Advances in Consumer Research, Volume XIII.
(Provo, UT: Association for Consumer Research, 1986).

ORDER FORMS ARE PROVIDED AT THE BACK OF THIS VOLUME

PREFACE

This volume contains papers that were presented at the sixteenth Annual Conference of the Association for Consumer Research, which was held October 17-20, 1985, at the MGM Grand Hotel in Las Vegas, Nevada. The conference program, reproduced elsewhere in this volume, consisted of 75 competitive papers and 45 Paper Fair presentations, which were selected through a competitive review process from a total of 153 competitive paper submissions. The Paper Fair presentations are published as brief Abstracts here, while the competitive papers are included in their entirety. In addition, 58 of the 128 special session presentations at the conference are published here. Since many special session presenters chose not to include their papers in the proceedings, the interested reader is encouraged to contact authors directly for further information pertinent to any paper listed on the program which does not appear in the Table of Contents. ACR has maintained this "optional publication" policy over the years as a means for encouraging participants to present their best work without precluding the possibility of publishing it in a professional or scientific journal.

Orchestrating a conference as large and as varied as an ACR Conference obviously entails the considerable efforts, coordination and cooperation of many people. I find myself in the position of having so many people to thank that I am not quite sure where to begin. And, I have this vague anxiety that once I've thanked everyone else who worked so hard to make the conference a success, the reader might be left wondering what exactly it was that I contributed to the effort! Nevertheless...

I would first like to thank Peter Wright, who, as President-Elect, both offered me the opportunity to serve in this role and then supported me unflinchingly in my vision for the conference. I also received incredible amounts of moral support, encouragement, and accumulated wisdom from Keith Hunt, our Executive Secretary. I would also like to acknowledge my Department Chairman, Alan Sawyer, for granting me not only the release time to take on this responsibility, but also the use of considerable Departmental resources.

Obviously, the conference would not exist without the contributions of the literally hundreds of scholars and researchers who contributed their work in the form of competitive papers and special session proposals. And, of course, the countless hours spent by the sixteen-member Program Committee and the 129 competitive paper reviewers, all of whom are acknowledged individually elsewhere in this volume, were very much necessary to make this a quality conference. Their efforts, though taken for granted, are most appreciated, and the dedication and thoroughness of both groups were truly remarkable.

My research assistant throughout the entire process, which ran roughly from February through October, 1985, was Douglas R. Hausknecht, who by now is a member of the Marketing faculty at the University of Akron. Most assuredly, a better assistant has never walked the face of the earth! Doug kept me and hundreds of papers, reviewers, authors, discussants, oversized sheets, and audiovisual requests organized; without him, I would have been a basket case. It is largely due to his efforts that the conference planning (and the printing of these proceedings) took place on a timely basis. And, he performed all these activities (and more too numerous to mention) in his characteristic good humor. As is undoubtedly obvious by now, Doug is the single person to whom I owe the biggest debt of gratitude. I may even sign off on his dissertation, now that he has time to write it!

I am also extremely appreciative of the outstanding job Debbie Scammon of the University of Utah did as Conference Arrangements Chair. Selectively perceiving her offer to "help out a little if you need it," I quickly thrust upon her full responsibility for conference registration, hotel interface and arrangements, site visits, menu selection, and cocktail parties - in short, everything important. She handled it all beautifully and essentially freed me up to worry about just program content. She has asked me to acknowledge the excellent work of her right-hand man, Jim McAlexander, who worked closely with her on the registration system. Also, a thank you goes to another student at Utah, Janeen Olson, who helped staff the Registration Desk at the conference.

Linda Loucks, the Marketing Department Administrative Assistant, was instrumental in budgeting, the procurement of emergency supplies, and the freeing up of secretarial support at crucial times in the process. Sylvia Palmer and Alicia Maxwell provided cheerful, timely and accurate typing of conference correspondence and proceedings modifications. All three of these ladies were invaluable to me in making this whole thing happen, and I promise to buy them all some more flowers.

Finally, I would be remiss if I didn't acknowledge the support and cooperation of my family, to whom running the conference basically translated into "Why isn't Daddy home?" So, to my wife Rachel and my son Matthew, all my love, and thanks for cutting me some slack. Dad's back!

To you, the reader, I hope you find much of interest in this volume, which I believe reflects the excitement and diversity of the emerging discipline of consumer research.

Richard J. Lutz, Editor

Association for Consumer Research

1985-1986 Officers

BOARD OF DIRECTORS

President, Peter Wright, Stanford University
President Elect, Russell W. Belk, University of Utah
Past President, Jagdish N. Sheth, University of Southern California
Executive Secretary, H. Keith Hunt, Brigham Young University
Treasurer, Elizabeth Hirschman, New York University
Director, Gary T. Ford, University of Maryland
Director, Larry Percy, Creamer, Inc.
Director, Hans B. Thorelli, Indiana University

COMMITTEES

Conference, Richard J. Lutz, University of Florida
Newsletter, Valarie Zeithaml, Texas A & M University

ADVISORY COUNCIL

Richard T. Curtin, University of Michigan
Mathew H. Greenwald, American Council of Life Insurance
Philip A. Harding, CBS, Broadcast Group
Thomas J. Maronick, Federal Trade Commission
John Payne, Duke University
A. Marvin Roscoe, Jr., AT & T
Lorraine C. Scarpa, Data Development
Chin Tiong Tan, National University of Singapore

CONFERENCE COMMITTEE

CONFERENCE CHAIR

Richard J. Lutz, University of Florida

ARRANGEMENTS CHAIR

Debra L. Scammon, University of Utah

PROGRAM COMMITTEE

Linda F. Alwitt, Leo Burnett Co.
Paul F. Anderson, Harvard University
David Brinberg, Baruch College
Noel Capon, Columbia University
Richard T. Curtin, University of Michigan
Sherman Hanna, Kansas State University

Program Structure

Six concurrent "tracks":

1. "Keynote" Special Sessions
2. Micro-Level Analysis of Consumer Behavior
3. Macro-Level Issues in Consumer Research
4. Effects of Marketing Variables on Consumer Behavior
5. New Methods and Measures
6. Choice Modeling/Social Influence Processes

Plus two "Paper Fair" sessions featuring a variety of consumer research topics.

Tuesday, October 17, 1985

EXECUTIVE BOARD MEETING

METRO 1
11 am - 4 pm

REGISTRATION

FOYER
4 pm - 9 pm

EARLY BIRD RECEPTION

METRO 5
6 pm - 8 pm

EARLY BIRD SPECIAL SESSION:

Everything You've Always Wanted to Know about How to Gamble: A Primer for the Uninitiated

METRO 6
7:30 pm - 8:30 pm

Chair: MICHAEL ROTHSCHILD, University of Wisconsin, Madison.

Panel: IVAN ROSS, University of Minnesota
ALLAN D. SHOCKER, Vanderbilt University

Wednesday, October 18, 1985

MORNING COFFEE

PROMENADE
8:00 am - 8:30 am

CONCURRENT SESSIONS

8:30 am - 10:00 am

1.1 Special Session: Whither ACR?

METRO 6

Co-Chairs: MORRIS B. HOLBROOK, Columbia University
ELIZABETH C. HIRSCHMAN, New York University

"Consumer Research is What Consumer Researchers Do"
PAUL F. ANDERSON, Harvard University

"What Should ACR Want to Be When It Grows Up?"
RUSSELL W. BELK, University of Utah

"Research as a Voyage of Discovery"
ALDEN G. CLAYTON, Marketing Science Institute
DIANE SCHMALENSEE, Marketing Science Institute

"Expanding the Thinkable: Consumer Research for Marketing Decisions"
GERALDINE FENNELL

"Marketing, Intellectual Creativity and Consumer Research"
ELIZABETH C. HIRSCHMAN, New York University

"Whither ACR? Some Pastoral Reflections on the Business-Research Continuum"
MORRIS B. HOLBROOK, Columbia University

"Rethinking the Domain of Consumer Behavior"
RICHARD J. LUTZ, University of Florida

"Inner Direction as a Social Character for Consumer Research"
MELANIE WALLENDORF, University of Arizona

"ACR: Interdisciplinarity, Creativity, Excitement, Discomfort, and Fun"
WILLIAM WELLS, Needham Harper Worldwide

1.2 Competitive Paper Session:

New Directions in Consumer Decision-Making Research

METRO 2

Chair: DIPANKAR CHAKRAVARTI, Duke University
Discussant: APRIL ATWOOD, University of Washington

"Some Evidence for Additional Types of Choice Simplification Strategies"
SURJIT CHHABRA, Indiana University
RICHARD W. OLSHAVSKY, Indiana University

"Related Theories of Complexity in Information Processing"
CAROLYN L. COSTLEY, University of North Carolina

"Positivity and Negativity Effects in Inferences About Products"
FRANK KARDES, Indiana University
WILLIAM M. STRAHLE, Indiana University

1.3 Special Session: The Effects of Alcoholic Beverage Advertising: Research Issues and Opportunities

METRO 3

Chair: EDWARD T. POPPER, Northeastern University

"The Effects of Alcoholic Beverage Advertising and Marketing Practices: The Current State of Affairs"
EDWARD T. POPPER, Northeastern University
Panel Discussion
ROBERT DENNISTON, NIAAA
GEORGE HACKER, CSPI
PHILIP HARDING, CBS-TV
DONALD KEENAN, Federal Trade Commission
RICHARD MIZERSKI, Florida State University

1.4 Competitive Paper Session: Situational Impact on Consumer Behavior

METRO 4

Chair: GABRIEL BIEHAL, University of Houston
Discussant: GARY BAMOSSY, Vrije Universiteit

"Toward a Methodology for Assessing Effects of In-Store Atmospherics"
MERYL PAULA GARDNER, New York University
GEORGE JOHN SIOMKOS, New York University

"Variations in Choice Strategies Across Decision Contexts: An Examination of Contingent Factors"
WAYNE D. HOYER, University of Texas-Austin

"The Person by Situation Interaction Myth: Implications for the Definition of Situations"
JOSEPH A. COTE, JR., Washington State University

1.5 Special Session: New Methods for Measuring Consumer Knowledge

METRO 1

Co-Chairs: JOSEPH W. ALBA & J. WESLEY HUTCHINSON, University of Florida
Discussant: JERRY C. OLSON, Pennsylvania State University

"Frequency Information: Its Encoding and Use as a Decision Heuristic"
JOSEPH W. ALBA, University of Florida

"Product Familiarity and the Strengths of Brand-Attribute Associations: A Signal Detection Theory Approach"
J. WESLEY HUTCHINSON, University of Florida
MICHAEL J. ZENOR, University of Florida

"The Measurement of Declarative and Procedural Knowledge"
PETER DACIN, University of Toronto
ANDREW A. MITCHELL, University of Toronto

1.6 Special Session: New Developments in Analyzing Complex Choice Problems

PALACE 6 & 7

Co-Chairs: RANDALL G. CHAPMAN, University of Alberta
JORDAN J. LOUVIERE, University of Alberta

"A Nonmetric Alternative to Traditional Model-Based Approaches to Conjoint Analysis"
PHILIPPE CATTIN, University of Connecticut

"Sequential vs. Simultaneous Estimation of Multistage Models of Perception, Preference and Choice"
RANDALL G. CHAPMAN, University of Alberta

"The Role of Choice Models in Competitive Analysis"
LEE G. COOPER, University of California, Los Angeles

"A Multistage Disaggregate Choice Model"
DENNIS H. GENSCHE, University of Wisconsin, Milwaukee

"Choice Set Configuration Effects on the Transferability of Probabilistic Choice Models"
ERIC JOHNSON, Massachusetts Institute of Technology
ROBERT MEYER, University of California, Los Angeles

"Applied Random Utility Modeling: The Options and Their Merits"
JOEL L. HOROWITZ, University of Iowa

"New Developments in Second Order Response Surface Design with Applications to Conjoint Judgment and Choice Problems"
JORDAN J. LOUVIERE, University of Alberta
DONALD A. ANDERSON, University of Wyoming

COFFEE BREAK

PROMENADE
10:00 am - 10:30 am

CONCURRENT SESSIONS

10:30 am - Noon

2.1 Special Session: Whither ACR?
(Session Continued)

METRO 6

2.2 Special Session: Perspectives on Experience and Decision Making

METRO 2

Chair: RICHARD ETTENSON, University of Maryland
Discussant: JAMES SHANTEAU, Kansas State University

"Experience vs. Expertise in Decision Making"

JACOB JACOBY, New York University
ALFRED KUSS, New York University
TRACY TROUTMAN, New York University
DAVID MAZURSKY, New York University

"Experience and Retail Buying: A Decision Making Analysis"

JANET WAGNER, University of Maryland
RICHARD ETTENSON, University of Maryland

"Experience as a Mediator in Recall and Use of Information in Consumer Decision Processes"

GARY J. GAETH, University of Iowa
CATHERINE COLE, University of Iowa

"A Categorizational Approach For Comparing Non-Comparable Alternatives"
JAMES R. BETTMAN, Duke University
MITA SUJAN, Pennsylvania State University

2.3 Special Session: Consumer Behavior and Energy Research

METRO 3

Chair: W. FRED VAN RAAIJ, Erasmus University Rotterdam
Discussant: THEO M.M. VERHALLEN, Tilburg University

"Energy Conservation Actions: Analysis of Predictors"

PATRICIA A. TRIPPLE, University of Nevada, Reno
CAROLE J. MAKELA, Colorado State University

"Determinants of Home Insulation Intentions"

W. FRED VAN RAAIJ, Erasmus University Rotterdam
THEO M.M. VERHALLEN, Tilburg University

"Marketing to Vulnerable Groups: Testing the Effects of Peers and Incentives On Elderly Response to Home Energy Audits"
R. BRUCE HUTTON, University of Denver
OLLI T. AHTOLA, University of Denver
DENNIS L. McNEILL, University of Denver

"Comparative Processes in Energy Conservation Feedback Effects"
THOMAS D. JENSEN, University of Arkansas

"A Longitudinal Study of Factors Affecting Household Energy Expenditures in Canada"
LOUISE A. HESLOP, University of Guelph

2.4 Competitive Paper Session: Retail Patronage Behavior

METRO 4

Chair: JUDITH L. ZAICHKOWSKY, Simon Fraser University
Discussant: GARY SULLIVAN, University of Texas, El Paso

"Perceived Correlates of Store Price Image: An Application of the Bootstrap"
B. KEMAL BUYUKKURT, Concordia University
MERAL BEMIRBAG BUYUKKURT, Concordia University

"Shopping Area Image: Its Factor Analytic Structure and Relationship with Shopping Trip and Expenditure Behavior"
CHOW HOU WEE, University of Singapore

"Relationships Between Affect, Patronage Frequency and Amount of Money Spent with a Comment on Affect Scaling Measurement"
LINDA L. GOLDEN, University of Texas, Austin
MARY R. ZIMMER, University of Texas, Austin

2.5 Competitive Paper Session:

Conceptualizing and Assessing Consumer Knowledge

METRO 1

Chair: VALERIE FOLKES, California State University, Fullerton
Discussant: MICHAEL D. JOHNSON, University of Michigan

"A Typology of Consumer Knowledge Content"
MERRIE BRUCKS, University of North Carolina

"Measuring Prior Knowledge"
CATHERINE COLE, University of Iowa
GARY J. GAETH, University of Iowa
SURENDRA N. SINGH, University of Kansas

"Subjective and Objective Measures of Product Knowledge Contrasted"
FRED SELNES, Norwegian Fund for Market and Distribution Research
KJELL GRONHAUG, Norwegian School of Economics and Business Administration

2.6 Special Session: New Developments in Analyzing Complex Choice Processes (Session Continued)

PALACE 6 & 7

LUNCHEON

METRO 5

Noon - 1:45 pm

Business Meeting

Chaired by: H. KEITH HUNT, Executive Secretary-Association for Consumer Research

Presidential Address

"Schemer Schema: Consumers' Intuitive Theories About Marketer Influence Tactics"
PETER WRIGHT, Stanford University

Concurrent Sessions

2:00 pm - 3:30 pm

3.1 Special Session: Perspectives on the Presidential Address

METRO 6

Chair: JAGDISH N. SHETH, University of Southern California
Participants: JAMES R. BETTMAN, Duke University
JERRY C. OLSON, Pennsylvania State University
GERALD ZALTMAN, University of Pittsburgh

3.2 Competitive Paper Session: Investigations of the Theory of Reasoned Action

METRO 2

Chair: MICHAEL J. RYAN, University of Michigan
Discussant: J. CRAIG ANDREWS, Marquette University

"Representing Attitude Structure: Issues and Evidence"

PAUL W. MINIARD, Ohio State University
THOMAS J. PAGE, JR., University of Wisconsin, Madison
APRIL ATWOOD, University of Washington
RANDALL ROSE, Ohio State University

"An Exploratory Investigation of Consumer Innovativeness and Interpersonal Influences"

WILLIAM O. BEARDEN, University of South Carolina
STEPHEN E. CALCICH, University of South Carolina
RICHARD G. NETEMEYER, University of South Carolina
JESSE E. TEEL, University of South Carolina

"The Self-Monitoring Concept: A Consumer Behavior Perspective"

JACQUES NANTEL, Ecole De Hautes Etudes Commerciales
WILLIAM STRAHLE, Indiana University

3.3 Competitive Paper Session: Consumer Perspectives on the Behavior of Markets

METRO 3

Chair: RONALD J. DORNOFF, University of Cincinnati
Discussant: ALAN R. ANDREASEN, University of California, Los Angeles

"The Concept of Consumer Market Efficiency: Toward Evaluating The Social Efficiency of Consumer Marketing"
JOHN F. GASKI, University of Notre Dame

"Defining and Evaluating Quality: The Consumer's View"
ELLEN DAY, University of Georgia
STEPHEN B. CASTLEBERRY, University of Georgia

"Marketing as an Agent of Social Change in Developing Countries: Some Public Policy Issues"
ELIZABETH C. HIRSCHMAN, New York University

3.4 Competitive Paper Session: Cognitive Processes in Advertising Response

METRO 4

Chair: JOHN R. ROSSITER, NSW Institute of Technology and the University of Pennsylvania
Discussant: CHRIS T. ALLEN, University of Cincinnati

"The Effects of Time Compressed Advertising on Brand Attitude Judgments"
DOUGLAS R. HAUSKNECHT, University of Akron
DANNY L. MOORE, Burke Marketing Services, Inc.

"Long-Term Memory for Emotional Advertising Messages"
MARIAN FRIESTAD, University of Wisconsin, Madison
ESTHER THORSON, University of Wisconsin, Madison

"The Generation Effect in Advertising Appeals"
DAVID J. MOORE, University of Oklahoma
RICHARD REARDON, University of Oklahoma
FRANCIS T. DURSO, University of Oklahoma

3.5 Special Session: Perils, Pitfalls, and Prescriptions for Research on Consumers' Scripts

METRO 1

Chair: RUTH ANN SMITH, Virginia Polytechnic Institute and State University
Discussant: DEBORAH ROEDDER JOHN, University of Wisconsin, Madison

"Four Script Studies: What Have We Learned?"
PAUL H. SCHURR, State University of New York at Albany

"Script Elicitation and Validation in Industrial Buying/Selling Settings"
THOMAS W. LEIGH, Pennsylvania State University
ARNO J. RETHANS, Pennsylvania State University

"Measuring Script Development: An Evaluation of Alternative Approaches"
RUTH ANN SMITH, Virginia Polytechnic Institute and State University
MICHAEL J. HOUSTON, University of Wisconsin, Madison

3.6 Special Session: Information Search: Models and Methods to Improve Choice Prediction

PALACE 6 & 7

Chair: MICHAEL C. HAGERTY, University of California, Berkeley

"Consumer's Prior Beliefs and Preferences as Determinants of Information Acquisition Priorities"
ITAMAR SIMONSON, Duke University
JOEL HUBER, Duke University
JOHN PAYNE, Duke University

"Consumer Search Among Stores and Brands"
BRIAN T. RATCHFORD, State University of New York, Buffalo

"Consumer Shopping Behavior, Information Flows, and Market Performance"
DAVID M. GREYER, California Institute of Technology
ALAN SCHWARTZ, California Institute of Technology
LOUIS WILDE, California Institute of Technology

"Improving Accuracy of Conjoint Analysis: Predicting What Information is Required"
MICHAEL R. HAGERTY, University of California, Berkeley

BREAK

PROMENADE

3:30 - 4:00 pm

CONCURRENT SESSIONS

4:00 - 5:30 pm

4.1 Special Session: The Transition to Post-Industrial Consumption

METRO 6

Chair: ALLADI VENKATESH, University of California, Irvine

"The Emergence of the Post-Industrial Person"
FRANCESCO NICOSIA, University of California, Berkeley

"The Emergence of the Prosumer"
PHILIP KOTLER, Northwestern University

"The Consumption of Culture and the Culture of Consumption"
JOHN SHERRY, Northwestern University

"Yuppies as Arbiters of the Emerging Consumption Style"
RUSSELL W. BELK, University of Utah

"Discontinuities in Consumption in the Post-Industrial Age"
NIK DHOLAKIA, Northwestern University and University of Rhode Island

4.2 Competitive Paper Session: Research on Memory and Categorization

METRO 2

Chair: JOHN G. LYNCH, JR., University of Florida
Discussant: JULIE EDELL, Duke University

"The Impact of Comparative Advertising on Perception Formation in New Product Introductions"

BETH A. WALKER, Pennsylvania State University

JOHN L. SWASY, Pennsylvania State University

ARNO J. RETHANS, Pennsylvania State University

"The Quintessential Snack Food: Measurement of Product Prototypes"

JAMES WARD, University of Minnesota
BARBARA LOKEN, University of Minnesota

"Retrieval Processes in Consumer Evaluative Judgment Making: The Role of Elaborative Processing, Context, and Retrieval Goals"

ALAIN d'ASTOUS, Universite de Sherbrooke

MARC DUBUC, Universite de Sherbrooke

4.3 Competitive Paper Session: Television Advertising and Consumer Miscomprehension

METRO 3

Chair: WILLIAM L. WILKIE, University of Florida
Discussant: KENNETH L. BERNHARDT, Georgia State University

"The Relationship of Miscomprehension to Deceptiveness in FTC Cases"

IVAN L. PRESTON, University of Wisconsin
JEF I. RICHARDS, University of Wisconsin

"Measuring Miscomprehension: A Comparison of Alternative Formats"

FLIECE R. GATES, University of Texas, Austin
WAYNE D. HOYER, University of Texas, Austin

"The Role of Knowledge in the Effects of Television Advertising on Children"

HENRIANNE SANFT, Carnegie-Mellon University

4.4 Competitive Paper Session: Visual and Emotional Advertising Effects

METRO 4

Chair: TERRY L. CHILDERS, University of Minnesota

Discussant: MICHAEL J. HOUSTON, University of Wisconsin, Madison

"If It Isn't A Duck Then Why Did It Quack? Competing Explanations For An Observed Effect of Illustrations in an Advertisement"

PETER R. DICKSON, Ohio State University
ROBERT E. BURNKRANT, Ohio State University

PAUL W. MINIARD, Ohio State University

"Visual Information Processing of Television Commercials: Cognitive Effects"

THOMAS D. JENSEN, University of Arkansas
LARRY W. ROTTMEYER, University of Arkansas

"Measuring Emotional Responses to Advertising"

RONALD P. HILL, American University
MICHAEL B. MAZIS, American University

4.5 Special Session: Confirmatory Multidimensional Scaling

METRO 1

Chair: LUTZ HILDEBRANDT, Technische Universitaet Berlin

"Modeling Distance Structures: Producing Useful Knowledge for Theory and Application"

DANIEL R. DENISON, University of Michigan

"Confirmatory Multidimensional Scaling in the Study of Consumer Behavior and Preference"

CLAES FORNELL, University of Michigan

"A Facet Theoretical Approach for Testing Measurement and Structural Theories: An Application of Confirmatory MDS"

LUTZ HILDEBRANDT, Technische Universitaet Berlin

"Graphic and Verbal Presentation of Stimuli: A Probabilistic MDS Analysis"

DAVID B. MACKAY, Indiana University
MARK ELLIS, Indiana University

4.6 Competitive Paper Session: Family Decision-Making

PALACE 6 & 7

Chair: NANCY THAL FRONTZAK, University of Colorado, Denver

Discussant: GEORGE E. BELCH, San Diego State University

"A Developmental Study of Family Financial Management Practices"

DONALD H. GRANBOIS, Indiana University
DENNIS L. ROSEN, Indiana University
FRANKLIN ACITO, Indiana University

"An Analysis of the Presence, Stability, and Antecedents of Husband and Wife Purchase Decision Making Influence Assessment Agreement & Disagreement"

ALVIN C. BURNS, Louisiana State University
JO ANNE HOPPER, Southeastern Louisiana University

"Television Advertising and Interpersonal Influences on Teenagers' Participation in Family Consumer Decisions"

GEORGE P. MOSCHIS, Georgia State University
LINDA G. MITCHELL, Georgia State University

4.7 Paper Fair Session I

Note: Paper numbers correspond to numbers on table placards.

Saturday, October 19, 1985

MORNING COFFEE

PROMENADE

8 am - 8:30 am

CONCURRENT SESSIONS

8:30 am - 10 am

- 5.1 Special Session:** A Revised Perspective on Diffusion Research

METRO 6

Co-Chairs: LINDA L. PRICE, and LAWRENCE F. FEICK, University of Pittsburgh

"Interdependencies Among Users of a New Technology"
EVERETT ROGERS, University of Southern California

"The Diffusion of High Technology Innovations"
THOMAS S. ROBERTSON, University of Pennsylvania
HUBERT GATIGNON, University of Pennsylvania

"The Product Enthusiast: Implications for Marketing Communications"
PETER BLOCH, Louisiana State University

"New Perspectives on Interpersonal Information Exchange"
LAWRENCE F. FEICK, University of Pittsburgh
LINDA L. PRICE, University of Pittsburgh

"Panel Discussion on Current and Future Diffusion Research"
Panelists:
JOEL B. COHEN, University of Florida
THOMAS S. ROBERTSON, University of Pennsylvania
EVERETT ROGERS, University of Southern California
GERALD ZALTMAN, University of Pittsburgh

"Concluding Remarks"
EVERETT ROGERS, University of Southern California

- 5.2 Competitive Paper Session:** Learning Theory and Consumer Behavior

METRO 2

Chair: RICHARD M. DURAND, Auburn University
Discussant: JOHN C. MOWEN, Oklahoma State University

"The Role of Radical Behaviorism in the Explanation of Consumer Choice"
GORDON ROBERT FOXALL, Cranfield School of Management

"The Opposite of Satiation: Motivational Priming as an Aftereffect of a Pleasurable Consumption Experience"
PETER J. DePAULO, University of Missouri, St. Louis

"Classical Conditioning Effects in Product/Character Pairings Presented to Children"
M. CAROLE MACKLIN, University of Cincinnati

- 5.3 Competitive Paper Session:** Sex and Consumer Behavior

METRO 3

Chair: MICHAEL BELCH, San Diego State University
Discussant: JOY WILLIAMS-JONES, NW Ayer, New York

"Sex-Linked Trait Indexes Among Baby-Boomers and Pre-Boomers: A Research Note"
BENNY BARAK, Baruch College
BARBARA STERN, Kean College

"Sex Roles and Consumer Perceptions of Promotions, Products, and Self: What Do We Know and Where Should We Be Headed?"
KATHLEEN DEBEVEC, University of Massachusetts, Amherst
EASWAR IYER, University of Massachusetts, Amherst

"Segmentation of Women's Market Based on Personal Values and Means-End Chain Model: A Framework for Advertising Strategy"
VED PRAKASH, Florida International University

- 5.4 Special Session:** The Impact of Television Program Context on Advertising Effectiveness

METRO 4

Chair: DONNA L. HOFFMAN, Columbia University

"Contingent Effects of Program Environment on Advertising Effectiveness"
DONNA L. HOFFMAN, Columbia University
RAJEEV BATRA, Columbia University

"Viewer Processing of Commercial Messages: Context and Involvement Preliminary Results"
C.W. PARK, University of Pittsburgh
GORDON W. McCLUNG, University of Pittsburgh
WILLIAM J. SAUER, University of Pittsburgh

"Over-Time Analyses of Viewer Involvement in Programming and Commercials"
ESTHER THORSON, University of Wisconsin, Madison
BYRON REEVES, University of Wisconsin, Madison

- 5.5 Special Session:** Photographic Stimuli, Data and Consumption Symbolism

METRO 1

Chair: SIDNEY J. LEVY, Northwestern University

"Emotions and Clothing Disposition"
MELANIE WALLENDORF, University of Arizona
ROBERT A. WESTBROOK, University of Arizona

"Consumers' Video Archives and Household Rituals"
DENNIS W. ROOK, University of Southern California

"Familiar Interlude: Autodriving in Consumer Analysis"
DEBORAH D. HEISLEY, Northwestern University
SIDNEY J. LEVY, Northwestern University

5.6 Special Session: Irrationality, Inconsistency, and Context Effects

PALACE 6 & 7

Chair: DONALD R. LEHMANN, Columbia University
Discussant: JOHN W. PAYNE, Duke University

"Situational Narratives vs. Simple Gambles: Is There a Differential Effect of Choice?"
JOEL HUBER, Duke University
CHRISTOPHER P. PUTO, University of Michigan

"Effects of the Cooperative Group Decision-Making Context on Preference Ratings"
KIM P. CORFMAN, Columbia University

"Certainty and Uncertainty in Risky Consumer Choice Contexts"
RASHI GLAZER, Columbia University
BARBARA KAHN, University of California, Los Angeles

COFFEE BREAK

PROMENADE

10:00 am - 10:30 am

CONCURRENT SESSIONS

10:30 am - Noon

6.1 Special Session: A Revised Perspective on Diffusion Research (Session Continued)

METRO 6

6.2 Special Session: Delayed Persuasive Effects of Advertising

METRO 2

Chair: ROBERT M. SCHINDLER, University of Chicago
Discussants: ROBERT M. SCHINDLER, University of Chicago
LINDA ALWITT, Leo Burnett Co.

"Expectations, Advertising, and Product Trial in Product Evaluation"
STEPHEN J. HOCH, University of Chicago
YOUNG WON HA, University of Chicago

"Persuasion as Directed Inference"
JOHN DEIGHTON, Dartmouth College

"The Effect of Delay on Advertisements Differing in Vividness"
JOLITA KISIELIUS, University of Illinois, Chicago

"Memory of Ads: A Schema-Based Model of Advertising Response"
JAMES HUNT, Temple University
JEROME B. KERNAN, University of Cincinnati
E.H. BONFIELD, Rider College

6.3 Special Session: Dialogues Across Methods and Meta-Theories: A Move Toward New Conceptualizations of Culture and Ethnicity

METRO 3

Chair: THOMAS C. O'GUINN, University of Illinois, Urbana-Champaign

"Materialism and Individual Determinism in U.S. and Japanese Print and Television Advertising"
RUSSELL W. BELK, University of Utah
WENDY J. BRYCE, University of Utah

"A Cultivist Perspective on the Investigation of Culture"
JOHN SHERRY, Northwestern University

"Effects of Stereotyping in Crosscultural Research: Are the Chinese Really Chinese?"
JAMES McCULLOUGH, Washington State University
CHIN TIONG TAN, National University of Singapore

"Acculturation: The Impact of Divergent Paths on Buyer Behavior"
THOMAS C. O'GUINN, University of Illinois, Urbana-Champaign
WEI-NA LEE, University of Illinois, Urbana-Champaign
RONALD J. FABER, University of Texas, Austin

6.4 Special Session: Perceptions and Knowledge of Price in the Supermarket

METRO 4

Chair: ALAN G. SAWYER, University of Florida

"Price Perceptions of Supermarket Shoppers at the Point of Purchase"
PETER R. DICKSON, Ohio State University
ALAN G. SAWYER, University of Florida

"The Accuracy of Price Knowledge: Issues in Research Methodology"
JERRY N. CONOVER, University of Northern Arizona

"The Influence of Price Awareness on Price Perceptions"
KENT B. MONROE, Virginia Polytechnic Institute and State University
PRAVAT K. CHOUDHURY, Howard University

6.5 Special Session: Innovative Analytical Methods

METRO 1

Chair: DAVID BRINBERG, Baruch College, CUNY

"An Idiographic Analysis of Consumer Behavior"
JAMES JACCARD, State University of New York, Albany
GREG WOOD, State University of New York, Albany

"Investigating Linear Structural Relations: Use and Misuse of LISREL"
WILLIAM R. DILLON, Baruch College, CUNY

"Meta-Analytical Techniques for the Quantitative Integration of Research Findings"
DAVID BRINBERG, Baruch College, CUNY
JAMES JACCARD, State University of New York, Albany

"Social Interaction Data: Procedural and Analytical Strategies"
DANNY L. MOORE, Burke Marketing Services, Inc.

6.6 Special Session: New Directions in Hierarchical Models of Consumer Choice

PALACE 6 & 7

Chair: RASHI GLAZER, Columbia University
Discussant: DONALD LEHMANN, Columbia University

"An Algorithmic Approach to the Induction of Hierarchical Choice Processes"
IMRAN CURRIM, University of California, Los Angeles
ROBERT MEYER, University of California, Los Angeles

"A Maximum Likelihood Disaggregate Model Utilizing Intervals Scaled Attributes in a Non-Tree Structure"
DENNIS GENSCHE, University of Wisconsin, Milwaukee

"An Experiment in External Constrained Choice"
BARBARA KAHN, University of California, Los Angeles
WILLIAM L. MOORE, University of Utah
RASHI GLAZER, Columbia University

"Phased Decision-Making at the Product Class Level"
C.W. PARK, University of Pittsburgh

LUNCHEON

METRO 5

Noon - 1:45 pm

Presentation of Ferber Awards
JAMES R. BETTMAN, Duke University

Presentation of Association for Consumer Research Fellows in Consumer Behavior Awards

JOSEPH W. NEWMAN, University of Arizona

Fellows' Addresses

"Consumer Research: Some Recollections and a Commentary"
HAROLD H. KASSARJIAN, University of California, Los Angeles

"Three Useful Ideas"
WILLIAM D. WELLS, Needham Harper Worldwide

CONCURRENT SESSIONS

2:00 pm - 3:30 pm

7.1 Special Session: Perspectives on ACR Fellows' Addresses

METRO 6

Chair: JOSEPH W. NEWMAN, University of Arizona
Participants: JOEL B. COHEN, University of Florida
SIDNEY J. LEVY, Northwestern University
JOHN G. MYERS, University of California, Berkeley
MICHAEL L. RAY, Stanford University

7.2 Competitive Paper Session: Affect and Cognition in Consumer Decision-Making

METRO 2

Chair: DEBORAH LEVY MARLINO, Massachusetts Institute of Technology
Discussant: DENA T. SALIAGAS, Georgia State University

"Effects of Affect on Judgment About Products"
GULIZ GER, University of Illinois, Chicago

"Affect and Cognition: A Closer Look at Two Competing Theories"
JAMES A. MUNCY, Texas Tech University

"Consumer Response to Marketing Stimuli: The Relationship between Affect, Cognition, and Behavior"
CAROL PLUZINSKI, University of Michigan
WILLIAM J. QUALLS, University of Michigan

7.3 Competitive Paper Session: Consumer Behavior in the Nonprofit Sector

METRO 3

Chair: J. MICHAEL MUNSON, University of Santa Clara
Discussant: MICHAEL B. MENASCO, University of California, Riverside

"A Model to Explain Charitable Donation/Health Care Consumer Behavior"
JERRY A. ROSENBLATT, McGill University
ALAIN J. CUSSON, University of Sherbrooke

"Understanding Donor Behavior: A Classification Paradigm"
JANE R.Z. SOJKA, Indiana University

"Toward a Theory of College Selection: A Model of College Search and Choice Behavior"
RANDALL G. CHAPMAN, University of Alberta

7.4 Special Session: New Approaches to Pricing and Sales Promotions for Packaged Goods

METRO 4

Chair: DIANE SCHMALENSEE, Marketing Science Institute
Discussant: LEIGH McALISTER, Massachusetts Institute of Technology

"The Relationship Between Price and Value"
CARL OBERMILLER, University of Washington

"Measuring Perceived Value for Packaged Goods"
VALARIE A. ZEITHAML, Texas A&M University

"The Long-Term Effects of Deal Retraction"
K. SRIDHAR MOORTHY, Yale University
RASHI GLAZER, Columbia University

"Factors Affecting Discount Depth and Duration"
JAMES LATTIN, Stanford University

7.5 Special Session: Applying Humanistic Methods To Consumer Research: Four Practical Examples

METRO 1

Chair: ELIZABETH C. HIRSCHMAN, New York University

"Wasps as Consumers: A Personal View"
ELIZABETH C. HIRSCHMAN, New York University

"I'm Hip: An Autobiographical Account of Some Musical Consumption Experiences"
MORRIS B. HOLBROOK, Columbia University

"Deep-Seated Materialism: The Case of Levi's Jeans"
MICHAEL R. SOLOMON, New York University

"Lifestyle Inference from Consumer Artifacts: Going Beyond What They Say"
MELANIE WALLENDORF, University of Arizona

7.6 Competitive Paper Session: Testing Formal Theories of Choice Behavior

PALACE 6 & 7

Chair: FLEMMING HANSEN, University of Copenhagen
Discussant: CHRISTOPHER P. PUTO, University of Michigan

"The Framing of the Insurance Purchase Decision"

JOSHUA L. WIENER, Oklahoma State University
JAMES W. GENTRY, Oklahoma State University
RONALD K. MILLER, Oklahoma State University

"Some Can, Some Can't and Some Don't Know How They Did It: A Direct Test of the Utility Maximization Hypothesis"
PETER R. DICKSON, Ohio State University
JOEL E. URBANY, University of South Carolina
PAUL W. MINIARD, Ohio State University

"A Conditional Logit Model of Household Attitudes, Mobility Expectations and the Probability of Homeownership: Studying the Influence of Value Systems on Consumption-Investment Decisions"
STEVEN D. SILVER, University of California, Davis

BREAK

PROMENADE

3:30 pm - 4:00 pm

CONCURRENT SESSIONS

4:00 pm - 5:30 pm

8.1 Special Session: Ferber Awards

METRO 6

Co-Chairs: JAMES R. BETTMAN, Duke University
HAROLD H. KASSARJIAN, University of California, Los Angeles

Award Winner

"The Framing of Buying Decisions"
CHRISTOPHER P. PUTO, University of Michigan

Honorable Mentions

"The Role of Attention in Mediating the Effect of Advertising on Attribute Importance"
SCOTT B. MACKENZIE, Indiana University

"The Ritual Dimension of Market Behavior"
DENNIS W. ROOK, University of Southern California

8.2 Special Session: Theoretical and Applied Perspectives in Understanding the Effect of Emotional Advertising

METRO 2

Co-Chairs: DAVID AAKER, University of California, Berkeley
ANDREW MITCHELL, University of Toronto
Discussant: WILLIAM WELLS, Needham Harper Worldwide

"Alternative Models of How 'Feeling' Advertisements May Work"
ANDREW MITCHELL, University of Toronto

"Affect in Advertising: Theory, Method and Application"
RAJEEV BATRA, Columbia University
MICHAEL RAY, Stanford University

"The Effect of Feelings Generated from Advertisements on Brand Response"
DAVID AAKER, University of California, Berkeley
DOUGLAS STAYMAN, University of Texas

8.3 Special Session: International Perspectives on Television Advertising and Children

METRO 3

Chair: THOMAS S. ROBERTSON, Wharton School, University of Pennsylvania
Discussant: W. FRED VAN RAAIJ, Erasmus University Rotterdam

"Children's Relationships Between Repetition and Effect"
THEO B.C. POIESZ, Tilburg University

"The 'Helplessness Syndrome' and Children's Media Behavior"
PETER VITOUCH, Institute Fur Psychologie Der Universitat Wien

"Parental Mediation of Television Advertising: A Cross-Cultural Study"
THOMAS S. ROBERTSON, University of Pennsylvania
SCOTT WARD, University of Pennsylvania
DONNA M. KLEES, University of Pennsylvania

8.4 Competitive Paper Session: Consumer Response to Price and Promotion

METRO 4

Chair: IVAN ROSS, University of Minnesota
Discussant: MARIAN C. BURKE, Duke University

"New Evidence Concerning Consumer Price Limits"
ANTHONY D. COX, Georgia State University

"The Effects of Sampling and Information on Brand Choice When Beliefs in Quality Differences are Ambiguous"
GEORGE BROOKER, University of Puget Sound
JOHN J. WHEATLEY, University of Washington
JOHN S.Y. CHIU, University of Washington

"An Examination of Consistency in Coupon Usage by Households across Product Classes"

KAPIL BAWA, New York University
ROBERT W. SHOEMAKER, New York University

8.5 Competitive Paper Session: New Measurement Technologies

METRO 1

Chair: ROHIT DESHPANDE, University of Texas-Austin
Discussant: MARTIN LAUTMAN, Arbor, Inc.

"Holistic Conjoint"

CAROLINE M. HENDERSON, Dartmouth University
DAVID J. REIBSTEIN, University of Pennsylvania

"Processing Complexity in Magnitude Versus Category Scaling"

BRUNO NEIBECKER, University of the Saarland

"Q-Tips: Using Qualitative and Quantitative Techniques in Tandem to Assess Reliability of Manipulations"

DON R. RAHTZ, College of William and Mary
DAVID L. MOORE, College of William and Mary

8.6 Competitive Paper Session: Social Influence in Consumer Behavior

PALACE 6 & 7

Chair: ARCH G. WOODSIDE, Tulane University
Discussant: HARISH SUJAN, Pennsylvania State University

"Self-Monitoring and Product Conspicuousness on Reference Group Influence"

DAVID BRINBERG, Baruch College, CUNY
LINDA PLIMPTON, Ohio State University

"People Who Use People: The Other Side of Opinion Leadership"

LAWRENCE F. FEICK, University of Pittsburgh
LINDA L. PRICE, University of Pittsburgh
ROBIN A. HIGIE, University of Pittsburgh

"Source Credibility: On the Independent Effects of Trust and Expertise When Attractiveness is Held Constant"

JOSHUA L. WIENER, Oklahoma State University
JOHN C. MOWEN, Oklahoma State University

8.7 Paper Fair Session II

Note: Paper numbers correspond to numbers on table placards.

METRO 5

S1. "Health-Related Aspects of Consumer Products: A New Determinant Attribute in Consumer Decision-Making"

JOEL RUDD, University of Arizona
GEORGE B. SPROLES, University of Arizona

S2. "Nutritional Evaluation and Safety of Various Food Items"

CHARLES WEBER, University of Arizona

S3. "Dermatological and Toxicological Problems Associated With Clothing and Household Textiles"

KATHRYN HATCH, University of Arizona

S4. "Designing Products for the Disabled: The Case of Clothing"

NAOMI REICH, University of Arizona

S5. "Barrier-Free Housing, Interiors and Furnishings: Problems Experienced by the Elderly and Disabled"

ROGER KRAMER, University of Arizona

S6. "Substance Use and Abuse in Special Populations: The Case of Alcohol and the Senior Citizen"

VICTOR CHRISTOPHERSON, University of Arizona

S7. "Clothing-Related Risk Perceptions of Disabled People"

PAULA BOUNDS-O'BANNON, K-Mart Incorporated
BETTY FEATHER, University of Missouri-Columbia
JOHN W. VANN, University of Missouri-Columbia

S8. "Applying Disengagement Theory from Social Gerontology to Predict and Explain Segments Within the Senior Market"

WILLIAM A. WEEKS, Washington State University

S9. "Consumer Involvement Related to Apparel Purchase Behavior"

ANNE-LOUISE VREEMAN, University of Wisconsin, Stevens Point
MICHELLE A. MORGANOSKY, University of Illinois

S10. "Retail Patronage Behavior: An Empirical Analysis of Purchasing Behavior in Alternative Areas"

MAIJA ROKMAN, University of Tampere

S11. "Understanding Investment Fraud: In Search of the Pot of Gold at the End of the Rainbow"

JAMES H. McALEXANDER, University of Utah
DEBRA L. SCAMMON, University of Utah

S12. "Factors Affecting the Development of Consumer and Non-Consumer Scripts in Children: Mindlessness, Temporality, Societal Influence, and Virginity"

AUDREY GUSKEY FEDEROUCH, University of Pittsburgh

S13. "Modeling Multiattribute Group Choice Behavior"

SUNIL GUPTA, Columbia University
DUANGTIP TANTIWONG, Fairleigh Dickinson University

S14. "Modeling the Process of Attribute Belief Formation"

GARY ERICKSON, University of Washington
CARL OBERMILLER, University of Washington

S15. "A Threshold-Based Disaggregate Noncompensatory Choice Model: Concepts and Issues"

DENNIS H. GENSCH, University of Wisconsin-Milwaukee
JOSEPH A. SVETKA, Cleveland State University
RAJSHEKHAR G. JAVALGI, University of Wisconsin-Milwaukee

Sunday, October 20, 1985

S16. "Amplification of the Bipolar Scale Response: Why Unipolar Scales Should Be Used"
ROBERT GILMORE, New York University

S17. "Physical Fitness: An Investigation of Consumer Involvement"
KENT L. GRANZIN, University of Utah
JANEEN E. OLSEN, University of Utah

S18. "Approach to Life Scale"
RICHARD HESLIN, Purdue University
BLAIR JOHNSON, Purdue University

S19. "The Effects of Comparative Advertising on the Evaluation of Information"
P.J. O'CONNOR, Baruch College
JOAN ROSENBERG, Baruch College
IRA BLOOM, Baruch College
LORRAINE ABRUZZO, Baruch College

S20. "A State Variables Reformulation of the Howard and Sheth Model"
PAMELA HOMER, University of Oregon

S21. "Social Adaptation Theory in Consumer Behavior"
LYNN R. KAHLE, University of Oregon
PAMELA M. HOMER, University of Oregon
SHARON E. BEATTY, University of Oregon

S22. "Interspousal Interactive Role Estimations Across Family Decision Making Stages"
OSWALD MASCARENHAS, University of Detroit
RAM KESAVAN, University of Detroit

S23. "The Effect of Color vs. Black and White Advertising Formats on Affective Ratings and Perceptions of Product Quality"
WAYNE D. HOYER, University of Texas
ROBERT L. LEONE, University of Texas
CATHY J. COBB, University of Illinois

Sessions End 5:30 pm

COCKTAIL PARTY

METRO 5

6:30 pm - 8:00 pm

MORNING COFFEE

PROMENADE

8 am - 8:30 am

CONCURRENT SESSIONS

8:30 am - 10:00 am

9.1 **Special Session:** The Use of Alternative Measures of Memory to Understand Advertising Effects

METRO 6

Co-Chairs: ANN BEATTIE, Columbia University
ANDREW MITCHELL, University of Toronto

"Effects of Advertising Repetition and Information Content on Brand Attitude Structure"
RAJEEV BATRA, Columbia University

"Advertising Effects on the Attitude-Behavior Relationship"
IDA BERGER, University of Toronto
ANDREW MITCHELL, University of Toronto

"Brand Name Familiarity and Advertising: Effects on the Evoked Set and Brand Evaluations"
WILLIAM E. BAKER, University of Florida
J. WESLEY HUTCHINSON, University of Florida
DANNY L. MOORE, Burke Marketing Services, Inc.
PRAKASH NEDUNGADI, University of Toronto

"A Model of Consumer Memory and Judgment"
THOM SRULL, University of Illinois, Urbana-Champaign

"Effect of Advertising Memory Cues on Brand Evaluations"
KEVIN LANE KELLER, University of California, Berkeley

"Acquisition of Product Information: Tangibility Effects on Attitude Components"
ANN BEATTIE, Columbia University

9.2 **Special Session:** Changing Views of Children's Consumer Information Processing

METRO 2

Chair: DEBORAH ROEDDER JOHN, University of Wisconsin, Madison
Discussant: NOEL CAPON, Columbia University

"Understanding Young Consumers: Cognitive Abilities and Task Conditions"
DEBORAH ROEDDER JOHN, University of Wisconsin, Madison

"The Impact of Task Conditions on Young Children's Performance"
M. CAROLE MACKLIN, University of Cincinnati

"Factors Affecting Children's Cognitive Responses to Television Advertising"
MERRIE BRUCKS, University of North Carolina
MARVIN E. GOLDBERG, McGill University
GARY M. ARMSTRONG, University of North Carolina

"Reasoning about Value: Why Children Understand Social Scarcity Before They Understand Scarcity in the Abstract"
TRUDY KEHRET-WARD, University of California, Berkeley

9.3 **Competitive Paper Session:** Consumer Satisfaction in the Health Care Domain

METRO 3

Chair: MARY GILLY, University of California, Irvine
Discussant: DAVID KRUEGEL, San Jose State University

"Satisfaction and Consumer Services"
DONNA J. HILL, Indiana University

"The Determinants of Satisfaction for a High Involvement Product: Three Rival Hypotheses and their Implications in the Health Care Context"
MARY BETH BARBER, University of Pittsburgh
MEERA VENKATRAMAN, University of Pittsburgh

"Research on Patient Satisfaction: Potential Directions"
RUTH B. SMITH, University of Maryland
PAUL N. BLOOM, University of North Carolina

9.4 Competitive Paper Session: The Role of Symbolism in Consumer Behavior

METRO 4

Chair: C.W. PARK, University of Pittsburgh
Discussant: MERYL PAULA GARDNER, New York University

"The Creation of Product Symbolism"
ELIZABETH C. HIRSCHMAN, New York University

"How Consumer Sub-Cultures Code Reality: A Look at Some Code Types"
JEFFREY F. DURGEE, Rensselaer Polytechnic Institute

"A Framework of Psychological Meaning of Products"
ROBERTO FRIEDMAN, University of Georgia
V. PARKER LESSIG, University of Kansas

9.5 Competitive Paper Session: New Concepts and Methods in Consumer Research

METRO 1

Chair: ANGELINA VILLARREAL-CAMACHO, San Diego State University
Discussant: P.J. O'CONNOR, City University of New York

"Methodological Limitations of the Hedonic Consumption Paradigm and a Possible Alternative: A Subjectivist Approach"
LAUREL ANDERSON HUDSON, Virginia Polytechnic Institute and State University
JEFF B. MURRAY, Virginia Polytechnic Institute and State University

"The Micawber Connection"
WILLIAM D. WELLS, Needham Harper Worldwide
THOMAS C. O'GUINN, University of Illinois
MARTIN I. HORN, Needham Harper Worldwide

"Information Utilization: A Validation Study"
PETER C. WILTON, University of California-Berkeley

9.6 Competitive Paper Session: Research on Consumer Socialization

PALACE 6 & 7

Chair: PETER REINGEN, Arizona State University
Discussant: SUSAN SPIGGLE, University of Connecticut

"Parental Diffusion Roles and Effects of Nutrition Education on Parents and Children"

SANFORD GROSSBART, University of Nebraska, Lincoln
LAWRENCE CROSBY, Arizona State University
LAURIE SMITH, University of Nebraska, Lincoln

"Family Communication Influences on the Development of Consumer Behavior: Some Additional Findings"

GEORGE P. MOSCHIS, Georgia State University
ANDJALI E. PRAHASTO, Georgia State University
LINDA G. MITCHELL, Georgia State University

"Family Decision Making in Leisure-Time Activities: An Exploratory Investigation of the Impact of Locus of Control and Parental Type on Perceived Child Influence"
WILLIAM K. DARLEY, Indiana University
JEEN SU LIM, University of Toledo

COFFEE BREAK

PROMENADE

10:00 am - 10:30 am

CONCURRENT SESSIONS

10:30 am - Noon

10.1 Special Session: The Use of Alternative Measures of Memory to Understand Advertising Effects (Session continued)

METRO 6

10.2 Special Session: The Multiple Roles of Music in Advertising

METRO 2

Chair: RICHARD F. YALCH, University of Washington
Discussant: JAMES CARLSEN, University of Washington

"Chasing the Wundt Curve: An Adventure in Consumer Esthetics"

PUNAM ANAND, New York University
MORRIS B. HOLBROOK, Columbia University

"The Complete Angler: Luring the Listener with Barbed and Barbless Hooks"
CARL OBERMILLER, University of Washington
APRIL ATWOOD, University of Washington

"Memory in a Jingle Jungle: Music as a Mnemonic Device in Advertising"
RICHARD F. YALCH, University of Washington
REBECCA ELMORE-YALCH, Market Decision Associates

10.3 Special Session: Debatable Issues in Consumer Satisfaction and Complaining Behavior

METRO 3

Co-Chairs: RALPH L. DAY, Western Michigan University
H. KEITH HUNT, Brigham Young University

"A Post-Dissatisfaction View of Complaining Behavior"
RALPH L. DAY, Western Michigan University

"Satisfaction as a Process: Origins and Dimensions"
FRANCESCO M. NICOSIA, University of California, Berkeley
PETER C. WILTON, University of California, Berkeley

"An Extended Perspective on Post-Purchase Phenomena: Is Satisfaction a Red Herring?"
RICHARD L. OLIVER, University of Pennsylvania

"Towards a Model of Consumer Redress Behavior"
JAMES D. FORBES, University of British Columbia
DAVID K. TSE, University of British Columbia

10.4 Competitive Paper Session: Consumer Response to New Products

METRO 4

Chair: PHILIP HENDRIX, Emory University
Discussant: WAYNE D. HOYER, University of Texas, Austin

"A Conjoint Model for Analyzing New Product Positions in a Differentiated Market with Price Competition"
JORDAN J. LOUVIERE, University of Alberta

"Consumer Reactions to Stylistic Extension of a Product-Line: The Theoretical Relevance of Two 'Anchoring' Theories"
KATHY L. PETTIT, Washington State University

"Perceived Risk as a Mediator in Repetition-Affect Relationships"
THEO B.C. POIESZ, Tilburg University

10.5 Competitive Paper Session: Measurement of Consumer Lifestyle Dimensions

METRO 1

Chair: WINSTON MAHATOO, McMaster University
Discussant: THOMAS J. PAGE, JR., University of Wisconsin, Madison

"Measure Validation in Consumer Research: A Confirmatory Factor Analysis of the Voluntary Simplicity Lifestyle Scale"
DEBORAH L. COWLES, Arizona State University
LAWRENCE A. CROSBY, Arizona State University

"The Congruence of Alternative OSL Measures with Consumer Exploratory Behavior Tendencies"
RUSSELL G. WAHLERS, University of Notre Dame
MARK G. DUNN, University of Notre Dame
MICHAEL J. ETZEL, University of Notre Dame

"Toward a Construct of Convenience in Consumer Research"
LAURA YALE, University of California, Irvine
ALLADI VENKATESH, University of California, Irvine

10.6 Competitive Paper Session: Research on the Consumer Adoption Process

PALACE 6 & 7

Chair: RICHARD J. SEMENIK, University of Utah
Discussant: MICHAEL D. REILLY, Montana State University

"A Re-Examination of Communication Channel Usage by Adopter Categories"
LINDA L. PRICE, University of Pittsburgh
LAWRENCE F. FEICK, University of Pittsburgh
DANIEL C. SMITH, University of Pittsburgh

"Correlates of Search Patterns for an Innovation"
JAMES W. HARVEY, George Mason University

"Communicating Innovations: Convincing Computer Phobics to Adopt Innovative Techniques"
THOMAS HILL, University of Tulsa
NANCY D. SMITH, University of Tulsa
MILLIARD F. MANN, University of Tulsa

Conference Ends Noon Sunday

TABLE OF CONTENTS

PRESIDENTIAL ADDRESS

"Schemer Schema: Consumers' Intuitive Theories About Marketers' Influence Tactics".....1
 Peter Wright, Stanford University

ACR FELLOWS' AWARDS

"Presentation of the ACR Fellow in Consumer Behavior Award".....4
 Joseph W. Newman, University of Arizona

"Consumer Research: Some Recollections and a Commentary".....6
 Harold H. Kassajian, University of California, Los Angeles

"Three Useful Ideas".....9
 William D. Wells, Needham Harper Worldwide

COMPETITIVE PAPERS

"Some Evidence for Additional Types of Choice Strategies".....12
 Surjit Chhabra, Indiana University
 Richard W. Olshavsky, Indiana University

"Related Theories of Complexity in Information Processing".....18
 Carolyn L. Costley, University of North Carolina

"Positivity and Negativity Effects in Inferences About Products".....23
 Frank R. Kardes, Indiana University
 William M. Strahle, Indiana University

"Toward A Methodology for Assessing Effects of In-store Atmospherics".....27
 Meryl P. Gardner, New York University
 George J. Sionkos, New York University

"Variations in Choice Strategies Across Decision Contexts: An Examination of Contingent Factors".....32
 Wayne D. Hoyer, University of Texas, Austin

"The Person by Situation Interaction Myth: Implications for the Definition of Situations".....37
 Joseph A. Cote, Jr., Washington State University

"Perceived Correlates of Store Price Image: An Application of the Bootstrap".....42
 B. Kemal Buyukkurt, Concordia University
 Meral D. Buyukkurt, Concordia University

"Shopping Area Image: Its Factor Analytic Structure and Relationships with Shopping Trips and Expenditure Behavior".....48
 Chow Hou Wee, National University of Singapore

"Relationships Between Affect, Patronage Frequency and Amount of Money Spent with a Comment on Affect Scaling and Measurement".....53
 Linda L. Golden, University of Texas, Austin
 Mary R. Zimmer, University of Texas, Austin

"A Typology of Consumer Knowledge Content".....58
 Merrie Brucks, University of North Carolina

"Measuring Prior Knowledge".....64
 Catherine A. Cole, University of Iowa
 Gary Gaeth, University of Iowa
 Surendra N. Singh, University of Kansas

"Subjective and Objective Measures of Product Knowledge Contrasted".....67
 Fred Selnes, Norwegian Fund for Market and Distribution Research
 Kjell Gronhaug, Norwegian School of Economics and Business Administration

"Representing Attitude Structure: Issues and Evidence".....72
 Paul W. Miniard, Ohio State University
 Thomas J. Page, Jr., University of Wisconsin, Madison
 April Atwood, University of Washington
 Randall L. Rose, Ohio State University

"An Exploratory Investigation of Consumer Innovativeness and Interpersonal Influences".....77
 William O. Bearden, University of South Carolina
 Stephen E. Calcich, University of South Carolina
 Richard G. Netemeyer, University of South Carolina
 Jesse E. Teel, University of South Carolina

"The Self-Monitoring Concept: A Consumer Behavior Perspective".....83
 Jacques A. Nantel, Ecole De Hautes Etudes Commerciales
 William Strahle, Indiana University

"The Concept of Consumer Market Efficiency: Toward Evaluating the Social Efficiency of Consumer Marketing".....	88
John F. Gaski, University of Notre Dame	
"Defining and Evaluating Quality: The Consumer's View".....	94
Ellen Day, University of Georgia	
Stephen B. Castleberry, University of Georgia	
"Marketing as an Agent of Change in Subsistence Cultures: Some Dysfunctional Consumption Consequences".....	99
Elizabeth C. Hirschman, New York University	
"The Effects of Time Compressed Advertising on Brand Attitude Judgments".....	105
Douglas R. Hausknecht, University of Akron	
Danny L. Moore, Burke Marketing Services, Inc.	
"Emotion-Eliciting Advertising: Effects on Long Term Memory and Judgment".....	111
Marian Friestad, University of Wisconsin-Madison	
Esther Thorson, University of Wisconsin-Madison	
"The Generation Effect in Advertising Appeals".....	117
David J. Moore, University of Oklahoma	
Richard Reardon, University of Oklahoma	
Francis T. Durso, University of Oklahoma	
"The Impact of Comparative Advertising on Perception Formation in New Product Introductions".....	121
Beth A. Walker, Pennsylvania State University	
John L. Swasy, Pennsylvania State University	
Arno J. Rethans, Pennsylvania State University	
"The Quintessential Snack Food: Measurement of Product Prototypes".....	126
James Ward, University of Minnesota	
Barbara Loken, University of Minnesota	
"Retrieval Processes in Consumer Evaluative Judgment Making: The Role of Elaborative Processing, Context and Retrieval Goals".....	132
Alain d'Astous, Universite De Sherbrooke	
Marc Dubuc, National Bank of Canada	
"The Relationship of Miscomprehension to Deceptiveness in FTC Cases".....	138
Ivan L. Preston, University of Wisconsin	
Jef I. Richards, University of Wisconsin	
"Measuring Miscomprehension: A Comparison of Alternate Formats".....	143
Flicee R. Gates, University of Texas, Austin

PRESIDENTIAL ADDRESS
SCHEMER SCHEMA: CONSUMERS' INTUITIVE THEORIES
ABOUT MARKETERS' INFLUENCE TACTICS

Peter Wright, Stanford University

I'd like to use this occasion to wonder aloud about a topic that I've been wondering privately about for some time. It's something I think many people would take for granted that we, as students of consumer psychology, obviously must know about; something that I too think we obviously should know about; but something we don't know much about. It's a theme each of the following incidents brings to mind:

On the second day of class, a student in my introductory advertising course states her strong view that a particular TV ad is highly effective because it's funny and because a celebrity, Bill Cosby, is in it.

I'm sitting in a tavern at Half Moon Bay on the Northern California coast. Two grizzled commercial fishermen sit nearby. I overhear them eagerly agreeing that subliminal messages are the key to successful advertising. One of them concludes that he could increase the amount of salmon he sells direct to locals off his boat if he could figure a way to paint a subliminal image into his "Fresh Fish" sign.

A sweet neophyte real estate agent who I know marvels aloud about all the tortured plotting and strategizing that house sellers and buyers engage in, about all the times she hears people reason "now if we do this, here's what they'll do because they're thinking that...". And, from repeatedly interacting with buyers, sellers, and other sales agents herself, I hear her begin to piece together her own intuitive hypotheses about how to nurture and influence people's bargaining and decision making.

Stew Bither and I are about to run an experiment to see if and when distraction increases an ad's persuasive impact. We nervously joke to each other that subjects will probably blurt out, midway through the ad, "Aha! The old 'Distraction Hypothesis'!"

A PhD student from the Economics department (of all places) comes to me and says the takeoff point for his dissertation is the assumption that consumers sometimes interpret a retailer's "Grand Opening Sale" as an intended signal to them about his cost structure and probable future competitive strategies. He asks what we know about the prevalence of that particular type of inference by consumers. I reply, "It sounds plausible and intriguing. But we know nothing, really. So, you're safe."

I pass out course evaluation questionnaires and say, nervously, "You know, some researchers have used the end-of-course Nielsen ratings as a setting for studying how attitudes can be changed. If I was to be really Machiavellian, here's what I'd do to increase the ratings you give. I would". Afterwards, several students say, "Gee, what you described doing is just what our Finance Professor did when we did his course ratings." I reply, "Oh really. How clever."

Finally, I'm asked to comment about recent research on "attitudes-toward-the ad." So I begin pondering how respondents produce answers to questions like "was that ad convincing?" or "was that a good or bad ad?". It occurs to me that they may interpret "good" in this context to mean "good at doing what ads are designed to do." And that to answer either question, they may well rely on personal theories they harbor about what makes ads persuasive. They're responding as critics, not as audience members.

Isn't it very plausible that people have intuitive theories about the tactics that are used in the game of marketplace selling-and-buying? They surely must have personal insights

that are pertinent for realizing "Aha! Somebody's scheming to sell me something! Somebody's trying to mind-screw me!", and for interpreting and evaluating and dealing with whatever influence tactics are being used. I'll call such an intuitive theory about marketers' influence tactics a "schemer schema." We don't know much about consumers' "schemer schema," about whether they're simplistic or complex, correct or incorrect, how often they're activated, or how easily they're modified. It's not something we've chosen to study directly. I'd like to speculate a little about that, and about why it'd be interesting to know more.

Why Haven't We Studied "Schemer Schema"?

Looking back, there are several reasons why consumer researchers haven't focused directly on people's intuitive theories about marketers' influence tactics. "Basic" behavioral scientists in general haven't studied this topic. Social psychologists, for example, have for decades studied the persuasion and education process. But they've almost always framed the research question as "what works," that is, what actually causes a change in people's preferences. Not what do the targets or the purveyors of influence attempts in everyday life believe about the social influence process --- about what tactics people are likely to try; about what tactics work, and when and why; and about how then to adjust one's own response process accordingly. The "what works" viewpoint is implicitly normative in its goals. It positions researchers to make recommendations about maximally effective intervention tactics to aspiring interventionists. If even "basic" behavioral scientists have taken this perspective, it's natural that consumer researchers would have done so too. Further, the person whose behavior is typically studied is the target of an influence attempt, not someone designing their own influence attempt. The act of designing an influence strategy requires use of an intuitive "schemer schema." Had we been studying that act we'd have naturally recognized that the same schema that guides the person when they're the "schemer" may come into play when they're a target (a "schemee"?). So certain historic preoccupations have distracted us from the concept that intuitive schemer schema are both likely to exist and likely to shape how people play either side of the marketplace game.

But isn't the playing of the marketplace game the phenomenon that is logically central to our field, and to no other? It seems we'd have naturally been drawn to a gaming and countergaming view of that key happening. To a bargaining and negotiation view. To the view that our unique focus should be on what unfolds in the minds of two players matching wits in a game where both realize full well that "somebody's trying to sell somebody something". And that each party's assumptions about "the player on the other side" are important to understand if we want to make sense of what occurs.

I think we never embrace that view in part because we've been hungry to make our young field legitimate. To do this, in the late 1960's and 1970's many influential researchers felt compelled to say, by their words and their choice of research topics, "Virtually all aspects of human psychology are relevant to someone's behavior as a consumer, so our domain of inquiry can be as broad and basic as any behavioral scientist's." I agree with that idea, of course. But its caused us to ignore that specific aspect of behavior --- the marketplace gamesplaying --- that is the unique centerpiece of our field. To just study how consumers interpret and cope with marketer's tactics seemed too "applied," too "parochial." So we spread our

small ranks thin trying to contribute in understanding the basics of human choice processes and memory processes, and I think we've helped. But in ignoring the nitty-gritty buyer-and-seller give-and-take process, I think we're missing an opportunity. An opportunity to really understand "our" unique phenomenon, a phenomenon that turns out not to be "merely" how buyers and sellers subjectively analyze each other but one that's a pervasive general phenomenon --- how aspiring interventionists or change agents and their targets analyze each other in any venue.

I'd hate to see us miss this opportunity. There are signs that people in other fields are starting to dabble with the question of "schemer schema." Psychologists like Robert Cialdini and David Kipnis and organizational theorists like Stuart Schmidt are doing some work on intuition about persuasion. At Stanford I'm surrounded by microeconomists active in the "information economics" area, like Bob Wilson and Dave Kreps and John Roberts, who are making all sorts of interesting assumptions about first-order and second-order signalling between sellers and buyers, and working out some implications. The major explanatory theories on the playing of marketplace influence and signalling games should, in my opinion, come from researchers who define themselves as consumer researchers. If it ultimately turns out that understanding the intuitive gamesplaying of sellers and buyers per se was important in building general theories of behavior, explanatory or normative, we should be the ones who did it. If it turns out that studying schemer schema was a blind alley, that people just don't have such things or don't use them as guides to action, we should be the ones to draw that conclusion.

The Schemer Schema As A "Control" Schema

In doing research on psychological processes, we don't typically seek to identify the contents of any particular schema or knowledge structure in people's minds. We don't go around cataloguing the contents of people's schema about, say, "motorcycles" or "fast food restaurants" or "gambling." The content of those particular schema is of concern only to people narrowly interested in knowing what people believe about motorcycles or gambling for some practical reason. As behavioral scientists, it's the processes related to schema, not their contents, about which we theorize. We're more comfortable asking, "By what psychological process is any schema formed, activated, used, and modified?" Why then should we depart from this rule, and actually theorize about and study the contents of people schema about other people's social influence strategies? Because that's just what I'm suggesting we do.

I think there is a good rationale for this. A "schemer schema", as I envision it, operates as what we might call a "control" schema. I don't mean that it deals with how people control other people. A "control" schema is one that, when activated, guides a person's subsequent response process. In particular, it guides their situational adjustments in response processes. So, for example, when someone encounters a sales message or promotional or pricing move related to "motorcycles," the response strategy they select is contingent on what their working hypotheses about selling or marketing tactics are like. To be sure, their schema about "motorcycles" per se is activated. But the control schema --- "what I believe about likely persuasion and promotion strategies" --- is first activated, and that guides the situation-specific process of response. In my example, the person's "motorcycle schema" supplies the input to the ultimate response process, and isn't something we'd bother theorizing about or studying. But the "background" schema that shapes the response process is different. To really understand the process of situational responses to marketers' influence attempts, it seems essential to attack the contents of the "background" control schemas directly in our theorizing and research.

The role of a control schema can be clarified by noting an analogous control schema in the context of "contingent decision making". For over a decade many researchers on behavioral choice processes have recognized that people

seem to adjust choice strategies to suit the situation. That is, people seem to "choose a choice strategy", to "decide how to decide." If so, so the theorizing goes, there's probably a control schema at work, which contains people's personal ideas about what outcomes various approaches to choosing may produce. This hasn't usually been discussed in schema terms, but those ideas constitute what we might call a person's "choice strategy schema." Somehow, it comes into play when people adjust choice strategies. It guides the very choice process that we want so badly to understand. And therefore it's essential that we formally theorize about and get insights on the contents of people's intuitive assumptions about choice strategies. Even though it's one step removed from the focal process, and even though it's hard to study, many researchers have concluded we must study "choice strategy schema" as directly as we can. This realization is a recent one. I'm proposing only that a parallel logic points to the existence of "schemer schema," and to the possible benefits from studying their contents directly.

