7,202$ ), they document a significant effect of choice set size on these subjective outcomes across studies without controlling for moderating effects. Specifically, they find that increases in choice set size lead to a detriment in subjective experience of choice.

Yet there is another, perhaps more important, question: Does adding options improve the quality of choice? While several studies have explored people's ability to choose the correct choice under varying choice set sizes, they have not been subjected to a systematic assessment. In this paper, we look at if and when choice set size influences choice accuracy. While more options might increase accuracy by providing options that are closer to the preferences of the decision-maker, more options might make finding the better option more difficult, decreasing the quality of the chosen option.

While either outcome is possible, we suggest the following:

*Hypothesis 1* Greater choice set size will have a negative impact on choice accuracy: more options will hurt accuracy.

*Hypothesis 2* However, the presence or absence of choice architecture will significantly moderate the effects of an increase in the number of options. More specifically, the presence of one of a large set of choice architecture tools may enable individuals to do better with larger choice sets enabling decision makers to overcome, and perhaps even exploit an increase in the number of options.

Our meta-analytic study includes papers that use the number of alternatives as an independent variable and a measure of choice accuracy as the dependent variable. These studies usually determine better choices by giving people a set of preferences, or by looking for errors in choice. Dependent measures are usually whether the best choice (binary yes or no) was selected, or some continuous measure (the average amount of money lost, or average quality measure).

In total, our meta-analysis includes 76 observations originating from 21 studies published in 16 articles. ( $N=12,077$ ). Each observation was coded to reflect the corresponding dependent variables, and we recorded each dependent variable as a separate observation. Since we were interested in the impact of choice architecture and the impact of set size, we also coded each observation to reflect these two potential moderators.

To combine all the individual studies into one meta-analytic model, we calculated Cohen's  $d$  to capture the difference effect between the small and large number of alternatives. In the context of our study, a positive  $d$ -value is associated with participants making better choices with a larger number of alternatives, and a negative  $d$ -value is associated with participants making better choice with a smaller number of alternatives.

We find that larger choice set sizes do lead to lower choice accuracy,  $d^+ = -0.20$ ,  $CI_{95} = [-0.30, -0.11]$ ,  $p < .0001$ ,  $I^2 = 78.21\%$ . This result is robust to running the model at either the study or article level,  $d^+ = -0.26$ ,  $CI_{95} = [-0.39, -0.14]$ ,  $p < .0001$  and  $d^+ = -0.33$ ,  $CI_{95} = [-0.49, -0.18]$ ,  $p < .0001$ , respectively. Adding our moderators further refines our story. First, we find that the presence of decision aids does increase the accuracy of choice with a larger number of alternatives,  $b = 0.37$ ,  $t(71) = 3.81$ ,  $p = .0003$ . Second, we do not find that choice overload is worse when the difference in the compared choice set sizes increases, as compared in a trichotomy of three levels (low, medium and high),  $b = -0.13$ ,  $t(71) = -0.85$ ,  $p = .4$ , and  $b = -0.18$ ,  $t(71) = -1.52$ ,  $p = .13$ . Finally, we find that the dependent variables converge in providing similar effect size results (all  $p > .05$ ).

Our results have important implications for both theoretical and applied work. First, choice overload influences choice on both subjective measures, as shown by Chernev et al. (2014), and objective measures, as shown here. In other words, there is evidence that choice overload extends not only to how choice feels, but to how good these choices are. Second, the analysis indicates that there are two ways of getting a more accurate choice. The first is to provide minimal options. The second is to present more options, but add choice architecture as well. These findings can serve as a basis for creating better choice sets for consumers across domains.

# Let's Get Together and Make A Difference: Experiencing A Community In Donation-Based Crowdfunding

Danit Ein-Gar, Tel-Aviv University, Israel

## EXTENDED ABSTRACT

Social-causes campaigns are the largest category in crowdfunding and donation-raising campaigns hold a big portion of this category (www.statista.com). However, most of the research in crowdfunding focused on equity-based crowdfunding and very little research has focused on donation-based crowdfunding. While there is a common assumption that virtual communities benefit equity-based crowdfunding campaigns (Belleflamme, Lambert, & Schwienacher, 2013; Colombo, Franzoni, & Rossi-Lamastra, 2015; Kraut et al., 2012), this assumption has not been tested in donation-based crowdfunding. The potential effect of community in such campaigns is interesting given past findings on prosocial behavior in the context of others. Past studies have suggested that the existence of others promotes prosocial behavior (Fischbacher, Gächter, & Fehr, 2001; Frey & Meier, 2004; Van Bommel et al., 2012; Garcia et al., 2009; Levine et al., 2002) while other studies have shown that the existence of others may hinder prosocial behavior (Darley & Latane, 1968; Fischer et al., 2011; Garcia et al., 2002). In light of these contradicting findings, it is important to explore how emphasizing the existence of a community in donation-based crowdfunding campaigns influences prospective donors.

This research shows that when prospective donors' experience the existence of a community in such campaigns it substantially impacts the campaigns' bottom line. As humans we have a fundamental need to connect with others and belong to a group (Alderfer 1972; Baumeister & Leary 1995; Maslow 1943; McClelland 1987; Ryan & Deci 2000), this research shows that when experiencing the existence of such communities, even when donors are strangers to each other, this need is activated and influences donation-giving. Furthermore, the need to connect with others is heightened when concerned with social exclusion, but weakened when feeling socially secured (Maner et al. 2007). In doing so, this research demonstrates how subtle cues in the campaign webpage can induce the perception of a community, activating the psychological need to connect with others to influence online donations.

In the first study, the hypothesis that emphasizing the existence of a community increases donations was tested. An "A/B testing" procedure was administered on 22 campaigns active on a crowdfunding platform (Jewcer.com) during 10 days. Donors saw either one of two versions (for each campaign) which differed only in the main slogan. In the community version the slogan was "Join our community of supporters and we can make a difference." In the control version the slogan was: "Support this cause and make a difference." Out of 3,523 web visitors, 504 made a donation. T-test analysis (combining all campaigns) show that for the community versions, donations were higher ( $M=\$62.39$ ,  $SD=\$78.15$ ) than for the control versions ( $M=\$49.61$ ,  $SD=\$55.42$ ;  $t(502)=-2.11$ ,  $p=.035$ ).

In the second study the mediating role of donors' sense of connectedness to the community was tested. MTurk participants ( $n=144$ , \$1 compensation) randomly saw one of two versions of a hypothetical crowdfunding campaign. In the control condition, donors were presented on the main page as anonymous. In the community condition, presence of others was strengthened by presenting donors with their full name. Participants reported how much of their compensation money they would like to donate (scale 0-\$1) and how connected they feel to this group of donors (scale 1-7). Finally, they completed an Interdependence orientation scale ( $\alpha=.83$ ; Singelis 1994) to rule

out interdependence orientation as the main alternative explanation. Results show that in the community condition donations and connectedness are higher ( $M_{don}=0.20$ ,  $SD=0.30$ ;  $M_{con}=3.20$ ,  $SD=1.06$ ) than in the control ( $M_{don}=0.11$ ,  $SD=0.22$ ;  $M_{con}=2.73$ ,  $SD=1.24$ ;  $t_{don}(142)=-2.05$ ,  $p=.043$ ;  $t_{con}(142)=-2.43$ ,  $p=.02$ ). Mediation analysis (PROCESS Model 4; with 5000 resamples; Hayes 2013) show that feelings of connectedness fully mediate the effect of community perception on donations, controlling for Interdependence ( $B=0.019$ ,  $SE=0.011$ ; 95% CI: [0.003, 0.050]).

In the third study the model was tested with a different community manipulation and connectedness scale: MTurk participants ( $n=202$ , \$1 compensation) randomly saw one of two campaign versions. In the control condition participants read about the campaign with no mention of other donors. In the community manipulation condition at the end of the campaign webpage participants read posts of donors that supported the campaign. Participants completed the sense of connectedness scale ( $\alpha=.94$ ; Lee, Draper & Lee 2001) and their willingness to donate a bonus prize (scale 0-\$50). T-tests show that in the community condition, donations and connectedness are higher ( $M_{don}=13.06$ ,  $SD=13.67$ ;  $M_{con}=4.28$ ,  $SD=1.31$ ) than in the control ( $M_{don}=7.98$ ,  $SD=10.35$ ;  $M_{con}=3.69$ ,  $SD=1.31$ ;  $t_{don}(200)=-2.99$ ,  $p<.003$ ;  $t_{con}(200)=-2.96$ ,  $p<.002$ ). Mediation analysis (PROCESS Model 4; with 5000 resamples) show that feelings of connectedness fully mediates the effect of community perception on donations ( $B=0.069$ ,  $SE=0.026$ ; 95% CI: [0.024, 0.124]).

The fourth study demonstrated that the effect is more likely to occur when consumers fear social exclusion than when they feel socially secured. In a 2 (social exclusion) by 2 (community perception) design, MTurk participants ( $n=321$ , \$1 compensation) first completed an extraversion scale and received (randomized) feedback on their score describing their future as socially secure or socially excluded (Twenge et al. 2007). They then saw one of two versions of a campaign. The community condition included a slogan of a community (as in study 1) and pictures of donors. The control condition had no community slogan and donors were anonymous. Participants reported feeling connected (as in Study 3), completed the PANAS scale (Watson, Clark, and Tellegen 1988) and their willingness to donate a bonus prize (scale 0-\$50).

In the moderation mediation analysis (PROCESS Model 7, with 5000 resamples), community perception serves as the predictor, social exclusion as the moderator, connectedness and PANAS-Negative as the mediators, and donations as the dependent measure. Connectedness significantly mediates the effect when feeling socially excluded ( $B=1.518$ ,  $SE=0.679$ ; 95% CI: [0.436, 3.117]) but not when feeling socially secure ( $B=0.120$ ,  $SE=0.583$ ; 95% CI: [-1.097, 1.255]). PANAS had no mediating effect.

Taken together, the results of four studies show that activating the perception of a community increases donors' responsiveness and the important role that donors' sense of connectedness to other donors has on donation giving. These findings provide important theoretical contribution to the literature on donation, crowdfunding and group processes as well as important implications for charitable organizations, crowdfunding platforms and campaign creators.

# Individual-level Carryover-Parameters in Reference-Price Models

Ossama Elshiewy, University of Goettingen, Germany  
Daniel Guhl, Humboldt University Berlin, Germany

## EXTENDED ABSTRACT

Reference-price models applied to real purchase data have a long history in marketing and consumer research (Winer 2014). Here, the researcher assumes that product choice is driven by deviations between current prices and consumers' reference-price. There is the consensus that ignoring unobserved consumer heterogeneity in reference-price models will overestimate consumer response to gains and losses (Mazumdar et al. 2005, Kopalle et al. 2012, Neumann and Böckenholt 2014). However, previous research has neglected heterogeneity for the carryover-parameters that explain the short- vs. long-term memory of consumers in reference-price formation. Consumer research acknowledges individual differences in consumer's ability to remember prices (Monroe and Lee 1999, Vanhuele and Drèze 2002). Hence, the current practice in reference-price modeling may disregard realistic choice behavior.

To the best of our knowledge, only two previous studies have made attempts to partly account for heterogeneity in the carryover-parameters. Erdem et al. (2010) used a Maximum Simulated Likelihood approach to estimate the mean and standard deviation of a Normal mixing distribution to account for heterogeneity. To obtain individual-level estimates, this approach would require an additional Bayesian updating step (see, Revelt and Train 2000). In addition, the authors assumed no correlation in the heterogeneity distribution which simplifies identification but impairs capturing realistic choice behavior. A second study by Dayaratna and Kannan (2012) provides a mathematical reformulation of reference-price models. The authors estimate a finite-mixture heterogeneity distribution with three segments (and therefore only three segment-specific carryover-parameters). In this context, Dayaratna and Kannan (2012) discuss hierarchical Bayesian (HB) approaches as an avenue for future research to obtain individual-level carryover-parameters.

Our study aims to fill this research gap. Previous studies using HB models to obtain individual-level estimates have fixed the carryover-parameter to either zero (Chang et al. 1999, Klapper et al. 2005) or to some predefined value (0.7, see Kopalle et al. 2012). These authors allowed correlation across the individual-level estimates but did not estimate carryover-parameters at all. We assume that Gibbs sampling has failed to simultaneously estimate heterogeneity in the utility drivers and the carryover-parameters. We contend that this is due to the strong impact of the carryover-parameters on the structural quantity of the gains and losses, which ultimately affect their own parameter estimates in the utility function. Recent advances in MCMC methods have led to an increased use of the so-called Hamiltonian Monte Carlo (HMC) algorithm. HMC provides improved sampling methods for HB models and can deal with such highly correlated parameters (see, e.g., Neal 2011). Hence, we propose a reference-price model that captures individual-level estimates for the utility drivers and the carryover-parameters. Our contribution to the literature is twofold. First, our approach allows modeling more realistic choice behavior that is in line with the behavioral literature in the area of consumer's price memory. Second, our results allow new insights with respect to heterogeneity in short- vs. long-term memory in reference-price formation.

It is common practice to estimate the internal reference price (*IRP*) for consumer  $n$ , choice alternative  $j$ , and time period  $t$  as a smoothed average of past prices (see, e.g., Mazumdar et al. 2005):  $IRP_{njt} = \lambda \cdot IRP_{njt-1} + (1-\lambda) \cdot PRICE_{njt-1}$ . Here,  $PRICE_{njt-1}$  are the prices

observed in the last choice situation and  $IRP_{njt-1}$  are the internal reference-prices from the last choice situation. The carryover-parameter  $\lambda$  can take values between 0 and 1, and determines how past prices affect the current reference-price (Briesch et al. 1997). Smaller values put more weight on the prices from the last choice situation for the current reference-price, which we denote as "short-term price memory." A carryover-parameter equal to zero means that the reference-prices in the current period are formed only by the prices of the last choice situation. Larger values for  $\lambda$  put more weight on the prices from less recent choice situations for the current reference-price formation, which we denote as "long-term price memory." A carryover-parameter equal to one does not provide meaningful estimates because then *IRP* remains equal to the initial-condition over the entire choice sequence. Ultimately, the magnitude of  $\lambda$  determines the structural quantity of *IRP* which is used in the utility function of the reference-price model.

Previous research has shown that consumers differ in their ability to remember prices (Monroe and Lee 1999, Vanhuele and Dreze 2002). For example, price-conscious consumers tend to process price information more thoroughly, which results in more accurate recall and long-term price memory (Monroe and Lee 1999). Moreover, long-term price memory increases with increasing loyalty (Vanhuele and Dreze 2002).

We first tested our model using the hybrid Gibbs sampler proposed by Train and Sonnier (2005). We did not achieve convergence with individual-level carryover-parameters, even after a large number of draws (200,000). Hence, we contend that the HMC algorithm is more suitable. First, the Gelman-Rubin test (Gelman and Rubin 1992) indicates successful convergence using HMC. Second, we observe a higher model fit for our proposed model compared to a benchmark model with common carryover-parameters (log Bayes-Factor = 12.467; indicates "strong evidence," see Kass and Raftery 1995). Third, we observe significant heterogeneity for the carryover-parameters. The range of  $\lambda$  for *IRP* allows interpretation in terms of short- vs. long-term price memory. In our model, the individual-level  $\lambda$  for *IRP* range from 0.285 to 0.454. Consumers in our sample tend to weight the prices from the last choice situation more than prices from the less recent choice situation in the internal reference-price formation. Importantly, we show that the consumers differ in their short-term memory for reference-price formation.

Our approach enables follow up analyses to obtain new insights into consumer choice behavior. First, our model also provides a posterior distribution for the correlation matrix of all utility drivers and carryover-parameters. These estimates can be used to assess the relationship of the price memory to any utility driver of interest (e.g., price-sensitivity or loyalty). Second, our model provides the assignment of the individual-level carryover-parameters to the consumers. This information can be used as a dependent variable in a regression analysis with consumer-related explanatory variables that may influence the price memory in reference-price formation.

# Brand Fan(atic)s: When Excessive Brand Loyalty Sends the Wrong Signal

Isabelle Engeler, IESE Business School, Spain

Kate Barasz, IESE Business School, Spain

## EXTENDED ABSTRACT

Consumers use brands in many combinations—from mixing-and-matching multiple brands (*multi-brand combination*; e.g., Nike shoes, Adidas shirt, Asics pants) to using only a single brand (*mono-brand combination*; e.g., Nike shoes, shirt, and pants). Albeit its relevance in everyday life, it is yet a “largely ignored area of branding research” (Rahinel and Redden 2013, p.1291). Addressing this gap, eight studies examine how such brand combinations (mono- vs. multi-brand) affect observers’ trust in the target consumers’ recommendations.

A pre-study established managerial intuitions. MBAs (N=124) imagined being a brand manager for Nike running shoes, employing social media influencers to promote their shoes. All learned of an influencer who posted a photo wearing five branded running products; half learned the influencer’s products were all from Nike (“*mono-brand user*”), the other half learned the products were from multiple brands (“*multi-brand user*”). Both influencers had on Nike running shoes—however, MBAs were more satisfied with the mono-brand user ( $p < .001, d = .93$ ), believing s/he would be more credible in promoting the running shoes ( $p = .09, d = .31$ ).

However, seven experiments contradicted this intuition: observers actually found mono-brand users *less* credible. Studies 1A-1C established this main effect. Study 1A (N=200) participants encountered (within-subjects) a mono- and multi-brand user of 5 real clothing brands (between-subjects: luxury or non-luxury brands); both users had an identical focal product (Gap or Louis Vuitton work bag). Participants trusted the mono-brand user less for work bag recommendations ( $p < .001, d = .84$ ) and general clothing recommendations ( $p < .001, d = .87$ ). Study 1B (N=200) replicated the finding using a between-subjects design (work bag:  $p < .001, d = .60$ ; clothing:  $p < .001, d = .94$ ). Study 1C (N=300) replicated the finding using fictitious clothing brands (work bag:  $p < .001, d = .62$ ; clothing:  $p < .001, d = .71$ ).

In all studies, the focal product was identical—only the broader brand combinations varied. Thus, differences in trust cannot be due to the particular choice of item. Instead, we propose this difference is driven by *inferences* about the users’ underlying purchase decision (e.g., Barasz et al. 2016; *forthcoming*; Bellezza et al. 2014; Rahinel and Redden 2013; Shalev and Schrift 2018): that observers infer mono-brand users were motivated relatively more by brand than other features (e.g., quality)—in essence, that they had used brand as a heuristic for their purchase decision—and had therefore less carefully considered which item to buy.

Studies 2-3 established this process using branded toiletries (e.g., shampoo, condition, soap); the focal product was always Dove body lotion. Both studies replicated the main effect (Study 2:  $p < .001, d = .86$ ; Study 3:  $p < .001, d = .86$ ). In addition, the two studies investigated observers’ inferences about (1) *relative importance of brand* and (2) *careful consideration*. Study 2 (N=202) measured these two mediators: participants believed brand was relatively more important to mono-brand (vs. multi-brand) users ( $p < .001, d = 1.20$ ) and inferred they were less careful in considering what body lotion to buy ( $p < .001, d = 1.16$ ). Mediation analysis revealed a significant total indirect effect of brand combination on trust in recommendation via the two sequential mediators (95% CI [-21.63, -11.39]). Study 3 (N=406) manipulated the mediators to turn off the effect ( $p = .584, d = .08$ ).

Studies 4A-4B tested the effect of mono- (vs. multi-) brand combinations on the observers’ own behavior. Study 4A (N=115) used distance runners (recruited via the facebook page of a race organizer) and choices of running gear; Study 4B (N = 67) new parents (recruited via a special interest online forum) and choices of baby gear. Both studies replicated the main effect of reduced trust (Study 4A:  $p = .008, d = .51$ ; Study 4B:  $p < .001, d = .92$ ), which followed through to reduced interest in purchasing (Study 4A, 95% CI [-.09, -.87]) or learning more about the focal product (Study 4B, Sobel  $Z = 1.78, p = .075$ ), and reduced intention to follow the target consumer on social media (Study 4B, 95% CI [-.95, -.25]).

These findings contribute to the literature on social learning and influence, specifically in contexts where people simply observe one another’s choices (e.g., Barasz et al. 2016; *forthcoming*; Bellezza et al. 2014). Past research has examined the effect of observed choice on consumer attitudes and behavior (e.g., Ferraro et al. 2013). Our findings suggest that it is also critical to understand what inferences these observations elicit: seeing someone wearing a pair of Nike running shoes *may* increase an observer’s own purchase interest, but whether or not it does depends on the inferences people make about *why* and *how* those running shoes were purchased. In other words, even holding the actual observed choice constant, the inferences consumers make *about* that choice can reduce trust in recommendations and observers’ own purchase interest. Many factors may affect those inferences; our work identifies a critical one—brand combinations.

Our results also have important practical implications. Given the growing importance of influencer marketing, surprisingly little academic research has so far examined the specific factors affecting social media influencers’ ability to *influence*. Some research has begun to tackle this question (e.g., Sah et al., 2018). However, this area seems broadly ripe for additional research. Our investigation highlights one such factor affecting influencers’ trustworthiness—the brand combinations they have supposedly chosen to consume—and speaks to the broader question: Holding the actual influencer constant, how should brands best position themselves—quite literally—in order to maximize the influencer’s influence? While a marketer’s rational goal is to push one’s own brand—to the exclusion of its competitors—our results suggest there may be a signal benefit to embedding one brand within the context of others.

## EXTENDED ABSTRACT

How large is the amount of \$100? How good is an SAT score of 1200? How large is the number of 800 people left homeless by a natural disaster? Evaluating attribute values is a cornerstone of virtually every judgment or decision that humans make. In this paper we advance and empirically test a theory of how people evaluate attribute values.

We posit that individuals may rely on four processes (or inputs) when evaluating attribute values. We conjecture and provide empirical evidence that the four inputs are ordered, in the sense that an input that is perceived to be more diagnostic and/or requires less cognitive effort is more likely to drive an attribute's evaluation. An input is diagnostic for a judgment—in this case an evaluation—to the degree that it is relevant for evaluating the target attribute value. The use of an input is effortful to the degree that it consumes cognitive resources. We propose that normally less diagnostic-more effortful inputs exert a stronger influence on evaluations when otherwise more diagnostic-less effortful inputs are unavailable. We describe the four evaluation inputs below.

The first input entails an evaluation of a target value without reference to other information. The second input entails a comparison of the target stimulus's target attribute value with another value on the same attribute. The second input has a stronger impact on evaluations when the target attribute value is not highly evaluable in isolation (Hsee 1996; Hsee et al. 1999). The third input entails a comparison of the target value with a compatible value on another (reference) attribute. The third input has a stronger impact on evaluations when the target attribute is not highly evaluable in isolation and there is lack of information about other values on the target attribute. The fourth input entails an inference about the target value based on an incompatible value on a reference attribute. The fourth input has a stronger impact on evaluations when the target attribute value is not highly evaluable in isolation, when no comparison can be made with another value on the same attribute, and when no comparison can be made with a compatible value on a reference attribute.

We test our theory in 13 studies. Given that prior research provides ample evidence for the first two inputs, our investigation is focused on providing evidence for the third and fourth input. Importantly, we also provide process evidence for our overall framework by demonstrating that the impact of each of these inputs on evaluations is contingent on the evaluability of the target attribute and on the availability of information about other values on the target attribute. We further show that the impact of the fourth input on evaluations is contingent on the degree of compatibility between the target attribute value and the reference attribute value.

Studies 1a-1c provide evidence for the third input of the evaluation process across different contexts. We show that, holding target values fixed, targets are perceived to be smaller (or worse) as compatible reference values increase. Consistent with our framework, in Study 2 we show that this effect is moderated when more diagnostic inputs are made available. Next, we turn our attention to the fourth input of the evaluation process. Studies 3a-3c provide evidence for the fourth input across different contexts. We show that, holding

target values fixed, target evaluations increase (e.g., target attribute values are perceived as larger or better) as incompatible reference values increase. Studies 4 and 5 provide further process evidence for our theoretical framework. In Study 4 we find that the effect of the value on an incompatible reference attribute on judgments about the value on a target attribute is contingent on the degree to which the target is evaluable. In Study 5 we show that judgments about the attractiveness of the incompatible reference value correlate positively with judgments about the attractiveness of the target value consistent with the fourth input of the evaluation process. Further, Study 5 also shows that the impact of the fourth input on evaluations is attenuated in joint compared to separate evaluation mode, presumably because—previously argued—same-attribute information is seen as more diagnostic relative to information from another attribute. In Study 6 we test whether the extent to which the two attributes are seen as correlated moderates the impact of the fourth input. Finally, in Studies 7a, 7b, and 8 we provide further evidence for our theoretical framework by influencing whether participants evaluate a given target based on the third or fourth input of the evaluation process. We directly manipulate whether the two attributes are compatible, and show that the direction of the effect of the reference value on evaluation of the target value is contingent on the compatibility of the two attributes.

Evaluability Theory (Hsee and Zhang 2010)—the most prominent framework in psychology with respect to attribute-level evaluations—discusses factors that determine the evaluability of a given attribute. These factors include the evaluator's knowledge about the target attribute, the nature of the target attribute, as well as the evaluation mode. Nonetheless, Evaluability Theory remains rather silent about whether, when, and how evaluators use information about other (i.e., reference) attributes when evaluating a target. To our knowledge, our theoretical framework is the first to provide an answer to these three questions. We build on Evaluability Theory, which essentially represents the first two inputs of the evaluation process, and add two additional inputs whereby evaluators rely on information about other (reference) attributes when assessing the magnitude of target values on attributes that are not highly evaluable. Therefore, our framework is the first that explains how individuals use both within- and between-attribute information to evaluate a target.

# When Small Predicts Large: The Effect of Initial Small Contributions on Subsequent Contributions in a Crowdfunding Project

Tingting Fan, Chinese University of Hong Kong, China  
Leilei Gao, Chinese University of Hong Kong, China  
Yael Steinhart, Tel Aviv University, Israel

## EXTENDED ABSTRACT

Crowdfunding is becoming an increasingly popular means for entrepreneurs to raise capital through online platforms. When deciding whether to support a project, a potential backer evaluates the project not only based on information provided by the entrepreneur, but also based on the amount already invested in the project. Some research has suggested that larger contributions are likely to create contribution momentum and elicit backers' herding behavior (Agrawal, Catalini, and Goldfarb 2015). Accordingly, it is common for entrepreneurs to ask their friends or families to "seed" investments in the early stages of a crowdfunding project. But does this "friendship-giving" really benefit crowdfunding projects?

We propose that the opposite is true, such that "friendship-giving" may impede rather than benefit a crowdfunding project. Our proposition relies on potential backers' awareness of the amounts invested during the early stages of the project and on the "friendship-giving" lay belief, according to which people believe that entrepreneurs' friends contribute more to their crowdfunding projects than strangers do. This lay belief was supported in a pilot study ( $n=99$ ; 4.69 vs. 2.94, respectively;  $t(98)=4.87$ ,  $p<.001$ ). Additionally, in that study, when participants were asked to think of themselves as friends of the entrepreneur, they were significantly more likely to choose a larger contribution amount than did those who were asked to consider themselves as strangers (53.8% vs. 8.5%;  $\chi^2(1)=23.20$ ,  $p<.001$ ).

We suggest that since potential backers cannot know for sure the relationship between the entrepreneur and the other backers, they use the percentage of large vs. small contributions in the initial period as a relationship indicator. Consequently, given the "friendship-giving" lay belief, a high percentage of large initial contributions is likely to signal to potential backers that the early backers are friends of the entrepreneur, and that the project is not necessarily worthy. In contrast, a large percentage of small contributions is expected to signal that many strangers find the project interesting, thereby motivating subsequent contributions. Thus, contrary to common beliefs, we predict that small, rather than large, initial contributions lead to more positive inference-making and to larger subsequent contributions.

Both large-scale field data and lab experiments supported this hypothesis.

First, we analyzed 902 projects on DemoHour, one of the largest reward-based crowdfunding platforms in China. Models 1 and 2 show that "the percentage of small contributions in the first day" has a positive and significant effect on "the total money pledged" as well as "the probability of success", suggesting that the higher the percentage of initial small contributions, the more money a project will raise. Additional analysis indicates that small contributions have a positive and significant effect on subsequent backers' contribution amounts, especially in the early stages of the project (Model 3).

Importantly, we examined the validity of the "friendship-giving" lay belief by identifying friendships (or the lack thereof) between 738 entrepreneurs and 31,388 backers, on the basis of their online social networks on Weibo.com (China's Twitter equivalent). Model 4 shows that "friendship between an entrepreneur and a backer" has a positive and significant effect on "the amount of money a backer contributes", suggesting that friends contribute more than

strangers. Model 5 further indicates that more friends contribute in the early stages than in the late stages.

Study 1 confirmed that individuals are willing to contribute a higher amount when the majority of initial contributions consist of small rather than large amounts, and that this tendency is driven by the "friendship-giving" lay belief. Participants ( $n=100$ ,  $M_{\text{age}}=35.58$ ; 47% female) read a description about a crowdfunding campaign in which the entrepreneur is raising funds to develop a smartphone-camera stabilizer. We informed participants that the entrepreneur was offering a thank-you letter for a \$10 contribution, and a \$50 price discount to purchase the product (when launched) for a contribution of \$50 or above, and that the project had already secured 10% of the target amount. We also told them that among all individuals who had contributed to the project on the first day of its launch, a majority had contributed either \$10 (small-initial-contribution condition) or \$50 (large-initial-contribution condition). We found that participants in the small-initial-contribution condition were willing to contribute a larger amount compared with those in the large-initial-contribution condition (\$23.38 vs. \$13.44,  $t(101)=1.83$ ,  $p=.07$ ), and were more likely to believe that the initial backers were total strangers to the entrepreneur (4.86 vs. 3.80,  $t(101)=3.12$ ,  $p=.002$ ). The effect of large/small initial investment percentage on the amount participants were willing to contribute was mediated by the belief that initial backers were strangers to the entrepreneur ( $b=-2.68$ ,  $SE=1.79$ , 95% CI: -7.54 to -.21).

Study 2 used a process-by-moderation approach in which we directly manipulated the accessibility of the friendship-giving lay belief. Specifically, participants ( $n=235$ ,  $M_{\text{age}}=35.91$ ; 46% female) read a description about a specific crowdfunding campaign. However, one group of participants was encouraged to "correct" their lay belief prior to their contribution decisions. An ANOVA revealed a significant interaction effect between initial investment and lay-belief-correction on participants' willingness to contribute ( $F(1,231)=3.99$ ,  $p=.047$ ). Specifically, among participants in the lay-belief-not-corrected condition, those in the small-contribution condition were willing to contribute a larger amount to the project ( $M=.93$ ,  $SD=.61$ ) than were those in the large-contribution condition ( $M=.70$ ,  $SD=.69$ ,  $F(1, 231)=3.65$ ,  $p=.057$ ). In contrast, in the lay-belief-corrected condition, the effect was attenuated.

Study 3 tested a boundary condition for the effect observed. Participants ( $n=130$ ,  $M_{\text{age}}=37.23$ ; 46% female) were randomly assigned to four conditions: 2(initial investment: small vs. large) x 2(campaign progress: early vs. late stage). An ANOVA revealed a significant interaction effect between initial investment and progress on participants' willingness to contribute ( $F(1,126)=4.38$ ,  $p=.038$ ). Specifically, when the project was in an earlier stage (10% of the total amount secured), participants were willing to pledge a larger amount when the initial investment was small rather than large (\$30.26 vs. \$11.22,  $F(1,126)=3.84$ ,  $p=.052$ ). The effect was eliminated, however, when the project had secured 90% of the total amount ( $M_{\text{small}}=\$21.87$  vs.  $M_{\text{large}}=\$31.00$ ,  $F(1,126)=.96$ ,  $p=.33$ ).

Taken together, our results show that smaller initial contribution amounts predict larger subsequent contributions, by signaling that strangers (vs. friends) support the project.