The Process by Which Schemer Schema Change and The Ways In Which They Change Are Both of Concern

In studying schemer schema, we will surely retain our basic interest in how such schema develop, how they're activated and used, and how they change. There's no obvious reason why the basic processes at work here will be different than those at work for any other type of schema. I'll return to this point in a moment.

However, it's alarming to realize that prevailing intuitive theories about persuasion or marketing tactics can change over time. It implies that the control mechanism underlying people's response strategies can change fundamentally. For example, what if people in general came to strongly believe, somehow, that the appearance of any imagery-evoking stimulus in a sales message signaled an attempt at mind control, and became very sophisticated at recognizing such stimuli --- vivid concrete language, stories, imagery requests, whatever. The relationships we had thought we'd documented between such stimuli and persuasive impact could well change, because the "targets" have uniformly changed their working control schemas. What if everything we as scientists learn about influence processes at a point in time were to be immediately transmitted to and understood by the general public. Kenneth Gergen posed this issue in an article called "Social Psychology as History". It's always bothered me. If targets and marketers were on perfectly equal grounds --- if both harbored the same working assumptions about influence processes --- the gamesplaying processes on both sides could change fundamentally. Or at least, enough so predictions we make from our theories are no longer accurate because we'd developed them from experiments on "uneducated" target subjects.

This implies another reason why it is prudent to document the contents of the schemer schema that prevail among the subjects we're studying now. And to study how response processes change when critical ideas in those schema are changed via education. If it turns out that changes in this control schema do cause changes in what we'd thought were dependable stimulus-response relationships, we'll have to keep up to date about prevailing schemer schema to make successful predictions about persuasive impact. That's what Gergen meant; we'll become behavioral historians.

Tentative Hypotheses About Schemer Schema

I'd like to switch gears now and speculate a little about the way schemer schema develop and get used. As with other schema, the firsthand learning process must be fragile. People need a chance to observe firsthand that a particular message or promotion or pricing tactic causes a change in their own or someone else's personal preferences. That's a difficult inference to make. Awareness that changes in preference have occurred in one's own mind or in someone else's is probably quite limited. Discerning what aspect of an influence attempt caused such a change is probably difficult. We might then expect prevailing schemer schema

based on personal inference to be simple and somewhat inaccurate.

Socially-supplied wisdom is readily available and may be influential. There's no shortage of popular books about "how I got so-and-so elected president" or "how I made a billion dollars in personal selling" or "how the mass media engage in wonderfully awesome mind-control." We teach a sizable fraction of all college students courses in "how to think effectively about marketing and advertising tactics." Some of them must succeed in integrating our teachings into their personal schemer schema. Has any of us, after teaching students about persuasion for 20 or 30 classes, ever tested whether they've become more insightful or complex in analyzing what they see marketers tossing at them as a target? Of course, compared to normative correct principles which we don't fully understand, what the books say and what we say in class is sometimes inaccurate.

The fact that people wear both hats --- aspiring advocate and target --- seems important and raises interesting issues. Practice in systematically thinking about how to influence other people, followed by careful attention to whether or not your tactic seemed to work, may greatly influence the development of a semi-sophisticated schemer schema. I've found that as long as someone envisions consumers solely as lifelong targets, they express doubt that consumers really harbor or use schemer schema. But if I define the consumer as someone who often spends time devising tactics to influence others, by occupation (say, a small businessman or executive or politician or educator or lawyer or...) or from self-interest or whatever, it seems a lot more plausible. Indeed, we might expect that people who study and dwell on practicing influence have fundamentally different schemer schemas than less Machiavellian people.

But, is there difficulty in the transfer? Does a schemer schema developed from the "marketer's" vantage point automatically function as a useful schema when you become a target? Probably not. The shift of perspective may defeat the transfer to some degree. Questions about the contents of the same person's "marketer" and "target" schema and the way these two correspond or differ seem very intriguing.

I'd think that people must have difficulty activating their schemer schema in some situations where they face an advertising or promotional or pricing maneuver. Think back to my "motorcycle" example. To respond to a message about a motorcycle, I must in theory activate both my "schemer schema" and my "motorcycle" schema and still decode the message and produce responses. So, response opportunity looms large. Activating a schemer schema may become highly automatized. Or, sometimes I may just ignore any situational analysis from my schemer schema and take an incoming message as if there's no gaming at work. That is, my default assumption when my schemer schema fails me is "no scheming." Other times, my schemer schema may suggest scheming but I haven't an opportunity to respond at all beyond a vague "ignore it" or "accept it." So there'd probably be some simplistic heuristics.

If I were an enthusiastic fan of self attribution theories, I'd speculate that people sometimes use a tortured "backwards" reasoning process. It would run like this: "that ploy has ingredients that make it effective, according to my schemer schema. Since my assumption tells me it's convincing, I must feel convinced. So, I give in...I'll hold the advocated attitude about that product." Maybe this isn't all that tortured, in situations where people have no true attitude to begin with.

Can I be more exact about the sorts of ideas we'd find in a well-developed schemer schema? This shouldn't be too surprising. There'd be a "message appeals" subschema --- intuitive ideas about the effects of or reasons for presence of anxiety-arousing material or humor or case histories in a seller's message. A "message format" subschema, that includes insights about the way sequencings

or visual displays of evidence affect judgments. A "framing" subschema --- this I find very intriguing --- for interpreting whether an explicit framing of a judgment is potentially biasing, and if so, whether it was intentional or coincidental. As part of this there might be a "secrecy" subschema, for judging why what's left out of a message was left out. Budget, time, or space constraints? Hiding something? Taking for granted that I'll already know about that? Of course, there'd be a "communicator" subschema --- why is this person describing those characteristics of herself? Why was she chosen to deliver this message to me? A "pricing/promotion" subschema: Why is this product being offered at this reduced price? Pride in what I'll discover about it? Dumping it because its going off the market? A signal of a low cost structure? An intent to survive by driving rivals from the market? A "bargaining" subschema: To interpret future offers based on current offers. In essence, a well-developed schemer schema could include all sorts of ideas relevant in interpreting and adjusting to the other player's tactics. And it would include some simple heuristics.

We've often theorized informally about some of these beliefs, treating them as mediators rather than as a key dependent variable. If we were to study such schema directly, we'd more often make them the primary dependent variables. For example, we'd pose and test theories about the way secrecy assessments are made, or the way people judge if a framing strategy is being attempted, or the way communicator credibility is judged.

Summary

What I've tried to do is excite interest in a topic we've neglected, which seems important and intriguing and uniquely a "consumer behavior" topic. What I know about influence processes tells me that what I've said won't send everybody scurrying out to study schemer schema.

Unless, of course, I've been devilishly clever in presenting myself and my viewpoint. Did I say anything at the outset to disarm you or heighten my credibility? Did I attempt humor? Or to arouse moderate anxiety about missed opportunities? Why did I discuss certain issues and leave others out? Was that a framing ploy on my part? Or a lack of time or imagination? Why did I just now disparage my probable success in piquing your interest? To invite you to counterargue? Did you sense that a purposeful attempt to mind-screw you was underway? No? Do you think you'd be consciously aware of your schemer schema in action, if indeed it has been?

Like many other "veteran" researchers, I feel the field of consumer behavior needs a shot of excitement. A challenging and intriguing and novel and seemingly pertinent research question. Maybe studying schemer schema is an activity whose time has come. A decade from now, we'll know.

PRESENTATION OF THE ACR FELLOW IN CONSUMER BEHAVIOR AWARD

Joseph W. Newman, University of Arizona

I have a very happy task today. I have been asked to speak for the Association in presenting its Fellow in Consumer Behavior award. This is especially pleasant for me because the awards go to two individuals I have known, respected and enjoyed for a good many years -- as I know many of you have.

Before saying more about the recipients, let me briefly remind you that the Fellow award is the Association's highest honor. It recognizes individuals who, in their careers, have had a major impact on consumer behavior scholarship.

The selection process began two years ago with the Awards Committee. The members were the then three immediate past presidents of the Association: Jerry Olson, Ken Bernhardt and Jerry Zaltman. I was named by the then president, Jadhish Sheth, to chair the committee.

Nominations were solicited from the membership but attention was not limited to suggestions from that source. The committee easily reached complete agreement. Our recommendations later were unanimously endorsed by the Board of Directors.

Prior to today, five Fellow awards have been made -- to John Howard and James Engle in 1980 and to Sidney J. Levy, Geroge Katona and Robert Ferber in 1982. Today we welcome William D. Wells and Harold H. Kassarijian into that elite circle.

In my remarks, I shall be brief -- too brief, really, to do justice to the recipients. But I must allow time for them to carry out their speaking assignments which will follow the presentations.

Bill and Hal have much in common, so I can start by talking about both of them at once. Both are psychologists who ventured into marketing. They did so at a time when such behavior was regarded as radical at best by psychologists and marketers alike. Fortunately, these skeptical views thawed over time to allow Bill and Hal to survive and, later, prosper. They became leaders in the study of consumer behavior and the promulgation of behavioral concepts and knowledge.

Both have held important positions in the American Marketing Association and the American Psychological Association. Both were elected Fellows of the American Psychological Association in 1972.

Both have been key figures in the formation and growth of the Association for Consumer Research and both have served as its president.

Both have ably performed in a number of roles -- as researcher, writer, editor, speaker, consultant and stimulating professional colleague.

Both are serious scholars but neither takes himself too seriously. While their styles differ, both are known for a keen sense of humor. And for the helpfulness and respect that has characterized their many interchanges with others.

I have decided to talk about Bill first because of his seniority. While he looks young, the fact is that he got his doctorate earlier than did Hal.

William D. Wells

Bill Wells is a man for whom one career was not enough. He has lived two -- one in academics and one in business.

He received his Ph.D. in Psychology from Stanford University in 1954. He then joined the Psychology Faculty at Rutgers University where he taught for 12 years. During that time, he learned marketing as a key consultant to Benton and Bowles, Inc., one of the first advertising agencies to develop a prominent interdisciplinary research group. In that role, Bill developed new research techniques, helped put together one of the first computer simulations of a consumer product market, and began his pioneering research on consumer life styles.

From 1966 to 1974, he was Professor of Psychology and Marketing at the University of Chicago. Concurrently, he continued working in the business world, serving Leo Burnett Company, Market Facts, the Federal Trade Commission and others. In 1974, he joined the organization now known as Needham, Harper Worldwide where he now is Executive Vice President and Director of Marketing Services.

Bill has been on the policy board for the Journal of Consumer Research and currently is on its Editorial Board. He also is on the Editorial Board for the Journal of Marketing and is a former member of the Editorial Board of the Journal of Marketing Research.

Many of you know Bill best for his writings. He has authored more than 30 articles in psychological and marketing journals; 10 chapters in various books; and more than 40 research papers presented at professional conferences. A number of his works are considered landmarks in the field and have been widely cited and reprinted.

In the 1950's, Bill was one of the first persons to study and write about product images.

In the 1960's, his publications showed his keen interest in improving research methodology. They included these titles:

- "The Influence of Yeasaying Response Style"
- "Measuring Readiness to Buy"
- "Hidden Errors in Survey Data"
- "Computer Simulation of Consumer Behavior"
- "Recognition, Recall and Rating Scales"
- "Communicating with Children"
- "Direct Observation of Purchasing Behavior"

Prominent among his articles in the late 1960's and the 1970's were the following:

- "The Life Cycle Concept in Marketing Research"
- "Patterns of Consumer Behavior"
- "Activities, Interests and Opinions"
- "Psychographics: A Critical Review"
- "The Modern Feminine Life Style"

In 1975, Bill addressed the effects of a major medium in his monograph on Television and Aggression. A year later, his book, Life Style and Psychographics, advanced thought and methodology on market segmentation. In 1977, he co-authored a consumer behavior textbook.

Bill has contributed much to understanding of many important topics. In so doing, he has shown unusual creativity, rigorous concern with reliability and validity of data, depth of thought and superb skills as a communicator.

Bill, if you will come up here, I will give you a plaque. It is inscribed as follows:

The Association for Consumer Research presents its Fellow in Consumer Behavior award to William D. Wells for his pioneering research, writing and teaching in consumer behavior.

Harold H. Kassirjian

When Hal Kassirjian earned his Ph.D. in 1960, he found that universities were not looking for social psychologists. So he took a job with a marketing research firm. A little later, he sought a faculty position, this time in marketing rather than psychology. UCLA hired Hal who became a lone psychologist in a department of economists. Over time, things changed. Hal led development of the department into the position of preeminence it now enjoys.

Along the way, he chaired 18 dissertation committees for doctoral students, many of whom are now well known members of ACR.

Hal discovered very early that he liked to see his name in print. He confesses that he still does. He also likes to speak. Those likings, along with intellectual curiosity, have led to more than 50 published articles, chapters in books, books, and research papers. He also has presented more than 100 unpublished papers at professional conferences and university colloquia.

Contrary to what you might expect, Hal's early publications were not based on his dissertation, but on his wife's. She had written on Riesman's theory of Inner and Outer Direction. She and Hal collaborated on several papers on that subject.

I shall mention the titles of a few of Hal's articles because they have been particularly widely cited and reprinted. The titles:

"Riesman Revisited," an article which helped stimulate research on the relationship of personality to consumer behavior.

"Personality and Consumer Behavior," an article written six years later to put what Hal regarded to be a timely end to research in that stream.

"Social Character and Differential Preference for Mass Communication"

"Cognitive Dissonance and Consumer Behavior," which received Honorable Mention in the 1966 McKinsey Awards

"The Negro and American Advertising"

"Content Analysis in Consumer Behavior"

The last two articles helped stimulate research on minorities and the role of women as portrayed in mass media.

Hal addressed a number of other topics: social values and consumer behavior; voting behavior; federal regulation of advertising, consumer behavior theory; low involvement; the integration of behavioral science into marketing; and the teaching of consumer behavior. He has written on survey research, projective methods, opinion measurement, and market segmentation techniques.

In the 1960's, a few universities started to offer courses in consumer behavior. Textual material was scarce, so Hal, with Tom Robertson, put together a book of readings entitled Perspectives in Consumer Behavior. It has continued to be widely respected and used in its subsequent editions. Later Hal, with Peter Bennett, co-authored a consumer behavior text.

As you can see, Hal has ranged widely within consumer behavior. In so doing, he acquired a perspective valuable in his editorial work. He has served on the Editorial Boards of the Journal of Consumer Research, Journal of Marketing, California Management Review, and Journal of Consumer Affairs. In 1982, he became Co-Editor of the Journal of Consumer Research. He is well known for the care he takes in writing constructive comments to authors. And for his skill in composing rejection letters which leave the recipients feeling as badly for the editor as for themselves.

No comment on Hal would be complete without recognizing his role as a perceptive, articulate spokesman for our profes-

sion. He has made it difficult for us to become either complacent or presumptuous. For example, take his presidential address in 1977 when our field was preoccupied with elaborate consumer decision models. He reminded us that, after all, the world is full of insignificant consumer decisions and that for them we probably do not need a grand theory of behavior. He has shown great sensitivity and appreciation in recognizing contributions of others as he did so eloquently in presenting the first Fellow in Consumer Behavior awards in 1980 and in his eulogy for Robert Ferber in 1982. He can express so well feelings we share. In a real sense, he has represented the conscience of the field of consumer behavior and of the Association.

Hal, will you come forward. The inscription on your plaque reads:

The Association for Consumer Research presents its Fellow in Consumer Behavior award to Harold H. Kassirjian for his scholarly contributions to consumer behavior as researcher, teacher and editor.

Harold H. Kassarian, UCLA

It seems that people who get an award often claim it is a humbling experience. Today, I understand why -- at a very personal level -- for upon accepting the title "fellow" awarded by my peers, it does humble one. Those fellows who came before Bill Wells and me, and those who will follow in years to come, may well be the only individuals who really know the feeling of honor that I am trying to express. To have been selected for this award is indeed an emotional experience. I consider this award to be the apex of my career.

But, alas, there is also a down side, for one must stand up here and address this audience. I am sure that those who have stood here before me -- the three living Fellow Award recipients and past ACR presidents, will agree -- it is a frightening experience. Nine hundred inquiring eyes await some significant comments. One is asked to be brilliant and creative, on demand. I assure you, it has led to some anxious moments over these past few weeks. The saving grace has been that my co-recipient may very well be brilliant and perhaps attention will be focused on him rather than on me.

In spite of, or perhaps because of that terror, this event has given me the opportunity to think and wonder about consumer research and the field of consumer behavior. We often hear that the field has matured and the excitement of nurturing the fragile coalition that we are, is no longer thrilling. There is nothing new that captures our excitement; that we are a field of fads; and that researchers are either like butterflies that flit from flower to flower, tasting but not drinking deeply; or statistically rigid methodologists who devise rigorous experiments with little understanding of validity. Is it really measuring what it purports to measure? Consumer behavior, we have been told again and again, has become boring.

It is true that we are maturing and perhaps we have become a bit boring. As a field matures, that is to be expected. Let me amplify that point by looking at the research life cycle (Kassarjian, 1979).

The Research Process

The first researchers to emerge with an idea, we can stereotype as innovators. Bright, sharp, the innovator may be exceptionally creative or he may be a creative borrower, but he or she is the first to come up with the idea or the first to do a study. The quality of that early work may not be the most sophisticated, but it is innovative. Festinger on dissonance or Bem on self-perception are examples from a sister discipline. Consumer behavior example abound and should be simple for this audience to generate: Levy's work on social class, Kuehn's work on linear learning models, Hupfer and Dave Gardner on low involvement, Haines and Bettman on information processing, the early contributions on personality, dissonance, attribution theory, multi-attribute attitude models and on and on.

Better quality research, advanced technology, sophisticated statistics and complex experimental designs are left to others. Merely the original, innovative, and creative thinking comes from the innovator. Without him, there is little that is exciting or new, and without him, there is no place for methodologists, statisticians, and experimental design specialists to ply their trade.

Following the innovator, comes the middle majority. Some of these are mainliners; alert to the literature and knowledgeable as to what is publishable. Their time has

come when a topic has become a fad. Nothing very innovative or particularly brilliant emerges. Rather, their important contribution is much like that of a mason that lays bricks, one on top of another, and not the creation of the architectural design.

Co-existing with the mainliner is the technician. Highly trained, mathematically sophisticated, this person is the technical expert. He or she is capable of advancing the field rapidly as new variables, more attributes, inter-relationships, and mass data processing skills are introduced. It is the data and its crunchability that excites this scholar. The emphasis is on method and he or she is not necessarily interested in the substantive content. Most of all, this individual is simply not concerned with external validity. His high-quality work is published in the best journals. His major contribution may be in development of sophisticated methodologies, but much more likely, it is in the rapid development of a concept and its hasty burial. For once, all the multi-variables are intercorrelated and controlled, interest in the topic drops.

The mainliners and the technicians follow the innovators to a new topic and the remaining work is left to the laggards. Perhaps the least interesting time in the research life cycle occurs after the innovators have left for greener pastures and the followers are near finished extracting from the second and third crushing of the grapes. Mainstream consumer research with its cognitive approach is in just that stage. The innovators have already left and moved on to new topics and the mainliners and technicians are finishing their work.

The Counter-Cognitive Revolution

However, if one takes a slightly broader view, the changes that are upon us can make this field as exciting today as it has ever been. And this time, the changes that we are seeing are more dramatic than, say, the shift from multi-attribute attitude models to information processing; for the innovators on this round are far more revolutionary. We are not just changing gears but rather are headed toward a new highway. But, let me back-up a moment.

On the surface, what seems to be in the doldrums is the revolutionary spirit, for consumer behavior had phenomenal growth, ferment, and excitement during the cognitive revolution in the social sciences. Having been freed from demographics, simple behaviorism, and psychoanalytic approaches in the early 1960's, the cognitive revolution was under way. From its early beginnings in cognitive dissonance to attribution theory, from attitude research and cognitive response to the complexity of memory factors in information processing, the cognitive revolution was upon us and we were part of it.

Now, I ask you to consider the 1985 ACR program. We have one session with attitudes in the title and almost a dozen sessions on information processing -- such topics as consumer knowledge, decisionmaking, information search, and memory. But, these are not in the majority anymore. Even more telling are the topics that have reappeared, those that had not been around for more than a decade. For today, we have sessions on emotional advertising, mood, emotional response, feeling, affect, learning and conditioned response, humanistic thinking, and even rituals. I count nearly a dozen such sessions and estimate perhaps three to four dozen such pieces.

Clearly, the innovators are again encroaching upon us. But this time, it is not just another new topic creatively borrowed from a sister field, for we are in the midst of a counter-cognitive revolution. And if nothing else, revolutions are exciting times. Our dependence on

¹With appreciation to Kent Nakamoto.

cognitive psychology is being seriously challenged. The cognitive model is giving way to a more exciting and more holistic approach on one hand and to a simpler conditioned learning paradigm on the other. After some two decades, we are swinging back.

But, it is not only us in consumer behavior who have a counter-cognitive revolution on our hands. Pribram (1985) has recently written, "Cognitive Psychology itself is beginning to feel its age. The vitality which characterized the revolution is ebbing. More and more experimentalists are concerned with refinements and, to outsiders, sometimes with trivia. There are suggestions of 'burn-out' -- that the revolution has come to an end, that activity will come to a standstill when it is realized that, after all, the radical behaviorists are right: language is too ambiguous to serve as the core of a science."

However, as an aside, it appears to me that the swings in our field are not like those of a pendulum -- we are not going back and forth -- but, rather, it is more like a spiral that narrows on top. With each swing or revolution, we seem to incorporate the best of that cycle and move to a higher level of understanding. Perhaps, once at the apex, we will have achieved a true appreciation of how and why the consumer behaves as he or she does. How high up that spiral are we? I suspect it really isn't very high and what we write about today will seem utter naive a decade from now on ACR's silver anniversary.

Although counter-revolutionaries have always been in our midst -- the motivation researchers, the humanists, those interested in physiological determinants -- we paid them little mind, for their work was not dubbed as "scientific" -- that is, it was not part of the prevailing research culture. The shock troops for the present counter-revolution were to come not only from the Freudians and the Pavlovians, but even more from those working in arousal and activation, and the low involvement researchers and theorists. It was these scholars who emphasized that much of consumer behavior involves trivial matters, stereotypic decisions, and psychobiological reactions -- behavior that does not require much in the way of cognitive processes. After all, how much cognitive effort goes into the purchase of a tube of toothpaste, or even a refrigerator? As Kroeber-Riel (1979) has pointed out, there are psychological and biological limits on the person's deliberate and conscious control of his behavior.

Mindlessness

Deliberative, mindful, inferential, and multi-attribute evaluations are simply not all that prevalent in the marketplace. In part, that is what the counter-cognitive revolution is all about. As Langer, Blank, and Chanowitz point out (1978, but also see Folkes, in press), much of present day theory takes for granted that people think, "with the underlying assumption that people attend to their world and derive behavioral strategies based on current incoming information. The question raised here is not whether these formulations are correct, nor is it whether people are capable of thoughtful action. Instead, we question how often people outside of the laboratory are actually mindful of the variables that are relevant for the subject and for the experimenter in the laboratory, and by implication, then how adequate our theories really are.

Langer then argues, that which is commonly assumed to be mindful, may be, in fact, rather automatic. That is, much of behavior, and certainly the massive blocks of behavior we as consumer researchers are interested in, can best be described as mindless. "Mindless in the sense that attention is not paid precisely to those substantive elements that are relevant for the successful resolution of the situation."

Rather, perhaps because of earlier learning, emotional state, or simple non-involvement and disinterest; behavior is stereotypically reenacted. This, then, is not a thinking, reasoning problemsolving individual capable of transforming, storing, and evaluating sensory inputs for every pound of coffee acquired or even the purchase of a refrigerator. Mindlessness, indeed, is a superior description of most consumer activity. And, I would venture that most of our data, particularly those collected outside the laboratory, would be quite consistent with the belief of the mindless consumer.

So that I am not misunderstood, by no means do I purport that the consumer is stupid, a mindless robot controlled by advertisers, package designers, motivation researchers, or nefarious un-nice people. Nor do I wish to claim that he or she is completely controlled by the adrenal cortex or the production of epinephrene or nor-epinephrene. Rather, I claim the consumer is quite shrewd and does not clutter his mind with the often irrelevant and even more often nonsensical information that impinges on him for every silly or significant purchase.

Once that individual is brought into the laboratory, read precise instructions under pretested conditions, little wonder he or she may become self-conscious. As Langer concludes, "This self-consciousness may be thought provoking and habit inhibiting." Thus, too often, "we are left with the situation where we are studying the responses of thinking subjects and then generalizing too successfully non-thinking people."

Perhaps, it is just such thinking that has excited both proponents and opponents of the importance or silliness of the Belk odyssey -- next summer -- a group of researchers who intend to spend the summer observing, recording, and videotaping, not in the laboratory, but in the field, the behavior of consumers -- at a wedding, a county fair, a swap-meet, a Beverly Hills jeweler, or a midwestern feed store.

Integration and the Middle Ground

And yet, most of those in the forefront of the counter-cognitive revolution would surely not purport to say that complete mindlessness is the appropriate description of the consumer. Those who are studying affect and mood, emotion, condition response, and holistic rather than piece-meal cognitive processing surely are not entirely dealing with mindlessness. By no means do I wish to obliterate the thoughtful thinking consumer for some purchases and under some conditions. I do not wish to deny that, at times past, perhaps, thoughtful information processing did occur. But, also, as Joel Cohen (1982) has pointed out in a delightful ACR paper, so too has the consumer learned schemas, categorization, stereotypes, and nonanalytic concept identification.

Rather, I wish to observe that research on the concept of a conscious mindful information processor has seen its day and even its most doctrinaire proponents are beginning to consider affect, and those other attributes of the counter-revolutionaries. However, it seems to me that there are potholes on our newly refurbished highway. Our recent attempts to take human responses, such as emotion, affect, and even conditioned response and squeeze them into our cherished models of cognitive processing and models of memory are probably counter-productive.

Many highly regarded researchers have tried to incorporate emotions with cognitions by claiming that affect is an interactive node in the memory model or an additional box in the ubiquitous flowchart. But, there are also others who view affective states more or less as independent of cognition -- a physiological reaction rather than a cognitive one. Further, it is clear to me that affect is so much more powerful that it completely dominates

rational processing. Unfortunately, I am not persuaded that most of us are equipped to study emotions or that they can be measured by paper-and-pencil questionnaires or by laboratory manipulations.

The revolution in the 1960s led to the flurry of excitement in our field once it was freed from its bonds to earlier modes of thinking. So too, the counter-revolution is upon us, having been freed to its bonds to cognitive psychology. What is wrong with the current paradigm in cognitive psychology, as Pribram (1985) has pointed out, is that it is based solely on the analogy with the serial processing computer and Von Neuman architecture. Serial Programming is excellent for symbol manipulation, but fails to provide access to the richness of texture involved in the totality of consumer behavior.

Interestingly, from its earliest days, the Association for Consumer Research has been promulgating the concept that consumer research is interdisciplinary. It never has been successful in reaching that goal, but it may very well be that within the counter-revolution, some of those interdisciplinary ideals may come to fruition. It will not be called interdisciplinary; but, rather, I expect, we will see it in the integration of the thinking of the old guard with the thinking of the counter-revolutionaries. If I remember correctly, that is really what we meant when we said interdisciplinary at the time this organization was formed. What we really wanted to do was to integrate the thinking of economists and psychologists and sociologists into a new field that would be called consumer behavior. It is now coming to pass. For, as I mentioned, I don't believe that the swing back is analagous to the movement of a pendulum, but rather having been freed from the cognitive bonds, we are ready to move up the spiral.

The work that is occurring, for example, on mood and affect has incorporated within it much of what it is we have learned during our cognitive days. Obviously, the work on attitudes, memory, and choice heuristics are not to be repudiated, but, rather, integrated into the new work that is emerging. The seeds of integration have already been planted by Bettman (1982) and Cohen (1982) in ACR papers presented in St. Louis. Very recently, I received a working paper by Debraix and Vanden Abeele (1985) along those same lines.

No, these are not boring times. For there is room, not only for the cognitive types, but also the humanists, the physiological researchers and even those that get excited by the Skinner Box and Pavlov's dog; not to mention situational and social determinants. Although ACR has always promulgated that this field was open to all, I am not persuaded that it has always been true.

Obviously, there is nothing particularly new in these comments other than to emphasize how very subtly the counter-cognitive-revolution has appeared on the scene and has overtaken much of our thinking. The encroachment started perhaps half a decade ago, and today, it is in full swing. Indeed, these are exciting times for both participant and nonparticipant observers.

The Muddling-Through Consumer

I would guess that we are approaching a middle ground that is more realistic and less pristine. The next turn in the spiral will bring us not to a mindful or a mindless consumer, not to a thoughtful or thoughtless decisionmaker, or one driven by hormones, rather than frontal lobe activity, but rather to a relatively different conceptualization: the individual that muddles through (Lindblom, 1959; Park, 1982). Decisions are made, purchases are consummated, children are sent to school, and bills are paid; all in due course, as the consumer gets on with the business of living.

The muddling-through consumer: one that flows with his emotions and learned responses, and processes information, but only when absolutely necessary; a cognitive miser, well protected by selective perception and selective attention, a satisficer, rather than a maximizer, one who invokes prior experience when it is essential and one who does not clutter his mind with variables we researchers today consider relevant. I expect to see the integration of mindlessness with deliberativeness, along with greater recognition of the ability of the consumer, perhaps automatically, to prioritize what is and what is not important in the business of living. As consumer researchers, we are wonderfully equipped with a subject matter that is indeed relevant and subjects, who as consumers, are indeed expert in the Art and Science of Muddling Through.

THREE USEFUL IDEAS

William D. Wells, Needham Harper Worldwide, Inc.

ACR was founded to promote exchange of ideas among government, industry and academia. The premise was that each of these entities has something to learn from each of the others, and that creative solutions to complex problems are most likely to occur at the border.

Over the years academia has provided most of ACR's agenda. For many good reasons, professors have organized most of ACR's symposia and submitted most of the competitive papers. Industry or government participants have usually been discussants or listeners.

In this sense the tripartite deal has been pretty one-sided. Academicians have done most of the work and the other two partners have reaped more than their small share of the benefits.

In the spirit of redressing the balance just a little, this talk will send three ideas from industry to academia. All three of these ideas have influenced my thinking about consumer behavior.

They have changed both research designs and action recommendations. And since we all have interests in common, I have reason to hope that they will prove both interesting and useful.

The first idea comes from efforts to understand advertising. The basic notion is that only part of an advertisement's effect occurs at the time of exposure. Another part -- and sometimes a very important part -- occurs later, when the consumer comes into contact with the product.

As many of you have demonstrated in your own research, the consumer's immediate reaction to an advertisement is most likely to be cognitive and rational. The advertisement makes claims about the product, and the consumer believes these claims or counterargues. Of course the process is never quite that simple, but that's a reasonable first approximation.

But that's not the end of the story. Something else happens later, and that something may be more important than what happens right away.

What happens later is that the advertisement and the product interact, and that interaction transforms the consumer's experience.

Transforming interactions occur because environments are complex, ambiguous, and open to multiple interpretations. Visiting a department store or a supermarket, taking an airplane trip, renting a car, going to a movie, preparing and serving dinner, visiting Las Vegas -- are all complex episodes, replete with multiple stimuli to be singled out or ignored and forgotten. Even comparatively simple events like ordering a beer or smoking a cigarette are subject to multiple interpretations, depending on the symbolism of the product and the meaning of the situation.

Advertising helps consumers interpret these experiences. It suggests what should be noticed. It provides cues and clues to help consumers understand and appreciate their feelings. And in this way it can change the nature of the response.

This way of thinking about advertising is not all that radical. More than thirty years ago, Solomon Asch found that he could change the way students evaluate a lecture by manipulating the lecturer's prior "reputation." And studies of prejudice have repeatedly shown that racial stereotypes, for instance, can have a powerful effect on interpretation of behavior.

Part of the information consumers use to interpret their experience is explicit, overt and cognitive. Advertisements make claims about products, and if these claims are halfway believed, they influence what the consumer thinks he is doing.

This part of the information is relatively easy to measure. It shows up on standard copy tests which focus on overt changes in cognitive structure.

But the other part of the information is much more subtle. It is encoded in casting, lighting, accents, dialogue, music, body language -- all the instruments of drama.

This part of the information is extremely difficult to measure. Our standard copy tests are insensitive to it, and indeed the consumer himself may not know how or where this information was acquired.

"I do not like thee, Dr. Fell.
Reason why I cannot tell.
But this I know, and know full well:
I do not like thee, Dr. Fell."

When the consumer comes into contact with the product, he uses both the overt, explicit information and the subtle cues to help him understand and interpret what is happening. And, as with the versifier who doesn't like Dr. Fell, the latent information may be decisive.

So here we have two separate problems. First, an important part of the information in advertisements is missed by current research procedures. And, in some cases at least, that missed information may carry the day. Second, advertisements have a delayed effect: they transform the consumer's experience with the product. Some of this delayed effect may come from easily measurable cognitive changes, but a very important part of it may come from subtle cues that are not noticed or remembered. In either case, the delayed effect itself cannot be measured at the time of exposure.

But of these problems present formidable research challenges. The first challenge is to develop research techniques that are sensitive to the subtle cues that influence later product perception. The second challenge is to develop research procedures to assess what happens when the residue from the advertisement encounters purchase or consumption. These research tasks are undeniably difficult. But the reward for mastering them would be a major gain in sophistication.

The second of three ideas addresses the question: must an advertisement be disliked to be effective? The idea is simply this: most products can be classified into three broad categories -- "approach" products, "avoidance" products, and products which we might call "utilitarian."

Approach products are products that most consumers approach spontaneously -- products like good food, new cars, new homes, entertainment and travel.

Avoidance products are products that most consumers would not purchase if the product did not forestall some even more unpleasant consequence. Most cleaning materials fall into this category, along with deodorants, mouthwashes, insurance, medical and dental treatment.

Utilitarian products are in between "approach" and "avoidance." Office supplies would be a familiar example.

The proposition is that advertising for approach products will be liked if it is effective. Approach products have so much intrinsic positive affect, that if consumers don't like the advertising, someone has botched the communication.

On the other hand, avoidance products are intrinsically negative. If a lot of people get warm and fuzzy about an advertisement for an avoidance product, it is prudent to consider the possibility that a lot of people have simply missed the point of the communication.

I don't mean to recommend that advertisers of avoidance products should strive to be hideous. I do mean to suggest that the relationship between affect and effect for avoidance products may well be zero or even somewhat negative.

What about utilitarian products? With the right kind of advertising and enough of it, an advertiser can change a utilitarian product into an approach product. McDonald's provides an obvious example. In principle, McDonald's is pretty utilitarian. But years of advertising have transformed consumers' experience. McDonald's advertising has provided an inventory clues that help consumers notice, interpret and appreciate the positive aspects of a visit to McDonald's, and help them ignore some of the negatives.

So the answer to the question, "must an advertisement be disliked to be effective?" is, "it depends upon the product being advertised." For approach products, the relationship between affect and effect is likely to be positive. For avoidance products, the relationship may be zero or even negative. And for utilitarian products, the relationship may be determined by the history of the advertising.

This answer has broader research implications. If the relationship between affect and effect varies by product type, then other relationships may vary by product type as well.

Right now, standard procedure in academic research is to generalize findings from one product to all products. Researchers who would never dream of conducting a study with N=1 respondents routinely conduct advertising research with N=1 products. It's basically a sampling problem. It may be just as dangerous to generalize from N=1 products as it is to generalize from N=1 persons.

The third idea has to do with Relevance. Don't tune out. This won't be another diatribe about the ivory tower. In this case Relevance has a very specific meaning, and to get at that meaning we need a little background.

Researchers have often wondered what consumers can tell them about advertising. To find out, they have employed adjective check lists and rating scales, open-end questions and depth interviews.

All this work has shown that consumers can say whether they like an ad or not, and are perfectly willing to do so. Thus "attitude toward the ad" has become an important research variable.

This work has also shown that consumers can tell us something else: They can tell us whether the ad says anything about the product that is relevant to their interests.

Without going into a lot of background detail, let me show you a ten-item rating scale that asks about the advertisement's relevance:

R Scale

1. The commercial made me think about buying the brand that was advertised.
2. The ad didn't have anything to do with me or my needs. (-)
3. The commercial made me want the brand that was advertised.
4. During the commercial I thought how the product might be useful for me.
5. The message in the commercial was important to me.
6. The commercial did not show me anything that would make me want to use their product. (-)
7. I have a more favorable view of the brand after seeing this commercial.
8. The commercial showed me the product has certain advantages.
9. It was meaningful for me.
10. It was worth remembering.

These ten items ask the respondent in slightly different ways whether the advertisement speaks to their interests. When an ad scores high on this scale, respondents are saying, "Yeah, that ad makes me want to buy the product." And when an ad scores low on the scale, respondents are saying, "No, it doesn't."

What are we to make of such answers? As research psychologists, we all know that we can't trust subjects to examine and report on their own motives. But as real people we often ask our friends to do just that, and we often behave as though we more than halfway believed the answers.

"Do you want a cup of coffee?"
"How about going to a movie?"
"Why did you do that!"
"How strongly do you feel about her?"

So the third idea is the R Scale -- R for Relevance. I think we should take Relevance seriously and see what it can tell us.

The R Scale has a lot going for it. It is internally consistent and reasonably reliable. It discriminates sharply among ads in ways that are intuitively appealing. And most important of all, the variable it represents has popped up in study after study -- across investigators, across methods and across media. A variable that pesky deserves some serious evaluation.

So three ideas are hereby returned from industry to academia:

1. Some advertisements literally transform the consumption experience. This effect is not captured by current advertising research methods.
2. Relationships between affect and effect--and probably other relationships as well--vary sharply by product. It is as important to sample products as it is to sample people.
3. Relevance, as defined by the R Scale, is an important variable. It is well worth serious attention.

Each of these ideas has the potential to change advertising research, maybe even for the better. If that should happen, it would confirm the premise on which ACR was founded--that different disciplines have something useful to say to each other, and that creative solutions to complex problems are likely to be found at the border.

SOME EVIDENCE FOR ADDITIONAL TYPES OF CHOICE STRATEGIES

Surjit Chhabra, Indiana University
Richard W. Olshavsky, Indiana University¹

Abstract

Consumer researchers now recognize that brand choices are made in a variety of ways. Recently, it has been suggested that the repertoire of consumer choice strategies is even broader in scope and involves the use of surrogates, recommendations and imitation in addition to those choice rules uncovered so far. This paper presents the results of a laboratory study that investigated brand choice strategies (using protocol analysis) for a variety of products; considerable support for the occurrence of these additional choice strategies was found.

Introduction

Consumer researchers grappling with the complexities of consumer choice processes have increasingly come to recognize that choices are made in a much more varied fashion than heretofore theorized (Bettman 1979; Kassarian 1978; Krugman 1965; Olshavsky and Granbois 1979; Payne 1982; Zajonc and Markus 1982). It is now generally accepted that choice occurs by a variety of rules other than the "linear additive" rule made popular by the research efforts of Fishbein (1967), Fishbein and Ajzen (1972), Ajzen and Fishbein (1977); Wilkie and Pessemier (1973). (Although some theorists maintain that all of these rules can be subsumed by an appropriately specified expectancy-value model.)

Specifically, researchers have uncovered choice rules such as "affect referral" (Wright 1975), in which the evaluation process is wholistic and based on preferences retrieved from memory. In addition to the classic linear additive rule, certain other compensatory rules such as the "additive difference" and "attribute dominance" have been identified (Tversky 1969). Certain noncompensatory choice rules (e.g., "conjunctive," "disjunctive," and "lexicographic") have also been identified (Bettman 1979). Further, there is evidence that consumers use "phased" rules in certain situations; here, two or more rules are applied in sequence (e.g., lexicographic first, followed by linear additive) (Wright 1974; Wright and Barbour 1977; Russ 1971).

Recently, Olshavsky (1985a; 1985b) has proposed an integrated information processing theory of choice that incorporates an even greater range of choice strategies. Olshavsky suggests that in addition to the rules just described, consumers simplify choice by using certain cues (such as price, country of origin, or store) as an index to the quality of a brand.

While a considerable amount of research has been done on the price-quality relationship (with price alone or with price in combination with other cues) nearly all of this research is atheoretical and separate from the mainstream of research on choice (Olson 1977; Rao 1984). Olshavsky (1985a) classifies the use of surrogates as another type of choice strategy and thereby integrates the stream of research on price-quality within a single, systematic information processing theory of choice. Olshavsky refers to all of the choice strategies described so far as "own based."

Olshavsky also proposes that consumers can "decide not to decide." That is, a consumer can "subcontract" a choice

to another person or organization (Olshavsky and Rosen 1985). He calls these types of choice strategies "other based." Two major types of other based choice strategies exist -- "following a recommendation" and "imitation."

Again, while there has been a considerable amount of research done on the effects of interpersonal influences (e.g., opinion leadership, word of mouth) and while various theorists have recognized these influences, these theorists treat interpersonal influences primarily as another source of "attribute-value" type information (e.g., the color of the shirt is blue). Information of this type received from sources such as friends is then assumed to be processed in some "own based" fashion (e.g., Bettman 1979; Engel and Blackwell 1982). Olshavsky acknowledges this type of influence, as well as normative influences (Bearden and Etzel 1982), but proposes that in addition, in some cases, the friend or organization actually does the decision making and the consumer simply accepts that friend's or organization's choice in the form of a recommendation (but, of course, recommendations are not accepted in all cases and not without some qualification of the referrer's expertise). Similarly, imitation of others may involve acceptance of brands used by others, with or without the acquisition of attribute-value type information from those being imitated. Indeed, for various reasons (such as losing face), a consumer may studiously avoid acquiring attribute-value information from those being imitated.

Olshavsky further proposes that surrogate based and other based choice strategies can be and frequently are combined with one or more of the choice strategies already identified. A "hybrid" strategy is one that combines an own based strategy with an other based strategy; e.g., a consumer may engage in some form of own based evaluation, but this evaluation process may be limited to only those alternatives recommended by one or more referrers. Other forms of combined strategies are possible, e.g., combining two or more own based strategies (as in a phased strategy) or combining two or more other based strategies (as in following a recommendation and imitating the brand purchases of others). Table 1 summarizes the various choice strategies proposed by Olshavsky.

Considerable evidence can be and has been cited by Olshavsky (1985a) for the occurrence of both surrogate based and other based choice strategies, but nearly all of this evidence is indirect. Few of the studies cited in support of this broadened taxonomy of choice were explicitly concerned with the identification of choice strategies or combinations of these strategies per se. Thus there exists a need for exploratory research on consumer choice processes to test the validity of Olshavsky's proposed taxonomy. The present paper reports the results of a laboratory study designed to enable the observation of one or more of all of the choice strategies described above in a variety of brand choice situations involving several disparate products.

If evidence is found for the existence of these additional strategies, then this result can be taken as support for Olshavsky's broadened theory of choice. This theory should help us to integrate at least three important streams of research related to choice strategies: 1) traditional research on decision making, 2) the price - quality literature, and 3) the literature pertaining to interpersonal influences. Some specific research directions that are implied by this theory are described in the discussion section.

¹Doctoral Student in Marketing and Professor of Marketing, respectively. Both authors contributed equally. In addition, Ms. Teresa Storm's help in transcribing the protocols is gratefully acknowledged.

TABLE 1
CHOICE STRATEGY TAXONOMY PROPOSED BY OLSHAVSKY²

Choice Strategy	Description
Own Based	
Decision Making (DM)	Refers to choice behaviors in which a consumer personally establishes or changes a preference for an alternative from among two or more alternatives on the basis of one or more evaluative criteria. For example, linear additive rule or conjunctive rule. ³
Surrogate Based	
	Refers to choice behaviors wherein a consumer forms an overall evaluation of each alternative on the basis of one or more cues which serve as an index or surrogate of the overall evaluation. For example, price as an index of quality.
Other Based	
	Refers to choice behaviors in which a consumer "subcontracts" the choice to others. Examples include following a recommendation and imitation. DM may be involved in the selection of the referrer or individual to be imitated.
Hybrid	
	Refers to choice behaviors wherein a consumer combines own based and other based strategies. An example is using a conjunctive rule to evaluate only recommended alternatives.
Other Combination Strategies	
	Refers to those choice behaviors wherein a consumer uses two or more own based strategies (e.g., a phased strategy) or two or more other based strategies (e.g., recommendation and imitation).

Method

Subjects

Ten students participated in this study. All were volunteers. Sample size was purposely small because of the large amount of time involved in protocol collection and analysis; this is consistent with prior research utilizing this approach (Payne, Braunstein, and Carroll 1978).

Products

Products were selected that, on theoretical grounds and on the basis of past research, were judged likely to increase the likelihood of occurrence of a wide range of choice strategies. Specifically, the importance of "number of alternatives" in determining choice strategy has been demonstrated empirically and has been given a theoretical explanation in terms of short term memory constraints (Bettman 1979; Lussier and Olshavsky 1979; Newell and Simon 1972; Payne 1976). Recently, for instance Malhotra (1982) has shown that the probability of correct choice decreased significantly as the number of alternatives was increased from five to ten or more. The "amount of infor-

² Affect referral is purposely omitted from this Table because it is classified by Olshavsky as an instance of "non-choice."

³ See Bettman (1979, pp. 179-185) for a detailed description of the various decision making strategies.

mation" about alternatives (Cox 1972; Jacoby, Speller and Kohn 1974a; 1974b; Lee 1971; Russo 1974; Summers 1974; Malhotra 1982), the "format" of information (Bettman and Kakker 1976; Russo, Krieser and Mijashita 1975; van Raij 1977), and the "complexity" of the product (Olshavsky 1979) were also taken into account in the selection of products to be included in this study.

Table 2 presents the ten products selected; for each, the number of brands presented and the number of attributes about which information was explicitly presented is also indicated.

TABLE 2
THE NUMBER OF BRANDS AND NUMBER OF ATTRIBUTES FOR EACH OF TEN PRODUCTS

Product	Number of Brands ⁴	Number of Attributes
Gold Chain	5	3
Watch (for self)	12	3 - 5
Watch (as a gift)	12	3 - 5
Fine China	10	2 - 5
Hairdryer	6	2 - 6
Portable Cassette Player	5	10 - 12
Color T.V.	5	7 - 10
Tennis Balls	4	3
Tennis Racquet	5	3 - 5
Bicycle	2	8

Procedure

The instrument used in this study was the 1983-1984 General Merchandise Catalog from Service Merchandise. This catalog was used because it features national brands (permitting the occurrence of affect referral) and is more realistic than the information display boards, matrix displays and 5" X 7" cards used by researchers in the past (e.g., Payne 1976; Lussier and Olshavsky 1979). (The recent rapid growth in direct marketing and especially the increase in catalog sales is another consideration that increases the realism of these materials.)

The subjects were interviewed one at a time for about one hour each. The order of presentation of the ten brand choice tasks was counterbalanced across subjects. Each subject was handed a copy of the 1983-84 Service Merchandise catalog. The experimenter then asked the subject to go to the relevant pages and to make a choice of a single brand in that category and to use whichever choice method s/he normally would use.

Data Collection

The data collection technique utilized was the simultaneous "think aloud" verbal protocols. The collection of verbal protocols is conceptually a straightforward method of obtaining data. The subject is asked to give continuous verbal reports while performing the task in question. The advantages and disadvantages of protocol analysis have been discussed in detail elsewhere and will not be repeated here (see e.g., Bettman 1979; Ericsson and Simon 1980; Newell and Simon 1972; Nisbett and Wilson 1977; Payne, Braunstein, and Carroll 1978).

Data Analysis

The recorded protocols were first transcribed and then they were broken up into short phrases, each phrase corresponding to an assessment of what constitutes a single task assertion or reference by the subject (Newell and Simon 1972).

⁴ Not counting alternatives within each brand.

The two authors classified the strategies utilized by each subject for each brand choice task based upon the classification of choice strategies proposed by Olshavsky (1985a; 1985b;). Specifically, each protocol was coded as affect referral, own-based (including decision making and surrogate based), other based (including following a recommendation and imitation), or some combination of these rules. While coding, the entire protocol for each brand choice situation was read carefully and attention was paid to the overall context of the protocol. This procedure avoids distortions in the picture of processing that finally emerges (Bettman and Park 1980; Biehal and Chakravarti 1982). No attempt was made to classify the own based, decision making rules into the specific rules involved (i.e., linear additive, additive difference, conjunctive, etc.) since this was not essential to the purpose of this study.

Results

Initial agreement between the two coders was 85%. After discussing those cases involving disagreement, agreement was increased to 92%. The principle source of these disagreements raises a basic issue that is taken up in the discussion section.

Table 3 summarizes the frequency of occurrence of the various choice strategies employed by these ten subjects across the ten products.

TABLE 3
FREQUENCY OF CHOICE STRATEGIES

Choice Strategy	Frequency
Affect Referral	9
Own-Based:	
Decision Making	47
Surrogate-Based	15
Other-Based	5
Hybrid (own-based and other-based)	5
Other ("affect referral" and own-based)	10
No Choice Strategy Identified (inadequate protocols)	1
Disagreement (between coders)	8

Affect Referral

In 9% of the cases, the subjects used affect referral to make their choice. In affect referral, as typically defined, a subject simply elicits from memory a previously formed overall evaluation for one or more of the alternatives and selects that alternative with the highest overall evaluation (Bettman 1979, p. 179; Wright 1976). Typical of the protocols classified as affect referral in this study was the protocol for a watch for Subject 10:

"probably would like an Elgin watch because I have an Elgin now"

And, again, for choosing a hairdryer, Subject 10 stated: "page 248, number 2, the Chairol ... I guess the reason I say that is because I have a Chairol hot burners and they are fine"

Own Based Strategies

In a majority (62%) of the brand choice situations, some type of own based choice strategy was employed. These

strategies were further sub-classified as either decision making or surrogate based.

Decision Making

Subjects frequently (47%) employed some type of decision making rule. Most of the decision making strategies previously described were observed to occur either alone (e.g., conjunctive or lexicographic) or in combination with others (e.g., lexicographic followed by conjunctive). No attempt was made however to classify these protocols at this level of detail.

Surrogate Based Strategies

In 15% of the cases, subjects employed a surrogate based strategy. Cues such as price and store were used as indices of quality and the choice was ostensibly made on that basis. For example, the protocol for bicycles for Subject 3 included these important utterances related to price as a surrogate of quality:

"the 'Carrera' is a 10 speed also..."

"that is real cheap ... its only \$87."

"that tells me, the \$87, that that bike is not going to last me too long for that kind of price."

"I guess what I am doing here is ... inferring quality based on price, which might not be correct but for that low of a cost I have to believe that bike is not going to give me long life."

Other Based Strategies

In 5% of the cases, the subjects used an other based choice strategy. Whenever choice was based on recommendation or imitation, it was classified as an other based strategy. (This type of strategy was observed even though no recommendations or information about the behavior of others with respect to these brands was provided; this aspect of the study will be discussed further in the discussion section). For example, the protocol for Subject 7 for hair-dryers reproduced in part below indicates that this subject is using an imitation strategy:

"... although I do have a friend who has #2 here, Clairol Son of a Gun and they are happy with this."

"and since there is not too much difference in these, I would choose #2."

"because I know a friend that has one of those ... #2."

Use of recommendation in choice was demonstrated by Subject 2 in choosing a tennis racquet:

"I know very little about tennis racquets--I would probably consult someone about buying one."

Hybrid Strategies

In another 5% of the cases, subjects were found to engage in a strategy involving both own based and other based strategies in some combination. For instance, Subject 5 seems to be using such a hybrid strategy (i.e., surrogate and recommendation) in choosing a tennis racquet as revealed in the following excerpts:

"Well, I think with these, #13 and #14...I think at this point, they might just be a little too cheaply priced"

"and you start to wonder that you are probably not getting a quality racquet"

"...so I think I would consult some of my friends who play tennis more than I do and I would probably have them come to the store with me and to look at these and see what they think about it."

Combined Strategies

A surprisingly large percentage of choices (10%) involved a choice strategy that combined affect referral with an own based strategy. (This assumes that affect referral does not preclude the possibility of having more than one strongly preferred alternative. This issue is discussed below.) As an example, the complete protocol for Subject 1 for tennis racquet is reproduced in Table 4.

TABLE 4

COMPLETE PROTOCOL FOR SUBJECT #1 FOR TENNIS RACQUETS

- A97: OK, I'd probably first decide if I wanted wood or graphite or aluminum
- A98: I've always used wood so I probably would go with the wood.
- A99: I don't like the oversize...like the Prince.
- A100: I guess the Wilson is too...yeah...oversize.
- A101: Those oversize ones...I don't like those.
- A102: I'd...the graphite ones, I'd look at them and see what the prices are.
- A103: They aren't that much more expensive.
- A104: I haven't really used them before.
- A105: So...because it is not something I can return... I'd probably go ahead and get a wood (racquet).
- A106: I would look for a name I know, Wilson, Head, probably one of those.
- A107: I have never heard of Donnay or whatever.
- A108: Bancroft I have heard of but I think I'd go with the Wilson.
- A109: That is what I've always used.
- A110: And after looking at different prices...let's see ...not that many wood ones.
- A111: I think that probably in this category I'd go for the higher priced Wilson.
- A112: It is not that much...well it is \$20 more but I think it is a better quality racquet.
- A113: The #12, Wilson Advantage wood racquet for \$39.96 over the other Wilson which is \$19.97 for the Connor's Pro.
- A114: I'd probably go with the Wilson #12 just because I'd be looking for wood.
- A115: The price doesn't really matter that much to me... it is pretty reasonable.
- A116: I think it is a quality racquet.

Intra-Subject, Intra-Product Regularities

Even though the sample size was small, some intra-subject and intro-product regularities were apparent. For instance, Subject 10 used an affect referral strategy in 6 out of the 10 choice situations. Subject 5 used a hybrid strategy in 3 out of the 10 brand choice environments.

Juxtaposing subjects' choice rules with the types of products, it was also evident that for color T.V. and cassette player, subjects were using combination strategies almost as often as decision making (e.g., linear compensatory, lexicographic, etc.) strategies. Typically a recommendation) or a combination strategy (involving affect referral with an own based choice rule) was being used for these two product categories.

Discussion

As expected, based on prior research and theory, subjects in this study were observed to use a variety of compensatory and noncompensatory decision making strategies alone or in some phased combination. Also, several instances of affect referral (in the strong sense of a single preferred alternative) were observed. Of greater interest however for the stated purposes of this study was the observation of choice strategies involving surrogates, recommendation, and imitation. We interpret these results as lending initial support to Olshavsky's position that

theories of choice must be broadened to encompass these additional types of choice strategies.

In several instances, subjects were observed to use affect referral in combination with other choice strategies. Other researchers have reported observing phased strategies to simplify choice (e.g., Bettman 1979, p. 184). However, in all of those situations two or more decision making strategies (usually a noncompensatory strategy is followed by a compensatory strategy) were utilized. This result raises an important conceptual issue concerning Wright's (1976) definition of affect referral; clearly, a consumer can have a very strong preference for a single alternative or strong preferences for more than one. In the latter case some additional type of choice strategy must be brought to bear unless the consumer elects to buy more than one brand. (This option was not permitted in this study.) Similarly, subjects may not have a strong preference for any brand yet they may have "positive feelings" for two or more brands that are used to quickly narrow down the number of options.

Another issue for future research that arose from the disagreements (8%) between the two coders concerned the interpretation of the meaning of "reputation of the manufacturer." In some instances, it was clear from the context that reputation was used as a surrogate for quality; yet in other instances, the use of the term reputation seemed to be closer to "recommendation" (i.e., my friends recommend it). Here too, as with affect referral, in future research much greater attention must be paid to the definition of terms.

This study is obviously limited due to the small sample size, the particular subset of products investigated, the subjective nature of the protocol analysis technique, and the fact that our procedure did not provide subjects with recommendations or knowledge of how others behaved toward these brands (a limitation which makes our results on the occurrence of other based strategies even stronger).

In spite of the stated limitations, we believe that these results can be interpreted as providing strong, although preliminary evidence for the occurrence of the types of additional choice strategies postulated by Olshavsky. It is our hope that these results will encourage other researchers to now study the contingencies proposed by Olshavsky (1985a) between these strategies and consumer and task environment factors.

Space does not permit a detailed description of Olshavsky's theory and the contingencies proposed therein (see Olshavsky 1985a for details.) Briefly though, Olshavsky postulates (as does Bettman (1979)) that the selection of a specific choice strategy or combination of these strategies is contingent upon the characteristics of the consumer (e.g., beliefs, information processing constraints, skills, knowledge) and the characteristics of the task environment (e.g., the number of alternatives present, the amount and quality of information available, and the nature of the products/services involved). For instance, it can be hypothesized that consumers will be more likely to adopt a surrogate based strategy involving price if the consumer believes that price is an index of quality (Cox 1962; Olson and Jacoby 1972). And consumers are more likely to adopt a recommendation strategy when the marketplace provides very little or very low quality information about the product or service involved, as with physicians or life insurance (Formisano, Olshavsky and Tapp 1982).

RELATED THEORIES OF COMPLEXITY IN INFORMATION PROCESSING¹

Carolyn L. Costley, University of North Carolina

Abstract

In recent years the information processing perspective has been integrated into Piaget's concept of stages of cognitive development to explain age differences in children's responses to advertising. The types of processing purported to be associated with the different stages of cognitive development bear remarkable resemblance to the kinds of processing associated with levels of involvement as set forth by Greenwald and Leavitt (1984). These two frameworks seem to be reflecting the same underlying concept, that processing of information progresses through hierarchical levels of complexity. This paper examines the similarities between these frameworks and notes some unique aspects of each which suggest interesting avenues for future research. Research exploring the relationship between knowledge and involvement, for instance, could provide some useful insights into information processing by both children and adults.

Introduction

As researchers examined the issue of advertising directed at children, they relied increasingly on Piaget's concept of stages of cognitive development to explain age differences in children's responses, (Blatt, Spencer, & Ward 1971; Rubin 1974; Wackman & Wartella 1977; Ward 1972; Ward, Wackman, & Wartella 1977). While in more recent years, children's responses have been discussed from an information processing perspective, stages of cognitive development have continued to be relied upon to explain differences, (Wackman & Ward 1975; Roedder 1981a; Roedder 1981b). The types of processing purported to be associated with the different stages of cognitive development bear remarkable resemblance to the kinds of processing associated with levels of involvement as set forth by Greenwald and Leavitt (1984). Although dealing with very different time frames, these two frameworks seem to be reflecting the same underlying concept, that processing of information progresses through hierarchical levels of complexity. This paper examines the similarities between these frameworks and discusses the notion of complexity of processing.

Complexity of Processing

The hierarchy of processing complexity is recognized in both the involvement literature (Greenwald & Leavitt 1984) and in the developmental literature (Kail 1984). "Complexity" is used here as it is defined in the New Webster's Dictionary to mean "intricacy." In each discipline the first level in the hierarchy is one of "no processing." It is a state of monitoring one's environment. When a stimulus captures attention (for reasons of novelty or importance) or when the infant's experience with monitoring has prepared it for more extensive processing, level two is entered and active processing begins. In this second level, the individual selectively attends to some perceptual aspect of the message. Attention may be focused, for example, on the physical appearance of the source while tuning out the content of the message. Comprehension of the message occurs in level three when the meaning and structure of the words or stimulus are processed. The greatest complexity of processing is reached when self relevant elaboration

takes place. At this level the individual adds to the message and reformulates it in terms of personal relevance.

The concept of progressively complex levels of processing has been developed independently with respect to involvement and regarding cognitive development. An individual examination of each of these areas follows, along with highlights of the similarities and differences between them.

Levels of Involvement

Greenwald and Leavitt (1984) identify four levels of involvement relevant to the concepts of attention and levels of processing. These levels are characterized by increasingly abstract and complex processing of message content. Messages processed at greater levels of complexity are associated with greater durability of memory. The concept of attention is a key one in their framework, also, and they note its limited nature. Some processing is sufficiently complex to demand allocation of capacity to the extent that other processing may be neglected.

Preattention

The preattention level of involvement acts as a sensory buffer and uses little attentional capacity. At this level, an individual is in a state of monitoring the environment for stimuli which stand out against the background. Such stimuli attract attention and orient the individual toward them. For instance, when one is in a room full of people at a party and hears one's name mentioned in a nearby conversation, one suddenly "tunes in" and likely turns or looks to see who is speaking. With regard to advertising, an individual may be paying "no" attention to the ads on the radio or television until one mentions something of interest. This orienting response amounts to the elicitation of focal attention.

Focal Attention

Focal attention is characterized by the selective centering of attention on one message source and its sensory content. Perceptual information may be encoded categorically, but not elaborated. This level is representative of Krugman's conception of low involvement (1965). The receiver doesn't think very much about it at the time. The impact of a persuasive communication processed at this level is outlined by Ray (1973). Awareness and affective value can increase through repeated exposure and focal processing. Behavior is likely to change next (after recognition of the product in the store) followed by attitude change.

Comprehension

Message-based persuasion is possible when processing is done at the comprehension level. At this level of involvement, semantic processing is taking place in which analysis of speech, the words and structure of the communication, results in a conceptual understanding of the message. This allows for persuasion based on the content of the message. In terms of the hierarchies developed by Ray (1973), comprehension implies the standard learning hierarchy under which belief change and affect change precede behavior change.

Elaboration

Elaborative processing is characteristic of what is traditionally called high involvement. The greatest amount of processing capacity is allocated to the situation.

¹Sincere thanks are extended to Merrie Brucks and David Plumlee of the University of North Carolina for their reviews of earlier drafts of this paper. Thanks also to the anonymous ACR reviewers for their insightful comments.

In this condition, processing goes beyond simple analysis of the message. Elaboration entails abstract thinking and associations between the message and information stored in one's memory. These associations are the "bridging experiences" identified by Krugman (1965). The results of these connections may elicit counter arguments if a discrepancy is found, support arguments if commonalities are found, or source derogation responses if the source is felt to be biased (Wright 1973). These cognitive responses and the comparisons from which they were generated are assimilated, become part of the message as it is stored in memory. To the extent that these self generated additions to the communication agree with the original message, persuasion may occur as intended. However, to the extent that these cognitions disagree with the original message, persuasion might actually be in the opposite direction. Thus, the message stored can have a meaning considerably different from that intended.

According to Greenwald and Leavitt (1984) the progression of processing through the levels of involvement is sequential. For a message to be analyzed at an upper level of involvement, it must have already been analyzed at all lower levels. In a similar vein, as we grow, we cannot skip a stage of cognitive development.

Stages of Cognitive Development

It has been noted in research on memory development that as children grow older, they progress through levels of increasing processing complexity (Kail 1984). They seem to develop the ability to process information in a more complex manner. Two explanations have been proposed to account for this increased ability. Either processing capacity is increased with age (Pascual-Leone 1970, 1978) or efficiency of processing due to practice allows them to process more (Kail 1984). Under the second hypothesis, children improve their cognitive skills with practice. This increased efficiency makes capacity available for greater complexity of processing. Efficiency may also be associated with greater complexity of cognitive structure making more thorough associations easier. Greater complexity may be achieved in the addition of relationships accomplished through repeated processing, i.e. practice. Increases in children's processing complexity are associated with the stages of cognitive development as defined by Piaget (Piaget & Inhelder 1969).

Although Piaget's theory has been strongly criticized, it is useful in a descriptive sense. It provides a sort of description of information processing in the developmental context. The similarity of this description to involvement theory deserves attention. Following is a brief description of Piaget's theory.

Sensorimotor

During the sensorimotor stage of cognitive development (ages 0-2) children familiarize themselves with the world. Through motor and sensory experiences and observation of behavior patterns, children begin to assess causality and become aware of the distinction between self and world. This is the stage during which the environment is monitored and attention is not yet focused. Responses are physiological as they tend also to be in the preattention level of involvement.

Preoperational

The preoperational stage of cognitive development (ages 2-7) is characterized by selective attention (centration) and sensory processing of dominant stimuli (perceptual boundedness). Regarding centration, Piaget found that children in this stage perceive the world in accordance with their own point of view, rather than with respect to actual relationships. Attention is bound to information which is directly observable and focused on the most visually dominant attribute. Because the child is considered incapable of reasoning

beyond the physical, perceptual information is encoded but not elaborated.

In accordance with this perceptual processing, children in this stage seem to discriminate commercials perceptually rather than conceptually (Blatt, Spencer, & Ward 1971). They are able to distinguish the commercial from the program because of the visual break in the action and change of image. However, they exhibit some confusion in conceptualizing the difference between the product and the commercial itself. Due to this emphasis on sensory aspects of stimuli, recognition responses may be expected to be more prevalent than recall or cognitive elaboration.

Concrete Operational

In the concrete operations stage of cognitive development, the development of conceptual organization allows a child to think in categorical terms and to understand a complete message. Because this more complex processing capability means that a complete message can now be stored in memory, better recall of commercials is expected. Categorization accounts for the findings that children at this age are aware of the functional differences between programs and advertisements as well as the selling intention of commercials (Blatt, Spencer, & Ward 1971; Robertson & Rossiter 1974).

The description of this stage implies that elaboration does not occur. If this is true, then even though they understand the intent to sell, semantic processing of the message with no cognitive elaboration may lead children to accept the message at face value. The absence of elaborative processing would indicate that a message would be stored in a more-or-less unaltered form. Message-based persuasion would thus be a possible outcome. Enlightenment on this issue may come from future investigations.

Formal Operational

It is only in the formal operational stage of cognitive development that children are considered able to think abstractly, make self relevant comparisons, take the role of the other person, and understand the gestalt. More importantly, the ability to make self relevant comparisons, to extend incoming information by relating it to existing knowledge, is realized at this stage. This indicates, of course, that elaborative cognitive responses are possible as defenses against persuasion.

That children progress through stages was observed in the early work dealing with advertising directed at children. In these descriptive studies, it was observed that children's reactions to ads differed across ages. For instance, Ward and Wackman (1973) found that the attention of children who were more perceptually bound (younger) was influenced more by the perceptual characteristics of commercials. Likewise, the attention of children less perceptually bound (older) was more influenced by the content of the communication.

In terms of the evolution of processing complexity, as attentional capacity is available to process more complexly (the comprehension level of processing is reached), the content of the message has more effect. This is comparable to what the levels of involvement notion predicts for adults. Researchers also found that older children were more likely to base their attitudes toward specific commercials on message characteristics rather than on attitudes toward the product. This also reflects the progress from focused processing to the more complex semantic processing.

In marketing, Roedder (1981a) has integrated some of these findings and descriptions regard differences in children's information processing. She offers an alternative approach to Piaget by emphasizing the influence of knowledge factors on these differences. She identified three groups of processors, based on age,

which differ in processing efficiency. The more efficient processors were able to learn the main information content of a message while those less efficient learned incidental material, but not the "whole." Although Roedder offers a knowledge related alternative to Piaget, she does not look at involvement theory. This remains for investigation.

Similarities

Each of the streams, cognitive development and involvement, has conceptualized a framework of four levels that is characterized by the notion of increasing complexity of mental processing. Each has outlined the kinds of processing and the kinds of responses typical of each level. In each orientation, the first level is one of "no processing" during which the environment is monitored and responses are physiological. The next stage is that of focused processing. Attention is centered on some dominant aspect of the stimuli. Recognition, a relatively low complexity response, is associated with this simple processing.

Semantic processing, the third stage, is a more complex mental activity. Processing the words and context of a message lead to comprehension. Acquisition of this ability to conceptualize the whole is observed in children around age seven or eight. Since processing is more complex, individuals are expected to be able to recall the message. In both orientations, the fourth and highest level identified is characterized by elaboration of incoming information. Connections made to knowledge in memory can elicit counter arguments, support arguments, and source derogation responses and thus reformulate the message for storage in memory.

Top-Down and Bottom-Up Processing.

Greenwald and Leavitt (1984) identify the direction of processing as a control for manipulating the level of involvement in an experimental situation. In bottom-up processing information is analyzed at ever-increasing levels of complexity, each level proceeding from the results of the previous level (Norman 1976). This is data driven. A complementary system is conceptually driven or top-down. Conceptualizations and expectations of the input influence the output at successively lower levels (Glass and Holyoak 1986). Although progression through the stages of involvement or of cognitive development is sequential, the procedure for information processing at any stage is both from the top down and from the bottom up. In cognitive development theory, the complementary processes of accommodation and assimilation are believed to describe the process of adaptation to new information (Flavell 1985). The relationship is much the same as the relationship of top-down and bottom-up processing to the processing of new stimuli.

Accommodation is like bottom-up processing in that it is data driven. One accommodates or adjusts one's cognitive structure to the data as it is presented. On the other hand, one has certain expectations and uses existing structure to interpret incoming information. Like top-down processing, assimilation plies incoming information to fit into existing structures.

Accommodation and assimilation are felt to be indissociable from each other (Flavell 1985). In like manner, top-down and bottom-up processing rely on each other. Both conceptualizations are considered to be simultaneous (or at least rapidly iterative). However, at any given level of processing, one direction seems weighted more heavily than the other. For instance, the monitoring stage principally utilizes a bottom-up approach. Concepts and expectations have not been activated. At the other extreme, in the elaboration stage, top-down processing is weighted more heavily. Expectations due to context and prior knowledge are the driving forces in processing. Input is modified to fit these expectations and thus elaboration occurs. Processing complexity, then, seems to be characterized by this

dichotomous process of adaptation.