# Trapped in the Rabbit Hole: Life History Strategies Modulate the Impact of Mild Stress on Hedonic Consumption

Bob M. Fennis, University of Groningen, The Netherlands  
Justina Gineikiene, ISM University of Management and Economics, Lithuania  
Dovile Barauskaite, ISM University of Management and Economics, Lithuania  
Guido M. van Koningsbruggen, Vrije Universiteit Amsterdam, The Netherlands

## EXTENDED ABSTRACT

The current research tests *how* and *when* consumer life history strategies (LHS) – short-term, reward-sensitive (fast) vs. long-term, goal-oriented (slow) foci- might drive food related decision making. Previous studies have pointed to the role of presently experienced stress, adversity or scarcity and have shown that under high levels of acute stress and anxiety, fast and slow strategists sometimes diverge in opposing directions –consumers with a fast LHS become more impulsive, reward seeking and less future oriented under severe stress or anxiety, whereas consumers with a slow LHS show the opposite and become more deliberate, less reward seeking and more future oriented (Griskevicius et al. 2011b; Mittal and Griskevicius 2016; Mittal et al. 2015). Yet, while illuminating, these studies have typically resorted to relatively “dramatic”, atypical, and impactful sources of stress and anxiety, such as (scenarios about) a severe economic crisis (e.g., featuring home foreclosure signs, unemployment lines, and emptied office spaces) or the salience of violence and death in one’s life and environment (Griskevicius et al. 2011a; Griskevicius et al. 2011b; Mittal and Griskevicius 2014). Thus, it is unknown whether, and if so to what extent, the distinction between a fast vs. slow LHS remains a meaningful predictor of health-related decision making under more mild, mundane conditions of stress, as faced by the bulk of consumers on a daily basis. Research suggests that it might –but not for everyone.

In particular, stress sensitization (or kindling) theory (Hammen et al. 2000; Post 1992) proposes that individuals who have experienced stressful and unpredictable conditions during early childhood become *sensitized* to such conditions and become more vulnerable to more proximate stressors, compared to individuals who have generally not been exposed to such conditions during childhood. Consequently, the *same* conditions that foster the cultivation of a fast LHS, also *lower* the threshold of stress tolerance later in life. We propose that mundane, mild and proximate stressors (e.g., the experience of daily hassles or time pressure) affect the decision making of fast, but not slow life history consumers. Hence, consumers who have experienced childhood stress and adversity and follow a fast LHS may become “trapped in a rabbit hole” –their past experienced stress levels have heightened their overall sensitivity to proximate stressors, such that their tendency for reward-seeking, opportunism and a focus on short-term gratifications can be triggered relatively frequently and easily by subtle, mild sources of stress. Under these conditions, these individuals may show an increased tendency for hedonic consumption, especially when such consumption presents itself as a scarce opportunity. Given the prevalence of such subtle, mild stressors in daily life, it stands to reason to assume that a fast LHS affects health related decision making to a larger extent than a slow LHS does, creating a possible self-perpetuating process, from which these consumers may not easily escape.

Stated more formally, we propose that life history strategies modulate the impact of acutely experienced stress due to mild stressors, such that experienced stress has an impact on food-related decision making for fast, but not slow LHS consumers. Under these conditions, we expect fast LHS consumers to show an increased

tendency for hedonic consumption, especially when such hedonic consumption presents itself as a rare, scarce opportunity.

Three experimental studies tested our hypotheses. Experiment 1 ( $N = 102$ ) set out to test the fundamental notion that acutely experienced stress due to a mild stressor may boost the tendency for hedonic consumption, as indicated by the willingness to pay for hedonic food products, particularly among consumers with a fast, rather than slow LHS. This experiment used a design with stress as a between subjects factor and individual differences in LHS as a continuous measured independent variable. Experiment 2 ( $N = 195$ ) aimed to replicate and extend our main findings, using the same design with a larger sample, a different proxy of hedonic consumption, and accounting for mood as an alternate explanation of our findings. Finally, experiment 3 ( $N = 101$ ) extended these results by assessing the impact on actual hedonic food intake and examined a direct corollary of the LHS logic. This field experiment used a design with stressor (time pressure present vs. absent) and scarcity cue (present vs. absent) as between subject factors and individual differences in LHS as a measured independent variable.

The three studies yielded consistent support for the notion that life history strategies modulate the impact of mild stress by boosting the tendency for hedonic consumption for fast, but not slow LHS consumers. Under these conditions, fast LHS consumers show an increased tendency for hedonic consumption as evinced by increased willingness to buy hedonic products (Exp. 1, Exp. 2), and actual consumption of hedonic foods (chocolate, Exp. 3.). Moreover, Experiment 3 showed that such hedonic consumption under these conditions is more pronounced when hedonic food items present itself as a rare, scarce opportunity. We advance the understanding of how people become sensitized to stress by revealing the role of experienced *levels* of current stress. Specifically, while it has been suggested that there are symmetrical effects of extreme levels of acute stress for fast and slow strategists (Griskevicius et al. 2011b; Mittal and Griskevicius 2014), our findings extend this research by building on a key assumption of stress sensitization theory demonstrating asymmetrical effects—mild stress levels affect behaviors of fast strategists but not that of slow strategists.

# How Do Platform-Based Networks Shape Systemic Value Creation through Experiences?

Bernardo Figueiredo, RMIT University, Australia

Daiane Scaraboto, Pontificia Universidad Catolica de Chile, Chile

## EXTENDED ABSTRACT

Understanding how to create valuable experiences for consumers and firms has been a priority for marketing researchers and practitioners (Lemon and Verhoef, 2016) as experiences are increasingly responsible for creating competitive edge in contemporaneous markets (Duncan et al 2016; Pine and Gilmore 1998). New systemic (Akaka, Vargo, and Lusch, 2012) and network (Prahalad and Ramaswamy 2004) perspectives introduced a co-creative view of customer experiences, where customers are no longer considered as 'passive' receivers of an experience, but 'active' participants in the co-creation of their own experience (McCull-Kennedy et al 2017).

As noted by De Keyser et al (2015), marketing thought is evolving towards a network-oriented view of the experience environment, hence emphasis on how multiple actors connect to each other is a more appropriate way to study CX in contemporary contexts. Following this call, we examine the role of platform-firms, i.e. the firms that mediate the online interactions happening in collaborative networks (Scaraboto 2015), in shaping the process of value creation through experiences in networked environments.

Prior consumer research demonstrates that value can aggregate at a systemic level (Figueiredo and Scaraboto 2016) in platform-based environments when networked participants "integrate and exchange resources to co-create value for themselves and for others" (Akaka et al. 2012, 15). Hence, to understand how networked experiences create value, it is important to look beyond how an experience creates value for individual participants, focusing instead on how experiences aggregate to create value in networked environments. We ask: *How can platform-based firms shape systemic value creation through experiences?*

To address this question, we conducted a 12-month netnography (Kozinets, 2015) of Couchsurfing, a platform-based collaborative network in which consumers share free accommodation and social experiences. Couchsurfing was launched in 2003 to connect individuals interested in staying as guests at hosts' homes, hosting travelers, socializing with locals and other travelers, or joining a cultural or social event while traveling. Couchsurfing is an ideal context for this type of research because it emphasizes other types of experiential value (beyond economic) and considers all members (both providers and takers of accommodations) as capable of simultaneously producing and living experiences for themselves and for others.

Our analysis suggests that individual experiences aggregate to create value in platform-based networks in a three-step process involving stages of transvaluation, assessment and engagement. The first stage consists of the registration of expectations, performances, and responses on the platform, thus materializing the value of individual experiences. In the second stage, aggregate experiences are assessed by couchsurfers, generating multiple value outcomes for network participants. In the third stage, participants in the network associate these value outcomes with the network, constituting the value of the Couchsurfing network for its members.

Platform-businesses can shape systemic value creation through experiences by supporting value creation at the level of individual experiences (expectations, performances, and responses), and at the level of aggregate experiences (network level). To support value creation at the level of individual experiences, platform-firms act in four ways: 1) *Supporting the provision of resources by networked members*; 2) *Shaping the types of performances that emerge in the*

*network*; 3) *Stimulating the individual management of expectations for value-creating performances*; and 4) *Suggesting individual responses to the value-creating performances*.

To support value creation at the level of aggregate experiences, platform-firms can interfere in any of the three stages of the process of systemic value creation. Platform-firms shape transvaluation in three ways: 1) *Deincentivizing the registration and public sharing of negative experience*; 2) *Rechanneling negative experiences*; and 3) *Reframing registration*.

Platform-firms shape assessment in three ways: *checking, channeling, and curating* transvalued experiences. Finally, platform-firms shape engagement by *highlighting the network's multiple value outcomes*.

Although researchers have argued for a more systemic and dynamic view of customer experience (Lemon and Verhoef, 2016; Verhoef et al., 2009), few studies examine experiences in platform-based networks, in which individual experiences aggregate. This netnographic analysis explains and vividly illustrates the process through which performances integrate resources to create experiences and how platform-firms help transvaluation and collective assessments of the value created by many.

In platform-based networks, individuals lead value creation and experiences. This study has examined how platform-firms can support and shape systemic value creation through experiences even when these have been framed and developed by consumers themselves. These findings extend SDL work on ecosystems (e.g., Akaka et al., 2012; Vargo and Lusch, 2008) by developing knowledge on how resources can be managed in platform-networks. Finally, by theorizing the role of experiences in value creation, our study expands CCT researchers' understanding of the sociocultural aspects of value creation in experiences.

# I, Me, Mine: The Effect of the Explicitness of Self-Anchoring on Consumer Evaluations

Adrienne E. Foos, Mercyhurst University, USA  
Kathleen Keeling, University of Manchester, UK  
Debbie Isobel Keeling, University of Sussex, UK

## EXTENDED ABSTRACT

While research on the formation of consumer attitudes often focuses on the evaluation of product and service attributes, Gawronski, Bodenhausen & Becker (2007) suggest the self-concept is possibly the most fundamental factor impacting the formation of attitudes toward objects. They argue that the self serves as an anchor for evaluating objects when the self is salient by transferring meaning from the self to the object through elaborative associations. Research is needed to unpack the process of self-anchored attitude formation and potential factors influencing this process.

One such important factor to examine is the impact of positive and negative information about products and services on attitudes. While prior research demonstrates interesting results for attribute evaluation (a small piece of negative information made consumers more favorable towards products) (Ein-Gar, Shiv, and Tormala 2012), the effect of positive and negative information when the self is salient may be even more fundamental to understanding the process of how self-anchored objects are ultimately accepted or rejected. In addition, traditional attitude theories often focus solely on immediate attitude formation (Cohen and Reed II 2006), however, understanding temporal changes in attitudes may be more useful in explaining observed behavior. In two experiments, we examined how consumer attitudes are affected by positive and negative information about a product and service, over time, when the self is salient.

According to self-anchoring researchers, the self-concept influences attitudes towards objects through the creation of elaborative associations (Walther and Trasselli 2003). Self-salience when evaluating objects is said to be sufficient to build self-object associations; the mode for affective transfer of meaning from the self to object (Gawronski, Bodenhausen, and Becker 2007; Walther and Trasselli 2003). Self-anchoring researchers suggest excitatory associations between the self and accepted objects, and inhibitory blocks dissociating the self from rejected objects in order to protect the positivity of the self-identity (Gawronski et al. 2007; Otten 2003; Walther and Trasselli 2003). Similar to self-anchoring, self-referencing is defined as processing information in relation to oneself (Burnkrant and Unnava 2000). The self is said to create elaborative associations, since it is a complex structure (Burnkrant and Unnava 2000; Greenwald and Banaji 1995). Consistent with previous self-anchoring and self-referencing research, we predicted self-salience results in meaning transfer through self-object associations.

With Experiment 1, we sought to demonstrate empirical evidence of self-anchoring-induced associations between the self and object (in this experiment, a tablet computer serves as the object) using an implicit prime manipulation. Contrary to previous self-anchoring research, Experiment 1 showed that implicit self-anchoring does not result in meaning transfer. This suggests the implicitness of self-anchoring does not generate associations capable of meaning transfer. With no evidence of the formation of associations between the self and object, there cannot be dissociation. The lack of dissociation means that consumers are not able to resolve positive and negative information over time, and instead either automatically and immediately accept positively-perceived objects or reject negatively-perceived objects.

With Experiment 2, we sought to confirm the implicit self-anchoring results of Experiment 1 and explored the impact of ex-

PLICITLY associating the self and object (hereafter referred to as self-referencing). We confirmed that implicit self-anchoring does not result in elaborative associations capable of meaning transfer, and it instead 'fixes' initial positive or negative attitudes over time. As predicted in the second experiment, in the self-anchoring and positive message group, the positive initial impression was persistent. Typically, there is a decay in the favorableness of attitudes over time positive message groups, however, this effect was not present. In this case, self-anchoring fixed the initial positive impression without the need for further processing. The automatic negative reaction to negative messages was also persistent. Experiment 2 demonstrated that only when participants explicitly imagined themselves consuming an experience (staying at an island resort), elaborative associations capable of meaning transfer were formed. Consumers who self-referenced were more involved in deeply processing the positive and negative information, which de-stabilized attitudes over time. The self-referencing groups did form elaborative associations capable of meaning transfer, which particularly aided participants in processing conflicting messages. However, compared to the self-anchoring groups, attitudes in the self-referencing and positive message group decayed over time.

The results of the experiments distinguish between the effects of two factors previously formulated as similar, and identifies their differing impact on meta-cognitive mechanisms and attitudes over time. The findings of the first experiment demonstrate that implicit self-anchoring, contrary to Gawronski et al. (2007), does not create associations capable of meaning transfer between the self and object, but rather automatic and evaluation of the object. This led to a re-formulation of the hypothesized processes in Experiment 2, and confirmation that implicit self-anchoring instead creates an automatic and persistent effect in which the self is attracted to positively-perceived objects and immediately rejects negatively viewed objects. Importantly, this indicates that for elaborative associations capable of meaning transfer and explicit attitude change, a higher level of processing is required (Perkins and Forehand 2012). To induce a higher level of processing, consumers must explicitly self-reference. The results of the experiments lend clarity to previous research on the impact of the self on attitude formation toward objects, and demonstrates two distinctive effects on attitudes, which are only revealed over time. Future research should replicate the findings of the second experiment, and continue to empirically test the theoretical assumptions of contemporary models of attitude formation and for consumer research.

# Major or Minor: When Foreign Language Increases versus Decreases Cheating

Phyliss J. Gai, Erasmus University, The Netherlands  
Stefano Puntoni, Erasmus University, The Netherlands

## EXTENDED ABSTRACT

The world is witnessing dishonesty of all magnitudes, from minor shoplifting to astounding financial traps, from embellishing dating profiles to faking identities. Given the prevalence of dishonesty, researchers have endeavored to learn which factors encourage or curb cheating, such as self-control (Kouchaki & Smith, 2014), self-serving justifications (Shalvi, Eldar, & Bereby-Meyer, 2012), and the salience of moral standards (Shu, Mazar, Gino, Ariely, & Bazerman, 2012). However, the role of language, the very vehicle through which most cheating behavior happens, has been neglected. While most people cheat in their native language, foreign-language cheating is also common, such as international students cheating on exams and overseas travelers cheating on custom declarations. Over half of the world population speaks more than one language and the number of bilinguals is increasing rapidly due to globalization (Grosjean, 2010). Therefore, it is important to understand how language (native vs. foreign) shapes people's propensity to cheat. To this end, we investigate in a series of experiments whether language affects cheating behavior.

Unethical behavior has been described as affect-rich and driven by emotion (Dienstbier & Munter, 1971; Haidt, 2001, 2003; Tangney, Stuewig, & Mashek, 2007). For instance, reduced amygdala activation, which implies less negative affective reaction toward cheating, predicts an increase of the magnitude of dishonesty (Garrett, Lazzaro, Ariely, & Sharot, 2016). Following this line of research, we propose that language may influence cheating behavior through emotionality. Indeed, one prominent finding in the bilingualism literature is that people tend to experience less intense emotions when reading or hearing the same expression in a foreign language than in their native language (Dewaele, 2004; Harris, Ayçiçeği, & Gleason, 2003; Puntoni, de Langhe, & van Osselaer, 2009).

How people feel about cheating should vary across magnitudes of dishonesty. Cheating often grants access to undeserved financial or other rewards, elevating one's mood (Meloy, Russo, & Miller, 2006; Ruedy, Moore, Gino, & Schweitzer, 2013). This positive feeling should dominate minor cheating, when people can still flexibly justify their misconduct and get ride of guilt and shame (e.g., "I deserve the prize because I could have made it") (Shalvi, Dana, Handgraaf, & De Dreu, 2011). However, as the magnitude of dishonesty increases, negative emotions associated with cheating tend to intensify (Peer, Acquisti, & Shalvi, 2014) and should overwhelm the positive emotions in the case of major cheating. Because foreign language attenuates the intensity of emotions associated with cheating, we predict that minor cheating should be less likely and major cheating more likely in a foreign-language context compared to in a native-language context.

We developed a spot-the-difference task to test our hypotheses. Participants who passed the pre-screening of foreign-language proficiency were randomly assigned to complete the task either in their native or a foreign language. We asked participants to find 3 differences between two images in each trial and awarded them a fixed amount of money for each success (self-reported successful find: Yes or No). Unknown to participants, we manipulated the real number of differences between 0 and 3 across trials. Therefore, each success claim (i.e., "Yes" response) must be cheating when there were less than 3 differences between images. Moreover, as the real number of between-image differences decreased (2, 1, 0), the magnitude of

dishonesty that was necessary for monetary gains increased (no need to cheat, minor, moderate, major). The task had 9 cheatable trials in total (3 trials per magnitude of dishonesty).

We conducted four studies with a variety of language pairs. Study 1 and 2 recruited native Mandarin speakers who spoke English (N = 153 and 133 respectively). Study 3 recruited native French speakers who spoke English (N = 70). Study 4 recruited native Mandarin speakers who spoke Korean as a foreign language. (N = 119). We adopted a meta-analytical approach to analyze the data across the studies. The outcome variable was the binary response with a logit link (successful find/cheating = 1, unsuccessful find/honest = 0). The magnitude of dishonesty served as the trial-level predictor (continuous) and the language condition as the individual-level predictor (binary). The model accounted for nested random effects. Across studies, there was a significant interaction between language and magnitude of dishonesty ( $b = 0.90$ ,  $SE = 0.21$ ,  $z = 4.22$ ,  $p < .001$ ). In two-difference trials (which allowed minor cheating), people in the foreign condition were less likely to cheat than those in the native condition ( $b = -0.89$ ,  $SE = 0.30$ ,  $z = -2.94$ ,  $p = .003$ ). In zero-difference trials (major cheating), by contrast, people in the foreign condition were more likely to cheat than those in the native condition ( $b = 0.90$ ,  $SE = 0.34$ ,  $z = 2.65$ ,  $p = .008$ ). In one-difference trials (moderate cheating), there was no language effect ( $p = .975$ ).

The results support our hypotheses that foreign language decreases minor cheating and increases major cheating. Our findings add to the growing evidence that judgment and decision-making are vulnerable to the influence of language (e.g., the "Asian disease" problem in Keysar, Hayakawa, & An, 2012) and extend existing work from hypothetical dilemmas (e.g., the "Footbridge dilemma" in Geipel, Hadjichristidis, & Surian, 2015) to real-world moral behavior. Bilinguals, like monolinguals, encounter ethical dilemmas on a routine basis, such as whether to download illegal software, whether to keep a promise, and whether to help those in need. Our findings suggest that the language we use has a significant impact on everyday moral decisions.

# Understanding the Framing of Recommendations

Phyliss J. Gai, Erasmus University, The Netherlands  
Anne-Kathrin Klesse, Erasmus University, The Netherlands

## EXTENDED ABSTRACT

Consumers receive product recommendations on a daily basis. Whereas prior research mostly focused on how to improve the accuracy of recommendations (e.g., Bodapati, 2008; Swaminathan, 2003), research on how recommendations should be communicated to consumers (i.e., how they should be framed) is non-existent. This is particularly surprising, considering the billions of dollars companies like Netflix and Amazon invest per year in recommendation algorithms (Koblin, 2017).

Our research is intended to close this gap by exploring the impact of different framings of the same recommendation on consumers' likelihood to follow it. We distinguish between two types of recommendation framings: *User-based* framing which emphasizes the similarity between users (e.g., "People who like this also like") and *item-based* framing which emphasizes the similarity between items (e.g., "Similar to this item"). In this research, we suggest that consumers are more likely to follow a recommendation when it is presented with the user-based rather than the item-based framing, which we term as the 'framing effect'. This proposition is rooted in research on conformity documenting that people tend to conform to the preferences of ingroup others (Bearden & Etzel, 1982; Cialdini & Goldstein, 2004). We propose that user-based framing enhances the recognition of social clustering (i.e., categorization of users based on preference overlap) as the recommendation strategy and, thus, prompts people to conform to similar others' preferences. Here, we present four studies (one field experiment) that tested our theorizing.

Study 1 is a field experiment that corroborates the advantage of user-based framing relative to item-based framing. We collaborated with a media company that pushed daily articles to 70,488 subscribers on WeChat, the top mobile application in China. The experiment was conducted at the article level. We randomly assigned 31 pre-selected articles to the user-based framing and another 31 to the item-based framing. Each article in the user-based condition ("People who like this article also like") was randomly paired up with one article in the item-based condition ("More reports of scientific research"). The 31 pairs of recommendations were randomly distributed across 31 days, inserted to the end of daily headline articles. Controlling for the reads of focal articles, user-based framing attracted more reads to recommended articles than item-based framing (Mean increase of reads: 7.9% versus 3.6%,  $p < .001$ ).

To understand why the framing effect emerged, we approached 780 subscribers of the media company to complete Study 2 (67% females,  $M_{\text{age}} = 24.4$ ). Participants were randomly assigned to read either the user-based framing or the item-based framing used in study 1. On a 6-point scale, we measured participants' interest in the recommendation and how much they perceived social clustering as the recommendation strategy (1 = strongly disagree, 6 = strongly agree). Consistent with study 1, participants were more interested in user-based recommendations ( $M = 4.65$ ) than item-based recommendations ( $M = 4.48$ ),  $p = .028$ . In addition, the framing effect was mediated by perceived social clustering (95% CI of the indirect effect = [0.02, 0.97]).

One important reason of social conformity is informational influence, resulting from people's perception that others' preferences and actions are the most appropriate ones (Deutsch & Gerard, 1955). This influence should weaken as people possess more consumption knowledge and thus have a lower need to rely on information from

others. Study 3 tested this proposition. We recruited 403 workers from Amazon Mechanical Turk (MTurk) to participate in an "Online Museum" study (186 females,  $M_{\text{age}} = 37$ ). Specifically, they viewed 50 focal paintings in a random sequence and could "like" each painting by clicking on a heart-shaped button. When participants liked a painting, another button showed up saying either "People who like this painting also like" (user-based framing) or "Similar painting to this" (item-based framing), depending on the condition participants were assigned into. Effectiveness of recommendation was operationalized as the probability that people clicked through the recommendation. To measure consumption knowledge, we asked participants to report how often they visited art museums in real life (1 = never, 2 = seldom, 3 = sometimes, 4 = often, 5 = very often). Linear regression revealed a significant interaction between framing and museum-visit frequency ( $b = -6.70$ ,  $p < .001$ ). Consistent with our prediction, user-based framing significantly increased the recommendation click-through compared to the item-based framing for people who never ( $p = .001$ ), seldom ( $p < .001$ ), or sometimes visited art museums ( $p = .015$ ). This effect diminished for people who often ( $p = .501$ ) or very often visited art museums ( $p = .642$ ).

While people conform to their ingroup, they diverge from outgroups' tastes (Berger & Heath, 2008) possessions, attitudes, or behaviors. Therefore, user-based framing should decrease recommendation click-through when there is an explicit cue signaling that other users are outgroup. We tested this prediction with a book-shopping scenario. We randomly assigned 360 MTurkers who were 25 years old or above (169 females;  $M_{\text{age}} = 38$ ) to one of three conditions, the user-based framing ("Customers who viewed this item also viewed"), the item-based framing ("Similar to this item"), and the user-based framing with an outgroup cue. The outgroup cue was the age group of other customers (18-24 years old). We replicated the advantage of user-based framing over item-based framing for attractive focal books ( $b = 0.72$ ,  $p = .045$ ). As predicted, the effect reversed when the outgroup cue was present ( $b = -0.98$ ,  $p = .001$ ).

Our findings imply that simply changing how companies describe their method of recommendation can have an impact on sales. The current research contribute to the theorizing of how consumers decode information about recommendations (Fitzsimons & Lehmann, 2004; Senecal & Nantel, 2004). Practically, managers can tailor framing of recommendations to different customers in order to boost the click-through of recommendations.

# Surprise!

## The Positive Impact of Uncertainty on the Evaluation of Experiential Purchases

Iñigo Gallo, IESE Business School, Spain  
Lily Jampol, Queen Mary University of London, UK  
Alberto Rampullo, IESE Business School, Spain  
Thomas Gilovich, Cornell University, USA

### EXTENDED ABSTRACT

Most people, most of the time, would prefer to have more information rather than less. Information generally leads to better decisions and hence greater utility (Stigler 1961). When individuals believe they lack sufficient information, they experience uncertainty (Miliken 1987) and most people, most of the time, would prefer to avoid the experience of uncertainty and its attendant anxiety (Calvo and Castillo, 2001; Chandrashekar et al. 2007; Loewenstein 1994).

Nevertheless, research has shown that there are some circumstances under which uncertainty is viewed positively (Goldsmith and Amir, 2010; Lee and Qiu 2009; Paley et al. 2015; Shen, Fishbach, and Shee 2015; Wilson et al. 2005). We suggest that one such circumstance lies in the distinction between experiential and material purchases. Experiential purchases are intangible events that a person lives through; material purchases are tangible goods that are typically kept in one's possession (Van Boven and Gilovich 2003). We propose that experiential consumption is more routinely associated with uncertainty and surprise than material consumption, so that uncertainty is not only more tolerated when making experiential purchases, but is sometimes actually viewed positively.

### Uncertainty is better tolerated

Three characteristics of experiences make them more associated with uncertainty. First, experiences are intangible, and with intangibility comes uncertainty and decision difficulty (Laroche et al. 2005). Second, experiences tend to be evaluated on more attributes or dimensions (Gallo et al. 2016). With more information, there is more to be uncertain about. And the task of integrating this information to form a judgment becomes more difficult, further increasing uncertainty (Miliken 1987; Urbany, Dickson, and Wilkie 1989). Finally, consumers recognize that there is more variation from one instance of the "same" experience to the next than there is from one instance of the same material good to the next (Murray and Schlacter 1990; Zeithaml 1981).

### Uncertainty is sought after

Previous research has uncovered two conditions under which uncertainty is experienced positively: the uncertain prospects must be positive and imaginable, this is, have the ability to evoke mental imagery (Lee and Qiu 2009). Many experiential purchases fulfill both conditions. First, with some notable exceptions, the very fact that consumers are willing to part with their money to make a purchase (material or experiential) is evidence that they view the purchase positively. Second, research indicates that experiential purchases tend to trigger more imagery in the consumer's mind (Gallo, Escalas, and Sood 2018; Holbrook and Hirschman 1982).

We examine our thesis in seven experiments.

### Study 1

Fifty-two MTurk participants were asked how open they would be to receiving a surprise (a purchase that doesn't conform to their expectations) for each of 5 material and 5 experiential purchases. As predicted, participants preferred the risky version of the experiential purchase ( $M = .54$ ,  $SD = .30$ ) significantly more often than they did

the risky version of the material purchase ( $M = .20$ ,  $SD = .23$ ),  $t(1, 51) = -6.350$ ,  $p < .001$ .

### Study 2a

Ninety-six MTurk participants were asked to think either about a material or an experiential purchase. Next, they rated the similarity of 36 word pairs by dragging a slider. Each participant rated all pairwise comparisons of the words *intrigue*, *disappointment*, *delight*, *excitement*, *pleasant*, *dismay*, *annoyance*, *frustration* (half positive, half negative) with the word *surprise*. As expected, there was a significant interaction of words (positive vs. negative) and type of purchase (material vs. experiential) ( $F(1, 94) = 4.060$ ,  $p < .05$ ). Surprise was more closely associated to the positive words in an experiential purchase setting.

### Study 2b

Seventy-four MTurk participants were asked to imagine making either seven experiential purchases or seven material purchases. Participants were asked to imagine they had pre-selected four options (within a category) that met their choice criteria on a specific site. "The site has a new shopping expert feature that will choose among your pre-selected options and send you the one it predicts you will like best. However, the choice will remain a surprise to you until you receive it." As expected, participants asked to consider various uncertain experiential purchases reported having more positive attitudes about the purchases than participants asked to consider various uncertain material purchases ( $M_{\text{experiential}} = 4.92$ ,  $SD = 1.31$  vs  $M_{\text{material}} = 4.44$ ,  $SD = 1.52$ ;  $t(516) = -3.84$   $p < .001$ ).

### Study 3a

Fifty-eight MTurk participants were presented with 16 purchases, half material and half experiential. Participants were asked to rate their openness to uncertainty about each purchase on a scale from 1 to 9. Participants reported being more open to uncertainty when considering experiential purchases ( $M_{\text{experiential purchases}} = 5.88$ ,  $SD = 1.60$  vs.  $M_{\text{material purchases}} = 6.92$ ,  $SD = 1.47$ ),  $t(57) = 4.34$ ,  $p < .001$ ).

### Study 3b

Ninety-four MTurk participants were presented with 14 purchases (from Gallo, Escalas, and Sood 2018), and rated, from 1 to 100, their openness to unforeseen aspects of each purchase. Participants reported being more open to unforeseen features of the experiential purchases ( $M_{\text{experiential purchases}} = 36.34$ ,  $SD = 19.29$  vs.  $M_{\text{material purchases}} = 28.82$ ,  $SD = 19.13$ ,  $t(93) = 4.13$ ,  $p < .001$ ).

### Study 3c

Ninety-six MTurk participants were presented, in random order, with the 14 purchases used in study 3b and asked to rate how critical they would be with consumers complaining that "this is not what I ordered", given that the purchased deviated somewhat from what was initially bought. Participants reported being more critical towards consumers' complaints about unforeseen aspects of experiential purchases ( $M_{\text{experiential purchases}} = 4.32$ ,  $SD = 1.04$  vs.  $M_{\text{material purchases}} = 3.88$ ,  $SD = 1.03$ ),  $t(95) = 3.60$ ,  $p = .001$ .

**Study 3d**

Sixty-one MTurk participants asked to indicate, by moving a slider along a 10-point scale (0 represented minimum tolerance to surprise), how far each of ten different purchases (half material, half experiential) could deviate from expectations before they would be unhappy or disappointed. Participants found surprise to be significantly more tolerable for experiential purchases ( $M = 4.87$ ,  $SD = 1.73$  vs.  $M = 3.91$ ,  $SD = 2.09$ ),  $t(1, 60) = -4.308$ ,  $p < .001$ .

# The Effect of Identity Conflict on Price Sensitivity

Huachao Gao, University of Victoria, Canada

Yinlong Zhang, University of Texas at San Antonio, USA

Vikas Mittal, Rice University, USA

## EXTENDED ABSTRACT

Social identity has been identified as an important driver of consumer decision making (Reed et al. 2012). Although existing literature has extensively examined the effect of *single* identity on consumer decisions, it is largely unclear how *multiple* identities that are simultaneously salient might affect consumer behavior (Reed et al. 2012). This is surprising given people do hold multiple identities (Ramarajan 2014) and it has long been recognized by prominent scholars (James 1890). Thus, the current research intends to examine how multiple identities influence price sensitivity.

Price sensitivity refers to the extent to which consumers respond to price changes (Wakefield and Inman 2003). Although previous research has focused on examining how companies can frame price increase differently to mitigate consumers' price sensitivity (Campbell 2007; Chen et al. 2012), more recent research starts to focus on the influences of consumer characteristics to manage efforts in price increases (Gao, Zhang, and Mittal 2017). From consumers' perspective, price can be viewed as gain of quality and sacrifice of monetary resources (Dodds, Monroe, and Grewal 1991). Building on this, Gao et al. (2017) find that when facing price increases where quality is unchanged, consumers will focus on the sacrifice dimension of price and conditions facilitate the activated sacrifice mindset -- consumers' readiness and willingness to give up valuable resources -- would reduce price sensitivity, as higher level of willingness to sacrifice makes price increases more acceptable.

Behavioral mindset theory suggests that a mindset is more likely to exert its effect on subsequent decisions if consumers process information automatically or when their cognitive resources are limited, such as experiencing ego depletion (Wyer 2011). Thus, we propose that ego depletion facilitates the work of sacrifice mindset when price is increased, resulting in lower price sensitivity. Furthermore, multiple-identities literature suggests identity conflict (vs. congruency) due to inconsistency between two identities depletes cognitive resources (Hirsh and Kang 2016), which is likely to facilitate the activated sacrifice mindset.

In this research, we specifically focus on two identities, gender and local-global identity, not only because they are important antecedents of price sensitivity, but also because they are potentially related. In doing so, we answer the call for better understanding of how multiple identities, especially those developed in the era of globalization, jointly impact decision making (Reed et al. 2012). According to Baumeister and Sommer (1997), one key difference between females and males is what type of social groups they seek to associate. Whereas females seek social connection in close personal relationships based on mutual dyadic intimacy, males seek social connection in broader sphere where people do not necessarily have personal connection (Melnyk et al. 2009). Regarding local-global identity, Arnett (2002) defines local identity as consumers' mental associations of their respect for one's local traditions and identifying with people from local community, whereas global identity as mental representations in which consumers are interested in global cultures and identifying with people around the world. This conceptualization suggests that consumers with an accessible local identity tend to identify with their local community, a relatively small group and within it people tend to have more personal connections. In contrast,

consumers with an accessible global identity tend to identify with the whole world, a much larger group and within it people tend to form much fewer personal connections.

Based on this, we propose that female and local identities are consistent for consumers' sacrifice decisions, as both emphasize identifying with smaller groups such as family and local community, where close and intimate relationships are present. Similarly, male and global identities are consistent as both emphasize identifying with large groups such as the whole world, where loose relationships are present. Accordingly, we expect when gender and local-global identity are in conflict (vs. congruent), consumers are likely in a sacrifice mindset and thus are less price sensitive.

Six studies were conducted to test our theorizing. Specifically, study 1A was a 2 (identity: local vs. global)  $\times$  2 (gender: male vs. female) between-subjects design field experiment, in which we manipulated local-global identity (Gao et al. 2017) and measured gender. The results indicated that consumers experiencing identity conflict (females with global identity or males with local identity) showed lower price sensitivity than those experiencing identity congruency (females with local identity or males with global identity). Studies 1B and 1C replicated the findings with lab design and with survey from organizational purchasers.

Study 2 was designed to test the mediating role of sacrifice mindset by measuring this construct directly. Results of this study replicated the identity conflict (vs. congruency) effect on price sensitivity of study 1. More importantly, a mediation analysis based on bootstrapping supported sacrifice mindset as a mediator.

Following the moderation-of-process design, studies 3 and 4 seek to further test the mediating role of sacrifice mindset by identifying theoretically relevant boundary conditions. Specifically, for sacrifice mindset to work, consumers need to have enough monetary resources and/or have an altruistic spirit (Gao et al. 2017). Based on this, study 3 found that the identity conflict (vs. congruency) effect is attenuated among consumers with low (vs. high) social class, as they tend to have less monetary resource to sacrifice. Study 4 found that the identity conflict (vs. congruency) effect is attenuated among consumers who are self-focused, as they are too selfish to make sacrifice.

This research makes several contributions to the related literatures. First, we go beyond the traditional identity research which focuses on the effect of a single identity, by examining how multiple identities that are simultaneously accessible affect consumer decision making. Second, we advance the local-global identity literature by showing that although it is a relatively new identity developed in the last several decades, it is deeply related to, not isolated from, our more traditional identities such as gender. Third, we contribute to the price sensitivity literature by showing a key antecedent determining consumers' responses to price increases: identity conflict versus congruency. Fourth, through examining the mediating role of a sacrifice mindset, we also intend to emphasize the importance of the sacrifice aspect of price in determining price sensitivity.

# Effects of Affective Language on Perceived Helpfulness of Online Reviews

Nikolay Georgiev, HEC Paris, France

Marc Vanhuele, HEC Paris, France

## EXTENDED ABSTRACT

### Introduction

Online communities that give their members the opportunity to rate and review products and services, like Yelp, Trip Advisor, Epinions, are highly valuable in helping consumers navigate through the unlimited volume of information they have access to. More positive ratings and reviews of a product or a service mean that more consumers are happy with that product or service, which through the influence of the reviews translates into increased commercial performance (Archak, Ghose, & Ipeirotis, 2011; Ludwig et al., 2013; Sonnier, McAlister, & Rutz, 2011). Online reviews are also useful to inform commercial marketing research and competitive intelligence (Lee & BradLow, 2011; Netzer, Feldman, Goldenberg, & Fresko, 2012).

The reviews that have the greatest influence on consumer behavior are probably those that consumers themselves consider most helpful. What then makes a review helpful? Past studies have examined various features of the review texts (O'Mahony & Smyth, 2010), features of review authors (Liu & Park, 2015), and features of the reviewed objects (Bakhshi, Kanuparth, & Shamma, 2015; Ghenai & Lizotte, 2015). In this research we investigate the effect of elements of affective language – positive and negative – of online reviews on their perceived helpfulness. On the one hand, we know that people naturally focus on positive, rather than negative things (Augustine, Mehl, & Larsen, 2011; Boucher & Osgood, 1969; Dodds et al., 2015). On the other hand, some studies suggest that negative words carry more information than positive ones (Garcia, Garas, & Schweitzer, 2012). Given these conflicting findings, whether and how use of positive words and use of negative words influence perceived helpfulness of evaluative textual units is an open question.

### Data and Analyses

**Data collection.** We developed several web-crawling and web-scraping computer programs to collect data from the websites of two online communities: epinions.com (product reviews) and yelp.com (service reviews). Furthermore, we used a publically available tripadvisor dataset (<http://www.cs.cmu.edu/~jiweil/html/hotel-review.html>), which we cleaned to include only reviews written in the English language. Our data consists of 1,701,559 consumer reviews in total.

**Perceived review helpfulness** is determined by votes of community members that indicate how helpful they perceive an online review to be. In epinions.com, each review was flagged as being 'very helpful', 'helpful', 'somewhat helpful', or none of these (an ordered categorical variable with 4 categories). In yelp.com and tripadvisor.com, the number of community members who found each review helpful could be seen (a count variable).

**Elements of affective language** are the uses of positive and negative words in a review. Like other contributions in the field (Ludwig et al., 2013), we use Linguistic Inquiry and Word Count (LIWC) (Pennebaker, 2007; Pennebaker, Francis, & Booth, 2001), an established structured top-down word count approach for psychological language analysis. LIWC has reliable and valid dictionaries of positive (e.g. love, happy, nice) and negative words (hate, annoyed, sad).

**Analyses.** In each of the three settings, we run regression models to estimate the effects of frequencies of positive and negative

words, controlling for star rating and total word count of the review, on perceived review helpfulness. For data from epinions.com, we estimate an ordinal logistic regression model. For data from yelp.com and tripadvisor.com, we estimate negative binomial regressions.

### Results and Conclusions

Overall we find that lower frequency of positive affect words and higher frequency of negative affect words lead to online reviews being perceived as more helpful (all  $p < .001$ ). Note that the directions of the effects of star ratings on perceived review helpfulness is different between epinions.com (positive), on the one hand, and yelp.com and tripadvisor.com, on the other hand (negative) due to how review helpfulness is technically operationalized in these communities and, respectively, distributed as a dependent variable.

Lastly, the effect holds under all models we estimate, in all the three settings. Furthermore, when we estimate the models within star rating data subsets, the same effect holds under all models in the five star and four star subsets for all the three settings (all  $p < .001$ ). Hence, lower frequency of positive words and higher frequency of negative words leads to higher perceived helpfulness of online reviews, and of online reviews giving maximally and moderately positive ratings, in particular.

### Discussion

Positivity bias – consumers' propensity to rate products and services overly positively, most often with the highest positive grade possible – seriously devalues the helpfulness of online ratings. Even though negative words are almost always vastly outnumbered by positive words (Augustine et al., 2011; Boucher & Osgood, 1969; Dodds et al., 2015), single negative words may provide more information than single positive words (Garcia et al., 2012).

Moreover, if a consumer is reading a product or a service review, that means that she/ he is already interested in the product or service in question. Very often consumers are considering and comparing only a few products or services in their consideration set (Roberts & Nedungadi, 1995). Negative information is especially useful in such situations and particularly when the consideration set consists of very highly rated products or services.

Our findings suggest that elements of affective language provide valuable evaluative information to consumers that could be particularly useful to abstract subtle nuances between reviews with equally positive ratings.

# Understanding Consumer Sensory Preferences: An Ethnographic Investigation of Sensory Flamboyance and Subtlety in India

Tanuka Ghoshal, Baruch College, USA  
Russell W. Belk, York University, Canada

## EXTENDED ABSTRACT

### Theory and Introduction

*“While driving back to the apartment, I looked into the rearview mirror. Mr. Ashok was wearing a t-shirt. It was like no t-shirt I would ever choose to buy at a store. The larger part of it was empty and white and there was a small design in the center. I would have bought something very colorful, with lots of words and designs on it.”*

*-Balram Halwai, domestic helper and driver, observing the clothing preferences of his employer in the Man Booker Prize-winning novel “The White Tiger” by Aravind Adiga*

Marketers use a variety of sensory appeals to communicate about their brands to consumers (Krishna 2012), but these may not be equally efficacious across consumers. We investigate whether basic preferences for sensory flamboyance versus subtlety are structured sociologically and by early childhood experiences, rather than by individual dispositions (Peck and Childers 2008). The opening quote depicts an Indian driver, in a low status occupation, from a lower caste and economic background, who favors “louder,” more visually prominent product designs, such as flashier, gaudier clothing, compared to his employer who is higher in social status, caste and cultural capital (Holt 1998; Bourdieu 1984). The relationship between status, power and conspicuous consumption of branded products has been studied (Veblen 1899; Belk, Bahn and Meyer 2001; Rucker and Galinsky 2008; Sivanthan and Pettit 2010; Han, Dreze and Nunes 2010), but what structures basic preferences for high versus low sensory intensity in consumption, including the use of bright colors, loud music, and strong tastes and fragrances?

Bourdieu’s (1984) framework suggests that status boundaries may be reproduced or potentially breached simply through the expressions of tastes. Varying levels of cultural capital (i.e. distinctive tastes, skills and knowledge) are manifested in unique styles of taste and consumption among members of different classes. This framework has been shown to provide insights into taste distinctions among high versus low cultural capital consumers in the United States (Holt 1998), and Turkey (Ustuner and Holt 2010). India’s deep rooted class and caste hierarchies suggest that consumption would reflect the assumed social hierarchies. Indeed, economic chasms create stark differences in habitus across classes, and the poor seem trapped in a virtual quagmire of disempowerment (Belk and Ghoshal 2017). Lower cultural capital is associated with lower economic as well as lower symbolic capital (power and status; Bhattacharyya and Belk 2017), a critical point of difference from previously studied contexts. Could sensory flamboyance (versus subtlety) in tastes be a critical currency of cultural capital in this context, and what might be the underlying reasons?

One potential explanation for affinity towards sensory flamboyance is compensatory consumption, which has been defined as consumption that is a reaction to and an attempt to make up for a general lack of self-esteem or self-actualization (Gronmo 1988; Woodruffe-Burton and Elliott 2005). Disempowerment is understood to be a critical aspect of the definition of poverty (MacPherson and Silburn 1998; Syrjala, maa-Leskinen and Laaksonen 2014). Because

they lack power, the poor have been found to develop power tactics and become empowered actors in the markets (Giddens 1991; Hamilton 2012) in order to reinforce their image of themselves as self-sufficient individuals (Hill and Stamey 1990; Syrjala, maa-Leskinen and Laaksonen 2014). In other research, Murali and Pons (2009) show that choosing bold options (that are more extreme, hedonic and unique) makes people feel more powerful. Batra and Ghoshal (2017) find that consumption of intense sensory experiences (such as bright colors and loud music) helps provide a mental escape from self threat and restores self-worth. Could sensory flamboyance be a form of compensatory consumption employed by those lacking economic and symbolic capital- i.e. an empowering strategy? Are there other potential explanations for the observed variations in sensory flamboyance in India?

### Context and Ethnographic Method

Despite the drastic social and economic changes that have occurred in India over the past two decades (Vikas, Varman and Belk 2015), the constituents and role of cultural capital in structuring consumption are yet to be examined. We interview 28 women from upper and lower socioeconomic classes to ascertain their cultural and symbolic capital resources, and consumption preferences across sensory domains such as clothing, food, music, touch and smells. Informants were classified into two broad groups -- low cultural capital (LCC) and high cultural capital (HCC) as jointly determined by the Indian socioeconomic classification and Holt’s (1998) classification system, using a procedure similar to Üstüner and Holt (2000), with adaptations for the Indian context. Along with observation and interviews, we utilized a projective technique that we dub “Dress-Up,” based on the Jennifer’s Wardrobe technique described by Fisher, Belk and Kozinets (2013). Informants were presented with a large paper cutout of a female figurine and prepared stimuli varying in their flamboyance (visuals of clothing, jewelry, purses, shoes, watches, and samples of clothing material and fragrances), and were asked to dress the figurine (described to be of a similar background as theirs) for different occasions, such as a family wedding, a distant relative or friend’s wedding, an office event, a birthday party, and a typical working day (figure 1). This helped ascertain norms regarding sensory flamboyance as per different occasions.

### Findings

#### *Home décor*

Flamboyant sensory visual elements were strikingly evident even before we entered the living spaces of our LCC informants. A myriad of homes had exteriors painted in colors such as bright pink and yellow (figure 2a), with interiors often in reds and yellows. We came across several decorative front doors, again adorned with eye-catching colors and motifs. Garlands of bright orange marigolds (also considered auspicious) were used to adorn front entrances as a *toran* (Sanskrit: sacred gateway) primarily meant to attract *Lakshmi*, the Goddess of Wealth, but also affording a colorful pleasant visual to welcome guests before they enter the home. Interior décor in the LCC homes consisted of simple items such as religious motifs and paintings, photographs of family, and artificial flowers, limited by available space. It was as though the LCCs preferred to envelope their world in a protective sensory shroud.

The visual aesthetic of HCC homes differed starkly, with interiors typically painted in neutral and light colors such as white or beige, with an occasional pop of color for a cherished object of décor. Doors were functional and plain. Treasured souvenirs from trips were usually given a pride of place in living rooms, but set apart from the surroundings with ample space, so as to let each item sing its story and speak of its origin. The HCC décor reflected a more natural aesthetic, with several instances of woodwork, hand-made goods and original artwork. The ambience was much more demure, with furniture and décor often blending into a seamless landscape, serving as a neutral backdrop to celebrate individual narratives of cherished objects.

#### *Clothing and accessories*

As evident through both LCC's personal wardrobes and through interaction with our prepared stimuli, clothing and accessories possessing elements of sheen, gloss, sequins, stones, glitter and light-reflecting mirror work were consistently preferred over the stimuli lacking these aesthetic elements. In the "Dress-up" and photo sorting activity using our prepared stimuli, LCCs almost consistently preferred big and bold gold-colored costume jewelry adorned with rhinestones and gemstones, over more subtle jewelry that lacked both size as well as flamboyant aesthetics (see also Fernandez, Veer and Lastovicka 2011; Vikas et al 2015). Real gold ownership was still a dream for many of our LCC informants, such as Vidya, who lamented that even her *mangalsutra* (necklace symbolic of marriage) was not made of gold, adding that gold would be a foremost investment should she come into extra money. We observe a parallel between the expectations from jewelry and the fascination for glitter in clothing. Isha (LCC) mentioned that for important daytime occasions such as weddings, she preferred traditional South Indian silk saris with borders crafted from golden thread embroidery because such saris were designed to naturally reflect sunlight and shimmer. She added, however, that for evening weddings, clothing with sequins, glitter and extensive mirror-work was desirable because it would reflect artificial lights more, allowing the person wearing it to make more of an impression upon others. Just as in home décor, there appeared to be a consistent need to create an aura of light around oneself at important occasions, presumably to draw attention to one's self and be noticed, making them feel bigger and more important -- again an empowering tactic. It is plausible that the penchant for glitter in clothing was also a result of a largely unfulfilled craving for the coveted and elusive yellow metal.

For LCC informants, consumption choices were largely shaped by family expectations and desire for conformity with their in-group, reflecting their collectivistic nature and adherence to rules (Holt 1998). However, a desire for conformity was also supplemented by a desire to shine or excel among comparison peers. Dressing for weddings was particularly ritualistic, with socially-specified expectations with respect to attire.

Seema (LCC): For a close relative's wedding you need to be more careful about what you're wearing. Have to go all out with the [expensive] silk saris and gold jewelry; tradition is critical. For distant relatives or friends, it is a little less critical. I can think of wearing "work saris" [synthetic, light, less expensive saris] or costume jewelry. What I wear, how much I dress up shows them [the hosts] how much I care about them - whether I consider them close or not.

Voluminous, flared dresses were consistently preferred over straight-cut silhouettes, for both women and girls' clothing and bright, accessorized patterns were strongly favored over dull-col-

ored, plain designs. Just as Bruner and Goodman (1947) found that powerless people were drawn to larger monetary objects, bigger sizes of clothes appeared to be an empowering technique used by our LCCs. LCC informants' color, material, and design preferences were even more intense when we asked them about clothing preferences for children. With big hopes and high aspirations for their children, most LCC informants preferred to dress them in clothing that they described as looking "grand" or "rich," including brightly colored, flared, printed dresses for girls. There seemed to be an overarching desire to dress their children in a manner that immediately announces their presence to others. As Lakshmi explained, she would prefer to dress her daughter in a voluminous outfit that increases her perceived stature and size making her look more impressive- as if the greater occupation of space with a frilly, full dress communicated a stronger presence.

In stark contrast, our HCCs preferred clothing and accessories strictly devoid of the same flamboyant elements that drew the interest of our LCC informants. For HCCs, comfort and fit were the most important criteria in selecting clothing, as was reflected in their clothing and accessory wardrobes. Both in their own wardrobes as well as in our photo selection activities, straight-cut designs were predominantly preferred for both women and children. HCCs frequently described their clothing preferences as being "sober" and "simple," with a conscious effort to not attract attention due to over-styled aesthetics. They preferred a minimalist aesthetic that allowed their presence to be demonstrated through their personalities rather than their clothing, similar to their home decor. Their clothes should be "nice" but not speak for them. For HCC consumers, dressing was seen as being integrally associated with portraying their upbringing, education, and higher cultural capital.

Padma (HCC): I didn't like these [selected stimuli] because of the glittery, shiny design. This looks rough, something that will irritate and poke when you wear it. It is not pleasant and does not give a decent look. It looks very low class. They ["low class" consumers] think it's grand but actually it's not grand looking -- in fact it has a cheap look.

In a notable deviation from LCC consumers studied in other parts of the world (Holt 1998; Üstüner and Holt 2000), our LCCs, while cognizant about HCC sensory preferences, did not reveal any desire to emulate them, contrary to what Simmel's (1954) Trickle Down theory would suggest. For example, an emic term used almost "respectfully" by LCCs to describe colors like white, beige, cream, olive green was "English colors." However, these colors were strictly not preferred for either their own clothing or home décor, and were considered dull and stodgy.

#### *Other sensory*

Preference for sensory flamboyance was evident across other sensory domains as well. All LCCs had mobile phones loaded with music and loud ringtones and listened to TV at high volumes as measured by our decibel app. HCCs, however, opined that listening to TV at a high volume denoted a lack of civic sense and sensitivity to other's needs, and Latha labeled such people as "cheap." They neither preferred loud music nor strong fragrances, in contrast with the LCC group. Tea and coffee served to us at some of the LCC households was high in sugar content, while their cooking made extensive use of spices. It is plausible that high levels of condiments in food and beverages was a way of magnifying the impact of gustatory experiences for the LCCs, in a way enlivening their senses and perhaps compensating for an impoverished environment. They seem to privilege the life of the body over the life of the mind, and this

is evident across all sensorial aspects. While the visual, olfactory and aural may be perceived by others, food consumption is largely private. Sensory flamboyance in taste could hence be a signal to the self, possibly helping them embrace life more boldly, feel more alive or simply experience mastery over something in their space.

## Discussion

We find that sensory intensity -- whether flamboyant or subtle -- is used by our informants to reinforce membership in their respective communities, socially insulate these communities from perceived outsiders or intruders, and to differentiate them from others perceived to be lower in status. For LCCs, sensory flamboyance appears to be a way to compensate for their economically impoverished environments, and may even be an attempt to experience life more boldly. It appears to be a compensating strategy to deal with the disempowerment they are faced with on a daily basis.

Our work answers calls from consumer culture theory researchers regarding contextual theory development (Arnould and Thompson, 2005; Askegaard and Linnet, 2011), and studying emerging forms of cultural capital in India (Chaudhuri and Majumdar 2006). It also reopens the neglected domain of sensory tastes and bodily pleasure and constraint (e.g., Falk 1994; Gronow 1997; Serres 1985/2008). Following the approach suggested by Belk, Rodner and Sobh (2018), we present multiple theories of the observed phenomena, including psychologically driven theoretical explanations, arguably enabling richer interpretations of complex phenomena. Our findings should be helpful in understanding the consumption dynamics of individuals in emerging economies, where not only are consumers' discretionary incomes increasing, but so are the demarcations between social classes (Ablett et al 2007), with implications for product and marketing communications design.

# Gossip: How the Relationship with the Source Shapes the Retransmission of Personal Content

Gaia Giambastiani, Bocconi University, Italy

Andrea Ordanini, Bocconi University, Italy

Joseph C. Nunes, USC Marshall School of Business, USA

## EXTENDED ABSTRACT

Consumers love gossiping about celebrities. It is a big part of our social interaction and is all over the media, both mainstream and social. The influence of celebrities in consumer's lives is undeniable (Thomson 2006). Much of what is being tweeted is the content of celebrities' lives; in addition, news feeds and tweets are filled of frivolous stories about famous persons (Zhao et al. 2011).

Previous research on gossip has shown that people love to talk about other people; after self-disclosure, talking about absent third parties is the most common topic of conversation (Emler 1990). Further, a considerable amount of content shared in people's lives is not self-generated, but passed on. In this research, we focus on content that originates with one individual and is shared by a different individual, and investigate what makes people prone to retransmit personal content about someone else.

We propose the retransmission of personal content (colloquially considered gossiping) can be explained by the sharer's relationship with the source of the content. We demonstrate that, when facing the choice of whether or not to retransmit personal information, the individual is pulled in opposing directions by two concerns, the perceived guilt of sharing something presumably private versus the perceived arousal of the content. How guilty and aroused one feels depends on the relationship that an individual has with the source of the content. On the one hand, sharing personal information about someone is generally seen as immoral, violating privacy norms. On the other hand, what makes personal information more arousing is its private nature. We demonstrate that personal information about famous persons (i.e., celebrities) is more likely to be shared because consumers experience lower guilt and higher arousal. By studying an overlooked type of content heavily shared by consumers and by focusing on human brands, we provide contribution to both gossip and WOM literatures.

One overarching goal of this research is to provide a coherent explanation for why celebrity gossip is shared so much more frequently than many other types of personal content. The celebrity gossip industry (anchored by sites like TMZ) constitutes a significant commercial market generating \$3 billion in combined revenue in the U.S. in 2011, according to The New York Times. We investigate the two opposing forces discussed earlier as the mechanisms affecting when personal information is more or less likely to be retransmitted and demonstrate that personal information about famous people (i.e., celebrities) is more likely to be shared because consumers experience lower guilt and higher arousal.

Drawing on Emerson's (1962) Power/Dependence Theory, we identify four different types of relationship with the source of the content that vary across two dimensions: mutual dependence and balance. According to Emerson "social relations commonly entail ties of mutual dependence between the parties." There is high degree of mutual dependence in a relationship when both parties strongly depend on each other. There is balance in a relationship when both parties depend on each other in the same way. A relationship can be very balanced, when both parts depend equally on each other (or conversely, neither depends on the other), or very unbalanced, when one party depends on the other more.

Combining mutual dependence and balance, we distinguish four archetypical relationships between the sharer and the source of personal information: (1) High Mutual Dependence and Balance (HDB) (e.g., close friends); (2) Low Mutual Dependence and Balance (LDB) (e.g., acquaintances); (3) Medium Mutual Dependence and Unbalanced with more power towards the other person side (MDU1) (e.g., celebrities); and (4) Medium Mutual Dependence and Unbalance with more power towards the respondent (MDU2) (e.g., someone who works for me). We predict that different sources have different effects on the propensity to share personal content. Specifically, we expect famous people (MDU1) to be the category for which the propensity to share personal information is the highest.

We predict the propensity to share personal content about someone else to depend on the opposing forces of how guilty sharing is perceived and how arousing is the information. Guilt arises when someone behaves in a way that causes a violation of the moral order for which people take responsibility (Duhachek, Agrawal and Han 2012). Whenever individuals receive personal intimate information from another subject, when they consider sharing this information, they evaluate the morality of the action and assess how guilty they would feel by doing it. Thus, we propose that personal information about an individual whom one has a balanced relationship (e.g. close friend) increases the perceived guilt attached to sharing personal information, as opposed to a relationship that is perceived as very unbalanced (e.g. celebrity).

Arousal is a subjective experience of energy mobilization leading to excitement (Mehrabian and Russell 1974). Berger (2011) showed that physiological arousal could explain information transmission because of the motivation elicited by this excitatory state. We predict that personal information about other individuals can be considered as something arousing and this increases when a relationship is characterized by higher mutual dependence.

Overall, we expect relationships characterized by medium mutual dependence and low balance (e.g., favorite celebrities) to be the category for which the propensity to share personal information is the highest. This is because the content is generally perceived as more arousing and sharing is characterized by less anticipated guilt.

We tested our predictions in three studies. Study 1 (1a and 1b, 100 and 513 MTurkers) provides empirical validation of our independent variable, the typology of relationships, and validates two one-way power measures drawn from Power/Dependence Theory (Emerson 1962).

Study 2 (362 MTurkers) tests for significant differences in the Propensity to Share personal information (PTS) contingent on the relationship with the source of the content. We varied the relationships according to mutual dependence and balance. We asked participants to think about one specific person and imagine they could share a gossip about them online. Results show significantly greater PTS for MDU1 relationships compared to all the other tested relationships (all *p-values* < .05), confirming our main prediction that personal information is shared in a different way depending on the relationship with the source of the content.

Study 3 (403 MTurkers) tests the difference in PTS offline including perceived arousal and guilt. The study followed the same procedure used in study 2; in addition, participants imagined that

they decided to share the content and indicate how arousing they perceived the information and how guilty they feel sharing. Results show a significantly higher PTS for MDU1 sources compared to all the other tested relationships (all *p-values* < .003). We conducted a mediation analysis investigating the simultaneous role of arousal and guilt in the relationship between the source and PTS, and found evidence of the presence of a significant indirect effect.

Across these three studies, we demonstrate that the relationships characterized by higher mutual dependence and low balance (e.g. favorite celebrities) is the category for which the PTS is the highest. While we recognize the existence of other potential causes, we advance one possible explanation through perceived arousal and anticipated guilt. Our goal was to demonstrate that only by combining these two dimensions is it possible to explain why some personal information is more or less likely to be shared, and this applies both online and offline. More importantly, we illustrate why it is the case that celebrity gossip is so widely shared by consumers. Our findings contribute to the literature on WOM retransmission by investigating personal information, a type of content frequently shared by consumers with scant coverage in the literature. We also contribute to the gossip literature by providing an explanation for why certain types of information like celebrity gossip is so frequently shared by individuals.

# Shopping For Freedom: Moroccan Women's Experience In Supermarkets

Delphine Godefroit-Winkel, Toulouse Business School, Casablanca Campus, Morocco

Lisa Peñaloza, KEDGE Business School, France

Samuel K. Bonsu, Ghana Institute of Management and Administration, Ghana

## EXTENDED ABSTRACT

Contemporary conceptualizations of consumer freedom rely on a Western view of the autonomous self (e.g. Arnould 2007). The idealized free agent has the capacity of choice and is the ultimate source of her will (e.g. Mick and Humphreys 2008). Deriving from this, studies on consumer freedom have largely investigated the various strategies of consumers to construct their freedoms along with their autonomy and independence (e.g. Peñaloza and Barnhart 2011).

On the other hand, recent works in non-Western contexts suggest that interdependence and conformity, rather than independence and autonomy, should be understood as manifestations of individual freedom. In this approach, freedom refers to the voluntary choice to conform to a dominant discourse and related norms (Abu Lughod 2013; Markus and Schwartz 2010).

Our research contributes to this ongoing debate. We propose an emergent conceptualization of consumer freedom at the meso level. We explore how consumers construct their freedom within the specificities of their socio-cultural contexts.

Freedom holds two conceptualizations: the negative and the positive (Berlin 1969). In its positive form, *freedom to* is about the presence of something (i.e. self mastery, autonomy). The positive form of freedom largely dominated in modern culture (Firat and Dholakia 1998). In its negative form, *freedom from* is about the absence of something (i.e. external constraints). External constraints refer to actions, influences, and/or intrusions of others in one's decision and lead to forms of interference (Berlin 1969), domination (Pettit 2011) or oppression (Arendt 1951; Sen 1999).

Our research questions include: What are the conditions to consumer freedom? What roles do consumers and the market play in the construction of consumer freedom?

We locate our research among Moroccan women in Casablanca and explore their shopping experiences in supermarkets. The Moroccan woman is constrained in her movements and thoughts by a dominant discourse that is of patriarchal kind (e.g. Mernissi 2010). The dominant power of the Moroccan male is supported by a rigid set of norms, which regulates women's behaviors (e.g. Sadiqi 2003). The market is one of the strongest male institutions in Morocco (e.g. Geertz 1978). Nevertheless, it seems to provide several conditions to facilitate women's freedoms (Kapchan 1996).

We rely on a three years ethnography to access and portray the experiences of grocery shopping among Moroccan women. The first researcher conducted the bulk of ethnographic work. We deploy various types of data including participant observation, in depth interviews (Mc Cracken 1988), and photographs (Dion 2007). The resulting data set comprises 61 interviews with 7 men and 54 women, 127 photographs and 122 pages of handwritten fieldnotes. Analysis followed recommendations for ethnographic research (Arnould and Wallendorf 1994).

Our findings show that the patriarchal dominant discourse is somehow suspended in the supermarket. A such, the supermarket offers a sense of anonymity, self-service and security, which permit women to construct forms of freedom from interference from the male (Berlin 1969), domination from the male dominant power (Pettit 2011) and oppression from the patriarchal dominant discourse (Sen 1999). Our findings also uncover the role of various consumers, supermarket employees, relatives and friends in women's construc-

tion of freedom. We shed light on the importance of freedom witnesses, who support and observe women's freedom, and of freedom facilitators, who bend the supermarket rules and serve women.

Our research suggests three theoretical contributions. First, our data analysis provides contextual elements to the ongoing discussion about the role of constraints in the construction of freedom. Our results are in line with Sartre (1943) who stated that constraints permit freedom to emerge. We also show that informants do not seek to overtly fight the dominant discourse. They voluntarily conform to social norms in their daily lives and in traditional spaces (e.g. the traditional market). Thus, in line with Fromm (1943), we state that absolute freedom is no ideal and that consumers need constraints.

Our study also nuances previous work on voluntary conformity as manifestation of freedom (e.g. Abu Lughod 2013). Our findings show that the Arab woman conforms to the dominant discourse in her daily life. However, when she finds a space where the norms are somehow suspended, she engages in consumption behaviors that manifest her will to free from the dominant discourse and related norms that infringe her behaviors in her daily life.