In conclusion, the similarities between the two frameworks are many. However, it is the findings unique to each field which may serve to benefit the other. These offer suggestions for avenues of future research which will be discussed in the following section.

Suggestions for Future Research

Suggestions for Research with Children

The involvement framework suggests differences in the process of "persuasion" depending on the highest level of processing complexity utilized to process persuasive communications. For example, the results of processing at low levels may first lead to behavior change and later to changes in attitudes and beliefs. On the other hand, message-based processing, at the level of comprehension, may result in a change in beliefs and attitudes followed by behavior change. This suggests that younger children may form attitudes after behavior and that older children may first change their attitudes and beliefs in response to persuasive communication. This is an example of a subject for future research in the children's information processing area which is suggested by work done related to involvement.

The comparison of levels of cognitive development and levels of involvement may seem to imply that young children cannot be highly involved in a message. When involvement is defined in terms of the kind of processing evidenced (Batra and Ray 1983; Krugman 1965) this would appear to be so. However, this suggestion would be disputed by most parents who take "involvement" to mean emotional excitement.

If involvement is interpreted as an emotional or motivational state which leads to different levels of processing (Mitchell 1981), then involvement is a necessary, but not a sufficient condition for complex processing. Elaboration demands knowledge. Petty, Cacioppo and Schumann (1983) note that in their Elaboration Likelihood Model, motivation is but one element. The ability to process information is also an important variable. Ability can indicate both procedural knowledge, as investigated by Roedder (1981a) and declarative knowledge (Brucks, Armstrong, and Goldberg 1985; Costley 1985; Sanft 1986).

Involvement, therefore, can lead to different processing results depending on the levels of these two kinds of knowledge. A deficiency in declarative knowledge may moderate the effects of involvement because the cognitive structure against which a message is interpreted doesn't have many links and thus associations are not made. Absence of the capability for higher levels of abstract thought (procedural knowledge deficiency) may also hinder the influence of involvement. The less complex cognitive structure of younger children may mean that a great variety of information is not likely to be accessed and that any analysis requires much of the available capacity, thus inhibiting the activation of other analyses. It may be that when children scrutinize messages in a high involvement state and no counter arguments result, it is merely because the limited complexity of their cognitive structures presented them with no discrepancies. Alternatively, the procedures for retrieving that information may not be fully developed. Investigation of the developmental factors mediating the effects of involvement might prove interesting.

Suggestions for Involvement Research

The results of work by cognitive researchers point strongly to the importance of knowledge in the processing of information. An intriguing experiment by Chi (1978) found that children knowledgeable of a subject (in this case, chess) performed better on a recall task than did novice adults. In terms of complexity of process-

ing, those with knowledge of the subject were able to comprehend and to elaborate on the information presented, while those just as highly involved but ignorant in the subject lacked the ability to process as complexly. Thus, knowledge and involvement may interact in inducing elaborative processing. Both must be considered in making predictions.

Both frameworks imply differences in storage of information resulting from different levels of processing. This suggests that retrieval of information will differ depending on how it was processed. Greenwald and Leavitt (1985) employ this notion in their discussion of levels of representation, levels of involvement, and advertising impact. From simple to complex, the levels of representation are features, categories, propositions, and conceptual interpretations. They say that if the audience involvement level is low, such that an ad elicits only focal attention, the impact of the message will be in terms of category representations. Repeated exposure to the ad should result in representations at higher levels.

In contrast, time series research on children has found retrieval of information to be dependent on mental development at the time of retrieval rather than at the time of storage (Piaget and Inhelder 1973). These results suggest for involvement theory that involvement at the time of retrieval may be the key to the level of representation retrieved. The level of processing complexity operative at the time of retrieval may reorganize what is stored in memory. Research along these lines can help determine if this phenomenon also functions with respect to involvement in the context of advertising or if this denotes an important difference between the two contexts.

Conclusion

The research streams in marketing and in developmental psychology have independently arrived at very similar organizations for the complexity of information processing. Each, however, offers some unique aspects which can benefit the other. The notion of differing hierarchies of effects depending on the complexity of processing of a persuasive message could prove useful in research on children. The interaction between knowledge and involvement in impacting information processing is an interesting avenue for exploration suggested by the analogy between levels of involvement and stages of cognitive development. With respect to information processing, this paper has pointed out the many similarities between involvement theory and cognitive development theory. In addition, it has identified some unique findings from each discipline and made suggestions for future research based on these.

POSITIVITY AND NEGATIVITY EFFECTS IN INFERENCES ABOUT PRODUCTS

Frank R. Kardes, Indiana University
William M. Strahle, Indiana University

Abstract

A pilot experiment was conducted to examine the effects of initial judgments and perceived technicality on inference processes. Respondents received technical information about a product. After reading this information, they answered leading questions designed to induce either a positive or a negative initial judgment of the product. The results suggest that initial judgments affect inference processes in conditions of moderate perceived technicality, but not under conditions of either low or high perceived technicality. Moreover, both positivity and negativity effects were observed. The conditions under which positivity effects are likely and the conditions under which negativity effects are likely are discussed.

Introduction

Recently a number of prominent consumer researchers have called for more research in the area of inference processes (Bettman 1979, Huber and McCann 1982, Loken 1981, Lynch and Srull 1982, Meyer 1981, Olson 1978). Unfortunately, it is not clear how one should study inference processes and as a consequence, little research has been conducted on this important topic. One notable exception, however, is a study conducted by Huber and McCann (1982). The present experiment was designed to extend Huber and McCann's (1982) findings.

The Negativity Effect

Huber and McCann (1982) conducted an experiment in which product price (\$1.50, 1.75, 2.00, 2.25, or 2.50) and product taste (better than 10, 30, 50, 70, or 90% of the competitors' products) information was varied. Either price, taste, or price and taste information was omitted systematically and respondents were either prompted or not prompted to draw inferences about the omitted information. The results revealed that both prompted and unprompted inferences influenced respondents' judgments of the product. Moreover, respondents did not substitute missing information about an attribute with the mean value of that attribute. Rather, respondents assumed that missing information about a particular attribute meant that this attribute had a below-neutral value. This was called the negativity effect.

Similar results were found in a study conducted by Meyer (1981). In this study, respondents received information pertaining to three attributes of hypothetical pizza restaurants: pizza quality, decor and music, and price. Attribute information was omitted systematically. The results indicate that a below-neutral value was assigned to an attribute for which respondents had no information. This value was integrated with the values of attributes for which information was provided to form an overall evaluation.

Under what conditions are positive inferential beliefs formed and under what conditions are negative inferential beliefs formed? To answer this question, one must consider the factors that may influence the inference process. The present experiment examines two such factors, initial judgments and perceived technicality.

The Role of Initial Judgments in the Inference Process

One factor which may influence the inference process is an individual's initial judgment or "first impression" of a product. Early judgments of a stimulus influence subsequent judgments of the stimulus and early judgments may even affect judgments of attributes for which no

information was made available (Carlston 1980, Lingle and Ostrom 1981). To test this notion experimentally, one could manipulate respondents' initial judgments of a target product by using a methodology that was developed by Carlston (1980). Carlston reasoned that when an individual is asked to judge a stimulus, the individual does not search memory for all of the information he or she has stored about the stimulus. Rather, only a small subset of one's stored knowledge is retrieved. The particular subset that is selected often depends upon the wording of the question one is attempting to answer. If the question pertains to a positive characteristic of the stimulus, the individual may form a positive initial judgment. If the question pertains to a negative characteristic, the individual may form a negative initial judgment.

If an initial judgment is processed deeply (see Craik and Lockhart 1972, and Greenwald and Leavitt 1984), the initial judgment may drive subsequent judgments and inferences. That is, deeply processed positive initial judgments may lead to positive inferences, whereas deeply processed negative initial judgments may lead to negative inferences. This has been called the initial judgment effect (Wyer, Srull, and Gordon 1984).

The present experiment was designed to determine the conditions under which the initial judgment effect is likely to occur spontaneously. Previous research has shown that the initial judgment effect occurs when respondents are asked to form an impression of a stimulus (Carlston 1980, Wyer et al. 1984). However, whether or not respondents will form an impression and exhibit the initial judgment effect in the absence of instructions to form an impression of a stimulus is unclear. We reasoned that spontaneous inference processes may depend upon levels of perceived technicality.

The Role of Perceived Technicality in the Inference Process

The characteristics of consumers may affect the depth of processing of new information about a product. For example, recent research has shown that consumers who are low in prior knowledge and experience, with respect to a particular product domain, are unlikely to process new information about that product class very deeply (Bettman and Park 1980, Johnson and Russo 1984). This is because they lack the prior knowledge and experience that is necessary for processing new information about the product class. As a consequence, they are forced to rely on what little information they have available in memory when asked to judge an instance of the product class.

Consumers who are high in prior knowledge and experience, on the other hand, possess the prior knowledge and experience that is necessary for processing new information. However, they may be unmotivated to process much new information because they may feel that they do not need to (Bettman and Park 1980, Johnson and Russo 1984). Instead they may simply rely on the large store of information they have available in memory when asked to judge a product.

Consumers who possess a moderate amount of prior knowledge and experience have the ability to process new information and they may be motivated to process new information deeply. This is because they have enough prior knowledge and experience to process new information effectively, but they do not have so much prior knowledge and experience that they feel that they can afford to rely solely on information available in memory when asked to judge a product (Bettman and Park 1980, Johnson and Russo 1984).

To elaborate, if a product description is perceived as high in technicality, an individual may consider the information provided in the description as confusing and, perhaps, overwhelming. As a result, the individual may be unwilling and/or unable to spend the time and energy required to make sense of this information. Consequently, the individual may fail to process this information deeply.

If a product description is judged to be not very technical, an individual may be very knowledgeable and as a consequence, he may be unmotivated to exert a great deal of energy in order to understand the description. Searching memory for information is faster and easier than deeply processing new information provided externally.

If a product description is perceived as moderately technical, however, an individual may consider the information provided in the description to be interesting and comprehensible. In this case the individual may be willing and able to process new information deeply. Thus, information may be processed more deeply in conditions of moderate perceived technicality than in conditions of either low or high perceived technicality.

The Present Study

In the present study, all respondents were exposed to identical information about a product. This information consisted of favorable information about one attribute and unfavorable information about another. After reading this information, respondents answered questions about either the positive attribute or the negative attribute. These questions were used to manipulate respondents' initial judgments. One week later, respondents rated the attributes which were mentioned in the original product description and they also judged an attribute which was never mentioned in this description. It was predicted that respondents' inferences about this unmentioned attribute would be congruent with their initial judgments only when the product information was processed deeply (i.e., in moderately technical conditions).

Method

Overview

Forty-four male and female undergraduate students were randomly assigned to one of two initial judgment conditions (positive or negative). Hence, there were 22 respondents per condition. Further, respondents were divided into one of three perceived technicality conditions (low, moderate, high) on the basis of their ratings of the technicality of the product description. The primary dependent measure was respondents' inferences about an attribute which was not mentioned in the product description.

The Product Description

All respondents read the same information about an ostensibly new stereo system which we referred to as the T85 stereo system. Two attributes of the product were described, the turntable and the loudspeakers. The information pertaining to the turntable had positive implications and the information pertaining to the loudspeakers had negative implications. Respondents were told, simply, to read the product description. They were told that they would be asked to rate the description for clarity so that it could be administered to another group of respondents. Respondents did not expect to judge the target product, nor did they expect to rate the product's attributes in a second session. After they read the product description, the description was collected and a questionnaire was administered.

The Initial Judgment Manipulation

Respondents in the positive initial judgment condition rated the favorability of the performance of the turntable and one component of the turntable, the tonearm.

Respondents in the negative initial judgment condition rated the performance of the loudspeakers and one component of the loudspeakers, the tweeter. All items were rated on seven-point semantic differential scales.

The Perceived Technicality Measure

Respondents were divided into three groups (low, moderate, and high perceived technicality) on the basis of their ratings of the technicality of the product description. A seven-point semantic differential scale with endpoints labelled "Not very technical" and "Very technical" was used.

Session Two

One week later, a second set of questionnaires were administered. Respondents' global judgments (e.g., summed ratings of respondents' overall impression of and liking for the target product), inferences (e.g., ratings of the favorability of the receiver's performance), and purchase intentions were measured on seven-point semantic differential scales.

Results

Manipulation Check

A 2 (Positive or negative initial judgment) x 3 (Low, moderate, or high perceived technicality) fixed effect between-groups analysis of variance was performed on respondents' initial judgment ratings to determine whether or not the leading questions were effective in manipulating respondents' initial judgments. Equal weights were used to handle unequal cell sizes (Kenny 1985). The analysis yielded a significant main effect for initial judgment condition, $F(1, 38) = 36.75, p < .001$, and no other effects (all F 's < 1). As Table 1 indicates, initial judgments were more positive in positive initial judgment conditions than in negative initial judgment conditions. Thus, the initial judgment manipulation was clearly effective.

TABLE 1

INITIAL JUDGMENTS AS A FUNCTION OF THE JUDGMENT CONDITION AND PERCEIVED TECHNICALITY

	Perceived Technicality		
	Low	Moderate	High
Positive Judgment	10.00 (4)	10.40 (10)	11.88 (8)
Negative Judgment	5.60 (5)	6.50 (12)	6.20 (5)

Note: Cell means are scored on a scale ranging from "2" (Not very favorable) to "14" (Very favorable). Numbers in parentheses indicate the number of respondents per cell.

Inferences About the Performance of an Unmentioned Attribute

A 2 x 3 analysis of variance was performed on respondents' judgments of the performance of the stereo system's receiver. Postexperimental interviews revealed that respondents failed to realize that information about the receiver was not provided in the product description. Nevertheless, respondents' judgments of the receiver varied as a function of initial judgment and perceived technicality. A significant main effect for perceived technicality was found, $F(2, 38) = 5.96, p < .01$. Respondents who perceived the product as moderately technical or highly technical formed more positive inferences than respondents who perceived the product as not technical. The main effect for initial judgment was not significant ($F = 1.30$), but the initial judgment x

perceived technicality interaction was marginally significant, $F(2, 38) = 3.11, p < .06$.

As predicted, initial judgments did not influence respondents' inferences in low ($F = 2.07, ns$) or in high ($F < 1$) perceived technicality conditions. In moderate perceived technicality conditions, however, initial judgments exerted a powerful influence on respondents' inferences, $F(1, 21) = 8.42, p < .01$.

As Table 2 indicates, initial judgments had no effect on inferences in low or high perceived technicality conditions. In moderate perceived technicality conditions (see the middle column in Table 2), inferences were more favorable in positive than in negative initial judgment conditions. Hence, when initial judgments are processed deeply, subsequent inferences are formed which are evaluatively congruent with the initial judgments.

TABLE 2

INFERENCES ABOUT THE PERFORMANCE OF AN UNMENTIONED ATTRIBUTE AS A FUNCTION OF INITIAL JUDGMENT AND PERCEIVED TECHNICALITY

	Perceived Technicality		
	Low	Moderate	High
Positive Judgment	2.00	5.00	4.38
Negative Judgment	3.20	3.75	4.20

Note: Cell means are scored on a scale ranging from "1" (Not very favorable) to "7" (Very favorable).

Ancillary Analyses

A 2 x 3 analysis of variance was performed on respondents' global judgments of the target product. This analysis yielded a significant initial judgment x perceived technicality interaction, $F(2, 38) = 5.76, p < .01$. The initial judgment effect tended to occur only in conditions of moderate perceived technicality.

Respondents' inferences were correlated with their initial judgments, $r = .27, p < .04$. Hence, initial judgments can be used to predict inferences. Moreover, respondents' inferences about one previously unmentioned attribute of the target product tended to correlate with purchase intentions, $r = .24, p < .06$. This correlation is surprisingly high, given that this is a correlation involving only one inference and respondents may have formed many inferences. However, global judgments were the single best predictor of purchase intentions, $r = .44, p < .01$.

Discussion

The results of the present experiment indicate that inference processes are not characterized solely by negativity effects. When initial judgments are processed deeply, positive initial judgments lead to positive inferences and negative initial judgments lead to negative inferences.

It is important to note that respondents were not told to form an impression of the target product while reading the product description. Further, respondents did not expect to judge the product or its attributes. Moreover, respondents did not expect to participate in a second session conducted one week after the first session. Nevertheless, respondents were able to express initial judgments and in some cases, these initial judgments affected respondents' inferences one week later. These inferences pertained to an attribute that was not mentioned in the product description. Therefore, it is clear that the product description could not have directly influenced respondents' judgments of this attribute. Any effect of the product description

on these judgments must have been mediated, at least partially, by initial judgments.

The present study raises some interesting issues for future research. Technicality was measured in the present study. Future work in which technicality is manipulated is needed. Moreover, a study in which instructions are manipulated (e.g., impression versus recall set) and in which appropriate control conditions are included could be useful in delimiting the initial judgment phenomenon.

Just as it is the case that seemingly trivial factors (e.g., subtle changes in a decision situation) can have a large impact on judgment and choice (see Payne 1982), so too it is the case that seemingly trivial factors (e.g., subtle changes in the wording of a question) can affect inference processes. In our view, similar processes may be involved in inference, judgment, and choice. The field of consumer behavior could profit greatly from an integration of these issues and future research should be directed toward such an integration.

TOWARD A METHODOLOGY FOR ASSESSING
EFFECTS OF IN-STORE ATMOSPHERICS

Meryl P. Gardner, New York University
George J. Siomkos, New York University

Abstract

This paper aims to facilitate the development of methodological approaches to investigate the influence of atmospherics on consumer perceptions of physical sensations. An empirical study is used to investigate two critical issues:

- (1) the feasibility of creating effective manipulations of store image in a lab through verbal descriptions, and
- (2) the effects of method type (third person versus role playing) on consumers' product perceptions.

The findings provide initial support for the feasibility of simulating store atmospherics with written descriptions. They suggest that such descriptions systematically affect consumer perceptions of physical sensations. The findings also imply that assessments of the effects of atmospherics are not biased by the use of role playing or third party methodologies. Suggestions for future research are provided.

Introduction

Pragmatic and intellectual challenges motivate researchers to examine the effects of marketing variables on consumer behavior. On a pragmatic level, understanding such effects facilitates the development of effective marketing strategies. On an intellectual level, insights into the effects of marketing variables on consumer behavior enhance our knowledge of human behavior in general.

Research indicates that non-product factors influence consumer perceptions of physical stimuli. Shimp and Yokum (1982) manipulated formulation and advertising content for fictional soft-drinks in order to create expectations and disconfirmation of these expectations. They found that taste ratings and repeat-purchase behavior were negatively related to disconfirmation but positively associated with the favorability of subjects' reactions to the advertisement. Huber, Holbrook and Schiffman (1982) manipulated formulation and taste conditions for a fictional citrus drink to investigate the impact of situational factors on sensory impressions. Taste condition was manipulated by having subjects exercise or not preceding taste tests. Findings indicate that exercise, a non-product factor, affected sensory perceptions.

One non-product factor of particular interest to marketers is atmospherics. Research in social psychology indicates that ambient settings strongly influence perceptual processes. For example, H.W. Smith (1978) studied the effects of social setting on perceptions of feeling "high" among experienced marijuana users. All subjects were given placebos and told that the pills had a 50/50 chance of being THC, the active component of marijuana. Subjects given the pills in a group setting reported feelings of "being high" and acted in ways which were associated with drug experiences, while subjects given the pills in solitude neither reported such feelings nor performed such behaviors. These findings suggest that the social and cultural aspects of drug consumption in group settings influence users' perceptions of their physical sensations.

In a marketing context, Kotler (1974) has suggested that store atmosphere may affect product perception and so, be considered one of the most significant features of a product. Obermiller and Bitner (1984) have suggested that the importance of atmospherics in brand evaluation may vary by product type and level of involvement. Donovan and

Rossiter (1982) suggest that retail store selection studies emphasize cognitive influences (e.g., price, location, quality of merchandise), and neglect the influence of store atmosphere. They suggest that emotional responses induced by in-store environments are primary determinants of the extent to which individuals spend money beyond their original expectations. Gardner (1985a) has suggested ways in which point-of-purchase settings may affect consumer mood states, which in turn may affect in-store beliefs and evaluations.

Methodological Issues

Given the importance of understanding the effects of atmospherics on consumer perception of physical sensations, it is surprising that greater emphasis has not been placed on the development of research approaches to study such influences. This paper aims to facilitate the development of this important area by examining two critical issues:

- (1) the feasibility of creating effective manipulations of store image in a lab through verbal descriptions, and
- (2) the effects of method type (third person versus role playing) on consumers' product perceptions.

Verbal Descriptions

Several approaches can be used to study the effects of atmospherics on physical sensations. One general typology of methods involves field and lab experiments. In field experiments, although the realism of the phenomenon being studied is apparent, there are two related problems: First, cover stories for random assignment of subjects to atmospherics conditions may be obtuse or transparent, resulting in confusion or demand characteristics, respectively. Second, if random assignment of subjects to conditions is not achieved, selection bias will result (Campbell and Stanley 1963). In lab experiments, random assignment of subjects to conditions is relatively easy, but the creation of store atmosphere is often difficult and expensive. Researchers can attempt to simulate atmosphere through verbal descriptions of in-store characteristics. It is not at all clear, however, that verbal descriptions of atmosphere can be powerful enough to systematically affect consumer perceptions of physical sensations. One goal of this study is to evaluate the feasibility of simulating in-store atmosphere with verbal descriptions. Specifically, we ask: Can verbal descriptions systematically affect consumer perceptions of physical sensations? If the answer is affirmative - i.e., if verbal descriptions can systematically affect perceptions - future research could be used to refine the descriptions and compare their effects to those obtained under field conditions.

Method Type

Approaches to research the effects of atmospherics on consumer behavior may involve projective techniques with subtle but important differences in semantics. The term "role playing" will be used to refer to techniques which require subjects to imagine themselves in hypothetical situations and to respond accordingly. The term "third person" method will be used to refer to techniques which require subjects to respond as they believe others would in hypothetical situations.

In some ways, role playing and third person methods are related to personal and societal judgments. The term "personal judgments" is used to refer to judgments about

oneself, and the term "societal judgments" is used to refer to judgments about other people (Tyler and Cook 1984). The impersonal impact hypothesis (Tyler 1980, Comstock 1982, Howkins and Pingree 1982) has been developed to examine personal and societal level judgments about social phenomena. Tyler and Cook (1984) have examined this hypothesis using a wide variety of natural and social hazards. Their findings indicate that individuals separate personal from more general views of the world, and that societal, but not personal judgments, are affected by media events.

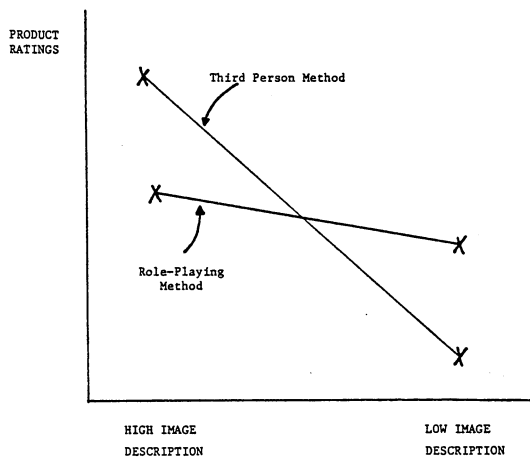

This might suggest that third person methods may be more sensitive to the effects of situational factors than role playing methods. Note, however, that the social psychology paradigm used to investigate the impersonal impact hypothesis may not be fully relevant to experiments involving atmospherics. One reason why social psychologists may have found that media has a greater influence on societal level judgments than on personal level judgments may be due to the fact that societal judgments involve direct inferences from the information presented in the media. For example, verbal reports of social risks, such as those used by Tyler and Cook, depict "others" in a host of situations. Note that personal judgments are only indirectly related to the opinions or experiences of "others" appearing in media stories. In contrast, marketers interested in the effects of atmospherics may be able to create involving settings or scenarios for use with either third person or role playing methodologies. We ask: Do role playing and third person methodologies systematically bias the findings of studies of the effects of atmospherics?

Research Approach

This paper presents an empirical study of the effects of written descriptions and method type on consumers' product perceptions. If written descriptions of store atmospherics can simulate field conditions, product ratings will be more favorable for subjects exposed to descriptions of high image stores than for those exposed to descriptions of low image stores. Such ratings are expected to reflect features of stores associated with the descriptions.

If method type affects consumers' product perceptions as postulated by the impersonal impact hypothesis, written descriptions and method type would interact to affect product ratings. As depicted in Figure 1, ratings would be most favorable for subjects exposed to a high image description and assessed by a third person method and least favorable for subjects exposed to a low image description and assessed by a third person method.

FIGURE 1

First, the experiment will be described, and findings presented. Then, implications for the development of methodologies to investigate atmospherics will be discussed.

Method

Subjects

Eighty subjects participated in the study. All were full time employees of a major corporation in New York City. Subjects varied in occupation, race, and age (18 to 65 years) and participated voluntarily, with neither coercion nor financial compensation.

Independent Variables

Verbal Descriptions

In order to examine whether or not verbal descriptions of atmospherics can be powerful enough to systematically affect consumer perceptions of physical sensations, two descriptions were used. One involved a low image store described as follows:

"...The lighting is very bright and harsh...the aisles are narrow and the counters and racks crowded and messy...the floors are white -- dirty, dingy white -- asbestos tile...there is no soothing background music...the mannequins are disheveled and wearing daddy clothes which do not fit...the sales persons are sloppily dressed, nasty and uncooperative, as are the customers...the dressing rooms consist of one big, smelly room with a couple of mirrors and no privacy...generally there is a feeling of scuzziness all around you."

The other description involved a high image store, described as follows:

"...The lighting is indirect and subtle...the aisles are wide and the counters and racks neat and uncrowded...the floor is covered with plush, bright carpeting...there is soothing mood music playing in background...mannequins are attractive and very fashionably attired...the sales persons are sophisticated, friendly and cooperative, as are the customers...generally, there is a feeling of elegance all around you."

Method Type

To examine the effects of role playing and third person methodologies, two sets of instructions were used. Role playing instructions asked subjects to imagine being in a high/low image department store. Third person method instructions involved telling subjects that "other" subjects were asked to imagine themselves in a high/low image store, and asking subjects to project the responses of those "others".

Experimental Design

A 2 X 2 full-factorial experimental design was used. As discussed in the dependent variables section, the two levels of Verbal Description were high and low image and the two levels of Method Type were role playing and projection. Equal numbers of males and females were assigned to each of the four experimental conditions, but otherwise, subjects were randomly assigned to treatments.

Product Selection

To examine perceptions of physical sensations, we chose to focus on assessments of the scent of a fragrance. Although consumers claim to base fragrance purchases on their evaluations of products' scent, marketers spend a large proportion of their advertising budgets associating non-product features with their brands. According to Pearl Nipon, who with her husband, has fashioned the floral/Oriental fragrance Albert Nipon, "fragrance conjures up images, memories and dreams" (Vogue, 1983). Frangiopani was selected for use in this study, because pretests indicated that it did not generate a consistent or strong set of beliefs or associations. In addition, the scent was not recognized and did not evoke strong affective reactions. It was presented as a "new" fragrance with no brand information provided.

Procedure

Subjects participated individually in what they were told was a test of a new fragrance sold in a local store. Each subject was asked to read one of the method type instructions and one of the verbal descriptions. (For instructions and descriptions, see Independent Variables section). After reading the appropriate scenario, each subject was instructed to write the name of the store which the scenario brought to mind and the number of times s/he had shopped in that store in the past six months. Subjects in the high image store (verbal description) condition were asked to describe the one thing they liked most about the store they mentioned. Those in the low image store (verbal description) condition were asked to describe the one thing they disliked most about the store they mentioned. These exercises served to embed the "store surroundings" in the subject's mind. All subjects were instructed to recall all of the things around them in the store. They were then asked to sniff the fragrance and to complete a questionnaire containing the dependent variables.

Dependent Measures

Fragrance advertisements were examined to generate a pool of potential items for inclusion in the questionnaire. Informal interviews were used to select from this pool those phrases used by consumers to describe their perceptions of a scent. The items selected were: likeable, sophisticated, youthful, sexy, sporty, exotic, modern, and traditional.

Two types of measures were assessed. Subjects were asked to rate the experimental scent using bipolar semantic differential scales (coded 1 to 7) for each item. For example, subjects were asked to rate the experimental scent on a 7-point scale anchored by traditional/not traditional. In addition, subjects were asked to evaluate each item to reflect their feelings about perfumes in general, using scales (coded -3 to +3) with endpoints labeled bad/good. For example, subjects were asked how good or bad they felt it was for a perfume to be traditional. To examine the favorability of ratings, evaluative beliefs were formed by multiplying each rating by its evaluation. Thus, one's evaluative belief for "traditional" reflects both one's rating of the experimental scent on that characteristic and one's evaluation (good/bad) of traditional perfumes in general.

Results

Analysis of variance was used to investigate the effects of verbal descriptions and method. First, the findings for evaluations will be discussed, then the findings for ratings, and finally, the findings for evaluative beliefs (ratings x evaluations).

TABLE 1
Means Of Evaluations

	HIGH IMAGE THIRD PERSON	LOW IMAGE THIRD PERSON	HIGH IMAGE ROLE-PLAYING	LOW IMAGE ROLE-PLAYING
Likeable	2.50	1.55	1.85	1.60
Sophisticated	2.00	1.61	1.75	1.40
Youthful	1.15	0.50	0.40	0.70
Sexy	1.45	1.72	2.10	1.15
Sporty	0.80	0.78	0.30	0.15
Exotic	0.65	1.11	1.15	0.75
Modern	1.05	1.06	0.70	0.50
Traditional	0.40	0.00	0.30	0.05

Cell means for evaluations of each characteristic for perfumes in general are reported in Table 1. Note that

all entries are non-negative, indicating in all conditions all features are on average, evaluated neutrally or favorably. Individual evaluations for each characteristic ranged from -3 to +3. Examination of cell means reveals the following pattern of responses across factors: With respect to verbal description, evaluations are more favorable for high image for 7 of the 8 characteristics and equal for 1. This pattern was not postulated a priori and will be discussed in the Discussion section. Analysis of variance results indicate that the main effect for verbal description for likeable/unlikeable approaches significance ($p < 0.056$). With respect to method type, evaluations are more favorable for third person conditions for 5 of the 8 characteristics, and more favorable for role playing conditions for 3 factors. Analysis of variance results indicate that neither the main effects for method type, nor the verbal description x method type interaction approach conventional levels of statistical significance (i.e., all p's > 0.10).

TABLE 2
Means Of Ratings

	HIGH IMAGE THIRD PERSON	LOW IMAGE THIRD PERSON	HIGH IMAGE ROLE-PLAYING	LOW IMAGE ROLE-PLAYING
Likeable	2.90	2.55	3.60	2.60
Sophisticated	3.35	2.10	3.75	2.25
Youthful	3.15	1.95	2.85	3.20
Sexy	2.95	1.95	3.10	1.80
Sporty	2.70	2.05	2.05	2.35
Exotic	2.55	2.15	2.90	2.40
Modern	3.20	1.90	3.05	2.50
Traditional	4.30	3.68	3.35	3.45

Cell names of ratings of the experimental scent appear in Table 2. Individual ratings for each characteristic ranged from 1 to 7. Inspection of cell means revealed that for all 8 characteristics, assessments were more favorable for subjects in the high image store (verbal description) condition than for those in the low image store (verbal description) condition. Analysis of variance findings indicate that the main effect for verbal descriptions is statistically significant for three of the variables (sophisticated: $p < 0.001$; sexy; $p < 0.002$; modern; $p < 0.018$) and approaches significance for a fourth (likeable: $p < 0.103$). Inspection of the means with respect to method type, indicates that ratings are more favorable for third person conditions for 2 of the 8 characteristics, equal for 1 and more favorable for role playing conditions for 3. Analysis of variance does not indicate any significant main effects for method type or for the method type x verbal description interaction - i.e., all p's > 0.10 .

TABLE 3
Means Of Evaluative Beliefs

(Evaluative Belief = Rating X Evaluation)

	HIGH IMAGE THIRD PERSON	LOW IMAGE THIRD PERSON	HIGH IMAGE ROLE-PLAYING	LOW IMAGE ROLE-PLAYING
Likeable	7.30	3.75	6.95	5.45
Sophisticated	7.70	3.50	7.00	-3.40
Youthful	3.30	0.89	0.60	2.90
Sexy	5.60	3.94	6.20	1.60
Sporty	3.35	1.88	0.40	1.35
Exotic	1.90	2.83	4.10	1.70
Modern	3.95	1.67	2.60	1.35
Traditional	1.25	-1.53	1.30	0.60

Cell means for evaluative beliefs appear in Table 3. Recall that evaluative beliefs were created by multiplying each rating by its evaluation. Inspection of means reveals that evaluative beliefs are more favorable for subjects exposed to the high image description than for those exposed to the low image description for 7 of 8 characteristics. For the characteristic, "youthful", evaluative beliefs were approximately equal for subjects in the two conditions. Analysis of variance results indicate that the main effect for verbal description is significant for two characteristics (sophisticated: $p < 0.004$; sexy: $p < 0.014$ and approaches significance for two more (likeable: $p < 0.067$; modern: $p < 0.103$). With respect to method type, evaluative beliefs are more favorable for subjects in third person conditions for 5 of the 8 characteristics and more favorable for subjects in role playing conditions in 3. Analysis of variance results indicate no significant main effects for method type, and one interaction which approaches significance (youthful: $p < 0.092$). Examination of means for "youthfulness" do not support the impersonal impact hypothesis - i.e., they do not correspond to Figure 1.

Discussion

Summary

Ratings, evaluations and evaluative beliefs were examined in order to investigate the effects of verbal description and method type on consumer perceptions. Findings indicate:

- (1) Evaluations are more favorable for subjects exposed to verbal descriptions of high image stores than for those exposed to descriptions of low image stores, for 7 of the 8 characteristics. This difference approaches conventional levels of statistical significance for only 1 of the characteristics (traditional).
- (2) Ratings are more favorable for subjects exposed to verbal descriptions of high image stores than for those exposed to descriptions of low image stores for 7 of the 8 characteristics. This difference reaches conventional levels of statistical significance for 3 characteristics (sophisticated, sexy and modern), and approaches conventional levels of significance for 1 characteristic (likeable).
- (3) Evaluative beliefs are more favorable for subjects exposed to verbal descriptions of high image stores than for those exposed to descriptions of low image stores for 7 of the 8 characteristics. This difference reaches conventional levels of statistical significance for 2 characteristics (sophisticated and sexy), and approaches conventional levels of significance for 2 characteristics (likeable and modern). In addition, the written description X method type interaction approaches statistical significance for 1 of the 8 characteristics (youthfulness).

Verbal Descriptions

The findings provide initial support for the feasibility of simulating high and low image store atmospherics with written descriptions. They suggest that such descriptions systematically affect consumer perceptions of physical sensations.

Ratings and evaluative beliefs were generally more favorable for subjects exposed to descriptions of high image stores than for those exposed to descriptions of low image stores. The level of significance associated with each product characteristic may indicate the association of that characteristic with the features of stores associated with the descriptions. For example, Bloomingdale's the store most often associated with the high image description, follows policies which emphasize:

- " - discovering the hottest young designers and letting their imaginations run wild

- turning the marketing of clothing, find and home furnishings into an art
- searching the globe to uncover - and invent - new trends
- creating sophisticated boutiques to rival the finest galleries
- using sophisticated promotions." (Stevens 1979).

These strategies may lead to a store image which is sophisticated, sexy and modern, the characteristics with relatively high levels of significance. Although some of the effects of verbal descriptions may be attributable to demand characteristics, the relationship of significance levels to features of the stores elicited by subjects suggests that responses were mediated by relevant internally generated cues.

Second, evaluations of attributes were generally more favorable for subjects exposed to descriptions of high image stores than for those exposed to descriptions of low image stores. Although this finding was not postulated a priori and only approached conventional levels of statistical significance, it suggests that subjects were responding to the verbal descriptions and provides direction for future research. One postulate may be that verbal descriptions affect consumer mood states which, in turn, affect evaluations (Clark and Isen, 1982; Gardner, 1985b).

Method Type

The findings fail to indicate an effect due to method type. The main effect did not approach conventional levels of statistical significance for any variable for any characteristic. The method type X verbal description interaction approached significance for only one of the 24 analyses of variance, well within the number expected by chance. These results suggest that, contrary to the impersonal impact hypothesis, assessments of the effects of atmospherics may not be biased by the use of role playing or third party methodologies. It appears that the verbal descriptions were equally involving, vivid, and informative under the two method type conditions.

Implications

The findings reported provide suggestions for future research involving the effects of atmospherics on consumer product perceptions. They indicate that method type may be relatively unimportant and that either third person or role playing methodologies may be used. Future research is needed to examine the effects of method type in studies of topics and products which are sensitive, personal or "embarrassing." Further investigations are also needed to explore the effects of method type on different types of beliefs and on consumers with various levels of product class knowledge.

The findings reported also suggest that verbal descriptions can be developed which systematically influence perceptions. Additional research is needed to compare the effects of verbal descriptions with those of their real-world counterparts and to examine the effects of verbal descriptions which vary along a continuum from extremely negative to extremely positive.

VARIATIONS IN CHOICE STRATEGIES ACROSS DECISION CONTEXTS:
AN EXAMINATION OF CONTINGENT FACTORS

Wayne D. Hoyer, The University of Texas at Austin

Abstract

Consumer decision strategies were examined across 12 different product categories. Results indicated that choice strategies vary significantly across decision contexts. An attempt was then made to examine how certain contingent factors (e.g., amount of advertising, number of brands available, perceived similarity of brands) were able to account for this variation. Implications of findings are then discussed.

Introduction

Recent work in human information processing has clearly recognized the fact that individuals are highly responsive to the situation or task at hand (Newell and Simon 1972; Belk 1975; Bettman 1979; Simon 1981; Payne 1982). That is, an individual may react quite differently depending on the contingencies surrounding the situation. For example, a consumer may be price-conscious in a product category where major price variations exist, but be brand loyal in another where there are few such differences. Thus, major questions which may be posed are: To what extent and why do consumers employ different decision strategies in different situations? Put another way, in order to develop a more complete theory of consumer decision making, the effects due not only to the individual, but also to the task and the task X individual difference interaction must be considered (Punj and Stewart 1983).

In response to this realization, a number of studies have begun to examine contingent effects upon decision making behavior (Payne 1982; Punj and Stewart 1983). Punj and Stewart (1983) summarized the major findings in this area and attempted to integrate them into a meaningful framework. This framework identifies the key task variables (e.g., number of alternatives, number of attributes, time pressure, etc.) and task X individual difference interactions (e.g., the exposure situation, impulse purchases, etc.) which impact on the decision process.

While a review of the studies in each of the areas is beyond the scope of the present paper (for the full review, see Punj and Stewart 1983), an examination of the findings reveals two important generalizations. First, many of the studies have focused on broad level types of processing which occur when a decision is made. A variety of different dependent variables have been examined including: the amount of information processing (as examples, Jacoby, Chestnut, and Fisher 1978; Bettman and Park 1980), the processing strategy employed (by brand or by attribute--e.g., Bettman and Kakkar 1977; Wright and Barbour 1977), the amount of time taken (e.g., Gardner, Mitchell, and Russo 1978), accuracy of choice (e.g., Jacoby, Szybillo, and Busato-Schach 1977), and intentions (e.g., Belk 1974, 1975). However, a major void concerns the examination of how different task and individual difference factors influence the specific choice rules used to make a decision. Only a handful of studies (e.g., Wright 1975; Wright and Barbour 1977; Park 1978; Crow, Olshavsky, and Summers 1980; Bettman and Park 1980) have focused on this dependent variable and these studies have been concerned with only one task characteristic--the number of alternatives available.

A few other studies have examined cross-product differences (e.g., Cunningham 1956; Massy, Frank, and Lodahl 1968; Wind and Frank 1969) but these studies have limited attention to general buying behaviors such as brand loyalty or private brand proneness. Blattberg, Peacock, and Sen (1976) examined differences in purchasing strategies across product categories, but their major interest was in determining how choice is influenced by general household

characteristics such as demographics and they examined differences across only two product categories.

Second, most of the studies have examined contingent effects in discrete situations where at least a moderate degree of information processing takes place (i.e., situations of high to moderate involvement). One must question, however whether the findings of these studies would generalize to situations where processing is relatively continuous or involves repeated decisions over time (Hogarth 1981) and where relatively little information processing occurs (i.e., low involvement situations--Ray, et al. 1973).

In light of these observations, the purpose of the present paper is to examine the very important effect of task variables in low involvement decision situations. The major question to be asked is to what extent do various aspects of the task influence consumers to employ a particular type of choice rule or heuristic. Hypotheses will be developed, followed by an empirical attempt to test these hypotheses.

The Nature of Low-Involvement, Repeat Purchase Decision Making

A recent article by Hoyer (1984) provides a view and empirical examination of consumer decision making for product categories which are purchased frequently over time and which are low in involvement or importance. The basic notion underlying this view is that consumers employ very simple choice heuristics when making low involvement purchases. These rules are referred to as "choice tactics" and they permit consumers to make a quick and effortless decision. These tactics are acquired as a result of a learning or "trial and error" process over time. In other words, depending upon the nature of the post-purchase brand evaluation (e.g., positive, negative, or neutral), consumers can "adjust" their decision heuristic on the next purchase occasion in order to provide a more satisfactory choice. Thus, low involvement repeat purchase decision making is viewed as a continuous as opposed to discrete processing situation and observed decision making at one point in time would appear to be very limited.

Some preliminary support for this notion has been provided in a study by Hoyer (1984). In examining the in-store purchase of laundry detergent, it was found that the median amount of time devoted to a purchase was about four seconds. Thus, on an observational level, there appears to be an extremely low level of in-store information processing. Further, when asked why they purchased the brand they did, 92% of the respondents supplied one simple reason (i.e., a choice tactic). These tactics tended to be of six major types: (1) price-oriented tactics (e.g., "buy the cheapest," "buy the brand on sale," "buy the brand for which I have a coupon," etc.), (2) performance tactics (e.g., "buy the brand which works the best," etc.), (3) affect-related tactics (e.g., "buy the most familiar brand," "buy the brand I like," etc.), (4) normative tactics (e.g., "buy what my parents bought," "buy what my friend advises," etc.), (5) in-store factor tactics (e.g., "buy the first brand I see," "buy the brand most prominently displayed," etc.), and (6) hybrid tactics (see Hoyer 1984). When viewed in conjunction with other studies (e.g., Olshavsky and Granbois 1980), there appears to be support for the notion that consumers employ simple choice rules in one type of low involvement situation.

In light of this fact, a major question which remains yet to be answered concerns the reasons why a particular tactic is employed. In particular, it is unlikely that the same tactic would be used in every product category. On the other hand, there will be certain individual difference

characteristics which will lead to the usage of a particular tactic. It is a major assumption of the present paper, however, that aspects of the situation (e.g., task variables) will also account for a significant portion of the potential within-subjects variance. Specifically, it is suggested that contingent factors will interact with individual difference factors to produce the usage of a particular choice tactic. Therefore, in order to more fully understand the nature of common, repeat purchase decision making, an attempt must be made to empirically examine the effects of these task variables upon the decision process.

In summary, a major purpose of the present research is to more formally examine the consistency of consumer decision strategies across a number of product categories. A major question concerns the extent to which consumers employ the same tactic or strategy across product categories or whether different strategies are used for different decisions. Specifically, consumers' choice tactics were assessed for 12 different product categories in order to examine both within-subject and across product consistencies.

In addition, the present research attempts to empirically assess the importance of a number of contingent or task factors: the amount of advertising for the product class, price variations within the product category, the number of brands available, and the perceived similarity of brands in the product category. In examining these factors, it is important to remember that interest is in examining factors which influence the specific reason why the brand was chosen as opposed to variables such as the amount of processing and the type of strategy employed (e.g., within-brand vs. within dimension). These hypotheses are not meant to be exhaustive; rather their intent is to provide initial evidence of the importance of contingent factors in determining the specific type of decision strategy employed. With this in mind, the following hypotheses are offered:

Hypothesis 1: The greater the amount of product class advertising, the more likely consumers will employ tactics based on affect or familiarity and less likely to base a decision on price tactics.

Given that familiarity which results from repeated exposures to advertisements is critical to the development of product-related affect (Ray, et al. 1973; Zajonc and Markus 1982), it is hypothesized that affect related tactics are more likely to be employed in product categories where there tends to be a heavy amount of advertising.

Hypothesis 2: The greater the range in prices for a particular product category, the more likely consumers will employ a price related tactic and less likely they will employ an affective, normative, or performance tactic.

If no appreciable variations in price exist, consumers must rely on some other form of criterion to make a decision. Put another way, little variance on the attribute would not permit it to be determinant (Alpert 1980). If, on the other hand, there are major price differences between brands, it is much more likely that this factor will come into play as a key decision criterion. This would be consistent with the finding that consumers are less brand loyal when prices are active (Farley 1964).

Hypothesis 3: The greater the number of brands, the more likely consumers will employ a price tactic and less likely to employ a performance tactic.

If there are a large number of brands available, it is likely that there are a number of alternatives which will satisfy consumers' needs. Therefore, consumers could select an inexpensive brand from this set. Further, research has indicated that consumers tend to be less loyal toward products with many available brands (Farley 1964).

Hypothesis 4: When the perceived similarity of brands is high, consumers will be less likely to base their decision on a performance tactic and more likely to employ a price tactic.

In other words, if the brands in a particular product class are perceived to be of roughly equal quality, some other form of tactic other than a performance-related one is likely to be employed. If there is a strong discrimination in terms of quality, however, a performance tactic will have a higher probability of being chosen.

Method

Subjects. The subject population consisted of 175 consumers in a Southwestern city who were intercepted as they engaged in grocery shopping. Shoppers were interviewed in eight different grocery stores (representing the three major local chains) throughout the entire city. Interviewing times were divided equally between the morning, afternoon, and evening hours. However, due to varying traffic patterns, 22 (12.5%) of the shoppers were interviewed in the morning, 117 (67%) in the afternoon, and 36 (20.6%) in the evening. One hundred twenty four of the subjects (70.9%) were women and 51 (29.1%) were men. When compared to city demographics, subjects approximately corresponded to the city population in terms of education, age, and income.

Product Categories (Independent Variables). Twelve different product categories were selected for study. These products were chosen to ensure variance along the major independent variables (i.e., the external factors): advertising expenditures, the number of brands available and the price range among brands. The remaining variable: (i.e., the internal factor of perceived similarity of brands) varies from individual to individual and, thus, was measured by means of a questionnaire item.

In order to select the product categories, information was collected along the previously mentioned dimensions for 24 common low involvement products. In each of the eight test stores, interviewers recorded the number of brands available, the number of shelf tags present, the price range (lowest to highest brands), and the face dominance (one, two, three, or no brand dominates). The values for each individual store were then combined to calculate an overall mean for each product for each variable. The product categories resulted by selecting products which were high, medium, and low in terms of the means for each external factor. The twelve products chosen adequately fulfilled this requirement. These products were: breakfast cereal, canned peas, canned soup, coffee, butter, shampoo, headache remedies, bar soap, toothpaste, aerosol bathroom cleaner, toilet paper, and tuna.

Assessment of Other Major Variables

Choice Tactic. The major variable of interest was the choice tactic(s) employed by consumers when making a purchase. Due to the fact that consumers were volunteering their time in the middle of a shopping trip to indicate their choice strategies for 12 different product categories, a verbal protocol was abandoned in favor of a more streamlined procedure.

On the basis of a number of previous studies (Deshpande, Hoyer, and Jeffries 1982; Cobb 1983; Hoyer 1984), six major types of choice tactics were identified. A list of these is provided in Table 2. A seventh category (I never buy this product) was added to account for subjects who did not purchase the product. Subjects were presented with these statements by means of an index card and were asked to read aloud the number of the statement(s) which best represented the way they usually bought the product. The response was then recorded on a special answer sheet by the interviewer.

Similarity of Brands. A similar procedure was employed to measure the perceived similarity of brands in the product category. Subjects were presented with an index card which contained categories ranging from 1=very similar to 5=very dissimilar. Subjects were asked to indicate how similar in quality the brands in the product category were. Again, responses were recorded by the interviewer.

Results

Variations in Tactic Usage Within Subjects

Table 1 presents a summary of the number of choice tactics employed by each subject. It can be seen from the Table that tactic usage varied fairly substantially among the decision makers. Only 7% (n=12) of the subjects employed the same tactic across all 12 product categories, while 49% of the sample (n=85) used 4 or more. Thus, it can be concluded that a substantial number of consumers do use different choice strategies across different product categories. This finding serves as the justification regarding further investigation as to the origins of this variation.

TABLE 1

NUMBERS OF DIFFERENT TACTICS USED			
Number of Tactics Used	n	Percentage	
1	12	7%	} 23%
2	27	16%	
3	50	29%	
4	54	31%	} 49%
5	26	15%	
6	4	2%	
7	1	1%	
	174	100%	

Choice Tactic Usage Across Product Categories

A second area of interest was to determine the specific types of tactics used across product categories. It can be seen from Table 2 that significant variations in tactic usage did exist. First, price-related tactics were most likely to be employed for decisions regarding toilet paper (42.3%), tuna (27.4%), and butter (24.6%), while price was of least concern for breakfast cereal (5.7%) and toothpaste (11.4%) decisions.

Performance-related tactics were most evident for decisions regarding shampoo (40.0%), breakfast cereal (36.6%), and toothpaste (30.9%), while least employed for canned peas (16.6%) and aerosol bathroom cleaner (16.9%).

Familiarity-related tactics were employed little across all product categories. This tactic was most evident for bar soap (10.3%) and canned soup (9.7%). One possible reason for this low reporting however may be the social undesirability of admitting this type of behavior. Normative tactics were also employed infrequently, but were most likely to appear in breakfast cereal decisions. This likely reflects the influence of children in the decision.

Finally, significant variations existed in the tendency to purchase habitually (i.e., always buy). This type of decision making was most likely to appear for toothpaste (40.0%), butter (32.0%), canned soup (29.1%), and bar soap (29.1%). This tactic was employed in choices regarding aerosol bathroom cleaner (9.1%) and canned peas (12.0%).

In summary, wide variations in tactic usage do appear to exist across product categories. Different types of tactics tend to be employed in different product categories. Merely documenting this fact however, does not provide provocative information to those interested in consumer decision making. What is needed is an attempt to explain the nature of the variations in tactic usage or why different tactics are employed across product categories. Attention is now turned to an initial investigation of several potential factors.

Tests of Hypotheses

Four exploratory hypotheses were presented to provide a preliminary explanation of strategy variation across product categories. Specifically, four major situational variables were investigated: amount of product class advertising, price variations within the product category, the number of brands available, and perceived similarity among

brands.

In order to test the hypotheses related to each of these variables, previously collected information regarding each of the independent variables was converted to ranks. For example, each of the product categories was ranked from 1 (=low) to 12 in terms of the amount of advertising, number of brands available, etc. These rankings were then correlated with a ranking for the presence of a tactic for the product category using a rank-order correlation statistic. Table 3 presents a summary of this analysis.

Hypothesis 1 stated that the greater amount of product class advertising, the more likely consumers will employ familiarity based tactics and less likely to base the decision on price factors. It can be seen from the Table that support for the hypothesis was mixed. Consumers were less likely to employ price tactics ($r = -.78$, $p < .01$) when product class advertising was high, but were not more likely to use a familiarity tactic ($r = .28$). It is important to note, however, that consumers did not indicate heavy usage of familiarity as a tactic across all product categories. It was interesting to find, however, that the usage of performance-related tactics increased with higher levels of advertising ($r = .66$, $p < .05$). One possible explanation for this finding is that advertising may create stronger performance perceptions in consumers' minds.

Hypothesis 2 states that greater price variations in a product category will lead consumers to use a price-related tactic and result in less usage of affective, normative, or performance tactics. From Table 3, it can be seen that support for this hypothesis was not in evidence. When price variations were higher, consumers were no more likely to employ a price tactic ($r = -.06$); rather, the incidence of performance ($r = .43$) and habitual tactics ($r = .50$, $p < .05$) were more in evidence. One possible explanation is that a price-quality relationship may be higher when price variations are greater.

Hypothesis 3 indicates that consumers will be more likely to employ a price tactic and less likely to employ a performance tactic when there are a greater number of brands available. In this case, findings were in the opposite direction from the hypothesis. As the number of brands increased, consumers were less likely to employ a price tactic ($r = -.50$, $p < .05$) and more likely to use a performance tactic ($r = .59$, $p < .05$). Perhaps with many brands available, consumers are more likely to rely on a favored brand in order to make the decision task more manageable.

Finally, Hypothesis 4 states that consumers will be less likely to use a performance tactic when the perceived similarity of the brands in the product category is high. As shown in Table 3 strong support for this hypothesis is in evidence. When perceived similarity was high, consumers were more likely to use a price tactic ($r = .49$) and much less likely to base their decision on performance ($r = -.79$, $p < .01$) and habit ($r = -.40$).

Discussion

The results of the present study indicate that significant variations in choice strategies do exist across product categories. First, a fairly substantial proportion of consumers employed 4 or more tactics across the 12 product categories. If individual difference factors were the major determinant of decision strategy, one would expect strategies to be fairly consistent across product categories. The findings of the present study suggest, however, that certain aspects of the task of decision situation intervene to cause subjects to employ different strategies across choice situations. As further evidence of this fact, a second finding was that the different types of choices were employed in different proportions across the product categories. For some products, price related tactics were dominant, while for other performance related, habitual, or other tactics tended to be employed. Again, it is suggested that certain aspects of the task cause these tactics to be applied in different proportions across the product categories.

TABLE 2
CHOICE TACTIC USAGE ACROSS PRODUCT CATEGORIES

Product Category	Choice Tactic							
	Performance	Price	Normative	Always Buy	Most Familiar	Strands Out on Shelf	Combinatorial	Never Buy
Breakfast Cereal	36.6% (11)	5.7% (1)	12.0% (12)	18.9% (3.5)	3.4% (1.5)	4.6% (12)	5.1% (7)	13.7% (9)
Canned Peas	16.6% (2)	20.6% (8)	2.3% (2.5)	12.0% (2)	6.9% (8)	-0- (1)	2.2% (3)	39.4% (11.5)
Canned Soup	26.3% (6)	15.4% (4)	4.0% (7.5)	29.1% (9.5)	9.7% (11)	1.7% (6.5)	2.9% (5)	10.9% (8)
Coffee	22.9% (3)	17.1% (5)	2.9% (4.5)	22.3% (6)	8.6% (9.5)	1.7% (6.5)	5.7% (10.5)	18.9% (10)
Margarine/Butter	25.7% (5)	24.6% (10)	2.3% (2.5)	32.0% (11)	5.7% (6.5)	1.1% (2)	2.3% (3)	6.3% (5)
Shampoo	40.0% (12)	13.1% (3)	2.9% (4.5)	24.0% (7)	5.1% (5)	4.0% (11)	5.1% (7)	5.7% (4)
Headache Remedy	30.3% (8.5)	18.3% (6)	4.6% (10)	26.9% (8)	4.6% (4)	3.4% (10)	1.7% (1)	10.3% (7)
Bar Soap	30.3% (8.5)	18.9% (7)	3.4% (6)	29.1% (9.5)	10.3% (12)	1.1% (2)	5.1% (7)	1.7% (3)
Toothpaste	30.9% (10)	11.4% (2)	4.6% (10)	40.0% (12)	4.0% (3)	1.1% (2)	6.9% (12)	1.1% (2)
Bathroom Cleaner	16.9% (1)	21.7% (9)	4.0% (7.5)	9.1% (1)	5.7% (6.5)	1.7% (6.5)	2.3% (3)	39.4% (11.5)
Bathroom Tissue	24.0% (4)	42.3% (12)	1.7% (1)	20.6% (5)	3.4% (1.5)	2.3% (9)	5.7% (10.5)	0% (1)
Tuna	26.9% (7)	27.4% (11)	4.6% (10)	18.9% (3.5)	1.7% (6.5)	1.7% (6.5)	4.6% (9)	7.4% (6)

^aNumbers in parentheses are ranks from 1 (lowest) to 12 (highest).

The present study attempted to provide initial evidence regarding the influence of several contingent factors or tactic usage. Results of this attempt was mixed. Both the amount of product class advertising and the perceived similarity of brands in the product class appeared to have a strong impact on the type of tactic employed. When advertising levels are high, consumers are more likely to employ performance related tactics and less likely to use price related tactics. The perceived similarity of brands in the product category had the opposite effect (i.e., greater use of price tactics and less use of performance and habitual tactics). In addition, the degree of price variations increased the level of performance tactic usage and the number of brands led to a decreased use of price tactics and more frequent use of performance tactics.

It is important to note a number of limitations of the present research. First, the present study, due to its exploratory nature, examined the effects of contingent factors in a global level. However, a complete understanding of the selection of a choice tactic involves individual level measurement that pertains to the purchase of a particular brand in a particular store and in a particular store environment. Further research is needed to examine the raised issues in this more individual level context. Second, in some cases, one may question whether the classification schemes for choice tactics are mutually exclusive. For example, knowledge of price or performance factors may be the bases for which consumers claim familiarity with or positive effect towards a brand. Future research of this nature might employ probes to determine the underlying nature of tactic usage. Also, further research is needed to evaluate the adequacy of the tactic measurement approach employed. The possibility exists that retrospective questioning may not be the most effective method for determining choice strategies.

These findings are taken as evidence of how meaningful hypotheses regarding the impact of contingent factors on the use of choice strategies can be developed. Future research is now needed to explore the effects of other contingent factors on the decision process. A number of potentially interesting variables can be identified. These would include both external factors which involve basic aspects of the task which are generally consistent across all individuals, and internal factors which are individual centered perceptions which the consumer brings to the situation. In addition to the number of brands, amount of product class advertising, and price variations, external factors would include product packaging, amount of shelf space,

brand placement on the shelf, the presence of coupons, the presence of displays, and price fluctuations. Also, the type of advertising may have a strong impact on the type of choice tactic used. For example, if the product class advertising was price-based or stressed particular performance attributes, these factors should logically influence the choice. Internal factors would consist of the nature of post-purchase evaluations, the perceived similarity of brands, product class experience, time pressure, and individual difference variables (e.g., frugality, dogmatism, self-confidence, etc.). It is hypothesized that both these internal and external factors will interact to determine the type of choice strategy chosen. Finally, studies which more specifically examine the task-individual interaction are needed.

In summary, the results of the present study indicate that we cannot assume a consistent decision process across all choice contexts. Individuals are reactive to their environment and a complete theory of consumer choice must specify how key contingent factors impact on the decision process. This study is viewed as an initial step in this direction. Future research is needed to develop richer hypotheses regarding these concepts and to test these hypotheses empirically.

TABLE 3

Factor	Price	Performance	Most Familiar	Always Buy	Normative

THE PERSON BY SITUATION INTERACTION MYTH: IMPLICATIONS FOR THE DEFINITION OF SITUATIONS¹

Joseph A. Cote, Washington State University

Abstract

This paper examines the ability of common versus individualized situational effects to predict behavior. The results show a greater generalizability of situational responses than previously thought. Some implications for the definition of situations are discussed.

Introduction

Past research on situational variables has assumed that situational effects depend upon the individual rather than being similar across individuals. This assumption has never been well tested in the consumer behavior area, yet has been used as a bases for defining and evaluating situational effects. The purpose of this paper is to discuss the generalizability of situational effects. Given the results, the current definitions of situations are reexamined.

Much of the work in situation research has argued that people react differently to a given situation, and it is this interaction between the person and the situation that explains most of the variance in behavior (Bowers 1973; Endler 1975). The basis for this claim comes from ANOVA studies of situations. In these studies, the person by situation interaction is often found to explain behavior better than either the person main effect or the situation main effect (Bowers 1973; Ekehammer 1974; Magnusson 1975; Sarason et al. 1975). These results have been used to claim that situational effects depend upon the individual. The belief is that the individualized effects of situations are more important (explain more behavior) than the common effects of situations.

The importance of the individualized effects of situations has been used as support for a subjective definition of situations (Lutz and Kakkar 1975, p. 440).

In restricting the definition of situations to 'observable aggregate effects,' Belk differs with most situational theorists. For example, Cottrell (1950) stated (rather categorically): 'We are quite certain that individuals and groups react to their own definitions of situations...' (p. 711), thus suggesting a subjective, rather than an objective definition.

Are Situational Effects Always Subject Specific

The conclusion that situational effects depend upon the subject may be misleading. The common effects of situations can be defined as the extent to which subjects behave similarly in a given situation. If a situation has a common effect on subjects, then all subjects should

behave the same in that situation. The opposite position maintains that situational effects are individualized, in other words, subjects behave differently in a given situation.

When consumer researchers began to examine situation effects they simply replicated the ANOVA procedure used in the psychology literature. The only difference was that consumer researchers examined a set of product choices rather than examining a single trait. This change, however, affects how the ANOVA results are interpreted (Bonner 1984). The situation main effect no longer measures common situational effects. Instead, the situation by response interaction indicates the common effect for situations (Bonner 1984). A similar problem exists when examining individualized situational effects. When trait categories are used the person by situation interaction indicates individualized situational effects. However, when product categories are used, the person by situation by product interaction indicates individualized situational effects.

Unfortunately, very few ANOVA studies in consumer behavior have reported the person by situation by response interaction. A reexamination of two of these studies (Belk 1974; Sandell 1968) indicates that common situational effects are a major predictor of behavior. In the Belk study, common situational effects accounted for 18.7% of the variance in behavior while individual effects accounted for 3.4%. In the Sandell study common situational effects accounted for 39.8% of the variance while individual effects accounted for 27.8%. These results indicate that while individualized situational effects exist, there are also significant common situational effects. In fact, these common effects may be as important (predict behavior as well or better) as the individualized effects.

Other evidence indicates that situations have common effects across individuals. Srivastava (1980) found that situational factors were stable across individuals and that individuals had similar response patterns to situations. In the ANOVA studies, situation scenarios are presented and subjects are asked to imagine their response to that situation. Therefore the situation by response interaction is the appropriate measure of common situational effects. In the regression studies, however, the occurrence or expected occurrence of a situation is measured rather than imagined. Some subjects experience the situation; others do not. In this case, the appropriate measure of common situational effects is the ability of occurrence to explain behavior. In other words, if a situation occurs, the regression coefficient indicates the effect of the situation for all subjects. Regression studies have also shown that situational effects can be similar across subjects (Wicker 1971; Bearden and Woodside 1976, 1978; Greer 1977; Cote, McCullough and Reilly 1985). These studies only included situation main effects; situation by person interactions were not included or

¹ The comments of James McCullough, Wendy Bryce, and an anonymous ACR reviewer are gratefully acknowledged.

were not found to be significant.

Hypotheses

The results discussed above raise two important questions. Do individuals have similar perceptions about the occurrence of a given situation and do they react similarly to that situation. An exploratory study was conducted to determine the extent to which consumers perceive and react similarly to situations. Both individualized and common situational variables were used to predict behavior.

Past research indicates that consumer reactions may be similar in a given situation. But if a situation is to have a common effect on behavior, then consumers must agree that the situation has occurred. For example, if all subjects have a major paper due before a social event, they should all indicate a high likelihood of the situation occurring. Therefore:

H1: If a situation is certain to occur, subjects should all perceive that the situation will occur.

Under normal circumstances, individualized situational effects would be expected to predict behavior better than common effects. This is true because individual effects allow for a subject's idiosyncratic behavior. However, this is only important when each subject has a completely different view of the world. In many situations, segments of people may have fairly similar views of the world. Within these market segments, common situational effects would exist.

As stated earlier, past research supports the idea that situations may have common effects on consumers. However, there has never been a direct comparison of individualized versus common situational effects. Hypothesis two is an explicit attempt to compare the predictive ability of common situational effects to individualized situational effects.

H2: Common situational effects should predict behavior as well as individualized situational effects.

If subjects respond similarly to a particular situation, then adding individualized situational effects should not improve our ability to predict behavior. Simply knowing that the subject experienced the situation would provide enough information to predict behavior. If subjects each have a different reaction to a particular situation, then behavior can not be predicted unless the individualized effect is included.

Methodology

Subjects

Data were collected on the intentions and actual attendance of 61 students to a social function (class party held by the instructor). Measures of intentions to attend the social function, the likelihood of various situations occurring, and the expected influence of the situations were collected at three different times over a two month period. A paper and pencil questionnaire was administered six weeks before the social function (long term

expectations), repeated three weeks before the social function (medium term expectations), and one day before the social function (short term expectations). Attendance at the social function and the actual occurrence of the situations was measured three days after the social function.

Intentions and Behavior

Intentions were measured using the following likelihood scale: "Given the information provided, how likely is it that you will attend the function?"

+	+	+	+	+	+	+	+	+
Defi	Probably	Not	Probably	Definitely	will	Sure	will not	will not
nitely	will	Sure	will not	will not	will	will	will	will
will	come	come	come	come	come	come	come	come
come	come	come	come	come	come	come	come	come

Intention values ranged from 0 (not come) to 100 (will come) depending on the distance the subject's mark was from the endpoint of the scale. Actual attendance was measured using a yes (1)/no (0) question three days after the social function.

Situations

The list of relevant situations was generated using focus group interviews. Students were asked to describe any situations they thought would affect their attendance to a social function. The researcher then reduced this list by combining similar situations and dropping variables that did not fit Belk's (1974) objective definition of situations. The following list of situations was used in the study:

- 1) Function is scheduled just before a big examination or class paper.
- 2) Function is scheduled just after a big examination or class paper.
- 3) Other functions or activities scheduled (not scheduled) at the same time as this one.
- 4) Student forgets about the function.
- 5) Directions are poor.
- 6) There are not many people at the function.
- 7) Ability to get transportation to the function.
- 8) Student gets involved in other things.
- 9) Bad weather (Social function occurred in the winter).
- 10) Friends or spouse want to do something else that night.
- 11) Any other situations.

To assess the individual effect of situations, subjects were asked to report the expected effect of a situation if it occurred. The questions on the expected effects followed the following format, "The function is scheduled just before a big examination or class paper. This would:"

+	+	+	+	+	+	+	+	+	
Insure	Increase	Have no	Decrease	Insure	that I	the like-	effect	the like-	that I
would	lihood	on my	lihood	would	would	I would	I would	not	would
come	I would	deci-	I would	come	come	come	come	come	come
come	come	sion	come	come	come	come	come	come	come

Scores ranged from 0 (Insure not come) to 100 (insure would come) depending on the distance the subject's mark was from the endpoint of the scale. The influence of "other situations" was measured by asking the subject to indicate any

other situations they expected to influence their behavior and the extent of that influence.

In addition, the expectation of the situation occurring was also measured. This question was worded as follows, "What is the likelihood that you will have a big exam or class paper just before the function?"

+ + + + + + + +
 Defi- Probably not probably definitely
 nitely will sure will not will not
 will

Scores ranged from 0 to 100% chance of occurrence depending on the distance the subject's mark was from the endpoint of the scale. The situational questions were repeated for each of the situations studied. The actual occurrence of the situations was measured using a simple yes (1)/no (0) format.

It was assumed that changes in intentions are attributable to unexpected situational effects (Cote, McCullough, and Reilly, 1985). Hence only changes in the expected effects or likelihood of occurrence were used in the analysis. Unexpected situational occurrences were defined as the difference between the expected probability of the situation occurring in the previous time period subtracted from the expected probability of the situation occurring in the current time period. Figure 1 outlines the model used in the study.

FIGURE 1
 SITUATIONAL MODEL

The first step in the analysis was to develop common and individualistic measures of unexpected situations. Common situational effects assume that all subjects will react the same in a given unexpected situation. The only information needed to determine common situational effects is whether the subject experienced the situation unexpectedly. If two subjects both unexpectedly experienced the situation, then the situational effect would be the same (assuming common effects). Since not all situational effects were controlled or known, self-reported unexpected situations (as defined above) were used as the measure of situational occurrence. Regression or discriminant analysis was then used to estimate the common situational effects given the occurrence of unexpected situations. As long as subjects had the same perceptions about the situational occurrences, the analysis assumed the effect of the situation on behavior was the same for all subjects. Therefore, common situational effects were estimated using the following equation.

$$BI_t = a + b_{t-1}(BI_1) + \sum_i (b_i * US)$$

or

$$B = a + b_1(BI) + \sum_i (b_i * US)$$

where:

B=Behavior (attend/not attend)
 BI=Intention
 US=Unexpected Situational Occurrences
 t=time period 2 and time period 3
 i=Situation 1 to 11
 b₁=Common Effect on Behavior (BI) for a given Unexpected Situational Occurrence i

Individualized situational effects were assessed by including the reported effect of the situation on behavior separately for each subject. This measure includes the subject's individual reaction to the situation. For example, two subjects could report that a given unexpected situation had occurred, but one might report that the situation had no effect on behavior while the other might report a large effect on behavior. The individualized measure needs to include both the unexpected occurrence of the situation and the effect of that situation on the subject. Therefore individualized situational effects were assessed by multiplying the expected effect of the situation by the self-reported occurrence of an unexpected situation. Individualized situational effects were modeled using the following equation.

$$BI_t = a + b_1(BI_{t-1}) + \sum_i (b_i * US * SE)$$

or

$$B = a + b_1(BI) + \sum_i (b_i * US * SE)$$

where:

B=Behavior (attend/not attend)
 BI=Intention
 US=Unexpected Situational Occurrences
 SE=Self-Reported Situational Effect
 t=time period 2 and time period 3
 i=Situation 1 to 11
 b₁=Effect on Behavior (BI) for the Subject's Reported Effect of a Situation i

Analysis

Several situational occurrences were controlled or known. The date for the function was set in period two. The function was scheduled right after a major paper was due in the class. Therefore, subjects should have realized that a major paper was due in the class just before the function. In addition, the weather the night of the function was clear and dry. If subjects had similar and accurate perceptions of reality, then they should have reported a high probability of occurrence for, "a major test or paper due before the function", and a low occurrence of bad weather. The first hypothesis will be supported if the expected occurrences of the major test due before the function is close to 100% and if the occurrence of bad weather is reported to be close to 0%.