Finally, our findings conflict with the ideal of an autonomous, independent agent, as a master of her own life (e.g. Mick and Humphreys 2008). We demonstrate that consumer freedom is not an individual matter and shed light on the social dimensions of consumer freedom. In particular, we show that Moroccan women rely on various supportive and observant witnesses, and on freedom facilitators to construct their individual freedoms.

# The Subjective Value of Popularity: A Neural Account of Socially Informed Functional Value and Social Value

Robert Goedegebure, Wageningen University, The Netherlands

Irene Tijssen, Wageningen University, The Netherlands

Nynke van der Laan, University of Amsterdam, The Netherlands

Hans van Trijp, Wageningen University, The Netherlands

## EXTENDED ABSTRACT

Popular products are often thought of as being popular for a particular reason. Consumers may come up with different reasons to assess a popular product's subjective value. This value may express functionality (Steinhart, Kamins, Mazursky, & Noy, 2014), or expectations on social approval (Berger & Heath, 2007). Research on social influence often distinguishes between two different routes through which popularity aids in value assessment by noting either informational (i.e. functional) incentives, or normative (i.e. social) incentives (Cialdini, Reno, & Kallgren, 1990; Deutsch & Gerard, 1955). For evaluations on functionality, a product may be evaluated in terms of workmanship and overall quality, and for social evaluations in terms of expectations of approval of social peers (Sweeney & Soutar, 2001). We argue that the neural computation of the subjective value of popular products, is dependent upon whether consumers focus on a product's functional value, or a product's social value. The primary objective of this study is to explicate the neural processes through which popularity exerts influence on behaviour along these routes. In doing so, we draw upon insights that show how consumers use single pieces dependent upon their focus (Hare, Malmaud, & Rangel, 2011).

Consumers' choices, including those informed by popularity, are often driven by activity in the brain's reward system (Bartra, McGuire, & Kable, 2013; Falk & Scholz, 2018). We propose that this activity is mediated by activity in other regions, dependent upon consumers' focus. Consumers with a quality focus, are likely to display brain activity in regions known to process aspects of quality and specific product properties (i.e. functional value), such as ventral and lateral regions of the temporal cortex (Chao, Haxby, & Martin, 1999). Consumers with a social focus, are likely to show activity in regions known to revolve around thinking about (the opinions) of others (i.e. social value), such as the temporoparietal junction and the anterior cingulate cortex (Baek, Scholz, O'Donnell, & Falk, 2017; Berns, Capra, Moore, & Noussair, 2010)). We propose that the final subjective value that consumers derive from popularity is mediated by activity in regions that revolve around functional value when consumers focus on quality, whereas the effect is mediated by activity in regions revolving around social value, when consumers focus on social aspects.

The study presents the results of an fMRI experiment ( $N = 30$ ), using a 3 (focus: normal / quality / social) X 2 (popularity: low / high) within-subjects design, in which participants evaluated 180 different food products in a MRI scanner. Brain activity (i.e. parameters) was extracted via region of interest (ROI) masks that were built using coordinates from literature (e.g. Bartra et al., 2013). Parameters were extracted from the quality, and social focus conditions, while controlling for normal focus, from the low and high popularity conditions (e.g. 'quality focus & popularity high' vs 'normal focus & popularity high').

The results demonstrate that in the quality focus condition, popularity influenced purchase intention ( $\beta X_{Pop} = .703, p < .001$ ). In contrast to our expectations, this effect was partially and negatively mediated by activity in the functional value regions ( $\beta ME_{Func\_val} = -.515, p < .05$ ), negatively by activity in the reward value regions

( $\beta ME_{Rew\_val} = -.798, p < .01$ ), yet positively by activity in the social value regions ( $\beta ME_{Soc\_val} = -.798, p < .01$ ). Activity in the functional, and social value regions did not interact with activity in the reward value regions ( $ps > .10$ ). In the social focus condition, popularity again affected purchase intention ( $\beta X_{Pop} = .764, p < .001$ ). In line with our expectations, we find that this effect is partially positively mediated by social value ( $\beta ME_{Soc\_val} = .368, p < .05$ ), with a positive interaction between activity in the social value ROIs and the reward value ROIs ( $\beta ME_{Soc\_val} ME_{Rew\_val} = .875, p < .001$ ). A surprising result is the negative effect of activity in the reward value ROIs ( $\beta ME_{Rew\_val} = -.479, p < .05$ ).

In addition to the fMRI experiment, the study presents the results of a behavioural task, using a similar paradigm. In this task, participants expressed their purchase intention, and evaluated products on functional value ('product has a good quality') and social value ('product will make a good impression on others'). These results show that popularity in itself is often equated with a higher functional value, expressed through inferences about quality. These inferences mediate the effect of popularity on purchase intention, but are negatively affected in conditions where consumers focus on a product's social value. In the social focus condition, participants do make positive inferences about social value that mediate the relationship between popularity and purchase intention.

The results of the study are partially in line with our expectations. As expected participants that held a social focus, used popularity to estimate a social value for products. The increased activity in the social value regions positively interacted with activity in reward regions and increased participants' purchase intention. These results hold for the neural data as well as for the behavioural data. In contrast to our expectations, participants with a quality focus did not show positive activity in the functional value regions. The results show an opposite effect, such that with a quality focus, activity in the functional value regions negatively affected purchase intention.

The present study adds to scientific literature by demonstrating different routes through which popularity may influence choice. On a behavioural level, we show that different inferences explain the effect dependent upon consumers' focus. On a neural level, we demonstrate that popularity evokes different types of value and offer initial evidence for the existence of two neural routes of social influence. The study demonstrates that a single piece of information may be processed through different routes, depending on the current focus, either on quality or social aspects. These results have important implications for practitioners. Popularity is often used on different sales platforms. Our results indicate that the value associated with the popular product may differ. Given the strong influence of popularity on behaviour, marketers are advised to carefully consider the focus of consumers when evaluating popular products.

# Deviating from the Majority When Resources Are Scarce: The Effect of Resource Scarcity on Preference for Minority-endorsed Products

Xiushuang Gong, Jiangnan University, China  
Yafeng Fan, Tsinghua University, China  
Ying Ding, Renmin University of China, China

## EXTENDED ABSTRACT

Resource scarcity has been a very pervasive phenomenon and plays an important role in consumer behavior. To date, plenty of research has examined the consequences of resource scarcity (Mehta and Zhu 2016; Roux, Goldsmith, and Bonezzi 2015). However, little has been done about how resource scarcity influences consumers' purchase behavior. One unanswered question that arises is, how does resource scarcity influence consumer preference for minority-endorsed products? Research by Baumeister and Leary (1995) has posited that under conditions of scarcity, forming a group or conforming to the majority will bring debatable advantages, reflected in resource sharing and resource deprivation within groups. In addition, though prior research has investigated the interaction effect of resource scarcity and childhood environments on conformity, resource scarcity was operationalized as economic uncertainty and monetary expenditures (Stamos, Bruyneel, and Dewitte 2016), diverging from the classic operationalization in most literature (e.g. Mehta and Zhu 2016; Roux et al. 2015), which we adopted in this paper. To our knowledge, no research has directly addressed whether and why resource scarcity may influence consumer preference for minority-endorsed products. The current research aims to address these issues.

Prior research on scarcity suggests that people in poverty are more discreet and do more trade-offs when consuming resources (Mullainathan and Shafir 2013), and become competition-oriented and unwilling to share resources with others in the face of scarcity (Roux et al. 2015). Furthermore, Rodeheffer, Hill and Lord (2012) found that during times of scarcity, individuals tend to narrow their definition of belongingness and include only people whose group membership is unambiguous. Building on these findings, we theorize that resource scarcity increases individuals' sensitivity to losses and their concern about resource deprivation. As a result, conforming to the majority may be more threatening than beneficial to individuals with scarce resources (Baumeister and Leary 1995). Since choosing minority-endorsed options blocks majority influence (Imhoff and Erb 2009), we propose that reminding consumers of resource scarcity may enhance their concern about resource deprivation, which subsequently strengthens minority preference.

Furthermore, perceived economic mobility (PEM) represents individuals' belief in the changeability of current economic status contingent on their own efforts (Yoon and Kim 2016; Yoon and Kim 2017). When PEM is high, consumers will be more optimistic about their future economic state and resource availability, which may eliminate or mitigate their resource deprivation concern heightened by the scarcity of material resources. On the contrary, when PEM is low, consumers may perceive low changeability of their current economic state, intensifying their resource deprivation concern induced by resource scarcity. We tested our assumptions in four studies.

In study 1 (N=95), we employed a one-factor (resource scarcity vs. no reminders of scarcity) between-subjects design. Participants were first instructed to finish an episodic recall task (Roux et al. 2015). In the scarcity condition, participants were asked to describe three or four episodes when they felt they didn't have enough of something, while participants in the control condition were asked to write down what they did during the past week. Afterwards, participants were presented with a product evaluation task and instructed

to indicate their preference for two mugs of different colors. Survey information regarding other consumers' choices of the two mugs was created to form a majority-endorsed option and a minority-endorsed option. Next, participants were asked to indicate their choice. Results suggested that participants in the scarcity condition had significantly higher tendency to choose the minority-endorsed mug ( $M_{scarcity}=6.44$  vs.  $M_{control}=5.21$ ,  $p<.04$ ).

Study 2 (N=80) extended the findings of study 1 by investigating the mediating role of resource deprivation concern. Resource scarcity was manipulated as study 1. Afterwards, all participants moved to the measurement of resource deprivation concern. Finally, minority preference was measured by using a survey on preference for brands with different market share across five product categories. Consistent with our prediction, results showed that participants reminded of resource scarcity were more inclined to choose brands with low market share ( $M_{scarcity}=7.16$  vs.  $M_{control}=6.02$ ,  $p<.05$ ). Furthermore, results of mediation analysis supported the mediating effect of resource deprivation concern (5000 samples, 95% CI: [-0.83, -0.01]).

In study 3 (N=85), we sought to replicate the results of the above two studies in a different product domain. The same episodic recall task as study 1 was used to manipulate resource scarcity. Afterwards, participants read a purchase decision scenario, where they struggled with the color of laptops but learned from the salesperson about previous consumers' choices. Resource deprivation concern was then measured as study 2. In addition, we measured competitive orientation as an alternative explanation. Results indicated that resource scarcity has a positive effect on the choice of minority-endorsed laptop color (scarcity: 59.5% vs. control: 27.9%,  $B=1.34$ ,  $p<.005$ ). Results of mediation analyses again supported the mediating role of resource deprivation concern (CI: [-0.99, -0.03]), while the mediating effect of competitive orientation was not significant (CI: [-0.13, 0.10]).

Study 4 (N=112) was conducted to test the moderating effect of PEM by particularly focusing on the scarcity of material resources. Participants were randomly assigned to a 2 (resource scarcity vs. no reminders of scarcity) \* 2 (PEM: high vs. low) between-subjects design. Participants were first instructed to complete a "Listing Task" regarding five different material resources, which was adapted from previous research to manipulate resource scarcity (Roux et al. 2015). Next, a reading task adopted from Yoon and Kim (2016) was used to manipulate PEM. Finally, participants were asked to complete the same brand preference task as study 2. Results further revealed that under high economic mobility, the mediating effect of resource deprivation concern was eliminated (CI: [-0.23, 0.23]), but under low economic mobility, the mediating effect of resource deprivation concern held (CI: [0.12, 0.73]).

In conclusion, our findings contribute to the literature by showing that resource scarcity has a positive effect on consumer preference for minority-endorsed products, which is mediated by resource deprivation concern. The current research also broadens the scope of research on resource scarcity by investigating perceived economic mobility as an important boundary condition.

# When High-End Designers Partner with Low-Cost Retailers: Bridging the Access Gap

Gabriel E. Gonzales, The Pennsylvania State University, USA  
Johanna Slot, The Pennsylvania State University, USA  
Margaret G. Meloy, The Pennsylvania State University, USA

## EXTENDED ABSTRACT

When high-end designers work with low-cost retailers to create co-branded collections (e.g., Karl Lagerfeld for H&M), such alliances are referred to as designer-for-retailer collaborations. Though extant research suggests that successful brand alliances' rely on high brand fit (Simonin and Ruth 1998), practice shows that designer-for-retailer collaborations generate positive consumer response. The current work explains the success of designer-for-retailer collaborations by introducing the construct *access gap* (i.e., the magnitude of the difference in consumers' ability to access products from the collaborating parties). Specifically, low-cost retailer's customers are typically unable to access the high-end designer's products due to budgetary constraints. Designer-for-retailer collaborations bridge this access gap by pairing mass distribution and affordable prices with designer products. Across four studies, we show that *access gap*, rather than brand fit, explains consumers' increased willingness to purchase (WTPR) designer-for-retailer products through anticipated conferral of status benefits (ACS). We explicate the roles of designer creative control and retailer's pricing strategies.

### Study 1: Brand Fit vs. Access Gap

In study 1, we manipulate the degree of brand fit between the designer and low-cost retailer. Participants ( $N=79$  students, 45% female, median age 19) imagined themselves in Target when seeing a designer-for-Target collection. The items are typically affordable to [everyday people (ED)/the rich and famous (RF)]. Participants indicated expected price (EP) and their WTPR (1-to-9 scale). Access gap was measured by asking participants to compare Target and the designer on relative prices, affordability, exclusivity, accessibility, level of luxury, and income level of typical customers (1="extremely similar" to 9="extremely different";  $\alpha=.88$ ). Brand fit was measured using five standard fit items ( $\alpha=.91$ ).

EP was significantly higher ( $M_{ED}=\$32.32, M_{RF}=\$55.22; p<.01$ ) and WTPR was directionally higher ( $M_{ED}=5.21, M_{RF}=5.64; p>.10$ ) for the designer targeting the RF versus ED. Brand fit for the RF designer was worse than ED ( $M_{ED}=5.31, M_{RF}=3.93; p<.01$ ) and had a significantly wider access gap from Target ( $M_{ED}=5.36, M_{RF}=6.98; p<.01$ ). We tested the effects of access gap and brand fit on WTPR as two competing mediators, controlling for EP. Access gap was significant ( $b=.38, p<.05$ ), whereas brand fit was not ( $b=.31, p>.05$ ). Bootstrapping (PROCESS model 4, Hayes 2017) revealed a significant indirect effect of designer type through access gap on WTPR ( $b_{\text{Indirect-AccessGap}}=.61; 95\%CI: \{.12, 1.33\}$ ). Access gap, but not brand fit, drove WTPR.

### Study 2: Access Gap Benefits

What benefits are conferred to consumers through designer-for-retailer collaborations? We examine ACS (Eastman, Goldsmith, and Flynn 1999; Escalas and Bettman 2003, 2005) controlling for anticipated quality (AQ). We again use two designer conditions (ED vs RF) like study 1. Participants ( $N=201$  students, 47% female, median age 19) reported the EP of a sweater from the designer-for-retailer collection and their WTPR. We included five items to measure AQ: craftsmanship, fabric quality, level of detail, design quality, and creativity ( $\alpha=.95$ ); access gap was measured (see Study 1,  $\alpha=.93$ ); three items assessed ACS from wearing the sweater ( $\alpha=.95$ ).

RF led consumers to a higher EP than ED ( $M_{RF}=\$49.99; M_{ED}=\$31.13; p<.01$ ). Despite this, however, those in the RF (compared to ED) condition also reported a significantly higher WTPR ( $M_{RF}=5.62, M_{ED}=4.85, p=.01$ ). Importantly, the access gap was larger for RF than ED ( $M_{RF}=7.11, M_{ED}=5.78, p=.01$ ). Finally, RF conferred more status benefits ( $M_{RF}=4.67, M_{ED}=3.88, p<.01$ ).

Serial mediation, from designer type to WTPR through both access gap and ACS, while controlling for anticipated quality and differences in EP was significant. We expected designer type on WTPR to be mediated through two different causal paths: 1) the indirect path from designer type  $\rightarrow$  access gap  $\rightarrow$  AQ  $\rightarrow$  WTPR, and, of focal interest, 2) the indirect path from designer type  $\rightarrow$  access gap  $\rightarrow$  ACS  $\rightarrow$  WTPR. Using PROCESS (Version 3.0; Hayes 2017), we tested both indirect effects. The indirect effect through access gap and ACS was significantly different from zero ( $\gamma=.11, 95\%CI: \{.01, .25\}$ ) and fully mediated the effect of designer type on WTPR ( $p=.57$ ). ACS drives WTPR.

### Study 3: Alliance Type

Study 3 addresses the role of creative control (Valesia, Nunes, and Ordanini 2016) in designer-for-retailer collaborations relative to licensing agreements. If the designer lacks creative control (McCracken 1989), ACS may be diminished. We compare different partners (designer vs athlete) in different co-branding alliances (collaboration (designer has creative control) vs licensing agreement (retailer has creative control) in a 2x2. Participants ( $N=103$  students, 59% female, median age 20) provided EP, WTPR, AQ (3 items,  $\alpha=.90$ ), and ACS from the item (9 items,  $\alpha=.93$ ).

As expected, controlling for EP, the interaction between alliance type and partner type on WTPR was significant ( $F(1,98)=5.13, p<.05$ ). WTPR was higher for the athlete under licensing than collaboration ( $M_{AthLic}=5.55, M_{AthCollab}=4.51; p<.10$ ). For the designer, the pattern was reversed ( $M_{DesLic}=4.86, M_{DesCollab}=5.86; p=.12$ ). A test of moderated mediation with partner as the IV, alliance type as moderator, AQ and ACS as parallel mediators on WTPR was significant ( $Index_{\text{ModMed}}=.62, 95\%CI: \{.01, 1.67\}$ ; Hayes 2017). *Athlete licensed* collections (vs. designer) had higher WTPR through increased ACS, whereas *designer collaboration* collections showed higher WTPR through increased ACS. Thus, collaborations appear most successful when the collaboration partner is a designer that has creative control.

### Study 4: Real Choice

Study 4 replicates the alliance findings of study 3 (i.e., Licensing, Collaboration, PL) in real choice using scarves (with custom-made labels sewn into the scarf). The second manipulated factor was price [ $\$14.99/\$49.99$ ] to examine pricing for designer-for-retailer product. After examination, participants ( $N=194$  female students, median age 19) indicated whether they would like to be entered into an auction for the scarf. If yes, they indicated their maximum bid.

Overall, 36% of participants bid. When the scarf was priced at  $\$49.99$ , the collaboration had the highest bid ( $M_{\text{Collab}}=\$31.66$ ) compared to the other scarf labels ( $M_{\text{TargetPL}}=\$20.55, M_{\text{Lic}}=\$22.04; p<.05$ ). However, when the scarf was priced at  $\$14.99$ , the collaboration and licensed scarves produced similar bids ( $M_{\text{Collab}}=\$17.59, M_{\text{Lic}}=\$18.17; p=.88$ ). Thus, we confirm the benefits of designer-for-retailer collaborations over licensing arrangements in a consequential setting,

and add a boundary condition. Designer-for-retailer items should be priced sufficiently higher than the retailer's other products.

### Discussion

The success of designer-for-retailer collaborations hinges on the presence of an access gap. When designers have creative control and when prices are sufficiently high (but not out of reach for low-cost retail customers), status benefits are anticipated, subsequently increasing WTPR. This study starts to explain the success of co-branding alliances despite a poor fit between the partners.

# The Impostor Syndrome from Luxury Consumption

Dafna Goor, Harvard Business School, USA

Nailya Ordabayeva, Boston College, USA

Anat Keinan, Harvard Business School, USA

Sandrine Crener-Ricard, Harvard Business School, USA

## EXTENDED ABSTRACT

Luxury brands symbolize cultural ideals and signal desirable qualities such as power, influence, and success, which embody individuals' aspirations and vision of their ideal selves (Belk 1998). Projecting an ideal self by wearing luxury can yield a number of benefits such as economic rewards, special treatment, respect, and recognition from others (Lee, Ko and Megehee 2015). However, projecting an ideal self also highlights a discrepancy between consumers' ideal and true selves, which may create psychological tension and dissonance (Erickson 1995; Clance and Imes 1978). Specifically, when individuals experience a mismatch between their external (i.e. projected) and internal (i.e. true) selves, they may feel inauthentic or like an impostor. Although self-authenticity is an important driver of individual behavior, which enhances physical and psychological well-being (Erickson 1995; Sheldon et al. 1997), prior marketing studies only examined consumers' pursuit of *authentic products and brands* and overlooked their pursuit of an *authentic self* (Grayson and Martinec 2004; Napoli et al. 2014). The only study linking consumption behavior to self-authenticity reported that individuals may feel inauthentic from consuming *counterfeit* products (Gino, Norton and Ariely 2010), leaving the question open of how self-authenticity may be enhanced or undermined from consuming *authentic* products.

Addressing this gap, we propose that although consuming luxury brands may garner external benefits (such as respect and recognition from others), it may also make consumers feel like an impostor because of the gap that it creates between consumers' projected selves and true selves. We call this phenomenon the "impostor syndrome from luxury consumption" and predict that it will not emerge when consuming non-luxury brands that do not project consumers' ideal selves. Furthermore, the impostor syndrome from luxury consumption should be more pronounced in individuals with low psychological entitlement, who perceive a large gap between their (deflated) view of their true self and the projected self, than in individuals with high entitlement, who perceive a small gap between their (inflated) view of their true self and the projected self. Finally, we explore the moderating effects of the detectability and malleability of the gap between consumers' true and projected selves. Six studies test our predictions.

Study 1 tested whether luxury consumption can boost individuals' external benefits, but also make them feel inauthentic. To ensure that the phenomenon was relevant for a typical target market of luxury brands, we surveyed female opera patrons during an intermission of a flagship show at the Metropolitan Opera in New York City. Participants imagined that they were shopping for a dress to wear to the opera and they were considering two options – a luxury dress and a non-luxury dress. They were asked to choose which dress would yield greater external benefits in terms of garnering recognition from others and which dress would make them feel more authentic. Whereas participants thought that the luxury dress would be more likely to garner them external recognition than the non-luxury dress, they also thought that it would make them feel inauthentic.

Studies 2 and 3 tested the effect of psychological entitlement on the extent of the "impostor syndrome from luxury consumption", and the process underlying this effect.

In Study 2, participants recalled a situation in which they wore a luxury or non-luxury product, and they rated how authentic they felt wearing the product. To test the role of psychological entitlement in determining the extent of consumers' impostor syndrome, we administered the psychological entitlement scale (Campbell et al. 2004). To examine the psychological process behind this effect, we measured self-brand connection, which captures how connected consumers think the brand (and hence the self projected by the brand) is to their true self and identity (Escalas and Bettman 2003). As expected, luxury consumption made consumers feel less authentic, and this effect emerged among unentitled individuals, not among entitled individuals. Individuals' self-brand connection (i.e. how closely or distantly individuals thought the brand projected their true self or identity) mediated this effect.

Study 3 replicated these findings using a manipulation, instead of an inherent measure, of psychological entitlement. The study also revealed that self-inauthenticity produced by luxury consumption has negative consequences for consumers' luxury experience (i.e. feeling inauthentic translates to lower levels of confidence, empowerment, success, sophistication, fitting in, comfort, and happiness while wearing luxury).

Studies 4-5 tested the boundary conditions of the phenomenon.

Study 4 explored whether manipulating the detectability of the gap between one's true self and projected self moderates the link between psychological entitlement and the "impostor syndrome from luxury consumption." Female participants read that they were going to a wedding and that they were wearing a Versace dress. To manipulate the detectability of the gap between one's true and projected selves, participants read that the wedding was attended by familiar others or by strangers. The results showed that the "impostor syndrome from luxury consumption" emerged and psychological entitlement significantly predicted it when participants imagined being in the company of strangers (to whom the gap between participants' true and projected selves was undetectable), but not when they imagined being in the company of familiar others (to whom the gap was detectable).

Study 5 tested the moderating role of the malleability of the gap by manipulating individuals' perceptions of the cultural capital (i.e. ability to appreciate cultural, artistic, and luxury goods) as fixed or malleable. Framing the cultural capital as malleable should lead people to perceive the gap between their true and ideal selves to be surmountable (vs. insurmountable when the cultural capital is framed as fixed). As a result, we found that the "impostor syndrome from luxury consumption" emerged and psychological entitlement predicted it when the cultural capital (and the gap between individuals' true and ideal selves) was perceived to be fixed, but not when the cultural capital was perceived to be malleable.

Study 6 showed that feeling authentic is important to consumers and that it drives consumers' choices of luxury (vs. non-luxury) products across many contexts.

Our work is the first to demonstrate the implications of luxury consumption for consumers' feelings of self-authenticity. The findings add useful insights to marketing theory and practice.

# Changes in Social Values in the United States – 1976-2017: Is a New Age of Tribalism Emerging?

Eda Gurel-Atay, Independent Scholar, USA

Johnny Chen, University of Oregon, USA

Wang Suk Suh, University of Oregon, USA

Lynn R. Kahle, University of Oregon, USA

## EXTENDED ABSTRACT

Social values, which represent society's goals, ideals, and conceptions of preferred states (Kahle 1996), are dynamic and always changing. Thus, a continuous understanding of changes in values over time can provide insight into individuals and society.

The current research builds upon three previous papers (Kahle and Timmer 1983; Kahle, Poulos, and Sukdial 1988; Gurel-Atay et al. 2010), expanding the view of changes in American social values across 40 years. Subtle trends in the previous 30 years now show a dramatic shift in social values in the last ten years which cuts across gender, age cohort, education, and ethnicity.

### Method

Four sequential cross-sectional national surveys were administered to representative samples of the US Census to compare findings across the 40-year period (1976, 1986, 2007, and 2017).

Social values were measured using the list of values (LOV, Kahle and Timmer 1983). The most important values from the LOV were analyzed across age groups, gender, ethnicity, and education groups. "Fun and enjoyment in life" and "excitement" were collapsed into a single value for analysis because few people selected "excitement" as their first choice in the surveys.

### Findings

#### *Self-respect*

The precipitous drop in 2017 in the ranking of self-respect as the most favored value in America since 1976 across all demographic groups represents the most substantial change in the American culture. The decline is made more dramatic with a corresponding increase in the ranking for a sense of belonging. The data suggest a shock in the American landscape that sharply shifted the priorities of inwardly focused self-respect to one of a sense of belonging or identification with others.

#### *Sense of Belonging*

The most dramatic change in values over the past decade has been the increase in people who endorse a sense of belonging. It went from the least popular value in 1986 and 2007 to the most popular value in 2017. This dramatic growth occurred in all demographic groups. Historically, US women who endorse this value were lower in education and income. They appeared to "belong" to their families, often not working for pay outside the home. The rise in the sense of belonging to the dominant value for most demographic groups seems today to belie the narrow stereotype of endorsers from previous decades.

#### *Being Well-Respected*

With the terminal rates at around 2-4% for rank in 2017, being well-respected has become the least important value for Americans. It appears that Americans today care less about the respect and opinions of others than the acceptance of others as being a member of the group. The general decline in all demographic groups combined with similar changes in ranking for self-respect suggests respect has been greatly de-prioritized in American culture.

#### *A Sense of Accomplishment*

The importance of this value increased from 1976 to 1986; however, its importance has been decreasing since then for all demographic groups. The biggest decline comes from the youngest age group: In 2007, 18.7% of this age group selected a sense of accomplishment as their most important value while in 2017, only 7.5% of the same group stated this value as their priority.

#### *Self-Fulfillment*

The importance of self-fulfillment has been increasing gradually over the years for almost all demographic groups. However, there is a more pessimistic view of self-fulfillment for those aged 50 and older whose rankings trended in the opposite direction. Indeed, for these two older age groups, the importance of all three internal excess values (i.e., self-respect, self-fulfillment, and sense of accomplishment) has been decreasing, suggesting that they depend on other people more to fulfill their values.

#### *Fun-Enjoyment-Excitement*

There has been an upward trend for this value over the last 40 years for all demographic groups. Interestingly, men ranked this value higher than women in 1976, 1986, and 2007; however, the difference between males and females became statistically insignificant in 2017. This suggests that fun-enjoyment-excitement is becoming equally important for both genders.

#### *Warm Relationships with Others*

This value seemed to peak in importance in 2007 for most demographic groups, but the overall trend appears to be waning over time. However, for the youngest age group and 50-59 years old age group, the trend was the opposite (i.e., declining in 2007 and increasing in 2017). This finding suggests that these two age groups are now more likely to look for support from families and friends.

#### *Security*

The importance of security declined over 30 years from 1976 to 2007 and has stayed steady since then in most demographic groups. This finding suggests that people's feeling of security has not changed in the last decade even in the presence of more terror attacks, the financial crisis of 2008, and the emphasis put on security during presidential elections.

### Discussion

The findings appear to support the notion that recently American society has fundamentally shifted as reflected in the expression of social values. Consumers have shifted away from the controllable and individual-focused excess value of self-respect, which has been the defining characteristic in American culture, to a sense of belonging, which is a more social and less controllable, externally-focused deficit value. Interestingly, while another internally focused, excess value (a sense of accomplishment) also declined in importance, two other excess values, one internally-focused (self-fulfillment) and one externally-focused (fun-enjoyment-excitement), have become more important for consumers.

These results suggest that advertisers and marketers will need to rethink their posture on messaging to a new generation of consum-

ers to align better with the global expression of social values. For advertisers, emphasizing group benefits may be more important, and emphasizing individual benefits may be less important. Consumers want to fit with their groups, and advertisers should show how products facilitate that desire. Advertisers may also want to utilize the combination of values that have been turning into more important values (i.e., a sense of belonging, fun-enjoyment-excitement, and self-fulfilling). For instance, sports-related products may be advertised with a focus on fun-enjoyment-excitement (e.g., having fun doing and watching sports) and a sense of belonging (e.g., being a part of a team). For marketers, segmentation may be more important than ever. Different subgroups have different desires, and as the subgroup identity grows, clarity of differentiation in lifestyle choices is ever more important. Marketers need to understand and address these differences.

# Attention to Missing Information: The Effect of Novel Disclosure Methods

Nikolos Gurney, Carnegie Mellon University, USA  
George Loewenstein, Carnegie Mellon University, USA  
Nick Chater, Warwick Business School, UK

## EXTENDED ABSTRACT

People and organizations frequently withhold information that, if made public, might impact their cause. Rational people—should—view withheld information as a sign that another party may have ‘something to hide.’ When people interpret language, they often draw elaborate, adverse conclusions from the withholding of information. Behavioral and experimental economic studies, however, frequently indicate that people are not that sensitive to withheld information, as if they are giving the ‘benefit of the doubt’ regarding missing information. It is worth noting that these results are usually the result of participants reviewing abstract tabular representations of information. It is possible that people might treat the withholding of information very differently in a conversational interaction. In three experiments, we show that people *are* substantially more sensitive to, and suspicious of, withheld information in a conversational context. Bringing together behavioral economics and experimental pragmatics, this work suggests that naturalist conversational interactions, whether auditory or written, when compared to abstract presentations of information, may best engage important aspects of human reasoning.

Decision makers often must make choices based on information selected by other parties with different interests. Buying a car with only partial access to its history, letting your teen go to a party based only on the information she provides, and hiring job applicants using the information that they choose to disclose are a few examples of a situation that is pervasive. Standard economic theory predicts that people will recognize when information is being withheld and respond to that awareness rationally. When rational economic agents interact in markets, economic theory predicts a phenomenon known as ‘unraveling’ whereby all information is disclosed, and people infer any (exceptional) failures to do so as indicating that the withheld information is as adverse as it could be (Grossman & Hart, 1980; Milgrom, 1981).

Although a small number of studies have provided some support for unraveling theory (Forsythe, Isaac, & Palfrey, 1989; Ippolito, 1992), most empirical research on the topic has challenged the theory’s assumptions and predictions (Dranove & Jin, 2010; Ben-Shahar & Schneider, 2011). Furthermore, interventions designed to enhance people’s attention to, and appropriate treatment of, missing information have generally had limited impact (Jin, Luca, & Martin, 2016; Bederson et al. 2016; Gurney & Loewenstein, 2017; Sah & Read, 2017). Responding to the limited success of these prior interventions, we propose and test a novel approach to disclosure, involving a switch from tabular to conversational presentation of information that rests on insight from the language sciences (e.g., Noveck, 2004; Grice, 1975; Levinson, 2000; Sperber & Wilson, 1986). In contrast to the unfamiliar and rather abstract tabular format, the conversational presentation of information is both more naturalistic and potentially engages the powerful reasoning mechanisms deployed in language understanding. In a series of experiments dealing with both restaurant choice and ATM overdrafts, we show that conversational disclosure can significantly enhance responsiveness and attention to missing information.

In study 1, participants interacted with a visual stimulus that was made to look like a Yelp screenshot *or* a recorded stimulus that was designed to contain the same information as the screenshot.

Participants first reviewed their assigned stimulus and then, using a slider anchored at 0 (definitely not) and 100 (Enthusiastic!), indicated what they thought about going to the restaurant with friends. Participants next progressed to a new page without the stimulus and answered a battery of questions about the restaurant. Two questions were particularly relevant: one checked participants’ recall of the SIG (or its presence) and the other requested an open-ended response about their reasoning behind their response to the stimulus.

The effect of audio disclosure relative to visual disclosure was dramatic; an ordinary least squares analysis revealed that, relative to the audio highest SIG (grade of ‘A’) condition ( $\beta = 84.36$ ,  $p < 0.001$ ), the audio missing information condition ( $\beta = -31.47$ ,  $p < 0.001$ ) produced significantly more skepticism than the standard (Yelp screenshot) missing information. Treatment condition also predicted the correct recall of the target information: audio participants were significantly more likely to correctly recall the value or absence of information.

For study 2, we tightened the experimental manipulations to reduce the variance in information across operationalizations of the disclosed content as much as possible. Despite these efforts, an audio disclosure, because of intonations and other voice cues that can only be conspicuously absent, inherently has more information than a visual disclosure (Scherer, 2003; Clark & Tree, 2002; Schroeder & Epley, 2015). Additionally, we tested script and unfolding chat treatments. Concisely, study 2 supported our hypothesis that the conversational disclosure would prove more effective and it added the insight that unfolding chats and scripts are similarly effective.

Study 3 extended our findings to a new domain, consumer banking, by testing willingness to uptake a personal checking account overdraft option. When information was missing in an email, participants were significantly more likely to sign up for the overdraft option if they reviewed and email than if they reviewed a phone conversation script.

Our results show that people can be sensitive to omitted information, with normatively appropriate skepticism, when that information is embedded in a conversational context, whether auditory or written. This fits with the observation from the language sciences that the interpretation of conversational input is exquisitely tuned *not* just to what is said, but to what might have been said, but was not (e.g., Grice, 1975). It also aligns with normative ‘unravelling’ predictions from economic theory (Grossman & Hart, 1980; Milgrom 1981). These results are significant in at least three ways: they suggest that theoretical conclusions from earlier studies suggesting insensitivity to omitted information may be premature; they suggest that conversational presentations of information may be important in communications between companies and consumers, regarding improving consumer welfare; and they suggest a concrete setting for future theoretical and empirical interaction between economics and the language sciences.

# Inequality and Market (In)efficiency

Serena Hagerty, Harvard University, USA

Michael I. Norton, Harvard University, USA

## EXTENDED ABSTRACT

Despite generally high rates of inequality, individuals have a tendency to underestimate the level of wealth inequality in their nation (Norton and Ariely, 2011). These inaccurate perceptions consequently inform individuals' opinions for redistribution policies. Recent research demonstrates that perceived inequality is a better predictor of policy preferences than actual inequality (Engelhardt and Wagener, 2014). There is therefore growing support for greater transparency of inequality. In two studies we demonstrate the effects of inequality transparency on the behavior of individuals with relatively high wealth, revealing potential unintended consequences of increased inequality transparency.

Study 1 demonstrates the market-level effects of inequality transparency. Participants (N= 1001) first completed a series of counting tasks to earn points. Participants thought their points were awarded based on performance, but in actuality, participants were randomly assigned to one of five conditions [22, 49, 72, 105, or 304 points], which represent the true income distribution of the United States. They were then told they could use the points to bid against four other participants for the chance to win YouTube videos. If they did not win any videos they would have to complete five more minutes of counting tasks. Any points they did not bid were converted into a monetary bonus. Half of the participants received information depicting how their score compared to the other participants in their auction group, while the other half were given no information other than their own earnings (Transparency vs No Transparency).

Overall, we find that wealthier participants win more videos [ $F(4, 909) = 8.80, p = 0.00$ ], even though they spend a smaller proportion of their budget [ $F(4, 815) = 3.93, p = 0.004$ ]. We also find that as earnings increase, liking becomes a weaker predictor of winning a video. The correlation between bidding and liking is significantly lower for participants in the highest earning quintile than for those in the lowest earning quintile (22 points) [ $r = .292$  vs.  $r = .432; z = 2.96, p = 0.02$ ]. In a binary logistic regression, even when controlling for liking of a video, participants earning more points were more likely to win any given video [ $B = 0.206, SE = .029, p < 0.001$ ]. As a result, participants in the highest earning quintile won their least favorite video at the same rate that participants in the lowest earning quintile won their favorite video (15.1 % vs. 15.3 %;  $X^2(2, N = 361) = 0.00, p = 0.98$ ).

There was no main effect of transparency on number of wins, but there was a significant interaction: participants in the highest quintile won more videos when inequality was transparent while all other participants won marginally fewer videos [ $F(4, 901) = 2.527, p = 0.039$ ]. This wealth-transparency advantage was the result of more efficient bidding, which we measured as the distance between the winning bid and the next highest bid (wasted points). While there was no effect on total number of points spent, there was a marginally significant interaction on wasted points: high income earners wasted fewer points in the transparent condition [ $F(4, 909) = 2.12, p = 0.078$ ]. There was also an interaction effect of transparency on the propensity to enter the market at all. In the no-transparency condition, only 55% of highest income earners bid non-zero amounts compared to 74% in the transparent condition [ $X^2(1, 89) = 6.788, p = 0.01$ ]. In all other quintiles the rate of participants bidding non-zero amounts was marginally smaller in the transparent conditions. This suggests that the wealthy benefitted from inequality transparency, not because they

increased the total number of points they spent, but because they were able to bid more strategically on more videos.

In study 2 we were interested in the effect of inequality transparency on subsequent consumption rates. We replicated the procedure from Study 1, with one critical change- participants (N=563) were told they could watch the videos for as long as they would like. Given past research on scarcity priming, we predicted that participants in the lowest quintile who were made aware of their disadvantage would watch their winnings for longer. Conversely, we predicted that participants in the highest quintile would watch comparatively less of their winnings when made aware of their relative wealth.

Our findings support our hypothesis- even controlling for total number of videos won, total number of video-minutes won, rank of video, and percentage of earnings spent, participants in the highest quintile watched a smaller proportion of their winnings when they were aware of their advantage ( $M_{transparent} = 0.11$  vs.  $M_{notransp} = 0.13$ ) while participants in the lowest quintile watched a larger proportion in the transparent condition [ $(M_{transparent} = 0.19$  vs.  $M_{notransp} = 0.15; F(1, 218) = 10.88, p = 0.01$ ]. This interaction is also significant when including all five point brackets in the analysis.

While previous literature has begun to develop an understanding of how income inequality awareness can alter opinions, emotions, and behavior for individuals with relatively less wealth, there has been less research devoted to how transparency and awareness shape the behavior of relatively wealthier individuals (Sharma & Alter, 2012; Cannon, Goldsmith & Roux, 2016). Understanding behavior across the income distribution, however, is critical to our understanding of the full impact of different policies.

In two studies we demonstrate potential unintended consequences of inequality transparency, primarily due to increased advantages for wealthier individuals. First we demonstrate that inequality transparency provides a disproportionate advantage to participants in the highest earning quintile, as it enables them to bid more efficiently and subsequently win more videos. Secondly, we provide preliminary evidence that by simply being aware of their wealth advantage, wealthy individuals consume less of their winnings.

## Examining Received Attention as a Social Benefit of Experiential Consumption

Matthew J. Hall, University of Nebraska-Lincoln, USA

Jamie D. Hyodo, University of Nebraska-Lincoln, USA

### EXTENDED ABSTRACT

Consumers frequently share experiences online for self-presentation purposes (Schau and Gilly 2003). Social benefits of such sharing are realized when others provide explicit feedback (likes and comments), which can affirm the sender's behavior (Toma and Hancock 2013). Therefore, consumers' experiential evaluations should only be influenced by online sharing if others provide explicit feedback affirming their choices (positive social influence or proof; Cialdini 1993). The present research leverages the attention economy to challenge this assumption by demonstrating that pure attention received from such experiential sharing (i.e., number of views) influences experiential perceptions, even when attention is unpolluted by valence or affirmation. By viewing attention as a social resource, we demonstrate that consumers are more satisfied with experiences that attract more attention.

The attention economy (Davenport and Beck 2001) proposes that human attention is a scarce and valuable resource sought by consumers (Derber 2000). When one receives attention, it signals the strength of one's social standing because others have deemed one's signal worthy despite competing available signals (Falkinger 2007; Kessous 2015). As such, receiving high levels of attention should increase one's perceived social self-esteem (Heatherton and Polivy 1991). When attention is attracted due to a consumption experience, attention-driven SSE should be viewed as a social benefit of consumption, thus increasing experiential satisfaction relative to those receiving low attention, and to one's initial (pre-sharing) satisfaction levels. Further, if attention is a social benefit of consumption, it should affect satisfaction similarly to other product benefits. Therefore, we propose that attention will have a stronger influence on satisfaction among consumers who have a stronger desire for peer attention (i.e., high public self-consciousness; Scheier and Carver 1980). Further, as a consumption benefit, the effect of attention on satisfaction should depend on consumer expectations (Oliver 1980). We therefore expect that negative disconfirmation (receiving less attention than expected) should have a stronger effect on satisfaction than positive disconfirmation (Anderson and Sullivan 1993). Lastly, an alternative explanation for our hypothesized effects is that, when explicit feedback is unavailable, consumers use received attention as a proxy for behavioral affirmation. To rule out this explanation, we test our proposed attention effects in the context of a negative experience. Because sharing negative experiences can decrease self-esteem (Moore 2014), attention attracted to a negative experience should only increase satisfaction if it is viewed as a social benefit of consumption.

To test our theory, we leveraged scenarios featuring Snapchat and Instagram's "Story" functions. Both platforms are popular for experiential sharing and limit feedback to the number of views received, making them ideal for testing our effects (unvalenced attention). S1 leveraged an undergraduate sample (n=88) and a haircut experience to demonstrate that, while satisfaction was equivalent prior to sharing the experience, satisfaction increased (difference of pre/post-attention satisfaction) after participants received higher levels of attention ( $M_{HighAttn}=40$ ), and decreased for those receiving low attention ( $M_{LowAttn}=49$ ;  $p<.001$ ). This suggests that experiences attracting more attention are viewed as more satisfying.

S2 featured an undergraduate sample (n=81) and a concert scenario to confirm the moderating role of consumers' attention preferences (PSC;  $F_{Interaction}(1,73)=9.87$ ,  $p<.01$ ) and the mediation of this interaction on satisfaction by social self-esteem (95%CI=[.02,.47]). After attending a concert and posting experiential content, high-PSC participants (+1sd) who received high attention reported higher SSE ( $M_{HighAttn}=3.92$ ,  $M_{LowAttn}=3.37$ ;  $p=.03$ ) and satisfaction ( $M_{HighAttn}=6.47$ ,  $M_{LowAttn}=5.61$ ;  $p<.01$ ). For low-PSC participants (-1sd), receiving high attention did not influence SSE ( $M_{HighAttn}=4.28$ ,  $M_{LowAttn}=4.71$ ; NS) and led to marginally lower satisfaction ( $M_{HighAttn}=6.18$ ,  $M_{LowAttn}=6.85$ ;  $p=.06$ ). This suggests that received attention is viewed as a social benefit of consumption and is subject to consumer preferences.

In S3, we manipulated Mturk participants' (n=429) attention expectations (high/low) and used the scenario and received attention manipulations from S2. We also added a control condition in which received attention was not mentioned. This analysis confirmed the moderating role of attention expectations, and again that of PSC (3-way interaction;  $p=.05$ ). The interaction was driven by high-PSC participants who expected high attention but received low attention ( $M_{LowAttn}=5.11$ ). This dissatisfaction was shown relative to high received attention ( $M_{HighAttn}=6.33$ ;  $p<.001$ ) and the control condition ( $M_{Control}=6.34$ ;  $p<.001$ ). Received attention did not influence satisfaction for high-PSC participants expecting low attention, or for low-PSC consumers regardless of expectations (all simple effect contrast  $F_s<1.00$ ). Overall, S3 findings suggest that, like other product benefits, the attention-related social benefits of shared experiences are subject to consumer expectations and preferences.

S4 featured Mturk workers (n=155) who read a scenario about a negative sporting event experience (it rained, their team lost, etc.) where either they or a friend posted photos (participant was not featured in the photos). SSE and satisfaction were measured before and after the manipulation (difference scores calculated). The expected interaction was observed on both satisfaction ( $p<.001$ ) and SSE ( $p<.01$ ). When the participant posted the photo, high-attention participants reported more positive changes in SSE ( $M_{HighAttn}=.14$ ,  $M_{LowAttn}=-.34$ ;  $p<.001$ ) and satisfaction ( $M_{HighAttn}=.67$ ,  $M_{LowAttn}=-.01$ ;  $p<.001$ ). However, when the friend posted the photo, receiving high attention did not influence SSE ( $M_{HighAttn}=-.04$ ,  $M_{LowAttn}=.05$ ; NS) and negatively affected satisfaction ( $M_{HighAttn}=-.07$ ,  $M_{LowAttn}=.33$ ;  $p=.03$ ). Further, SSE mediated the effect of attention on satisfaction (95%CI=[.01,.49]). These findings suggest that attention as a social resource, not inferred behavior affirmation, leads to increased satisfaction.

Space limitations prohibit the detailed discussion of a fifth study replicating the effect from S4. However, S5 demonstrates that high attention attracted by photos featuring the focal participant only influenced satisfaction when the photo was shared by the participant (i.e., no differences in the FriendPost condition, despite the participant being featured in the photo). Thus, S5 suggests that attention must be directed at the focal consumer (i.e., their profile) and come from their social network in order to influence satisfaction.

Overall, our findings suggest that attention received from one's experiences is a social benefit of consumption that increases experiential satisfaction. However, these effects are dependent on consumers' attention expectations and their attention preferences. Our findings contribute to literatures on the attention economy and expe-

riental consumption by suggesting that experiential satisfaction is in part subject to received attention. Further, they suggest that consumers' attention-seeking motives may influence experiential choice.

# Alternative “Facts”: The Effects of Narrative Processing on the Acceptance of Factual Information

Anne Hamby, Hofstra University, USA

David Brinberg, Virginia Tech, USA

## EXTENDED ABSTRACT

Recent research in persuasion has distinguished between “narrative” processing, evoked by stories, and “analytical” processing, evoked by facts (Escalas 2007). In practice, consumers often encounter information in a blended format; for example, a pharmaceutical advertisement may feature a testimonial describing an experience with a drug, followed by a list of facts about the drug’s efficacy and side effects. The current research addresses the question: Does the processing of a narrative influence how facts presented separate from a narrative are recalled and endorsed?

Past work has examined narrative processing (i.e., transportation; Escalas 2007; van Laer et al. 2014) as a passive influence of persuasion-related outcomes. In the current work, we demonstrate that narrative processing also takes an active form and can be used to integrate messages of distinct formats (rather than narrative formats, alone). The current work contributes to narrative persuasion research by introducing situation model construction to explain message comprehension (understanding), its subsequent effect on beliefs, and expand current understanding of how narratives lead to persuasion. We demonstrate that information is more likely to be viewed as true if it helps the reader understand a previously-encountered narrative and show that this effect persists even when information is labeled as false. The current work illustrates a cognitive bias: if external facts help to understand a prior (narrative) message, then these facts are more likely to be perceived as true.

## Conceptual Development

The dominant process to understand the effect of narratives on persuasion-related outcomes in the consumer literature has been narrative transportation (van Laer et al. 2014). Narrative transportation theory, however, does not address how the information encountered after a story can be influenced by narrative processing of the story.

Research in discourse psychology suggests readers create a situation model during story processing: a network of relations that reflect the reader’s representation of the causal information presented within a narrative (Zwaan and Radvansky 1998). Readers who encounter information in a separate context (outside the narrative “world”), but causally-related to the situation model, may integrate it into their situation model to enhance story comprehension.

When presented with external facts following a narrative, we expect the reader to integrate this information into her mental representation of the narrative, given that the facts are relevant to some aspects of the cause-effect story sequence. We propose that facts integrated into a situation model create a sense of coherence which enhances the fact’s perceived truth (Schwartz and Newman 2017), even though narrative understanding does not provide evidentiary value to the information’s truth. In other words, the external fact may augment narrative comprehension and may then have a stronger sense of “truthiness.”

We expect an external fact to be endorsed when it helps to explain a less-well understood narrative (i.e. ambiguous causality in a story) compared to a narrative with a coherent (less ambiguous) cause-effect sequence:

*Hypothesis 1 External facts that are encountered following a narrative are more likely to be endorsed (a) and*

*recalled (b) when they are causally-connected to the storyline.*

We expect facts that are causally related to and presented after the narrative will facilitate comprehension of the context of the cause-effect sequence of the situation model, which influences belief endorsement and recall.

*Hypothesis 2 Narrative comprehension mediates the relationship between external facts that cohere with and are encountered following a narrative on belief endorsement and recall.*

Past work suggests that information which plays an explanatory role in understanding a situation is particularly difficult to falsify (Johnson and Seifert 1994). Ecker and colleagues (2010) suggest readers prefer an incorrect but complete situation model over an incomplete but correct situation model. Based on this work, we expect facts which have been integrated into a situation model will continue to be endorsed even when the facts are learned to be false.

*Hypothesis 3 Facts which have been integrated into a situation model, but have been falsified, will be endorsed more than the same information not integrated into the situation model.*

We test these hypotheses with four studies. Study 1 demonstrates that facts which provide a causal explanation presented after a narrative (but not a nonnarrative message) are more likely to be viewed as true (and those that are inconsistent are more likely to be rejected) than when the facts are presented before the narrative. Controlling for narrative transportation did not remove the effects of interest, suggesting that a separate process explains the effects. Study 2 shows that when a fact presented after the story was directly related to the narrative plotline (and thus, the reader’s situation model), participants were more likely to view it as true than when the fact was peripheral related to the storyline. This study is consistent with the proposal that causal-relatedness of a fact enhances integration into the reader’s situation model, which enhances belief or the sense of “truthiness” of information. Study 3 shows that information integrated into a situation model continues to be viewed by readers as true, despite later learning it is false: when an external fact helped create a coherent situation model (ambiguous story condition) it was more likely to be viewed as true versus when the situation model was already coherent (unambiguous condition). Finally, study 4 shows that exposure to facts that provide a causal explanation for the story are more likely to be endorsed because they are integrated into the reader’s situation model (comprehension). Moreover, we show the observed effects are attenuated for individuals *higher* in Need for Cognition: those who are higher in NFC are less susceptible to the “truthiness” effect of accepting information as true because the information provides a sense of coherence.

# “Once? No. Twenty times? Sure!” Uncertainty and precommitment in Social Dilemmas

David J. Hardisty, University of British Columbia, Canada

Howard Kunreuther, Columbia University, USA

David H. Krantz, University of Pennsylvania, USA

Poonam Arora, Manhattan College, USA

Amir Sepehri, Western University, Canada

## EXTENDED ABSTRACT

In many real-world social dilemmas, interdependent actors must decide whether to invest in preventive measures against uncertain losses. For example, when consumers decide whether to get the flu shot each year, the likelihood of getting sick depends not only on the actions of the individual consumer, but also on the actions of those around her. If everyone invests in protective measures, there is herd immunity (and some people can free-ride without getting the flu shot).

Uncertainty about losses lowers cooperation between individuals quite substantially. For example, while cooperation rates in a loss-framed, repeated prisoner's dilemma (PD) may hover around 60-75%, uncertainty lowers the cooperation rate to around 25-40% (Gong, Baron, & Kunreuther, 2009; Kunreuther, Silvasi, Bradlow, & Small, 2009). Thus, cooperation rates under uncertainty are up to 3 times lower. Because individuals are less likely to cooperate under uncertainty, and because so many real-world situations of interest resemble interdependent-security (IDS) situations (with uncertain, negative prospects), behavioral research should explore ways to increase cooperation under uncertainty. One possibility comes from Slovic, Fischhoff, and Lichtenstein (1978) work on single vs aggregate probabilities: consumers were not concerned with the likelihood of being killed in a single ride when presented with the probability of around 0.0000025 of being killed and about 0.00001 of becoming injured, whereas they were more likely to use their seatbelt when the aggregated probabilities for a lifetime were presented (about 0.01 and 0.33 for death and injury, respectively).

In the present research, we explore whether consumers in social dilemmas may make different choices when making decisions one at a time versus when precommitting twenty decisions in advance. Precommitment may serve as a form of choice-bracketing (Read, Loewenstein, & Rabin, 1999), where repeated decisions can be mentally represented as either a series of one-off, individual choices (ie, narrow bracketing) or as a single, combined set of choices (broad bracketing).

We hypothesize that individuals in IDS situations focus mostly on probability and less on the social dilemma nature of the situation and the actions of their counterpart. We further hypothesize that when participants are forced to precommit their actions for multiple rounds, it leads them to reflect on a longer time horizon, thereby increasing their subjective perception of the likelihood of at least one loss during this period. This may lead them to increase their investment rates. In other words, precommitment may buffer against the negative effects of uncertainty on cooperation. When precommitting for 20 rounds, the perceived likelihood of at least one loss during this time period increases and the same player may now invest in protection.

Cooperation rates in a social dilemma are much lower when outcomes are probabilistic. However, have participants precommit their choices in the probabilistic dilemma significantly reduces this gap, as seen in Studies 1 and 2. Several lines of evidence suggest that players in stochastic prisoner's dilemmas are not very responsive to their counterpart: players are less likely to mention their counterpart in stochastic games, their choices are less well correlated with their predictions of their counterparts' choices, and their choices are less

well correlated with their counterparts' previous choices. It seems, then, that players in a stochastic social dilemma are subjectively playing a *probability* game more than a social dilemma. Building on previous literature in probability and the framing of multiple prospects, precommitment appears to be a successful, though modest, intervention for raising investment rates in stochastic social dilemmas. Presumably, those participants who play one round at a time see a 4% chance of loss as very low and decide not to invest in protection. In contrast, those participants who must precommit their choices over a much longer time horizon may think, “A loss will probably happen to me, so I should invest in protection.”

Likewise, in Study 3, when there was no counterpart to interact with or consider, forcing participants to precommit their choices dramatically increased investment rates. It is worth restating that both the repeated and precommitted participants knew they would play 4 blocks of 20 rounds each -- the only difference was whether participants were forced to precommit their choices or not. Rationally, there should be no difference between the two conditions. Further supporting the hypothesis that precommitment influences subjective probability, we observed that those in the precommitment condition were much less likely to mention a low probability of loss. In other words, it is likely that those who precommitted *felt* that the probability of loss was considerably higher than 4%.

As seen in Study 4, precommitment initially has no effect on investment/cooperation in a deterministic prisoner's dilemma, but with repeated plays it rapidly decreases investment. One possibility is learning effects. Initially, participants do not fully understand the game, but soon realize that they can take advantage of the other player (or be taken advantage of) without repercussions. These results may help explain why precommitment is more effective in solo games (Study 3) than in stochastic social dilemmas (Studies 1 and 2): on the one hand, precommitment under uncertainty raises subjective probabilities, thereby increasing investment. However, in a stochastic social dilemma, this is tempered by the knowledge that one's counterpart may defect without repercussions. On balance, participants are more sensitive to probabilities than to their counterparts. Therefore, precommitment in the stochastic dilemmas has a positive, though modest, effect.

Precommitment is an intervention designed to increase the relevant time horizon and raise investment rates under uncertainty. For example, a home-owner might make different choices if buying fire-insurance monthly or annually. The chance of a fire happening next month is likely to be viewed as small so the homeowner may not invest in protection voluntarily. However, when considering an annual policy, the chance of fire is subjectively larger, and the same homeowner might want to purchase insurance, or purchase a more expensive policy. If fire insurance were tied to a mortgage the homeowner might be even more interested in buying insurance since the time horizon will normally be 15 to 20 years.

# Explaining the Attraction Effect: An Ambiguity-Attention-Applicability Framework

Sharlene He, Concordia University, Canada  
Brian Sternthal, Northwestern University, USA

## EXTENDED ABSTRACT

The attraction effect describes a phenomenon where the addition of a third option (i.e., a decoy) to a set containing two alternatives (target and competitor) enhances the choice of the alternative to which it is most similar. For example, suppose a target and competitor offer a tradeoff between two attributes, such that the target has a better price but the competitor has better quality. Adding a decoy that is similar but inferior to the target increases the share of the target (Huber, Payne, and Puto 1982). The attraction effect has been of both practical and theoretical interest to marketing researchers for several decades.

While the attraction effect has been robustly demonstrated with numerical stimuli, recent work has shown that it is difficult to find with perceptual stimuli (Frederick, Lee, and Baskin 2014; Yang and Lynn 2014). Failures to observe this effect with such stimuli point to gaps in understanding this effect (Simonson 2014).

The contributions of the present research are twofold. One, we develop a cohesive framework specifying the necessary conditions for the attraction effect to occur, regardless of whether the stimuli are numerical or perceptual. The attraction effect requires *ambiguity* in choice, *attention* to the target-decoy comparison, and *applicability* of the decoy as a standard for evaluating the target. We refer to these three factors as the A3 framework. Two, by drawing on insights from this framework, we demonstrate the attraction effect with perceptual stimuli similar to those that failed to produce this effect in prior research. In doing so, we systematically test the ambiguity, attention, and applicability factors as distinct and necessary conditions for the attraction effect.

Ambiguity exists when information is conflicting or inadequate (e.g., Cabantous 2006; Ellsberg 1961; Norton 1975; Smithson 1999). In the context of the attraction effect, ambiguity is produced by the superiority of the target on one attribute and the competitor on the other. To make a choice, consumers must resolve this ambiguity. The A3 framework suggests that the attraction effect occurs when individuals' *attention* is drawn to a specific means of disambiguating choice: a comparison between the target with the decoy, which is an *applicable* standard by virtue of its similarity to the target (Mussweiler 2003).

The paper reviews evidence that implicates these factors in producing the attraction effect. The A3 framework offers a perspective on why the attraction effect has been difficult to find with perceptual stimuli: individuals may not detect the applicability of the decoy as a standard for the target because the vividness of perceptual stimuli focuses their attention elsewhere. This is not an issue for numerical stimuli, which are relatively simple and therefore comparable. This insight suggests that to produce the attraction effect with perceptual stimuli, attention must be directed to the target and applicable decoy. Five experiments test the A3 framework, primarily using perceptual stimuli.

*Experiment 1* assessed whether drawing attention to the target-decoy comparison would allow the attraction effect to emerge with perceptual stimuli that are similar to those that failed to produce the effect in prior research (Frederick et al. 2014). The choice alternatives consisted of gambles for which probability of winning was depicted perceptually in a pie chart and the amount won presented numerically. Participants (N=118) chose from one of two choice sets. The choice set in the control condition consisted of the competitor and

target gambles. The choice set in "target-decoy attention" condition additionally contained the decoy, and the target and decoy pie charts were shaded in the same color to draw attention to this comparison. The attraction effect emerged: choice of the target in the target-decoy attention ( $M=45.76\%$ ) was significantly higher than in the control condition ( $M=20.34\%$ ;  $p=.004$ ).

*Experiment 2* provided evidence that the attention and applicability factors are distinct. Using a similar manipulation to that in experiment 1, focus of attention was varied either to the applicable target-decoy comparison or to the nonapplicable competitor-decoy comparison. In the latter case, no attraction effect was expected to occur. Participants (N=211) were assigned to the control, target-decoy attention or competitor-decoy attention condition. The target-decoy and competitor-decoy attention conditions contained the same choice set; the only difference was the use of color to vary the focus of attention (see figure). It was found that the attraction effect occurred in the target-decoy attention condition ( $M=68.57\%$  vs. control  $M=50\%$ ;  $p<.03$ ), but not in the competitor-decoy attention condition ( $M=49.30\%$  vs. control;  $\chi^2=0.01$ ,  $p=.93$ ).

*Experiment 3* examined the ambiguity factor and demonstrated that the presence of all three A's is required for the attraction effect to occur. The ambiguity factor was assessed through individual differences in intolerance for ambiguity. The logic was that the attraction effect should only emerge among those intolerant of ambiguity, who are averse to disambiguating choice between the competitor and target directly. Moreover, for the attraction effect to occur, the *attention* of these individuals must be directed to a particular means to resolve ambiguity, i.e., a comparison of the target and *applicable* decoy. This experiment (N=204) retained the three conditions from experiment 2 and the intolerance for ambiguity scale was administered (Budner 1962). First, the results of experiment 2 were replicated. Second, an interaction between the target-decoy attention condition and intolerance for ambiguity emerged; spotlight analysis revealed that the attraction effect occurred for intolerant individuals ( $p=.017$ ) but not for tolerant individuals ( $p=.859$ ).

Two additional experiments tested the applicability factor further. While the decoy might be presumed to be applicable due to its similarity to the target, it might be perceived as *inapplicable* if consumers viewed it as an inappropriate standard because the decoy was inferior to the target. In this case, the attraction effect would not be found even if attention was paid to the target-decoy comparison. Data from these experiments support these predictions using perceptual and numerical stimuli.

In sum, this work makes both theoretical and phenomenological contributions to the literature. It develops and tests a conceptual framework that specifies the necessary conditions for the attraction effect, and demonstrates the attraction effect can occur with perceptual stimuli when these conditions are in place.

# How Do Consumers React to Anthropomorphized Brand Alliance? Applying Interpersonal Expectations to Business-to-business Relationships

Dongjin He, The Hong Kong Polytechnic University, Hong Kong

## EXTENDED ABSTRACT

Brand alliance refers to the cooperative marketing activities between two or more brands aimed at achieving a common objective, including co-branding, co-marketing, joint branding, and jointing promotions (Rao and Ruckert 1994; Simonin and Ruth 1998). Recent years have witnessed an explosive growth of brand alliances in the industrial world. However, not all brand alliances last forever. In reality, more than 50% of brand alliances are terminated within four years (Greve et al. 2010). Despite the high possibility of its early termination, to our knowledge no research in the consumer behavior literature has looked at the termination of a brand alliance, particularly its impact on consumer attitude and behavior. Previous research on branding and business-to-business relationships looked at the formation and termination of brand alliance mostly through a strategic perspective (e.g., Cui 2013; Greve et al. 2010; Lunnan and Haugland 2008), with the underlying assumption that the relationship between the allied brands should be contingent on the fair economic exchange between them (e.g., Das and Teng 2000; Gulati 1998). The present research takes the consumers' perspective to look at this issue. Specifically, bridging research on anthropomorphism, branding, and interpersonal relationships, we investigate how brand anthropomorphism influences consumer reaction to the termination of a brand alliance.

Anthropomorphism refers to individuals' tendency to imbue humanlike features or characteristics to nonhuman entities—such as gadgets, animals, supernatural beings, or abstract concepts (Aggarwal and McGill 2007; Epley, Waytz, and Cacioppo 2007). Existing research has robustly shown that anthropomorphism elicits human-related knowledge structure and prompts consumers to apply these knowledge (including lay beliefs) to judge and comprehend nonhuman entities (e.g., Aggarwal and McGill 2012; Hur, Koo, and Hofmann 2015; Higgins 1997). Applying these findings to business-to-business relationship, we predicted that, when brands in alliance are seen as human beings, consumers are likely to use their knowledge and beliefs about person-to-person relationship to understand the relationship between the anthropomorphized brands.