The second hypothesis will be tested by predicting "current" intentions and behavior using previous intentions and unexpected situations (each situation included as a separate variable). Stepwise regression will be used to model intentions at each time period. Stepwise discriminant analysis will be used to model actual behavior. Models will first be fit using the common situational effects equation described above. A second set of models will be fit using the individualized situational effects equation described above.

The second hypothesis will be supported if the two sets of models (common effects vs individual effects) predict intentions and behavior equally well.

Limitations

Several limitations should be kept in mind when interpreting the results. First, the relative importance of common versus individual effects can not truly be assessed unless all relevant situations are included in the analysis. Therefore the estimated situational effect in this study will be biased since all relevant situations are not included in the study. Secondly, terms like "just after", and "good weather" may mean different things to different people. Therefore, comparing subject's perceptions to the researcher's perceptions may be inaccurate. Finally, the research assumes that subjects will be able to accurately report the effect a situation may have on them. This may not be the case, especially if the subject does not expect the situation to occur.

Results

Hypothesis one was not well supported by the data. Subjects may not have accurately perceived the known situational occurrences. In period three and four, the expected probability of occurrence should have been close to 100% for, "have a paper due just before the function." The reported expected probability was 28.7% for period three and 24.6% for period four. This finding may have been caused by the use of the term "just before." The class paper was due the day before the function. Therefore, subjects may not have felt it was "just before" the function. The reported occurrence of bad weather was as expected. No subjects should have stated there was bad weather, and only 0.2% of the subjects did report bad weather.

The data did support hypothesis two. Common situational effects predicted behavior as well as individualized effects. The results of the analysis are presented in Table 1. When examining medium term intentions common situational effects explained 64.7% of the variance while individual situational effects explained 38.7%. The findings for short term intentions were similar with common situational effects explaining 75.3% and individual effects explaining 64.3% of the variance. Finally, common and individual effects explained about the same amount of behavior (attendance) 91.8% and 86.9% respectively.

These results agree with previous studies which indicate that individualized situational effects did not predict behavior better than common situational effects. This supports the idea that there might exist certain market segments that would react similarly to a given situation.

Discussion and Summary

A reanalysis of past research has shown that situations can have common effects across consumers. The results of this exploratory study supports this position. Individualized situational effects do not appear to be needed to accurately predict behavior. However, some subjectivity may be required to model situational effects since subjects may not accurately perceive all situations.

TABLE 1

ABILITY OF PREVIOUS INTENTIONS AND CHANGES IN SITUATIONAL VARIABLES TO EXPLAIN PRESENT INTENTIONS AND BEHAVIOR

Dependent Variable	REGRESSION ANALYSIS

or

$$BI_t = a + b_1(BI_{t-1}) + \sum_i (b_i * US * SE)$$

² Model is as follows:

$$B = a + b_1(BI) + \sum_i (b_i * US)$$

or

$$B = a + b_1(BI) + \sum_i (b_i * US * SE)$$

Implications for the Definition of Situations

As stated earlier, the use of the subjective definition of situations is based on the possibly false claim that situational effects depend on the person. Given that a basic premise of the subjective definition of situations may be erroneous, it would be wise to reconsider its use.

There are several additional problems with the subjective definition of situations. The subjective definition is concerned with whether and how the subject perceives, processes, and responds to the situation. This definition, in fact, contains two separate issues, what is a situation, and what is the subject's response to the situation. Taken to the extreme, the subjective definition of situations is actually a type of behavior because it is concerned with response. It makes sense to separate these issues. We need to first determine what a situation is and then examine the effect of its occurrence.

The subjective definition also does not allow for lawlike generalizations. As stated by Mausner (1963, p. 107), "If one specifies the stimulus in terms of the nature of the

receiver, lawfulness becomes impossible." Belk (1975, p.429) also notes that the subjective definition may lead to a tautology, "(the subjective definition) tells us no more than the comparably hollow individual differences explanation that this is the sort of behavior engaged in by the sort of person who engages in this sort of behavior."

Given the problems associated with the subjective definition of situations, it would appear reasonable to consider only an objective definition of situations. The objective definition not only has numerous advantages over a subjective definition, but contributes to definitional parsimony by excluding several additional concepts from the definition of situations.

Subjective versus Objective Orientation?

The real question being raised by the subjective versus objective debate is not really how a situation should be defined, but what orientation situation research should take. Lutz and Kakkar (1975) argue that, "there appears to be a need to adopt a subjective view of the situation in order to understand its effects on human behavior." The ability to explain variations in behavior should not be the focus of situation research. Instead, research should focus on why and how situations affect behavior. This clearly has merit, but may lead to two important misconceptions. First, that the definition of situations should include other constructs such as subject responses. Second, that the use of situations to predict behavior is not interesting in itself.

The selection of the appropriate orientation toward situations will depend to some extent on the topic of interest to the researcher. If the researcher is interested in understanding consumer behavior, then the subjective orientation is preferable. If the researcher is interested in how to manipulate situations or what differentiates situations from other types of environmental stimuli, then an objective orientation is more appropriate. When it comes to predicting behavior, the researcher can use either orientation.

PERCEIVED CORRELATES OF STORE PRICE IMAGE:
AN APPLICATION OF THE BOOTSTRAP¹

B. Kemal Buyukkurt, Concordia University
Meral D. Buyukkurt, Concordia University

The findings of this nonexperimental study suggests that consumers perceive correlations between store attributes and store price image, and may use the former to predict the latter. Within a multiple regression context, the propensity to heuristically use such perceived predictors seem to be related to (1) perceived difficulty of basing the price image judgment exclusively on self acquired price samples, (2) time pressures, (3) self assessment of experience as a shopper, and (4) the extent to which price variation is expected across stores. Also, an application of the bootstrap, a resampling procedure, is presented which provides a nonparametric estimate of the expected error of prediction for the estimated regression equation.

Introduction

In a comprehensive study published more than a decade ago, Brown and Oxenfeldt (1972) reported that consumers perceived covariation between various store attributes and store price levels, and used the information regarding the former to predict the latter. One of the two major objectives of this study is to examine whether and to what extent, perceptions as such still exist today. The second objective is to relate the propensity to use such still exist today. The second objective is to relate the propensity to use such perceived correlations as predictors of price image to individual and task related variables. Both types of information should be valuable to managers in charge of pricing decisions at the retail level, since price image is theorized (Berry 1969 Hansen and Deutscher 1977-78, Kelly and Stephenson 1967), and reported to affect store choice (Progressive Grocer 1981, 1982).

Literature Review

Perceived Covariates of Store Price Image

Judgements of covariation between events is a critical aspect of cognitive behavior. Knowledge regarding which attributes or events are related and the degree of their relationship helps individuals to infer causal relationships between the variables observed in the past, control some events in the present through manipulation of a set of covariates, and predict the future or present value of a criterion given the values of some diagnostic predictors (Bettman, John and Scott 1984, Crocker 1981, Nisbett and Ross 1980, Hogarth 1980). Indeed, many psychological and socio-psychological theories are based on the notion that individuals detect covariation between cues, variables and events. Examples are Brunswik's Lens Model (e.g., Castellan 1973), Anderson's Functional Measurement (1981), and Kelley's Attribution Theory (1973).

Similarly, Brown and Oxenfeldt's (1972) findings suggest that consumers assume covariation between various store attributes and store price levels and use the information regarding the store attributes to predict store price levels. This large scale survey covered five cities (Havertown, Greensboro, New York, San Francisco, St. Louis), 60 different food retailing outlets and included more than 1,000 interviews with housewives regarding the price of 80 product items at different stores in their neighbourhood.

Respondents in each of the five cities were asked to rank

¹This study was funded by a research grant from Marketing Department, Graduate School of Business, Indiana University.

perceived price levels given 11 store attributes. These attributes included whether the store was new, untidy, in a large shopping center, engaged in lots of advertising, had wide assortment, promoted "loss leaders", gave trading stamps, had an expensive interior, was open late, provided extra services and was small. A high degree of similarity existed across five communities in terms of rankings as summarized by a high coefficient of concordance (.92).

The authors concluded that consumers expected extra costs incurred by a store to be reflected in higher prices: in descending order of importance extra services offered by the store, late hours of operation, having expensive interiors and giving out trading stamps are perceived to be cues related to high prices. On the other hand, store attributes which may be regarded as indicators of large volume of operations were predictors of lower prices: being located in a large shopping center, lots of advertising and having a wide assortment of products were correlated with low prices. While small size was perceived to be the strongest correlate of high prices, untidiness and being a "new" store in the community were generally ranked at the top of indicators of low prices. The authors stated that, "These findings sketch the beginning of a model which links operating characteristics of stores to perception via cues involving expenses and volume" (Brown and Oxenfeldt 1972, p. 49).

Heuristic Use of Perceived Covariates as Predictors

Brown and Oxenfeldt (1972) argued that consumers heuristically use store attributes in their price image judgments as part of a task simplification strategy possibly because of the complexity of the price structure at stores. They found that, for a basket of 80 product items, a given store may have higher than average prices for some items and lower than average prices for other items in the basket. Therefore, they implied that, overall price image of the store may be cognitively difficult to assess only by sampling prices from the marketed assortments, but easier to predict from non-price store attributes perceived to be correlated with store price image. Consequently, consumers can rely on the perceived correlates if they believe a more careful decision rule such as examining the prices of a self-selected basket of items is not likely to improve the outcome of the judgment process substantially (Svenson 1979) and if the cost of the first strategy outweighs the expected benefits from it (Christensen-Szalanski 1978). The use of such predictors are encouraged also when they are perceived to be causally related to the criterion of interest as in this context (Azjen 1977). Brown and Oxenfeldt concluded (1972, p. 42):

"This deductive process of applying a broad generalization to specific situations occurred in several phases of our research. It is one of the more pervasive results. Misperceptions often occur when the environmental situation is contrary to intuitive or logical generalizations. The generalization, not the facts, gives rise to perception. The facts seldom alter a logical conclusion."

Similar store profile effects have been reported by Wheatley and Chiu (1977) in consumer judgments of product quality. Consumer predictions of one attribute value from a correlated attribute have also been observed in price-quality tradeoffs (Levin and Johnson 1984) and product evaluations (Huber and McCann 1982).

In general, use of judgmental heuristics are found to be encouraged by factors which induce cognitive complexity such as time pressure, distractions, and information overload (e.g., Hogarth 1980, Newell and Simon 1972, Payne 1976, Wright 1974). Such factors may operate in the judgment task studied here and therefore motivate prediction of price image from perceived correlates. Distractions such as crowding, noise and indoor advertising within a store may aggravate the complexity due to price structure mentioned above. Also, some consumers feel more time pressure than others and/or perceive the comparison of the price images of different stores based on self sampled prices to be more difficult than the comparison of the price images based on perceived correlates of price image. Therefore, perceived time pressures may lead to higher propensity to use the perceived correlates as predictors of price image.

As alternatives to predicting store price image exclusively from perceived correlates, the prediction based on self acquisition and cognitive integration of a price sample independent of the perceived correlates or in conjunction with them requires examination of a basket of prices. In such a task, the magnitude of the deviations of the sampled prices from some subjective reference prices (Monroe 1973) need to be judged and cognitively intergrated into an overall judgment about the observed basket and then generalized to the whole store as the price image of the store. Thus, the comparison task and the final judgment will involve some uncertainty due to uncertainty associated with the subjective reference prices since their recall is expected to be less than perfect especially for infrequently purchased and low priced items.

Since decreases in the uncertainty regarding the subjective reference prices is likely to alleviate the perceived difficulty of basing the price image judgment on a price sample, those individual related variables which enable or stimulate more attention to and better recall of prices are expected to lead to lower propensity to use the perceived correlates as predictors of price image. Self assessments of experience as a shopper, accuracy of recall of prices, overall sensitivity to prices, perceived budget constraint, and the extent to which shopping is enjoyed can be suggested as a possible list of such individual related variables.

Finally, if the consumer believes that there are no significant price differences from one store to another (say, in food retailing) then the propensity to heuristically use the the perceived correlates should decrease because the need to compare the stores in question with regard to price subjectively does not exist.

Given the above discussion, Table 1 summarizes the expected relationships between the propensity to use the perceived correlates of store image as predictors of price image and the individual related variables. In order to build on the previous research by Brown and Oxenfeldt (1972), the shopping context is limited to grocery purchases. The individual related variables are presented in Likert scale form as they appear on the questionnaire.

Methodology

A mail survey was conducted to collect the data of the study. The questionnaire included the Likert scales exhibited in Table 1 and the items in Table 2. The second set of items attempts to measure the direction and the degree of perceived correlation between each of various store attributes and store price image on a 5-point scale ranging from -2 on the left to +2 on the right. By presenting the poles of the scale as the characteristics of two different stores and by instructing the subjects to indicate the store they would expect to have a "higher" or "somewhat higher" grocery bill, both the magnitude and the direction of correlation is measured through a single response. The central response category reflects perceived lack of correlation between that attribute and the overall price image of the store. The store attributes

in the table are based on the Brown and Oxenfeldt study (1972) and informal discussions with eight experienced grocery shoppers.

One potential problem with the instrument as it is presented in Table 2 is that the store description presented on the same side of the page may be perceived as a profile of a store and the attributes examined earlier in the questionnaire may affect the responses to the later items in the questionnaire. This may happen despite the two warnings on the questionnaire to evaluate each attribute (i.e., pair of stores in a given item) independently. In order to cancel out such "profile effects," three forms of the questionnaire were constructed. The second form presented the last one third of the items at the top, and the left pole descriptions were interchanged with the ones on the right pole. The third form moved the middle one third of the items to the top of the list and similar interchanges of the poles were made.

A total number of 270 questionnaires (i.e., 90 of each form) were mailed to potential respondents in four adjacent zip code areas in a Midwestern city. A city directory was used as the sample frame and the addresses were selected through a systematic random sampling method. The primary grocery shopper was asked to fill out the questionnaire. Thirty-five questionnaires could not be delivered. Eighty-nine questionnaires were returned making the response rate 37.9 percent. Four of the returns were not useable. The final number of useable responses for the three forms of the questionnaire were 27, 33 and 29.

Results

Perceived Correlates of Price Image

The data regarding the perceptions of correlation between the store attributes and the store price image are summarized in Table 3 and Table 4. While the t-tests on means in Table 3 test whether the data confirm the expected direction of the perceived correlations, Table 4 summarizes the χ^2 tests on variances which attempt to assess the consistency of the perceived correlation across the sample.

As it is presented in Table 3, consumers expect extra operating expenses and investments in the store to be reflected in higher prices (rarely waiting a long time in the check-out line because a sufficient number of lines are open, ready availability of salespeople, being located at a major shopping center and therefore paying higher rent,¹ being open 24 hours, being tidy and neat, displaying products on the shelves rather than carton boxes, providing extra services, having elegant store and lighting). Similarly, small volume of business at the store and company level is believed to indicate higher prices (few shoppers on Saturday, one of the smaller food retailers in the city, family owned, independent store rather than being part of a chain organization which owns a large number of stores). Also, if the assortment is extended to include gourmet food, deli and bakery, and non-food products, price image is adversely affected.² Finally, high frequency of printed retail advertising and large number of featured items per advertising are perceived to be associated with lower prices. Overall, these results parallel Brown and Oxenfeldt's (1972) findings.

The above perceived correlations seem to be consistent across the sample as suggested by the χ^2 tests on variances of the perceived correlation scores for each store attribute. It was judged to have a variance less than unity for each attribute so that only a relatively small percentile of the distribution of the scores would extend over to either side of the central category. Store attributes numbered 1, 2, 3, 4, 5, 7, 8, 11, 14, 15 and 16 met this criterion.

Prediction of store price image from the above store attributes was confirmed by two follow-on studies. In

the first study, two store profiles were constructed by retaining the subset of the above attributes for which the average score was significantly different from zero (implying positive or negative perceived correlation) and variance less than or equal to one (implying relatively consistent perceived correlation across the sample). While the combination of those verbal descriptions which defined the negative poles of the scales constituted the "high" priced store profile, the combination of the verbal descriptions at the positive poles made up the "low" priced store profile (Buyukkurt 1985). The two store profiles were tested in a drop-and-pick-up survey using an independent sample and found to lead to significantly different perceptions of "high" versus "low" priced stores ($t=12.30$, $d.f.=62$, $p=.000$). Confidence in these judgments was high for both store ($\bar{x} > 7.4$ given a 10-point rating scale) but not significantly different across the two stores ($t=1.35$, $d.f.=62$, $p=.163$). In this survey, field workers contacted 75 residences and completed 69 interviews, out of which 64 were usable. 29 and 35 respondents were exposed to the "high" and "low"-priced store profiles respectively.

The same two profiles were later used in an experimental setting as a manipulation of store profile effects where 240 grocery shoppers judged the perceived value of a self selected basket of grocery items. Again, price judgments were affected by store profile ($F=5.886$, $d.f.=1,190$, $\alpha = 0.02$) (Buyukkurt 1985),.

Regression Results

The hypotheses in Table 1 regarding the relationship between the individual related variables (independent variables) and the propensity to use the perceived correlates to store image as predictors of store image (dependent variable) were tested by conducting a step-wise multiple regression analysis.

The dependent variable was operationalized by summing the absolute values of the perceived correlation score across all store attributes in Table 2 for a given subject. This sum increases (1) as the degree of perceived covariation between an attribute and price image increases and (2) as the number of such perceived covariations increases. As such, the sum, as an indicator of the propensity to use the perceived correlates as predictors of price image, is based on the assumption that the probability that a cue will be used in predicting a criterion increases as the perceived predictive validity of that cue increases.

Also, the higher the number of such predictors, the more likely it is that the prediction will be affected by such perceived correlates. If the degree of perceived correlation between an attribute and price image is conceptualized as the strength of a belief, then a theoretical justification can be provided for the above operationalization, for example, from the attitude research (Fishbein and Azjen 1975) and research on information search (Duncan and Olshavsky 1982) where beliefs and tendency to act are theorized and shown to be related.

Stepwise regression was preferred to ordinary least squares mainly because of the exploratory nature of the study. Selection of the variables into the equation was controlled through "tolerance" and on F-value-to-enter. Technically, tolerance is equal to one minus the squared multiple correlation between an independent variable which has not yet been included in the equation and those that are already in the equation. In this study, tolerance was set equal to 0.9 F-value-to-enter was 2.8 which assures statistical significance at $\alpha = .10$ for the regression coefficients of the entered variables.

A stepwise inclusion history of the independent variables is presented in Table 5. Four independent variables were included in the equation with final adjusted $R^2 = .38$. In their order of inclusion, these variables are perceived difficulty of making price image comparisons by sampling prices (X7), not being able to pay enough attention to grocery prices because of time pressures (X4), belief that no significant differences exist in grocery prices from one store to another (X3), and self ratings of experience as a grocery shopper (X2).⁴ Except for the last variable, the signs of the regression coefficients are expected. The positive coefficient for X2 indicates that the the propensity to use the perceived covariates as indicators of price image increases as self perception of experience as a shopper increases. A posteriori, this finding is not extremely surprising because (1) the perceived covariates may in fact be valid predictors of price image in the market for this sample and their beliefs may have been confirmed over time or (2) since people often see what they expect to see (Hogarth 1980, Nisbett and Ross 1980), confirmation of their hypotheses may have been mainly illusory since accurate judgments based on self acquired price samples will involve substantial uncertainty.

The Bootstrap and Cross-Validation

One immediate question about the regression findings is the predictive ability of the final model since the regression weights are based on a relatively small sample size. To eliminate this concern the bootstrap was used to estimate the expected excess error of prediction (Efron 1979) by randomly drawing samples of a fixed size with replacement from the original sample. A parallel estimate of expected excess error was obtained from another method of sample reuse widely known in the marketing literature as cross-validation (Appendix).

The expected error of prediction is 2.237 and 2.120 for cross-validation and the bootstrap respectively which are not substantially large given a dependent variable with a mean of 14.31, a minimum value of 4.0 and a maximum value of 31.

Conclusions

More than a decade after Brown and Oxenfeldt's (1972) study, the data from a geographic area which was not included in their study confirmed that consumers still predict store price image through store attributes which are perceived to be indicators of expense and volume. Furthermore, these perceived correlations seem to be rather consistent as suggested by the sample studied here.

The propensity to use such perceived correlations in predictions of price image seem to be positively related to (1) perceived difficulty of basing the price image

judgment on self-acquired samples, (2) time pressures, and (3) self perception of experience as a shopper, and negatively related to whether the consumer believes that there are significant differences in terms of price across stores. The regression coefficients on which the above conclusions are based seem to be stable and the expected prediction error seem not to be excessive as indicated by the nonparametric resampling methods. These methods, however, should not be regarded as perfect substitutes for sufficiently large sample sizes, and therefore, this study should be replicated by taking larger samples, preferably in different geographic areas, to reflect possible variations at the retail level. Such an effort is already under way with replications in the northeast and the northwest.

Further research in this area seems to be warranted. Knowledge about the cognitive integration of the perceived correlates in a judgment context and the relative subjective importance assigned to each correlate should be valuable to retail strategists. Also, perceived correlates of store price image can be conceptualized as beliefs (Duncan and Olshavsky 1982) or hypotheses (Bettman, John and Scott 1984), and their development and revision as new information is gathered can be studied.

Footnotes

1. In Brown and Oxenfeldt's (1972) study, being "located at a major shopping center" was perceived to be related to higher volume, and, therefore, associated with lower prices. During the questionnaire construction stage, the housewives who were interviewed associated it with higher rents, therefore, higher prices. The respondents of the survey seem to believe along the same lines.
2. This finding regarding extension of the assortment should be viewed with caution since the scales in Table 2 ask the respondents to indicate the store for which they expect their grocery bill will be higher. It is possible for some consumers to think of some additional items that they can purchase when the assortment is richer and therefore expect their grocery expenses to increase for the store with the extended assortment rather than thinking about possible differences in the prices of a given basket of items in the two stores described as the poles of the scale.
3. Naturally, the number of predictors that can be used does not increase indefinitely because of information processing capacities of human beings.
4. As far as multicollinearity is concerned, the null hypothesis of zero population correlation coefficient could be rejected at $\alpha = .05$ only for the sample correlation between X5 and X7 ($r = .475$). Because of the stringent tolerance value, it is apparent that X5 was kept out of the equation after the entry of X7.

Appendix

THE BOOTSTRAP AND CROSS-VALIDATION ESTIMATE OF EXPECTED EXCESS ERROR

Assume a linear regression model

$$Y_i = X_i \beta + \epsilon_i, \quad i = 1, 2, \dots, n$$

Where X_i is known ($1 \times k$) vector of predictors, β is a ($k \times 1$) vector of unknown parameters, and ϵ_i are i.i.d. $\sim F$, where F is an unknown probability distribution with an expected value equal to zero.

1. Having observed $Z_i = (Y_i = y_i, X_i = x_i)$ $i = 1, 2, \dots, n$, define \hat{F} as the empirical probability distribution of the data:

$$\hat{F} : \text{mass } \frac{1}{n} \text{ at } Z_1, Z_2, \dots, Z_n$$

2. Draw a bootstrap sample from \hat{F} with replacement

$$Z_1^*, Z_2^*, \dots, Z_n^* \quad \text{iid } \hat{F}$$

and calculate $\hat{\beta}^*$, ($k \times 1$) vector of bootstrap estimates, using ordinary least squares.

Given a bootstrap sample as in step 2 above, the resampling vector

$$P^* = (P_1^*, P_2^*, \dots, P_n^*), \text{ where } P_1^* = \frac{\text{number of } \{Z_j^* = Z_1\}}{n} \text{ has a rescaled multinomial distribution}$$

$$P^* = \frac{\text{Multinomial}(n, P^0)}{n} \quad (1)$$

Then, the bootstrap estimate of Expected Excess Error is:

$$EEE(\text{Boot}) = E^* \sum_{j=1}^n (P_j^0 - P_j^*) (y_j - \hat{y}_j^*)^2$$

here E^* indicates expectation under (1) and \hat{y}_j^* is the predicted value of the criterion y_j given $\hat{\beta}^*$.

The cross-validation estimate of expected excess is:

$$EEE(\text{CV}) = \frac{1}{n} \sum_{i=1}^n (\hat{y}_i - y_{(1)i})^2 - \frac{1}{n} \sum (y_i - \hat{y}_i)^2$$

where $\hat{y}_{(1)i}$ and \hat{y}_i refer to predictions of y_i when x_i is and is not held out.

The above notation is adopted from Efron (1979). See the original article for further details.

SHOPPING AREA IMAGE: ITS FACTOR ANALYTIC STRUCTURE AND
RELATIONSHIPS WITH SHOPPING TRIPS AND EXPENDITURE BEHAVIOR

Chow Hou Wee, National University of Singapore

Abstract

Few studies have focused on the image of a shopping area and its relationship with shopping trips and expenditures. This research focuses on the development of a scale to measure the image of a downtown shopping area. Of the four component scales identified, two - the operational and facilitative factors - were found to significantly affect shopping trips and expenditures.

Introduction

Marketing research on image had historically been confined to the store level. However, with the emergence of more and more shopping centers as business entities, there is a need to focus research on the image of a shopping area. In fact, there is no theoretical reason why image research at the store level cannot be extended and applied to the shopping area level. The importance and relevance of image research to shopping area patronage was recognized some 15 years ago by Moore and Mason (1969):

"Socio-economic variables do not satisfactorily explain the retail centre patronage decisions of the residents of the study area. It may be inferred that psychological or attitudinal differences of the residents are perhaps of more importance."

With the development of shopping centers, studies have begun to focus on image-like variables of shopping areas (Frederick et al. 1975; Carter 1978, 1981; Hauser and Koppelman 1979; O'Neill and Hawkins 1980; Berman 1983). Studies by Bellenger, Robertson and Greenberg (1977), and Gentry and Burns (1977) have confirmed the importance of image-like variables in shopping center patronage.

However, the most significant study on shopping area image thus far has been that of Houston and Nevin (1980). In their study of the downtown area and four shopping centres on 16 image items, Houston and Nevin used factor analysis to identify three major dimensions or factors of shopping area image. The first factor consisted of six items -- quality of stores, variety of stores, merchandise quality, product selection, special sales/promotion, and great place to spend a few hours -- which were related to the assortment of benefits offered by the area. The second factor (6 items) consisted of features that helped to ease the shopping effort -- parking facilities, availability of lunch/refreshment, comfort areas, easy to take children, layout of area, and special events/exhibits -- and was named the facilitative nature of the area. The third factor (4 items) -- general price level, atmosphere, store personnel, and conservative -- were associated with positioning of the area as an integrated complex of stores, and was named market posture.

Some Areas of Concern

There are several areas of concern that still need to be addressed with regard to the study of shopping area image. The first concern involves the appropriateness of applying the items drawn from the store image literature to that of shopping area research. Houston and Nevin (1980) developed their scale from a review of earlier store image research and discussion with shopping center managers. Whether the items were appropriate, especially in the eyes of the consumers, were not considered. This limitation was clearly recognized by Howell and Rogers (1980). Thus, to begin

with, it may be more appropriate to sample a wider domain of items, especially at such an exploratory level, in order to have a better understanding of the underlying dimensions of shopping area image.

The second concern involves the issue of familiarity. Acito and Anderson (1979) found that image was more differentiated, better articulated and of higher dimensionality for recent shoppers compared with non-recent shoppers of a retail store. The same concern was shared by Hirschman (1981). In essence, image research that is based on ratings by consumers without taking into account the extent of their familiarity with the stores or areas is not likely to provide meaningful results that managers can act upon. For example, can one rely on the ratings of consumers, whether favorable or unfavorable, if they have never been to particular shopping areas, or only been there once or twice a year? When one considers that respondents are typically asked to react to some 15 to 20 items on the image scale, the problem is further compounded. It can be argued that the image of a shopping area may be more complex than that of a single store, since a shopping area is a conglomerate of different kinds of stores that offer a wide variety of products and services. In fact, in a recent study, Wee (1985) found that the factor analytic structure of the image scale for a shopping area differed with regard to recency effects and the size of the shopping area. Thus, the need for the consumer to be familiar with the shopping area is crucial to any assessment of its image.

Finally, the relationship between shopping area image and patronage behaviour, especially in terms of actual consumption behavior like number of trips made and the amount of expenditure spent at the area, needs to be better established. The findings by Nevin and Houston (1980) should not be taken as conclusive in that they included a variable on preferred store, measured in a dichotomous basis, in their study. To the extent that the image of a shopping center is correlated with the image of that store (whether or not shopping center image actually exists), the significance of shopping center image will lessen. Thus, it is possible for a shopping center image to exist and help determine shopping behavior, yet emerge as insignificant from Nevin and Houston's analysis.

The Study

The purpose of this study is to focus on the relationship between shopping area image and patronage behavior by taking into account the need to develop an appropriate shopping area image scale and to ensure that shoppers are familiar with the area before they are asked about its image. To this end, data was obtained from a large scale study that was designed to obtain information on the shopping behavior of consumers in London (a mid-size city with a very well-developed public transportation system), Canada. The study required the respondent to complete an eight-page questionnaire that included questions on the image of the downtown shopping area, and to keep a two-week diary that recorded information on shopping trips and expenditures to that area. Based on the results of two pilot studies, it was decided that principal shoppers, who in most cases may be females, would be the subjects of this study. Thus, initial contact letters, personally addressed to the female heads of households whenever possible, were mailed to 2070 residences in the city. A telephone call followed a few days after the letter. Of the 1269 principal shoppers reached by telephone, 823 agreed to participate in the study and a total of 679 returns were received. Of these, 482

respondents completed both the questionnaires and diaries and they formed the usable data-base sample. The return rate was equivalent to 58.6% of those who agreed to participate or 38.0% of those reached by telephone. Considering the level of difficulty of the survey instruments, the return rates were considered very satisfying.

To overcome the familiarity issue, only those respondents (n=479) who had ever been to the downtown area were considered for the analysis. The respondents represented a cross-section of residents in the city in that they did not differ from the original sampling frame by postal region. In addition, consistent with prior expectation, 91.3% of the principal shoppers were females and only 51.3% were employed. Non-response bias was determined in two ways. For those people who refused to participate in the study, three demographic questions on age group, educational level and years living in the city were asked over the telephone. The results of the difference of means test of the non-participants against the data-base sample showed that there were no significant differences with regard to the length of residence in the city and the education level. The only significant difference was that of age. Considering the nature of this study, the results were not surprising as older people tend to have more difficulties with their seeing and writing capabilities and thus tend to shun away from participating (Dillman 1978, p.53). In fact, the refusal rate was 42.1% for those people over 55 years of age.

As this study involved completion of both the questionnaire and diary, non-response bias was further assessed between those respondents who completed only the questionnaire versus the data-base sample. Comparison between these two groups were made along 7 criteria -- age, education, Siegel's (NORC) job prestige scale, income, years of living in the city, years living at the present address, and the number of shopping areas visited over the last three months. The only significant difference, using the difference of means test, between these two groups, at the conventional 5% level of significance, was that of educational level. Again, this result was not unexpected. It was possible that those participants with lower level of education had more difficulty in responding to both the questionnaire and diary.

Taking into account that there were no significant differences within each of the two sets of comparisons that were discussed above, it was concluded that non-response bias was not a serious problem in this study.

Development and Testing the Image Scale

To begin with, the number of items in the image scale were developed from several sources. A list of items was first drawn from a literature review of store and shopping area image research. Three "experts", consisting of the author, another doctoral student, and a professor then discussed and evaluated the items. The list of items were then pilot tested on a group of 6 retailers in the downtown area and a group of 8 consumers (6 females and 2 males). A focus group interview was conducted where among other items in the questionnaire, the image scale items were discussed among the 8 consumers and the three experts. This led to editing, purification and improvement in the scale. The improved scale of items was then tested on the same 6 retailers and another 7 female consumers. Another consumer focus group interview was conducted and the scale was purified and edited further. This finally resulted in a list of 31 items for the image scale which could be considered to have content and face validity, or intrinsic validity (Nunnally 1978, p.91-94 Guilford

1954, p.400). It is also important to point out that a 5-point Likert type scale was adopted after taking into account various factors that could affect a scale construction (Andrews 1982), and that 15 of the 31 items were stated negatively to prevent response style bias.

Upon collection of data, the domain sampling model (Nunnally 1978, p.193-200) was used to purify the scale further. However, as all the items were highly inter-correlated, no item was eliminated from the scale. The internal consistency of the items in the image scale was further checked by the Cronbach's coefficient alpha (Cronbach 1951) which was 0.82.

Factor Analytic Solution of Image Scale

Factor analysis was next carried out on the image scale to determine the component structure. R-factoring with principal component analysis was used and the obtained factors were rotated using the varimax method. Using the criterion of meaningfulness advocated by Gorsuch, and also shared by Cattell (1979, p.485), those items that did not have a factor loading of at least 0.30 on any factor were eliminated. In addition, those items that loaded heavily on more than one factor were also eliminated (Gorsuch 1983, p.210; Churchill 1979). Applying these two criteria resulted in 4 items been removed from the scale, leaving 27 items.

With regard to the number of factors to be extracted, two criteria were considered. Using the roots criterion (eigenvalues greater than 1), a maximum of 9 factors would be extracted. However, the roots criterion is only accurate when the number of variables is small to moderate and the communalities are high. When large number of variables are involved, the roots criterion becomes inaccurate (Gorsuch 1983, Ch.8; Stewart 1981). A better procedure for extracting factors is that of Cattell's scree test (Cattell 1979, Ch.5). The scree plot, however, did not provide a very clean break in the "elbow", and suggested a possible 3 or 4 factors. However, taking into account that the final conclusions of a factor analysis are likely to be more distorted by underfactoring than over-factoring (Cattell 1979, p.55), 4 factors were extracted (see Figure 1).

FIGURE 1

CATTELL'S SCREE PLOT OF IMAGE SCALE

The plot suggests that it is more adequate to extract four factors.

TABLE 1
COMPONENT IMAGE SCALES

26	Visited when weather is bad	0.458	0.432
30	Visited when short of time	0.395	0.477
RELIABILITY COEFFICIENT ALPHA (4 items)		0.57823	
TOTAL SCALE (27 items) ALPHA		0.81957	

The newly identified component scales are shown in Table 1. The first factor contained 7 items that were related to the total product and service offerings of the area, and was accordingly named assortment factor. The second factor had 9 items that were related to making the area more attractive to the shopper by its supportive facilities; that is, they were variables that helped facilitate the competitiveness of the area. Accordingly, it was named facilitative factor. The third set of 7 items were related more to maintaining the competitiveness of the area, and hence was appropriately called maintenance factor. Finally, the last set of 4 items were related to the day-to-day operations of the area, and was named operational factor. The coefficient alphas of these four factors ranged from 0.58 to 0.74.

Construct Validity of Scale

The best way to test construct validity would have been the multi-trait, multi-method matrix (Campbell and Fiske 1959). However, available resources did not permit the application of this method in the design and development of the instruments. Another acceptable way to test the adequacy of the outline of a domain relating to a construct is to determine how well the measures of observables "go together" in empirical investigations (Nunnally 1978, p.100). In this case, the construct validity of the image scale can be tested empirically by

determining how well the item scores correlate with one another. Thus if all the measures purportedly measure the same construct, they should be highly correlated or in Blalock's (1968) term, an "epistemic correlation." In addition to high correlations, the series of items should also display internal consistency. Coefficient alpha is useful for this purpose because it provides both a summary measure of the homogeneity of a set of variables and an estimate of the reliability of alternative forms of the instrument.

TABLE 2
EVALUATION OF CONSTRUCT VALIDITY OF IMAGE SCALE

Item	Description	Item- Total Corr.	Squared Multiple Corr.
1	An interesting place to shop	0.431	0.396
2	Has everything I need	0.383	0.310
3	Is not old and tired	0.358	0.223
4	Place to find out new and fashionable	0.316	0.345
5	Is place to shop with children	0.378	0.251
6	Has greater store selection	0.495	0.415
7	Has better eat and drink places	0.231	0.179
8	Does good job advertising	-	-
9	Has good lighting	0.366	0.269
10	Is well-planned	0.457	0.322
11	Is clean and well maintained	0.253	0.214
12	Has attractive landscaping	0.266	0.185
13	Has enough parking	0.316	0.283
14	Has convenient public phones	0.311	0.166

20	Has convenient washrooms	0.380	0.239
21	Is not like other shopping area	-	-
22	Salespeople care more	0.216	0.184
23	Store hours are convenient	0.422	0.280
24	Parking is not too expensive	0.242	0.246
25	Stores are not too spread out	0.473	0.319
26	Visited when the weather is bad	0.256	0.304
27	Stores have better product selection	0.361	0.308
28	Easy to park where I shop	0.384	0.356
29	Has enough direction information	0.409	0.224
30	Visited when short of time	0.238	0.275
31	Merchandise prices are lower	0.348	0.215
RELIABILITY COEFFICIENT ALPHA (27 Items)		0.8196	
DETERMINANT OF CORRELATION MATRIX		0.0051	

Table 2 provides very strong support that the image scales used in this study had considerable construct validity. Overall, the high inter-item correlations were reflected by the very low value in the determinant of the correlation matrix of 0.0051. This was further supported by the fairly high item-total correlations and the respective squared multiple correlations, where the majority of the values was over 0.30. The coefficient alpha for the final total scale was 0.82 giving credence to support the fact that all the image items were related to a single underlying construct.

Image Effect on Shopping Behaviour

The summated scores of each of the four components of the image construct -- the assortment factor (7 items), the facilitative factor (9 items), the maintenance factor (7 items) and the operational factor (4 items) -- were then used to determine the relationship between image and shopping behaviour. Stepwise regressions were used and the results are shown in Table 3. Only two out of four factors -- the operational and facilitative factors -- were significantly loaded in the final equation for both the trip and expenditure data. For the trip data, the operational and facilitative factors accounted for an adjusted R-square of 0.162. The same two factors accounted for an adjusted R-square of 0.118 for the expenditure data.

TABLE 3

IMAGE EFFECTS ON SHOPPING TRIPS AND EXPENDITURE.

* Significant at 0.0000 level

In terms of explanation, the operational factor was clearly the more dominant factor as it entered the regression equation first in both cases and also had a much higher beta value. It was at least 2.5 and 2.0 times as great as the effect of the facilitative factor for the trip and expenditure data respectively. In both regression equations, the two factors were highly significant as indicated by the T-values.

Discussion and Implications

In terms of the image construct, it is interesting to note that the assortment and facilitative factors of the image scale contain items that are very similar to those of Nevin and Houston (1980) study. However, the maintenance and operational factors contain very different items. The results confirm remarks made by Lindquist (1974-75) and other researchers about the complexity of the image construct. More importantly, the maintenance and operational factors in this study contain items that tend to reflect more the characteristics of a shopping area, and underline the importance of sampling a wider domain of items in a shopping area image study.

What has made earlier image research practical, acceptable and useful is that the findings have been applied to the positionings and development of marketing strategies by stores and shopping centers. The underlying assumption is that image can affect patronage behavior. This study provided the empirical evidence to support the impact of image on shopping trips and expenditure. It also confirmed the predictive validity of the shopping area image scale that was developed for this study. What was interesting, however, was the type of image components that were significant or insignificant in predicting and explaining shopping behavior. The assortment factor which represented the

"product and service offering" of the area and the maintenance factor were both not significant in affecting patronage behaviour. There are intuitive reasons for the lack of affects of these two factors. In general, shoppers may take for granted that for a large shopping area like downtown, it has to have a large assortment of stores and services. Therefore, because of this expectation, the assortment component of the image scale will not become a discriminating factor for visiting the area. Similarly, the downtown is generally the "heart" of the city, and shoppers may expect that it should be well kept and maintained. As such, this could possibly explain for the lack of effects of the maintenance factor.

The two image components that significantly affected shopping behaviour were operational and facilitative factors. In particular, the operational factor was at least twice as important as the facilitative factor in explaining patronage behaviour. Therefore, improving the operational factor should be an important element of a downtown strategy. This can include extending the store hours as well as providing some protection against the elements of nature. For example, building canopies along sidewalks may be a good approach to take. In the long run, it may be worthwhile to consider providing internal linkages within the whole downtown core so as to enable it to be marketed as a truly integrated shopping area.

Many of the items within the facilitative factor relate to making downtown a more attractive shopping area. Creating a more congenial environment for shopping, such as providing more common facilities like washrooms and children's play areas should help increase the level of patronage. In particular, there were three items representing parking. Improving the parking situation should help the business in downtown. This can be done in many ways. For example, merchants can help absorb part or all the parking costs of customers who made purchases at the stores. Lobbying the City officials for more parking spaces in downtown as well as extending the time on street parking meters may help. More importantly, there should be enough parking spaces near to where customers are shopping. In addition, in any future expansion or renovation in downtown, parking should be a key consideration in any building plans.

Limitations and Future Research

This study is not without weaknesses. By focusing only on one shopping area, it is impossible to infer what attributes determine a consumer's choice among various shopping centers. Although it has been shown that there is a relationship between patronage behavior and the image of a particular shopping area, it is difficult to know if the presence/absence of other shopping areas (and their images) would have affected the results.

Image, in terms of the operational and facilitative factors, only accounted for 16% and 12% of the variance of shopping trips and expenditure respectively. There remains a large proportion of variance not explained by the image construct. Variables like the size of the shopping area, the distance of the shopper's home to the shopping area, the presence or absence of large well-known stores, travel mode attributes, and other situational factors may be useful predictors to include in future studies. In fact, some studies have shown that the size of the shopping area and the distance to it can affect patronage behavior (for example, Gautschi 1981; Wee and Pearce 1985).

There are several other questions that remain to be answered with regard to research on retail images. For example, to what extent does the image of a store influence the image of a shopping center, and vice versa? So far, there have been no study on this. Does shopping center image influence some consumers more than

others? Within the same consumer, does shopping center image influence him/her more in some situations than others? In other words, does image have situational effects? Finally, do consumers form similar images of different stores (branches) that belong to the same company, that is, can image be transferable? These are worthwhile avenues for future research.

RELATIONSHIPS BETWEEN AFFECT, PATRONAGE FREQUENCY AND AMOUNT OF MONEY
SPENT WITH A COMMENT ON AFFECT SCALING AND MEASUREMENT

Linda L. Golden, University of Texas at Austin¹
Mary R. Zimmer, University of Texas at Austin

Abstract

This paper investigates relationships between affect, patronage frequency and amount of money spent for three retail stores: Sears, K-Mart and Wards. Predictions for a statistically significant relationship between affect, patronage frequency and spending were supported. Examination of two different scaling techniques, modified semantic differential and graphic, yielded no statistically significant differences.

Introduction

The concept of affect has been widely researched and discussed in psychology, but, more recently, has been introduced into the consumer behavior literature. In the psychology literature, affect has often been conceptualized as a "positive mood state" and treated as an experimental (manipulated) variable. In this context, a "positive mood state" has been associated with a variety of different variables, including: an increased propensity to engage in helping social behaviors and being more generous (Berkowitz 1972, Isen 1970, Isen and Levin 1972); reducing risk taking behaviors (Isen and Patrick 1983); reducing hostility in negotiations (Carnevale and Isen 1983); more positive expectations, evaluations and judgments of stimuli (Isen and Shalke 1982, Isen, Shalke, Clark and Karp 1978, Schiffenbauer 1974); increased efficiency in decision-making (Isen and Means 1983); and, a tendency to discriminate less among categories (simplified decision-making), increased memory and more creative problem solving (Isen 1984).

In an atypical study that investigated "negative mood states," Johnson and Tversky (1983) found that a report of a tragic event produced a strong increase in estimates of the frequency of risks and other undesirable events. They concluded that people tend to make judgments compatible with current mood, even if the subject matter is unrelated to the cause of the mood.

What the psychological research suggests is that "affect matters." It matters for cognitive processes, decision-making processes and results, as well as behavior. Indeed, interest in the processes by which happiness leads to helping behaviors produced studies concerning the influence of affect on decision-making and other cognitive processes (Isen 1984).

The potential implications for consumer behavior are self-evident and, hence, have inspired the interest of consumer behavior researchers in new directions for the study of affect. Until recently, affect studies in consumer behavior have focused on affect as a component of attitude rather than as a global measure of "feeling."

Affect and Consumer Behavior

A number of conceptual articles discussing affect have appeared in the consumer behavior literature. Cacioppo, Losch, Tassinari and Petty (1984) view affect as a "... system with motivational, perceptual, cognitive, physiological, motor expressive and subjective manifestations," and point out that by focusing solely on the "cognitive" consumer, researchers overlook potentially predominant,

although crude, forces on consumer behavior. Zajonc and Markus (1982) also present the thesis that affective factors potentially play an important role in the development and maintenance of preferences relevant to consumer behavior. Others have discussed the role of affect in categorization (Cohen 1982), the difficulties of measuring the cognitive neuropsychological effects of affect (Ray and Batra 1983) and measurement aspects of manipulating and assessing buyers' moods (Gardner 1984).

Empirical investigations of affect (as an experimental variable) in the marketing and consumer behavior literature have been relatively few. (The discussions of the difficulties of measurement and manipulation are not unfounded.) Yet, the consumer research studies that have treated affect as an experimental variable have tended to support predictions parallel to the findings in psychology.

For example, Gorn (1982, experiment one) found that subjects were more likely to choose a pen that had been accompanied with "liked" music than "disliked" music. In a second experiment, Gorn's (1982) subjects selected a pen advertised with attribute information when they were in a high consequence condition, but chose the pen advertised with music when they were in the low consequence condition. Thus, it was concluded that affect influenced choice more strongly than information when the situation was of low consequence.

These results are consistent with those that would be predicted with Petty and Cacioppo's Elaboration Likelihood Model of attitude change (Petty, Cacioppo and Schumann 1983). This model views simple affective cues as being more powerful determinants of attitudes when motivation and/or ability to process issue-relevant information is low (the peripheral route).

In a series of studies, Srull (1983) manipulated mood states and found that positive mood states lead to more favorable product evaluations at the time of information acquisition. A contrast effect of judgments occurred when the mood state at the time of retrieval was inconsistent with the major evaluative implications of the stimulus information. This appears to be due to a tendency to recall more items inconsistent than consistent with mood at the time of retrieval.

In another paper, Srull (1984) reported a study that manipulated mood and distinguished between computational and retrieval information processing objectives. Affective (mood) states had a direct effect on product evaluations for persons in computational (figuring out their evaluations), but not retrieval (recalling evaluations) situations.

Moore and Hutchinson (1983) studied the relationships between affective reactions to advertising and advertising effects. Immediately after exposure to print advertisements subjects had greater change in brand consideration as affective reactions became more positive. This same effect occurred for measurements taken two days after exposure; however, after a seven day delay, products associated with advertisements eliciting positive or negative affect showed greater change in brand considerations than did neutral advertisements. Thus, at least for some situations, over time the "positive affect effect" may converge to have the same impact as "any affect effect" (excluding neutrality). (Final implication added by these authors, not Moore and Hutchinson.)

¹This research was sponsored by a grant from the New York University Institute of Retail Management.

Response categories provided were: Never (1), Once a year or less often (2), Two to six times a year (3), Seven to twelve times a year (4), Two to three times a month (5), and Once a week or more often (6). Respondents wrote their response in the space provided beside the names of Sears, K-Mart and Wards.

The second behavioral measure investigated the amount of money spent at each of the three stores during 1983. Respondents were asked, "Approximately how much did you spend at Sears, K-Mart and Wards during 1983?" Again, responses were written in a space provided by the name of each store.

The questionnaire was pre-tested on a small convenience sample of individuals under actual field conditions. Minor wording changes were made for clarity.

Data Collection and Sample Description

A sample frame of 1600 adults from a nationwide consumer mail panel was selected to represent sex, region, population density and demographic criteria proportionate to the population of the United States.

The cover letter instructed the panel member to fill out the questionnaire him/herself in half the mailings with the other half of the cover letters instructing the panel member to ask his/her spouse to fill out the questionnaire. Thus, an attempt was made both in the administration and sample selection to balance the sample by sex (due to the larger number of females likely to respond). Subjects were randomly assigned to one of the four treatment combinations.

Questionnaire returns were terminated six weeks after mail-out. The final sample consisted of 894 usable surveys resulting in a response rate of 56 percent. Approximately twenty surveys were not usable.

More women (58.8 percent) returned the survey than did men (41.2 percent). The annual household income distribution for the sample was: 29.3 percent earned less than \$15,000 a year, 28.2 percent earned between \$15,000 and \$24,999 a year, 26.3 percent earned between \$25,000 and \$39,999 a year, and 16.2 percent earned \$40,000 or more a year. Approximately ten percent (10.4) of the sample had less than a high school education, 39.4 percent had graduated from high school, 25.1 percent had some college, and 25.1 percent had four years of college or more. Respondents represented the following geographical regions: New England (6.0 percent), Middle Atlantic (16.1 percent), East North Central (18.5 percent), West North Central (8.7 percent), South Atlantic (16.9 percent), East South Central (6.4 percent), West South Central (9.7 percent), Mountain (5.8 percent), and Pacific (11.9 percent). Thus, the sample represented a cross-section of the United States' population.

Preliminary Data Analysis

The preliminary analysis involved a two-way analysis of variance to determine the effect of scale type (semantic differential or graphic) and affect placement (before or after image) on affect ratings for each store separately. There were no significant main or interaction effects for any of the three stores (within an alpha level of .12). Thus, the format and positioning of the affect scales did not influence responses at a statistically significant level and the four treatments were collapsed for the remaining analyses.

Analyses and Results

In order to determine the pairwise relationships between affect, patronage frequency, and dollar amount spent at each store, Pearson correlations were calculated as indices of linear association. All of the pairwise correlation coefficients were significant within an alpha level of .01 for all three stores, as presented in Table 1.

Since the numerical values assigned to question responses

represent ranked categorical data, the treatment of these data as interval through Pearson correlations may tend to "artificially deflate r and systematically underestimate ρ " (Peterson 1982, p. 494). That is, the relationships may actually be "stronger" than these results represent.

The correlations between affect and patronage frequency and between affect and dollar amount spent include the total sample. However, because of the built in association between patronage frequency and dollar amount spent (no patronage, no spending), the "never shop" subjects were eliminated from the analyses.

TABLE 1
RESULTS OF PEARSON CORRELATIONS

Variables Correlated	r	r^2	d.f.
Affect with Patronage Frequency			
Sears	.46	.21	836
K-Mart	.54	.29	811
Wards	.53	.28	684
Affect with Amount of Money Spent			
Sears	.26	.07	783
K-Mart	.26	.07	761
Wards	.34	.12	583
Patronage Frequency with Amount of Money Spent			
Sears	.40	.16	760
K-Mart	.37	.14	732
Wards	.49	.24	447

As can be seen from inspection of Table 1, there is a considerable amount of consistency across stores within each of the three pairwise correlations. The strongest relationship emerges for affect and patronage, followed by patronage frequency and the amount of money spent. The association between affect and amount of money spent is not as strong as the other two relationships (lower explained variance).

In order to further investigate the relationship of affect and behavior, the data were submitted to partial correlation analyses with each of the behavioral measures treated as a partial. The subjects who never shopped at a store were eliminated from these analyses (for each store separately). The results of the partial correlation analyses are reported in Table 2.

TABLE 2
RESULTS OF PARTIAL CORRELATION ANALYSIS

Variables Correlated	Partial r	r^2	d.f.	p
Affect with Dollars (controlling for patronage frequency)				
Sears	.10	.0100	759	.003
K-Mart	.08	.0064	731	.017
Wards	.07	.0049	446	.070
Affect with Patronage Frequency (controlling for dollars)				
Sears	.35	.1225	759	.001
K-Mart	.45	.2025	731	.001
Wards	.45	.2025	446	.001

The results presented in Table 2 further support the relatively strong relationship between affect and patronage frequency and the very weak relationship between affect and amount of money spent. Although the partial correlations for Sears and K-Mart are statistically significant,

the amount of explained variation between affect and amount of money spent (controlling for patronage frequency) is virtually negligible. In contrast, the proportion of variability in affect associated with variations in patronage frequency (controlling for amount of money spent) is relatively substantial and consistently statistically significant for all three stores.

The data were submitted to a series of one-way analyses of variance to determine patterns of affect and expenditure means according to patronage groups. These analyses provide additional insight into the relationship between affect and patronage and patronage and dollar amount spent and treat the patronage frequencies as categorical data (as opposed to metric as in the correlational analyses).

The tabulation below presents the sample distribution of patronage frequency by store.

	Sears	K-Mart	Wards
Never	32	61	276
Once a year or less	120	82	224
Two to six times a year	309	174	155
Seven to twelve times a year	241	213	100
Two to three times a month	151	241	44
Once a week or more often	31	106	8

Wards is characterized by relatively infrequent shopping patterns, as can be seen from the number of subjects who "never" shop there (approximately one-third). More subjects actually shopped at Sears with some degree of frequency than either at Wards or K-Mart; however, K-Mart evidenced the highest frequency of shopping patronage (approximately one-third of the sample shopped there two to three times a month or more often). Only eight subjects said they shopped at Wards once a week or more often. The results for this cell are problematic statistically; however, the cells were not collapsed in order to preserve the consistency of calibrations across stores. Paired comparisons for this cell will be presented but should be interpreted with extreme caution.

As is shown in Table 3, there is a statistically significant effect of patronage frequency on both affect and dollar expenditures for all three stores. The F-ratio for all one-way ANOVAS were highly significant (within an alpha level of .01). Again, the analyses for affect and patronage frequency included all the subjects and analyses for patronage frequency and amount of money spent included only subjects who shopped at the store (i.e., eliminating the "never shop" subjects for each store).

TABLE 3
RESULTS OF ONE-WAY ANALYSES OF VARIANCE
FOR PATRONAGE FREQUENCY GROUPS

Dependent Variable	Store	M.S. Between	M.S. Within	F-Ratio	Eta Squared
Affect	Sears	134.45	2.65	50.81	.23
	K-Mart	161.72	2.43	66.44	.29
	Wards	147.09	2.54	57.84	.30
Dollars	Sears	8929440.91	209785.67	42.57	.22
	K-Mart	5218529.68	166492.32	31.34	.16
	Wards	3499463.20	91543.96	38.23	.25

Degrees of Freedom (between, within): Sears affect=5,832; K-Mart affect=5,807; Wards affect=5,680; Sears dollars=4,791; K-Mart dollars=4,763; Wards dollars=4,468.

Table 4 displays the mean affect and dollars spent by patronage frequency category. The letters that "match" beside the mean ratings indicate means that are significantly different from each other at the .05 level of alpha. These are the results of a Duncan's Multiple Range Test for each paired comparison.

TABLE 4
MEAN RATINGS AND RANGE TEST
FOR ANALYSES OF VARIANCE RESULTS

Patronage Frequency	Mean Affect Rating		
	Sears	K-Mart	Wards
Never	1.88 ^a	2.39 ^a	2.39 ^a
Once a year or less	3.18 ^{ab}	3.35 ^{ab}	2.89 ^{ab}
Two to six times a year	4.41 ^{abc}	4.12 ^{abc}	3.83 ^{abc}
Seven to twelve times a year	5.17 ^{abcd}	5.02 ^{abcd}	5.11 ^{abcd}
Two to three times a month	5.53 ^{abcd}	5.53 ^{abcde}	5.07 ^{abcde}
Once a week or more often	5.86 ^{abcde}	6.30 ^{abcde}	6.38 ^{abcde}

Patronage Frequency	Mean Dollars Spent		
	Sears	K-Mart	Wards
Once a year or less	98.75 ^a	40.15 ^a	38.03 ^a
Two to six times a year	237.37 ^{ab}	121.73 ^b	171.26 ^{ab}
Seven to twelve times a year	478.53 ^{abc}	249.33 ^{abc}	394.15 ^{abc}
Two to three times a month	650.03 ^{abc}	378.16 ^{abcd}	531.46 ^{abc}
Once a week or more often	727.13 ^{ab}	600.35 ^{abcd}	501.25 ^{ab}

The results presented on Table 4 indicate that people do what they "like." Clearly, the relationship between affect and patronage frequency is a strong one, as evidenced by the amount of variation in affect ratings explained by shopping frequency (Table 3). Further, in terms of paired mean differences, forty-three out of forty-five mean affect comparisons were significantly different from each other.

The same strength and direction of relationship results from the association between dollar amount spent and patronage frequency. Twenty-five of thirty possible paired mean comparisons were significantly different from each other. The conventional wisdom that "the more people come into your store the more they spend" appears to hold.

Conclusions and Implications

The results indicate that all three hypotheses were supported for each retail store. There were statistically significant relationships between affect and patronage (Hypothesis 1), affect and dollar amount spent (Hypothesis 2), and between patronage and dollar amount spent (Hypothesis 3). In addition, there were no statistically significant differences between the two scaling techniques for affect: semantic differential and graphic positioning.

Thus, a single item, global measure of affect was a fairly strong predictor of shopping frequency for a heterogeneous sample of consumers, validated across three retail stores, and supported by results with a relatively high amount of explained variance. However, with respect to the relationship between affect and dollar amount spent, although statistically significant, the explained variance is negligible. Patronage frequency appears to have a stronger relationship with dollar amount spent than does affect. People do, indeed, shop where they like and like where they shop.

This study measured affect on a continuum from dislike to like. Since affect may be conceived as a "system" that "lends its power to memory, to perception, to thought and to action no less than to drives," (Tomkins 1984, p. 164) there are many other "affective states" (beyond liking) appropriate for consumer behavior measurement (or manipulation). This research does suggest, however, that a single, easily applied measure of affect (operationalized as like/dislike) can contribute to explaining a reasonably "large" amount of variation in behavior.

A TYPOLOGY OF CONSUMER KNOWLEDGE CONTENT

Merrie Brucks, University of North Carolina

Abstract

It is well accepted that stored knowledge about a domain affects the processing of new information about that domain; however, there is little agreement among consumer researchers on how to measure knowledge. It is argued here that consumer knowledge can be classified and measured by its content. A typology of consumer product knowledge content is proposed, based on a review of the relevant literature. An empirical study finds that this typology is comprehensive, reliable, and able to classify knowledge into empirically distinguishable categories.

Introduction

Stored knowledge about a domain affects the processing of new information about that domain. In one of the earliest studies to demonstrate this effect, de Groot (1965, 1966) found that expert chess players were able to recall mid-game chess positions better than novice chess players. Later research (Chase and Simon 1973a, 1973b) indicated that the experts' superior memory for chess positions was based on their knowledge of prototypical game patterns as opposed to a superior memory in general. Analogous conclusions have been drawn in at least eight other domains: physics, electronics, music, baseball, programming, and the games of Go, Gomoku, and bridge (Chi, Glaser, and Rees 1981). All of these findings indicate that differences in the content and organization of domain-specific knowledge between experts and novices result in differences in the processing and recall of domain-related information.

Recently, several studies have examined the effect of variables related to knowledge (e.g., product class experience, familiarity) on various consumer information processing activities (e.g., Alba 1983; Bettman and Park 1980; Bettman and Zins 1977; Brucks 1985; Edell and Mitchell 1978; Johnson and Russo 1984; Park 1976; Punj and Staelin 1983; Srull 1983; Sujan 1985). With few exceptions, the consumer behavior literature has treated knowledge as a unidimensional variable. However, recent research indicates that knowledge is a complex construct that is characterized by the structure and the content of information stored in memory (Brucks and Mitchell 1981; Hutchinson and Alba 1985; Kanwar, Olson, and Sims 1981). The structure of knowledge refers to how knowledge is represented and organized in memory. The reader is referred to Hutchinson and Alba (1985) for an outstanding review of this topic. The content of knowledge refers to the subject matter of information stored in memory. For example, three types of knowledge content are knowledge about terminology, knowledge about specific brands, and rules for evaluating a new brand. This paper reviews some previous typologies of knowledge content, and proposes a new, more comprehensive typology, which is empirically examined.

An understanding of the composition of knowledge content will aid researchers in developing objective tests of knowledge by indicating what questions need to be asked. Furthermore, a multi-dimensional account of knowledge content may provide a better understanding of consumer behavior if different types of knowledge content affect behavior in different ways.

Background

There are many possible ways to classify knowledge by its content, and in fact, several typologies have been proposed. One early typology was proposed by educational psychologists in an effort to help teachers construct exams that tap all types and levels of knowledge (Bloom et al. 1956). This comprehensive classification system, while developed for an entirely different application,

provides many useful ideas for developing a typology of consumer product knowledge. The relevant portion of this hierarchy is presented in Table 1.

TABLE 1

TYPOLGY OF KNOWLEDGE CONTENT FROM EDUCATIONAL PSYCHOLOGY (BLOOM ET AL. 1956)

1. Knowledge of Specifics
 - 1.1 Knowledge of terminology: knowledge of the referents for specific verbal and non-verbal symbols.
 - 1.2 Knowledge of specific facts: knowledge of dates, events, persons, places, sources of information, etc.
2. Knowledge of Ways and Means of Dealing With Specifics
 - 2.1 Knowledge of conventions: knowledge of characteristic ways of treating and presenting ideas and phenomena.
 - 2.2 Knowledge of trends and sequences: knowledge of the processes, directions, and movements of phenomena with respect to time.
 - 2.3 Knowledge of classifications and categories: knowledge of the classes, sets, divisions, and arrangements that are regarded as fundamental or useful for a given subject field, purpose, argument, or problem.
 - 2.4 Knowledge of criteria: knowledge of the criteria by which facts, principles, opinions, and conduct are tested or judged.
 - 2.5 Knowledge of methodology: knowledge of the methods of inquiry, techniques, and procedures employed in a particular subject field as well as those employed in investigating particular problems and phenomena.
3. Knowledge of the Universals and Abstractions in a Field.
 - 3.1 Knowledge of principles and generalizations: knowledge of particular abstractions that summarize observations of phenomena.
 - 3.2 Knowledge of theories and structures: knowledge of the body of principles and generalizations together with their interrelations that present a clear, rounded, and systematic view of a complex phenomenon, problem, or field.

More recently, other ways to classify knowledge by its content have been proposed. One useful and well-accepted dichotomy distinguishes declarative knowledge from procedural knowledge (Anderson 1976). Declarative knowledge refers to knowledge about concepts, objects, or events. Procedural knowledge, on the other hand, refers to knowledge of rules for taking action. Declarative knowledge is currently believed to be stored in an associative network and organized into schemas, whereas procedural knowledge is believed to be stored and organized into production systems.

The content of knowledge about physics has been examined for physics experts and novices (Chi, Glaser, and Rees 1981). In this study, two graduate physics students (experts) and two undergraduate physics students (novices) were asked to tell everything they knew about a

selected sample of 20 physics concepts. The protocols generated from this task were then analyzed on the basis of knowledge content. The analysis indicated, first, that both experts and novices possessed fundamental knowledge about the basic properties of physics objects (such as "inclined plane"), but the experts possessed a more complete, or detailed, knowledge of these properties, as well as additional knowledge based on the major physical laws affecting the object (such as "conservation of energy"). Second, the experts closely linked explicit problem-solving procedures with declarative knowledge of physical objects in long term memory. Novices showed almost no such linkages. And third, the experts had much more knowledge about the conditions under which the major physical laws are applicable to the object.

To generalize these results to the domain of consumer products, one might expect that both experts and novices possess knowledge about basic properties of a product class, possibly knowledge about which attributes characterize the product class. This knowledge would, however, be more detailed in experts, possibly including knowledge of how attributes are related to each other and how attribute types and levels affect performance. Second, we might expect that experts would have more knowledge about how to choose and buy a product in the domain. And third, we might expect that experts would have more knowledge about how the conditions under which the product will be used would affect the important attributes for evaluation. For example, compared with a novice, a stereo expert would be more likely to know that requirements for sensitivity and selectivity in stereo tuners and receivers differ between rural and urban settings. The discussion above suggests that detailed knowledge of attributes be classified separately from knowledge of the existence of attributes, and that classifications are necessary for procedural and situational knowledge.

Finally, this discussion of possible knowledge content classifications concludes with some notable research from the consumer behavior literature. Hastie (1982) makes a distinction between generic product knowledge and individual product knowledge. Generic product knowledge includes "general information about classes of products, instances exemplifying the products, the existence of different types of products (implying knowledge of correlations between product attributes, such as luxuriousness and gas consumption of an automobile), and information about the attributes or dimensions that are relevant and important in making decisions concerning the products (e.g., the distribution of existing product types along the price dimension)."

Individual product knowledge includes "information such as prices, color, taste, durability, features, etc., of each product. Furthermore, this knowledge structure would include information about relationships among the products. For example, that product X is more expensive than product Y, or that product A and product E are manufactured by the same company."

An approach that focuses on "individual product knowledge" is advocated by Russo and Johnson (1980). They propose that product knowledge be classified by level of inference and whether it is linked by attribute or by brand. Level of inference refers to the degree to which information available in the environment has been processed by the individual and retained in memory. The type of linkage refers to whether individuals link attribute values for each brand by brand or by attribute. In other words, individuals may link all the attribute values for a single brand together or they may link all the brands together for a single attribute. Russo and Johnson's classification scheme appears to be useful in that 80 percent of knowledge statements that had been generated by a knowledge probe fit into the scheme. Bettman and Park (1980) developed a coding scheme for classifying the use of prior knowledge during decision-making. This coding scheme includes brand evaluations, attributes of specific brands, and evaluations of particular levels of attributes.

In this section of the paper a comprehensive typology for consumer product knowledge content is proposed. The typology has continuously evolved over time. An early version, presented in Brucks and Mitchell (1981), was modified after some initial exploratory research. This initial research consisted of obtaining responses from a convenience sample of subjects to the probe "Write down everything you know about [product class]." Products used were microwave ovens, sugar, and aspirin. Analysis of the responses indicated that the typology was not sufficiently comprehensive, i.e., many statements of knowledge did not fit in any of the categories.

Based on this research, a new typology was proposed and a coding scheme developed. As the research described in the following section progressed, it became apparent that some minor changes were needed in this coding scheme. Modifications to the coding scheme (and therefore the typology) were made to satisfy three objectives:

- 1) The typology and coding scheme should be easy to use and seem logical to people who are using the coding scheme.
- 2) The typology should cover as many of the subjects' statements as possible while remaining relatively parsimonious.
- 3) The categories in the typology should be as distinct from each other as possible.

The following typology was developed in an attempt at satisfying the above objectives. It also incorporates many of the ideas from the research previously cited.

1. Terminology refers to knowledge of the meanings of terms used within a domain, for example, knowing that "pronation" refers to heels that turn in while running.
2. Product Attributes refers to knowledge of which attributes are available for evaluating a brand. It includes knowledge of attributes that a person would use in making a decision and also those that she would not use but is aware of their existence. For example, the statement "Some people consider light weight essential in a new running shoe" indicates knowledge of the attribute "weight" whether or not the individual thinks this a relevant attribute for her own decision making.
3. General Attribute Evaluation refers to knowledge of the overall evaluation for an attribute or an attribute level, for example, "I like waffle soles" or "I don't like a heavy shoe."
4. Specific Attribute Evaluation on the other hand, refers to knowledge of specific criteria used to evaluate an attribute, i.e., cut-off points or reference points used to judge how satisfactory an attribute level is, for example, "I won't spend more than 30 dollars." It also refers to how an attribute (or a specific level of an attribute) is related to other attributes and/or performance criteria, for example, "A lightweight shoe doesn't last very long."
5. General Product Usage refers to knowledge of how the product can be used, what characteristics of the usage situation are relevant when a purchase is being considered, and which product characteristics are affected by these usage situation characteristics. Included in this category are normative rules for usage, for example, "You should not wear running shoes to play tennis," and knowledge of how the product class can be categorized based on usage, for example, "There are several types of running shoes: competition shoes, training shoes, track shoes, and cross-country shoes."
6. Personal Product Usage knowledge includes memories of usage experiences, knowledge of memories of usage experiences of personal acquaintances, and knowledge of the salient characteristics of one's own usage situation and

the usage situations of personal acquaintances. For example, knowledge of characteristics of personal usage situations includes such knowledge as "I don't run long distances" or "My sister once wore out a pair of shoes in 3 weeks."

7. Brand Facts refers to knowledge of how brands "score" on an attribute, overall evaluations of a brand, and other brand facts such as comparisons between brands on an attribute. Example are "I'd never wear Adidas" or "Adidas have an antimicrobial sole."

8. Purchasing and Decision Making Procedures refers to knowledge about the purchasing process. Included in this category are memories of personal purchase experiences and also normative models of the purchase process. An example of the former is "I bought my last pair of shoes from Mitchell's Attic." An example of normative knowledge is, "You shouldn't buy the first thing you see."

Notice that categories 1 through 7 versus category 8 represent the distinction between declarative and procedural knowledge (although category 5 also contains some procedural knowledge). Declarative knowledge is further classified as either general product class knowledge (categories 1 through 6) or individual product knowledge (category 7). Within the declarative, general product class knowledge category, the distinctions made were inspired by Bloom et al. (1956), Chi, Glaser, and Rees (1981), and pretest results.

The usefulness of the proposed typology depends on how well these categories characterize a person's total knowledge structure, how well these categories can be measured, to what extent they exist independently of each other, and to what extent they have some differential impact on behavior. The study presented in the following section addresses the first three of these issues.

Empirical Examination of Typology

Specifically, the objectives of this study are:

- 1) to provide a test of the comprehensiveness of the typology,
- 2) to assess the inter-judge reliability of the coding scheme, and
- 3) to provide an estimate of the inter-correlations between the amount of knowledge in each of the categories.

Since this research is concerned with naturally occurring knowledge structures, there were no experimental manipulations of product knowledge. Rather, memory probes were used to elicit existing product knowledge. A relatively unstructured technique was chosen to measure the subjects' knowledge in order to minimize any biases that would result from imposing a preconceived structure. Thus, a free recall procedure was employed using the following memory probe: "I want you to think about purchasing a [product]. Now, tell me everything that comes to mind about [product]." The intent of this probe was to encourage the subjects to produce as much knowledge about the product class as they could. In this regard, the probe is similar to those used by Chi, Glaser, and Rees (1981) and Russo and Johnson (1980).

It was judged unlikely, however, that subjects would recall everything they knew in response to a single probe. Therefore, a double-layered series of probes was used in which subjects were asked to elaborate on each of the points that they had mentioned in response to the general probe. No estimates exist for the reliability of this procedure. The procedure used in this study was modeled after a multi-layered probe method described by Olson (1979). Olson's procedure was designed to measure the structure of stored knowledge in memory, thus his subjects were supposed to verbalize knowledge as it had been stored in memory. In the present study, however, subjects were not limited to reporting knowledge as it

exists in memory. Rather, they were allowed to make inferences and verbalize them during the reporting process. Such inferences have been termed "constructive recall." It was decided to allow constructive recall as well as stored knowledge in this study because it seems to better represent the knowledge that people actually use during decision making than stored knowledge alone. The statements elicited by these probes were classified according to the type of knowledge content as previously defined.

Subjects

The thirty-one subjects participating in this experiment were undergraduate college students. They agreed to participate in return for a three dollar cash payment. Subjects participated in the study individually, and the experimental sessions lasted 50 to 60 minutes on average, although only 20 to 30 minutes were devoted to the data collection described here.

Products

The product chosen was running shoes. This product showed substantial variance in self-reported expertise among a pretest population of 86 students. Running shoes were also considered complex enough to warrant study of knowledge, but not so complex as to create a frustrating task for the more knowledgeable subjects.

Experimental Procedure

At the beginning of each experimental session, the subject was given a practice verbalization task about a different product class--bicycles. This task was used to familiarize the subject with verbalizing her/his knowledge about a product class. The experimenter provided feedback to help the subject understand the desired breadth and depth of the response.

At this point, the tape recorder was turned on and the subject was asked, "I want you to think about purchasing a pair of running shoes. Now, tell me everything that comes to mind about running shoes." When the subject had finished, the subject was asked to elaborate on each of the points he or she had made (which the experimenter had recorded on paper and then read back to the subject one at a time). The entire verbalizing process, including the elaboration, took an average of about ten minutes. Because of tape machine failure, data from 5 subjects were unusable, resulting in a final sample size of 26. The author numbered the subjects' statements on the transcriptions of the audiotapes, and a research assistant classified these statements according to the coding scheme (which may be found in Brucks 1984). The author also coded the first 8 tapes that were transcribed in order to provide an estimate of inter-judge reliability.

Interjudge Reliability

The eight transcribed tapes that were coded by both judges yielded a total of 542 statements and 765 classifications. These 8 tapes represented 42 percent of the statements recorded. The judges agreed on seventy-two percent of the classifications, indicating that the elements in the proposed typology can be consistently identified.

In order to rely exclusively on the coding of one judge, it should be demonstrated that the coding of this judge does not systematically differ from the coding of the other judge. A repeated measures ANOVA was performed in order to test whether the judges systematically used the categories differently (i.e., whether they "favored" different categories). The factors (within-subject) were categories and judges, and the dependent variable was the number of coded pieces of knowledge. Since there were two judges, ten categories, and eight subjects, the ANOVA was computed based on 160 observations on the dependent variable. A significant Category X Judge interaction would imply that the judges were systematically assigning

category codes differently from each other. As Table 2 shows, this effect was not significant.

TABLE 2

ANALYSIS OF VARIANCE FOR NUMBER OF STATEMENTS CODED

Source of Variation	Sum of Squares	Degrees of Freedom	Mean Square	R
Mean	15073.81	1	15073.81	28.55
Error	3696.04	7	528.01	
Categories	11294.51	9	1254.95	8.92
Error	8864.14	63	140.70	
Judges	1.41	1	1.41	1.81
Error	5.44	7	.78	
Cat x Judge	70.41	9	7.82	.84
Error	589.24	63	9.35	

Fiske and Cox (1979) suggest a measure of interjudge reliability that may be derived from this analysis. They point out that as the Judge X Category mean square error goes to zero, the following expression approaches unity, thus providing a measure of reliability:

$$\frac{\text{MSE (Categories)} - \text{MSE (Judges x Categories)}}{\text{MSE (Categories)}}$$

This formula yields an estimate of reliability of .934 for the present study. This means that although the judges disagreed on category classifications twenty-eight percent of the time, these differences were not systematic.

In order to investigate the possibility that the judges were systematically assigning category codes differently from each other for the most infrequently used categories (which might not be revealed by the above ANOVA), the total number of assigned statements per category for each judge was compared. At most, the student judge's assignments differed from the author's by 29 percent (for General Attribute Evaluation). Based on these results, it was decided to use the coding of the student judge exclusively.

Data Description

In total, 1295 statements were elicited from the 26 subjects. Of these, 65 (or 5.0 percent) were judged by the coder to be irrelevant to running shoes. A typical example of an irrelevant statement is "My parents took my brother to the doctor because he had really bad fallen arches." Eliminating these statements reduced the total number of statements to 1230. The number of relevant statements elicited for an individual varied from 15 to 130. The average was 47.

Composition of Elicited Knowledge

Over 98 percent of the relevant statements were classified into one of the eight categories of knowledge, clearly demonstrating that the typology is sufficiently comprehensive. As the data in Table 3 indicate, knowledge content was more likely to fall into some categories than others. In fact, over 60 percent of the statements were classified as Attribute or Attribute Evaluation knowledge. Almost 40 percent were classified as Specific Attribute Evaluation, indicating a possible need for subdivision within this category. On the other hand, less than one percent of the statements were classified as Terminology knowledge. In contrast to Russo and Johnson (1980), only a small proportion of elicited statements dealt with specific brands. This difference is probably due to the different probes used in the two studies to elicit product knowledge. As Rossiter (1980) noted, the Johnson and Russo probe emphasized brand knowledge.

TABLE 3

COMPOSITION OF KNOWLEDGE FOR RUNNING SHOES

Knowledge Category	Number	Percentage
Brand Facts	72	5.7
Attributes	224	17.9
General Attribute Evaluation	49	3.9
Specific Attribute Evaluation	494	39.4
Purchasing	112	8.9
General Usage	152	12.1
Personal Usage	120	9.6
Terminology	7	0.6
Unclassifiable	24	1.9
Totals	1230	100.0

It may be erroneous to conclude, however, that the frequencies in Table 3 represent the actual amount of knowledge that people have stored in memory in each of these categories. First, the general probe may have produced biases in the types of knowledge elicited. The accessibility of a piece of knowledge is related to how strongly it is associated with the probe (Collins and Loftus 1975). Consequently, a biased assessment of the composition of knowledge may result from the use of a probe that differs in its strength of association with the various types of knowledge content. For example, running shoe terminology may not be as closely associated with buying running shoes as evaluations of running shoe attributes are. Second, the number of statements elicited in a category may not represent the amount of knowledge in that category if information is "chunked" in memory, i.e., if a single statement summarizes a lot of detailed knowledge. This problem was somewhat reduced by the use of the double-layered probe technique and the coding instructions. Specifically, a statement could receive more than one code if it was judged to contain more than one piece of knowledge.

Relationships Between The Knowledge Categories

If the levels of knowledge (i.e., numbers of statements) in each category are highly correlated with each other, the proposed typology would be very limited in usefulness. First, high correlations would signify that a unidimensional measure would be sufficient to assess knowledge content. Second, high correlations would indicate that little benefit would be gained from isolating the effects of each type of knowledge on decision making behavior (since the knowledge variables would rarely occur in isolation). Of course, the knowledge categories are not conceptually independent, so a moderate level of correlation is to be expected.

Table 4 displays the correlations between the number of statements in each category. Of these, nineteen are below .3 and four are between .3 and .5. Only five correlations are higher than .5. The results indicate that these categories of knowledge content are, in general, fairly distinct. Since a few of the correlations are very large, however, it is useful to analyze the pattern of correlations in order to gain some insight into the relationships between the measures of the different categories.

Factor analysis was used to examine these relationships. Since there is no reason to expect the factors to be uncorrelated, an oblique rotation was used. Only those factors with eigenvalues greater than one were selected, resulting in a three factor solution. Direct oblimin was selected as the rotation procedure. A moderate degree of correlation between the factors was specified by the delta parameter. The sensitivity of the solution to this parameter was investigated by altering the delta parameter and refactoring the data. The resulting solutions led to the same conclusions as the

Factor 2		-.0818

solution presented here.¹ The factor loadings are displayed in Table 5.

Three factors are identified by this analysis. The first factor can be interpreted as a "product attributes" factor, including knowledge of the existence of product attributes and knowledge of how to evaluate specific attribute values. Knowledge of Attributes, General Attribute Evaluation, and Specific Attribute Evaluation load highly on this factor. Three knowledge types load highly on the second factor: Specific Attribute Evaluation, Terminology, and General Usage. These three types are useful to a serious runner who needs to be able to communicate with other runners and choose shoes that will perform well in the various running situations that the serious runner encounters. Specific Attribute Evaluation and General Usage correspond to some of the differences in knowledge between experts and novices found by Chi, Glaser, and Rees (1981). The third factor represents knowledge of a personal nature, the kind of knowledge that is likely to arise directly out of personal experience. Knowledge of Purchasing Procedures and Personal Usage load highly on this factor. Brand Facts did not

¹An orthogonal solution was also obtained, again with very similar results.

load highly on any of the factors.

The results raise some interesting questions concerning how knowledge develops and how the knowledge content of experts differs from that of novices. It appears that consumers learn about product attributes somewhat independently of personal experience with the product. Only serious users of the product may acquire much knowledge of terminology and of the relationship between product usage situations and the appropriate product characteristics. Future research is needed to further explore these issues.

Summary and Conclusions

The coding scheme for knowledge content was found to be sufficiently reliable and comprehensive. In general, the knowledge categories were distinct from each other although there were some notable exceptions. The factor analysis indicates that, for running shoes, there may be fewer than eight empirically separable dimensions of knowledge content. This analysis is limited in generalizability, however, because of the small sample, the limitations of the free-elicitation measurement method, and the characteristics of the specific context of running shoes.

This research indicates that knowledge content is multidimensional, which has two important implications for future research on consumer product knowledge. First, measures of consumer knowledge should include a variety of questions in order to capture the full range of the knowledge construct. For example, Brucks (1985) developed structured and open-ended questions to measure product knowledge based on a modified version of this typology. Second, the different types of knowledge content may have different effects on decision-making and purchasing behavior. For example, knowledge of "Brand Facts" may be used to substitute for external information search, (thus decreasing search) while knowledge of "Terminology" may facilitate external information search (thus increasing search). Future research is needed to address the effects different types of knowledge content on decision-making behavior.

MEASURING PRIOR KNOWLEDGE

Catherine A. Cole, University of Iowa
Gary Gaeth, University of Iowa
Surendra N. Singh, University of Kansas

Abstract

This paper assesses the convergent, divergent and criterion validity of alternate methods of measuring prior knowledge. The context used to study the validity issue is the playing of board games. Evidence is found for all three types of validity for objective test and self-reported knowledge measures of prior knowledge. Usage measures appear to be more problematic.

Introduction

Intuitively, we know that our current behavior is influenced by our prior knowledge of a given area. If we usually buy Sears brand power tools we tend to notice and recall a newspaper advertisement for a Sears power tool sale. This proposition as well as other about the effects of prior knowledge on consumption behavior have been empirically tested. For example, there is a large body of literature examining the impact of prior knowledge on recall and use of new information about products. (See for example Brucks forthcoming and Johnson and Russo 1984). However, one of the major difficulties with this stream of research is the lack of consensus over appropriate methods of measuring prior knowledge.

The objective of this paper is to examine the convergent, divergent and criterion validity of alternate methods of measuring prior knowledge. The context used to study this issue was the playing of board games. One reason games were chosen was that pretesting indicated that there was considerable variance among undergraduates in prior experience with the board games, Monopoly and Life. Another reason was that intrinsically motivated behavior, such as game playing, has been under-investigated in the consumer behavior literature (Holbrook et al., 1984).

Background

First there is a need to develop a good working definition of prior knowledge. The definition we will use is particularly appropriate for this context and has been put forth by a group of psychologists working in the area (Chiesi, Spilich and Voss 1979). They view "knowledge of a domain as an understanding of its basic contents, as well as its goals, rules and/or principles." A review of the literature suggests that there are three approaches to measuring consumers' prior knowledge of a product class: tests of knowledge, self-assessed measures of knowledge and self-reported usage history.

Objective tests of knowledge are designed to assess how much a person knows about a particular domain. A person who receives a high score on the test is considered knowledgeable. Both psychologists and consumer behavior researchers have implemented this definition by administering tests to subjects to assess their knowledge of a particular product class. (See Bruck forthcoming, Spilich, Vesonder, Chiesi & Voss 1979, Staelin 1978). The underlying assumption is that people with equivalent scores on the knowledge test should perform in similar ways on tasks such as recall of new information.

Another method is to use a self-assessed measure of knowledge. Here subjects are asked to rate how much they know about a particular domain. For example in a recent political science study political expertise was defined using a self-reported measure of knowledge, interest and participation (Fiske, Kinder and Larter 1983). Researchers in consumer behavior have also used self-assessed measures of knowledge (Johnson & Russo 1984). The problem with these measures is that they may reflect generalized self-confidence more than any actual state of knowledge because people who are self-confident may report more knowledge than those with less confidence.

Finally, some researchers have measured knowledge by assessing usage or purchasing behavior. Here the assumption is that if you have used, purchased or sought out information on a product class then you have an increased level of prior knowledge. For example, Bettman and Park (1980) classified subjects based on responses to questions about whether or not the respondent had ever used, ever owned or ever searched for information about a microwave. The difficulty with this approach is that different types of experience could create different types of knowledge and thus affect behavior in different ways. For example, two researchers found that some types of experience (classroom training) had no effect on while other types of experience (interactive training) had an effect on the ability of judges to ignore irrelevant information (Gaeth and Shanteau 1984).

Hypotheses

In this study we used two different board games: Monopoly and Life. Prior knowledge of each board game was assessed in the three different ways described above. In addition we measured the emotional responses of subjects to the experience of playing each game. The main hypotheses is that measures of knowledge for the same board game should be related (convergent validity), while measures of knowledge for different board games should be unrelated (discriminant validity). In other words, the underlying proposition is that there is a distinct prior knowledge construct for each game and that each of the three measures of knowledge is an appropriate way to assess this construct.

An additional hypothesis is that because games are part of intrinsically motivated consumer behavior, people who have acquired a great deal of knowledge of a game should report high positive affect toward the act of playing the game (criterion validity). Previous research has suggested that the PAD scale, developed by Mehrabian and Russell (1974), can be used to characterize affective responses to intrinsically motivated behavior such as leisure activities, creativity and game playing (Holbrook et al. 1984). Consequently it is expected that prior knowledge should correlate positively with scores on the PAD scale.

The key issues in the study are summarized in the following three hypotheses:

- H1: Scores on self-assessed knowledge tests, usage questions and true/false knowledge tests should be positively correlated when the tests all relate to one particular board game (convergent validity).
- H2: Scores on self-assessed knowledge tests, usage questions and true/false knowledge tests should not be correlated when the tests relate to two different board games (discriminant validity).
- H3: All three measures of experience should correlate positively with scores on the PAD scale (criterion validity).

METHODOLOGY

Subjects

Forty-five undergraduate students completed the questionnaire in sessions conducted outside the classroom in groups of 8-10. The students were given class credit for participating in the study.

Content of questionnaire.

The following information was collected in the following order: self-reported knowledge of Monopoly, self-reported knowledge of Life, usage information for Monopoly, usage information for Life, PAD scale information for Monopoly, PAD scale information for Life, test of knowledge of Monopoly and test of knowledge of Life.

Self-reported knowledge measure. Fourteen Likert statements were administered to subjects to assess self-reported measures of

knowledge. A sample item is "I know most of the rules in Monopoly." Both the Monopoly and Life scale contained seven items, with coefficient alpha of .834 and .933 respectively.

Usage. Usage of the two games was determined by two open ended questions. One for Monopoly and one for Life: How many times have you played Monopoly (Life) in the last three years?

Test. Objective knowledge was assessed through a true/false test. Subjects responded to 9 true false statements about the rules of Monopoly (e.g., at the start of Monopoly each player is given \$1500) and 9 true/false statements about the rules of Life (e.g., in the game of Life you must land on a red pay day space to collect your salary). Response categories were definitely true, probably true, probably false and definitely false. This knowledge measure was taken last because it might bias responses to other questions.

Emotional Response (PAD scale). Subjects were told to think about the last time they played Monopoly (Life) and place a mark closest to the point which represents their feelings about the prior experience of playing Monopoly (Life). Subjects then completed the Mehrabian and Russell (1974) PAD scale. The scale consists of 18 items, 6 measure pleasure-displeasure, 6 measure arousal-nonarousal and 6 measure dominance-submissiveness. The form of the scale is a semantic differential. The coefficient alpha's and a sample item are reported in Table 1.

TABLE 1
COEFFICIENT ALPHA'S FOR THE PAD SCALE

Scale	Sample Item	Coefficient Alpha for Monopoly	Coefficient Alpha for Life
Pleasure/Displeasure	Happy/Unhappy	.91	.90
Arousal/Nonarousal	Stimulated/Relaxed	.85	.85
Dominance/Submissiveness	Influential/Influenced	.55	.84

Results

First consider the evidence for convergent validity. Prior knowledge was measured in three ways for two games. The six correlations of relevance here are reported in the multi-trait, multi-method matrix (Table II). Each one has the subscript C next to it. All are non-zero, suggesting that in fact self-reported measures of knowledge, usage experience and tests of knowledge all assess the same underlying construct.

TABLE 2
CORRELATIONS BETWEEN MEASURES OF KNOWLEDGE

		Self-Reported Knowledge		Usage Experience		Objective Test	
		Monopoly	Life	Monopoly	Life	Monopoly	Life
Self-Reported Knowledge	Monopoly	1.0	.108 _F	.39 _C **	-.257 _D	.47 _C **	.02 _D
	Life		1.0	.08 _D	.63** _C	.10 _D	.56** _C
Usage Experience	Monopoly			1.0	.79** _F	.34* _C	.19 _D
	Life				1.0	-.10 _D	.77** _C
Objective Test	Monopoly					1.0	-.01 _F
	Life						1.0

* p < .05
** p < .001

Next consider the evidence for discriminant validity. This requires considering three criteria. First, the correlations between two different measures of the same variable should be larger than the correlation between that variable and any other variable which has neither trait nor method in common (Campbell

and Fiske 1959). To test this, each of the 6 entries labeled C were compared statistically to each of the 6 entries labelled D. (The r to z transformation of R. A. Risher as discussed in Sachs 1982 page 427-432 was used). Of the 36 comparisons, all were in the predicted direction and 26 were statistically different from each other (α = .05). Consequently this condition is partially satisfied.

Additional evidence of discriminant validity is garnered by examining the coefficients labeled C in relation to the correlations labeled F. The correlations in C should be higher than those labeled F because correlations within a trait measured by different method should be higher than correlations between traits which have a method in common." Of the 18 comparisons made, 10 are statistically different in the predicted direction (α = .05, using the r to z transformation). Six of the nonsignificant comparisons involve the correlation between usage of monopoly and usage of life which is unexpectedly large and significant. This suggests that there is some method variance present in the usage question.

Finally additional evidence of discriminant validity comes from examining the pattern of correlations labeled (F) and (D). The correlations labeled F share common methods but not traits, while the correlations labeled D share neither method nor trait in common. The rank order of correlations should be the same in both group F and group D. In this case all these correlations are close to zero, except for the usage measure. Again, using the r to z transformation, we found that none of the correlations labelled c differed from each other (α = .05) or from zero. In addition, the same pattern was observed for correlations labelled D, except for the correlations of usage for the two games. Consequently, the third criterion for discriminant validity is only partially satisfied.

A final question concerns criterion validity. Do these measures of prior knowledge predict some criterion measure? To assess criterion validity, we analyzed the correlation between prior knowledge and responses to the PAD scale. These are reported in Table III.

TABLE 3
CORRELATIONS BETWEEN MEASURES OF EMOTION AND MEASURES OF KNOWLEDGE

	Monopoly			Life		
	Self-Reported Knowledge	Usage	Objective Test	Self-Reported Knowledge	Usage	Objective Test
Score on Pleasure Scale	.43***	.06	.28**	.26**	.55**	.01
Score on Arousal Scale	.42***	.26**	.15	.09	.38*	.05
Score on Dominance Scale	.41***	.27*	.23	.33***	.33	.10

*** p < .01

** p < .05

* p < .1

One thing to note is that all the correlations are in the predicted direction. That is for the correlations that are significant there is a positive relationship between prior knowledge with a particular board game and reported feelings of pleasure, arousal and dominance. Because this is a relatively unexplored area, one way of looking at the data is to compare the effects of prior knowledge on the experience of playing Monopoly with the effects of prior knowledge on the experience of playing Life. For both games self-reported knowledge correlated with self-reported feelings of pleasure and dominance. Usage of Monopoly correlated with feelings of arousal and dominance, but usage of Life correlated with feelings of pleasure and dominance. The scores on the test for Monopoly correlated positively with the reported pleasure from playing monopoly. This relationship did not hold when Life was the game in question.

Consequently, the following generalizations can be made regarding criterion validity: (1) experience with playing a game is positively related to reported feelings of affect associated with playing the game; (2) all measures of prior knowledge do not have the same effect on feelings of affect; (3) the relationship between prior knowledge and reported affect seems to be somewhat idiosyncratic to the particular game in question.

Conclusions

Evidence was found for convergent validity of all three measures of prior knowledge. In other words objective tests of knowledge, self-reported measures and usage measures of the same trait correlated positively.

Evidence was also found for discriminant validity. However, the measure of Monopoly usage correlated with usage of Life. This result may indicate one of two things. First it may be that respondents who play one board game also tend to play other board games. This explanation, however, is weakened because the other measures of prior knowledge of Monopoly did not correlate with measures of prior knowledge of Life. An alternate explanation is that the usage measured suffered from psychometric flaws. For example, it is possible that respondents tended to overestimate or underestimate how many times they had played both games because the usage questions were asked at the same time and with the same question.

The evidence for criterion validity was less straightforward. All measures of knowledge that were significantly related to affect were in the predicted direction. In other words, when knowledge was related to a dimension of affect it tended to enhance the positive nature of the affect. However, not all measures of knowledge had the same effect on dimensions of the PAD scale. In particular for both games, self-reported knowledge is most clearly related to self-reported affect. However, objectively assessed knowledge seems to be least related to scores on the PAD scale. This pattern could arise for one of two reasons. It is possible that although the different measures of knowledge are clearly related, they do not measure identical constructs. Consequently these different measures of knowledge influence and are influenced by other constructs in unique ways. Beattie (1982), for example, suggests that the type of advertising copy one should use depends on whether the target audience has high knowledge as assessed by product usage or by product knowledge.

Alternatively, it is possible that the strong positive relationship between self-reported knowledge and self-reported affect reflects the fact that both measures are self-report scales.

There is a growing body of literature examining the impact of prior knowledge on all aspects of consumer behavior. In order to synthesize this literature, we need to know more about the psychometric properties of the alternate measures of prior knowledge. This paper represents an initial effort in that direction. One limitation of this research is that the psychometric properties of these measures were tested on just one product class. It makes intuitive sense that a person who frequently plays Monopoly will be a high scorer on a test of the rules of monopoly. However, it also makes intuitive sense that a person who frequently listens to a stereo system may not be a high scorer on a test of the technical attributes of a stereo system. Consequently, by choosing a product that one has to know a lot about in order to use, we may have obtained results that are not generalizable across product classes.

In conclusion, the data in this study suggest that one can generalize with caution across measures of knowledge. This seems to be especially true for objective test and self-reported measures of knowledge. Usage measures of knowledge need to be refined and used with care.

SUBJECTIVE AND OBJECTIVE MEASURES OF PRODUCT KNOWLEDGE CONTRASTED

Fred Selnes, Norwegian Fund for Market and Distribution Research, Oslo, Norway
Kjell Grønhaug, Norwegian School of Economics and Business Administration, Bergen, Norway

Abstract

The present paper contrasts subjective and objective measures of product knowledge. Findings from a study related to home computers reveal that the two set of measures are related, but also that they not are substitutable. Objective measures seem preferable when focusing on ability differences among consumers, while subjective measures should be preferred when focusing on motivational aspects of product knowledge.

Introduction

The purpose of the present paper is to contrast "objective" and subjective measures of product knowledge.

Product knowledge can be defined as product related information stored in memory, such as information about brands, products, attributes, evaluations, decision heuristics and usage situations (Marks and Olson 1981). The concept is considered being of crucial importance among consumer researchers, not at least due to the following:

- First, knowledgeable consumers are expected to possess superior ability in approaching new information. Due to more developed knowledge structures such consumers are assumed more able to interpret and intergrate new information than are their less informed counterparts (Johnson and Russo 1984; Chase and Simon 1973).
- Second, product knowledge is assumed to impact the decision-heuristics applied in handling buying decisions. A few examples may clarify this point. Park and Lessig (1981) found informed consumers to make more use of functional attributes than did their less knowledgeable counterparts. Consumers low in product knowledge are assumed to be more inclined to seek external information than are consumers high in product knowledge (cf. Cox 1967; Newman 1977; Punj and Staelin (1983). An inverted U-shaped relationship between product knowledge and intensity of information search due to lower ability to handle and integrate among consumers low in product knowledge, have, however, been reported (Bettman and Park 1980).

Measurement of Product Knowledge

Consumers develop product knowledge through search and use of information as well as through experience (Howard and Sheth 1969). Based on our above definition, the content of the knowledge domain may be described in terms of objects or brands known by the consumer, his or her knowledge about product attributes and usage situations, the ability to discriminate between product alternatives, and product evaluations.

In several studies the consumer's product class experience has been used as a proxy for his or her product knowledge (Bettman and Park 1980; Jacoby et al 1978; Katona and Mueller 1955; Newman and Staelin 1972). There are, however, several conceptual problems associated with the use of product experience as a measure of product knowledge.

- First, product knowledge may be developed through information search and use, and may thus be present without personal product experience.
- Second, increasing product experience may occur without subsequent increase in product knowledge. Bettman (1979) argues that development of product knowledge in general and decision heuristics in particular do not only depend on product experience as such, but also on how this experience is interpreted and causal inferences with regard to decision outcome made. An outcome as expected may lead to simplified decision heuristics, and thus increased ex-

perience may cause no change in product knowledge at all.

Subjective as well as objective measures have been used when studying consumers' product knowledge. Subjective measures are based on consumer's interpretation of what s/he knows, while objective measures are based on another person's evaluation of this knowledge. In consumer research there has been a tendency to prefer subjective measures (Brucks 1985; Park 1976), while there has been preference for objective measures among researchers from other disciplines such as social cognitive psychology (cf. Streufert and Streufert 1978). This has also been noted by Brucks (1985). Moreover Sujan (1985) has recently applied objective measures, and Brucks (1985) objective and subjective measures as well.

Whether subjective or objective measures are chosen should depend on the purpose of the research (Mitchell 1982). In our view objective measures are preferable when the research objective is related to the consumer's ability to encode new information or to discriminate and choose between product alternatives. Objective measures are related to the organization of the individual knowledge structure. Organization of information and knowledge structures is closely connected to the ability to filter out irrelevant information (Taylor and Crocker 1980); to retrieve relevant information from memory (Sternthal and Craig 1982); to rehearse or encode new information (Fiske, Kinder and Larter 1980). Knowledgeable consumers, objectively assessed, should therefore be superior to less knowledgeable consumers in encoding product related information, and be better able to choose an alternative close to the ideal or preferred.

Subjective evaluation of ones product knowledge should have significant impact upon the motivation to conduct various behaviors. A consumer perceiving s/he knows everything that matters about a specific product class, and the various bits of knowledge are in balance, will feel confident and perceive the level of risk and cognitive conflict associated with the buying decision as low or modest (Cox 1967). A confident consumer is among other expected to acquire less information, to seek less advice from friends and more information from commercial sources. Their confidence make them feel better able to handle any attempt of commercial "manipulation".

One possibility is that subjective measures are perfectly correlated with objective measures. That is novices¹ perceive themselves as novices and experts perceive themselves as experts. Another possibility is that the two types of measures are modestly or not correlated.

If the subjective measures don't match the objective measures, this implies that som real novices perceive themselves as experts, and some real experts perceive themselves as novices. Novices that perceive themselves as experts overestimate their own knowledge. Experts that don't perceive themselves as experts underestimate their ability judge and choose among the various alternatives.

An intuitive research question is: What is the relationship between subjective and objective measures? In our opinion the relationship could - in the language of factor analysis - be either orthogonal, oblique or perfectly correlated. In case of the latter outcome, perfect correlation, choice of product knowledge measure, i.e. objective or subjective, would not matter at all. In such a situation the consumer interpret what s/he knows from in-

¹ A novice is here a person with a low level of product knowledge, objectively assessed. Similarly an expert is a person with a high level of product knowledge.

formation stored in memory. If the two measures are orthogonal, and thus unrelated, the researcher should be extremely careful in choosing between which measure to use. In the case of correlated, but not perfectly correlated measures, perceptual knowledge will depend on the interpretation of what is actually stored as well as other individual and situational factors.

Methodology

Below is reported on the methodology underlying the present study designed to empirically explore the relationship between subjective and objective product knowledge measures.

Due to lack of relevant secondary data, primary research was conducted. A cross-sectional survey study was found appropriate to explore the relationship between the two sets of measures due to the requirement of keeping the intra-individual product knowledge constant.

Personal computers were chosen as reference-product in the present study due to expected variation in product knowledge. The factual knowledge related to this product, also makes it relatively easy to construct objective measures of product knowledge.

The sample consisted of 297 students attending a one-year introductory program in management. The students were very heterogeneous with regard to previous education (including students with high-school only as well as college degrees in engineering, sociology and law) and work experience (ranging from no experience at all to several years of well-paid middle-management training).

Data collecting procedure: The participants were asked to complete a questionnaire addressing their familiarity with personal computers, not being allowed to talk to each other during the test. The data collection was conducted during the first week of the program.

Measurement

The following subjective measures were used:

- (1) Level of subjective knowledge, SEV
- measured by the respondents' agreement of the degree to which s/he knew the relevant decision criteria².
- (2) Confidence, OEV, measured by asking how the respondents thought their closest friend would evaluate their familiarity with personal computers.
- (3) Advicegiving, ADV, assessed by questioning whether the respondents had been asked for advice.
- (4) Selfevaluation of brand knowledge, OBK, assessed by asking about success in a hypothetical computer purchase.

Objective measures: Level of differentiation, discrimination, and integration are important dimensions to describe and map the individual knowledge structure (Streufert and Streufert 1978). Level of differentiation reflects the number of salient dimensions in the consumer's cognitive domain, level of discrimination is related to the number of categories among which the consumer is able to discriminate, and level of integration relates to the ability to associate different dimensions. In addition to cognitive structure, product knowledge is related to terminology or understanding of the product language. The following objective measures were used.

- (1) Level of differentiation, two measures
 - ATT - number of attributes
 - BKN - number of salient brands

²The same operationalization has been reported by Park (1976).

- (2) Level of discrimination, DSC
 - inferred from the question used to assess ATT³
- (3) Level of integration, INT
 - interpreted from a picture drawn by the respondents.
- (4) Terminological complexity, TER
 - based on twenty 'what-is-meant-by' - questions reflecting various aspects of personal computers.

Appendix A gives a more detailed description of the various measures. The level of each dimension, that is level of discrimination (DSC), was determined from a table developed during the research process (see Appendix B). A qualitative analysis on a sample of questionnaires was the input in producing this table. The table shows that respondents used quite different terminology to describe the same aspect of the product. For example, some students referred to the 'size' or the 'capacity' of a PC, whereas others were more advanced and referred to 'number of bits', 'RAM', 'ROM' and similar to describe the same aspect of a PC. Eight different aspects of personal computers emerged in this analysis. The average respondent, however, mentioned only a few of these aspects. Even if the table is biased toward the author's perception of the product domain, other 'experts' on personal computers found the table to be quite sensible.

To obtain the DSC measure, each attribute or characteristic the respondent mentioned was given a number from 1-4, reflecting the level of complexity as illustrated in the table. The weighted attributes were summed and averaged:

$$DSC = \frac{\sum_{i=1}^n w_j C_i}{ATT} \quad (1)$$

DSC: Level of discrimination

ATT: Number of attributes

C_i : Characteristic or attribute i

w_j : Weight assigned to attribute i ; $w_j = 1, 2, 3$ or 4 .

Level of integration (INT) was interpreted from the chart illustrating how the respondent believed the various characteristics belonged together. The charts were given scores from 0 to 6. Zero points were given to those respondents that did not answer the question. Points were awarded on the basis of how the respondent managed to give a wholistic picture of the product, that is illustrate how the different characteristics were connected. The most advanced charts had clearly divided between software and hardware related characteristics, and hardware was further divided into categories like processing capacity and 'cosmetic' characteristics like terminal, display, printer and so on.

Level of terminology (TER) was inferred from the 20 questions reflecting the respondent's understanding of words and expressions often used in the product language. Each answer was given a score from 0 to 2, where 0 indicates no understanding; 'some understanding'; and 2 a good understanding of the word or phrase in focus. The 20 questions were summed to produce TER. Cronbach's α (Nunnally, 1978) was computed to analyze the internal consistency of the scale:

$$\alpha = \frac{k}{k-1} \left(1 - \frac{\sum \sigma_i^2}{\sigma^2} \right) \quad (2)$$

³A score, ranging from 1 to 4 was given for each characteristic. The average score across characteristics were computed for each individual (see Appendix A).

where k is the number of items, σ_1^2 is the variance of the measuring instrument item (each question), and σ_y^2 is the variance of the sum of the k items. Alpha for the 20 items was 0.898, indicating a very strong internal consistency among the 20 items.

Findings

Below are summarized the main findings:

TABLE 1. CORRELATION COEFFICIENTS (r)^{*}

	\bar{X}	SD	ATT	DSC	INT	BKN	TER	SEV	OEV	ADV	OBK
ATT (O)	2.27	1.91	1.0								
DSC (O)	1.00	0.73	0.72	1.0							
INT (O)	0.99	1.21	0.58	0.54	1.0						
BKN (O)	0.76	1.27	0.29	0.26	0.40	1.0					
TER ^{**} (O)	0.58	0.51	0.40	0.43	0.60	0.45	1.0				
SEV (S)	1.41	0.54	0.34	0.29	0.44	0.41	0.58	1.0			
OEV (S)	1.51	0.59	0.28	0.28	0.37	0.26	0.51	0.65	1.0		
ADV (S)	1.32	0.47	0.31	0.23	0.37	0.31	0.42	0.42	0.38	1.0	
OBK (S)	1.91	0.74	0.39	0.33	0.48	0.41	0.61	0.61	0.49	0.46	1.0

*) All coefficients significant at $\alpha = 0.01$ level

**) Coefficient alpha for the 20 items is 0.9.

Table 1 reports means, standard deviations and correlation coefficients between the variables used.

The average correlation within the objective measures (i.e. off-diagonal elements) is .467 and the corresponding standardized item - alpha⁴ is .81. The high alpha indicates that the measures correspond with some underlying score. The square root of alpha equivalates the correlation of the test with the true score (Nunnally 1978), i.e. .9 with the true score.

The average correlation within the subjective measures is .5, and the corresponding standardized item-alpha amounts to .8. The square root of Alpha is .89, i.e. the correlation coefficient between the subjective measures and the true score.

The average correlation coefficient between the subjective and objective measures is .38 ($p < .100$). Thus a significant relationship is present between the two sets of measurements. Due to the somewhat higher average within correlation for the objective (.467) and subjective measures (.5), there is, however, some support for separating the two sets of measures. Due to different scales involved (three - five points, numerical counts) some of the relationships might have been understated.

A principal component factor analysis was conducted to infer the underlying dimensionality of the variables. Inspection of the table revealed that all variables are loading high on the first factor, which indicate some common score. The first factor explained almost 50% of the variance, the second 13%. Number of attributes (ATT) and level of discrimination (DSC) load high on both the first and the second factor. The eigenvalue on the third factor dropped to 0.77. As we also expected two significant

⁴The standardized item α is described in Hull and Nie (1981). The computational formula is given by:

$$\alpha_s = \frac{k \bar{r}}{1 + (k-1)\bar{r}}$$

where \bar{r} is the average correlation between items. This is equal to standardizing each item, and thus making the various measures comparable.

factors, we concluded only the two first factors in the remaining analysis.

By conducting an orthogonal rotation on the first two factors extracted, the following picture emerges:

TABLE 2. VARMAX - ROTATED FACTOR - LOADING MATRIX

	FACTOR 1	FACTOR 2
SEV (S)	<u>0.84</u>	0.15
OEV (S)	<u>0.77</u>	0.09
ADV (S)	<u>0.63</u>	0.17
OBK (S)	<u>0.76</u>	0.26
TER (O)	<u>0.72</u>	0.38
ATT (O)	0.20	<u>0.88</u>
DSC (O)	0.14	<u>0.89</u>
INT (O)	<u>0.45</u>	<u>0.68</u>
BKN (O)	<u>0.53</u>	0.27

Inspection of Table 2 reveals that the structural variables, except for number of salient brands, BKN, and the subjective variables together with TER (terminology) and BKN are clustered together. As discussed above, the two factors (subjective and objective) may not be orthogonal, but rather correlated. Oblique rotations were conducted.

TABLE 3. OBLIQUE-ROTATED FACTOR - LOADING MATRIX

	FACTOR 1	FACTOR 2
SEV (S)	<u>0.86</u>	-.08
OEV (S)	<u>0.81</u>	-.12
ADV (S)	<u>0.65</u>	-.01
OBK (S)	<u>0.78</u>	0.05
TER (O)	<u>0.72</u>	0.19
ATT (O)	0.11	<u>0.85</u>
DSC (O)	0.05	<u>0.88</u>
INT (O)	0.40	<u>0.57</u>
BKN (O)	<u>0.54</u>	0.12

Table 3 reports the results from an oblique rotation of the factor-loading matrix. Delta equals -.6 and the correlation coefficient between the two factors is .37. Inspection of Table 3 reveals that all the subjective variables are loading on the first factor, while three of the five objective factors are loading high on the second factor. The two remaining objective variables, TER and BKN are loading on both factors, but most on the first one. In sum, the results to some extent support the assumption that product knowledge has subjective as well as objective aspects. Moreover, the two aspects are related.

Discussion

Based on previous research two aspects of product knowledge were assumed at the outset of this paper. The reported findings support this assumption. The observed relationship between subjective and objective measures, does not, however, allow for straight forward recommendations, except for the obvious one that research purpose should guide the actual choice of measures. Based on the reported findings it can also be argued according to our previous discussion that objective measures are preferable when research is focusing on ability differences, while subjective measures should be preferred when preoccupied with motivational aspects of product knowledge.

The present piece of research including one product only, definitely has its limitations. However, the findings falsify the hypothesis that subjective and objective measures always can be substituted. The two aspects of knowledge are related, but the shape and degree of relationship will probably be influenced by other individual variables, situational factors as well as by the product involved.

As objective and subjective measures of product knowledge are related but not substitutable, this implies that some consumers overestimate their own ability to buy the product, while others underestimate their ability. Future research should focus on these different types or constellations of knowledge and how the different types affect other consumer behavior variables. Most interesting would it be to investigate the relationship to information search intensity and direction, and also to the ability to select good alternatives in a product differentiated market.

Variable Operationalization

INT "We will illustrate this question by an example. The task is to group the characteristics you gave on the previous question the way you mean they naturally belong together. The characteristics should first be divided into main categories, then further into sub categories and sub-sub categories and so on. To illustrate this we can think of softdrinks, and we assume that the following characteristics is given: sweetness, taste, carbonic acid, caffeine, sugar, color, bottle, glass, plastic, cork and cocktailmix. These can be divided into two main groups: 1) Content and 2) canning. Content can be divided into "tastechemicals" and color; canning can be divided into bottle and cans. These can further be divided into subgroups, and we draw the following picture:

We may not be able to place all the characteristics. This is quite natural, and you should not try place a characteristic unless you believe it is a natural connection (e.g. "cocktailmix").

On this question, there is no right answer. What we want to know is the way you believe these characteristics belong together.

Your task is to make a similar chart with the characteristics you provided on the previous question.

You are not to make any corrections on the previous question, but you may add new characteristics on this task if someone comes to mind. Use the nest page to make the chart".

REPRESENTING ATTITUDE STRUCTURE: ISSUES AND EVIDENCE¹

Paul W. Miniard, The Ohio State University
Thomas J. Page, Jr., University of Wisconsin-Madison
April Atwood, University of Washington
Randall L. Rose, The Ohio State University

Abstract

The representation of attitude structure and associated causal issues has been a topic of considerable interest recently. This research examines whether variations in outcome evaluation produce corresponding variations in attitude, the discriminant validity between the cognitive and affective components of attitude, and the accuracy of a "cognition determines affect" causal ordering.

Introduction

In the past few years, the consumer research literature has witnessed a renewed interest in the Fishbein-Ajzen behavioral intention model (Ajzen and Fishbein 1980; Fishbein and Ajzen 1975). A primary thrust has been an examination of the model's causal properties (Bagozzi 1982, Burnkrant and Page 1982, Miniard and Page 1983, Ryan 1982, Shimp and Kavas 1984). This focus is quite understandable given the increased interest in structural equations as an analytical tool and the relatively strong theory specification offered by the Fishbein-Ajzen model.

One area of concern in these causal investigations involves the representation of attitude structure. A review of the literature reveals that researchers have rarely employed the same approach for representing the cognitive structure underlying attitude. Rather, several alternative approaches have been proposed which vary along conceptual and/or methodological dimensions. In the following section we discuss these alternative representational approaches and associated causal issues.

Background

As a starting point, let us consider the relevant causal assumptions underlying the Fishbein-Ajzen model. It is postulated that the distinction between cognitive ($E_{b_i e_i}$) and affective (A_p) components of attitude is a meaningful one. Specifically, beliefs about behavioral outcomes weighted by the evaluation of these outcomes are viewed as the building blocks for overall evaluation of performing a behavior.

Evidence concerning this proposition has yielded mixed support. Experimental research by Lutz (1975) revealed that a manipulation of beliefs produced changes in both the cognitive and affective components, but that a manipulation of outcome evaluation altered the cognitive component without influencing the affective component. Furthermore, when Lutz (1977) employed path analysis for these data, $E_{b_i e_i}$ was a significant predictor of A_p in only the belief manipulation experiment.

Nonexperimental research has also reported challenging results. Burnkrant and Page's (1982) LISREL analysis of a survey focusing on charitable blood donation behavior found a lack of discriminant validity between the cognitive and affective components. That is, the affective and cognitive latent variables were so highly related that the parameter estimate between them did not significantly differ from one! Obviously, this result leads to very different conclusions about attitude relationships than those suggested by Lutz's (1977) findings. To the best of

our knowledge, no other study of the Fishbein-Ajzen model has found the cognitive and affective dimensions to be so highly related that they would not achieve discriminant validity.

A further assumption underlying the Fishbein-Ajzen model is that the cognitive component is best viewed as a unidimensional construct in which different behavioral outcomes are aggregated into a single index of cognitive attitude. In accordance with this assumption, research has typically employed a unidimensional representation of cognitive attitude although such research has utilized a variety of approaches in doing so. Some studies (e.g., Miniard and Page 1983, Shimp and Kavas 1984), for example, have used the $E_{b_i e_i}$ index as the sole indicator of cognitive attitude. Unfortunately, this approach is constrained by its inability to divest the influence of measurement error on parameter estimates.

Other research has avoided this limitation by employing multiple indicators of cognitive attitude. Ryan (1982), for instance, used each behavioral outcome as a separate indicator. This approach, however, may undermine the measurement model fit since each salient behavioral outcome may not yield, by itself, a valid estimate of cognitive attitude. Consider the person who perceives a product as too expensive but is favorably impressed with the product because of its performance on nonprice attributes. In this example, a behavioral outcome measure capturing pricing concerns, unlike nonpricing outcomes, would yield a less accurate estimate of cognitive attitude. Although this salient pricing outcome should not be deleted from the measurement model on theoretical grounds, its retention would have an adverse impact on model fit. Consequently, the requirements for the measurement model may be unfulfilled when salient behavioral outcomes are inconsistent (some are very positive while others are only slightly positive or even negative). However, when salient outcomes are consistent, then the problem essentially disappears.

Alternatively, some researchers have used different attitude scaling techniques as multiple indicators of cognitive attitude. Burnkrant and Page (1982) employed the $E_{b_i e_i}$ index and Likert scaling as separate indicators, while Bagozzi and Burnkrant (1979) used Guttman, Likert, and Thurstone scaling as alternative assessments of cognitive attitude. Lacking, however, is research which has developed separate estimates of the $E_{b_i e_i}$ index, an approach that would seem most appropriate for operationalizing Fishbein and Ajzen's conception of cognitive attitude.

Research Objectives and Hypotheses

The following study provided additional evidence concerning the structural and discriminant relationships among cognitive and affective attitude constructs as conceptualized and operationalized within Fishbein and Ajzen's theory and model of intentions.² We examined the relationship between cognitive and affective attitudes in an

¹The authors wish to thank anonymous reviewers for their useful comments and suggestions. Financial support for this research was provided to the senior author by the Marketing Faculty Research Fund, The Ohio State University.

²An important characteristic of Fishbein and Ajzen's formulation is that all outcomes, both personal and normative, are reflected by attitude. Other formulations, however, do not share this perspective (e.g., Miniard and Cohen 1983).

attitude formation experiment (Carnegie Mellon Seminar 1978). Consequently, we could control the outcomes which determined subjects' attitude for this novel behavior, a feature very desirable in restricting measures of cognitive attitude to salient beliefs.

Our first hypothesis (H1) is that a manipulation of outcome evaluation will produce corresponding variations in both cognitive and affective attitude. This hypothesis is consistent with Fishbein and Ajzen's conceptions of attitude relationships, although Lutz (1975) did not substantiate this prediction in his experiment. We believe, however, that Lutz's null finding is attributable to methodological limitations which the present study overcomes (see Discussion section).

A second hypothesis (H2) which follows from Fishbein and Ajzen's model is that the affective and cognitive components of attitude are related but distinct constructs. We would expect this distinction to be more meaningful and vivid when the components are assessed in close temporal proximity to their creation. In this study, the components were measured only minutes after their formation.

It is also hypothesized (H3) that a "cognition determines affect" causal flow would occur in our study. As detailed below, subjects were required to process information about the outcomes of a novel behavior. Although there may be situations in which cognition does not precede affect (e.g., Zajonc and Markus 1982), the informational approach used in the present experimental procedures dictates a causal ordering of "cognition determines affect."

Method³

Subjects

One hundred and twenty one male and female undergraduate marketing students participated in the experiment as partial completion of class requirements. The task was designed specifically for these subjects in order to heighten involvement and relevance. Accordingly, marketing students were placed in a "case analysis" type of setting involving a new product introduction. Subjects were assigned randomly to one of the two cells comprising the single factor design.

Procedure

Subjects were lead to believe that they were participating in a study of factors (e.g., communication patterns, group cohesiveness) that influence group decision making. Subjects were told that they would act as a marketing consulting group for a company that was introducing a new boiling bag food item. The group's task was to select one of two alternative brands (identified as Brands B and F) for market introduction. After reviewing with the experimenter a written copy of the experimental procedures, subjects were placed in separate rooms and read the materials describing the case situation. A critical section of this material was the product trial results consisting of target consumers' brand ratings on product attributes considered by these consumers in making their purchase decision. Brand B was rated as excellent in taste, good in nutrition and convenience, and average in price. Brand F was rated less favorably on taste (good) and nutrition (average), but more favorably on price (good) and convenience (excellent). These brand ratings were intended to make the two alternatives fairly equivalent in overall attractiveness. As a result, the influence of the manipulation (explained below) could more easily manifest itself. A configuration of attribute ratings which clearly favored a particular brand would have greatly lowered the manipulation's potential to impact on subjects' choice behavior.

³The current study employs essentially the same methodology reported in Miniard and Cohen (1983). The reader is referred to their article for additional details about the experimental procedures.

After they had reviewed the case materials and attribute ratings, subjects received via the experimenter a written message from the group leader advocating brand F. This was followed by messages delivered sequentially from the remaining group members that supported the leader's choice. All messages were in fact fictitious and predetermined by the experimenter. Following these messages, subjects transmitted their communication, responded to a questionnaire, and indicated their choice on a brand recommendation form.

The experimental manipulation was operationalized in the form of a "group member award." This award was justified to subjects on the grounds that, due to the temporary nature of the group, it was unlikely that cohesiveness (claimed to be a group characteristic of interest) would be as prevalent in the present experimental group as it would be in more "natural" groups. Consequently, the award was to be given by the group through a voting system to the member demonstrating the highest level of "team spirit" in order to compensate for this study limitation. Subjects understood that this vote should be based "solely upon a group member's willingness to work in a harmonious fashion with the group and upon a member's loyalty to the group" and that the group could not vote for someone "unless he or she acts in a cohesive manner which, in this situation, is defined as recommending the same brand as the leader."

In one condition, the winner of the award was simply to be known as the best or most loyal group member. In the other condition, the award was to be accompanied by a \$20 cash prize. Thus, the manipulation was intended to vary the importance subjects attached to one of the outcomes (i.e., winning the award) associated with their choice behavior. This manipulation of outcome evaluation, if successful, permits a further test of Lutz's (1975) challenging result where variations in outcome evaluation did not produce corresponding changes in affective attitude.

Questionnaire

The questionnaire began with one and a half pages of instructions on the appropriate usage of the 7-point bipolar response scales employed for measuring the various constructs. Although the questionnaire contained measures for all of the constructs within Fishbein and Ajzen's intention model, only measures relevant to the focus of this paper are discussed here.⁴ The affective attitude toward recommending each brand (A_B) was measured by five evaluative semantic differential scales (good-bad, wise-foolish, beneficial-harmful, satisfying-dissatisfying, rewarding-punishing).

Cognitive attitude was assessed in accordance with the procedures for operationalizing the $\Sigma b_i e_i$ index. Beliefs (b_i) that recommending the brand would lead to a particular outcome were assessed by three probabilistic scales (likely-unlikely, possible-impossible, probable-improbable). Outcome evaluation (e_i) was measured by three evaluative scales (good-bad, beneficial-harmful, rewarding-punishing). Beliefs and outcome evaluations are typically assessed with one, not three, measurement scales. The use of three scales, however, allowed us to construct three separate $\Sigma b_i e_i$ indices by arbitrarily pairing belief and evaluation scales.⁵

In order to identify the salient behavioral outcomes underlying subjects' choice behavior, a pretest was under-

⁴The ultimate objective of this research is to test the entire causal model proposed by Fishbein and Ajzen. In this first cut at the data, however, we restrict our focus to cognitive and affective attitude relationships.

⁵One might be concerned that the causal results may vary across different measurement pairings. However, a comparison of results using different pairings revealed virtually no difference.

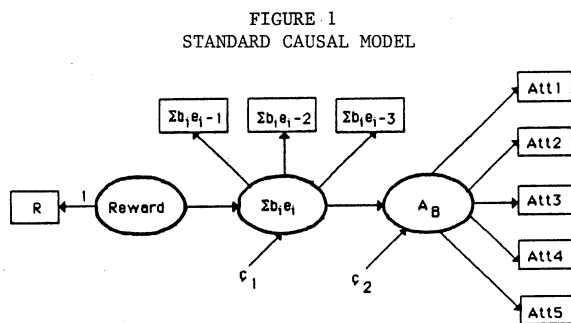

taken in which approximately 25 subjects participated in the experiment as described above, with one exception. Rather than completing a questionnaire concerning beliefs, attitudes, and intentions prior to their choice behavior, pretest subjects responded to a questionnaire consisting of several open-ended questions following their brand choice. These questions asked subjects to identify those considerations important to them in making their brand choice (e.g., the advantages/disadvantages of choosing brand B/F).

This pretest revealed that subjects' decision making largely focused around picking the best brand within the case context (a personal outcome). Winning the award (a normative outcome since it is under the control of others) was also considered by subjects, particularly by those in the \$20 condition. Further evidence substantiating the salience of this outcome is presented in the Results section. Some subjects expressed concerns over attributions the group might make about them (e.g., "I chose F because I didn't want the group to think I was being defiant"), another normative outcome. These various concerns were represented in the form of three consequences which were used in the belief and outcome evaluation measures: meeting the needs of the target market, winning the group member award, and having the group act and/or think favorably about the subject.

Causal Model Analysis

Because measurements were collected for each brand individually, one analytical approach involved testing a causal model for each separate brand. However, Ajzen and Fishbein (1969) have demonstrated greater predictive accuracy when attitudes toward all behavioral alternatives are considered simultaneously (i.e., when difference scores are employed) than when the attitude toward only one of the possible alternatives is considered. Consequently, difference scores between the cognitive and affective attitudes for brands B and F were also used for deriving the correlation matrix employed in the LISREL VI analyses.

Figure 1 contains the basic causal model tested in this research. The experimental manipulation (Reward), treated as a dichotomous variable, should have a causal impact on cognitive attitude (assessed by three $\Sigma b_i e_i$ indices). Cognitive attitude, in turn, should both determine affective attitude (assessed by five evaluative scales) as well as completely mediate the influence of the manipulation on affective attitude (i.e., Reward should not have a direct effect on A_B).

Results

Impact of the Manipulation

It would of course be inappropriate to test the first hypothesis if the manipulation failed to influence outcome evaluation. Consequently, it was necessary to establish that the manipulation of the group member award's monetary value was successful in altering subjects' evaluation of the "winning the award" outcome. As expected, subjects' responses to the three evaluation scales (e_i) pertaining to this outcome were significantly ($p < .001$) more favorable when the award carried a \$20 cash prize than when it lacked a monetary value.

It is also useful to consider the manipulation's impact on subjects' choice behavior. In the condition where the award did not carry a financial incentive, nearly half (21 out of 47) of the subjects chose the same brand (F) as the group. In the condition where the award was accompanied by the \$20 cash prize, two-thirds (49 out of 74) of the subjects selected brand F. This variation in choice behavior was significant ($p < .02$). In addition to substantiating the manipulation's effectiveness, these findings further support that winning the award was a salient consideration in subjects' decision making.

Causal Model Findings

Findings concerning various goodness-of-fit indices, the measurement model, and the structural model parameters are presented in Tables 1-3 respectively. Note that these tables contain the results based on difference scores as well as for the individual brand responses. As can be seen, the results are highly similar for the difference and individual brand models. The fact that the path estimate between Reward and $\Sigma b_i e_i$ is positive for the brand F model but negative in the other two models simply reflects the impact of how the dummy manipulation variable was coded (no \$20 = 1, \$20 = 2) as well as the manner in which difference scores were estimated (brand B response minus brand F response).

TABLE 1
CAUSAL MODEL RESULTS FOR GOODNESS-OF-FIT INDICES

Model	Chi-square	df	p	RMR	Rho
Diff	85.37	26	.000	.031	.941
Brand B	63.24	26	.000	.045	.948
Brand F	98.88	26	.000	.028	.923
Reverse Diff	93.29	26	.000	.048	.933
Reverse B	72.23	26	.000	.063	.936
Reverse F	101.49	26	.000	.036	.920

Note: The top half of the table contains the results for causal models assuming cognition before affect while the bottom half results represent causal models with the opposite ordering.

TABLE 2
MEASUREMENT MODEL RESULTS

TABLE 3
STANDARDIZED STRUCTURAL MODEL PARAMETERS

Path	Diff	Brand B	Brand F
Rew $\rightarrow \Sigma b_i e_i$	-.310	-.307	.257
$\Sigma b_i e_i \rightarrow A_B$.770	.741	.747
<u>Residuals</u>			
$\Sigma b_i e_i$.904	.906	.934
A_B	.406	.451	.443

Note: All parameter estimates are significant ($p < .05$).

As was the case for all the causal models examined here, the chi-square test was highly significant ($p < .001$). However, there seems to be a growing consensus that this indicator of model fit is too conservative. Indeed, the results for alternative fit indices such as the root mean square residual (RMR) and Bentler and Bonett's (1980) rho statistic (ρ) suggest that the causal model depicted in Figure 1 provides a very good representation of data relationships.

The measurement model results are also quite strong. All factor loadings except one (Att 5 for brand B) are estimated to be greater than .80 and most exceed .90. In addition, the measured variables are excellent indicators of the latent factors as evidenced by the strong reliabilities reported in Table 2. However, several of the affective attitude measures shared considerable measurement error. Indeed, simply freeing three of the parameter estimates representing correlated measurement errors resulted in a model with a more "acceptable" chi-square. The results for the difference model, for example, were: $\chi^2(23) = 34.01$, $p = .065$; RMR = .027; $\rho = .988$. Finally, as shown in Table 3, both causal paths (manipulation to cognitive attitude and cognitive to affective attitude) are significant ($p < .05$) for all models.

Research Hypotheses

The preceding analyses have yielded several findings supportive of H1. It was shown that the evaluation of the "winning the award" outcome was affected by the manipulation. Accordingly, the manipulation had a significant impact on cognitive attitude, as reflected by the significant path estimate between Reward and Σb_{1e} in the prior causal model analysis. Similarly, the path estimate between cognitive and affective attitude was also significant.

These latter two results, while suggestive, do not directly show that the manipulation of outcome evaluation did in fact influence affective attitude. Consequently, a direct test of this issue is necessary, particularly since it bears directly on Lutz's (1975) finding that such a manipulation did not influence affective attitude. An analysis of the difference model excluding cognitive attitude (i.e., only Reward and affective attitude were included) revealed a significant ($p < .05$) path between the manipulation and affective attitude (the same result also occurs in the individual brand models), the final piece of evidence necessary for supporting H1. Interestingly, this path estimate ($\gamma = -.169$) was smaller than the estimate observed between the manipulation and cognitive attitude ($\gamma = -.310$). These results suggest that the manipulation had a stronger impact on cognitive attitude and are consistent with the hypothesized causal flow of cognition determining affect (H3).

Examination of the discriminant validity between cognitive and affective attitude (H2) involved two analytical procedures. The first procedure involved testing whether the path estimate between cognitive and affective attitude differed from one. Although this path estimate in the difference model was substantial ($\beta = .770$, $s.e. = .067$), it did significantly ($p < .05$) differ from one. Similarly, the path estimates in the individual brand models also differed ($p < .05$) from one.

The second approach employed confirmatory factor analyses. A single factor model in which cognitive and affective indicators were loaded on one factor was compared to a two factor model consisting of separate but related cognitive and affective components. A comparison of the chi-square values for these two models revealed that the two factor model provided a significant ($p < .01$) improvement in representing data relationships for both the difference and individual brand models. The findings from both approaches therefore support the second hypothesis that cognitive and affective attitudes, while strongly related, are distinct components.

Evidence relevant to H3 was attained by analyses which reversed the ordering of cognitive and affective attitudes in the causal model. The results of these reverse order models are summarized in the bottom half of Table 1. Comparisons of the goodness-of-fit indices for models differing in their causal ordering of the attitude components reveals that the reverse order model results are only slightly worse than those found for the hypothesized order model.

In contrast, consideration of cognitive attitude's ability to mediate the influence of the manipulation on affective attitude (and vice versa) proved quite informative. A cognition before affect ordering suggests that the manipulation should influence affect only through cognition and should not have a direct effect on affect. Similarly, the affect before cognition ordering implies that the manipulation should influence cognition only through affect. Consistent with the hypothesized causal flow, the manipulation did not have a direct effect ($p > .05$) on affective attitude for either the difference or individual brand models. For the reverse order models, however, the manipulation did have a significant ($p < .05$) influence on cognitive attitude which was independent of affective attitude. We interpret these results as supporting H3.

Discussion

This study provides additional support for the conceptualization offered by Fishbein and Ajzen concerning attitude structure. First, the results show that a manipulation of a salient behavioral outcome had a significant impact on both cognitive and affective attitude. This inconsistency with Lutz's (1975) findings (where the influence of the experimental manipulation on cognitive structure did not "carry over" to affective attitude) may be due to methodological differences. Lutz's study attempted to influence subjects' attitude toward an unknown brand of laundry detergent by varying information relevant to their evaluation of a detergent's sudsiness, a relatively minor attribute.

In contrast, the current study employed a powerful financial manipulation for altering outcome evaluation as well as a highly involving choice situation. The likelihood that affective attitude would also reflect influences impacting on cognitive structure would seem to be greater in the present study given subjects immediate need to make a choice between two alternatives which differ considerably in their outcomes (i.e., only one leads to the reward). Finally, Lutz's study did not enjoy the advantage of multiple measurements and structural equations analysis, and thus one can not eliminate the possibility of "biased" results due to measurement error.

Fishbein and Ajzen's position that cognitive and affective attitudes are distinct but highly related in that cognition is the basis for affect development is also supported by this research. Of course, other settings may generate different causal relationships than observed here. The informational approach employed in the experiment for affect formation and the assessment of the attitudinal constructs in close temporal proximity to their development would seem to be major determinants of the present findings.

AN EXPLORATORY INVESTIGATION OF CONSUMER INNOVATIVENESS AND INTERPERSONAL INFLUENCES

William O. Bearden, University of South Carolina

Abstract

Alternative weights within the theory of reasoned action were proposed for both innovators and noninnovators. The models were tested for nine brands for both a private necessity and a public luxury product--situations in which reference group influences are expected to vary. Tests of the behavioral intention equation supported the hypothesized pattern. However, the results of the normative crossover effects analysis were inconclusive.

Introduction

Consumer innovativeness and the diffusion of innovations are two of the most frequently researched concepts in consumer behavior. Midgley and Dowling (1978) have provided an excellent summary of the issues involved in the conceptual definition and measurement of consumer innovativeness. One outcome of their thoughtful discussion is the conclusion that "innovativeness is the degree to which an individual makes innovation decisions independently of the communicated experience of others" (Midgley and Dowling 1978, p. 235). As such, innovativeness is posited to be a generalized personality trait and adoption decisions are seen as a function of product interest, individual situations, personal characteristics, and a network of interpersonal influence. It is this later premise, i.e., the potential relationship between innovativeness and differences in interpersonal influence, that precipitated the present study.

In the exploratory effort that follows, differences between innovators and noninnovators in interpersonal influence effects within the theory of reasoned action are hypothesized and tested for multiple brands of two products assumed to differ in perceived reference group influence. Prior to describing that study and the ensuing results, a brief review of prior research and the research hypotheses are presented.

Theoretical Perspectives

Innovativeness and Interpersonal Influence

Much communication and diffusion research has ignored the effects of social influence (Rogers 1976, p. 298). Social influence can be categorized into informational and normative influence. Informational influence occurs when individuals accept information as evidence of reality while normative influence involves conformity to the expectations of others (Burnkrant and Cousineau 1975, pp. 206-207). These social influences are thought to operate through the processes of internalization, identification, and compliance (Kelman 1961). Information is internalized if it is perceived as enhancing the individual's knowledge of the environment. Normative social influence may also occur if the individual is motivated to realize a reward or avoid a punishment. Compliance in this situation would occur if the individual believes the behavior is visible or known to others.

It is generally accepted that word-of-mouth communications often affect the eventual acceptance and diffusion of new products (Midgley and Dowling 1978; Rogers 1983). However, empirical evidence addressing the link between the trait of innovativeness and perceived interpersonal influence is limited. Further, the evidence that is available is equivocal. For example, Berning and Jacoby (1974), in their study of information acquisition in new product purchase decisions, concluded that the decision-making process preceding the purchase of an innovation differs

from the process preceding the purchase of an established alternative. The principle difference underlying that process was concluded to be that innovators first seek information from other people. In contrast, and in support of Midgley and Dowling's view, Carlson and Grossbart (1984) found a significant positive relationship between independent judgment making and inherent novelty seeking. [It should be noted that the Berning and Jacoby (1974) study focused upon actual new products while Carlson and Grossbart (1984) assessed their constructs using generalized multi-item scales.]

The replication and extension of Raju's (1980) optimum stimulation paradigm by Joachimsthaler and Lastovicka (1984) indicates that the relationship between innovativeness and information seeking is quite complex (bicausal). However, close examination of the content of the statements comprising the information seeking scale reveals that the items comprising the scale contained a mix of both personal and impersonal sources of information.

Interpersonal Influence Differences

One explanation of interpersonal influence in consumer behavior is the theory of reasoned action (Ajzen and Fishbein 1980). This frequently applied model provides a vehicle for exploring some of the differences in interpersonal influences between innovators and noninnovators. Interpersonal influence is assumed operative in several linkages within the model. The basic equation proposes that behavioral intention is affected directly by subjective norms and attitudes-toward-the act of purchase. Social influences on behavioral intentions are thought to operate principally through an overall measure of subjective norms. Subjective norms, in turn, are presumed to stem from the combination of normative beliefs, i.e., beliefs that certain referents think the person should or should not perform a particular behavior, and motivations-to-comply with the referent group.

Two phenomena exist which make the isolation of perceived reference group influences in the theory of reasoned action problematic. These issues are raised now since one provides a basis for one of the research hypotheses proposed in the next section. These two issues are: (1) multicollinearity between the Aact and SN predictors of behavioral intention and (2) crossover effects from the model's exogenous cognitive and normative structures to the summary constructs of attitudes and subjective norms.

Multicollinearity among predictor variables in the theory of reasoned action makes the interpretation of the relative weights in the model problematic. Since this paper attempts to examine the relative weights in the model, caveats regarding this problem are warranted. However, in an effort to address the multicollinearity issue, both correlated and uncorrelated models are tested and, for one set of analyses, an extra-sums-of-squares test is used involving reductions in explained variance when predictors are omitted. Miniard and Cohen (1981) have outlined the theoretical arguments for interdependence among the personal and normative components of the Fishbein and Ajzen model. In fact, it has been proposed that for those interested in distinguishing between personal and normative influences that an alternative model is more appropriate. These criticisms stem largely from the premise that the normative component does not discriminate adequately between informationally-based social influence and influences that are truly normative in nature (Miniard and Cohen 1981, 1983).

Crossover effects between normative structure and attitude and between cognitive structure and subjective norms have been addressed in recent tests of the theory of reasoned action (Ryan 1982; Shimp and Kavas 1984). Since differences for noninnovators and innovators in crossover effects for normative structure to attitudes are hypothesized and tested in the present study, some justification for these effects is warranted. Ryan (1982) proposes that inferential belief formation accounts for many of the crossover effects in the theory of reasoned action and the interdependency between attitudinal and normative variables. From Ryan's summary of earlier research, empirical studies have found that (1) normative information was more favorably evaluated if it supported the listener's views, (2) respondents more readily accepted an attitude in line with reference group majority opinion, and (3) respondents were more likely to act in accord with stated attitudes if such attitudes were consistent with the actions of others. Shimp and Kavas (1984) argue for a normative structure-attitude crossover relationship for couponing. The expectation is that because couponing is a form of behavior that has direct consequences for important others, the consumer will utilize others' opinions in addition to his/her personal beliefs when forming attitudes toward coupon usage.

Research Hypotheses

Innovativeness has been defined as the degree to which an individual makes innovation decisions independently of the communicated experience of others, i.e., information passed verbally between individual consumers (Midgley and Dowling 1978, p. 235). Based on the premise that noninnovators learn from others (including some feel for their expectations), the following hypothesis regarding the relative influence of subjective norms is proposed:

H₁: Subjective norms will exhibit less relative influence on behavioral intentions for innovators than for noninnovators.