Past research on interpersonal relationship has suggested two types of interpersonal relationships: exchange and communal (Aggarwal 2004; Clark and Mills 1979, 1993). People in exchange relationships care the benefits they receive for what they give, while people in communal relationships help or give benefits to others out of a genuine concern for others' well-being (Clark and Mills 1979). Between these two types of relationships, communal relationships probably represent a more *unique* human touch. The tendency to form communal relationships is biologically based since it is evolutionally important for human survival (Clark and Mills 1993); that is probably why most people cherish communal relationships (Mills and Clark 1982).

We propose that, when brands in alliance are anthropomorphized, consumers are more likely to treat the anthropomorphized brands as social entities (as opposed to pure economic entities), and expect these allied brands to behave according to norms that govern interpersonal social relationships. Given that most social relationships involve certain levels of communal relationship strength (e.g., Clark and Jordan 2002; Clark and Mills 1993), we further predict that

consumers will expect stronger communal relationships between anthropomorphized (vs. non-anthropomorphized) brands, which in turn influence consumers' responses to the brand alliance termination.

Specifically, the greater the communal relationship strength, the more the relationship partners should exhibit tolerance, trust, and genuine care for each other (Krackhardt 1992; Uzzi 1996). Accordingly, when the anthropomorphized brands split up, consumers should feel more negative because the split/separation violates people's expectation for communal relationships (Darke, Ashworth and Main 2010). Taken together, we hypothesize that consumers will react more negatively to the termination of a brand alliance when the allied brands are anthropomorphized (vs. when they are not), and this occurs because consumers expect a more communal relationship between the allied brands. Formally, we put forward the following hypotheses:

*Hypothesis 1* Consumers will react more negatively toward the termination of brand alliance when the allied brands are anthropomorphized (vs. not).

*Hypothesis 2* The effect of brand anthropomorphism on consumer reaction to brand alliance termination will be mediated by the perceived violation of communal relationship norms/expectations.

We further predict that the effect of anthropomorphism on consumer reaction to brand alliance termination is likely to be attenuated under certain conditions. Given that communal relationship strength increases according to the closeness of the relationship (Clark and Jordan 2002; Clark and Mills 1993) and the length of the relationship can positively influence the closeness between relationship partners (Clark and Mills 1993; Kelley 1983; Mills et al. 2004; Storbacka, Strandvik, and Grönroos 1994), we hypothesize that consumers will hold a weaker expectation about the communal relationship when anthropomorphized brands have a short alliance history. Consequently, the negative reactions toward the termination of such a short brand alliance will be reduced. Formally, we hypothesize as follows:

*Hypothesis 3* The effect of anthropomorphism on consumer reaction toward brand alliance termination will be less evident when the brands allied for a short (vs. long) period.

In addition, past literature has shown that active cognitive deliberation increases the influence of social norms (Fazio 1990). Similarly, Melnyk et al. (2011) found that cognitive load limited the formulation of both descriptive (i.e., what most people do) and injunctive (i.e., what ought to be done) norms. Given that the activation and application of relationship norms in anthropomorphized brand alliances require cognitive resources (e.g., Gao, Li, and Wyer 2016; Shiv and Huber 2000), we predict that the proposed effect will be weakened when consumers are under high cognitive load. Formally, we hypothesize as follows:

*Hypothesis 4* The effect of anthropomorphism on consumer reaction toward brand alliance termination will be less evident when consumers are under high (vs. low) cognitive load.

### Study 1

Study 1 provides initial support for our basic hypothesis. US participants (N=90) first read and comprehended a news article about two companies, K.P. and V.N. (real names hidden). The article reported the formation of the K.P.-V.N. alliance. After reading the news report, participants indicated how the reported news made them feel along a 9-point scale ranging from 1 (*very bad*) to 9 (*very good*). To enhance the believability of the design, we gave participants a filler task (listing the names of ten states in the USA) before reading a second news report. Next, all participants read another news article reporting the termination of the K.P.-V.N. alliance. Participants indicated how the reported brand split made them feel along a 9-point scale ranging from 1 (*very bad*) to 9 (*very good*). Finally, they responded to a 15-item individual differences in anthropomorphism questionnaire (IDAQ; Waytz et al. 2010), which captures people's tendency to humanize nonhuman agents. Regression analysis revealed a significant alliance  $\times$  IDAQ interaction. Consistent with our expectation, participants who had a generally higher tendency to anthropomorphize showed more negative reactions to the termination of the brand alliance,  $p = .024$ . On the other hand, however, the effect of anthropomorphism on participants' feeling toward the formation of a brand alliance was positive,  $p = .011$ .

### Study 2

Study 2 replicated the finding of study 1 using manipulated anthropomorphism and provided evidence for our proposed mechanism. Undergraduate students (N=174) were randomly assigned to either the anthropomorphism or the non-anthropomorphism condition. They first completed a reading task in which they read a news article about the termination of the alliance between Sanofi and Merck. We manipulated brand anthropomorphism through the instructions for the reading task (adapted from Aggarwal and McGill 2012). Specifically, participants in the anthropomorphism condition were instructed to think about brands in the news report as two persons while those in the non-anthropomorphism condition were instructed to think about the two brands as two economic entities. After reading the news report, participants reported their emotional reaction to the termination of the brand alliance by indicating the extent to which the reported termination made them feel bad, sad, and disappointed ( $\alpha = .87$ ). Next, Participants' expected strength of the communal relationship between allied brands was measured with four items ("I think the two brands should care about each other/... treat each other well/...have consideration for each other/...understand each other";  $\alpha = .89$ ; Aggarwal 2004; Frei and Shaver 2002; Kaslow and Robison 1999). As expected, participants in the anthropomorphism condition reported more negative emotional reactions to the termination of the brand alliance than those in the non-anthropomorphism condition,  $p = .01$ . The former group also indicated a higher expectancy of communal relationship between the two allied brands than the latter one,  $p < .001$ . Mediation analyses showed that communal relationship expectation mediated the effect of brand anthropomorphism on consumers' negative reaction.

### Study 3

Study 3 tested the moderating role of alliance history by employing a 2 (brand anthropomorphism: yes vs. no)  $\times$  2 (alliance history: short vs. long) between-subjects design. After the same

instruction-based anthropomorphism manipulation as in study 2, US participants (N=196) read an alliance termination news article about two transportation companies. In the long (vs. short) history condition, the length of the alliance was described as 20 years (vs. 1 year). After reading the news, participants reported their reactions to the brand alliance termination on the same three-item scale ( $\alpha = .95$ ) used in study 2. We predicted that anthropomorphism should lead consumers to have more negative reactions to the alliance termination when the alliance history is long. As expected, a 2 (brand anthropomorphism)  $\times$  2 (alliance length) ANOVA on consumers' reaction toward the brand alliance termination revealed a main effect of anthropomorphism ( $p < .001$ ) along with a significant 2-way interaction,  $p = .038$ . Specifically, participants in the long history condition reported more negative reactions toward the brand alliance termination when the brands were anthropomorphized (vs. not),  $p < .001$ , whereas participants in the short history condition showed a much weaker effect, although still significant,  $p = .025$ . Thus, we replicated the proposed main effect and showed that such effect increased when the length of the brand alliance increased.

### Study 4

Study 4 tested the moderating role of cognitive load. Undergraduate students (N=231) were randomly assigned to conditions of a 2 (anthropomorphism: yes vs. no)  $\times$  2 (cognitive load: high vs. low) between-subjects design. They first took part in a purported memory task in which they were asked to memorize different stimuli (e.g., Jiang et al. 2016; Jiang and Hong 2014). In the high (vs. low) load condition, participants were asked to remember an 11-digit (vs. 2-digit) number throughout the research session. After the memory task, participants completed the same brand anthropomorphism manipulation and news article comprehension task that we used in study 2. The same anthropomorphism manipulation check and consumer reaction measures ( $\alpha = .91$ ) were collected. Then participants reported the number they were asked to memorize. As predicted, a 2 (brand anthropomorphism)  $\times$  2 (cognitive load) ANOVA on consumers' negative reactions toward the termination of the brand alliance revealed only a significant two-way interaction,  $p = .030$ . Specifically, participants in the low load condition replicated our earlier findings by showing more negative reactions toward the Sanofi-Merck termination when the brands were anthropomorphized (vs. not),  $p = .018$ . However, such effect was eliminated for participants in the high cognitive load condition,  $p = .49$ .

### Study 5

This study demonstrates the downstream consequences of the anthropomorphism-induced negative reactions. We predicted that the enhanced negative affective reaction to the brand alliance termination induced by anthropomorphism is consequential in that it would lead consumers to engage in pro-social behaviors. Past research shows that engaging in pro-social behavior is effective in regulating negative emotions (e.g., Basil, Ridgway, and Basil 2008; Manucia, Baumann, and Cialdini 1984). Therefore, in study 5, we examined the impact of brand anthropomorphism on consumers' willingness to engage in brand helping behavior following their exposure to a brand alliance termination. US participants (N=257) were randomly assigned to either the anthropomorphism or the non-anthropomorphism condition. After the same instruction-based anthropomorphism manipulation as in previous studies, participants read a news article about the termination of a brand alliance between an animal charity brand RedRover and an animal food brand MyFoodie. Participants then reported their emotional reactions to the brand alliance termination on the same three-item scale ( $\alpha = .94$ ) as in previous

studies. Next, all participants proceeded to a reverse typing task with the cover story of helping the animal charity brand RedRover. They were told that for each correct reversely typed string, a donation of 10 grams of pet food would be made to RedRover, and they could stop typing any time they wanted. Replicating the findings from previous studies, participants in the anthropomorphism condition showed more negative emotional reactions toward the brand split than those in the non-anthropomorphism condition,  $p = .026$ . Moreover, the former group typed more words (i.e., put in greater efforts to help the brand) than did the latter one,  $p = .042$ . Mediation analysis showed that the negative emotional reactions mediated the effect of brand anthropomorphism on helping behavior.

### General discussion

Brand alliance has grown explosively in the modern business world. However, we know little about how consumers respond to the termination of brand alliances. Bridging the literature on brand alliance, anthropomorphism, and interpersonal relationships, this research finds that anthropomorphism leads to more negative consumer responses to brand split (study 1). This effect occurs because anthropomorphism leads people to perceive the target brands as social entities and brand alliance as a communal-based social relationship. As a result, behaviors that violate expected communal norm (e.g., termination of the alliance) will elicit negative emotions (study 2). Moreover, such effect is attenuated when the allied brands have stayed together for only a short (vs. long) period of time so the communal relationship norm is not fully justified (study 3), and when consumers have limited (vs. abundant) cognitive resources to activate communal relationship norms and apply them to brand judgment (study 4). Finally, the negative affective responses resulting from the brand split increase consumers' engagement to help the split brands through donations (study 5).

This research makes several important contributions. First, this research extends the current literature on brand alliance by documenting the novel effect of anthropomorphism on consumer reaction to brand alliance. The current literature on brand alliance, especially in the marketing area, has primarily focused on consumer responses to the formation of brand alliance (e.g., Janiszewski and van Osselaer 2000; Monga and Lau-Gesk 2007). We bring to light the impact of anthropomorphism on consumer responses to brand alliance termination. Second, this research adds to consumer research on anthropomorphism. Whereas extant research has primarily focused on how anthropomorphism affects single brand evaluation (Aggarwal and McGill 2007, 2012; Kim and McGill 2011; Puzakova et al. 2013), we are the first to look at the impact of brand anthropomorphism in a brand-to-brand relationship context. By doing so, this research enriches our understanding of the nature of anthropomorphism and the impact it has on consumer behavior. Third, this research also contributes to the literature on interpersonal relationships. Past research has shown how consumer-brand relationships can follow the rules that govern person-to-person relationships (e.g., Aggarwal 2004; Aggarwal and Larrick 2012). This research is the first to show that communal relationship perceptions can also apply to brand-to-brand relationships, when brands are anthropomorphized.

# Consumer Response to Innovations: The Differential Effects of Focused and Defocused Attention on Perceived Novelty, Usefulness and Symbolism

Maria Sääksjärvi, Delft University of Technology, The Netherlands  
Katarina Hellén, University of Vaasa, Finland

## EXTENDED ABSTRACT

Focused and defocused attention has been shown to foster novel product ideas (Ansburg and Hill 2003; Friedman, Fishbach, Förster and Werth, 2003; Nijstad, De Dreu, Rietzschel and Baas 2010) but how these impact other product dimensions than novelty is unclear. Focused attention refers to limiting the mental stimuli so that the ideator's cognitive effort becomes centered towards a specific problem while defocused attention means widening the mental scope toward abstract considerations (Ansburg and Hill 2003). The purpose of this study is to investigate the role of focused and defocused attention on novelty, usefulness and symbolism as well as investigate market potential of these products.

### Study 1

In the *ideation phase* 73 industrial design master were asked to generate a solution for the watering of house plants when the owner of the house is out of town. Participants were asked to generate as many ideas as they could (Liikanen and Perttula, 2006). Participants were randomly assigned to the focused or defocused condition using the outline by Baird et al. (2012). Participants generated 127 ideas in total; 69 in the focused condition, and 58 in the defocused condition.

In the *market response phase*, 689 consumers (45.8% male, 54.2% female) assessed the generated ideas and rated them in terms of novelty, usefulness, desirability, and willingness to pay. Each consumer was asked to assess between five to ten ideas. A one-way ANCOVA with *novelty* as the dependent variable, type of focus (focus vs. defocus) as the independent variable, and level of detail as a covariate was conducted. There was a significant effect of type of focus on novelty, such that ideas that were generated in the defocused condition,  $M = 4.02$  ( $SD = .61$ ), were considered to be significantly more novel than those generated in a focused condition,  $M = 3.82$  ( $SD = .64$ ),  $F(1,124) = 3.99$ ,  $p = .048$ . An OLS regression analysis was conducted with novelty as the independent variables and product desirability as the dependent variable. The results showed that novelty was a significant predictor of product desirability,  $B = .258$ ,  $t = 5.56$ ,  $p < .001$ . An OLS regression with willingness to pay as the dependent variable and product desirability as the independent variable showed that product desirability, in turn, is a significant predictor of willingness to pay,  $B = .237$ ,  $t = 2.73$ ,  $p = .007$ . We used PROCESS (Model 4) for examining the mediating impact of novelty on the link between defocus and product desirability. The results showed that novelty mediates the impact of type of focus on product desirability, as the indirect effect of type of focus via novelty is significant, CI 95% [.0009; .3367].

### Study 2

In the *ideation phase* 222 students (Master level) were randomly assigned to one of two groups: They were either asked to design a lamp for an entrance hall for a museum, or to design a lawn chair that could seat several people. Each participant worked individually, with 124 participants generating an idea for the lamp, and 104 for the chair. We executed the focus and defocus manipulation with the use of constraints (Moreau and Dahl 2005).

In the *market response phase*, 499 consumers (35.3% male, 64.7% female) rated the ideas. Each rater saw five ideas. An ANCOVA with *novelty* as the dependent variable, type of focus (focused vs.

defocused) as the independent variable, and concept presentation as a covariate showed a significant effect of focus and defocus on novelty,  $F(1, 490) = 4.76$ ,  $p = .030$ , such that the ideas generated in the defocused condition,  $M = 4.77$  ( $SD = 1.61$ ) were rated as significantly more novel than the ideas generated in the focused condition,  $M = 4.48$  ( $SD = 1.61$ ). An ANCOVA with *usefulness* as the dependent variable, type of focus (focused vs. defocused) as the independent variable, and concept presentation as a covariate showed a significant effect of focus and defocus on novelty,  $F(1, 490) = 5.07$ ,  $p = .025$ , such that the ideas generated in the *focused* condition,  $M = 4.71$  ( $SD = 1.53$ ) were rated as significantly more useful than the ideas generated in the *defocused* condition,  $M = 4.47$  ( $SD = 1.56$ ).

Using the scale for *symbolic innovation* as the dependent variable, type of focus (focused vs. defocused) as the independent variable, and concept presentation as a covariate showed a significant effect of focus and defocus on novelty,  $F(1, 490) = 19.73$ ,  $p < .001$ , such that the ideas generated in the *defocused* condition,  $M = 4.17$  ( $SD = 1.66$ ) were rated as significantly more symbolic than the ideas generated in the *focused* condition,  $M = 3.44$  ( $SD = 1.58$ ).

An OLS regression analysis with novelty, usefulness, and symbolic innovation as independent variables and product desirability as the dependent variable showed that all three independent variables were significant predictors of product desirability,  $B = .166$ ,  $t = 4.61$ ,  $p < .001$  for novelty;  $B = .552$ ,  $t = 16.64$ ,  $p < .001$  for usefulness; and  $B = .209$ ,  $t = 5.58$ ,  $p < .001$  for symbolic innovation. An OLS regression with willingness to pay as the dependent variable and product desirability as the independent variable showed that product desirability, in turn, is a significant predictor of willingness to pay,  $B = .338$ ,  $t = 7.97$ ,  $p < .001$ .

We used PROCESS (Model 4) for examining the mediating impact of novelty, usefulness, and symbolic innovation. Novelty mediates the impact of type of focus on product desirability, as the indirect effect of type of focus via novelty is significant, CI 95% [-.3170; -.0045]; usefulness also serves a significant mediator for type of focus CI 95% [.0243; .2547], as does symbolic innovation CI 95% [-.5287; -.1613].

These findings contribute to the innovation literature by demonstrating that focused and defocused attention differently affect product dimensions, more specifically, a defocused attention helps generate product ideas that consumers rate as novel and symbolic whereas focused attention is linked to product ideas that are useful. Secondly, novelty, usefulness and symbolism mediate the relationship between focused and defocused attention and market reactions.

# The “Healthy=Lighter” Heuristic

Nico Heuvinck, Iéseg School of Management, France

Yi Li, Macquarie Graduate School of Management, Australia

Mario Pandelaere, Virginia Tech, USA

## EXTENDED ABSTRACT

Prior research suggests that consumers rely mostly on heuristic-based decision making when it comes to food related decisions (Wansink and Chandon 2014). For instance, a “health=expensive” intuition states that consumers associate healthy food with higher prices (Haws et al., 2017). An “unhealthy=tasty” intuition suggests that consumers hold a lay belief that unhealthy food tastes better (Raghunatan et al., 2006). Finally, a “healthy=less filling” intuition states that consumers consider healthy food as less filling/satisfying (Suher et al., 2016). This article adds to this stream of literature by adding a new intuition: consumers infer that healthier food weighs less than unhealthy food. We term it the “healthy=lighter” heuristic.

Consistent with other heuristics, we argue that the healthy-lighter heuristic derives from both internal (i.e., example generation: items such as (burgers/chips) salads/fruits that are (heavier) lighter in calorie content are more likely to come to mind when thinking about (un)healthy food) and external sources (i.e., market communications: food containing less fat often have “light” labels, e.g., Coke light). Although in both sources, heavy/light refers to calorie content of food, rather than the weight. Thus, two important mechanisms underlie this heuristic. First, the calorie estimation links food healthiness and heaviness/lightness perception. Second, people generalize the metaphorical meaning of heavy and light to their literal meaning on weight. Building on the bidirectional influence of metaphors, we argue that people will also use literal meaning of weight to infer the healthiness of food. Taken together, we predict that people will expect healthier food to weigh less than normal or unhealthy food. In the meantime, people will also consider food that weighs less to be healthier.

In study 1, we showed 251 MTurk panelists two cakes with the same list of ingredients: one traditional chocolate cake containing regular ingredients (e.g., whole milk) and one healthier chocolate cake containing healthy ingredients (e.g., non-fat milk). Participants were randomly assigned to one of the following two conditions: participants saw either the weight of the traditional (healthier) chocolate cake (600 grams) and had to guess the weight of the healthier (traditional) chocolate cake. Results denote that in both conditions, consumer inferred the healthier cake to weigh less than the traditional cake.

Study 2 employed a 2 (healthiness: increasing vs. decreasing)  $\times$  4 (percentage: 25% vs. 50% vs. 75% vs. 100%) mixed-factorial design, where the healthiness was manipulated between-subjects and the percentage was manipulated within-subjects. We showed 102 MTurk panelists a recipe of making four servings of vanilla pudding (240 grams and 1440 calories). Among the list of ingredients, in the increasing healthiness (decreasing healthiness) condition, the original recipe uses 2 cups of whole milk (skim milk). We asked participants to guess the calories and weight of the vanilla pudding, if we replaced  $\frac{1}{2}$  cup (25%), 1 cup (50%),  $1\frac{1}{2}$  cup (75%), and 2 cups (100%) of the whole (skim) milk with skim (whole) milk. As expected, in the decreasing (increasing) healthiness condition, increasing the percentage of whole (skim) milk increased (decreases) the estimated weight. Moreover, a mediation test showed that calorie estimates mediate the effect of food healthiness on weight estimates.

In the following studies, we will turn to the other side of the heuristic and test whether people also use weight information to infer the healthiness of the food.

In study 3, 154 MTurk panelists read that Susan was following a recipe to make 300 grams of rice pudding. They were randomly

assigned to one of the following two conditions: in the light (heavy) condition, participants read that Susan ended up with 250 (350) grams of rice pudding. After, participants chose between five pairs of ingredients the ones that Susan most likely used. Each pair contained one normal ingredient and one healthy ingredient (e.g., regular vs. organic butter). Results denote that the rice pudding in the light (vs. heavy) condition contained more (vs. less) healthy ingredients which supports that people inferred products lighter in weight as healthier.

In study 4, 50 business students sampled M&M’s from two identical cups. They were told that M&M’s recently introduced a healthy version and we asked whether they could tell the difference in taste and identify which cup contains the healthy M&M’s. In reality, both cups contained identical M&M’s but one cup was heavier (250 vs. 175 grams) because of a piece of metal that was added at the bottom, not visible to participants. Participants held both cups in their hands while a research assistant explained the procedure of the study. After receiving the instructions, participants put the cups on a table, started sampling and indicated their guesses, purchase intention, and WTP for a pack of M&M’s (300 grams) from each cup respectively. The majority of the participants indicated the lighter cup contained the healthier M&M’s. In addition, participants were more inclined to purchase and were willing to pay more for a pack of M&M’s in the lighter cup.

Study 5 employed a 2 (order: order 1 vs. order 2)  $\times$  4 (healthiness comparisons between two food items) mixed-factorial design. 153 MTurk panelists had to do four rounds of healthiness comparisons between two food items varying in weights by indicating whether the lighter food item was healthier, both items were equally healthy, or the heavier food item was healthier. The order variable counterbalanced the weights of the items in the pair. We also varied the level of weight difference between two food items in each pair, from 0.5 ounce to 1.5 ounce. After the healthiness comparison task, we provided the calories count of the lighter food item in the pair, and participants had to guess the calories of the heavier food item. Finally, participants had to indicate the density level of all eight food items. Our results suggest that calorie estimates mediate the weight-healthiness path. In addition, the weight difference moderates this inference: increasing the weight difference between two food items increases the likelihood that the food lighter in weight to be considered as healthier. Finally, the density difference did not mediate the heuristic, ruling it out as an alternative underlying mechanism.

# Resolving Humorous Incongruity in Advertising Facilitates Impressions of Firm Competence

Chi Hoang, BI Norwegian Business School, Norway  
Klemens Knöferle, BI Norwegian Business School, Norway  
Luk Warlop, BI Norwegian Business School, Norway

## EXTENDED ABSTRACT

Humor is a common executional tactic in advertising (Eisend 2009). Given that humor affects impression formation in inter-individual settings (Greengross, Martin, and Miller 2012), we propose that humor influences the impressions that consumers form of a company that uses humor in advertising. Although both warmth and competence impressions can result from observing humor, we focus on the competence impressions, which take priority in consumers' choice of products and service providers (Kirmani, Hamilton, Thompson, and Lantzy 2017). The first goal of this research is, therefore, to identify a humor execution that particularly enhances competence impressions of advertisers. The second goal is to explain why this effect occurs.

Research has identified three humor processes that can elicit laughter, namely incongruity-resolution, tension-relief, and humorous disparagement (Speck 1991). Incongruity-resolution represents a humor process in which perceivers first experience something surprising, peculiar, or unusual and later are able to resolve it. This process is characteristic of humor forms such as puns, punchlines, or comic irony. Since the resolution of incongruity requires cognitive skills (Martin 2010), we predict that incongruous humor, if successfully resolved, triggers competence impressions of advertisers. Tension-relief, on the other hand, mainly induces laughter as a way to release nervous energy. This humor process leads perceivers to experience empathetic emotions, which can be transferred to improve any subsequently evaluations of advertisers, but not specifically competence evaluations. Lastly, humorous disparagement mostly harms, rather than improves competence impressions, since it may indicate the deprecators' unjust ridicule and ignorance of social boundaries (i.e. other-disparagement) or draws attention to the deprecators' real weaknesses (i.e. self-disparagement) (Greengross and Miller 2008).

Study 1 (N = 3487) explored the effects of all three humor executions. We distributed 300 real ads to eight groups of Mturk raters; each group rated a subset of ads on a different variable. Specifically, a group evaluated either the extent to which ads used one of the three humor executions or rated ads on one of the impression dimensions (warmth/ competence). The results indicated that both incongruity-resolution and tension-relief had positive effects on competence impressions, while both self- and other-disparagement had negative effects. Incongruity-resolution did not alter warmth impressions, while tension-relief enhanced both warmth and competence impressions. This suggests that tension-relief improved the overall impression of advertisers via a rather generic affect transfer account. Contrarily, humorous incongruity, once successfully resolved, specifically and most strongly enhanced competence impressions. Our subsequent studies, hence, focused on incongruity-resolution.

Study 2 (N = 100) replicated the effect of incongruity-resolution on competence impressions. Since Study 1 was a correlational study, an alternative explanation for its findings may be that competent advertisers tend to use incongruous humor (rather than incongruence-based humor triggering competence impressions). To rule out this explanation, we asked Mturk participants to evaluate incongruous/congruous ads of the same advertisers; their impressions of the advertisers were then compared across ad conditions and participants.

The results confirmed a positive causal relationship between humorous incongruity and competence impressions.

Study 3 (N = 300) examined whether the effect of incongruity-resolution persisted when the advertisers were not perceived as the humor source (i.e. when an external agency produced the ads). Furthermore, since incongruous ads are often creative, Study 3 examined whether creativity was the driver of the effect. The study had a 2 (ad: incongruous vs. congruous)  $\times$  2 (ad agency: major vs. minor) between-subject design. The ad-agency manipulation was intended to alter the belief about whether the advertisers or the agencies were the source of humor. Specifically, we predicted that when consumers perceived a bigger (compared to smaller) external agency as being responsible for the ad, they would be less likely to see the advertisers as the main contributors to the ads, and thus less likely to form competence impressions about the advertisers. The results confirmed our prediction: Incongruity-based humor, when successfully resolved, enhanced competence impressions of the advertisers, but only in the minor-agency condition. Furthermore, when controlling for the effect of perceived ad creativity, the positive effect of incongruity-resolution remained, suggesting that creativity was not the only driver of the effect.

Study 4 (N = 301) tested a competence projection process as a potential driver of the effect of incongruity-resolution. Extant research supports the idea that appreciation of humor, especially incongruity-based humor, signals similarity between the perceivers and the source of humor (Flamson and Barrett 2008). On one hand, similarity is an antecedent of projection, the act of introspecting one's own qualities and ascribing them to others (Ames 2004). On the other hand, resolution of incongruity may signal to the perceivers their mastery of competent skills such as flexible thinking and problem solving (Martin 2010). We thus proposed that perceivers, while resolving and appreciating incongruity-based humor, may project their perceived self-competence to the advertisers. To test this process, each participant in Study 4 evaluated one ad (incongruous or congruous) on the measures of incongruity, ad familiarity, advertiser competence, self-perception of competence, and perceived self-advertiser similarity. We then ran a serial mediation model where incongruity-and-resolution was the independent variable, advertiser competence is the dependent variable, while self-perception of competence and perceived self-advertiser similarity were the two mediators. The results confirmed significant serial mediation, and thus supported the proposed process. Particularly, those who successfully decoded incongruous humor first perceived themselves as more competent and then more similar to the advertisers (on competence domains); this dual perception (which might have caused competence projection) then led to increased competence impressions of the advertisers.

It is well established that humor influences our impressions of people in social settings. However, the fact that this mechanism also applies to companies using humor in their marketing has not been demonstrated until now. Our research addresses this gap by documenting that incongruity-resolution is the only major humor execution that specifically enhances competence impressions of advertisers. This effect seems to work via competence projection, a novel process that distinguishes incongruity-resolution from other types of humor. Practically, our findings provide implications to optimize the

use of humor in impression management, which is essential in guiding consumers' choices and interactions with companies.

# Consumers' Attribution of Mind to Possessions as an Impediment to Sharing

Chi Hoang, BI Norwegian Business School, Norway  
Klemens Knöferle, BI Norwegian Business School, Norway  
Luk Warlop, BI Norwegian Business School, Norway  
Aradhna Krishna, University of Michigan, USA

## EXTENDED ABSTRACT

Research has established that people perceive minds in a variety of objects and along two dimensions: agency referring to the capacity to plan and act, and experience referring to the capacity to sense and feel (Waytz, Gray, Epley, and Wegner 2010). In the current research, we propose that ascribing mind to a possession reduces people's intention to share the possession with other users. This negative effect of mind attribution on sharing is driven by a concern about the possession being mentally harmed during contacts with others. While a mindful versus mindless possession may be similarly susceptible to physical damage, only a mindful possession is susceptible to mental harms, for example, the possession adapts to certain immoral characteristics of other users. We posit that such a concern about mental harms impedes sharing of the possession. We conducted four studies to test our predictions.

Study 1 examined whether ascribing mind to an iPad discouraged sharing of the iPad with close versus distant others. 108 students from a European business school participated in the study. Each was given an iPad and was instructed to ask Siri one of the two sets of questions pertaining to a mind-attribution or a control condition. Participants in the mind-attribution condition asked Siri questions that generated unexpected answers, while those in the control condition asked Siri questions that generated predictable answers. Unpredictability (regarding Siri's answers) was the manipulation of mind (see Waytz et al. 2010 for explanation). All participants then imagined owning the iPad and indicated their willingness to share the iPad with a close friend or a distant co-worker. Results revealed that mind attribution significantly reduced willingness to share iPad with a co-worker, but it did not alter intention to share the iPad with a friend. The closeness between owners and borrowers is thus a boundary condition for the effect of mind attribution on sharing.

Study 2 examined the effect of mind attribution on sharing in a collaborative-consumption setting. 111 car owners recruited from Amazon Mechanical Turk (AMT) participated in the study. Participants in the mind-attribution condition described their cars in human terms, while those in the control condition simply described the features of their cars. All participants then read about a fictitious car-sharing website and indicated their willingness to rent out their cars on the website for money. Familiarity with car-sharing services was measured to account for a potential floor effect (i.e. participants unfamiliar with car-sharing services would be unwilling to use the services regardless of the mind-attribution conditions). Results confirmed that mind attribution significantly reduced willingness to rent out cars among participants highly familiar with car-sharing services but not among those unfamiliar with such services.

Study 3A and Study 3B examined the effect of mind attribution on sharing with regards to goldfish, a living, rather than non-living, possession. Both studies tested a moderator related to borrowers' morality in order to demonstrate that a concern about mental harms (i.e. moral contamination) discourages people from sharing their mindful possessions. We operationalized mental harms in terms of moral contamination for two reasons. First, current research has documented people's strong belief about the transfer of moral essences from individuals to objects during contact. For example, a sweater worn by Hitler was found more evil (Nemeroff and Rozin 1994), or a chair

touched by a theft became a source of guilt (Eskine, Novreske and Richards 2013). Due to this rampant belief about moral contagion, a concern about possessions being morally contaminated during contact with others would be salient. Second, morality is perceived as a fundamental components of identity that people agonize over changing (Riis, Simmons and Goodwin 2008). Therefore, a concern about moral contamination is expected to be a strong driver of people's (sharing) behaviors.

100 AMT workers participated in Study 3A. Participants in the mind-attribution condition read about goldfish having high mental capacity, while those in the control condition read about goldfish having limited brain power. Next, all participants read about a fictitious pet-sharing website and indicated their willingness to share their goldfish with strangers via the website. Participants then completed the Interpersonal Trust Scale (Rotter 1967); higher scores on this scale imply that participants believe others, including potential borrowers of their goldfish, to possess higher levels of goodwill and morality. Meanwhile, low scores on the scale implied that the participants believed others to be typically immoral. If a concern about moral contamination drives the effect of mind attribution on sharing, mind attribution should discourage sharing to a larger extent among low-trusters than among high-trusters. Indeed, results indicated that mind attribution had a significant and negative effect on sharing intention among low-trusters but not among high-trusters, confirming our prediction.

221 AMT workers participated in Study 3B of a 2 (mind-attribution vs. control condition)  $\times$  2 (moral vs. immoral borrower) between-participants design. The participants first completed a manipulation of mind attribution and read about a pet-sharing website, similar to that of Study 3A. Instead of measuring the participants' individual trait as a proxy for their belief about borrowers' morality as in Study 3A, we directly manipulated the morality of borrowers in Study 3B. In the moral-borrower condition, the borrower was described as being kind but inexperienced with goldfish, while in the immoral-borrower condition, he was described as being manipulative but taking very good care of goldfish. After learning about the borrower, participants in both conditions indicated their expected payment for sharing goldfish with the assigned borrower. Results confirmed that mind attribution significantly increased expected payment for sharing goldfish when the borrower was described as being immoral but not when he was described as being moral. The results further supported our proposed mechanism.

Across four studies, we demonstrate that ascribing mind to living and non-living possessions reduces people's intention to share the possessions with relative strangers. The effect seems to be driven by people's concern about mindful possessions being mentally harmed during contacts with others. Given the rise of the sharing economy and its benefits, our research uncovering impediments to sharing behaviors will contribute to support the success of the model.

# Consumers' Implicit Mindsets and Responses to Cause-related Marketing Campaigns

Meng-Hua Hsieh, Kent State University, USA

Ozge Yucel-Aybat, Pennsylvania State University-Harrisburg, USA

## EXTENDED ABSTRACT

Cause-related marketing (CRM) efforts (e.g., contributing a portion of sales to charities) enhance purchase intentions (Henderson & Arora, 2010), while donation amount that CRM garners (Elfenbein & McManus, 2010) or in-kind/monetary contributions of the company (Hildebrand et al., 2017) play significant roles. Although CRM has been steadily gaining in popularity, research linking consumers' characteristics to CRM is limited. Current research shows that consumers' implicit mindsets—whether they believe that characteristics can change (growth mindsets) or not (fixed mindsets)—may influence their responses to CRM efforts. Moreover, the interactive effect of benefits offered (for the consumer or for those in need) and firm-cause fit moderates the results.

CRM messages may appeal to consumers through the self or others. With every pair of shoes purchased, TOMS donates one pair of shoes, an other-benefit appeal focusing on helping others (White & Pelozo, 2009). Conversely, in a self-benefit appeal by Wendy's, consumers receive a free milkshake for their support. Current research explores the ramifications of implementing these appeals in CRM campaigns. Extant literature identifies two mindsets that consumers may endorse: fixed and growth (Dweck & Leggett, 1988). Those with a fixed mindset perceive things as fixed/unchangeable entities, while growth mindsets perceive things in more dynamic/flexible ways (Plaks et al., 2005). Butler (2000) argues that beliefs in immutability make fixed mindsets more receptive to outcome-related information. Conversely, growth mindsets are more sensitive to information about intermediary processes (Molden et al., 2006). Jain and colleagues (2009) show that while viewing an ad, fixed mindsets generate more outcome-related thoughts, but growth mindsets' thoughts are mostly related to ad-tactics, proving their focus on the process. Mathur et al. (2016) suggest that growth (vs. fixed) mindsets more strongly value fairness of procedures used to achieve positive outcomes. Conversely, fixed mindsets focus on outcomes.

In our CRM context, outcome favorability captures the extent to which CRM campaigns bring positive outcomes. CRM procedures are fair when they comply with ethical standards and do not involve self-interests (Leventhal et al., 1980). Because growth mindsets are concerned with procedural fairness, they should respond more favorably to other- (vs. self-) benefit appeals which focus on helping others (vs. benefiting consumers), a fair (vs. unfair) procedure to achieve positive outcomes. Conversely, as we show next, fixed mindsets should be indifferent between benefit frames because they focus on outcomes.

In Study 1, we manipulated implicit mindsets by presenting 171 MTurk-participants with proverbs that supported either fixed or growth mindsets (Poon & Koehler, 2006). Then, participants viewed the other-benefit (self-benefit) ad of a fictitious company that would donate to UNICEF with a slogan "Buy Brand X shoes and help children enjoy life" ("Buy Brand X shoes and get a UNICEF membership, which is a big plus on your resume"; Park & Lee, 2015). They marked their purchase likelihood, attitudes toward Brand X, and how much they trusted the brand.

Manipulations worked as intended. Growth mindsets were more likely to purchase in the other-benefit (vs. self-benefit) condition, while fixed mindsets were indifferent. Similar results were found for trust and brand attitudes. However, these results do not explain which particular causes firms should support to enhance CRM effec-

tiveness. A high degree of firm-cause fit involves supporting a cause that matches company's image (Gray 2000). To check participants' firm-cause fit perceptions, we ran a follow-up study with 102 MTurk-participants by using the manipulations and stimuli as before and measured how UNICEF fit with Brand X. Firm-cause perceptions did not differ according to predictor variables, and all means were above the midpoint of the scale, indicating a higher-fit between UNICEF and Brand X. However, firms also collaborate with organizations that do not match their businesses perfectly, which we examine next.

If the firm-cause fit is strong, consumers view the company as capable of assisting the charity because it can leverage its expertise and resources (Alcañiz et al., 2010). However, low-fit leads consumers to believe that the company has firm-serving motivations (Weiner 1985) and makes them doubt the company's aspirations. Growth mindsets, because of their concern with procedural fairness, should perceive lower-fit scenarios as unfair regardless of benefit framing. Moreover, under lower-fit, fixed mindsets should perceive the firm as less capable of bringing positive outcomes when it uses self-benefit (vs. other-benefit) appeals as they will perceive that the outcome is less attainable.

In Study 2, we manipulated implicit mindsets as before and presented 286-MTurk participants with other-benefit (vs. self-benefit) messages of a notebook company donating to the National Education Association (Conservation Fund) in higher-fit (lower-fit) conditions (Robinson et al., 2012). We measured purchase likelihood, brand attitudes, and trust as before. Participants also indicated whether procedures used by Brand X were fair and outcomes of this campaign would benefit those in need (Wu et al., 2016).

Manipulations worked as intended. As before, growth mindsets were more likely to purchase when viewing other-benefit (vs. self-benefit) appeals in higher-fit conditions; however, fixed mindsets were indifferent. Conversely, in lower-fit conditions, fixed mindsets expressed lower purchase intentions in self-benefit (vs. other-benefit) conditions; however, growth mindsets were indifferent. Similar results were found for trust and brand attitudes. Moreover, according to bootstrap analysis (Hayes, 2013; Model 12), while procedural fairness mediated growth mindsets' purchase likelihood, attitudes, and trust in higher-fit conditions, no such mediation occurred for fixed mindsets. While positive outcome perceptions mediated growth mindsets' responses in higher-fit conditions, they mediated fixed mindsets' responses in lower-fit conditions.

This research provides theoretical and practical insights. We introduce implicit mindsets to the CRM context, an under-explored research topic, and examine the interplay between benefit framing and firm-cause fit while identifying the psychological mechanisms driving the effects. We show that companies can benefit from using other-benefit (vs. self-benefit) appeals in CRM campaigns. Moreover, we identify a condition to bolster the effectiveness of CRM efforts supporting a lower firm-cause fit: other-benefit appeals paired with lower-fit can be more effective for fixed mindsets.

# Attenuating Endowment Effect with Venmo: Online Payment Systems Make it a Pleasure to Pay

Liang Huang, University of Arizona, USA  
Jennifer Savary, University of Arizona, USA

## EXTENDED ABSTRACT

People typically demand more to relinquish a good they own than they would be willing to pay to acquire the good. This phenomenon is known as the endowment effect (Kahneman, Knetsch, and Thaler, 1990). The economic impact of the endowment effect is consequential. The discrepancy between sellers' willingness to accept (WTA) and buyers' willingness to pay (WTP) leads to irregularities in valuation between buyers and sellers, increases people's reluctance to trade and causes market inefficiencies. Thus, the endowment effect has generated great interest among scholars from a variety of fields, including marketing, economics, psychology, and public policies (Morewedge and Giblin, 2015).

Recent years have witnessed a huge increase in consumer-to-consumer business where individuals act as sellers and buyers in the marketplace to exchange goods or services. In addition to traditional off-line marketplaces, online transactions are also becoming more popular. eBay is one of the most famous examples. Coinciding with the development of the online market is an increase in the use of online payment systems such as Venmo, Zelle, and Paypal, etc. Online payment systems enable people to manage their bank account through their online bank applications. With a single click on the app, consumers can transfer money to and receive money from others, split checks, and more. While traditional payment methods such as cash still occupy a large share of consumer payments (25.6%), the share of electronic payment methods reached 10.5% in 2014 (Greene, Schuh, and Stavins, 2016). The use of electronic payment methods is still on the rise. In the current work, we examine how the shift to the cash-less market affects marketing efficiency. Specifically, we look at how using online payment systems influence the endowment effect.

Research has investigated an array of different explanations for the endowment effect. One of the most common explanations is loss aversion, where the pain of losing the product looms larger than the gain of acquiring the same product (Kahneman and Tversky, 1979). Other processes, including the building of self-product association (Kim and Johnson, 2010; Morewedge et al., 2009), biased information processing (Carmon & Ariely, 2000; Saqib et al., 2010), and concerns about transaction disutility (Weaver and Frederick, 2012), also contribute to the endowment effect. Morewedge and Giblin (2015) summarized various causes of the endowment effect under the umbrella of biased attribute sampling bias. The attributes refer to value-relevant qualities and properties such as the positive or negative features of goods, transaction utility, the cost of new or used alternatives, opportunity costs, and non-transferrable associations (Morewedge and Giblin 2015). Morewedge and Giblin argue that sellers perceive the goods to have more value because attributes suggesting that one should keep the product are more salient to them. In contrast, buyers perceive the goods to have less value because attributes suggesting one should not acquire the good are more accessible.

Most of the literature on the endowment effect focuses on people's evaluation of the endowed product, such that it appears sellers value a product more than buyers. In contrast, money, as a medium of exchange, does not seem to be subject to the endowment effect (Novemsky and Kahneman, 2005; Svirsky, 2014). For example, Svirsky finds an endowment effect for chocolate coins, but no endowment effect for money or for chocolate coins that are described as to-

kens. In other words, the endowment effect is never considered to be driven by buyers' reluctance to exchange their money for goods. Yet, a large body of work on the psychology of money shows that people do feel a sense of loss when parting from their money (Prelec and Loewenstein, 1998; Raghurir and Srivastava, 2008; Soman, 2003). Building on this stream of literature, we take a novel perspective to invest the endowment effect and suggest that consumers' aversion to parting with their money may have more to do with the endowment effect than previously thought. By decreasing the salience of the act of parting from money (e.g. when buyers make a payment through online payment systems), we are able to attenuate the endowment effect by increasing buyers' WTP.

When making a purchase, consumers normally experience an immediate pain of parting from their money. Such psychological discomfort is known as the pain of payment (Prelec and Loewenstein, 1998). The pain of losing money is supported by neuro studies (Knutson et al., 2007; Knutson and Greer, 2008) where excessive prices activate the insula, the brain region that is known for responding to pain and has been shown to be active during the loss of one's possessions (Feng, Zhao, and Donnay, 2013). Typically, the more vivid and transparent a transaction is, the more painful it is to make a payment (Prelec and Loewenstein, 1998; Raghurir and Srivastava, 2008; Soman, 2003). For example, paying with cash, which involves handing over a physical manifestation of money, feels more painful than using less transparent methods such as credit cards (Raghurir and Srivastava, 2008). Based on this logic, making a payment through online payment systems should feel less painful than paying with cash.

We propose that the use of online payment systems should decrease the endowment effect because low salience of payment encourages buyers to be willing to pay a higher price for the product. Evidence consistent with our proposition comes from past work on the downstream consequences of the pain of payment. For example, paying with less painful payment methods, such as a credit card rather than cash, can lead to an acceleration in spending. This leads to consumers buying more products than they would have when paying with cash (Hirschman, 1979; Prelec and Simester, 2001; Raghurir and Srivastava, 2008; Soman, 2001). Such acceleration in spending is also accompanied by a reduced sensitivity to price, where consumers are willing to accept a higher price in order to acquire a product (Monger and Feinberg, 1997). Thus, we predict that the endowment effect will be attenuated when payments are made online because online payments increase the buyer's willingness to pay.

Our research contributes to the marketing field in two ways. Theoretically, we add to the literature on the endowment effect by showing that it is not only driven by seller's high evaluation of products, but also by buyer's reluctance to spend their money. More importantly, our research provides a simple and practical way of solving the market inefficiency problems caused by the endowment effect: by encouraging the use of online payment systems, there would be less discrepancy between buyers' willingness to pay and sellers' willingness to sell. In the following section, we present four studies and a single-paper meta-analysis to support our hypothesis.

The first study tests whether making a transaction using online payment apps attenuates the endowment effect. One hundred and eighty-six participants from the mTurk online panel (43% female,

Mage=29) who had experiences using online payment apps successfully participated in the study. We employed a 2(payment method: cash vs. online apps)\*2(role: seller vs. buyer) between subject design. All participants saw a picture of a coffee mug. Participants in the seller condition were told that they were endowed with the hypothetical coffee mug and were told that they may sell the mug at the price that is acceptable to them. Participants in the buyer condition were asked to examine the mug and were told that they would have an opportunity to buy the mug at the price they were willing to pay. Within the seller and buyer conditions, half of the participants were told to use cash to make the exchange. The other half of the participants were told that all money transactions would be made online using electronic mobile payment applications like Venmo or Zelle. Across all conditions, participants were told that all payments would occur immediately and that there would be no transaction fees. All buyers indicated their maximal willingness to pay and sellers indicated their minimal willingness to accept in an open-ended question (e.g. I am willing to buy/sell the mug for as much as \$ \_\_, but no more/less). We log-transferred the participants' WTP/WTA data (here and in the following studies) to serve as our dependent variable. As expected, in the cash conditions, the classical endowment effect was replicated. The sellers requested a payment that was almost twice as much as the price that buyers were willing to pay (Mcash\_sell=9.99, Mcash\_buy=5.33,  $F(1, 266)=4.69$ ,  $p<.05$ ). In contrast, the WTA-WTP discrepancy was eliminated when transactions were conducted online (Monline\_sell=9.76, Monline\_buy=7.24,  $F(1, 266)=1.15$ , n.s.).

Study 2 replicates the results of study 1 with identical procedures. Two hundred and two Mturk workers successfully participated in the study (56% female, Mage=19.5). The study again used the 2(payment method: cash vs. online apps)\*2(role: seller vs. buyer) between subject design. Participants were randomly assigned to one of the four conditions. To strengthen our payment method manipulation, we added pictures of cash and online payment apps in the cash and e-payment conditions respectively when participants were asked to indicate their WTP/WTA. Study 2 replicated the effects of study 1 with an interaction effect ( $F(1, 198)=4.64$ ,  $p<.05$ ). More specifically, while the data revealed a significant endowment effect in the cash condition (Mcash\_sell=8.29, Mcash\_buy=3.77,  $F(1, 198)=14.28$ ,  $p<.05$ ); there was no significant difference between WTA and WTP in the online payment condition (Monline\_sell=5.44, Monline\_buy=5.40,  $F(1, 198)=0.502$ , n.s.). We also show that buyers who made payments online offered significantly higher prices than buyers who made payments with cash ( $F(1, 198)=3.89$ ,  $p=.05$ ). In comparison, payment methods did not affect sellers' willingness to accept ( $F(1, 198)=1.17$ , n.s.). Thus, the attenuation of the endowment effect is mainly driven by the increase in willingness to pay among participants who pay using the online system.

In study 3, we test our effect among college students using identity relevant products. Previous literature on the endowment effect has shown that selling is perceived as an implicit self-threat (Chatterjee, Irmak and Rose, 2013). The selling of in-group (i.e. identity-relevant) products strengthens the endowment effect relative to the selling of out-group products (Dommer and Swaminathan, 2012). In study 3, we aim to show that our effect is robust in contexts where identity relevant products are sold and where the endowment effect is believed to be strong. One hundred and sixty-eight students participated in the study for course credit (51% female, Mage=21). Students were randomly assigned to either sell or buy a coffee mug with the school logo on it. They were told that they will either complete the transaction using cash or through online payment apps. All students indicated their WTP or WTA based on the condition they were in. Again, as expected, among students who were asked to make trans-

actions using cash, there was a significant difference between sellers' WTA and buyers' WTP (Mcash\_sell=10.37, Mcash\_buy=7.56,  $F(1, 164)=5.53$ ,  $p<.05$ ). However, the WTA-WTP discrepancy was attenuated among students who made transactions online (Monline\_sell=10.74, Monline\_buy=8.39,  $F(1, 164)=1.53$ , n.s.).

In study 4, we further take the endowment effect to a more realistic market setting in which participants trade products in a campus second-hand market. In other words, instead of selling endowed products, sellers in study 4 trade the product that they had owned and used before. One hundred and ninety students participated in the study (40% female, Mage=20). They read a scenario where they plan to trade a calculator. Students in the seller condition read that they have a fairly new Texas Instrumental BAII Plus financial calculator that they no longer need and plan to sell it in the campus second-hand market. Students in the buyer condition read that they plan to buy a calculator in the same market. As with the previous studies, payments were manipulated to be made either online or with cash. Unsurprisingly, we observe the expected interaction ( $F(1, 186)=5.301$ ,  $p<.05$ ). Specifically, the WTA-WTP discrepancy is significant in the cash condition (Mcash\_sell=30.75, Mcash\_buy=16.75,  $F(1, 186)=9.068$ ,  $p<.05$ ), but was eliminated in the online payment condition (Monline\_sell=23.71, Monline\_buy=20.34,  $F(1, 186)=.06$ , n.s.). In addition, we show that among all buyers, participants who paid online offered higher purchase prices than participants who paid with cash ( $F(1, 186)=2.92$ ,  $p<.1$ ). There was no difference between sellers who accepted cash and sellers who accepted online payments ( $F(1, 186)=2.39$ , n.s.).

Across all four studies, we show that using the online payment system attenuates the endowment effect. The effect is mainly driven by the increase in the buyers' willingness to pay when electronic payment methods are used. In a stronger test of our effects, we conduct a single-paper meta-analysis (SPM, Mcshane and Bockenholt, 2017) using an online platform (<https://blakemcshane.shinyapps.io/spmeta/>). The meta-analysis provides estimates that are more reliable than those based on single studies and generally have narrower uncertainty intervals. It thus provides more powerful tests for hypothesized null and non-null effects (Mcshane and Bockenholt, 2017). We conduct five planned contrasts to test our effect. Contrast 1 tests the moderation effect that payment methods have on the endowment effect. Contrast 2 tests the endowment effect in the cash condition. Contrast 3 tests the endowment effect in the electronic payment condition. Finally, contrasts 4 and 5 test the effect that payment methods have on buyers' WTP and sellers' WTA respectively. We use the log\_price as our dependent variable, as with all the studies. An SPM of our studies estimates the first effect at -0.14 morsels (95% CI: -0.252, -0.037), showing that the endowment effect is moderated by payment methods. Specifically, the endowment effect is significant with cash payments (contrast 2; effect: -0.20; 95% CI: -0.271, -0.128) but not with online payments (contrast 3; effect: -0.06; 95% CI: -0.134, 0.023). Further, the effect is qualified by an increase in WTP among buyers who pay online rather than with cash (contrast 4; effect: -0.08; 95% CI: -0.16, -0.008). But it is not qualified by the change in WTA among sellers (contrast 5; effect: 0.06; 95% CI: -0.014, 0.134).

In sum, we show in four studies that the use of different payment methods can moderate the endowment effect. More specifically, the endowment effect is attenuated when consumers make payments through online payment systems instead of using cash. We demonstrate that the elimination of the endowment effect is mainly driven by the increase in the willingness to pay among buyers who pay with online apps. These findings contribute to the literature by examining the role that the form of money can play in the endowment effect. a

factor that has been ignored or otherwise believed to have no impact. Further, while past literature has gained a significant amount of insight into the cause of the endowment effect, there is still a lack of efficient and easy-to-implement ways to attenuate the endowment effect in the real marketplace. As consumers become more familiar with and get used to online payment systems, we suggest a simple method of increasing market efficiency by encouraging the use of online payment systems.

## EXTENDED ABSTRACT

*"We have proposed a system for electronic transactions without relying on trust." (Nakamoto 2008, 8)*

Alongside money, trust is inevitably an important part of society's existence. The system works because we *trust* it to work. And yet, so much our lives are lived in constant *dis-trust* such as fear of others at airports, the lack of trust that leads to police brutality, or the existence of borders that solidify fear. To state that consumer trust has been shaken in recent years would be an understatement. From the financial crisis of 2008, the Edward Snowden NSA leaks of 2013, the 2016 US elections, the Panama Papers, to the branding scandals of Volkswagen, Equifax, and Theranos, and most recently the data leaks at Facebook: *dis-trust* is the order of the day. We now even accept the oxymoron "fake news". Trust is increasingly negated by *dis-trust*.

While a healthy skepticism of large corporations has been a continuous narrative (Holt 2002, Klein 2010, Kozinets and Handelman 2004, Darke and Ritchie 2007), social media and technology have fundamentally changed the way we now trust others. Technology has fuelled the growth of collaborative consumption with the rise of sharing and pseudo-sharing online which are based on trusting previously unknown others (Belk 2010, 2014, Scaraboto 2015, Bardhi and Eckhardt 2012, John 2017) including living in strangers' Airbnb homes or riding in strangers' Uber cars (Botsman 2017). We know that brands often go to great lengths to inspire trust and legitimacy through their hard-earned reputations (Humphreys and Thompson 2014, Lowry et al. 2008, Giesler 2012). However, we know a lot less about how consumers trust an entity that makes no attempt at being trustworthy. What if the need for trust was eradicated from the picture altogether?

In this paper, we analyze the notions of trust and deeper *dis-trust* that have fueled the Bitcoin/Blockchain ecosystem. The peer-to-peer cryptocurrency, Bitcoin, came into being in 2008 as a white paper posted on an inconspicuous mailing list. Despite its "In God We Trust" slogan, the US Dollar demands trust in the US government to warrant its promises. But, Bitcoin demands trust in algorithms and the purity of code which are linked to the Cypherpunk Manifesto: "In Code We Trust". Bitcoin's existence involves major trust issues. By all standards, it should not exist the way it does today. In the early years, many dismissed it as a folly, yet after almost 10 years, it has surprised and baffled many. Bitcoin's creator still remains anonymous, although there have been various false prophets claiming to be Satoshi (Humayun and Belk 2018). Mainstream media largely ignored Bitcoin until 2011 and the lack of information about Bitcoin in the early days led to the creation of an independent media ecosystem. While it was eponymously declared 'a fraud' by JP Morgan's CEO Jamie Dimon in September 2017, in December 2017, Bitcoin's price came just shy of \$20,000, an unthinkable feat in 2009 when two computers were mining away creating the first Bitcoins on the blockchain. Since then Bitcoin has appeared on mainstream magazine covers and spun off thousands of cryptocurrencies and competing crypto-brands in which the trust issue becomes even more crucial.

This paper is based on a longitudinal ethnographic and netnographic study of Bitcoin since 2014. The narratives are drawn from thirty-three in-depth interviews and more than 200 informal interviews with individuals involved in the Bitcoin/Blockchain/Crypto

community. Participant observation was conducted in Toronto, Amsterdam, Berlin, Miami, New York, Prague, San Francisco, Cancun and Boston. The netnography is primarily focused on Twitter, Bitcoin subReddits, Bitcointalk, alongside archival data from newspapers and various blogs and news websites. The findings were analyzed using a hermeneutic process (Thompson, Pollio, and Locander 1994). Bitcoin's awareness and adoption have been spurred by breaches of trust in traditional institutions, particularly banks, governments and corporations, and by the increasing fragility of our connected lives online.

Our analysis adds a socio-cultural understanding of how trust is shaped online in decentralized ecosystems and how erosion of trust in traditional institutions lays the groundwork for such disruptive changes. Many people who enter the Bitcoin ecosystem trust others who trust Bitcoin. This creates a fragility and the potential for online manipulation. Some prominent actors in the community have verified Twitter or Facebook accounts, which are means of establishing a different kind of legitimacy as influencers. Our findings show how the Bitcoin brand was kept afloat in its early days when trust was more blind. Our results have implications for studies of reputation and legitimacy conferred online, particularly the powerful role that social media giants play in endorsing some voices over others, and the challenges of finding trust in decentralized systems where the entire point is to 'trust no one' and 'verify everything'.

# Making the Wait Worthwhile: Experiments on the Effect of Queuing on Consumption

Sezer Ülkü, Georgetown University, USA  
Chris Hydock, Georgetown University, USA  
Shiliang Cui, Georgetown University, USA

## EXTENDED ABSTRACT

Customers spend a significant amount of time waiting in lines, however, the effect of waiting in a line on consumption decisions is not known. Existing literature indicates waiting results in psychological costs such as boredom, frustration, and anxiety and unpleasant negative emotions and cognitions (Maister 1984; Larson 1987; Taylor 1994; Carmon and Kahneman 1995; Hui and Tse 1996; Brady and Cronin 2001; Dabholkar and Bagozzi 2002). However, a long stream of behavioral literature suggest that consumption decisions may be positively influenced by sunk (temporal) costs incurred when waiting in lines due to mental accounting of investments (Thaler 1985).

In the queuing context, time invested waiting prior to making a consumption decision opens an account, and we anticipate consumers purchase more so as to be able to close the account with a more favorable balance. In order to explicitly attribute the effect of queuing on consumption decisions to the sunk-cost fallacy, we demonstrate that the effect is moderated by customers' individual susceptibility to the sunk-cost fallacy. That is, we propose that individuals with greater susceptibility to the sunk-cost fallacy exhibit a greater positive effect of queuing on purchase decisions. Finally, we examine the moderating impact of operational levers which influence the waiting experience, and in turn consumers' mental accounting. Because "the same quantity of time investment may have a different sunk cost impact in different settings, i.e., when the quality of the experience was different" (Soman 2001), we anticipate service improvements which increase satisfaction and reduce the perceived cost of waiting will moderate the relationship between waiting and consumption. In other words, service improvements decrease consumers perceived temporal investments (despite the same objective temporal investment), and as a consequence, consumers do not have to increase their consumption to close their mental account more favorably.

We test these hypotheses over four studies including two experiments, a field study, and transaction data. Study 1 provides external validity for the relationship between waiting time and increased consumption by showing purchase intent for consumers waiting in a real line increases with time spent waiting. Different consumers provided their purchase intent at different points in a line; purchase intent increased with the objective amount of time consumers had spent in line (as well as the perceived amount of time), and this effect existed even when controlling for quality perceptions.

Study 2 provides additional evidence for the effect of mental accounting on consumption in queues with a controlled experiment that randomly assigned participants to simulated waits in short or long lines, and measured of participants' sunk-cost susceptibility scores. As expected consumption was greater in the long line condition relative to the short line condition. Moreover, the effect of line length was greater for participants that were more susceptible the sunk cost fallacy, suggesting the effect of queuing on consumption is driven by mental accounting.

Study 3 provides further evidence for the mental accounting as a driver of the effect and sheds light on the effect of operational levers by manipulating the waiting experience. Participants were randomly assigned to one of four conditions involving a simulated wait and purchase decision: a short wait, a long wait, a long wait with a menu, or a long wait with a video. Following our hypothesis, the presence of a menu or video ameliorated the waiting experience and resulted in a

decreased consumption for these conditions relative to the 'base' long wait condition; this is because their presence improved the waiting experience, causing it to be perceived as less of an investment. In turn, this reduced consumers need to increase consumption amount in order to close out their mental account with a more favorable balance.

Finally, in Study 4 we analyze a data set containing transaction data over the course of one year from a fast-casual salad shop, to provide additional external evidence in a new context. Using a proxy for line length (transaction density) we find that line length led to increased consumption, even when controlling for day of the week and time of the day.

Over four studies, we provide novel insights into the implications and psychology of queues. We find that customers have the tendency to adjust consumption upwards after a long wait. This is an instance of the sunk-cost fallacy; when customers wait for a long time, they try to make the larger economic and temporal investments worthwhile by spending more, thereby amortizing the cost of waiting over a larger purchase. While past literature recognizes that temporal investments are different from monetary investments because people have a hard time accounting for time (Soman 2001; Okada and Hoch 2004), this work provides additional evidence that sunk temporal costs do affect consumption decisions. We also show that consistent with the mental accounting for sunk cost hypotheses, the relationship between waiting time and spending depends on the perception of that time as an investment. We show that by introducing distractions or reducing unoccupied waiting time, the positive relationship between waiting time and purchase quantity can be diminished.

# To Apologize, or not to Apologize? That is a Question - How Should an Organization Respond to Executive Employees' Private Life Misconducts?

Zayed Bin Islam, University of Guelph, Canada

Juan Wang, University of Guelph, Canada

Towhidul Islam, University of Guelph, Canada

## EXTENDED ABSTRACT

Crisis is a low-probability but high-impact phenomenon that hurts an organization's credibility and reputation (Pearson and Clair, 1998). Crisis can result from employees' misconducts in the workplace (e.g., employee making racist comments on customers; Coombs and Schmidt, 2000), and beyond (e.g., executive abusing child in private life; Johnson, Folks, and Wang, 2018). While research has looked into the effectiveness of response strategies in dealing with workplace employee misconducts, there has yet been any discussion upon appropriate responses to non-workplace misconducts, seemingly assuming the same strategies can be taken. This research aims to fill this gap.

Among the many response strategies to crisis, apology and apologia are frequently compared and discussed (Bradford and Garrett, 1995; Dutta and Pullig, 2011). By definition, apology refers to admissions of responsibility and showing regret about the unwanted event (Hargie, Stapleton, and Tourish, 2010), whereas apologia is about denial of responsibility and relevance to the event (Tsarenko and Tojib, 2015). When an employee's misconduct happens within the workplace, where the firm is expected to have control over employee behaviours, it is unlikely for the firm to shred or deny its responsibility in the event. As a result, apology can help attenuate the advert effects of misconduct (Coombs and Schmidt, 2000). When responding to employee misconducts happening beyond the workplace, however, whether to use apology or apologia depends on the extent to which the organization is perceived to be responsible for the event. Although an organization usually has no control over its employee's private life behaviour, there are reasons to believe that it could still get scrutinized for responsibilities, and this is particularly true for employee misconducts that violate an organization's core value.

Organizational membership works as an implicit endorsement of an organization's values (Effron, Lucas, and O'Connor, 2015). Employees are expected to uphold the same core values that their organizations promote. This is especially true for executives as they are usually seen as representatives of an organization (Zhu and Chang, 2013). As a result, if an executive violates the organization's core value (same domain misconduct), be it in the workplace or private life, the organization is not only perceived to be responsible but also be hypocritical as it promotes one value but acts oppositely by allowing its executive to violate it (Barden, Rucker, and Petty, 2005; Wagner, Lutz, and Weitz, 2009). When someone is accused of hypocrisy, denying responsibility can further increase this perception (Shkler, 1979) and hypocrisy could lower moral reputation (Laurent et al. 2014). Based on this theorizing, we expect that apologia (vs. apology) can hurt, instead of help with, organization reputation when dealing with same domain employee misconduct. On the other hand, if an executive's misconduct is unrelated to the organization's core value (different domain misconduct), the organization is not perceived to be responsible, or hypocritical as there is no contradiction of value claim and actions. As a result, apologia and apology can be similarly effective in retaining the organization's reputation. Two studies, with different employee misconducts and organizational values, are used to provide evidence for our expectations.