Crossover effects from normative structure to attitude representing the impact of social influence on affect reflect a susceptibility or general willingness to incorporate or infer social influences on one's attitude structure. Normative information from others signals the direction of the attitudinal norm and implies that others will like the subject for holding an attitude consistent with these norms (Oliver and Bearden 1985). Again, since innovators are defined as making decisions independently of others, and, in contrast, other adopter categories seek information "from their near peers whose subjective opinion of the innovation ... is most convincing" (Rogers 1983, p. 170), a second hypothesis regarding crossover effects is proposed:

H₂: Innovators will exhibit a lesser tendency than non-innovators to exhibit crossover effects from normative structure to attitude.

As alluded to above, the normative structure component of the theory of reasoned action reflects exclusively beliefs about referent expectations (Miniard and Cohen 1981, p. 315). This conceptualization of normative influence is similar to the utilitarian influences of Deutsch and Gerard (1955). However, social influence can be based upon both informational and normative sources. The findings of Berning and Jacoby (1974) suggest that innovators seek information from others. In contrast, the Midgley and Dowling (1978) definition stresses the absence of communicated experiences for innovators (i.e., information). Given these conflicting perspectives, no formal hypothesis is offered regarding the differential role of informational versus utilitarian influences. However, the relationships

¹This hypothesis is similar to the recent proposition of Gagnon and Robertson (1985, p. 856): consumers who are highly dependent on normative influence (conformity intention) will be slower to adopt.

between overall subjective norms and both informational and utilitarian (normative) influences will be examined for innovators and noninnovators.

Method

Data were collected from 139 undergraduate male and female marketing students. Responses were obtained for nine brands of two products -- toothpaste and luxury automobiles. The products were selected to represent products varying in susceptibility to reference group influence. Consistent with the typologies of Bourne (1957) and Bearden and Etzel (1982), toothpaste and luxury automobiles represent private necessities (PRN) and public luxuries (PUL), respectively. Private necessities are hypothesized to be not susceptible to reference group influence while reference group influence is hypothesized to operate for brand selection decisions among luxury automobiles.

Analysis

The sample was divided equally using a median split into innovators and noninnovators. Responses to the ten seven-place agree-disagree statements comprising the innovativeness factor identified by Raju (1980, p. 278) were used to operationalize innovativeness. (Efforts in this study to assess the reliability of the scale are described below.) Aggregate cross-sectional tests of the principle behavioral intention equation of the theory of reasoned action were conducted first for each subsample. Second, crossover effects from normative structure to attitudes were tested for both innovators and noninnovators. Third ordinary least squares regression was used to estimate the subjective norm equations using utilitarian and informational influences as predictors. For the aggregate Aact-SN and the crossover effects analyses, correlations were used as input into LISREL VI to test the alternative models (Joreskog and Sorbom 1983).

Operational Measures

The two sets of modal referent groups (Ajzen and Fishbein 1980, p. 75) used to represent normative influences were elicited in separate pretests of 15 undergraduate students. The elicitation procedure employed open-ended questions to identify referents most likely to influence toothpaste and luxury automobile purchases. Three referents were found for each product: close friends, family members, and dentist for toothpaste and close family members, friends and relatives, and salesperson for luxury automobiles. All measures were developed in the context of the respondent's next purchase.

Two measures of subjective norms (SN) were employed. One measure was the standard item: "Most people who are important to me think I (should/should not) purchase (brand)." The alternative measure was worded: "The important people in my life would ... (want/not want) me to purchase (brand)." Respondents provided their attitude toward the act of purchasing (Aact) each brand on three seven-point semantic differential scales labeled good-bad, foolish-wise, and beneficial-harmful. Behavioral intentions (BI) was assessed using a single seven-place item scale labeled likely-unlikely designed to reflect intentions to purchase. The direction of the SN and Aact items were reversed to limit acquiescence bias.

Normative beliefs were also assessed using measures similar to those typically employed in tests of the Fishbein extended model. Respondents indicated their normative beliefs for each referent by indicating "the extent to which (referent) would expect you to buy (brand)." The seven-point scales were labeled definitely would not expect me to buy (-3)/definitely would expect me to buy (+3). Motivation-to-comply was operationalized using measures such as: "With respect to the purchase of toothpaste, I want very much to (6)/I want very much not to (0) do as my (referent) expects." The use of a unipolar motivation-to-comply scale is consistent with the premise that people are unlikely to be motivated to do the opposite of what their salient referents think they should do (Ajzen and

Fishbein 1980, p. 75). These measures were also converted into analogous statements reflecting the availability and willingness to obtain information (cf. Park and Lessig 1977). These latter operationalizations were used later to explore the feasibility of including both utilitarian and informational measures as predictors of subjective norms.

Reliability Estimates and Manipulation Checks

Innovativeness. The coefficient alpha estimate of internal consistency reliability for the ten-item innovativeness scale was .77. Additional evidence of reliability is provided by its correlation with other measures collected to examine the properties of the scale. First, the innovativeness measure was significantly correlated (Pearson correlation = .63, $p < .01$) with a similarly measured seven-item scale (reliability = .71) of agree-disagree statements used by Needham, Harper, and Steers. Second, the Raju scale was positively correlated ($r = .44$, $p < .01$) with a summed index reflecting the purchase (non-purchase) of 30 newly introduced or innovative products and services. This type of cross-sectional innovativeness measure has the advantage of controlling for some of the situational and communication effects associated with individual products (Midgley and Dowling 1978) and has been used in a number of earlier innovativeness studies (e.g., Darden and Reynolds 1974; Baumgarten 1975).

A twenty-item measure of dogmatism ($\alpha = .68$) (Troidahl and Powell 1965) was also assessed to assist in examining the validity of the Raju scale. Dogmatism is one of the psychological traits proposed by Midgley and Dowling (1978, p. 236) as affecting innate innovativeness. A strong, negative correlation was anticipated between dogmatism and the innovativeness measure. However, the resulting correlation was .09 ($p = .15$). In retrospect, this low correlation might be attributed to one or both of two reasons. First, a closer reading of the items comprising the twenty-item dogmatism measure questions whether or not the scale addresses receptivity of new ideas (close-mindedness). Second, the results of Coney and Harmon (1975) suggest that the relationship between dogmatism and innovativeness is subject to situational influences and may not be linear as initially thought.

The dimensionality of the scale was also examined using confirmatory factor analysis (Jöreskog and Sörbom 1983). Three alternative factor models were tested: a one-factor model, a three-factor uncorrelated model, and a three-factor correlated model. The three factor structure was hypothesized based on the item category assignments used by Raju (1980, p. 278) in which different items were posited as reflecting multiple categories of exploratory purchase behavior. The one factor solution ($\chi^2 = 86.41$, $p < .01$, 35 df) provided the best fit to the data. The three-factor correlated model was indeterminate; the uncorrelated solution resulted in a χ^2 of 192.81 ($p < .01$, 35 df). In the one factor solution, all indicator estimates were significant; however, several of the individual items did possess low loadings (i.e., below .50). Nine of these same items were used by Joachimsthaler and Lastovicka (1984) to operationalize innovativeness in their reevaluation of Raju's general explanation of the role of optimum stimulation level (OSL). Their measurement model results indicated that split-half combinations of the items provided reliable indicators of innovativeness.²

Subjective Norms and Attitudes. Multiple indicators for social norms and attitudes provided the opportunity to also assess their reliability. These estimates along

²Data from a two-state consumer panel study ($n=218$) were also available regarding the Raju innovativeness items, the Needham, Harper, and Steers measures and dogmatism scale. The coefficient alpha estimates were .81, .71, and .79, respectively. Similar validating correlations between innovativeness and the Needham scale ($r = .59$, $p < .01$) and the dogmatism measure ($r = -.06$, n.s.) were found.

with average brand/construct correlations are provided in Table 1. The average internal consistency reliability estimates are shown in the diagonal. These high reliability estimates are undoubtedly due to the similarity in measurement methods across indicators (e.g., bipolar semantic differentials following an attitude statement).

TABLE 1

Aact AND SN BRAND INTERCORRELATIONS

		Toothpaste		Luxury Autos	
		SN	Aact	SN	Aact
<u>Toothpaste</u>

	Across Brands	<u>.18</u>	[.23]		
<u>Luxury Autos</u>					
SN:	Paired Brands	--	--	(.94)	
	Across Brands	.03	.01	[.25]	
Aact:	Paired Brands	--	--	<u>.64</u>	(.91)
	Across Brands	.04	.05	<u>.23</u>	[.34]

^aFigures in parentheses average internal consistency estimates.

^bBracketed entries reflect average within construct/ across brand intercorrelations (e.g., Aact₁-Aact₂).

^cUnderlined correlations represent average SN-Aact correlations across nine brands (e.g., Aact₁-SN₁).

Given the large number of brands addressed and the length of the survey, the potential for methods variance was present. Some evidence regarding the discriminant validity of the SN and Aact measures and the intercorrelation among predictors is provided by examining the remaining correlations presented in Table 1. The bracketed entries suggest only moderate correlations between the SN and Aact measures within construct and product category (i.e., correlations among the SN measures for toothpaste). The low across product and construct correlations give additional evidence of the discriminant validity of the SN and Aact measures for the different brands and products. However, the underlined table entries suggest considerable intercorrelation among the two predictors in the behavioral intention equation of the theory of reasoned action.

Product Perceptions. Manipulation checks were included to verify respondent perceptions of the two types of products studied. These manipulation checks were designed to assess perceptions regarding the conspicuousness dimensions (i.e., public-private and luxury-necessity) underlying the reference group hypotheses of Bourne (1957) and Bearden and Etzel (1982). Definitions of each conspicuousness dimension were provided prior to seven-place scales for each product labeled "a public product-a private product" and "a necessity-a luxury." The resulting paired t-test values were 24.42 ($p < .01$) and 37.27 ($p < .01$) for the public-private and luxury-necessity dimensions, respectively. These significant values and the relative mean scores indicate that the two product categories were perceived as intended.

Results

Analyses were first conducted across subjects for both the behavioral intention equation and for the hypothesized crossover effects. The aggregate tests of the behavioral intention equation are presented in Table 2 for both an

overall analysis (i.e., across the nine brands for each product) and averaged across brands.³ In general, the resulting pattern among the Aact and SN weights were similar for the overall and averaged models and for the correlated and uncorrelated results. The effects of allowing the two predictors of behavioral intention to be correlated resulted in improved fit as estimated by the chi-square statistic and some reduction in the absolute value of the standardized beta coefficients.

Average: High	.35	.54	.31	.47	.70	9.3	.41	.80
Low	.18	.59	.12	.60	.67	12.3	.28	.85

^aBased upon regressions for each of nine brands, each regression using 71 and 68 subjects as data points for the innovative and noninnovative groups, respectively.

The nonsignificant chi-square values for the individual brand models suggest that the correlated model provides an adequate fit to the data. This conclusion is supported by the relatively high adjusted goodness-of-fit indices.

Examination of the relative sizes of the beta coefficients supports the hypothesis of higher relative normative influence for noninnovators for the luxury automobiles. Similar (but slight) differences in weights for the private necessity product (i.e., the product for which reference group influence was not hypothesized) were also found. The differences between the Aact and SN weights for the averaged results regarding the public luxury product were .16 and .48 for the innovators and noninnovators, respectively. It is interesting to note, however, that much of this differential results from the lower Aact weight for the noninnovators.

Differences in crossover effects from normative structure to attitudes (cf., Shimp and Kavas 1984) were also posited for innovators and noninnovators. The model tested in these analyses is shown in Figure A. The corresponding results are summarized in Table 3 for both correlated and uncorrelated versions of the model. Due to the limited number of indicators and exogenous constructs, bicausal paths between Aact and SN could not be estimated simultaneously. Consequently, an alternative model allowing the construct error terms for Aact and SN to be correlated was tested. The principal differences between the correlated and uncorrelated models were associated largely with model fit. No significant changes in structural path coefficients were found between the correlated and uncorrelated models.

³Ryan (1982, p. 269) reported similar weights (Aact beta = .25 and SN beta = .53) in his pooled regression results regarding behavioral intention prediction for a fictitious toothpaste brand and a .60 intercorrelation between Aact and SN.

Low: Correlated	.37	.51	.03	.65	26.92	.78	.03
Uncorrelated	.35	.51	.08	.64	43.08	.75	.01

^aBased upon regressions averaged across nine brands, each regression using 71 and 68 subjects as data points for the innovative and noninnovative groups, respectively.

^bSN and Aact were allowed to be correlated through freeing the ψ_{11} (2,1) element. Degrees of freedom were 11 and 12 for correlated and uncorrelated models, respectively.

As shown in Table 3, significant crossover effects were found for both groups and for both products. However, the largest crossover effects were found for the innovators in the automobile analyses. This finding is contrary to the hypothesized effects anticipated. It is interesting to note that the pattern of relative weights for attitudes and subjective norms was consistent with the results presented in Table 2 (i.e., prior to introducing the summated normative belief construct).

An additional set of aggregate brand analyses were run to test the hypotheses reflecting informational versus normative influences on subjective norms for innovators and noninnovators. These results are depicted in Table 4. Again, the estimates represent averages across nine brands with each regression using 71 and 68 subjects as data points for the innovative and noninnovative groups, respectively.

TABLE 4
 AGGREGATE ANALYSIS OF INFORMATIONAL AND NORMATIVE
 PREDICTION OF SUBJECTIVE NORMS^a

Product	Average Beta Coeff.		Adj. R-Square ^b
	NORM	INFO	
<u>Toothpaste</u>			
High	.27	.29	.21
Low	.41	.26	.31
<u>Automobile</u>			
High	.50	.17	.32
Low	.41	.19	.29

^aBased upon regressions averaged across nine brands, each regression using 71 and 68 subjects as data points for the innovative and noninnovative groups, respectively.

^bAll brand regression equations resulted in significant overall F-values ($p < .01$).

The hypothesized pattern of expected greater relative normative influence for noninnovators was observed only for the toothpaste brands. For the luxury automobiles, normative expectations were more highly correlated with subjective norms (in comparison to informational influence) for both innovators and noninnovators. The interpretation of these regressions was also confirmed by examination of predictor usefulness -- defined as the amount of decrease in explained variance when a variable is dropped from an equation (Draper and Smith 1966). For both groups and across brands, measures of variable usefulness were consistent with the relative beta coefficient sizes.

Discussion

This exploratory effort attempted to examine the role of interpersonal influences in Fishbein and Ajzen's theory of reasoned action across two groups of respondents partitioned into innovators and noninnovators. The study was designed as an initial effort to examine the role of interpersonal influence perceptions across individuals differing along a general measure of innovativeness, and as such, represents only a limited test of Midgley and Dowling's (1978) innovativeness definition. The study also suffers from a number of limitations. Caveats are in order regarding the use of existing brands and student subjects. To maintain a reasonable sample size, a median sample split was used. However, innovators are typically described as only the first few number (i.e., 2, 5, or 10 percent) of purchasers. Further, innovativeness was measured using scale items taken from another study. While the scale did appear to be reliable, the need remains for the formal development of an innovativeness scale using sound psychometric scale development procedures. Lastly, while substantial time was provided for the respondents and careful monitoring of the actual data collection effort was insured, the task required of the subjects was lengthy.

With these limitations in mind, this exploratory study does provide some implications regarding interpersonal influences on innovative behavior and supports recent tests of the theory of reasoned action. Regarding the latter, social norms and attitudes were correlated with intentions at both the aggregate and individual levels. Some evidence was also provided that the Aact and SN weights reflected differences for the two products (i.e., the public luxury and private necessity) as predicted by the theory. However, significant multicollinearity among the predictors of intentions and crossover effects from normative

structure were found. These results reiterate the conclusions of Ryan (1982, p.274) and Shimp and Kavas (1984, p. 807) that behavioral intentions are not a function of parallel, independent sets of inseparable attitudinal and normative variables, but of a complex set of interdependencies.

Crude measures of informational reference group influence were found correlated with subjective norms and did explain (at least, for one product) some unique variance beyond that accounted for by the traditional normative-expectation-based predictor of subjective norms. This very tentative finding lends credence to the arguments of Miniard and Cohen (1981, 1983) and the growing recognition that the social influence variables are under-developed.

The results of this study also provide some mixed support for Midgley and Dowling's conceptual view of innovativeness. On the positive side, the relative weights derived from aggregate tests of the behavioral intention equation of the theory of reasoned action and the prediction of subjective norms by the normative and informational measures are somewhat consistent with that predicted by Midgley and Dowling's arguments. First, for both the correlated and uncorrelated models, the relative pattern among the Aact and SN weights varied as anticipated for the public luxury and private necessity products. (It was noted, however, that the subjective norm coefficients were high for both innovators and noninnovators.) Second, highest normative weights (compared to the informational weights) were found for the product hypothesized to involve greater reference group influence. In contrast, the results of the crossover effects were not directly supportive of the hypothesized reference group paths. For both products (and particularly the luxury automobiles), the crossover effects were unexpectedly highest for the innovators.

THE SELF-MONITORING CONCEPT: A CONSUMER BEHAVIOR PERSPECTIVE¹

Jacques A. Nantel, Ecole des H.E.C., Montréal
William Strahle, Indiana University

Abstract

The impact of the self-monitoring construct on the attitude-behavior relationship was examined under conditions of social pressure in a student setting. The experimental results, consistent with those in social psychology, suggest an explanation for variations in attitude-behavior consistency across consumers in the presence of situational cues.

Introduction

Beginning with Lapiere's (1934) classic article, the use of the attitude construct to explain and predict behavior has been under constant attack in both the psychological and marketing literature (Bettman 1981). In an extensive review of this literature, Wicker (1969) reported that the majority of studies linking attitudes to behavior showed correlation coefficients only in the order of .30. He concluded that "... as a whole, these studies suggest that it is considerably more likely that attitudes will be unrelated or only slightly related to overt behaviors than that attitudes will be closely related to actions" (1969, p. 65).

In marketing, the use of the attitude construct has been influenced by Fishbein's (1967) conceptualization which has generated an important stream of research. The research ranges from theoretical and measurement issues (Bennett and Harrell 1975, Bettman, Capon, and Lutz 1975, Mazis, Ahtola, and Klippel 1975, Ryan and Bonfield 1975) to more practical issues such as advertising (Dover and Olson 1977, Smith and Swinyard 1983). Overall, the Fishbein model has been of most interest for marketing and consumer behavior researchers mainly because product evaluation is frequently viewed as a multiattribute decision process (Wilkie and Pessimer 1973).

While Fishbein's extended model can offer satisfactory insights about how attitudes might influence behavioral intentions, it still suffers somewhat from an inability to adequately predict behavior (Songer-Nocks 1976a, 1976b). In fact, closing the 1976 *JESP* debate (a total of four articles and replies), Azjen and Fishbein (1976a, 1976b) themselves concluded:

"... consistent with our theory, the prediction of behavior from attitudinal and normative components was limited only by the strength of the intention-behavior relationship. Clearly then what does need to be further specified are those factors that limit the prediction of behavior from intentions." (1976b, p. 593).

Several of these moderating variables have since been identified (for a comprehensive summary see Zanna and Olson 1982; and Zanna and Fazio 1982), and one of the most important was found to be the manner in which the attitude was initially formed. Fazio and Zanna (1981) proposed that when attitudes are formed on the basis of previous behaviors, the attitude-behavior relationship should show greater consistency than when they were not. This relationship has been previously tested in a consumer behavior context (Smith and Swinyard 1983). However, a second factor proposed by Snyder and Tanke (1976), self-monitoring, has thus far been overlooked as a possible moderator for the attitude-behavior relationship. Our objectives are, therefore: to review the self-monitoring construct

and to test for its mediating role in both the attitude-behavior intention and the behavioral intention-behavior relationships.

Background

Snyder (1974) suggests that self-monitoring represents the degree to which individuals have the ability to be sensitive to the situational cues which guide their behavior in a variety of situations. Using as a theoretical basis the human need for social appropriateness which had been shown by Ash (1946, 1951, 1956) to have an impact on behavior, his intention was to provide an adequate operationalization for the construct.

The construct itself is defined as follows:

"The self-monitoring individual (read high self-monitor) is one who, out of a concern for social appropriateness, is particularly sensitive to the expression and self-presentation of others in a social situation and uses these cues as guidelines for monitoring his own self-presentation" (Snyder 1974, p. 528).

In the same vein,

"Non self-monitoring individuals (read low self-monitors) have less concern for the appropriateness of their social behavior and attend less to situational cues as guides to their social behavior" (Snyder and Monson 1975, p. 637).

These definitions suggest that the attitude-behavior intention as well as the behavioral intention-behavior relationships may be moderated by the extent to which individuals use social cues as guides to behavior and that the self-monitoring construct can be used to categorize individuals according to their degree of sensitivity to those cues.

Our interest in the self-monitoring concept itself stems from the partial explanation it has provided for the typically low correlation observed between attitudes and behavior in other contexts (see, for example, Fazio and Zanna 1981; Snyder 1974; 1982; Snyder and Tanke 1976; Zanna and Olson 1982; and Zanna and Fazio 1982). In a recent article, Azjen, Timko and White (1982) measured subjects' attitudes toward smoking marijuana, as well as their perception of the social norms concerning that activity. The results, which were integrated using Fishbein's extended model, revealed a significantly greater amount of consistency between the attitudes and behaviors of low self-monitors than for the high self-monitors--providing support for previous findings.

Hypotheses

In the past, marketing studies have produced conflicting results in the use of Fishbein's extended model:

$$B \approx BI = (A \text{ act}) w_0 + (NB.MC) w_1 \quad (1)$$

where B = Behavior; BI = Behavior intention; A act = Attitude toward the act; NB = Normative belief (that is, the degree of belief that others expect or do not expect the individual to perform a specific act); MC = Motivation to comply or not comply with the expectations of others; and w_0 and w_1 are weights to be generated by a regression.

In a review of 35 marketing studies using Fishbein's extended model, Ryan and Bonfield (1975) found multiple correlation coefficients varying between .24 and .81 and beta

¹The authors are grateful to Richard Olshavsky, Robert Smith, and Russel Fazio for their helpful comments.

weights varying between .03 and .68. These authors suggest that the efficiency of the fishbein model, and more specifically the social norm component, might well be a function of the products studied as well as of the degree of attitude centrality (Ryan and Bonfield 1975; see also: Glassman and Fitzhenry 1976). Based on the self-monitoring perspective, a third factor could be added to the ones proposed by Ryan and Bonfield. That is, if high self-monitors are more sensitive to their external environment, then their behavioral intentions should be affected to a greater degree by their social norms than the behavioral intentions of the low self-monitors.

Consistent with our position, it could be argued that the attitude towards a behavior would predict the intentions of high self-monitors as well as those of low self-monitors, assuming that the behavioral relevance of such attitudes is apparent to both types of people.

Finally, given that an individual has formed a behavior intention, if the situation is to be performed in the presence of social pressure (situational cues), we would expect that the degree of consistency between BI and B would be greater for low than for high self-monitors. From the preceding discussion the following formal hypotheses can be stated:

- H₁: The impact of social norms (SN) on behavioral intentions (BI) should be greater for high than for low self-monitoring individuals.
- H₂: There should be no significant difference in the impact of attitudes on behavioral intentions between the high and low self-monitoring individuals.
- H₃: Under conditions of social pressure, low self-monitoring individuals will show a greater degree of consistency between their behavioral intentions and their behavior than high self-monitoring individuals.

Methodology

Ninety-four undergraduate students from Indiana University participated in the study. About three weeks prior to the experiment, subjects were asked to complete the Snyder self-monitoring scale. The initial questionnaire was presented by the principal investigator as part of a study whose objective was to assess the reliability of the 25-item scale (and provide tracking information). Three weeks later the same subjects were probed via a follow-up questionnaire regarding their attitudes, perceptions of social norms and their behavioral intentions towards the purchase of the Time-Life musical collection (presented in the form of an advertisement).

After collecting the questionnaires, the students were told that, in order to thank them for their cooperation, they would have the opportunity to purchase the music collection at a discount of \$2 off the regular price (\$29.96). To take advantage of the opportunity, the interested students had to raise their hands and ask for a special form to be used to send them a \$2 coupon applicable to the purchase of the Time-Life music collection.

Following a pre-test of four products, the music collection was retained as the target product. The criterion used to select the target product was that no more than 30% of the pre-test sample (N=30) should indicate a favorable attitude towards it. The purpose of using such a product towards which the majority of subjects were to have an unfavorable attitude, was to generate a sufficient level of social pressure for those individuals who would be forced to display a public interest in acquiring the product. That is, since the experiment was to be conducted in a classroom setting, it was assumed that if the majority of the students were not to raise their hands, indicating their lack of interest for the product, it

would generate a certain degree of social pressure for the minority of subjects who might be interested in buying the product. Our decision to use students in a classroom setting was based on the earlier work of Park and Lessig (1977) who found that students--particularly in a classroom setting--were extremely sensitive to their reference group. Too, such a procedure implies that the subjects are "forced" to participate, and in our design it was crucial to avoid using only "volunteer" subjects since they would seem more likely to be low self-monitoring individuals (Rosenthal and Rosnow 1979). Thus it was important to control for the strength of the situational cues that the experiment was to generate, and we felt that if at least 70% of the participants were not to raise their hands it would result in a situation such that those high self-monitoring subjects who might otherwise have been interested in "buying" the product would probably refrain from doing so because of the situational cues provided by their environment. Conversely, it was assumed that those same situational cues would not affect the behavior of the low-self-monitoring individuals who intended to acquire the music collection.

Experiment

The experimental questionnaire contained three main sections, with the first measuring subject attitudes using a multi-attribute expectancy-value model. Belief strength (E), and attribute evaluation (V) were collected for each of five attributes selected on the basis of pre-test relevance ratings. Consistent with previous operationalizations (Fishbein and Azjen 1975; Smith and Swinyard 1983), belief strength (E) was measured on a 7-point scale which asked subjects to indicate, "How likely do you think it is that the Time-Life musical collection is (product attribute i)?" Attribute evaluations (V) were measured on 7-point scale (from "extremely bad" to "extremely good") by asking subjects "If you were considering buying a musical collection, how would you evaluate one that offers (product attribute i)?" In order to obtain an estimate of the subject's attitude ($\sum EV$) toward the target product, his/her scale values were multiplied and summed over all five attributes.

In order to test our hypotheses, a conceptually parsimonious measurement of the subjects' motivation to comply to social norms was necessary. As initially specified in Fishbein's extended model (Equation 1), the tendency to comply to normative pressures is (SN) = NB*MC, where NB is the normative belief component and MC is the motivation to comply. In order to operationalize the SN construct, Glassman and Fitzhenry (1977) tested different measurement approaches by varying the level of specificity of the different components. Their results indicate that the use of a single question such as "most of the people whose opinion is important to me would think that the (behavior) is _____," is quite acceptable. In fact, this is consistent with Fishbein's (1973) position that the MC component may not improve predictability as only positive evaluated others tend to be elicited. Thus, we elected to measure subjects' social norms by using a 7-point adjectival scale (ranging from "extremely bad" to "extremely good") as response categories to the question "most of the people whose opinion is important to me would think that the purchase of the Time-Life musical collection is _____."

Behavioral intentions were measured as responses on a 7-point likelihood scale (ranging from "zero-likelihood" to "certain") to the question "How likely or unlikely is it that you would buy the Time-Life musical collection?" Finally, the completed forms that subjects had to ask for and return in order to receive the \$2 discount coupon were used as the measure of behavior.

Analyses and results

The following analyses are based on 94 usable sets of data representing subjects who had completed and signed both questionnaires. Subjects' self-monitoring scores varied

from 5 (low self-monitoring) to 21 (high self-monitoring) out of a possible range from 0 to 25, with a mean of 12.46 and a standard deviation of 3.52. Following Snyder (1974), subjects with a self-monitoring score greater than or equal to 15 (N=28, 29.7%) were classified as being high self-monitors, and those with a score less than or equal to 10 (N=30, 32%) were classified as being low self-monitors.

We first tested for any differences in the reported attitudes toward the musical collection *per se* between the two types of self-monitors, that is, whether the target product had more appeal for one group than for another. This seemed crucial since any initial differences between the attitudes held by the two kinds of self-monitors could confound the rest of the analyses. A one-way ANOVA was performed testing for differences in attitude scores (EV) between the high and the low self-monitors, and this analysis revealed that the extent to which an individual is a self-monitor had no apparent effect on his/her attitude toward the musical collection (H.S.M. \bar{x} =2.1, N=28; L.S.M. \bar{x} =1.9, N=30), $F(1,56)=0.57$, $p=.811$.

Next, in order to test the first two hypotheses, subjects' attitudes (EV) and social norms (SN) were combined using Fishbein's extended model and were used to generate an overall regression equation. Two similar regression equations were then generated, the first using only the scores of the 30 low self-monitors and the second using only the scores of the 28 high self-monitors. The results presented in Table 1 show some support for our use of the Fishbein's extended model.

TABLE 1

PREDICTIONS OF BEHAVIORAL INTENTIONS (BI FROM ATTITUDES (ATT) AND SUBJECTIVE NORMS (SN)

	Correlations		Regression Weights				R ²
	Att-BI	SN-BI	Att-BI	p	SN-BI	p	
Total Sample (N=94)	.41	.35	.26	.001	.37	.003	.25
Low Self-Monitors (N=28)	.48	.14	.47	.01	.09	.602	.23
High Self-Monitors (N=30)	.40	.45	.40	.04	.35	.026	.32

While both components of the model contributed significantly to the explanation of behavioral intentions when using the total sample, of somewhat more interest is the comparison between the low and the high self-monitoring regressions. Here the social norm component (SN) was significant only for the high self-monitoring subjects (H.S.M., $p=.026$; L.S.M., $p=.602$) suggesting that situational cues (normative pressures) have an impact on the formation of behavioral intentions only for high self-monitors. While this doesn't mean that only the high self-monitors perceive social norms, it does mean that only the high self-monitors use them as guides for their behavior. This last point is an important one since use of an ANOVA revealed no differences in the reporting of social norms between the low and the high self-monitoring subjects (H.S.M. \bar{x} =.22; L.S.M. \bar{x} =.17), $F(1,56)=.1$, $p=.970$ - a finding quite similar to that of Azjen, Timko and White (1982). Thus the first hypothesis predicted that the impact of social norms (SN) on behavioral intentions would be greater for high than for low self-monitoring individuals, and our results failed to disconfirm this hypothesis.

Our position has consistently been that high and low self-monitors differ in the degree to which they use situational cues rather than in the degree to which they use attitudes to guide their behaviors. However, the beta weights for the attitude component in Table 1 suggest that the low self-monitoring subjects might be more likely to use their attitudes in forming their behavioral intentions than do the high self-monitoring subjects (L.S.M. $\beta=.47$; H.S.M. $\beta=.40$). The difference was tested by comparing the partial correlations between Att and BI using Fisher's r to Z transformation for independent samples. The finding of no difference between the two coefficients (even at the .10 level) suggests that the two types of individuals do not differ in their propensity to use their attitudes to guide their behaviors, again replicating the findings of Azjen, Timko and White (1982). Thus, the second hypothesis of no significant differences in the impact of attitudes on behavioral intentions between the high and the low self-monitoring individuals could not be disconfirmed.

Out of 94 subjects, only 20% (N=18) indicated a favorable behavioral intention towards obtaining the target product. These results were consistent with those of the pre-test and were deemed necessary in order to generate a sufficient amount of situational pressure on those who were favorably inclined toward product "purchase." Only 5 subjects requested the discount coupon by raising their hands. Fortunately, none of these subjects had indicated an unfavorable behavioral intention toward buying the product, thus minimizing the possibility that an individual could ask to receive the coupon in order to resell it or to give it to someone else. Under these conditions, since the majority of the subjects indicated an unfavorable behavioral intention and acted consistently by not "buying" the product, a simple correlation between behavioral intention and behavior would be meaningless. Of greater interest is the behavior of those individuals who had a favorable behavioral intention towards product purchase. Our third hypothesis predicted that in the presence of social pressure, low self-monitoring individuals would show a greater degree of consistency between their behavior and their behavioral intentions than high self-monitoring individuals. In order to test this hypothesis, a chi square analysis was performed using the 18 subjects who had indicated a positive behavioral intention toward the purchase of the Time-Life collection. Table 2 shows the configuration of the analytical design. The result offer strong support for the third hypothesis ($\chi^2=6.978$, $df=1$, $p<.010$).

THE REPARTITION OF THE 18 SUBJECTS WHO HAD A FAVORABLE BEHAVIORAL INTENTION

	Bought	Did not buy
Low self-monitors	5	0
High self-monitors	4	9

Implications, limitations, and futur research

With some exceptions, the self-monitoring concept doesn't seem to have been extensively used in consumer behavior. Becherer and Richard (1978) found personality to have a greater impact on behavior among low self-monitors than among high self-monitors. Becherer, Morgan, and Richard (1980) found that low self-monitors were more subject to reference groups' influence than were high self-monitors. Our research is conceptually closer to Snyder's work. The self-monitoring construct is presented here as a variable which can moderate the impact of attitudes. The relationships presented in this paper could be of some theoretical interest for the area of consumer research. Since attitude is one of the central constructs proposed in most

consumer behavior models a closer look at the factors which can mediate the attitude-behavior relationships seems important. In a recent publication, Smith and Swinyard (1983) have proposed several such mediating variables and have urged for more research along these lines. From a more practical standpoint the present research might also have some relevance. For marketing managers and marketing researchers, interpreting the results of pre-tests of advertisements, products and product concepts that use behavioral intentions as the dependent variables should be made with greater care if a sufficient number of subjects are found to be high self-monitoring individuals.

Although the present paper offers some interesting implications several limitations are worth mentioning. First, in recent years, the self-monitoring scale has come under close scrutiny by many researchers (Briggs, Cheeks, and Buss 1980, Gabrenya and Arkin 1980). These authors suggest that the self-monitoring scale is a multidimensional rather than an unidimensional scale and that further research is needed in order to fully understand the exact nature of the constructs it taps. Along these lines, Lennox and Wolfe (1984) have suggested a revised version of the scale. Second, the SN and BI components of our equation were measured using only one item scales. Although the measures were based on other studies, the use of single measures in the present study is weak from a construct validity standpoint. Finally, the strategy of placing every one in a social pressure condition where non-behavior supports the hypothesis, although an original one, could have been better if the social pressure condition would have been manipulated.

The main objective of the present research was to generate some interest for the self-monitoring construct. At this point, future research could and should be considered. Very little has been done concerning the sociometric dimensions of the self-monitoring construct. Also, the concept could be of some interest for the researchers interested in the diffusion of innovations. That is, given a certain amount of interest in a product, its adoption could still be jeopardized if there were too few individuals actualizing their intentions and failing to provide favorable situational cues for others in the marketplace. It could also be that those individuals labeled as "innovators" are much more likely to be low self-monitoring individuals, though this remains an empirical question. It is our hope that our findings will sensitize marketing researchers to the use of the self-monitoring concept and generate additional research on its use in consumer behavior.

THE CONCEPT OF CONSUMER MARKET EFFICIENCY:
TOWARD EVALUATING THE SOCIAL EFFICIENCY OF CONSUMER MARKETING

John F. Gaski, University of Notre Dame

Abstract

This paper develops a concept of market efficiency from the consumer's perspective, that is, value received from consumption of a product category relative to the cost of consumption. After conceptual specification, an initial suggestion for operationalizing the construct is offered. The purpose of these efforts is to develop an ability to appraise various product markets in terms of how well they are performing the basic task of delivering satisfaction to consumers efficiently.

Introduction: The Issue and the Literature

Considering the recognized importance of such issues as consumerism, the social responsibility of business, and ethical standards in marketing, development of an objective method for evaluating the net contribution of consumer marketing to human welfare would be useful and significant. There have been occasional exhortations in the marketing literature for analysis of the "social efficiency of marketing," as this concept may be designated, as well as suggestions for possible measures. Some representative illustrations of these views follow.

Expression of the "net" social contribution of marketing implies a comparison of marketing's costs with its benefits, in other words, an imput/output-type measure of efficiency. Some initial appraisals have been concerned with the efficient intra-firm performance of marketing functions, with societal benefits implicit upon aggregation (Barger 1955; Beckman 1957; Bucklin 1970; Stewart and Dewhurst 1938), for example, estimates of distribution efficiency. Hollander (1961) observed that labor hours and monetary costs are the "only two measures by which we can evaluate the total inputs into the total marketing system." Regarding outputs, sales or consumer "votes in the market place" were offered as the appropriate index. This is intuitively appealing since purchase prices should approximately reflect value, or at least anticipated value, in perhaps all cases except attainment of extreme bargains and, possibly, monopoly. (Even in monopoly situations with artificially high prices, consumers have the option of declining purchase. Monopolies are only permitted to exist where society has decided their benefits surpass these additional costs.) However, Hollander also has identified a potential problem in that profits, or the difference between sales and costs, are generally such a small percentage of the total that "input and output will always be roughly equal." This complicates the task of determining efficiency. The same criticism can be applied to suggestions of value-added as a measure of marketing output (Beckman 1957; Hollander 1961).

Profit, itself, is an attractive surrogate for marketing's net social contribution. This assertion is supported by the free-enterprise axiom that the producers which most efficiently provide the goods and services that people desire the most will be the most successful. In the words of Czepiel and Rosenberg, "the cash register and profit-and-loss statement generate powerful feedback for . . . society about the satisfaction resulting from a given product/service" (1976). It is conceivable, of course, that higher profits will not always translate into greater social welfare, e.g., price increases without comparable increases in value. So profit, although attractive, appears an imperfect indicant of marketing efficiency.

A parallel argument has been presented by Balderston (1964), who suggests that "one criterion of the efficiency of marketing organization may be the maximization of total net revenues of all market participants other than final buyers," to which Preston and Collins (1966) protest that

this "specifically neglects the welfare of consumer participants." Total revenue appears to be a better approximation of marketing input than output.

The Market Perspective

Perhaps a more analytically promising way to assess the concept of consumer marketing efficiency would be by isolating the performance of individual markets. Since markets can be considered components of the marketing system, and the function of marketing is to actualize potential exchanges in markets for the purpose of satisfying human needs and wants (Kotler 1976, p. 5), this approach would seem to have merit. However, prevailing descriptions of "market efficiency" tend to restrict the scope of the issue to a level far beneath a full consideration of social consequences. Stigler (1961) has adopted the position that since "the basic function a market serves is to bring buyers and sellers together," existence, continuity, and stability are necessary conditions for market efficiency. He adds: "A market is efficient when cost changes are readily reflected in price changes, demand changes reflected in volume changes, and random instability not associated with fundamental readjustments is at a minimum." Preston and Collins define market efficiency as "the facility and effectiveness with which the potential exchanges are accomplished," while acknowledging their neglect of "the specific character or quality of goods or services subject to exchange" (1966). Finally, the economic concept of pareto-optimality, or the condition by which no market participant can gain without a loss to another (Henderson and Quandt 1971, pp. 255-8), while conceptually impeccable, does not consider the welfare gains of innovation and variety associated with market imperfections (Lundstrom and Lamont 1976).

From the preceding discussion it can be posited that there is an implicit, qualitative aspect to marketing output that is far more difficult to specify than the inputs to the marketing system which may be subject to monetary measurement. It is advocated here that the proper specification of this elusive construct is utility, in the strict economic usage, or the term's marketing-language translation: satisfaction. Justification for applying this interpretation to the question of social efficiency comes from marketing's ultimate purpose of consumer satisfaction (Czepiel and Rosenberg 1976; Kotler 1976). Obviously, a sizable measurement problem has just been created.

Some Measurement Background

There have been relatively few efforts to empirically measure customer or consumer satisfaction in this general context. Among representative examples, Cardozo (1965), in attempting to isolate the influence of effort and expectation on customer satisfaction, operationalized the construct as a product rating on a scale of zero to 100, representing "very inferior" to "vastly superior" in comparison to other products. Swan and Combs (1976), designating consumer satisfaction as a function of the expectation-product performance relationship, merely asked respondents to state instances of satisfaction and dissatisfaction, and "what happened to make you satisfied (dissatisfied) with this item?"

Some have found it convenient to focus entirely on consumer dissatisfaction, defined by Anderson as "the degree of disparity between expectations and perceived product performance" (1973). In his study of the effects of disconfirmed expectancy, Anderson developed a quasi-monetary measure of satisfaction by having subjects estimate the cost (worth) of ballpoint pens they had been

given. Lundstrom and Lamont, on the other hand, took a more global view in their 82-item, six-point Likert-type "Consumer Discontent Scale," designed to measure the general state of consumer attitudes toward business (1976). Sample statements from the scale include "Business profits are too high"; "All business really wants to do is to make the most money it can"; and "The consumer is usually the least important consideration to most companies." Of course, there is an entire literature on the subject of consumer satisfaction/dissatisfaction, but not on the subject precisely as interpreted here.

Some preliminary ponderings on how to measure marketing's contribution to the "quality of life" are found in Reynolds and Barksdale (1978): Andraesen (1978) discusses shortcomings of indices such as sales, repeat purchasing, and expressions of consumer satisfaction as measures of health care quality, and recommends actual reports of problems as a preferable indicator. Bechtel (1978) explicates a life-quality satisfaction scale ("never" to "always satisfied") with respect to a number of product categories and marketing functions.

While the measurement attempts described above are intriguing and productive, there does appear to be considerable potential for improvement in quantifying the output side of consumer marketing efficiency. Product quality evaluations do not necessarily capture satisfaction experienced, and overall sentiment toward business, or even marketing, may be subject to invidious social biases. Surely a concept such as satisfaction, or utility, can be assigned a more precise valuation. This premise provides the basis for the following discussion.

Conceptualization of a Measure

The case for a measure of marketing's social efficiency rests on these tenets, which have been stated or implied:

- (1) Measurement of marketing efficiency constitutes an input-output, or cost-benefit, analysis.
- (2) Marketing input is comparatively quantifiable. Total sales or revenues are acceptable measures for this (from the consumer perspective), reflecting all costs of the marketing system including return to the entrepreneur, i.e., profit.
- (3) Since the objective of marketing is customer satisfaction, this specifies the system's output. Quantification of this dimension, when compared with the input, would yield an objective efficiency ratio highly consistent with the concept of social benefits in relation to costs. (The advantage of such an input-output comparison over traditional satisfaction measures, therefore, is that it considers consumer satisfaction in relation to an objective standard, rather than in isolation.)
- (4) Given the ambitiousness of such a measurement project, the most realistic procedure may be to examine the efficiency of the components of marketing, or individual markets.

The present discussion, therefore, will be limited to the efficiency of markets, specifically consumer product markets. At this time, to establish a reference analog, it may be instructive to consider a measure of market efficiency already developed and widely accepted in another context.

In the field of finance, the concept of market efficiency is applied to capital markets and manifested in the Efficient Market Hypothesis (EMH). According to the EMH, a capital market is efficient only if prices fully reflect available information; that is, there exists no trading system based on available information by which a return could be earned in excess of the equilibrium expected return of the market portfolio or an individual security (Fama and Miller 1972). Furthermore, it has been suggested, tested, and supported that, with few exceptions, the actual capital markets in existence are efficient (Fama

1970).

This framework can be adapted to consumer marketing. While capital market efficiency is expressed as a comparison of investment returns to an absolute standard, consumer market efficiency would involve a relative comparison of consumption spending returns in various markets. Consumption spending return can be defined as the benefit/cost ratio in each particular market and will necessarily be relative because of the apparent absence of a limiting value to satisfaction, which would serve as the numerator. The measure of return in consumer markets, therefore, appears:

$$\begin{array}{l} \frac{\text{Benefits}}{\text{Costs}} \\ \text{or} \\ \frac{\text{Output}}{\text{Input}} \\ \text{or} \\ \frac{\text{Satisfaction (Utility)}}{\text{Expenditure (Total Sales)}} \\ \text{or} \\ \frac{\text{"Return"}}{\text{Investment}} \end{array}$$

Taking the view of marketing's social purpose, consumer satisfaction/expenditure seems a valid expression of the concept, and is analogous to the financial measure of discounted net present value of cash flows/initial investment (Van Horne 1971, p. 60), i.e., the "profitability index." With the marketing measure, satisfaction and expenditure flows would simply be expected to occur in the same period.¹ More precisely,

$$\frac{\text{Benefits} - \text{Costs}}{\text{Costs}} \text{ or } \frac{\text{Satisfaction} - \text{Expenditure}}{\text{Expenditure}} \text{ would be the}$$

proper measure of return in consumer markets, as can be illustrated by the following discussion of the consumer exchange process.

Typically, a consumer purchase involves an amount of money exchanged for a product (good or service). For the exchange to occur, the consumer must value the product more than the money. That is, unless a greater value is attached to the object of purchase than is represented by its price, or the amount of money that must be given up for it, there is no incentive for the consumer to make the exchange. Symbolically,

$$V(P) > V(\$)$$

with $V(P)$ = value of the product

and $V(\$)$ = value of the money.

For the purpose of defining a market efficiency measure, the amount of difference between $V(P)$ and $V(\$)$ is of importance. The algebraic difference $V(P) - V(\$)$ represents value, or benefit, provided by the product in excess of its cost. (This is a micro-representation of the concept known in economics as "consumer surplus.") Identification of what this value is for any given exchange may be accomplished with the assistance of the consumer involved. Theoretically, a consumer would be willing to pay an amount approaching $V(P) - V(\$)$ for the privilege of obtaining $V(P)$ worth of value for only $V(\$)$. For example, if a consumer buys a product for \$10, he or she must value this product more than s/he values having the \$10. Say the subjective valuation of the object of purchase is \$15. Therefore, s/he should be willing to pay an amount very near \$5 to be able to exchange \$10 for \$15 in value. Provided consumers can make accurate estimates of such

¹Products of long purchase-cycle, such as consumer durables, would pose only a slight conceptual problem here. Either a "discounted net present value of future satisfaction" would have to be determined to define the numerator, or the "period" would have to conform to the purchase- or product life-cycle. The denominator would then include all life-cycle costs, a la Hutton and Wilkie (1980), rather than just initial expenditure.

maximum acceptable transaction "fees," the ratio

$\frac{V(P) - V(\$)}{V(\$)}$ would represent excess benefit, or excess

satisfaction, in relation to expenditure (analogous to return on investment), and $V(P)/V(\$)$ would reflect total satisfaction per unit of expenditure, or an efficiency ratio of output/input. Aggregated across all transactions within a product class, an overall measure of market efficiency for that product would be derived. The relative efficiencies of different product markets could then be compared. All that remains now is to generate an accurate monetary measure of consumer satisfaction in specific product markets to be compared with expenditure. This, of course, will be no small task.

A Tentative Step toward Operationalization

As indicated, the fundamental purpose of this discussion is to develop a procedure for comparing the social efficiency of various product markets on the basis of the inputs and outputs described in the previous section. This will involve estimating consumer satisfaction and expenditure associated with different products. As this is done, a means will be provided for the testing of the following hypothesis.

- H: There are significant differences between different consumer product markets in terms of social efficiency provided (expressed as the monetized value of satisfaction relative to expenditure).

Confirmation of this hypothesis would actually be trivial. However, the rank ordering of different product markets on the basis of efficiency ratings could be highly revealing. Failure to confirm the hypothesis might be the most meaningful finding of all, suggestive of a kind of unanticipated equilibrium level of satisfaction per dollar across all product categories.

The principal problem to overcome in any such research effort remains the development of a means of establishing quantified or monetized values corresponding to consumer satisfaction. One imperfect suggestion for accomplishing this is summarized in the remainder of this section.

First, a representative sample of consumers must be selected. Perhaps the ideal approach would be to interest one of the national polling organizations in the project and utilize their resources to obtain an adequate sampling of the consumer population. Given the importance and relevance of the issue, this hope may not be too unrealistic. Failing that, another possibility would be to purchase commercial market research. The samples employed by the MRCA consumer panel, National Family Opinion, and Market Facts, Inc. would be highly suited to the purpose. In the event that such assistance cannot be obtained, then a less ambitious sampling plan could be designed, such as telephone sampling or use of commercial mailing lists.

Regardless of which sampling procedure were to be used, the intention is to assign a value to the amount of satisfaction derived from a given market for a specified period. This value might be estimated by consumer subjects' responses to a hypothetical situation statement similar to the one that follows, presented to them in personal interview context:

I want you to think about an imaginary situation. Suppose I am the all-powerful ruler of the United States, or some supreme world authority, and that I have the power to do anything I want. Suppose I am a very capricious ruler and that, for no reason at all, I decide to prevent you from buying (product) for an entire month. Not only do I prevent you from buying _____, but I also prevent you from having your family or friends get it for you--in other words, I prevent you from obtaining _____ in any way for a period of one month. I won't even let you use the _____ you already have. Remember, since

I am all-powerful, I can do this.

But imagine that, even though I rule the world, I am still very fond of money. In fact, if you pay me enough money, I will agree not to deprive you of _____ for the one-month period. That is, I will let you purchase the right to continue buying _____.

Now think about what it would be like to do without _____ for a whole month, and think about whether it would be unpleasant or difficult, or not so bad. What I want to know is: How much would you pay me not to keep you from having any _____ for a whole month?

Accurate answers to this question, if attainable, should represent a true valuation of the excess utility or satisfaction which consumers derive from the specified product market for the stated period, in this case, one month. In other words, consumers would be expected to pay the "supreme authority" an amount up to, but not exceeding, their valuation of anticipated surplus benefit from participating in the market. (It would be emphasized to the subjects that the answer given should be the maximum amount, rather than an initial bargaining position.) As long as the question is understood and the responses genuine, a monetary expression of excess consumer satisfaction for a product market should result, which can then be compared with expenditure. This latter figure could be obtained simply by asking subjects how much they spend per month on the given product (which would be done subsequent to the satisfaction measurement to avoid any possibility of influencing that rather delicate response). This procedure would be repeated for other products in order to generate values for several product markets. Relative market efficiency can be determined (for each consumer) by comparing measures of return:

$$\frac{V(P)_x - V(\$)_x}{V(\$)_x} \geq \frac{V(P)_y - V(\$)_y}{V(\$)_y}$$

with subscripts indicating markets.

Since utility is not comparable across individuals (Henderson and Quandt 1971, p. 255), intra-subject rankings would have to be averaged for each product market to compute an aggregate measure of relative market efficiency. That is, differences between markets are to be determined by comparing median ranking (across consumers) for each product market.

Although the hypothetical scenario measure may appear unrealistic and operationally intractable at first (and possibly thereafter), a similar approach was demonstrated by Marquardt, et al. (1972) who, essentially, asked consumers the question, "How much would you be willing to sell your camper for?" Marquardt, et al. simply attempted to identify the value necessary to receive before deprivation of a product would be accepted, instead of the price willing to be paid to avoid deprivation. Naturally, the measure suggested in this paper (which is only intended as a conceptual starting point) could be recast in similar fashion. Consumers could be asked, in effect, "How much would I have to pay you to do without (product) for one month?"

The same idea, i.e., excess value received from consumption, is also illustrated by the quasi-experiment reported in the Exhibit.

Validation

The kind of market efficiency/consumer return measure which has been suggested may be meaningful or it may be totally specious, but this cannot be known until its validity is assessed. To accomplish this, a more conventional psychological scale should be constructed to measure consumer attitudes toward the applicable markets. A five-point Likert scale, incorporating items such as those shown in the Table, could be developed to capture the conceptual domain designated as "value received in relation to cost."

93 TV 'addicts' spurn offer for a \$500 turnoff

DETROIT (AP)—A Detroit newspaper thought it had an offer few could reject—\$500 if a family agreed to turn off its television set for one month.

The Detroit Free Press approached 129 families with the offer. And 93 turned it down.

The paper said it was trying to study "television addiction."

Only 27 of the families that were approached agreed to exchange their TV viewing for the \$500, the paper reported in its Sunday editions.

A TYPICAL response came from a suburban Romulus woman who said: "My husband would never do it. He comes home from work and sits down in front of the TV. He gets up twice—once to eat and once to go to bed."

The newspaper selected five families that agreed to accept money in ex-

change for television and sent TV repairmen into their homes on Sept. 19 and 20 to disconnect their sets.

The paper reported these results:

- One couple stopped talking. Six days into the project, the husband ducked behind a newspaper and never came out. "I think he's suffering from withdrawal," his wife said.

- Two people started smoking heavily—one going from 1 to 2½ packs a day.

- All the subjects said they saw more movies, read more, visited friends and relatives more often, and took more weekend trips.

- While some children played together peacefully, others became cranky, bored, and begged to have the set turned back on. Most of the fathers said they got to know their children better, and four families said they were drawn closer by the experience.

Source: Chicago Tribune, c. 1977.

It appears these consumers attach a high monetary value to the "excess satisfaction" obtained from television viewing. This must be a highly socially-efficient consumer product market.

Assuming measures are taken for multiple product classes across multiple consumer subjects, convergent validity can then be determined by at least two methods: (1) The "efficiency" of the various product markets can be ranked according to each of the two measures, and the within-subject rank correlations computed. (2) After intra-subject ranks for each product are determined by the two methods, simple correlations between the ranks yielded by each method can be calculated for each product across subjects.

Potential Difficulties

At this point, some unanswered questions should be addressed. First of all, is total consumer monetary expenditure the appropriate measure of marketing input? It can be argued that the consumer's time and effort should also be included in the investment base (Hollander 1961). So, might the market efficiency ratio be inflated by not including non-monetary expenditure in the denominator?

In response to this, it will be acknowledged that there is, indeed, a non-monetary aspect to marketing input. However, this time and effort expenditure can be regarded either favorably or unfavorably by consumers, i.e., as either a benefit or a cost, because, for instance, some people like to shop (Hollander 1961). Therefore, it is suggested that, depending on whether this aspect is evaluated positively or negatively, it will be manifested in the proposed efficiency measure as an implicit addition to or deduction from the satisfaction value.

Another potential objection concerns the impact of effort on expectancy and, in turn, satisfaction. For example, increased effort, financial or otherwise, may raise expectations and, therefore, influence product evaluation (satisfaction) upward or downward upon disconfirmation,

I get good value for my money when I buy (product).

The people who sell _____ are rip-off artists.

_____ costs too much.

The price I pay for _____ is about the same as the quality I receive.

I generally get what I expect when I buy _____.

Buying _____ is often a foolish waste of money.

_____ companies make too much money compared to what they do for consumers.

Most of the _____ I buy is overpriced.

_____ prices are reasonable given the high cost of doing business.

_____ companies take advantage of consumers by charging higher than normal prices.

I usually get my money's worth from _____.

(Some items adapted from Lundstrom and Lamont 1976.)

depending on the operative psychological model: assimilation, contrast, generalized negativity, etc. (Anderson 1973; Cardozo 1965). Will such a condition confound the relationship between the components of the market efficiency ratio? Possibly, but it should be recognized that the relationship of interest is between actual marketing costs and actual benefits. The measure assumes that expenditure level affects satisfaction. (For example, an extremely high or exorbitant monthly expenditure level would certainly decrease the amount a consumer would be willing to pay for the privilege of continuing to spend that money. In other words, excessively high prices impact upon satisfaction. This does allow a two-fold, or magnified, effect on the market efficiency ratio, which simply makes the measure volatile with respect to price changes.) If these costs also influence satisfaction through the intermediation of expectancy, this is simply another manner in which marketing input impinges upon consumer well-being, accounted for by the measure, but unnecessary to control.

More fundamentally, it is acknowledged that a restrictive interpretation of "social efficiency" has been employed here. Efficiency has been defined only from the perspective of the customers in a particular market, ignoring the clear possibility of externalities, positive or negative, impacting on the larger society. (For instance, producers of goods which satisfy their customers very efficiently might also be discharging pollution into the environment.) Since the nature of externalities may be so difficult to assess, the approach in this paper is offered as a substantial enough starting point. But a reasonable working assumption may be that the democratic process, manifested primarily in government regulation, will attend adequately to the externality problem, ever controlling externalities at a tolerable, and roughly equal, base-line level relative to market benefits across industries.

Regarding the hypothetical scenario statement, the classes of products selected for subject consideration may also be significant. A comparison between vital necessities, or products which are required for basic physiological survival, with discretionary products, for example, may not be valid. It could be argued that urgently needed products would be deserving of the enormous satisfaction values they

would be expected to receive because of the priceless needs they fulfill at finite costs, but for purposes of realistic comparison it appears prudent to consider only non-essential, although valued, products. Consumer convenience goods would seem to be potential candidates.

Related to this, it is conceivable that a consumer's income level could artificially limit the stated $V(P) - V(\$)$ amount, removing it from a true expression of excess utility. Restricting the chosen product categories to discretionary and/or low-priced items may be useful for circumventing this potential problem also. In such a situation it seems unlikely that $V(P) - V(\$)$ would be significant enough relative to consumer income to abort the validity of the analysis.

The one-month time frame may also be a problem. Anticipation of a relatively imminent lifting of the "authority's" prohibition might cause understatement of the satisfaction-valuation assessment. Perhaps an open-ended scenario, requiring payment of a monthly or annual stipend, would provide for greater accuracy.²

Concerning the question of comprehensibility, it would appear that there is nothing contained in the presentation to violate this requirement. Although the imaginary situation is highly unrealistic, the essential proposition is quite simple and straightforward. Final resolution of these issues will only be determined by empirical test, of course, and this is to be the subject of a forthcoming paper.

Conclusion

The preceding has

- described how the issue of the social contribution of marketing activity can be reduced (at least at a product/market level) to one of value delivered to consumers relative to product cost;
- developed a symbolic specification of this construct;
- suggested two approaches, one primary and one validation, to initial operationalization of the construct;
- advocated the potential significance of determining the comparative social "efficiencies" of different product markets; and
- addressed some potential difficulties associated with the procedure.

Considering the significance of the issue to many audiences--marketing researchers and practitioners, consumer researchers and advocates, consumers themselves, and public policy makers--and the relative scarcity of attention it has received, the modest aim of this paper, itself a precursor of an empirical study, has been to regenerate conceptual and empirical interest in this vital matter. A foreseeable outcome of this type of project might be the more accurate targeting of public policy and consumer lobby efforts, that is, the focusing of attention on less efficient markets. Actually, it may not be at all extreme to suggest that identifying the social performance of marketing, in the sense of individual product markets (i.e., industries) delivering value to consumers efficiently, may be one of the highest aims of marketing and consumer research.

²This would also be pertinent to the concern expressed in footnote 1 about products with a long purchase-cycle. Approximation of "discounted net present value of future satisfaction" might be achieved by asking how much would be paid to avoid the hypothetical prohibition over the consumer's entire life-cycle.

DEFINING AND EVALUATING QUALITY:
THE CONSUMER'S VIEW

Ellen Day, University of Georgia
Stephen B. Castleberry, University of Georgia

Abstract

Market conditions are causing marketers to re-examine quality of products and services as a means of achieving a competitive advantage. Despite extensive research, however, relatively little is known about consumers' perceptions and evaluation of quality. Therefore, a research project has been undertaken to investigate the role of "quality" in consumer purchase and consumption activities. This paper describes the initial findings from focus group interviews, which reveal interesting, if tentative, insights into the meaning of "quality" and how quality of products and services is evaluated before and after purchase/consumption.

Introduction

Unstable economic conditions, combined with intense foreign competition and changes in consumer demand, have forced many American businesses to reconsider their strategic focus. The competitive potential of quality, for example, is receiving considerable attention as evidenced by both the academic and popular press (e.g., Garvin 1984; Phillips, Chang, and Buzzell 1983; Reich 1980).

By maintaining a high degree of quality or implementing a program to increase the relative quality of the product or service, many firms have positioned themselves in a profitable strategic niche. Several reasons for the success of such a strategy can be cited. For one, producing "higher quality" goods and services allows a firm to compete more effectively against foreign competition (Blum 1981; Gale 1983). In addition, demand for "high quality" goods and services increases among some consumer segments during unstable economic times (Reich 1980; Bohr 1980), and changes in consumer values are being reflected in a greater focus on quality ("Social Changes..." 1984).

Given this renewed interest in quality, there is considerable discussion-cum-debate as to just what "quality" means, as well as what role quality plays in gaining a strategic advantage (Garvin 1984). This situation notwithstanding, relatively little research to date has directly addressed issues related to quality from the consumer's perspective. Therefore, the purpose of this paper is to present the initial findings from a research project that reopens and reinvestigates the meaning of quality in consumer purchase and consumption activities.

Purpose of the Study

The purpose of the first (exploratory) stage of the research project was to investigate (1) the meaning of "quality" from the consumer's perspective and (2) consumers' evaluation of quality before and after purchase takes place. Because of the nature of the inquiry, no particular definition of "quality" was assumed. "Quality" was simply viewed as a hypothetical construct that plays an instrumental role in consumers' efforts to minimize perceived risks (i.e., financial, social, psychological, physiological, and/or time) in the purchase of goods and services. In other words, quality, per se, is not the ultimate concern in the evaluation of products and services, except perhaps in cases of "conspicuous consumption." Rather, prepurchase evaluation of "quality" is a means by which consumers make judgments about the likelihood of a product or service fulfilling some perceived need, and postpurchase evaluation of quality is the means by which consumers assess whether their

expectations have been met or exceeded. However, there was no a priori assumption that (conscious) evaluation of quality takes place either before or after a purchase, since consumers may pursue alternative means of reducing perceived risks before a purchase (e.g., obtaining recommendations from others) or simply feel satisfied and not make an explicit evaluation of quality after a purchase.

Since little research to date has directly explored consumer perceptions and evaluation of quality, the specific objectives of this preliminary investigation were:

- o To determine, in general, what the word "quality" means to consumers;
- o To determine if consumers' definitions of quality vary across product/service categories;
- o To determine if consumers evaluate quality before purchasing, and if so, how;
- o For those consumers who do not evaluate quality before purchasing, to determine what, if any, alternative prepurchase behavior replaces explicit consideration/evaluation of quality;
- o To determine if consumers evaluate quality after purchase/consumption, and if so, how;
- o To determine if perceptions and evaluation of quality appear to vary across subjects.

Review of the Literature

Given the importance of the topic, it is not surprising that a great deal has been written about quality. Because space limitations preclude a comprehensive review (see Castleberry 1985), only the literature that is germane to the objectives of this exploratory study will be discussed here.

Unlike the approach taken in this paper, many authors have offered definitions of quality. For example, Crosby (1979) defined it as "conformance to requirements," while Kotler (1983) defined it as "the rated ability of the brand to perform its functions." Others have highlighted aesthetic considerations. Thus, Bohr (1980) notes that quality "...also means aesthetic and sensuous pleasure as well...it is timeless style, simple elegance and a sensation that makes people feel comfortable and satisfied to be near it." Garvin (1984), however, concedes that the definition of quality "remains a source of confusion." He states that quality often is equated with conformance to tight manufacturing standards but that there are many other dimensions of quality as well, to wit: performance, durability, reliability, serviceability, the "bells and whistles," and aesthetic elements. In a similar vein, Gronroos (1984) acknowledges the need to define quality of services in terms of consumer perceptions and suggests that service quality may be a function of a number of variables, i.e., consumer expectations, technical and functional characteristics, and image.

After classifying definitions of quality that have appeared in marketing and other disciplines, Holbrook and Corfman (1985) developed a definition of quality within the framework of value theory, specifically: quality is the "extrinsic, self-oriented, passive value." An empirical test of their conceptual definition was only marginally successful and the authors concluded that they had provided only a partial answer to the question of the meaning of quality. Years ago Wittgenstein (1953) stated that to understand quality from the consumer's standpoint (which is one of the

objectives of the current study), one must be concerned with the everyday use of the word. However, as evidenced by examples from the literature, researchers generally have not adopted this approach. Moreover, no study was found which explored the extent to which consumers' definitions of quality depend upon the product or service being considered.

Another line of inquiry in the current study is whether consumers evaluate quality before and/or after purchasing a product or service and, if so, how. Economists, who probably have contributed most to this topic, are divided into two groups. Wilde (1981) represents those who feel quality is a search attribute (i.e., quality perceptions are formed before purchase). Others (e.g., Hey and McKenna 1981), however, feel that perceptions of quality are formed only after purchase and hence quality is an experience attribute. Thus, the current study can provide additional insight into this controversy.

Of the many issues relating to quality, consumer researchers seem to be most interested in how consumers evaluate quality. Most work has explored the effects of various cues and cue combinations on perceptions and evaluation of quality (see Olson 1972, Olson 1977, and Monroe and Krishnan 1985 for reviews). Recently, Gronroos (1984) and Parasuramen, et al. (1984) have developed conceptual models of service quality and have identified possible determinants of perceived service quality. The fact that these are service quality models suggests that the evaluation, as well as the definition, of quality is likely to be context-bound. Gronroos, however, has only tested his model with a sample of service business executives, and the Parasuramen, et al. model is now being tested empirically. Therefore, considerable work must be done before a better understanding of the meaning and role of quality from the consumer's perspective is achieved.

Methodology

As the first step in the study of consumers' perceptions and evaluation of quality, semi-structured focus group interviews were conducted. Four such interviews--each lasting approximately 90 minutes--were completed, with a total of 36 subjects. Two groups comprised white-collar and professional persons recruited from a church organization; one group comprised a cross-section of graduate student volunteers; and the fourth group constituted volunteers from an undergraduate marketing class.

Questions directed to the groups related to three main topics: (1) the meaning of the word "quality" for four product and service categories, specifically laundry detergents, physicians, refrigerators, and restaurants; (2) whether "quality" is evaluated before and/or after a purchase, and if so, how, for banks, (over-the-counter) cold medicines, automobiles, and hairdressers/barbers; and (3) the meaning of "quality" in general. Particular products and services were selected so as to represent a sampling from a tangibility-intangibility continuum, where a refrigerator exemplifies a tangible (and very functional) product and a hair style is more of an intangible (and sensory) service. In addition, a series of questions was asked about the meaning of "quality," in general, in order to encourage subjects to provide other examples of what "quality" means and if/how quality is evaluated. Content analyses of these (tape-recorded) interviews were then performed. The results are presented in some detail in the following section.

Results and Discussion

Because only qualitative research has been conducted so far, the findings must be considered preliminary and tentative. This situation notwithstanding, the initial findings have been illuminating and suggest the viability of exploring the concept of quality from the perspective of consumer risk reduction. At the same time, the findings suggest the complexity of the research questions.

The Meaning of Quality

With respect to the general meaning of the word, "quality" appears to relate to performance, to how well something "does what it's supposed to do." This situation is true even in the case of a haircut, which is supposed to look good and to make the consumer feel more attractive. "Quality" also appears to be perceived as a property or inherent characteristic of a good or service (which is consistent with the definition in The American Heritage Dictionary, if not that of other researchers--e.g., see Monroe and Krishnan 1985), along with attributes such as style, color, and size. In addition, subjects indicated that they judged quality along a continuum from low to high quality.

Subjects suggested that "no quality" meant that the product or service simply did not perform the function for which the product or service was intended. Similarly, "high quality" meant that the product or service did what it was supposed to do very well, and "low quality" meant that the product or service performance was marginal, or barely adequate.

Not surprisingly, subjects tended to describe or define quality of products in terms of construction, durability, and performance; in contrast, "quality," as it related to more intangible services, typically was defined in terms of the person(s) rendering the service. With respect to the particular products and services investigated, subjects defined quality in laundry detergents as "it gets the job done; it cleans," for physicians as "he/she shows concern, is trustworthy, is knowledgeable," in refrigerators as "well-made, has a warranty, is maintenance-free," and for restaurants as "attentive service, pleasant ambience." In short, while subjects could offer conceptual definitions of quality, quality was equated to specific components or characteristics when subjects were provided a product or service context.

Evaluation of Quality

It became clear in the interviews that the subjects did not always (consciously) evaluate quality before, or even after, a purchase, which is consistent with Wilde's (1981) findings. Situations in which quality was not explicitly considered included the purchase of a specific designer label (a specialty good) and the purchase of products perceived to be commodity goods, e.g., milk.

In other cases quality was evaluated indirectly through the use of surrogate indicators, e.g., brand name (or other extrinsic cues) and recommendations of significant others. Less often, quality was directly assessed through inspection or examination of the product or through an evaluation of the results of services rendered to others, i.e., through the use of intrinsic cues.

For the particular set of goods and services investigated, subjects indicated that they primarily evaluated quality in banks on the basis of service (courteousness, expediency, and accuracy), cold medicines on the basis of efficacy and/or brand name, automobiles on the basis of reputation of the manufacturer and workmanship, and a hairdresser/barber on the basis of concern for the customer, conscientiousness, and advice on proper style and care. However, it was clear that different subjects used different means to evaluate quality before a purchase. To illustrate the complexity of quality evaluation, across the four groups subjects mentioned the following considerations in evaluating the quality of automobiles: reputation of the manufacturer (one component being the number of recalls), duration and terms of warranty, gas mileage, construction and workmanship (e.g., how much plastic was used and how "solid" the automobile appeared to be), performance, reliability, design/style, and trade-in value. Obviously, some of these characteristics could only be evaluated after purchase or consumption, suggesting the difficulty--but not necessarily the absence of--prepurchase evaluation of quality.

Indeed, some subjects explicitly referred to the difficulty of evaluating the quality of services before purchase, one person stating, "it's really hard to tell [about the quality] until you have tried them [banking services]." That consumers may perceive prepurchase evaluation of services to be more elusive is not too surprising, considering (1) the lack of meaningful--or familiar--quality-connoting cues such as brand name, (2) the inability to inspect most services beforehand, and (3) the person rendering the service possibly changing from one purchase to the next. However, subjects did say that they often evaluate the quality of services after purchase/consumption.

One important observation was that subjects would sometimes form an affective rather than quality judgement after purchase or consumption. That is, persons were "pleased with" or "liked" the results emanating from the consumption act, though subjects were not always cognizant of an assessment of the "quality" of the product or service. Clearly the perceptions and evaluation of quality were dependent upon the product or service category. In other words, although "quality" generally related to overall performance (or "excellence") of a product or service, specific mention of a product or service category evoked particular associations (see Exhibit I), as might be expected. While there was considerable agreement among subjects, the meaning and assessment of quality did vary somewhat. That is, typically there was a consensus among participants with respect to attributes associated with "quality" for a particular product or service, while differences across respondents represented more a matter of emphasis than debate. These situations suggest that definitions, perceptions, and evaluation of quality are likely to be somewhat product/service-specific and person-specific.

EXHIBIT I
THE MEANING OF QUALITY FOR FOUR PRODUCT/SERVICE
CATEGORIES: RESULTS FROM FOCUS GROUPS INTERVIEWS

PRODUCT/SERVICE CATEGORY	RESPONSES EVOKED
Laundry detergents	"gets the job done" "does what it's supposed to do" "not harsh, not irritating" "leaves clothes soft, fresh-smelling" "good price"
Family physicians	"shows concern for patient" "communicates with patient" "honest" "is sensitive, compassionate" "not 'out to get my money'" "trustworthy" "knowledgeable, up-to-date" "available" "good reputation" "reasonable fees" "efficient office personnel"
Refrigerators	"well-made, durable" "comes with warranty or guarantee" "good after-sale service" "maintenance-free" "energy-efficient" "availability of extra features" "well-known brand name"
Restaurants (dining out)	"treated special" "friendly, unobtrusive service" "presence of little 'extras'" "efficient, consistent service" "positive attitude of service personnel" "elegant, comfortable" "pleasing atmosphere" "not like at home" "food cooked properly" "fresh ingredients"

Lest the inference be drawn that future research on consumers' perceptions and evaluation of quality may be intractable, there was sufficient similarity across product groups, service groups, and individual subjects to suggest that additional research can contribute to a better understanding of quality from the consumer's perspective.

Price and Quality

In the majority of cases, subjects appeared to employ some implicit reference point, such as price, when discussing and defining quality. That is, there appeared to be some set of expectations evoked by a reference point and "quality" seemed inextricably linked with whether the product or service exceeded, met, or fell short of those expectations. Nevertheless, subjects did seem to have a notion of a quality continuum across a product or service category, e.g., Rolls-Royce representing "high quality" among automobiles.

Although subjects rarely made explicit reference to a price-quality relationship, they appeared to use a price-quality heuristic when discussing purchases. As an illustration, one subject explained that she would on occasion intentionally buy a product that she perceived to be of "lower" quality because she restricted herself to a certain (low-end) price range, e.g., in buying faddish clothing.

That the price-quality relationship becomes a preoccupation with consumers, marketers, and researchers might be explained by the fact that price so often is the first delimiter, or evaluative criterion, in the purchase decision process. It follows that if quality is a considered criterion then quality likely is evaluated relative to the price. Moreover, in the absence of (other) quality-connoting cues, it seems reasonable to assume that price will be viewed as a quality indicator (Enis and Stafford 1969; Jacoby, Olson, and Haddock 1971). While these points were not specifically explored in the interviews, such behavioral patterns could reasonably be inferred from the discussions.

A theme that permeated the group discussions was that of getting value for the money, of getting "your money's worth" [which suggests that Holbrook and Corfman's (1985) approach has considerable merit]. Here again, the implication appears to be that quality is evaluated relative to the price, which, in turn, influences consumers' expectations. However, subjects stressed that the product or service must possess some "quality," since "no quality" was equated to "junk" and to inadequate performance.

Evaluative criteria employed and the relative importance of same were not directly investigated; however, it became apparent that price was often the primary criterion in delimiting the range of options considered and then some attempt at maximizing quality for the acceptable price point/range was made. However, other criteria sometimes were considered to be relatively more important than price or perceived quality, based on the primacy, emphasis, and frequency of evaluative criteria mentioned by the subjects. That is, subjects were willing to trade some perceived quality for some other attribute they considered more salient. For example, in general subjects related quality of banks to various service dimensions (e.g., courtesy, speed, accuracy). But some subjects deemed convenience and accessibility to be most important in their current choice of banks, while complaining about the "lousy" service!

Quality and Risk Reduction

When subjects were queried as to why "quality" is important, why they evaluate quality, responses typically related to one or more types of risk that might be incurred in making a purchase. Comments such as "I don't want to get a lemon [automobile]" suggested the perception of financial risk. "I want the [hair] cut to

look good; I don't want to be embarrassed by it" implies social and psychological risk. The notion of perceived physiological risk was conveyed through remarks such as "there shouldn't be any harmful side effects [from cold medicines]" and that safety features were important in evaluating an automobile. Although the time risk is less often cited in scholarly discussions of perceived risks, several subjects expressed a concern about the amount of time that might be "wasted," especially in the consumption of services. For example, speed of teller service and transaction processing was important in the evaluation of the quality of banking services. In addition, subjects indirectly referred to the time risk when they talked of not wanting to "waste two hours watching a bad movie" or having to wait a week or more for a bad haircut to grow out. However, "quality" was not the only means of trying to reduce risk, e.g., buying a particular designer label because it was "the thing to do" (read: reducing/avoiding social and psychological risks).

Other Insights

Two additional questions led to enlightening discussions with respect to consumers' perceptions and evaluation of quality. When asked if they believed and were influenced by the claims of quality in advertising, virtually every subject responded that he/she generally attached little believability to such claims, particularly if unsupported. However, although claims of quality appeared to have little impact on subjects' evaluation of quality, the fact that a brand was highly advertised did seem to positively influence the assessment of quality (to quote one subject, "they couldn't advertise it if it were a really bad product"). Another line of questioning pertained to perceived quality in generically branded goods, i.e., how "quality" was assessed in the absence of brand-name surrogates. There was consensus that quality was highly variable across product categories, based on beliefs and actual experience, and that trial was the primary means of evaluating quality of generic or store (house) brands.

Future Research

It is obvious that this exploratory study has only begun to address important questions regarding consumer perceptions and evaluation of quality. For one, even though the findings suggest that quality is not always consciously evaluated before a purchase [which is consistent with Olshavsky and Granbois' (1979) contention that a cognitive decision process does not necessarily precede a purchase], it is important--both to theoreticians and practitioners--to identify those types of purchases, and possibly consumers, for which explicit prepurchase evaluation of quality does not take place. Some possibilities include: when there are no alternatives (e.g., in the purchase of emergency goods or services); in routine or habitual purchases; in the purchase of low-involvement (read: low-risk) goods and services; when trial is intended or forced by the lack of relevant evaluative information; and when one purchase is tied to another and therefore is nondiscretionary (e.g., the tires on a new automobile).

A myriad of other questions and issues need to be addressed as well. For research to be actionable, it will be necessary to investigate the more specific meaning and evaluation of quality for particular product/service categories. This study clearly indicated that quality cannot meaningfully be judged without considering specific tangible or intangible characteristics of a product or service. That is, "quality" is an abstract notion that must be operationalized in some way and that appears to be multidimensional. If this is true, then considerable research to date has yielded rather vacuous results, e.g., perceptual maps of products using "quality" and some other dimension. Certainly there are--perhaps somewhat disturbing--implications for marketers who attempt to differentiate offerings on the basis of quality and for advertisers who tout quality without

equating the term to those product and service characteristics consumers use in evaluating quality. Soon a cross-sectional consumer survey will be undertaken in order to test hypotheses formulated on the basis of findings from the first stage of this research. While somewhat speculative at this point, it is likely that hypotheses will represent more refined statements of the following (tentative) propositions:

- consumers do not always evaluate quality of a product or service before purchase;
- quality is more likely to be evaluated through the use of surrogate indicators, i.e., indirectly, than directly through inspection;
- the process by which quality is evaluated will vary across product and service categories;
- prepurchase assessment of quality is a means by which consumers attempt to reduce or avoid perceived risks in a purchase/consumption act;
- the types and levels of perceived risk will vary across different demographic and/or psychographic groups;
- the process by which quality is evaluated will vary across different demographic and/or psychographic groups.

Investigating these propositions should contribute to a better understanding of the importance and role of quality in consumer decision-making and, in turn, contribute to theory development in consumer behavior. The most significant contributions are likely to emanate from investigating these and other propositions from a particular theoretical or conceptual perspective, such as Holbrook and Hirschman's (1982) "experiential consumption" view.

Further research on consumer's perceptions and evaluation of quality should also result in important implications for marketing managers. That is, an awareness of the relative importance of quality and the manner in which quality is evaluated over a range of goods and services can help direct the practitioner in the design, pricing, and promotion of a particular marketing offering. It is likely that findings from future research also will provide valuable insights into more effective market segmentation. Moreover, it is anticipated that additional research will lend clarity to some conflicting and inconclusive findings from previous research relating to quality, in particular, the price-quality relationship.

MARKETING AS AN AGENT OF CHANGE IN
SUBSISTENCE CULTURES: SOME DYSFUNCTIONAL CONSUMPTION CONSEQUENCES

Elizabeth C. Hirschman, New York University

Abstract

This paper argues that several dysfunctional consequences may arise for consumers in subsistence cultures when modern marketing practices and products are introduced into their social system. Empirical examples of these dysfunctions are provided and a plea is made for higher ethical standards among multinational marketers in Third World countries.

Introduction

Despite assumptions within the marketing literature that subsistence cultures are better-off if transformed into developed societies with modern consumption values (cf, Meyer 1965; Dunn 1976; Michell 1979); there is evidence that this may not be so. The evidence falls into two categories--first, there are several instances in which the consumption values and behaviors of subsistence societies have served as adaptive responses to their environments. Second, there are several examples of destructive and dysfunctional consequences arising in subsistence cultures when modern consumption values and behaviors have been introduced. The first set of evidence is examined below.

Adaptive Response in Subsistence Societies

Current investigations of one of the world's most undeveloped countries--New Guinea--have revealed a highly adaptive and effective set of exchange relationships between productive resources and consumption demands. Brown (1978, p.265) states, "...we are beginning to see the processes whereby the indigenous population has developed intensive techniques of agriculture and animal husbandry. With this has come increased food and livestock production, [and] larger settlements...None of these could have occurred without the creative use of local resources and development of the land's potential. The expansion of productive capacity has kept pace with population increases; the two variables are interdependent." Thus, instead of being inefficient and static, as they are often depicted, the New Guinean consumption system has shown adequate potential for change and the potential for constructive adaptation consistent with environmental requirements.

Similarly, Dyson-Hudson and Dyson-Hudson (1980, p.34) report that native livestock practices in West Africa, labeled as irrational by earlier Western observers, are in fact, highly adaptive to the local environment. For instance, earlier change agents, guided by modern agricultural norms, had condemned the tribal practice of maintaining very large herds as economically inefficient and had encouraged the market sale of "excess" animals. However, these earlier change agents had failed to take into account the longer lead time required to rebuild herd size in the African climate in the event of a natural disaster (e.g., drought, fire). Mathematical simulations by the Dyson-Hudson's (1980) indicated that the traditional tribal animal husbandry patterns were, in fact, environmentally optimal, and that the adoption of modern practices would have led to an unacceptably high risk of herd devastation. The Dyson-Hudsons reviewed several other studies of pastoral practices in subsistence settings--the Peruvian Andes, Arab Tunisia, Peloponnesia--and concluded that in almost all instances a very high level of energy efficiency, appropriate degree of labor specialization, and production-consumption equilibrium were present.

With regard to another subsistence consumer population--Arctic Inuit (Eskimos)--Moran (1981) cites several exam-

ples of adaptive consumption practices. First, Inuit apparel permits rapid adjustment to temperature changes and precipitation. Second, Inuit snow shelters (igloos) and seal oil lamps work synergistically to provide a tightly-insulated, well-heated internal environment, requiring minimal energy expenditure. Third, Inuit family members generally sleep nestled together, which conserves body heat and enhances affiliative bonding.

The Inuit, like many subsistence peoples, have a non-economic exchange system based on social reciprocity, which creates durable inter-familial social bonds. Food, apparel and shelter are consumed on a communal basis, with resource reciprocity serving to form an integrated social network. Hospitality and sharing are the currency of exchange; hence, more formalized financial institutions are largely superfluous.

Findings such as these, Hoben (1982, p. 368) notes, "have undermined the deep-seated ethnocentric assumptions that 'non-Western' people's behavior is more tradition-bound than our own and that their production systems are poorly adjusted to their natural and economic environment... In-depth studies have shown that many small-scale farming systems are sensitively adjusted to local ecological, economic, and political conditions... If developmental programs are to succeed, they must take account of the strengths of existing institutions and recognize that they persist because they meet real needs... New technologies and organizational forms will be accepted only if they meet those needs more effectively without introducing additional costs and risks."

Dysfunctional Consequences of Marketing Development

The latter part of Hoben's statement is relevant to the incremental costs and risks incurred when modern marketing technologies, consumption values, and products are introduced to subsistence cultures. In specific instances, dysfunctional consequences have resulted from the introduction of such innovations. These fall into several categories: (1) the creation of economic dependency, (2) the stimulation of unnecessary/harmful demand, (3) population displacement and unemployment, and (4) the intensification of social stratification and economic disparities.

Creation of Economic Dependency

Of the several types of dysfunctional consequences resulting from the modernization of subsistence cultures, one of the most common is the creation of economic dependency (Wallerstein 1975; 1976; 1980). Zaltman and Duncan (1977, p. 327) describe such dependency effects as a function of change agent motivation: "Is the change agent really concerned about the welfare of the target system, or does change activity satisfy (the agent's) own needs for power and control? If the latter motives are operating, this might cause the change agent to be more manipulative in dealing with the target system... (The change agent) may not allow the target system to develop its own capabilities for dealing with the problem situation. As a result, the target system becomes overly dependent on the change agent."

Several Latin American scholars argue that the introduction of modern production and consumption practices has created a condition of dependency upon the more developed countries, particularly the United States (Nash 1981). Dos Santos (1973, p. 76) states, "dependence is a conditioning situation in which the economies of one group of countries (the undeveloped) are conditioned by the expansion of others (the developed)... Some coun-

tries expand through self-emulation while others, being in a dependent condition, can only expand as a reflection of the dominant countries".

One of the primary vehicles for the creation of economic dependency in a subsistence culture is to induce its adoption of technological innovations produced by modern countries (Nash 1981). Once traditional production techniques have been replaced by modern machinery and systems imported from developed countries, the undeveloped country becomes dependent upon the supplier-country to acquire replacement parts and trained personnel to keep the new technology operative. The more thoroughly modernized its production sector becomes, the more dependent the client country is on the multinational corporations supplying the technology. Thus, the supplier-country soon comes to exert great influence over the economic welfare of the client-country (Nash 1981), and this dependence relationship may become irreversible as traditional production technologies are forgotten or disintegrate. In some instances, the marketing literature has not only recognized, but advocated the creation of such dependency effects within developing countries (e.g., Freedman 1969, Michell 1979, Weber 1974).

The creation of economic dependency can also be accomplished by altering traditional production and consumption practices, without the necessity of introducing novel technology. In the African Sahel region, Swift (1977, p.473) described the traditional practices of tribal herders versus the commercial orientation advocated by external change agents: "Traditional production is characterized by mixed (goat and camel) herds to spread risk..., by the use of non-market forms of livestock exchange (i.e., social reciprocity and redistribution), and by the sale of only excess male livestock. In contrast, commercial production is characterized by the production of cattle and sheep, and the market sale of more animals, rather than their use for non-market transactions or as security in the pastoralist's own herd."

The shift from traditional to commercial production practices has had profound effects on Sahelian pastoral societies. Swift (1977, p.473) reports, "Sahelian markets have become unstable, and the pastoralists have no control over fluctuations in the prices of what they sell and what they buy. As a result, they have become increasingly vulnerable to both long-term changes in terms of trade for their products and also to short-term fluctuations... Their situation is made worse if they have modified their herd composition toward cattle and sheep, since these species are less resistant to drought than camels and goats... This is especially dangerous in drought years when the market is flooded with animals, pushing their prices down to derisory levels." He also notes that since the commercialization of livestock production in the Sahel, traditional redistributive practices, which provided resources to community members in dire need, have disintegrated. As a result, many people have died of starvation.

Moran (1981) has detected the creation of similar dependency effects among the Inuit. In order to purchase and repair the rifles and snowmobiles that have replaced their traditional hunting equipment, Eskimos must take low-paying, menial jobs or rely on welfare subsidies; whereas prior to modernization they were economically self-sufficient. Similarly, Laplanders who converted to snowmobiles from reindeer-sledding for herd management, now must sell up to one-third of their animals annually to maintain their equipment. The result has been a serious depletion of herd size and a decline in economic worth (Moran 1981).

A final example is provided by Adams (1968) in his discussion of trading posts established on Indian reservations in the United States. Like many of the people residing in subsistence cultures, reservation Indians find it necessary to depend upon commercial agents (e.g., trading post operators) to conduct transactions via credit or currency. These agents are in a powerful position vis a

vis their clients and sometimes abuse this power to gain financial resources for themselves. One common practice is to extend credit to an Indian totaling his/her entire annual earning potential, "thereby insuring that whatever cash came into the community is encumbered in advance... (Adams 1968, p.142)." "Trading post operators frequently refuse to cash checks for their Indian customers, unless a certain percentage (usually 50%) is used to purchase merchandise at the store. [Further], the trader uses his position and influence... in other ways. He discourages or impedes mobility on the part of his clientele. He would not loan them money to buy cars, or furnish credit references to car dealers in town. Although obliged by his operating license to sell gasoline, he is often 'temporarily out' (Adams 1968, p.144).

Stimulation of Unnecessary and/or Harmful Demand

Production processes operant in modern societies typically require continual market expansion to maintain profitability (Ayal and Ziff 1979). Expansion and growth, which have come to signify progress in advanced economic systems, are premised upon increasing levels of both production and consumption (Nash 1981; Wallerstein 1976). To achieve this objective, marketers in advanced societies may turn to undeveloped societies as sources of novel demand, when their home markets become saturated (Nash 1981). Much recent literature has been devoted to techniques, technologies, and strategies for initiating and enhancing the demand for products manufactured in advanced countries by consumers in undeveloped countries (c.f., Ayal and Ziff 1979; Michelle 1979). Rarely, however, do these treatises consider the direct and indirect negative consequences which the stimulation of such demand may have on the consuming population. Instead, products are generally depicted as contributing positively to the life style of the consumer (e.g., Freedman 1969), or only evaluated by profitability criteria relevant to the firm (Ayal and Ziff 1979).

Products from modern societies which are introduced and promoted within subsistence cultures may have two primary types of dysfunctional demand consequences. First, they may stimulate demand which is "unnecessary"—that is, which diverts consumers' resources from more critical to less critical products. Also belonging to this category are novel products which replace traditional products, but are more costly and/or less effective. A second category contains products introduced that are a priori known to be harmful and/or destructive to consumers.

UNNECESSARY DEMAND The stimulation of unnecessary demand was recognized early in the literature. Robinson (1961, p.19), stated, "The stimulation of non-existing demands for new consumer goods or demand based on brand name, style obsolescence, or new packaging may well cause an unjustified waste of scarce materials and skills, or an unnecessary commitment of them." He then cites as an example a technologically-sophisticated pesticide spreader introduced in Africa by a U.S. firm. The spreader was intended to replace a coarser, less-efficient pesticide spreader then in use. However, the new spreader not only cost substantially more than the older model, but its technical complexity caused it to incur more repair and maintenance expenses. Hence, even though the advanced model was superior in technological efficiency, it was economically inferior for use in that social system (Robinson 1961).

Moran (1981, pp.11,15) cites several examples of dysfunctional demand that have occurred among the Inuit as a result of modernization: "Concentration in villages has led to abandonment of traditional housing and adoption of less healthy shelter. Instead of sod and snow igloos, the Inuit now live in plywood shacks or government-built prefabricated homes heated by coal stoves. Air is not properly humidified and the population is more susceptible to respiratory infections and deafness... Vitamin C is in greater scarcity as a result of changes in cooking patterns. Anemia is now a frequent nutritional problem. Obesity is found with greater frequency. Hypercholester-

olemia is increasing, particularly in the aged. Increased opportunity to obtain sweets and less frequent use of the teeth as tools have led to a rapid increase in periodontal diseases."

Another example, and perhaps the most disturbing within this category, is the marketing of infant formula in subsistence cultures. Although this undesirable practice has already been cited within the marketing literature (Fox and Kotler 1980), it bears reiteration within the present discussion. Infant formula is a cows' milk derivation chemically structured to approximate maternal breast milk. The particular brands of infant formula most closely resembling human milk in nutritional value are also the most expensive (Post and Baer 1981). Companies producing brands such as Lactogen, Similac and Enfamil have actively marketed these formulas in undeveloped countries via advertising, health personnel employed by the company, and free samples. The result has been that many new mothers switched from breast-feeding their infants to feeding them commercial formula.

Once this switch is made, the mother ceases to lactate, and she and the baby are effectively bound to use of the infant formula. Several dysfunctional consequences have resulted from this shift in consumption. First, formula must be mixed with local water which is often contaminated—resulting in illness and even death for the baby. Second, because of the expense of the formula, many mothers overdilute it resulting in malnutrition and mental retardation for the infant. Third, the affected mothers suffer emotional trauma as they find themselves unable to properly feed their babies. Finally, government health officials are placed in ethically compromised positions by payments from formula marketers to permit continuation of the practice. Despite the fact that this marketing practice has been widely condemned, it currently continues (Post and Baer 1981, Higgins 1984).

Stimulation of Harmful Demand

The marketing of infant formula in subsistence cultures lies on the borderline between stimulation of unnecessary demand and stimulation of harmful demand. Although the infant formula product is safe when used correctly, it is difficult to safeguard its proper use in such societies. Two examples will now be cited, however, of marketers who have a priori knowledge of their products' harmful effects on consumers, yet continue to encourage their purchase and use.

The first example is the attempt to increase tobacco consumption in subsistence cultures. Although tobacco products have been declared health hazards in the United States and are currently subject to demarketing via governmental public policy efforts (e.g., the cigarette package warning label), such normative restrictions have not been applied to tobacco products distributed in many subsistence societies (Huebner 1982). In fact, tobacco products are included as nutritional subsidies in the Food For Peace program sponsored by the Department of Agriculture.

Huebner (1982, p.52) reports that "since 1955, more than \$700 million worth of tobacco products have been sent to South Vietnam, the Philippines, Cambodia, Egypt and other Third World Countries." As a result of this effort and company-sponsored promotional programs, tobacco product usage has risen 33 percent in Africa, 24 percent in Latin America, and 23 percent in Asia during the period 1969 to 1980 (Huebner 1982). Given the causal linkage between cigarette smoking and several major illnesses (cancer, emphysema, heart disease) and the relatively expensive cost of tobacco products, it is difficult to justify the introduction of such products into subsistence societies as improvements to the quality of life.

A final example is the case of Lomotil (Medawar and Freese 1981). Lomotil, produced by Searle, Inc., is an anti-diarrheal drug currently being marketed in several subsistence societies as a diarrhea treatment for young

children. (In many of these countries, diarrhea is the primary cause of death in children under 3). Despite the fact that Lomotil is dangerous when administered to young children and is therefore prohibited by the FDA for administration to children under age two in the U.S., it is currently promoted for medicating infants aged three months to six months in Hong Kong, Thailand, and the Philippines (Medawar and Freese 1981).

Population Displacement and Unemployment

A third dysfunction caused by the introduction of modern consumption practices and products into subsistence cultures can be population displacement and unemployment. This commonly results when labor is shifted from agriculture to technological modes of production, or when farming practices are modernized via the use of mechanically sophisticated equipment, e.g., tractors, harvesters, hullers (Barlett 1980; Slater 1968). Such alterations are advocated because the modernized production systems are more capital efficient than their predecessors. However, as Currie (1968) has noted, the resulting displacement and underutilization of labor within the modernized production system may more than offset the increased rate of return to capital investment.

Dawson (1980) cites as an example of this phenomenon the introduction of mechanical rice hullers into Indonesia by several companies during the 1970's. Although the mechanized hullers were substantially more efficient than the traditional hand-hulling method, they acted to eliminate the jobs of several thousand laborers. Subsequent rioting by these unemployed workers caused the Indonesian government to severely restrict the future importation of technological innovations.

In those countries where the importation of agricultural technology is unrestricted, farmers who were once economically self-sufficient may be placed in an easily exploitable situation vis a vis those who are supplying the novel technology. Nash (1981, p. 403) proposes that "technological innovations reinforce the costs of production and... the centralization of control over the means of production." As a result, the power and independence of the indigenous laborer is diminished.

By causing the displacement and unemployment of certain segments of the population (e.g., farmers, harvesters), although simultaneously creating jobs for other segments (e.g., factory workers), the introduction of modern methods of production may result in a net reduction of the total jobs available. Native laborers and their traditional modes of production may be replaced by outside laborers and modern methods of production. Displaced from their now obsolete jobs and unqualified for positions within the modern production setting, such laborers may become permanently un- or under-employed.

Two examples of this are the Alaskan Inuit and the aboriginal population of Australia. Discussing the Inuit, Moran (1981, p.16) states, "Despite the boom conditions in Alaska, most jobs have gone to skilled outsiders. The result has been an annual unemployment rate of 70% for Eskimo workers." The majority of Inuit now are dependent upon multiple forms of government assistance, including food stamps, subsidized housing, welfare payments, and unemployment benefits (Moran 1981).

Even more marked has been the effect of modern production technology and purposeful economic exclusion upon the Aboriginal population of Australia. Yengoyan (1979, p.409, 410) states, "...the European impact on Aboriginals culture can only be described as devastating... The best example of this is the modernized cattle industry of Northern Australia where Aboriginals are not only underpaid to a marked degree, but also suffer chronic unemployment, underemployment, and deliberate social and personal abuse." Hence, rather than improving the economic welfare of the native populace, some modernization programs may actually reduce these consumers' earning potential and employment opportunities.

The Intensification of Social Stratification

A final dysfunctional consequence of modernization can be the intensification of social class differences between poor and affluent consumers. The exacerbation of social stratification has occurred on two levels-- international and intranational. Nash (1981, p. 407) states, "The widening gap between core and peripheral regions, and between rich and poor classes, is becoming increasingly apparent... A decade of development focusing on import substitution, industrialization, and Green Revolution agriculture not only failed to improve the position of Third World populations, but has contributed to trade imbalances, increasing debt, and impoverishment as revealed in indices of infant mortality and life expectancy."

In many instances, the majority of consumers in subsistence countries have been left in more economically impoverished conditions subsequent to modernization, than prior to its arrival (Nash 1981). One primary reason for this appears to be a corporate strategy of rapid repatriation of profits by multinational marketers from their foreign subsidiaries (Nash 1981)--a strategy advocated by some authors in the marketing literature (Holton 1970; Weber 1974).

The exacerbation of social class differences as a result of modernization may also occur on an intranational basis. In this instance, a small segment of consumers become the primary beneficiaries of modernization programs, while the majority of the population receives no benefits or has its standard of living reduced (Nash 1981). Michell (1979, p. 92) notes that with the introduction of modern marketing systems "...a dual society usually emerges in developing countries; an elitist segment demands the products of the industrialized economy, while the vast majority continue their present subsistence economy." Schwartz (1978, p. 249) states this position more forcefully, "Several studies demonstrate that externally introduced resources--technical, economic, political, social service--are distributed along lines of existing inequality and thus reinforce it..."

Some writings in the marketing literature seem to encourage the exploitation of this widening gap within subsistence societies (cf. Freedman 1969). Strategies are advocated which will enhance the consumption opportunities of those in the modern, elite segment of consumers, while ignoring or even further reducing those in the subsistence sector (cf. Dichter 1965). As Surkel (1972, p. 519) concludes "...Access to the means and benefits of development is selective; rather than spreading them, the process tends to insure a self-reinforcing accumulation of privilege for special groups, as well as the continued existence of a marginal class."

Ethics And Consumer Welfare

The material presented provides disquieting evidence that some marketing practices may result in dysfunctional consequences for consumers in subsistence cultures. This possibility raises several ethical issues; perhaps the foremost of these is whether or not marketers should concern themselves with the dysfunctional consequences of their actions. In other words, is one's responsibility limited only to devising successful marketing programs or does moral culpability extend as well to the negative consequences which occur when those marketing programs are implemented?

The current literature appears divided on this issue. Sheth and Frazier (1982) for example, provide detailed prescriptions for achieving change agent objectives, even in the face of attitudinal and behavioral resistance on the part of the target system. In contrast to this strategic stance are articles by Fox and Kotler (1980) and Lacznia, Lusch and Murphy (1979) which argue for the consideration of ethical responsibilities prior to the implementation of any social change marketing program. Lacznia *et al* (1979, p. 34) state, "Marketing practitioners have a responsibility to carefully consider the

ramifications of their social marketing campaign" and that "by venturing into the wholesale development of social marketing, marketing professionals may acquire considerable social power without prudently assessing the resulting responsibility that they necessarily must bear." Similarly, Fox and Kotler (1980) advocate the use of counter-marketing experts by governments in undeveloped countries to overcome campaigns by multinational marketers which promote harmful products. However, they do not address the pragmatic issue of how such countermarketing efforts are to be mounted, given the large budgets of the MNC's and the potential for corruption of local regulatory officials.

In the original article on marketing and planned social change (Kotler and Zaltman 1971), the authors explicitly called for a consumer sovereignty orientation in the implementation of such programs "...Most of the effort [should] be spent on discovering the wants of a target audience and then creating the goods and services to satisfy them... In social terms, it is held that this marketing philosophy restores consumer sovereignty in the determination of the society's product mix and the use of national resources (p. 5)." The consumer sovereignty viewpoint--that the existing values of consumers should be attended to by marketers and not altered to create demand for the marketers' current inventory of products--has been extended to the realm of multinational marketing by several authors (cf., Sheth 1972; Wind, Douglas, and Perlmutter 1977). These authors, however, have also detected a certain reluctance on the part of multinational marketers to act in accordance with the consumer sovereignty principle. Wind *et al* (1973, p. 21), for example, argue for the explicit recognition of consumers' interests in the formulation of international marketing policies, but note that "the relative lack of information available regarding international customer characteristics... may imply a low degree of marketing [i.e., consumer] orientation [on the part of multinational marketers]... Emphasis on the production and distribution savings associated with a standardized marketing strategy may result in a tendency to ignore differences among world customers."

What may result from such an orientation on the part of multinational marketers is the purposeful alteration of the production and consumption systems in subsistence cultures to create markets for the MNC's current inventories of unsold products. The dysfunctional consumption consequences which come about as a result of such market modernization efforts do not appear to be given adequate consideration. As Warwick and Kelman cautioned over a decade ago (1973, p. 395), "There is more than a real possibility that change agents will view the problem from the perspective of their own group and set goals that will... accrue to the benefit of their group at the expense of the target population... There are sound reasons for believing that [developmental] programs will end up serving the purposes of the advantaged group at the expense of the disadvantaged."

In the several instances cited previously and in others not reviewed in detail here (cf., Davis 1969; Hoskins 1971), it appears that some marketing modernization programs may act more as instruments of social control than as stimulants to societal development. The primary benefits of their implementation may accrue to multinational corporations and not to the consumers they are said to be serving. Given this, it perhaps time for marketers to re-examine their goals and priorities in developmental programs. Marketing strategies and implementation have varied effects upon the consumption environment. Where these effects have been beneficial and positive, we have been eager to take the credit. Where these effects have been dysfunctional and negative, can we be any less willing to accept the blame?

THE EFFECTS OF TIME COMPRESSED ADVERTISING
ON BRAND ATTITUDE JUDGMENTS¹

Douglas R. Hausknecht, University of Akron
Danny L. Moore, Burke Marketing Services Inc.

Abstract

Three models of time compression effects on brand attitudes are presented and contrasted. A previous study which competitively evaluated the three theories is replicated and potential shortcomings in the design are corrected. The results of the present study support the earlier conclusion that time compression affects advertising by interfering with message processing. However, the increased attention to non-message cues reported in the prior investigation was not replicated.

Introduction

Recently, time compression has gained increasing acceptance among advertisers as a method of reducing media costs by placing more copy into promotional spots (*Advertising Age* November 19, 1979; *USA Today* November 19, 1984). The principal difference between compressed and normal speed ads is that the speaking rate in compressed ads is faster; typically, an ad is recorded at a normal speaking rate (i.e., 140 to 160 words per minute) and electronically processed to achieve a faster presentation without distorting sound quality. While most advertisers only compress ads between 105% and 130% of normal speed to minimize the likelihood that consumers will detect the fast speaking rate, some commercials have been compressed by as much as 160% (e.g., from 48 seconds to 30 seconds in length).

The purpose of this paper is to report one experiment in a program of research designed to evaluate the effect of compressed ads on consumers' attitude toward the advertised brand. Two classes of models are tested: 1) perceptual/evaluative models and 2) a cognitive elaboration model. The mediating processes postulated by these models are summarized in Figure A to facilitate discussion.

Models of Time Compression Effects

Perceptual/Evaluative Models

Perceptual/Evaluative models assume that the effect of compressed ads on brand attitude is mediated by consumers' perceptions of the advertisement or source. Specifically, these models predict that time compression enhances the favorability of brand attitude judgments because consumers react more favorably to compressed presentations or because fast speakers are perceived to be more knowledgeable about the subject matter.

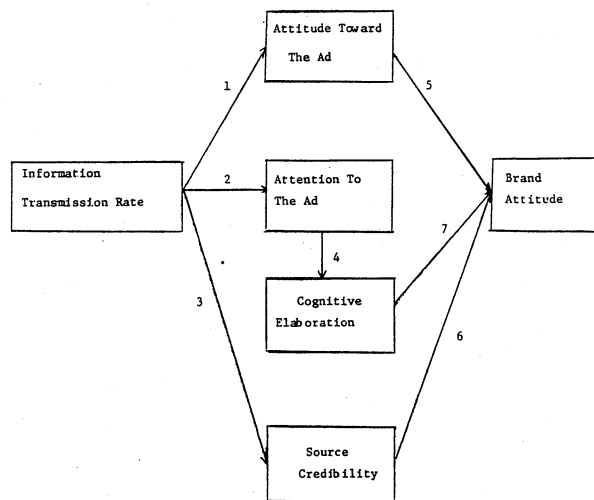

The Preference Hypothesis. MacLachlan and his associates (LaBarbera and MacLachlan 1978; MacLachlan 1982; MacLachlan and Siegel 1980) have proposed that consumers prefer ads compressed between 120% and 130% of normal-speed. They postulate an optimal information transmission rate and find evidence from paired comparison tests that consumers rate moderately compressed ads more favorably than normal speed and highly compressed ads. This suggests that compression effects on brand attitude may be mediated by affective reactions to the ad. Furthermore, brand attitude judgments should be curvilinearly related to time compression; compression rates between 120% and 130% are predicted to generate the most favorable brand attitude judgments. In Figure A, the processes hypothesized by MacLachlan's preference model are depicted by links 1 and 5.

Source Credibility Hypothesis. A second evaluative mechanism that may enhance the effectiveness of compressed presentations has been postulated by MacLachlan (1982) and Miller, Maruyama, Beaver, and Valone (1976). MacLachlan hypothesized that consumers may use speaking rate as an index of the source's confidence because confident speakers tend to talk faster and pause less frequently. This conjecture is supported by person perception studies that show that fast speakers are judged as more competent, truthful, fluent, and persuasive than slow speakers (Apple, Streeter, and Krauss 1979; Smith et al. 1975). In addition, Miller et al. (1976) found that fast speakers were more persuasive when delivering messages about "the dangers of caffeine" and "hydroponic gardening". A simple interpretation of these findings is that the effects of compressed ads on brand attitude judgments are mediated by evaluative reactions to the source (links 3 and 6 in Figure A).

A Cognitive Elaboration Model of Time Compression Effects

Moore, Hausknecht, and Kalaiarasi (forthcoming) noted that time compression is likely to affect the way consumers process advertising information. According to their model, fast presentation rates disrupt cognitive elaboration; that is, consumers generate fewer associations between advertising information and information contained in memory. If so, then time compression may either enhance or reduce persuasion by reducing the number of favorable or unfavorable associations to the brand. Moore et al.'s formulation is consistent with a

TABLE 1

SUMMARY OF TIME COMPRESSED ADVERTISING RESEARCH					
Study	Listening Condition	Medium	Speeds	Attitude Measures	Significant Effects of Compression Reported
MacLachlan & LaBarbera 1978	Laboratory	TV	100,125	Rated Interest	2/6 ^a Higher Interest 1/6 Lower Interest
LaBarbera & MacLachlan 1979	Laboratory	Radio	100,130	Rated Interest	3/6 Higher Interest
MacLachlan 1982	Laboratory	Radio	100,125	Ratings of	1/4 More Knowledgeable 2/4 More Enthusiastic 3/4 More Energetic
Stephens 1982	Laboratory	TV	100,120	No Attitude Measures	
Moore et al. forthcoming (Exp't 3)	Laboratory	Radio	100,130, 160	Cognitive Responses; Attitude toward Brands, Ad; Ratings of source credibility to Speaker	Speed affects target of cognitive response; Speed interacts with argument strength and affect brand attitude
MacLachlan & Siegel 1980	Field	TV	100,125	No Attitude Measures	
Lautman & Dean 1983	Field	TV	100,115	Commercial Ratings; Buying Intention	1/4 Improved Rating
Riter et al. 1983	Field	TV	100,125	Motivation to Buy	No tests
Schlinger et al. 1983	Field	TV	100,120	Viewer Response Buying Intention	6/52 (measures) were "worse" for response profile

^a Results are reported to indicate: Number of Commercials (measures) for which the significant finding was reported relative to the total number of Commercials (measures) evaluated.

variant of Petty and Cacioppo's (1981) Elaboration Likelihood Model (ELM) and Kisielius and Sternthal's (1984) availability-valence hypothesis.

The ELM interpretation predicts that consumers' attitude judgments are determined by cognitive responses to both message-related (or "central") and nonmessage (or "peripheral") factors. In advertising contexts, message-related thoughts represent inferences about message claims or product features. Nonmessage thoughts, in contrast, include evaluations of the source and ad, and are assumed to require fewer cognitive resources. Moore et al. proposed that fast presentation rates draw attention to nonmessage elements of the ad and distract attention from the central, message cues by inhibiting subjects' ability to process the ad fully (Petty and Cacioppo 1981 -- Consumer behavior researchers may be more familiar with motivational operationalizations of the ELM, such as found in Petty, Cacioppo and Schumann 1983). Thus, for compressed ads: 1) the relative impact of nonmessage cues on subsequent attitudinal judgments should increase, 2) the relative persuasive impact of messages evoking counterarguments should increase, and 3) messages that generate favorable reactions should be less persuasive.

In comparison with the perceptual/evaluative models, the ELM interpretation does not predict changes in the valence of affective reactions to the ad or source; instead, the relative weight that consumers give to the ad or source when evaluating the brand should increase for compressed ads because message and product information is processed less elaborately. In Figure A links 2, 4, and 7 depict the processes implied by the cognitive elaboration model.

Empirical Research on Time Compression

To conserve space, an overview of time compression research is given in Table 1. The discussion in this section is limited to a brief description of the major findings related to the processes depicted in Figure A. The link between time compression and affective reactions (#1 in Figure A) to the ad has received the most attention in previous research. MacLachlan and LaBarbera (1978) and LaBarbera and MacLachlan (1979) found that ads compressed to 120%-130% of normal speed are rated as more interesting than normal-speed presentations. However, Schlinger et al. (1983) reported that compressed ads are

rated as more patronizing and less personal. Finally, Moore et al. (forthcoming) found no difference between compressed and normal speed ads on a set of semantic differential scales designed to measure attitude toward the ad. Thus, the prediction that time compression affects consumers' attitude toward the ad has received only marginal support.

Only one study has examined the relationship between time compression, attention processes and cognitive response (#2 and #4 in Figure A). Moore et al. (forthcoming) found that compressed ads capture less attention. They also reported that consumers generate fewer cognitive responses to advertising claims and the product and more cognitive responses to ad execution factors when ads are compressed beyond 130% of normal-speed.

The evidence that time compression influences consumers' judgments of source credibility in advertising settings (#3 in Figure A) is mixed. MacLachlan (1982) found that spokespersons are rated as more enthusiastic and energetic when ads are compressed to 125% of normal. However, no significant compression effects on source attractiveness and expertise scales were reported in the Moore et al. study. Thus, even though person perception research suggests that fast speakers are rated as more confident, fluent, and persuasive, this does not appear to occur in advertising contexts.

With respect to the prediction that time compression influences brand attitude judgments, Wheelless (1971) and Lautman and Dean (1983) found no significant compression effects. However, other studies have shown that product ratings are more favorable for compressed versions of some ads, but normal-speed versions of other ads evoke more favorable reactions to the product (Riter et al. 1982; Schlinger et al. 1983). Moore et al. (forthcoming) demonstrated that time compression generates more favorable brand reactions for ads containing weak, unpersuasive arguments; they also found a small decline in the favorability of brand attitude when ads containing strong, persuasive arguments were compressed.

In short, the pattern of evidence from previous research provides little support for the predictions of the preference and source credibility hypotheses. Time compression does not appear to exert strong effects on affective reactions to the ad nor does it appear to enhance source credibility. Furthermore, time compres-

sion does not simply enhance brand attitude judgments. Instead, the evidence suggests that compression interacts with advertising characteristics to produce an effect on brand attitude, favoring the cognitive elaboration model.

Overview of the Present Study

The experiment reported in this paper was designed to test further the predictions of the three models. At present, the only explicit competitive test of these models was conducted by Moore et al. (forthcoming). In their research, consumers listened to a series of ads with a critical test ad occupying the middle position. Following each ad cognitive responses were collected. This procedure has two potential shortcomings. First, the experimental setting bears little resemblance to natural communication settings. When ads are embedded in a program and when consumers are engaged in distracting activities, compressed ads may be preferred because consumers view advertising as an unpleasant interruption in the program. Second, collecting cognitive responses to the ad forces consumers to focus their attention on message arguments, spokespersons, and ad execution. Thus, the observed effects in Moore et al.'s study may not replicate when cognitive responses are not collected.

To overcome these problems, we attempted to replicate Moore et al.'s findings in a more natural listening setting. Several versions of a radio ad were created by manipulating source credibility, argument strength, and time compression - factors identical to those used in the Moore et al. study. The message reception environment was modified by: 1) embedding commercials within a radio program, 2) instructing consumers that their task was to evaluate the radio program rather than the ads, 3) providing a concurrent distractor task, and 4) eliminating the cognitive response measures. Thus, the critical problem addressed in our study is whether the cognitive elaboration model provides an adequate account of time compression effects when attention is not focused on advertising material. More important, the experimental design permitted a further competitive test of hypotheses examined in the Moore et al. study.

- H1: The Preference Hypothesis: Moderate increases in presentation rate (i.e., 130%) produce more favorable reactions to the ad and brand than slow or fast presentation rates.
- H2: The Source Credibility Hypothesis: Compressed ads enhance the perceived credibility of the spokesperson and produce more favorable reactions to the brand.
- H3: The Cognitive Elaboration Hypothesis: Time compression reduces consumers' ability to process message assertions. This reduces the impact of message arguments and enhances the impact of source credibility on brand attitude judgments.

Method

Subjects

Students in an introductory Marketing class participated in the experiment for course credit. Of the 254 participants, data from 11 were discarded due to item non-response leaving results from 101 women and 142 men for subsequent analysis.

Design

Subjects listened to one of 24 radio commercials generated from a 2 x 2 x 2 x 3 between-subjects factorial design. The factors in the experiment were Product Class (Calculators or Razors), Argument Strength (Strong versus Weak), Source Credibility (High versus Low), and Message Exposure Rate (100%, 130%, and 160%). The between-subjects manipulation was chosen to control for demand

effects which may arise from within-subjects manipulations of presentation speed.

Materials and Stimuli

The stimulus commercials used were identical to those used by Moore et al. (forthcoming), as were the non-critical commercials used to simulate clutter. A thirty minute segment of a syndicated rock and roll program provided by a local radio station constituted the main tape in which commercials were embedded at logical breaks. Five "puzzles" (maze, wordsearch, etc.) were photocopied and provided the distractor task.

Procedures

The experiment was conducted in a language laboratory that seated 24 subjects at individual booths, each containing a tape recorder and a set of headphones. Subjects participated in groups ranging in size from 11 to 22. At the beginning of the experiment, instructions were read that explained the use of the tape recorder and indicated that the purpose of the experiment was to evaluate the appropriateness of a radio program for the local, predominantly student market. Subjects were also instructed to work on distractor tasks while listening to the radio program. The use of the distractor tasks was explained as necessary since, "[people] usually read or go about their normal routine when listening to the radio..we'd like everyone to work on these puzzles so that all of you are doing similar activities during the program".

The critical ad appeared midway through the program (third in a total of five ads presented during the thirty minutes). The calculator commercials contained a testimonial communicated by either a "Princeton Professor" (High Credibility) or a "high school student" (Low Credibility). The "strong arguments" version listed such reasons to buy as, "provides an ideal combination of financial and statistical capabilities needed in college courses" and "performed computations with the speed and accuracy of a computer". The "weak arguments" version relied on reasons like, "comes with a case that can be attached to your belt" or "does not provide a warranty, but I don't believe that you'll need one".

The razor commercials provided endorsements from either professional athletes (High Credibility) or citizens of a southern city (Low Credibility). Sample strong arguments are, "designed with a new advanced honing method that creates unsurpassed sharpness" and "special chemical coating eliminates nicks and cuts". Weak arguments included, "designed for beauty" and "can only be used once". The razor commercials were based on ads used in previous investigations of the elaboration likelihood model (Petty et al. 1983).

At the end of the program segment, subjects were instructed to complete a questionnaire that could be found in an envelope in the booth. The questionnaire first asked for ratings of the program (both to provide an intervening task and to justify the stated purpose of the study) and then probed for recall of products and brands advertised. Finally, copy point recall, brand attitude, attitude toward the ad and various manipulation checks relevant to the critical ad were collected.

Dependent Measures

The primary dependent measures were: 1) unaided recall of the brand name; 2) copy point recall; 3) brand attitude ratings; 4) ratings of the critical ad; 5) ratings of the product endorsers; and 6) ratings of argument strength. Recall measures were dummy-coded mentioned/not mentioned and ratings were collected on seven point semantic differential scales.

Results

Ratings of Argument Strength

Three semantic differential scales were used to assess perceptions of the message arguments: 1) strong-weak, 2) persuasive-unpersuasive, and 3) important-unimportant. These items loaded on the same factor and were summed for subsequent analyses (Cronbach's $\alpha = .89$).

Three significant effects were revealed in the analysis: 1) a main effect for Argument Strength, $F(1, 217) = 6.58$, $p < .02$, 2) an Argument Strength x Exposure Rate Interaction, $F(2, 217) = 3.03$, $p < .03$, and 3) a Source Credibility x Argument Strength interaction, $F(1, 217) = 4.77$, $p < .03$.

Although the Argument Strength effect indicated that subjects rated strong arguments as more persuasive ($M=11.67$) than weak arguments ($M=10.33$), this difference was not constant across Exposure Rate and Source Credibility conditions. Figure B shows the pattern of means for the strong and weak argument conditions within each exposure rate condition. As this Figure shows, subjects did not discriminate between the strong and weak arguments in the 160% condition, but argument strength significantly affected ratings in the 100% and 130% conditions. This result is consistent with the Cognitive Elaboration Model (H3) and suggests that message cues were not considered carefully in the fast exposure rate condition.

Simple main effect tests on the Source Credibility x Argument Strength interaction revealed that strong arguments were rated as more persuasive than weak arguments in the high credibility condition ($p < .05$) but not in the low credibility condition ($F < 1$). This pattern is not unusual in persuasion research and suggests that subjects' interpretation of argument strength was influenced by source cues (cf. Norman 1976).

Attitude Toward the Ad

The Preference Hypothesis (H1) predicts that consumers react more favorably to ads played at 130% of normal speed. Responses to a set of eight semantic differential scales about the ad were used to test this hypothesis. Preliminary factor analyses of these scales revealed three underlying dimensions. To conserve space, these factors will be referred to as "ad affect", "ad credibility", and "speed of speech".

Ad Affect. Analyses of five summed ad affect scales (Cronbach's $\alpha = .87$) revealed a significant effect for Product Class, $F(1, 218) = 5.26$, $p < .03$. Subjects reacted more favorably to the razor ads ($M=18.54$) than the calculator ads ($M=16.69$). No additional effects were significant.

The failure to find a significant effect of Exposure Rate on ad affect is damaging to the Preference Hypothesis. Inspection of the means for the Exposure Rate conditions indicated a pattern consistent with the Preference Hypothesis. The 130% condition evoked the most favorable reactions ($M=18.46$) followed by the 100% ($M=17.95$) and the 160% ($M=16.47$) conditions. However, the difference among these means did not reach a conventional level of statistical significance, $F(2, 218) = 2.22$, $p < .12$.

Ad Credibility. The analysis of summed ratings for the two ad credibility scales (Cronbach's $\alpha = .74$) indicated a main effect for Product Class, $F(1, 216) = 5.60$, $p < .02$. The razor ads were rated as more believable and truthful ($M=8.93$) than the calculator ads ($M=8.16$). All remaining main effects and interactions were not statistically significant.

Speed of Speech. An interesting issue for practitioners concerns whether or not consumers notice that ads are compressed. In previous research this issue has been examined with open-ended questions that probe for aware-

ness of time compression (e.g., MacLachlan & Siegel 1979). In the present study awareness of the time compression manipulation was examined by comparing

FIGURE B

ARGUMENT STRENGTH RATINGS FOR THE ARGUMENT STRENGTH X EXPOSURE RATE INTERACTION

ratings of the commercials on a semantic differential scale ranging from slow to fast. A significant Exposure Rate effect, $F(2, 217) = 28.32$, $p < .0001$ and interactions between Product Class and Argument Strength, $F(1, 217) = 6.54$, $p < .02$, and Product Class and Exposure Rate, $F(2, 217) = 4.35$, $p < .02$, were uncovered in the analysis. The most important of these effects was the Product Class x Exposure Rate effect. Table 2 shows the mean ratings for each Exposure Rate condition by Product Class. Comparisons of the speed ratings within each Product Class indicated similar trends. No significant differences were detected for comparisons between the 100% and 130% condition; however, the 160% condition was rated as significantly faster for both the razor and calculator ads. Thus, subjects did not report significant increments in speed until the compression rate surpassed 130%.

TABLE 2

EFFECT OF EXPOSURE RATE ON PERCEIVED SPEED OF ADS WITHIN EACH PRODUCT CLASS

Product Class	Exposure Rate		
	100%	130%	160%
Calculator Ads ^{a,b}	3.0A	3.6A	5.5B
Razor Ads	3.5A	3.2A	4.6B

^a The scale ranges from 1=slow to 7=fast.

^b Within each row of Table 2, numbers followed by the same letter are not significantly different at $\alpha = .05$ using Tukey's HSD test.

Perceptions of the Product Endorsers

According to the Source Credibility Hypothesis (H2), time compression should enhance the perceived credibility of the product endorsers. Nine semantic differential scales were included to test this hypothesis. We expected these scales to reflect an attractiveness dimension and expertise dimension (cf. Moore et al. forthcoming). However, a factor analysis yielded only one factor. Therefore, in our analyses all nine scales were summed (Cronbach's $\alpha = .95$).

Three significant effects emerged from the analysis. First, high credibility endorsers were perceived to be more credible ($M=38.38$) than low credibility endorsers ($M=29.03$), $F(1, 217) = 49.27$, $p < .0001$. This effect was qualified by a Product Class x Source Credibility inter-

action, $F(1, 217) = 5.73, p < .02$. Simple main effect tests of this interaction indicated a significant product effect for the high credibility conditions ($M's = 41.13$ and 35.74 for the calculator and razor ads respectively), $p < .05$; the product effect was not significant in the low credibility conditions ($M's = 28.52$ and 29.52 for the calculator and razor ads respectively). Thus, subjects generally rated the "Princeton Professor" in the calculator ads as a more credible source than the "professional athletes" used in the razor ads, but the other sources were perceived as equally credible.

The third significant effect in the analysis of source ratings was an Argument Strength x Exposure Rate interaction, $F(2, 217) = 4.32, p < .02$. Table 3 shows the relevant mean ratings for this interaction. This Table indicates that product endorsers were not simply given higher ratings as exposure rate increased (Hypothesis H2). Instead, when strong persuasive arguments were given, the endorsers were rated lower in the 160% condition than in the 100% and 130% conditions. However, consistent with Hypothesis H2, fast speakers were perceived as more credible when weak message arguments were given. One plausible interpretation of this finding is that subjects used argument strength as a cue for their ratings of source credibility. When the exposure rate reached a point where subjects did not respond to message quality, the suppressing effect of weak arguments was reduced. This interpretation is clearly at odds with the simple process postulated by the Source Credibility Hypothesis (H2).

TABLE 3

EFFECT OF EXPOSURE RATE ON PERCEIVED CREDIBILITY OF PRODUCT ENDORSERS IN THE STRONG AND WEAK ARGUMENT CONDITIONS

Argument Strength	Exposure Rate		
	100%	130%	160%
Strong Arguments ^a	34.93A	35.25A	31.95B
Weak Arguments	31.54A	32.02A	36.93B

^a Within each row of Table 2, numbers followed by the same letter are not significantly different at $\alpha = .05$ using Tukey's HSD test.

Brand Attitude Judgments

Analysis of three summed brand attitude scales (Cronbach's $\alpha = .90$) provided the critical test of the hypotheses. Both the Preference Hypothesis (H1) and the Source Credibility Hypothesis (H2) predict a main effect for Exposure Rate. The Cognitive Elaboration Hypothesis (H3), in contrast, predicts that message arguments should exert less impact and source credibility should exert more impact on brand attitude judgments as exposure rate increases; if so, then an interaction among Argument Strength, Exposure Rate, and Source Credibility should occur (cf. Moore et al. forthcoming).

The analysis provided little support for H1 and H2; Exposure Rate did not exert a significant main effect on brand attitude judgments, $F < 1$. However, a significant Argument Strength x Exposure Rate interaction emerged, $F(2, 218) = 3.20, p < .05$. Figure C shows the pattern of brand attitude judgments for this interaction. Follow-up tests revealed that strong arguments evoked more favorable judgments than weak arguments in both the 100% and 130% conditions ($p < .05$). For the 160% condition, the Argument Strength effect did not approach significance. This pattern is consistent with the Cognitive Elaboration Model and suggests that fast exposure rates reduce the impact of message quality on attitudinal judgments. However, the expected Argument Strength x Source Credibility

x Argument Strength interaction was not significant; this suggests that a decrease in the utilization of message cues is not necessarily accompanied by an increase in the use of source clues.

FIGURE C

BRAND ATTITUDE RATINGS FOR THE ARGUMENT STRENGTH X EXPOSURE RATE INTERACTION

The Argument Strength main effect and the Source Credibility x Argument Strength interaction were also significant. These effects were in the expected direction (e.g., strong arguments delivered by a high credibility source elicited the highest brand evaluations), and since they are not critical to the hypotheses, they will not be discussed further.

Brand Name and Copy Point Recall

The attitude results suggest that subjects may have ignored test ads when the compression rate surpassed 160%. The recall data support this interpretation. As Table 4 indicates, recall of the brand name and copy points was significantly lower in the 160% condition.

TABLE 4

EFFECT OF EXPOSURE RATE ON BRAND NAME AND COPY POINT RECALL

	Exposure Rate			F(2, 219)
	100%	130%	160%	
Brand Name ^a	.56A	.59A	.40B	3.89
Copy Point ^b	2.16A	2.15A	1.48B	6.65

^a Proportion recalling brand name for the test ad.

^b Average number of copy points recalled out of nine.

Note. Numbers in the same row followed by the same letter are not significantly different ($\alpha = .05$).

Discussion

The data collected in the present study consistently indicated that message quality effects diminish when compression rates surpass 130%. This finding appeared in the analyses of argument strength ratings, source credibility ratings, and brand attitude judgments.

There are two plausible accounts of the observed data pattern. First, high levels of time compression may cause consumers to ignore advertising information. If so, then one would expect lowered recall and reduced message quality effects. A second process that could account for our data is that the fast speaking rate distracted attention from processing message claims and product information and focused attention on executional components of the ad. Although this latter interpreta-

tion is consistent with the conclusions of Moore et al. (forthcoming), there are some discrepancies between our findings and the results reported in their research. Moore et al. found that high levels of compression are associated with reductions in the impact of argument strength cues and increased effects of source credibility cues on brand attitude judgments. In the present study we found the reduction in argument strength effects on brand attitude judgments, but source credibility effects did not increase in the high compression rate conditions. This difference could be attributed to procedural differences between our study and the Moore et al. study. That is, when consumers were not specifically instructed to generate cognitive responses to the ads, source credibility did not play a major role in brand attitude judgment. Since this could be due to a number of factors we feel that it will be more constructive to focus the discussion on consistencies; that is, why time compression reduced the effects of message quality cues in both the present study and Moore et al.'s study.

Neither the Preference Hypothesis nor the Source Credibility Hypothesis predicts an interaction between time compression and advertising characteristics. Thus, it is difficult to account for the observed data with perceptual/evaluative mechanisms. This points to cognitive elaboration models as the most promising account of time compression effects. The diminished effect of message quality is predicted by both the Elaboration Likelihood Model and Kisielius and Sternthal's (1984) availability-valence hypothesis. The key distinguishing characteristic between these models is that the ELM predicts that peripheral cues exert more impact on attitude change when cognitive elaboration is limited whereas the availability-valence model is mute on this point. Both models can account for our findings.

Perhaps the major conclusion that can be drawn from both our findings and Moore et al.'s data is that there are clear limits to the use of time compression in advertising settings; rates exceeding 130% seem to interfere with message reception. Note that the 130% rate is not offered as a maximum level for advertisers, or even a theoretically critical level. The present data reveal that time compression affects learning and attitude change processes at relatively low compression levels even though comprehension may be unaffected (up to rates of 200% - see, for example, Fairbanks, Guttman and Miron 1957). Thus optimal speeds are dependent on message and non-message aspects of each specific ad. More important, since we have ignored more subtle effects such as alterations in the consumers' interpretations of advertising claims, future applied research is likely to provide additional insights by incorporating measures of comprehension and acceptance as well as brand attitude.

Finally, the cognitive elaboration investigations of time compression have been limited to radio advertising, whereas much of the previous work dealt with television (Table 1). It is conceivable that compression may affect visual information processing differently than verbal. Relatively modest compressions can result in unintentionally humorous "Keystone Cop" movements that can detract from the impact of a commercial by creating new execution related cues.

EMOTION-ELICITING ADVERTISING: EFFECTS ON LONG TERM
MEMORY AND JUDGMENT

Marian Friestad, University of Wisconsin-Madison
Esther Thorson, University of Wisconsin-Madison

Abstract

Six to eight weeks after a single viewing of emotional and neutral advertising messages, subjects were phoned and given memory and judgment questions about the messages and brands. The original viewing had involved two encoding instructions, one that encouraged episodic processing; the other, semantic processing of the messages. Results showed stronger memory and more positive judgments associated with emotional messages. Memory was stronger with episodic processing, while judgment was more positive with semantic processing. Emotion and encoding instructions showed some interaction. The findings are discussed in terms of the viewing conditions under which emotional messages will enhance memory and judgment.

Introduction

The study reported here is part of a research program that explores the role of emotion in memory and judgment about advertising messages. One objective of the study was to test memory and attitudinal differences for emotional and neutral messages after an extensive delay (six to eight weeks). The second objective was an examination of the effects of encoding instructions designed to initiate either episodic or semantic processing of the messages. The third objective was to see if emotion operates differently in episodic and semantic memory.

Emotion's Role in the Processing of Commercials

Attempts to understand and define human emotion have a long history (e.g., Darwin 1872/1965; James 1890/1950; Canon 1914; Arnold 1968). In this paper, emotion will be treated as a process that occurs over time, varies in intensity (Simon 1982) and valence (Russell 1980), and exhibits a variety of concomitant indices: conscious appraisals of internal states and physiological changes in heart rate, blood pressure, and adrenalin levels. Emotion's ability to redirect attention and produce arousal distinguishes it from the concept of mood (Simon 1982). Finally, emotion is assumed to be a powerful influence on memory and judgment for at least three important reasons: emotion's developmental primacy (Mandler 1984), its evolutionary importance (Plutchik 1980), and the general pervasiveness of its impact on human functioning (Lazarus 1980).

A review of emotion in the marketing and advertising literature is not feasible here (see Kreschel, 1984, for a good introduction). It should be noted, however, that in marketing and consumer behavior, emotion has typically been defined in four ways. First, emotion has been treated as a type of appeal that is opposite from appeals emphasizing factual attributes of products (Preston 1968; McEwen and Leavitt 1976). Second, emotion has been defined as how much viewers like a commercial (Mitchell and Olson 1981; MacKenzie and Lutz 1982; Moore and Hutchinson 1983). Third, emotion has been defined as mood state during the viewing of commercials (Srull 1983). And fourth, emotion has been identified in the structure of cognitive responses that people make about commercials (Wright 1973; Leavitt 1968; Stout and Leckenby 1984).

Unfortunately, none of these definitions capture three critical attributes of emotion: the fact that it resides in individuals rather than in commercial message structure, that it is intense enough to elicit "feelings experienced," and that it fluctuates over time. Under the present approach, an "emotional message" refers to a vehicle that creates over-time flow of feelings that people report as emotional experience. It is not the type

of information in the message, the mood of the viewer, or how much the viewer can articulate liking the ad.

The paper turns now to an episodic-semantic model of consumer memory that incorporates this conceptualization and measurement of emotion.

Episodic and Semantic Memory and Consumers

Endel Tulving (1972) first suggested that a distinction should be made between memory that stores information about specific events experienced by a person, and memory that stores general knowledge about the world in a logical and categorized way. The first kind of memory he termed episodic, and the second, semantic. All incoming experience is stored initially as episodic information. In this system, associations between events are generally in terms of their contiguity in time. Semantic information must be derived by performing mental operations on information in episodes. When episodes are categorized, judged, evaluated, generalized, compared or in some other way acted upon by mental operations that information then becomes part of semantic store.

When people watch commercials, there is episodic processing of the audio and video events in the ads. There is also simultaneous processing of events in the viewing context (e.g., other people in the room, a doorbell ringing) and internal events such as physiological states (hunger, pain), thoughts, and feelings. Episodic traces of commercials contain all of this information. Furthermore, the traces vary in strength as a function of various parameters such as the intensity of the experience, subjective importance and meaningfulness of the experience, and the individual's ability to understand the message. One of the most important determinants of the strength of the episodic trace is emotion. In fact, there is extensive evidence that episodes experienced while people are emotionally aroused leave much stronger episodic traces than those experienced without arousal (Meltzer 1930, Postman 1947; Pillemer 1984).

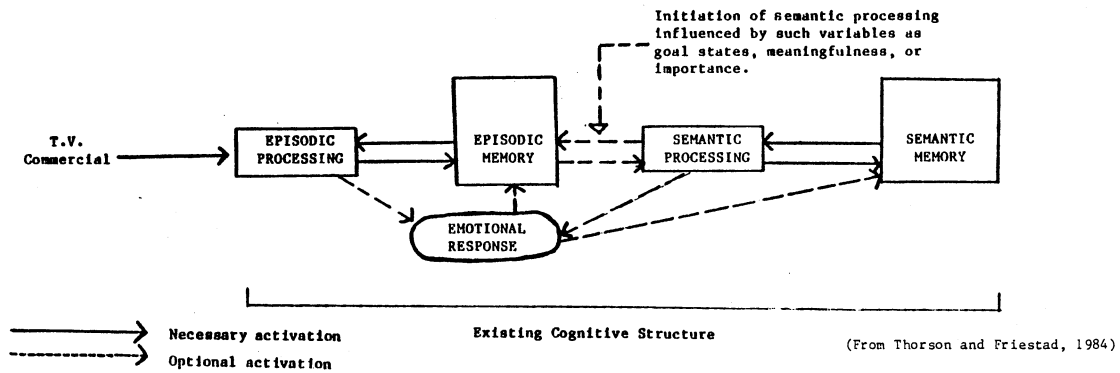

While marketers like to think of consumers carefully operating on advertising episodes to enter product-related information into semantic memory, such operations may not occur, or they may occur only at some time after the episode is experienced. There are factors that increase the probability such operations will occur. These include relevance of episodes to the individual's goal states, the meaningfulness or importance of the message, and whether the episode arouses emotion. It seems reasonable to assume that under ordinary low-involvement viewing of television (Krugman 1965), primarily episodic memory traces are created. On the other hand, if subjects are instructed to make judgments as they view, both episodic and semantic traces should be created.

As can be seen, then, it is important to consider two kinds of memory structure that can result in response to advertising messages. It can also be seen that emotion is relevant to the structure of both memories, as well as to the likelihood that mental operations will create semantic information from episodic traces. These relations are represented in a flow diagram of memory processes shown in Figure 1.

This model suggests that emotion experienced while viewing a commercial will strengthen the episodic memory trace for that message. The model does not assume, as do many involvement theorists (Mitchell and Olson 1981; Batra and Ray 1983; Lutz, Mackenzie, and Belch 1983; Moore and

FIGURE 1

EPISODIC AND SEMANTIC MEMORY PROCESSING OF TELEVISION COMMERCIALS

Hutchinson 1983; Petty, Cacioppo, and Schumann 1983; Park and Young 1984), that low-involvement processing is based on emotional processing and high involvement is cognition-based; but rather that an emotional response may be present in both high and low involvement situations. The model also differs from the distinction (Gardner, Mitchell, and Russo 1985; between brand and non-brand processing. Certainly brand processing would be largely semantic, but non-brand processing (e.g., evaluating an ad) could also be semantic. The approach closest to the present one is the distinction between retrieval and computational processing (Srull, 1983). Retrieval instructions would produce episodic processing. Computational instructions would demand semantic memory.

The paper turns now to a study that explores the predictive use of the episodic-semantic model for messages that differ in their ability to generate emotional responses in viewers.

Experimental Design and Hypotheses

The present design is a subcomponent of a larger study that manipulated subjects' encoding and retrieval processes (episodic/semantic) and type of message (emotional/neutral). Subjects were exposed to a series of television program segments and promotional messages. In the episodic processing condition, the viewers were simply told to watch all of the material carefully. Subjects' processing of the stimuli was, therefore, unstructured by any imposed task. Subjects in the semantic processing condition were instructed to watch all of the messages and evaluate them in terms of their ability to "influence your thoughts, opinions, and beliefs." These instructions imposed a semantic processing task on the subjects' encoding of the stimulus material.

Immediately after viewing, subjects were tested on their recall of the commercials, products, and brands, as well as their attitudes about the messages. These data are still being analyzed and not included in this paper. After a delay of approximately two months, the subjects were telephoned, reminded of their participation in the study, and again tested on memory for and judgments about the commercials (primarily an episodic task).

Hypotheses

Both the theoretical importance of emotion in strengthening episodic and semantic memory traces, and previous empirical findings that emotional commercials are more strongly remembered under short term memory conditions (Batra 1985; Friestad and Thorson 1985) led to the expectation that for long term recall:

- H1: Commercials that produce strong emotional responses during viewing will be more likely to be recalled, and recalled in more detail

than commercials that produce little or no emotional response during viewing.

Expectations about the effects of encoding instructions were more exploratory. It could be that episodic encoders, although they had also developed semantic traces during the immediate testing conditions, retained strong episodic traces and therefore when the long term memory task (primarily episodic in nature) was given, would perform better. This notion leads to the expectation that:

- H2a: Memory performance for viewers who encode episodically will be better than memory performance for those subjects who encode the messages semantically.

On the other hand, since all commercial information must first be recorded episodically, the semantic encoders would, during viewing, lay down structures in both memory systems (double trace strength) and hence, remain at an advantage even for the long-term episodic task. This alternative conception leads to the expectation that:

- H2b: Memory performance for viewers who encode semantically will be better than memory performance for those subjects who encode the messages episodically.

It should be noted that more complex recall conditions had been used in the immediate recall condition, but these differing recall conditions were evenly distributed between the two encoding groups.

A second set of exploratory hypotheses concerned whether there exist independent or interactive relationships between message type and encoding instructions. Because emotional experience may be stored in both episodic and semantic memory, equally strong operations of emotion in both encoding conditions (i.e., no interaction) seemed a reasonable possibility. However, a theoretical case for expecting greater impact of emotional messages in either episodic or semantic encoding could be made. For example, it might be that because episodic encoders presumably do not lay down semantic information during viewing, emotion creates greater strength differences between emotional and neutral message traces. This notion would lead to the expectation that:

- H3a: Emotion will show greater recall enhancement effects for episodic encoders.

But it might also be that because semantic encoders must share processing capacity between episodic and semantic trace production, their episodic traces are generally weaker, and enjoy greater benefit of the presence of emotion than do those of episodic encoders. Hence:

- H3b: Emotion will show greater recall enhancement effects for semantic encoders.

Finally, although the model of episodic and semantic memory shown in Figure 1 does not have theoretical representations of message liking and judgments of influence, there is empirical support in short-term memory tasks that emotional commercials receive more positive responses than do neutral ones (Stout and Leckenby 1985; Batra 1985; Friestad and Thorson 1985), therefore:

- H4: Emotional messages will be better liked and produce more positive effects on judgments of influence than neutral messages.