Study 1 showed that with same domain executive misconduct, apologia is less effective than apology in retaining organization reputation. Sixty-nine undergraduate students (35% female) participated in this one-factor between-subjects study. They read an article about the CEO of SCAA (Stop Cruelty Against Animal) kicking and choking a puppy in a hotel elevator (modified from a real-life case). Then, participants were either shown an apology or an apologia statement issued by the organization. Finally, participants rated organizational reputation (Coombs and Holladay, 2002,  $\alpha = .78$ ) and response appropriateness (Johnson et al., 2018,  $\alpha = .93$ ). As expected, apology (vs. apologia) resulted in significantly higher organizational reputation ( $F(1,67) = 5.29, p = .02$ ). In addition, apology was considered a more appropriate response with same domain employee misconduct ( $F(1,65) = 7.90, p < .01$ ).

Study 2 tested the moderating role of misconduct domain and the underlying mechanism of hypocrisy perceptions. One hundred and fifty undergraduate students (60% female) participated in this 2 (response strategy: apology vs. apologia) X 2 (misconduct domain: same vs. different) between-subjects study. For the same domain manipulation, participants read that the CEO of SCAA (Stop Cruelty Against Animal) kicking and choking a puppy in a hotel elevator (the same as study 1), whereas for different domain, the same misconduct was committed by the CEO of FFL (Foundation of Family Literacy), an organization promoting education and literacy. After reading apology or apologia statements, participants rated organizational reputation ( $\alpha = .72$ ), hypocrisy perception (Wagner et al., 2009,  $\alpha = .86$ ), and the organization's responsibility (Lee 2005,  $\alpha = .73$ ).

The results revealed a significant interaction between response strategy and misconduct domain on organization reputation ( $F(1,146) = 7.71, p < .01$ ) and hypocrisy perceptions ( $F(1,146) = 2.95, p < .10$ ). With the same domain misconduct, apologia (vs. apology) enhanced hypocrisy perceptions of the organization ( $F(1,146) = 6.571, p < .05$ ), and thus undermined organization reputation ( $p < .01$ ). With different domain misconduct, apologia and apology did not influence hypocrisy perception ( $p > .90$ ) or organization reputation ( $p = .57$ ). Hypocrisy perception mediated the interaction of response strategy and misconduct domain on organization reputation ( $B_{\text{indirect}} = .20, se = .13, CI = [.001, .555]$ ). With the same domain misconduct, apologia significantly reduced organization reputation by increasing hypocrisy perception ( $B_{\text{indirect}} = -.21, se = .10, CI = [-.473, -.050]$ ); whereas with different domain misconduct, hypocrisy perceptions did not mediate the relationship ( $B_{\text{indirect}} = -.01, se = .07, CI = [-.165, .158]$ ). Correspondingly, the organization was assumed to bear more responsibilities when employee misconduct violated the same (vs. different) value the organization promoted ( $F(1,144) = 3.71, p = .056$ ).

Taken together, this research established the fact that effectiveness of response strategies largely depends on the organization's own corporate values. Hypocrisy perception is the underlying mechanism that distinguishes strategy effectiveness. This research not only extends our understanding of crisis literature, but also enriches the hypocrisy literature by showing how other's action can make someone look hypocritical.

# The Price of a Threat: How Social Identity Threat Influences Price Sensitivity

Jorge Jacob, Fundação Getúlio Vargas, Brazil

Yan Vieites, Fundação Getúlio Vargas, Brazil

Eduardo Andrade, Fundação Getúlio Vargas, Brazil

Rafael Goldszmidt, Fundação Getúlio Vargas, Brazil

## EXTENDED ABSTRACT

João is a reliable worker in a low-pay but quite stable job. Nonetheless, João is black, uneducated, and lives in a favela. No wonder he is highly sensitive to cues that threaten one or multiple dimensions of his social identity and that makes it clear that racial segregation is well and alive in the city. Cues that, whenever possible, he tries to avoid.

Given the financial constraints, standard economic theory and sheer intuition would predict consumers like João to be highly price sensitive. For many purchase decisions, that is indeed the case. Scholarly research has successively demonstrated that the poor are more price sensitive than their wealthier counterparts (Jones, Chern, and Mustiful 1990). However, as João's example highlights, most consumers on the far-left side of the income distribution are not only short on money. They are also uniquely sensitive to the marketplace cues that threaten one or several dimensions of their social identity. In this paper, we investigate how these two income-covarying forces—perceived social identity threats (SITs) and financial paucity—influence consumers' sensitivity to the monetary dimension of the target choice.

Our research advances the field by documenting when and why consumers from impoverished areas (i.e., hereafter, identity-vulnerable consumers) become, counterintuitively, less price/prize sensitive than their much wealthier counterparts (i.e., hereafter, identity-guarded consumers). We expand the so-called "ghetto tax" (Eckholm 2006) by showing that even when consumers can exert price sensitivity, they often choose not to do so in a systematic attempt to avoid the SITs of the purchase environment where the cheapest option or most valuable prize happens to be located. In doing so, our findings broaden the array of consequences of SITs (Seibt and Förster 2004; Steele, 1997) while contributing with a new effect to the burgeoning scarcity literature (e.g., Shah, Shafir, and Mullainathan 2015).

Across three experiments, we have shown that to avoid intergroup contact in commercial settings, identity-vulnerable (i.e., poor) consumers were willing to pay a higher price for both products and services and accepted lower-value rewards when compared to identity-guarded (i.e., wealthy) consumers. Whereas mediation analysis (study 1) showed that identity-vulnerable individuals were less price sensitive due to a higher anticipated prejudice, moderation data (study 3) demonstrated that this effect was contingent on the consumers' level of collective self-esteem. Subjects' choices of grocery coupons in a consequential scenario (study 2) provided external validity for these findings.

More precisely, study 1 employed a 2 (consumer identity: vulnerable vs. guarded; observed) x 2 (type of group contact at the commercial setting: intragroup vs. intergroup) between-subjects design. Residents from wealthy and impoverished areas of the city of Rio de Janeiro were asked to make a hypothetical choice between two options in which a trade-off between price and location/convenience was at stake. In one condition, the cheapest option was available in an intragroup commercial setting (i.e., a store that targets a social class similar to that of the participant) whereas on the other condition, it was available in an intergroup commercial setting (i.e., a store that targets a social class different from that of the participant).

Identity-vulnerable consumers were less sensitive to price when the cheaper option was available in an intergroup commercial setting than in an intragroup commercial setting. Identity-guarded consumers (i.e., from the high echelons on the socio-economic ladder), on the other hand, were equally sensitive to price, irrespective of the social class most associated with the commercial setting. Furthermore, we tapped into the SIT mechanism using a moderated mediation model. When faced with an intergroup (vs. intragroup) commercial setting, identity-vulnerable consumers anticipated more discrimination in the marketplace and were, therefore, willing to pay higher prices for the flip-flops to avoid the discriminatory cues (i.e., SITs). Conversely, identity-guarded consumers facing the same situation anticipated less discrimination when faced with an intergroup (vs. intragroup) commercial setting and were therefore not willing to pay more for the flip-flops.

Study 2 employed a 2 (consumer identity: vulnerable vs. guarded; observed) x 2 (type of group contact at the commercial setting: intragroup vs. intergroup) between-subjects design to assess whether vulnerable and guarded consumers prefer to obtain a lower vs. a higher-value grocery coupon to be redeemed at either an intra or an intergroup commercial setting. Group contact had no impact among identity-guarded consumers but strongly influenced identity-vulnerable consumers, such that poorer consumers were much less value sensitive in an intergroup than in an intragroup setting. Further, in line with the literature and intuition, poorer consumers were more value sensitive than their wealthier counterparts. But that happened only in an intragroup commercial setting. The effect reversed when the higher-value coupon was to be redeemed in an intergroup commercial setting.

Relying on a different setting (i.e., bank) and purchase option (i.e., financial services), study 3 employed a 2 (group contact: intragroup vs. intergroup; manipulated) x 2 (level of identity vulnerability: high vs. low; observed) between-subjects design and assessed consumers' ex-ante level of identity vulnerability to threatening environments (i.e., attachment to one's social group and public collective self-esteem). Level of identity vulnerability moderated the effect of group contact such that those with high identity vulnerability preferred to pay a higher fee for a financial service to avoid incurring group contact, but no such differences emerged among participants with low identity vulnerability.

With identity-vulnerable consumers from a developed country (i.e., residents of low-income areas of New York City), study 4 employed a 2 (consumption environment: physical vs. online) x 2 (prejudice salience: salient vs. neutral) between-subjects design. The awareness of the likelihood of prejudice toward low-income people (i.e., *prejudice salience*) reduced participants' price sensitivity when their purchase would occur in a physical store. However, no such differences emerged among participants assigned to purchase in an online store. As expected, the interaction between prejudice manipulation and purchase channel was significant, such that prejudice manipulation did not affect price sensitivity for participants on the online store. These findings are consistent with the proposition that SITs make identity-vulnerable more willing to pay higher prices to alleviate the sentiment of threat in these environments.

# Meaningful Numbers: Consumer Response to Verbal Reaffirmation of Numerical Nutrition Information

Steffen Jahn, University of Goettingen, Germany  
Monique Breaz, University of Goettingen, Germany  
Till Dannewald, Wiesbaden Business School, Germany  
Yasemin Boztug, University of Goettingen, Germany

## EXTENDED ABSTRACT

Although the types of front-of-package (FOP) nutrition labels that best engage and influence consumers' product evaluations and decision-making processes are still poorly understood (Newman, Howlett, and Burton 2016), research seems to converge on the idea that some combination of numerical and easy-to-process information is most effective across a variety of situations (Newman et al. 2018; Sanjari, Jahn, and Boztug 2017). The GDA-Traffic Light (GDA-TL) is one label scheme that combines condensed numerical information about key nutrients (e.g., fat, sugar, and salt) with color indicating whether the amount of each key nutrient is below a defined value (FSA 2016). Due to this combination of numerical information and simple color coding, GDA-TLs are often regarded as the superior FOP nutrition labeling scheme (Borgmeier and Westenhoefer 2009; Grunert, Bolton, and Raats 2012; Siegrist, Leins-Hess, and Keller 2015; van Herpen, Hieke, and van Trijp 2014).

Despite the promising features of the GDA-TL label, it is not without its shortcomings. For example, this labeling scheme does not assist consumers in distinguishing between multiple products with the same color profile. Color profiles often do not differ within a category, limiting their usefulness in decision making. Moreover, the color cue is ambiguous when it does not directly reaffirm the numerical information. For instance, three products that contain 6g, 21g, and 23g sugar would be color coded as *amber*, *amber*, and *red*, respectively (FSA 2016). As this example shows, the numerical information would lead to a different inference (i.e., product 1 contains substantially less sugar than the other two) than the color profile (i.e., product 3 contains substantially more sugar than the other two). Against this background, it is not surprising that the GDA-TL does not always work better than a purely numerical label such as the GDA (Crosetto, Muller, and Ruffieux 2016; Koenigstorfer, Groepel-Klein, and Kamm 2014). From a consumer research perspective, this means that some combinations of numerical and easy-to-process information—especially if the cues do not perfectly align—are not always able to keep their promise of assisting consumers with nutrition information processing.

The main goal of this research is to examine the effectiveness of FOP labels that align numerical and easy-to-process cues. Specifically, we study consumer response to FOP labels where numerical nutrition information is unequivocally reaffirmed by a simpler cue. For example, numerical information can indicate that a product contains above-average calories in a given category by disclosing the calorie count of the product *vis-a-vis* the average amount of calories in the respective category (Jahn et al. 2018; Viswanathan 1994; Viswanathan and Hastak 2002). Because consumers have to first understand the connection between these numbers, there is some margin for error. An additional verbal cue stating, "this product has an above-average calorie amount" would then provide an easy-to-process reaffirmation of the numerical information. Because the verbal information is redundant of the numerical one, both cues are aligned.

Research in educational psychology has shown that students learn better with redundant rather than with nonredundant verbal explanations provided no other competing visual materials are presented simultaneously (Moreno and Mayer 2002). This means that

while the verbal information is redundant and hence might unnecessarily add complexity, it can be advantageous because it immediately provides meaning (Huber 1980). There is also evidence that consumers look for information that reaffirms advertisers' claims and then believe the claims even more (Hoch and Ha 1986). Thus, from an information processing perspective the verbal reaffirmation of the numerical information could assist consumers' decision making. Interestingly, consumer researchers have not yet addressed this important issue. Hence, we seek to shed light on how redundant, reinforcing information on FOP nutrition labels influences consumers' product evaluations and decision making.

To examine if and when easy-to-process cues that are paired with numerical ones improve consumer response, we focus on nutrition information that is essentially redundant. The redundancy of both cues helps avoid a problem in existing research where the effectiveness of cues is confounded with the issue of cue match. For example, it is difficult to test the strength of the GDA-TL if the numerical and the color cue do not perfectly align. By contrast, redundant information always aligns and thus allows for targeted assessment of cue pairing effectiveness. We use numerical information (calorie amount plus reference point) that is accurate yet cognitively demanding. By contrast, verbal information is less accurate (e.g., it does not inform about the magnitude of the deviation from the reference point) but easily understood. The combination of both cues has the potential to combine both advantages, ultimately resulting in improved consumer decision making. For reasons of simplicity, we consider only one key nutrient (calories), but the underlying mechanism is expected to generalize to more complex labeling schemes.

Across four studies, we demonstrate that numerical reference information can affect purchase behavior (Pilot Study) as well as perceived healthfulness and purchase intentions of hedonic but not healthful products (Study 1). The latter could be caused by a category-elicited health halo where consumers pay less attention to the nutrition information. As predicted, however, a verbal reaffirmation of numerical information was effective across categories (Study 2). Adding a reaffirming verbal cue assisted consumers in avoiding the category-elicited health halo and resulted in an accurate distinction between relatively healthful and unhealthy variations of ice cream and granola. Importantly, it was the reaffirmation and not the verbal cue alone that enabled consumers to identify within-category healthfulness differences of healthful products (Study 3). Beyond providing important theoretical contributions to consumer research, our findings reveal a potentially influential mechanism for decreasing category-evoked health halo effects and effectively increasing consumer understanding of nutrition information.

# Feeling Bad by Wanting More or Wanting More by Feeling Bad: The Materialism - Well-Being Cycle

Esther Jaspers, Massey University, New Zealand  
Rik Pieters, Tilburg University, The Netherlands

## EXTENDED ABSTRACT

Across the world, holding strong materialistic values is associated with reduced subjective well-being. The common inference is that higher levels of consumer materialism uniformly lead to lower levels of subjective well-being (Karabati and Cemalcilar 2010; Kasser et al. 2014; Wang et al. 2017). Our research challenges the idea that higher levels of materialism uniformly reduce subjective well-being. Using a representative longitudinal database of over 5,300 Dutch consumers across three years (2013-2015) our research improves over previous, predominantly cross-sectional, studies both methodologically and conceptually. It shows that materialism is not inherently bad and moreover that subjective well-being may also influence consumer materialism.

Our multivariate autoregressive cross-lagged model address three potential sources of endogeneity which may systematically bias the size, sign and direction of the relationship between materialism and subjective well-being: measurement error, simultaneity, and omitted variables (Wooldridge 2002). Any of these sources of endogeneity causes a correlation between materialism or subjective well-being and the error term, leading to biased, and sometimes inefficient, estimates. We account for endogeneity by decomposing the observed association between materialism and well-being into true shared variance and error.

First, we include the measurement model that decomposes the total variance of our measures of materialism and well-being into their true variance and measurement error components, which we label “measurement decomposition.” This reduces potential attenuation bias due to unaccounted measurement error, yielding more precise and efficient estimates of the relationship between materialism and well-being.

Second, the model decomposes the total shared variance between materialism and well-being into two causal directions, which we label “directional decomposition.” This reduces bias due to unaccounted potential simultaneity of effects. The vast majority of materialism research is based on survey data collected at a single point in time, which impedes causal inferences. Even the few longitudinal studies have assumed that the causal direction runs from materialism to well-being, without allowing for the possibility of reverse causality (Wang et al. 2017). We propose that the relationship between materialism and subjective well-being is reciprocal. This has in fact been suggested previously (Burroughs and Rindfleisch 2002; Dittmar et al. 2014; Rustagi and Shrum 2017), but empirical research to address the issue is to our knowledge not yet available. Our model estimates both pathways simultaneously, and as such moves closer to understanding the causal processes.

Third, we control for various potentially confounders based on substantive theory, reducing the possibility of bias due to omitted variables (“covariate decomposition”). Particularly, we include age, income, education, and employment and marital status, which have been shown to affect materialism, subjective well-being, or both, as covariates (Charles, Reynolds, and Gatz 2001; Glenn and Weaver 1981a, b; Jaspers and Pieters 2016; Pieters 2013; Richins and Dawson 1992).

Our research also aims to make a conceptual contribution. We decompose the aggregate relationship between overall materialism and subjective well-being into disaggregate relationships for three key materialism dimensions, which we refer to as “construct decom-

position”. We build on the leading conceptualization of materialism by Richins and Dawson (1992) as a multidimensional construct with three dimensions: acquisition as the pursuit of happiness, acquisition centrality, and possession-defined success. These dimensions are conceptually and empirically distinct and have differential relationships with related variables such as age and loneliness (Jaspers & Pieters, 2016; Pieters, 2013). Correspondingly, they are likely to have distinct relationships with subjective well-being. Specifically, we propose that acquisition as the pursuit of happiness drives the negative association between overall materialism and well-being. This dimension reflects a dissatisfaction based on a perceived gap between consumers’ actual and desired material states. This dissatisfaction extends beyond the material domain, leading to reduced well-being. Acquisition centrality and possession-defined success are inherently more positive, reflecting emotional and social benefits of acquisition and ownership of possessions. Their associations with subjective well-being are therefore expected to be neutral or even positive. Decomposing the aggregate relationships between overall materialism and well-being disentangles the negative and potentially positive effects that materialism and well-being have on each other and informs our understanding of the mechanisms underlying them.

We found that materialism and well-being influenced each other over time, which supports the hypothesized reciprocal relationship. Specifically, higher levels of materialism led to lower later levels of well-being ( $-.045, p < .001$ ), and higher levels of well-being led to lower later levels of materialism ( $-.060, p < .001$ ). Importantly, the difference between these two standardized cross-lag effects was not significant ( $.015, p = .406$ ), implying that the two effects did not differ significantly in strength. As predicted, acquisition as the pursuit of happiness drove this negative relationship. Consumers who scored higher on acquisition as the pursuit of happiness were less satisfied in subsequent years ( $-.150, p < .001$ ), and consumers who were less satisfied later scored higher on acquisition as the pursuit of happiness ( $-.110, p < .001$ ). Possession-defined success also had a reciprocal relationship with well-being. However, possession-defined success had a positive effect on later levels of well-being ( $.054, p < .001$ ), while the effect of well-being on later levels of possession-defined success was negative ( $-.050, p < .001$ ). For acquisition centrality the relationship was unidirectional: consumers who scored higher on acquisition centrality had higher later levels of well-being ( $.047, p < .001$ ), but well-being did not affect later levels of acquisition centrality ( $.011, p = .373$ ).

Taken together, our contributions based on four decompositions (methodological and conceptual), move us closer to more accurate inferences about the size, sign, and direction of the relationship between materialism, its three dimensions, and subjective well-being. It answers to repeated calls for longitudinal studies to examine this vexing issue (Dittmar et al. 2014; Rustagi and Shrum 2017). Our findings highlight the potential of longitudinal data to make plausible causal inferences when experimental research is difficult or unethical. It emphasizes the importance of treating materialism as a multidimensional construct to reveal the distinct relationships that the three dimensions have with antecedents and outcomes. Treating materialism as unidimensional conceals these underlying relationships and suggests that materialism negatively affects well-being, despite two of its three dimensions actually having positive effects on well-being.

# The Impact of Previews on the Enjoyment of Multicomponent Multimedia Experiences

Jayson S. Jia, The University of Hong Kong, China  
Baba Shiv, Stanford University, USA

## EXTENDED ABSTRACT

Previews, ranging from movie trailers to music samplers, commonly preface the consumption of extended multimedia experiences such as movies, television shows, and music. Given the ubiquity of such previews, one might wonder if they have downstream effects on the final consumption experience. For example, could seeing a movie's trailer change how much consumers later enjoy the movie?

There is some theoretical precedence for the notion that previews, and the information processing they engender, can qualitatively affect downstream consumption experiences. After all, consumer experiences are to a significant degree contextually and subjectively constructed within consumers' minds, often under the guidance of marketers, rather than objective experiences (Alba and Williams 2013; Ariely and Norton 2009). A growing literature on marketing placebo effects also shows that information processing taking place before consumption can qualitatively change the subsequent enjoyment of an experience (Lee, Frederick, and Ariely 2006; Plassmann et al. 2007; Shiv, Carmon, and Ariely 2005). The rationale behind these and related findings is that pre-experiential information processing can activate expectations that become salient in consumers' minds, and change how they approach upcoming experiences (Mandel and Nowlis 2008; Shiv et al. 2005; Wadhwa, Shiv, and Nowlis 2008). Could previews have an analogous impact on the consumption of multimedia experiences? Could the nature of the preview affect how much consumers enjoy an upcoming experiences?

In investigating these questions, we focus on the impact of previews on 'extended' multimedia experiences (Ariely and Zaubergerman 2000) comprised of multiple components (e.g., several scenes in a television episode, etc.). Our conceptualization bridges a research gap between the marketing placebo effect literature and the literature on 'extended' consumer experiences, which documents the structure, composition, and time course of complex, longitudinal experiences (e.g., Ariely and Loewenstein 2000; Ariely and Zaubergerman 2000, 2003; Diehl, and Ariely 2006; Kahneman 2000; Hsee and Abelson 1991; Teixeira, Wedel, and Pieters 2012; Wirtz et al. 2003). The former, which explores how marketing actions can qualitatively change consumer experiences, typically focuses on structurally simple, 'single component' experiences (e.g., one bite of chocolate, one taste of wine). The latter, which maps the time course, structure, and composition of complex longitudinal experiences, typically does not consider how marketing actions or information processing can qualitatively change the nature of those experiences. We combine the two conceptual perspectives.

We find that the impact of previewing on enjoyment is mediated by how much a preview affects the upcoming multimedia's 'experiential coherence,' or how well the different parts of a multicomponent experience fit together. Our conceptualization predicts when previews have a negative impact (when previews induce narrow focalization on a single component, similar to focalism; Wilson et al. 2000), when the negative impact is attenuated (when previews have a broader focus on multiple components, even including the less enjoyable components), and also when previews can enhance enjoyment (when previews improve experiential coherence). This also reconciles our results with previous findings that 'spoilers don't spoil stories' (Leavitt and Christenfeld 2011). Throughout, we use real consumer experiences to enhance the ecological validity of our findings.

In Study 1, we find that a poster previewing scenes from a Mr. Bean episode will reduce the online enjoyment of the upcoming episode when the preview narrowly highlights the funniest scene;  $M_{\text{prev.}} = 6.25$ ,  $M_{\text{narrow}} = 5.73$ ,  $F(1, 256) = 4.76$ ,  $p = .03$ ,  $d = .584$ . The effect is attenuated when the preview is expanded to include pictures of other scenes (while still including the scene in the narrow preview condition).

Study 2 replicates the basic effect and moderation by exploring how different audio music previews of a new song affect the enjoyment of the song's audio-visual music video, and operationalizes relative focus of previews by manipulating how much of a song is played as a preview. A narrow preview that plays only the iTunes preview of the song results in less enjoyment of the music video;  $M_{\text{no preview}} = 6.51$ ,  $M_{\text{narrow}} = 5.78$ ,  $p = .048$ ,  $d = .511$ . However, previewing the full song (broad preview) attenuates the effect, while simultaneously ruling out alternative mechanisms such as adaptation or cognitive load.

In Study 3, we find that the effect is mediated by experiential coherence, or how well the different components of the experience fit together. We find that watching the official movie trailer of an award winning 5 minute short film reduced its enjoyment, , and that this was mediated by experiential coherence, 95% CI = [-0.708, -0.032].

We replicate the mediation in Study 4 where we manipulate (narrow) style of processing. All participants previewed a set of paintings in thumbnail form before examining each painting in full screen form. In a narrow preview condition, the preview highlighted that one of the thumbnails was a sensual female nude (all participants were male); this subsequently resulted in less enjoyment of the virtual art gallery,  $M_{\text{non focal}} = 5.59$ ,  $M_{\text{focal}} = 5.10$ ,  $F(1, 213) = 5.10$ ,  $p = .025$ ,  $d = .614$ . Again, this effect is mediated by experiential coherence, 95% CI = [-.2353, -.0177].

In Study 5, we show that previews that increase experiential coherence can improve enjoyment,  $M_{\text{control}} = 4.87$ ,  $M_{\text{broad}} = 5.30$ ,  $F(1, 198) = 4.35$ ,  $p = .038$ ,  $d = .546$ , and that this improvement is mediated by experiential coherence, CI = [0.068, 0.465]. Specifically, we create a preview for a comic book that either explains how the subsequent comic panels relate to each other narratively. Finally, Study 6 replicates the main effect and moderation results in a field setting, where participants report their online enjoyment of a popular TV show via text message. Besides finding significant differences in online enjoyment, we also found significant differences in post-experiential ratings of enjoyment, willingness to purchase, and willingness to share with friends in each study.

These findings have direct managerial implications for the marketing and consumption of multimedia and digital products, for which previewing is often an unavoidable part of the consumption experience (e.g., movie trailers on YouTube, song previews on music platforms, expert gameplay on Twitch).

# Attribution of Authenticity: The Benefits of Self-Disclosure of Unfavorable Information

Li Jiang, George Washington University, USA  
Maryam Kouchaki, Northwestern University, USA  
Francesca Gino, Harvard Business School, USA

## EXTENDED ABSTRACT

In the 2016 U.S. presidential election, questions of authenticity loomed large (Sergent, 2016; Szalai, 2016; Talbot-Zorn & Marz, 2016; Zimmer, 2016; Zogby, 2016). We suggest that when a person voluntarily discloses her/his weaknesses, because disclosing one's weaknesses is costly, this costly behavior can be only interpreted as that the target truly embraces his/her true self, and therefore, observers will view the person as an authentic individual who has embraced both negative and positive aspects of the self. Moreover, we suggest the effect of disclosing unfavorable information relies on *voluntary self-disclosure*. When disclosure of unfavorable information is not *voluntary*, the lack of information about the target's *intention* or *will- ingness* to disclose unfavorable information will prevent the recipient from making dispositional inferences about his/her authenticity.

In Study 1a, participants ( $n = 200$ ) were asked to imagine they were on an interview and met a CEO of the company. The CEO introduced himself. We randomly assigned participants to one of two conditions: The CEO either disclosed an unfavorable piece of information (being nervous about public speaking) or not. Afterward, we measured participants' impressions of the CEO on three dimensions: perception of authenticity (six items,  $\alpha = .93$ : e.g., authentic, genuine, adapted from Hahl & Zuckerman, 2014, and Ridgeway & Correll, 2006), competence (four items,  $\alpha = .89$ : e.g., competent, skillful), and warmth (four items,  $\alpha = .87$ , e.g., kind, friendly) on a scale from "not at all" (1) to "very much" (7). Each of these scales was randomly mixed in with other scales. We also measured individuals' overall impression of the CEO on a scale from "very negative" [-5] to "very positive" [5].

Compared to the no-unfavorable information condition, participants in the unfavorable information condition perceived the CEO to be more authentic ( $M_{\text{unfavorable information}} = 5.74$  vs.  $M_{\text{no-unfavorable information}} = 5.34$ ,  $F(1, 198) = 7.96$ ,  $p = .005$ ), and had better overall impressions of him ( $M_{\text{unfavorable information}} = 3.05$  vs.  $M_{\text{no-unfavorable information}} = 2.54$ ,  $F(1, 198) = 4.13$ ,  $p = .044$ ). However, perception of competence did not differ ( $F(1, 198) = .61$ ,  $p = .44$ ). Importantly, as we predicted, based on bootstrapping with 10,000 resamples, we found that authenticity [95% bootstrapped confidence interval (CI): 0.098, 0.586] and not competence (95% bootstrapped CI: -0.102, 0.090) mediated the relationship between unfavorable information disclosure and overall impression. Study 1b replicated Study 1a with a different unfavorable information: "not able to keep track of technological changes". Study 1b also examined a behavioral outcome of perceived authenticity: participants' propensity to take the job from a manager when has disclosed unfavorable information about himself if offered a position.

Study 2 tested the behavioral consequences of self-disclosure of unfavorable information using a trust game (Berg, Dickhaut, & McCabe, 1995) with real money. We randomly assigned 218 participants to play the role of either a manager or a potential employee ( $n = 109$  for each). Managers were given a script for their self-introduction. They were randomly assigned to the control condition or the unfavorable information condition. In the unfavorable information condition, they said: "I'm quite shy. I am nervous about public speaking, and I have a habit of cracking my knuckles." After the task, we separated each pair. The employee rated the manager on the following dimensions, similar to study 1: perception of authentic-

ity, competence, as well as the extent they wanted to work with the manager again.

Next, the employee (sender) played the trust game with the manager (receiver) with whom they were paired. The employee received an endowment of \$3 and was told he/she had to decide how much of the \$3 to transfer to the manager; any amount between and including 0 and \$3, in an increment of \$0.25 (a quarter), was feasible. The employee was told that any money would be tripled in transit. In turn, the manager would then have the option to send some, all, or none of the money back. The money allocation served as another key dependent measure in the study.

Compared to the no-unfavorable information condition, employees in the unfavorable information condition perceived the CEO to be more authentic ( $M_{\text{unfavorable information}} = 5.27$  vs.  $M_{\text{no-unfavorable information}} = 4.88$ ,  $F(1, 107) = 4.17$ ,  $p = .044$ ). However, perception of competence did not differ ( $M_{\text{unfavorable information}} = 5.17$  vs.  $M_{\text{no-unfavorable information}} = 5.05$ ). Similarly, participants in the unfavorable information condition wanted to work with their manager again compared to those in the no-unfavorable information condition ( $M_{\text{unfavorable information}} = 5.36$  vs.  $M_{\text{no-unfavorable information}} = 4.77$ ). In addition, those in the unfavorable information condition gave more money to their manager in a trust game ( $M_{\text{unfavorable information}} = \$2.39$ , vs.  $M_{\text{no-unfavorable information}} = \$2.02$ ),  $F(1, 107) = 4.16$ ,  $p = .044$ . Authenticity mediated the relationship between unfavorable information disclosure and as well as wanting to work with the manager again.

Study 3 demonstrated the volitional act of self-disclosure is central to our account: the choice to embrace weaknesses is the key that leads observers to make inferences about the "type of person" the discloser is. When unfavorable information is disclosed as a mandatory (not voluntary) request or when the information is disclosed by a third person (not self-disclosure), the effect no longer holds. We randomly assigned participants ( $n = 240$ ) to one of four conditions in a 2 (type of unfavorable information: unfavorable information, no unfavorable information) by 2 (disclosure of the unfavorable information: voluntary, requested) between-participants design. Significant interactions suggested that in the voluntary self-disclosure condition, candidates perceived the manager to be more authentic and were more willing to work with the manager when the manager voluntarily self-disclosed unfavorable information about himself than when the manager disclosed no unfavorable information. However, in the requested-disclosure condition, when the manager disclosed unfavorable information due to a specific task requirement, the effect disappeared.