In addition, there is evidence consistent with the idea that semantic processing involves making product and commercial evaluations (Srull 1984). In the present study, the semantic encoders would be more likely to have these responses available, even long after the experience. The episodic encoders would have to retrieve the relevant episodic trace and then make judgments. Given the weakened state of the trace, more neutral judgments would be expected. Hence:

- H5: Semantic encoding would lead to more positive message liking and perceived message influence for both emotional and neutral messages.

Method

Emotional and Neutral Commercials

Target messages were selected to create two levels of emotional response in subjects: strong emotional, and neutral. The messages were chosen on the basis of previous research (Friestad and Thorson 1985) in which subjects turned a dial up from a neutral point as they experienced positive feelings, and down as they experienced negative feelings. The resultant dial-reading patterns were averaged over each 30-second message. The five emotional messages had produced the largest mean divergence ($X = 28.1$) from the neutral dial reading, and the five neutral messages had produced the least mean divergence ($X = 15.4$).

Because of the complexity of finished commercials it is difficult, if not impossible, to control all sources of variation. A number of steps were taken to minimize this problem. First, a variety of production techniques and executional styles were represented in both message types. Second, while many advertising and consumer behavior studies have used only one or two commercials to represent a particular category, in this study, a total of five messages in each message type were used. The specific messages in each category were as follows: Neutral: a) a home economics teacher and students, in a classroom setting, comparing a smoked sausage product to other cuts of meat; b) an off-camera spokesman describing an air freshener in strip form; c) a small child drawing on a chalkboard and asking for understanding rather than pity for disabled people; d) a slow-paced close-up of a light beer product with voice-over; and e) an on-screen woman presenting a new combination tomato sauce/tomato paste product. Emotional: a) children watching a Punch & Judy puppet show with a male voice-over talking about child abuse; b) a family reunion scene promoting a soft drink product; c) a series of outdoor scenes presented in a slow-paced manner with musical accompaniment sponsored by a bank; d) a young couple in a romantic setting with a male voice-over stating the woman had been killed by a drunk driver; and d) a series of family scenes with voice-over and jingle promoting house paint. It should also be noted that the commercials and public service announcements used in the study are similar to those used by other researchers examining emotion in advertising (Batra 1985; Aaker, Stayman, and Hagerty 1985).

Finally, because familiarity has been associated with increased memorability, it was important to have the two message types as comparable as possible on this dimension. Information from a separate group of subjects (also college students) was used to establish ratings of the "familiarity" of the brands or organizations sponsoring

each of the messages. On a ten-point scale, (10=high) mean familiarity of emotional messages was 4.59, and mean familiarity for neutrals was 5.18 (n.s.d.).

Programming and Buffer Commercials

Subjects viewed the ten target commercials embedded in an environment of program segments and buffer commercials. This procedure was used to control for primacy and recency effects, as well as to provide a more naturalistic viewing context. The program segments used were five- to six-minute "human interest" stories similar to what might appear on "PM Magazine." Each subject saw four buffer commercials, a program segment, five target commercials, a second program segment, five target commercials, a third program segment, and four buffer commercials. The order of the program segments and buffer commercials remained constant across the three counterbalanced orders of target commercials.

Subjects

The subjects in this study were undergraduate students who had participated in a laboratory experiment for course credit during the previous semester. Ninety-four of the original 170 participants were telephoned and interviewed for this study. No reward was given for participation in the phone interview. The length of delay between the initial laboratory session in which the advertisements were viewed, and the telephone contact ranged from 48 to 71 days (mean delay = 61 days).

Procedures

In the initial experimental session, subjects were told the purpose of the study was to "aid in the understanding of how viewers watch TV," and that they would be watching both programming and commercials. There were two encoding conditions: episodic and semantic. Instructions for the episodic encoding conditions were simply to watch the programs and commercial messages carefully, thereby encouraging an unstructured processing situation. The instructions for the semantic encoding conditions were to think about the programs and commercial messages in terms of their effectiveness in shaping thoughts, opinions, and beliefs. These instructions imposed an evaluative task on the subjects' processing of the messages. After viewing, subjects were asked to retrieve everything they could about the viewed commercials, and then answer additional questions about each of the target and buffer commercials. The laboratory study took an average of 75 minutes.

Six to eight weeks later, interviewers telephoned subjects and identified themselves as calling on behalf of the Wisconsin Department of Journalism and Mass Communication. Subjects were reminded of their participation in the original study, and asked to answer some additional questions. If they agreed to participate, they were given a free recall test, product recognition questions, and finally asked for some judgments.

Dependent Measures

There were five kinds of dependent measures: free recall, additional free recall, recognition, liking for the messages, and judgment of how influential the messages were.

Free recall was measured by asking respondents to remember all they could about messages presented during the initial test study. This question produced six recall measures: Number of messages recalled, total information in the recall protocols, and numbers of executional, product category, claim, and brand names contained in the protocols. After respondents were able to recall no more messages, they were given an additional recall prompt: "Are there any other images, thoughts, or events you can recall from the messages you saw?"

Both free and additional recall responses were transcribed word for word, and later coded into the four categories of executional elements, product category, claims, and brand

name. Three coders performed these tasks, and their intercoder reliabilities were: executional elements (.92), product category (.98), claims (.98), and brand name (.98).

Next, respondents were given product categories and asked whether they remembered an ad for each one (Recognition). Subjects were asked to rate on seven-point scales how much they liked each message (Liking) and how much it had influenced them (Influence). Finally, because syndicated delayed memory scores are often a combination of free recall and recognition (e.g., Bruzzone) or cued recall (e.g., Burke), the number of messages generated by a combination of the two methods (Recall Plus Recognition) was used.

Results

Each of the dependent measures was subjected to a 2 (Message Type) X 2 (Encoding Condition) analysis of variance (anova) with message type a within-subjects variable, and encoding a between-subjects variable. Occasional differences in number of subjects per analysis are attributable to missing data.

Free Recall

The anova for the number of messages recalled showed a significant main effect of message type ($F(1,90)=35.29, p < .0000$). Encoding had no effect and there was no interaction. As can be in Figure 2, Hypothesis 1 was supported, in that emotional messages were more likely to be recalled than neutral messages.

FIGURE 2

Free recall of executional elements, product category, and brand name mentions showed the same pattern of results, with emotional messages producing significantly higher response levels than neutral messages. As in number of messages recalled, episodic coding was always higher than semantic coding, but not significantly. Only free recall of claim (no significant differences) failed to show this pattern, presumably because claim scores were so low.

It is interesting to note that although the means for brand name recall were quite low, there was a marginally significant main effect for encoding condition ($F(1,90) = 3.9, p < .08$), with the episodic mean ($\bar{X} = .36$) higher than the semantic ($\bar{X} = .10$). This main effect provides marginal support for Hypothesis H2a. The levels of brand recall in this study ranged from .10 to .46, and are very similar to levels of delayed recall (28 days) reported by Craig, Sternthal, & Leavitt (1976) in their study of long-term repetition effects.

Total Amount of Information in Free Recall

A sum of the number of executional elements, product category references, product claims, and brand names recalled was calculated for the two message types. Again, in support of Hypothesis 1, there was a significant main effect for message type ($F(1,90) = 4.72, p < .03$). The mean amount of information recalled for emotional messages, collapsed across encoding conditions, was 3.17. The mean for neutral messages was 1.60.

Additional Free Recall

After the respondents had spontaneously recalled as many commercials as possible, they were prompted with a request for any other images, thoughts or events that came to mind. These responses were coded in the same way as the initial free recall responses. For this variable, there was a main effect for message type ($F(1,91)=15.61, p < .001$). The mean number of additional emotional messages recalled was .42; the mean for neutral messages was .10.

A sum of the four different types of information (execution, product category, claim, and brand) was also analyzed for these additional messages. In this case there was a main effect for encoding ($F(1,91)=4.49, p < .03$), with episodic subjects recalling more information ($X = 2.0$) than semantic subjects ($X = .33$).

Although encoding effects were generally weak in the memory data, there was a consistent direction in the differences. Episodic encoding always produced more recall than semantic encoding. This result, together with the two instances of marginal or significant differences, provides preliminary support for H2a, namely that episodic encoding will produce stronger memory than semantic encoding.

Recognition

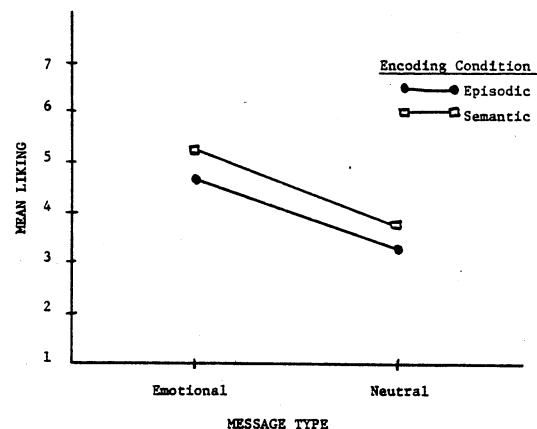

The number of commercials not recalled but correctly recognized was next analyzed. In this anova, there were no significant effects.

Liking and Influence

Figure 3 shows the results of respondents' rating of how much they liked each message. Here, message type produced a significant main effect ($F(1,86)=47.42, p < .0000$), with emotional messages better liked. There was no interaction, but encoding had a marginally significant effect ($F(1,86)=3.02, p < .09$), with semantic encoding producing more positive liking than episodic.

FIGURE 3

MEAN LIKING FOR ALL RECALLED AND RECOGNIZED MESSAGES

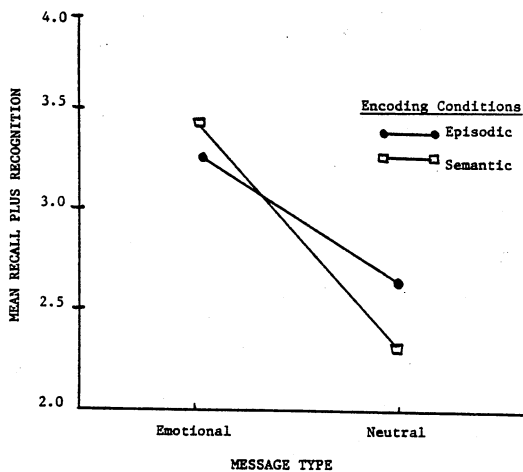

The anova on perceived influence showed a similar pattern. Encoding did not produce a significant effect, but semantic encoding was more positive than episodic. Message type was again significant ($F(1,86)=29.03, p < .0000$). There was no interaction.

The liking and influence results show clear evidence for H4, that emotional messages are responded to more positively than neutral messages. There is weaker evidence for H5, that semantic encoding leads to more positive delayed responses than episodic coding.

Recall Plus Recognition

In this measure, messages free-recalled and those recognized were combined. There was a significant main effect for message type ($F(1,92)=35.53, p < .001$), no effect of encoding, and a marginally significant interaction ($F(1,92)=2.89, p < .09$). Follow-up two-tailed *t*-tests showed a significant ($p < .05$) difference only for neutral messages. As can be seen in Figure 4, contrary to Hypotheses 3a and 3b, emotion did not differentially affect episodic and semantic encoders. Instead, encoding condition affected memory only for neutral ads which showed higher recall under episodic coding.

FIGURE 4
MEAN RECALL PLUS RECOGNITION

Discussion

The most striking aspect of these results is the positive long-term effect of emotional messages on memory. For every dependent variable except free recall of claims, where memory exhibited a floor effect, the emotional messages showed stronger memory than the neutral messages. This finding is in contrast to the popular conception in advertising that emotional ads "don't recall well" (Zielske, 1982), but consistent with recent scientific tests (Choi and Thorson 1983; Thorson and Friestad 1984; Batra 1985).

A second important aspect is the directional support of memory differences as a function of encoding instructions. While the main effect of encoding did not reach statistical significance as often as did message type, the consistency in the direction of the differences make the encoding results worthy of consideration. The fact that episodic encoding consistently showed better memory than semantic encoding lends support to the notion that encoding instructions did lead to differential memory processes. The alteration of this pattern in the judgment tasks adds further credence to the idea that consumers may differentially store information in memory as a function of differing "processing objectives" (Srull, Lichtenstein, and Rothbart 1985).

Finally, there are the findings of interaction between message type and encoding. The only dependent measure that indicated an interaction was the combination measure, Recall Plus Recognition. Here, encoding made no significant difference for emotional messages. However, neutral messages benefited from episodic encoding. Because the encoding effect was weak, interpreting the interaction patterns should await analysis of the data on immediate performance. Nevertheless, some speculation on the delayed performance results are in order. Given that most of the individual recall measures (number of messages recalled, product category, brand name mentions, executional, and claim information) show parallel effects of message type and encoding, the data support the idea that memory trace enhancement from the presence of emotion plays a similar role in both the episodic and the semantic systems. The interaction for Recall Plus Recognition under this interpretation may indicate that when total memory performance is indexed, the enhancing effect of emotion is strong enough to overwhelm encoding effects, and that the advantage of episodic coding can only be observed in neutral messages.

One of the inherent frustrations in the type of research presented here is that the most interesting variables are also those that carry with them significant methodological problems. The limitations of the data reported in this paper are directly tied to: 1) the problems associated with using complex stimuli (commercials), and 2) the difficulty of effectively manipulating the thought processes of individuals (encoding instructions). For example, it is not possible to "know" in a completely objective sense if emotion was the critical difference between the two sets of messages. Nevertheless, the steps taken to control for some of the more likely confounding variables (e.g., familiarity), the use of multiple messages, and the variation in products and executional styles help to address this problem.

Further, the difficulty of determining processing strategies of individuals is a problem for all researchers interested in cognition. In the data presented here, it cannot be unequivocally claimed that the manipulation was successful. With more effective control over strategies and without the immediate testing condition, the differences as a function of encoding condition might have been stronger. It is likely that the short-term performance data will help to clarify this issue.

In general, the long-term delay in this study created a difficult test of the episodic-semantic encoding distinction and the effects of viewer emotion during commercials. After only a single exposure and a long delay, emotional messages nevertheless had a decided advantage over neutral messages. The effects of the episodic-semantic encoding distinction are only suggestive as yet, but they point toward a model of processing that has potential significance to students of consumer behavior.

THE GENERATION EFFECT IN ADVERTISING APPEALS

David J. Moore, University of Oklahoma
Richard Reardon, University of Oklahoma
Francis T. Durso, University of Oklahoma

Abstract

When subjects are allowed to generate for themselves semantic responses to experimental stimuli (internally-generated information), memory performance is often better than if they are allowed to be mere passive recipients of the information (externally-presented information). This paper reviews the current research related to this "generation effect", and presents the findings of two experiments. The first demonstrates the role of the degree of elaboration of semantic networks in facilitating a generation effect. The second, using radio broadcast materials, confirms that the generation effect can also be produced in an advertising context. Implications for marketing researchers and directions for future research are discussed.

A large body of recent research in cognitive psychology has demonstrated that retention of experimental verbal material may be more significantly enhanced when subjects are allowed to be active cognitive participants in the learning process rather than mere passive recipients of the experimental stimuli (e.g., Jacoby 1978; Slamecka & Graf 1978; Tyler, Hertel, McCallum, & Ellis 1979). In other words, memory tends to be better when subjects are forced to engage in a greater degree of thinking in order to generate a response to an experimental stimulus or problem (internally-generated information) than when those same subjects are presented all the answers/solutions by the experimenter (externally-presented information). We believe that this phenomenon has significant implications for research involving memory for advertising materials.

Most of the current literature in advertising has focused on memory for perceptual events derived from externally-presented stimuli, ignoring the potential influence of internally-generated information (Edell & Staelin 1983; Kisielius & Sternthal 1984; Saegert 1978; Saegert & Young 1982). There have been a few attempts to examine the role of internal generation on the memorability of advertising stimuli. For example, Heimbach and Jacoby (1969) found better recall of incomplete versions of TV ads compared to complete versions. MacLachlan and Janan (1984) reported better memory for ads that were incomplete or preceded by question prompts. However, there has been an obvious lack of a unified theoretical framework which could give guidance to this area of research. Information processing interpretations (e.g., Craik & Lockhart 1972) are intermingled with drive reduction explanations (e.g., Berlyne 1965; Zeigarnik 1927).

More attention should perhaps be paid to the growing body of research in cognitive psychology that relates to specific, testable issues concerning cognitive generation and memory. A consideration of this literature may provide a basic-process oriented theoretical framework which is more useful in directing the applied research in advertising and marketing communications. For example, a recent line of research in cognitive psychology on the "generation effect" (Slamecka & Graf 1978) may have something very compelling to say about the basic processes underlying cognitive generation.

This paper will review the current research related to the generation effect and then present the results of two experiments. The first demonstrates some of the conditions under which the generation effect is likely to occur. The second demonstrates the generalizability of the generation effect to a broadcast advertising context. The paper concludes with a discussion of the implications

for advertising researchers and practitioners, and directions for future research.

The Generation Effect

The generation effect refers to the greater memorability of internally-generated versus externally-presented stimuli. Slamecka and Graf (1978) conducted a series of experiments with the following basic paradigm. Subjects were presented with a number of complete and incomplete word pairs. Their task was to read the complete pairs, and to read the first word and covertly generate the second word of the incomplete pairs. The complete pairings constituted the externally-presented conditions; the incomplete pairings, the internally-generated conditions. In an external-presentation condition, for example, subjects would read both the stimulus word "rapid," and the response word "fast." In an internal-generation condition, subjects would be shown the word "rapid," but would have to generate the response word given only a first letter cue, "f_____." The generation effect was found with several different encoding rules (e.g., the pairs were synonyms, antonyms, homonyms, and so forth), and, of course, with appropriate counterbalancing of materials across conditions. Free recall and recognition confidence performance were better for the internally-generated words than for the externally-presented words.

Slamecka and colleagues turned to a consideration of possible theoretical explanations for the phenomenon. Several experiments implicated the involvement of semantic memory. McElroy and Slamecka (1982) noted that the effect was not found when subjects generated nonwords. Graf (1982) found the effect for completions of meaningful sentences but not for completions of anomalous sentences. Slamecka and Fevreski (1983) demonstrated that the activation of the correct semantic network that presumably occurs when subjects attempt to generate the correct word, even if they fail to actually generate it, is sufficient for subjects to better remember the correct word compared to a word they read. Additionally, Slamecka and Fevreski looked at incorrect generations and found that the more semantically related the error to the desired correct response, the larger the generation effect. Gardiner and Rowley (1984) have neatly concluded that "any type of item may give rise to the generation effect provided that it activates some existing representation in some knowledge system in semantic memory" (p. 445).

We turn now to a presentation of our experiments. For the first, a more complete account was presented in a recent professional symposium (Reardon & McGahan 1985). However, we felt it important to give a summary here because it confirms the importance of semantics, specifically from the perspective of degree of elaboration of semantic networks, in facilitating a generation effect. In the second, we attempted to extend the generation effect to an advertising message retention problem.

Experiment 1

If, as Slamecka and colleagues have argued, the generation effect rests on the reliance on semantic features compared with surface features, it should have important implications for memory differences between experts and novices. This, in turn, may be an important consideration in advertising communications because expertise defines a dimension on which consumers vary with respect to products (Conover 1981; Marks & Olson 1981). Some

consumers are familiar and involved with a particular class of products, or with a societal problem or need which the class of products proposes to meet. Others are not so familiar. Research on expertise has shown that such differences can be considered in terms of the degree of elaboration of semantic networks in memory.

Experts differ from novices in having a larger knowledge base in the area of expertise that benefits from an efficient chunking of smaller units into larger units based on the meaningful relations among the smaller units (Charness 1976; Chase & Simon 1973; Egan & Schwartz 1979; Newell & Simon 1972). Additionally, the units for experts are connected extensively, and often redundantly, with other units in the domain (Anderson 1976; Hayes-Roth 1977). Experts organize domain-relevant stimuli conceptually, at a deeper more abstract level, whereas novices organize domain-relevant stimuli using surface or syntactic features (Adelson 1981; Chase & Ericsson 1981; Chi, Feltovich, & Glaser 1981). The rich knowledge base of the experts together with the reliance of novices on surface features leads to the expectation that the generation effect should be attenuated for novices in general, and for experts outside of their area of expertise.

One of the primary purposes of Experiment 1 (Reardon & McGahan 1985) was to examine the proposed relationship between the generation effect and expertise. Experts (22 psychology faculty and advanced graduate students) and novices (22 junior-senior level psychology majors; the male-female ratio was the same for both experts and novices) engaged in a task requiring them to generate some words and read others (e.g., Durso, Reardon, & Jolly 1985; Johnson, Raye, & Durso 1980). They saw or generated words in a domain for which only one group was expert (psychology: domain-relevant) and words in a domain for which both groups were comparable (sports/leisure: domain-irrelevant). Recognition memory was then tested by asking subjects to identify words as ones they had read, ones they had generated, or as ones new to the experiment (Johnson & Raye 1981). We expected differences in the magnitude of the generation affect only with materials for which the groups differed in expertise.

Our results showed that superior memory for internally-generated events relative to externally-presented events was greatest for experts dealing with events from their area of expertise (i.e., the critical test, the internal/external source x domain x expert/novice interaction, was significant, $F(1,42)=4.47, p < .05$). Thus, the expectation that experts would show a large generation effect, but only in their area of expertise was confirmed.

Consistent with Slamecka and Fevreski's (1982) contention, experts, who tend to process domain-relevant information semantically, showed a strong generation effect relative to novices, who tend to rely more heavily on surface features. The mechanism underlying the generation effect may be that richly interconnected networks provide multiple access routes to the to-be-retrieved concept. These access routes are needed in order to generate the word initially, but they are not important when the subject simply reads the word presented by the experimenter. The fact that experts and novices differed little in their recognition of externally-presented psychology terms supports the idea that the expertise advantage in memory lies in the experts' ability to utilize the rich knowledge structure. When this knowledge structure is not brought to bear, as when subjects read a terminal word, the expertise advantage is not found.

What do these results suggest for advertising communications? Simply that the generation effect is most likely to occur when the stimulus materials (e.g., an advertising appeal) activate a rich semantic network/knowledge base. That is, a generation effect may occur only when consumers are involved/familiar with a product area and the class of products designed to address that area. Only then can cognitive generation tap, and thus take advantage of an extensive, redundantly connected network.

In the experiment below, we attempted to extend the above findings and theoretical discussion to a commercial message retention problem.

Experiment 2

Method

Subjects. Subjects were 62 undergraduate business administration students who participated for course extra-credit.

Procedure. A sugar-free high-nutritional soft drink was selected as the target product. Informal discussions conducted with other groups of subjects from the same population had revealed that soft drinks were frequently consumed by our population, and that the ingredients of these drinks were often of concern. The product was positioned as a new brand of soft drink just being introduced to the market. A fictitious brand name, Prime Time, was chosen in order to minimize any experimental complications caused by varying degrees of prior familiarity with well-known brands.

In order to minimize possible sources of reactivity within the design and prevent any artificial set to respond unnaturally to the stimulus, the target ad was embedded within a 15 minute excerpt of radio broadcast material containing 10 other advertisements and several songs. The broadcast material (which actually could have been presented on the air) was taped and appropriately edited in the studio of a local radio station, and the target ad was read by a professional radio announcer. Subjects were led to believe that the material was taken directly from a radio broadcast. The target ad itself (almost 70 seconds long) was designed so that the copy was delivered with the same cadence and inflection as many radio ads that use mock "news bulletin" formats. It stressed the following points: (1) Recent findings of medical science have shown that a high intake of sugar (usually found in soft drinks) reduces the body's ability to fight disease. (2) In response to the health needs of consumers, General Foods has developed Prime Time, a new, delicious, sugarless soft drink sweetened with aspartane. (3) Prime Time is fortified with vitamin B complex and vitamin C to help build resistance to disease and infections.

Scripts for both versions of the ad were essentially identical, with the product name being mentioned four times during the course of the ad. The manipulation of the independent variable occurred at the end of the ad. In the external-generation condition, the ad ended with an overt mention of the target product brand name. For the internal-generation condition, the end of the ad was structured so that subjects would covertly generate the brand name. This version ended with the words "Hey, what was the name of that new soft drink again....?"

Two days after the experimental exposure, subjects were surprised with a delayed recognition test. They were presented with a list of 13 brand names. Included in this list, and randomly ordered, were 7 of the brand names heard on the tape, 5 new brand names (foils) that were similar to the names heard, but which were not in fact on the tape, and the target brand name, Prime Time. Using a scale from 1 (not confident at all) to 7 (extremely confident), subjects were asked to indicate the degree to which they were confident that a given brand name was one that was mentioned on the tape they heard. Finally, to confirm the degree of semantic memory engagement, and to ensure that this engagement was comparable for both conditions, subjects were asked to respond to 8 items that assessed their interest and knowledge of health, nutrition, and concern with product ingredients (e.g., frequency of exercise, regularity of vitamin consumption, "junk" food habits, frequency of keeping up with nutritional news, etc.). Subjects responded to these items on 7-point scales, where higher numbers indicated greater familiarity/involvement.

Results and Discussion

Mean recognition confidence for the target product for the external-presentation group was 3.83; for the internal-generation group it was 6.25. These means were significantly different $t(60)=4.42$, $p < .0001$. In contrast, mean confidence responses of the two groups to other products that actually appeared in ads on the tape did not significantly differ (external-presentation: 4.17; internal-generation: 4.74). An examination of false positive responding, i.e., recognition confidence that the foils appeared on the tape, was undertaken to test for a possible recognition response bias on the part of either group. If anything, there was a slightly greater tendency on the part of the external-presentation group to indicate greater confidence that a foil was on the tape, but the difference between groups was not significant (external-presentation: 2.45; internal-generation: 1.96). The recognition confidence results must be considered in light of our postexperimental checks on subject familiarity/involvement. These measures confirmed that our subjects were, in fact, reasonably well-informed and concerned about health and the nutritional value of the foods they consume (both groups' mean scores on these items were above the midpoint of the 7-point scale in the direction of greater familiarity/involvement; external-presentation group: 4.21; internal-generation group: 4.02). Importantly, there were no differences in involvement/familiarity between the two groups. As a precaution, the measures of involvement/familiarity were covaried (individually, and as a sum) from the target recognition scores. The difference between groups remained significant (all $F_s > 15.00$ with 1 and 59 df), and none of the covariates reached significance (all $F_s < 1.00$).

One concern applied researchers have had with basic research in cognitive psychology is that it is conducted in artificial settings with socially impoverished stimuli (cf, Taylor 1981). Therefore, the generalizability of effects produced there are sometimes suspect until they are demonstrated in more ecologically valid settings. In the case of our study, we were able to replicate a finding in basic cognitive psychological research with "real world" materials in an applied context. We took two groups of relatively involved and aware subjects, and with broadcast advertising stimuli, produced a generation effect in the condition in which one was expected with no effect in the other condition. Experiment 2 is, of course, preliminary. By choosing a stimulus domain in which all of our subjects were fairly familiar, we could not test adequately the familiarity/involvement dimension. One should also be cautious about a result that is based on a single ad. We are currently planning more comprehensive tests of the generation effect in the marketing-advertising domain that involve a more systematic manipulation of generation and involvement/familiarity across a number of different types and modes of advertising presentations. Nonetheless, Experiment 2 opened the door on this research direction for us, and hopefully for others in marketing and advertising research who may share our interests.

General Discussion

What does the generation effect literature offer to marketing researchers and practitioners? At a concrete level, it suggests a technique for getting people to better remember certain aspects of an advertising appeal (e.g., brand name). There are boundary conditions on this, however. The audience should have a reasonably extensive knowledge base/semantic network which can be activated by the generation process.

The generation effect literature, at a more general level, offers something important that goes beyond a simple, concrete advertising technique. For example, the theoretical underpinnings associated with the generation effect may contribute something unique to recent studies in persuasive communications based on cognitive response/cognitive structure models (e.g., Olson, & Dover 1982;

Wright 1973; among others). These models have been used to explain how the message recipient's cognitive responses (defined as subvocal spontaneous thoughts generated during exposure to a persuasive message) mediate subsequent attitudinal and behavioral responses. The generation effect posits that elaborate knowledge bases/semantic networks are activated by the generation process. These networks are made up of meanings, relations, rules, images, and so on, but also include evaluative/emotional states and reactions. The generation effect is simply a manifestation of an activation of a semantic network. The cognitive response models may involve the same basic process.

The most extensive model of persuasion that includes cognitive response components is Petty and Cacioppo's (1983) Elaboration Likelihood Model (ELM). Nevertheless, Petty and Cacioppo (1985) admit that the ELM is a particularly simple and general framework, which does not "ultimately indicate why certain variables affect information processing" (p. 86). The generation effect phenomenon can conceivably provide a basic process explanation for that aspect of the ELM that deals with self-generated responses to persuasive appeals. To a limited extent, both the ELM and the generation effect make similar predictions concerning the message recipient's responses to various experimental stimuli. For example, according to the generation effect literature, internal generation leads to better memory performance when the person making the generation is equipped with a rich knowledge base for which the generation is relevant. Similarly, it may be inferred from the ELM that when the motivation and ability to respond to a message is high (as, for example, when a subject has high prior knowledge of or familiarity with the attitude issue) message elements may become more salient in memory, leading to better memory performance. Indeed, Cacioppo, Harkins & Petty (1981) have demonstrated that the advantage of self-generation over passive reception in persuasion settings is more pronounced when message recipients possess some prior knowledge base concerning a given topic, or are equipped with some relevant schema.

Future research will have to be directed toward a confirmation of the linkage of the generation effect to other cognitive response/cognitive activity models. Certain conceptual issues and consistency of terminology will have to be addressed if the two research areas are to be linked successfully. For instance, cognitive response researchers typically make a distinction between memory (defined as recall or recognition of message elements) and cognitive responses (Petty, Ostrom, & Brock 1981). Cognitive psychologists, as we have seen, make no such distinction. For them, message elements and generations are both memorial, but they have different sources (external versus internal; Johnson & Raye 1981; Slamecka & Graf 1978). We think the latter formulation is the more useful, particularly in helping provide a link between marketing research and current thinking in cognitive psychology.

Finally, it might be interesting to establish a linkage with the reality monitoring literature (Johnson & Raye 1981). Reality monitoring deals with the confusions people tend to make between internal and external sources of memories. Johnson and Raye (1981) have demonstrated that individuals make surprisingly many of these confusions. That people often confuse what they think with what they hear and see may have important implications for research on persuasive appeals.

THE IMPACT OF COMPARATIVE ADVERTISING ON PERCEPTION
FORMATION IN NEW PRODUCT INTRODUCTIONS

Beth A. Walker, The Pennsylvania State University

Arno J. Rethans, The Pennsylvania State University

Abstract

The applicability of categorization theory for assessing the effects of comparative advertising is discussed in light of Gorn and Weinberg's (1984) results. Findings of an exploratory study are presented to illustrate the associative and differentiating properties of comparative advertising.

Introduction

Advertisers are making increasing use of comparative advertising in which reference is made to a named or recognizably presented competitor. Concomitant with this use is an increasing number of empirical studies attempting to assess the effectiveness of comparative advertising, particularly in terms of the differential effects of comparative versus noncomparative communications

The majority of these studies suggests that comparative advertising is no more effective than traditional advertising when it comes to believability (Boddewyn and Marton 1978; Prasad 1976; Wilson 1976; Wilson and Mudderrisoglu 1979), recall (Jain and Hackleman 1978), attitude toward the product (Belch 1981; Goodwin and Etgar 1980), purchase intentions (Golden 1976), and actual behavior (Swinyard 1981). In some instances, in fact, comparative advertising was less effective than traditional advertising (Levine 1976; Shimp and Dyer 1978).

A recent study by Gorn and Weinberg (1984, 1983), however, does provide some support for the continued use of comparative advertising. They suggest that the purpose of most comparative advertising is a reduction in the psychological distance between a challenger and the brand leader. Accordingly, the authors focused on perception formation as the critical dependent variable in their relative effectiveness test. It was found that comparative magazine advertising did significantly increase perceived brand leader-challenger similarity as well as the perceived similarity between all brands in a product class. Given these initial and encouraging findings, the authors called for more research focusing on the effectiveness of comparative advertising on perception formation.

In this paper we extend the Gorn and Weinberg effort by suggesting a theoretical framework for their approach and by illustrating this framework within the context of a study on consumer reaction to comparative television launching commercials for a regional premium beer. Specifically, we propose the use of categorization theory as a framework for analyzing the differential effects of comparative advertising.

Review of Literature

The communication effectiveness of comparative advertising has been an issue ever since the Federal Trade Commission encouraged advertisers to name competing brands as an alternative to the then more prevalent "brand X" euphemism (Cohen 1976). Wilkie and Farris (1975) proposed that such comparative advertising should be more effective than more traditional advertising in generating increased attention and recall, increased comprehension of claims, and greater yielding to claims. Of the studies investigating the relative effectiveness of comparative advertising, most were not supportive of these initial propositions. Comparative advertisements were often perceived as more confusing, less believable, and no more persuasive than noncomparative advertisements (Belch 1981; Shimp and Dyer 1978; Swinyard 1981).

More positive findings, however, were recently reported by Gorn and Weinberg (1984, 1983), who tested the relative effectiveness of comparative advertising by focusing on perception-related dependent variables. These authors argue that, in practice, comparative advertising is usually started by a challenger with the objective of placing the challenger in the same league as the brand leader in the mind of the consumer. A favorable result, then, for the challenger's comparative ads would be a reduction in the perceived psychological distance between the two brands.

In their study, Gorn and Weinberg focused on perceived challenger-leader brand similarity as the dominant dependent variable. They manipulated type of ad by the challenger (comparative, noncomparative), context (leader ad present, leader ad absent) and product category (cigarettes, golf balls, toothpastes). They found that greater perceived challenger-leader similarity was obtained with comparative advertising than with noncomparative advertising across the three product categories. Type of ad, however, did not affect attitude toward the product, a finding similar to previous research results. This latter result led these researchers to speculate that attitude may not be the most sensitive dependent measure and that longer term exposure might be necessary to affect attitude since attitude is a higher order response. Cognitive response data did not illuminate possible underlying processes which might have shaped and determined these results. As a result, Gorn and Weinberg called for more theoretical and empirical research on perceived challenger-leader similarity as an indicator of comparative advertising's effectiveness.

One promising theoretical framework for the analysis of perceived brand similarity focuses on the cognitive processes of categorization and prototyping (Rosch 1975, 1978). Casual observation as well as recent research attest to the pervasive human tendency to categorize both objects and persons into groups, types and other categories so that non-identical stimuli can be treated as if they were equivalent (Cantor and Mischel 1979; Rosch, Mervin, Gray, Johnson and Boyes-Braem 1976). Categorization simplifies the individual's processing task of the potentially overwhelming number of stimuli in the environment. Research further indicates that knowledge in a given category is internally structured around a typical (i.e., exemplar) or ideal instance (i.e., prototype) which captures the meaning of the category (Cantor, Mischel and Schwartz 1982). Categorization of a new stimulus under this perspective is accomplished by a prototype-matching process and is a function of the degree of similarity between the new stimulus and the category exemplar or prototype. In this way, categorization influences the processes of attention, integration, storage and retrieval of information.¹

The potential usefulness of the categorization perspective in examining consumer reaction to marketing stimuli was recently demonstrated by Sujana (1985). The results of her study suggest that category-based expectations guide

¹The issue of whether individuals perceive categories based on exemplars or based on prototypes has been debated in the categorization literature (Cantor and Mischel 1979; Medin and Smith 1984). For our purposes, no strong distinction is made between these two approaches. Rather we follow Elio and Anderson (1981) and assume that either the exemplar or the prototype or both provide the consumer with a set of expectations (cf. Sujana 1985).

consumer evaluation processes. In particular, her research suggests that consumers have well-defined categories stored in memory which enable them to perceive and evaluate new products. When applied to an analysis of comparative advertising, Sujan's findings suggest that by making reference to particular comparison brands, the consumer may categorize the new brand as an example of this category and retrieve the affect associated with the activated category. As a result, the categorization perspective is viewed as an interesting paradigm for understanding comparative advertising effects.

Study Hypotheses

The primary objective of the current study was to explore the impact of comparative television advertising on consumer perceptions of a new entry into a product category. Specifically, the goal of the advertising campaign to be reviewed here was to associate a new brand of beer with the leading prototypes in the premium beer segment.² Cast within the categorization framework this campaign goal translates into the following hypotheses:

H1a: Perceived similarity between the new entry and prototype brands will be greater with exposure to a comparative (vs. noncomparative) television commercial.

H1b: Perceived dissimilarity between the new entry and non-prototype brands will be greater with exposure to a comparative (vs. noncomparative) television commercial.

Study Methodology

Experimental Design and Procedure

The part of a larger experimental study examined here can best be represented as a simple two-group comparison of comparative versus noncomparative advertising. The larger study was designed to measure the effectiveness of various types of launching commercials for a new regional premium beer. Since the study was conducted before the actual introduction of the new brand, it permitted a "clean" assessment of comparative advertising's impact, free of the confounding effect of prior brand knowledge.

Upon arrival at the test site, pre-screened subjects were led to a television viewing room ostensibly to evaluate different types of news programming. Subjects were told that they would watch some news programming for about thirty minutes and would be asked some questions following the presentation. In addition, they were informed that the programming would be interrupted periodically so that they could report their thoughts, ideas, and opinions on the segment preceding the interruptions. To overcome the potential inadequacies of the single message exposure noted by Gorn and Weinberg (1984), the experimental commercial was embedded three times within the total news programming effort. Following the television programming subjects responded to the dependent variable measures contained in a questionnaire booklet and then were debriefed and paid.

Experimental Stimuli

Professionally produced 30-second television launching commercials for a new regional premium beer were used as the experimental stimuli in this study. The comparative version of the ad featured implicit comparisons between the new brand and three well known premium brands. In the opening and closing scenes of the ad, the three competitor brand bottles were shown turning and transforming into three bottles of the new beer. These visual comparative cues were accompanied by an audio track stating "Now there is a beer with a taste that will turn you around." To provide a reference point for judging the effects of the comparative ad, a second introductory ad was used. This

²The comparison brands contained desirable or positive features. Therefore, the objective of the comparative advertisement was association rather than differentiation.

"noncomparative" version of the ad, opened with a scene of a glass blower creating a new bottle in his 19th century shop conveying a sense of tradition and quality, followed by close-up shots of the new beer's bottle and label.

The use of actual, professionally developed television commercials precluded the manipulation of the comparative cues exclusively. We recognize that the inability to manipulate the presence or absence of the comparative cues reduces the internal validity of the study results. Additional data collection measures were therefore taken to address alternative explanations.

Dependent Variables

The categorization approach to an association and differentiation strategy of comparative advertising suggested the need for a careful definition of the prototypes against which the new product was to be compared. Discussion with the client's advertising agency personnel revealed that Budweiser, Stroh's, and Miller were perceived to be the relevant exemplars for the new premium beer. A focus group conducted with members of current research population confirmed this belief. Further, the three most frequently mentioned brands constituting the super premium beer category were Michelob, Heineken and Lowenbrau. Accordingly, semantic differential scales employing the anchor points of "low similarity" and "high similarity" were used to measure similarities to each of the premium and super-premium beers. A similarity and dissimilarity score for each category was then derived by averaging responses on the three respective scales.

The cognitive responses reported during the programming and after the test commercials were coded so as to assess the frequency of responses that were comparative in nature.

Subjects

To ensure a minimum ability to categorize beer-related stimuli, study participants were pre-screened for their level of knowledge and experience with the product category of interest. Based on responses to a pre-screening questionnaire covering usage patterns for a variety of product and media habits, non-beer drinkers were excluded from the study. A total of forty student volunteers at a major Northeastern university participated in the study and were paid \$5.00 for their participation.

Results

Perceived Brand Similarity

Subjects exposed to the comparative advertisement perceived the new beer brand to be more similar to premium beers than did subjects exposed to the noncomparative advertisement (4.25 vs. 3.78). Although these means were in the predicted direction, their difference was not statistically significant, ($F(1,38) = 1.13, p = .29$). As predicted, however, similarity to super-premium beers was significantly affected ($F(1,38) = 4.63, p < .03$). Subjects in the comparative advertisement condition perceived the new brand to be less similar to the super-premium brands (2.90 vs. 4.10).

One alternative explanation to the above interpretation of the findings is based on the nonequivalence of the information in the two ads. Because the visual and audio contents of the treatment advertisements were not identical (i.e., beyond the presence or absence of the comparative cue), it is not possible to definitively attribute the brand perception findings exclusively to the brand comparison cues. Hence, to provide more evidence that the visual comparative cues affected consumer's ad processing, additional analyses were performed.

First, to determine if the perception results were influenced by the general visual portion of the advertisement, a control group receiving the audio portion of the ad was conducted. The "radio commercial" was embedded in a news programming environment similar to that experienced by our

treatment groups. Thus, the comparative television commercial (comparative visual cues, other visual cues and audio cues) was compared to a radio ad (audio only, in which the brand comparison was not mentioned). It was hypothesized that exposure to the television (vs. radio) commercial would result in greater perceived similarity between the new brand and premium brands, and less similarity to super-premium brands. As predicted, a significant effort on similarity to premium beer brands ($F(1,38) = 4.75, p < .04$) was observed. Subjects viewing the television advertisement perceived the new beer brand to be more similar to premium beer brands than subjects in the radio condition (4.25 vs. 3.37) (1=low, 7=high similarity). For the super premium category index, the means were in the expected direction, although the difference was not statistically significant ($F(1,38) = 1.65, p=.21$). An examination of the three super premium brands separately revealed significant differences in similarity with Heineken (2.45 (tv) vs. 3.65 (radio), $F(1,38) = 3.76, p=.06$) and Lowenbrau (2.55 (tv) vs. 3.75 (radio), $F(1,38) = 3.24, p=.08$), but not for Michelob (3.80 (tv) vs. 3.60 (radio), $F(1,38) = 0.10, p=.75$). These results suggest that the effects on perceived similarity are attributable to some visual cue(s). Unfortunately, we cannot discern from this analysis if the effects are due specifically to the comparative visual cues.

Secondly, to more clearly identify the role of the comparative visual cues, cognitive responses were analyzed to assess whether the comparative cues captured the viewers' attention. The responses were examined for explicit references to the comparative nature of the premium beer brands. Seventy-five percent of the subjects who viewed the comparative television advertisement reported at least one comparative cognitive response. Only 10% of the subjects in the noncomparative treatment condition recorded one or more comparative thoughts. In combination, these results increase our confidence that the visual comparative cues affected the categorization of the new brand. We recognize that due to the confounding visual cues, however, the effect of the comparative cues cannot be unambiguously determined. Further research is needed to determine specifically whether the surrounding visual cues hindered or enhanced the impact of the comparative visual cues on perception formation.

Discussion and Future Research

In this paper we proposed the potential usefulness of categorization perspective for the analysis of the impact of comparative advertising on perception formation in new product introductions. In such situations, the objective of the attending advertising campaign frequently is to position the new entry in the same league as a named or recognizably presented competitor in the mind of the consumer (Prasad 1976). Under these conditions, the prototype-matching processes suggested by the categorization approach forms an appealing explanation for consumer reactions to this type of advertising.

A study using launching commercials for a new regional premium beer was used as an initial exploration of the proposed categorization framework. In contrast to many earlier studies, the comparisons of the new brand in this study were implicit rather than explicit and involved multiple comparison brands rather than a single market leader brand. The data were found to be generally consistent with the proposed framework and suggest that further tests of the theory are warranted.

Several interesting research areas are highlighted. Comparative advertising has been shown to reduce the psychological distance between the sponsored brand and the brand to which it is compared. What psychological distance are we talking about? What is the nature of this distance? That is, what specific beliefs may be affected? In a challenger/leader comparison, two different psychological processes may result depending on the extent of information evoked by the market leader. If the brand leader is processed as an individual brand not associated with a category, the reduction of psychological distance may be

with respect to the challenger brand and the particular brand leader. If the brand leader is processed as a category exemplar or prototype, however, the reduction in psychological distance is more likely to be between the challenger brand and a product category. The specific beliefs that are generalized to the challenger brand may depend on which type of processing is evoked.

If the psychological distance is reduced between the challenger brand and the leader as processed on an individual brand basis, the features and attributes associated with that particular brand will be generalized to the challenger. If the psychological distance is reduced between the challenger and a product category, the beliefs associated with the product category will be associated with the new brand. The extent to which specific brand beliefs differ from beliefs associated with a product category will determine how differently the new challenger brand will be perceived by the consumer depending on the resulting process. For example, a new car may be compared to a Mercedes Benz. If Mercedes Benz is processed as an individual brand and not as a representative of a "luxury car" product class, the new car may be perceived as an import with high quality, handling, and durability. If the Mercedes Benz is processed as a prototype of the product class luxury cars, however, the new car may be perceived as big, comfortable, smooth ride, and as a gas guzzler. The beliefs associated with the new car would depend on how the comparison brand is processed. The set of beliefs that the advertiser wants to create for the new brand would determine the most appropriate prototype or exemplar selected for comparison.

A second issue concerns the use of multiple brand comparison ads. What is the effect when a challenger is compared to more than one other brand? The consistency/inconsistency within the group of comparison brands may affect the consumer's processing and resulting perceptions of the challenger or sponsored brand. A consistent comparison set is defined here as one that is internally homogeneous and congruent with a consumer's ideas regarding category membership. An inconsistent comparison set is less homogeneous among themselves, but is still representative of the product class category. If the category set of comparison brands is consistent, category based processing is likely to result. The beliefs associated with the new brand will be that of the category. In contrast, if the set of comparison brands is inconsistent, piecemeal processing may result. For example, if a multiple brand comparison group included Heineken, Lowenbrau, and Budweiser, the beliefs about the sponsored brand are not likely to be the result of category based processing but are determined on a piecemeal basis. The reduction of psychological distance that occurs may only be belief specific depending on the degree of inconsistency. If the brands overlap on one attribute, that attribute may be transferred to the challenger brand.

The consistency/inconsistency of the multiple brand category may also mediate the influence of the comparative ad on attitude towards the new brand. If the category is consistent, category based processing may result and the affect associated with that category may be transferred to the challenger brand (cf. Sujan 1985). If the category is inconsistent, piecemeal processing may result. Therefore, attitude towards the new brand may be specific to the processed features or attributes of the comparison brands. The impact of ad type on attitude may also depend on the valence of the attitude toward the activated category. If the attitude towards the category is strongly positive or negative, we may be more likely to see a comparative ad effect on brand attitude than if the subject had a neutral initial attitude toward the category. The effects of consistent/inconsistent categories assumes a certain level of consumer knowledgeability about the advertised product class. It is the consumer who judges the heterogeneity of a product class as well as the consistency of the sub-category is within it. Consumer knowledgeability, then, also may play a role in mediating the impact of comparative advertising.

The third issue concerns several of Gorn and Weinberg's findings regarding psychological distance reduction and the categorization framework. Specifically, Gorn and Weinberg (1984) asked subjects to rate the similarity of the challenger/leader brands. Higher similarity responses were reported by subjects in the comparative (vs. noncomparative) ad conditions. This reduction in psychological distance is consistent with the categorization framework. Subjects were also asked to rate the similarity between two fictitious brands of the same product class (i.e., golfballs, cigarettes, toothpaste) as well as between two brands for unadvertised product categories (i.e., cola and deodorants). One issue is whether exposure to a series of comparative ads leads consumers to view the entire product class as more homogeneous. Secondly, whether this comparative advertisement exposure effect generalizes to perceptions of other unadvertised product classes. Higher similarity responses were reported between the two fictitious brands by subjects in the comparative (vs. noncomparative) ad conditions. It is difficult to explain why two new hypothetical brands would be seen as more similar following comparative ad exposures. Perhaps the comparative advertisement focused attention on the homogeneity of the entire product class rather than on distinctive sub-categories. Also, the advertised product classes may be perceived as homogeneous instead of as a heterogeneous set of sub-categories. Gorn and Weinberg also demonstrated that this effect generalized for "colas" (i.e., cola brand "A" and cola brand "B") but not for deodorants (i.e., brand "A" roll-on and brand "B" aerosol spray deodorant). Perhaps the question's cue context affected these results by priming or directing the level of categorization. That is, colas were perceived as more similar because they were categorized at a more general or inclusive level (Cantor and Mischel 1979). In contrast, the deodorants were perceived as different because the question distinguished the form of the deodorants, forcing categorization at a more specific or exclusive level. If a comparison between diet cola A and caffeine-free cola B, and deodorant "A" and deodorant "B" had been used instead, we suspect that Gorn and Weinberg may have found different results.

An interesting pattern of perceived similarity results presented in table two in Gorn and Weinberg's paper may also be explained by the level of categorization at which the brands were processed. In each case, the two fictitious brands were perceived as being more similar to each other than the challenger/leader brands presented in the advertisement. Respondents had no information about the two fictitious brands besides very general product category information. At the product category level, then, these brands were perceived as similar to each other. Subjects had much more specific information about the challenger and leader brands. The two brands are likely to be similar on some aspects but different on others. This more specific information probably served to differentiate the brands. Consequently, categorization occurred at a more specific level and these brands were perceived as less similar to each other than the fictitious brands.

One important issue underlying this discussion and research is that the accurate determination of the exemplars or prototype that represent a category is essential to assess the impact of comparative advertising in association and differentiation between brand categories. This issue became clear to us when analyzing the data for the super premium brands of beer. Identifying the bases that consumer's use for representing categories (i.e., prototype matching, exemplars, mixed models) is difficult and has not been resolved in the categorization literature. The particular bases used to represent a category, however, may influence the selection of prototypes or exemplars used in the similarity/dissimilarity measures. In this research we used focus group interviews to determine the representative brands in a category. In future research multidimensional scaling techniques and/or clustering (Cantor and Mischel 1979) may be used to more accurately determine consumers' category structure.

THE QUINTESSENTIAL SNACK FOOD:
MEASUREMENT OF PRODUCT PROTOTYPES¹

James Ward, University of Minnesota
Barbara Loken, University of Minnesota

Abstract

A laboratory study was conducted to assess the applicability of family resemblance and prototypicality measures developed by Rosch and Mervis (1975) to product categories. Free recall category member listings, family resemblance scores, and mean prototypicality ratings were rank-ordered and correlated for 16 snack foods and 16 brands of shampoo. Snack food, but not shampoo, data were consistent with earlier findings in categorization research. Possible explanations for these differences, including the level of category abstraction and the use of a visual stimulus, are discussed.

Introduction

The growing prominence in the marketplace of generic products, private labels, and "me-too" products may be one factor which has prompted recent attention to the effects of product typicality and similarity on consumer behavior. Nedungadi and Hutchinson (1984), Troye (1984), Howard (1983), Cohen (1982), and Hirschman (1981) have discussed the effects of "typicality" on issues ranging from the composition of the awareness set to strategic planning. But an important issue that has not been addressed in the consumer behavior literature is what underlying factors determine whether a product is judged more or less typical of a product category.

According to Rosch and Mervis (1975), objects within natural categories vary in their typicality because they vary in their degree of family resemblance to one another. Rosch defines the degree of a category member's family resemblance to other category members as the degree to which it has attributes in common with the other members. More typical category members have a greater degree of family resemblance, i.e. have more attributes characteristic of other members of the category. Around this core of prototypical members radiate less typical items that share progressively fewer characteristics of other category members as the fringes of the category are approached. So typicality effects are a function of the relation of a category member to the attribute structure of a category. Rosch and Mervis (1975) demonstrate that family resemblance scores and independent measures of typicality that do not rely on attribute listings are correlated in the .8 to .9 range for several natural categories.

Purposes

This paper has five purposes: (1) to discuss the implications of the family resemblance structure of categories for several theoretical and applied issues, (2) to address the issue of what factors underlie typicality judgements by demonstrating the graded structure of product categories, (3) to assess the relation of family resemblance scores to such variables as brand awareness and subjects' subjective perceptions of typicality, measured independently of attribute listings, (4) to lay out a practical, efficient methodology for computing family resemblance scores and (5) to discuss some of the problems that may be encountered in attempted applications of the technique.

¹The authors wish to thank Lisa Snyder, Jon Strobel, and Jan Shimanski for their comments and assistance in the study design.

Further insight into how family resemblance is measured and how it relates to the attribute structure of a category can be gained from an example. Suppose a simple category is made up of four products, each of which consumers perceive to have three discrete attributes. The products are ABC, BCD, ADE, and AFG. Note that no single attribute is common to all the products but that each product shares at least one attribute with others. The family resemblance of these products could be computed by setting up the product by attribute matrix shown in Figure 1, checking the attributes each product possesses, and then weighting each shared attribute by the number of products that possess it. Finally, each product's weighted sum of scores is totaled to yield an overall family resemblance score. In this category ABC has the highest family resemblance score and would tend to be rated as most typical of the category. ABC's attributes overlap the more frequently occurring attributes of other category members to a greater degree than any other member's attributes.

FIGURE 1

Example of Family Relevance Score Computation

	Product			
	ABC	BCD	ADE	AFG
Attribute A	(3)*		(3)	(3)
B	(2)	(2)		
C	(2)	(2)		
D		(2)	(2)	
E			(1)	
F				(1)
G				(1)
Family Relevance Score:	7	6	6	5

*Numbers in parentheses represent the scores associated with each attribute, computed by summing the number of products in the set that contain that attribute.

The measurement of family resemblance has a number of very practical marketing implications. A few are discussed below.

Cognitive Effects of Typicality

The measurement of family resemblance might help marketers to understand the effects of typicality on a product's likelihood of entering the consumer's awareness set and from there his or her evoked set. Several cognitive advantages accrue to prototypical members of a category. They come into a consumer's "awareness set" first as category members, and are classified more quickly and accurately than less prototypical stimuli as category members (Rips, Shoben, and Smith, 1973; Mervis and Rosch, 1981). Measuring family resemblance shows which attributes most influence the degree of a product's prototypicality within a category. Given this understanding, products could be designed or repositioned so they would "come to mind" quickly and easily as members of a particular category. Perhaps with this intent, trade associations of both dairy producers and orange growers have attempted to promote milk and orange juice as snack foods good anytime and anywhere, two attributes that our empirical data will show are very typical of snack foods.

Consumers may also use typical products as reference points for the evaluation of other products. Rosch (1975) has shown that in statements of the form "_____ is essentially _____", subjects consistently place more prototypical category members in the latter position. This finding suggests that consumers may use prototypical products as references for evaluating other less typical category members.

Mervis and Pani (1980) have shown that people learn about a category more quickly and accurately if they are initially exposed to more prototypical examples of the category rather than nonrepresentative examples. Furthermore, typical members of a category tend to be learned before atypical members by children (Mervis and Rosch, 1981; Mervis, 1980). These findings suggest that trade associations or marketers who wish to educate consumers about a new product category could introduce consumers to more representative examples of the category first if their goal is to maximize the speed and efficiency of learning.

Strategic Rationales for Typicality

The strategic circumstances that favor designing a more typical product are several. The marketer may wish to facilitate the acceptance of a new type of product in an established category. Family resemblance scores might show that "Taro root" would be more readily categorized as a snack food if the product were designed to have prototypical snack food attributes (e.g. convenient packaging, easy to eat finger food).

If a marketer chooses not to pursue a strategy of product differentiation, the design of a more prototypical product might have certain advantages. A prototypical product might encourage consumers to infer that the attributes of competitors' products also apply to the prototypical product (Mervis and Pani, 1980). Therefore, marketers who wish to compete with larger, better known rivals whose products have a reputation for quality may benefit by designing a prototypical product that maximizes generalization from competitors' products (cf. Peterson 1985).

Awareness Set and Evoked Set

Past marketing studies have explored the effect of typicality on cognitive variables but no past study has assessed what features determine the judged typicality of a product. Nedungadi and Hutchinson (1984) demonstrated the effect of typicality on the salience of a brand in a consumer's awareness set. They found that the prototypicality of a brand of beverages or magazines is significantly related to a brand's order of mention in unaided recall of brands in a designated product category and, furthermore, that prototypicality is related to brand attitudes. Troye (1984) also demonstrated the effect of typicality on the consumer's awareness. However, neither Nedungadi and Hutchinson (1984) nor Troye (1984) empirically assess the perceived attributes of products that underlie and produce their subjects' variations in typicality or brand similarity ratings.

Product Positioning

Howard (1983) has suggested use of Rosch's theory in product positioning. Howard suggests that the concept of a "product hierarchy", a consumer's cognitive picture of a product market, is important for marketers to understand because consumers cognitively position a product by its family resemblance to other products in the hierarchy. The product hierarchy has several uses: (1) It suggests a customer responds to a new and unknown product by matching it to the product it most closely resembles in the hierarchy. This match determines who existing competitors to the product will be. (2) The hierarchy is a means of mapping and identifying market segments. If a customer's ideal product is distant from the prototypical product in a category, a market segment

is suggested. (3) The product hierarchy helps determine whether a product will be perceived as an innovation or not. Howard characterizes the product hierarchy as a very practical concept, but argues that it is not well-measured and that the measurement techniques used by Rosch are not easily adapted to marketing practice. The present study is a step toward assessing the practicality of Rosch's concepts and measures in an applied context.

Study Overview

The purposes of the first empirical study were to (1) test whether product categories have a graded structure that can be measured by family resemblance scores, (2) test the relation of such family resemblance scores to prototypicality ratings and free recall production ranks, and (3) lay out a procedure for computing family resemblances. These purposes are intended to explain and validate an alternative, richer measure of product typicality. Two categories, types of snack foods and brands of shampoo, were used as stimulus categories. These were selected because they differed in their level of abstraction. Snack foods represented a superordinate category of product types, very similar to the natural categories used by Rosch and Mervis (1975). In contrast, brands of shampoo represented a more subordinate category, consisting of a relatively homogeneous set of stimuli. Consumers may focus on product types or brands depending upon the decision they need to make, how their attention is directed by promotions and situational factors. Brands of shampoo were selected to include a representative sample, including both national and private-label brands, both frequently and infrequently-used shampoos. Prototypicality ratings, free recall of products or brands and attribute listings used to compute family resemblance scores were collected for each product category. The data collection procedure is reported below.

Methodology

Overview and Procedure

Snack Foods. Procedures developed previously by Rosch and Mervis (1975) were used, in a laboratory setting, to obtain family resemblance scores and two other measures of prototypicality. The study consisted of three parts. In part 1, subjects were asked to list all the snack foods they could think of, in a free recall format, in the order that they thought of them. Subjects wrote each snack food on a separate line, and up to 20 different types of snack foods could be listed. Subjects were given 1.5 minutes to complete this task. No one gave all 20 responses. In part 2 of the study, subjects completed prototype ratings (described more fully later) for 16 types of snack foods. Subjects were given 20 seconds to complete each rating. Finally, subjects listed the attributes of each snack food to provide the raw data for computation of family resemblance scores.

Shampoos. The same procedures discussed above were used on an independent group of subjects to obtain family resemblance scores, free recall of brand names, and prototypicality ratings for 16 brands of shampoo. Differences between procedures used for shampoo and snack food stimuli were slight, but where appropriate are noted below.

Subjects

Subjects were students in two introductory marketing classes who participated in the study as part of the course. Sample sizes were 66 in the first class, where shampoo stimuli were tested, and 33 in the second class, where snack foods were tested.

Free Recall Category Member Listings

At the start of the experiment, prior to being exposed to individual brands of shampoo or individual snack

food, subjects were asked to list, on a page, "as many brands of shampoo [snack foods] that you can think of, in the order that you think of them." Subsequently for each of the sixteen shampoo stimuli and each of the sixteen snack food stimuli an average rank order of mention was computed from the free recall lists provided by subjects. Production norms for the stimuli were then created by ranking the snack food and shampoo sets from lowest to highest average rank.

Prototypicality Measures

Following Rosch and Mervis (1975), subjects were instructed to rate their perception of the prototypicality of products as shown below. In the case of snack foods (shown in brackets), the instructions varied slightly in that the type of snack food was written on the questionnaire form and a slide of the snack food was not shown.

. . . In this study we would like you to judge how good an example of a product category various brands in [members of] the category are. The brands in [members of] the category will be shown in a picture; you will be told the name of the product category and then shown pictures of some items in category.

. . . Then rate how good an example of the category each brand [food] is on a 0-10 point scale. A 10 means that you feel the picture [food] is a very good example of your idea or image of what the category is; a 0 means you feel the picture [food] fits very poorly with your idea or image of the category (or is not a member at all). A 5 means you feel the picture [food] fits moderately well. Use the other numbers of the 0-10 point scale to indicate intermediate judgments

A brief example was provided for color ("red" vs. less "red") and dog ("German Shepherd" vs. "Pekinese") categories to explain this technique.

Subjects completed prototypicality ratings on 0-10 scales with endpoints "extremely poor example" and "extremely good example". Sixteen brands of shampoo were rated in class 1 and sixteen snack foods were rated in class 2.

Family Resemblance Measures

Each of the 16 snack foods and 16 shampoos were printed at the top of a page. Subjects in class 1 each gave family resemblance attribute listings for one of 4 different sets of 4 shampoos. Each subject in class 2 provided attribute listings for one of two different sets of 8 snack foods. Within each class, all sets of stimuli were counter-balanced to control for order of presentation effects. Instructions (again following Rosch and Mervis, 1975) included the following:

. . . The next part of the project is a simple experiment to find out the characteristics and attributes that people feel various brands (snack foods) possess.

For example, if I asked you to list the characteristics of Tylenol pain reliever, you might list such characteristics as red bottle cap, extra-strength, round bottle, safety-sealed, red and white capsules, acts fast, is expensive, etc.

. . . At the top of the page . . . you will see the first brand [snack food] you should write about, then the next on the second page and so on . . .

At the top of each of the pages intended for listing attributes was the name of the product (snack food, shampoo) and the clause "Attributes or characteristics you think describe this product:".

To compute a measure of family resemblance--the degree to which an object has attributes that overlap those of other category members--for snack foods and shampoos, procedures developed by Rosch and Mervis (1975) were employed. First, all attributes mentioned by one or more subjects for any snack food (or shampoo) were written down on a master list. Second, each snack food (or shampoo) for which that attribute had been listed was credited with having that attribute. Following Rosch and Mervis' instructions, the two researchers deleted cases for which the brand-attribute match was clearly false, and included cases for which a brand-attribute match was clearly true but not mentioned by subjects. No new attributes were added to the master list for snack foods or shampoos (i.e. no attributes not listed by subjects were added). In cases where the two judges disagreed, no brand-attribute match was included. Heavily value-laden attributes were omitted from analyses (e.g. "high quality") since a judgment about which brands should be credited with these attributes would be highly subjective.

Next, each attribute in the master list received a score from 1 to 16, representing the number of types of snack foods (or shampoos) that contained that attribute. Therefore, attributes were weighted by the number of category members that contained them. Finally, to compute the total family resemblance score for each snack food and each shampoo, the weighted scores of each of the attributes that had been listed for a particular product or brand were summed.

Results

Results, reported in Table 1, demonstrate that family resemblance is related in expected ways to the two typicality measures in the case of the superordinate product category "snack foods." Spearman rank order

TABLE 1

correlations between median free recall production ranks, mean prototypicality ratings, and family resemblance scores for snack foods are all highly significant, ranging from .82 to .92. Rank order data are shown in Table 2. As shown, the rank orders yielded by the different measures are markedly similar. Furthermore, the rankings have face validity. Quintessential snack foods like potato chips, popcorn and peanuts tended to rank highly (be very typical) on all measures. Inspection of Table 2 supports Rosch and Mervis' (1975) argument that family resemblance underlies and determines typicality. Snack foods such as popcorn which have the highest family resemblance scores--i.e. have attributes which overlap those of other snack foods to the greatest degree--have the highest typicality scores.

Olives	111
Yogurt	102

Further analysis of our data provides insight into the underlying graded structure of product categories. According to Rosch and Mervis (1975), "A family resemblance relationship consists of a set of items of the form AB, BC, CD, DE. That is, each item has at least one, and probably several, elements in common with one or more other items, but no, or few, elements in common to all items" (p. 575). Figure 2 shows the number of attributes that respondents applied to only one product type, two types, three and so on to all sixteen types.

FIGURE 2

The figure supports Rosch and Mervis' (1975) argument that members of a category do not possess necessary and defining features that are common to all members of that category. No attribute was shared by all sixteen category members. Instead, snack foods have features that overlap some but not all other members of the category. The figure reveals that the different product types in the category were perceived as possessing relatively few (an average of 4-5) completely unique product characteristics.

The correlations for the shampoo data between mean prototypicality ratings, free recall production ranks and family resemblance scores are also reported in Table 1. The relationship between the rank order of mean prototypicality ratings and median free recall production rank is strong and significant although significantly lower ($p < .05$) than the correlation for snack foods. However, the correlation of family resemblance scores with the other measures is markedly low and nonsignificant, and significantly lower than the corresponding correlations for snack foods ($p < .05$). The possible reasons for the difference in results between the two types of categories--a superordinate category of product types and a more subordinate category of brands within a type--suggest the circumstances under which family resemblance scores can and cannot be validly computed.

By inspection of the attribute listings, we found that respondents reacted to the shampoo stimuli very differently than the snack food stimuli. Differences in family resemblance scores for shampoos were determined to a great extent by small, idiosyncratic differences in package design (e.g. "gold trim on label"). We speculate this is because shampoo attributes (e.g. "cleans hair") did not differentiate the brands to which subjects were exposed, and therefore were not mentioned. In contrast, the family resemblance scores for snack foods were better related to the degree to which the foods shared salient attributes of the category. The subjects' tendency to focus on minor details of package design in the shampoo attribute listings but not the snack food listings may have been accentuated by three factors: (1) subjects viewed slides of shampoos but not snack foods while listing attributes; (2) the instructions may have focused subjects on details of package designs which were salient for shampoos but not snack foods; (3) subjects listed attributes of different brands of shampoo and different types of snack food. The use of slides for shampoos but not snack foods likely increased subjects' mention of package details in describing the shampoos simply by making such details more available. In the absence of the slides, subjects might have focused more on attributes related to the brands' functions or images. Subjects also might have focused on package details simply because brands of many personal care and household products tend to be differentiated more by the details of package design than by substantive differences. Furthermore, the correlations between the measures for brands of shampoo may have been weaker than for types of snack food because of the influence of other variables like the relative advertising budgets of brands, their length of time in the marketplace, and familiarity. Unfortunately, the influence of these latter factors is difficult to assess in an experiment using natural stimuli. A similar study using artificial brands could control for such variables as frequency of exposure to advertising.

Discussion

Measurement of Family Resemblance

To increase the comparability of our data with that of past studies, we closely followed Rosch and Mervis' (1975) procedure for computing family resemblance scores. In doing so, we noted that some aspects of the procedure were problematic and might be improved upon for our stimuli. The instructions to subjects, as reported in Rosch and Mervis (1975, p. 578) and adapted here, did

little to focus subjects on the more salient common attributes of objects so subjects tended to mention many trivial attributes which made coding and computation complicated and time consuming. Perhaps instructions to focus on salient common attributes, or a time limitation placed on responses, would simplify the procedure.

Another difficulty pertained to the way family resemblance scores were computed. If one or more subjects mentioned that an object had an unique attribute, not shared by any other item in the category, the unique attribute still increased the object's family resemblance score by "1". Thus, an object with a plethora of unique characteristics could conceivably gain a higher "family resemblance" score than another very typical object. This scoring procedure seems to be a serious conceptual flaw in the measure.

Finally, the Rosch and Mervis procedure allows researchers to credit an object with attributes not mentioned by any subject but "clearly and obviously" (p. 570) true of the object. Allowing such a degree of judgement may compromise the objectivity of the measure.

Considering the problems discussed above, an opportunity exists to improve upon the current means of measuring family resemblance. Further research is needed on the reliability of the current measurement procedure across different stimulus sets at different levels of abstraction from subordinate to superordinate categories. The robustness of Rosch and Mervis' technique to changes in task instruction and to the means of presentation of the stimulus items also requires further investigation.

Structure and Manipulation of the Evoked Set

The measurement of family resemblance could be useful in the study of a number of applied issues. Members of a category having more family resemblance to other members are more likely to be part of a consumer's awareness set for a product category and thus have a greater chance of inclusion in a consumer's evoked set since the consumer can only select products from this set that "come to mind" as a member of the awareness set. In measuring prototypicality, family resemblance scores have an advantage over simple ratings because they do more than merely predict inclusion in the awareness set. The data entering into their computation shows which of a product's attributes have the most weight in determining a product's membership in and order of mention in the awareness set.

Attributes shared by the greatest number of snack foods have the most weight in making a product more typical of snack foods and thus more likely to be mentioned as a snack food. Table 3 shows the attributes shared by eight or more snack foods. The Table shows that a food is more likely to be perceived as a snack item if it has

TABLE 3 (continued)

Number of Snack Foods to which Attribute Applied	Attribute

8	Needs cold storage.
8	Easy to transport.
8	Good for you.
8	Usually served in small pieces.

different flavors or varieties, it is good with other foods, it is easy to prepare and easy to eat, it tastes good and it can be eaten any time of the day in a variety of situations. The most typical snack foods--popcorn, potato chips, peanuts--share almost all these attributes. Information on the determinants of typicality could be useful to a marketer in a number of ways. For example, a marketer wishing to promote cauliflower as a snack item could advertise its versatility, convenience, and compatibility with many other types of foods.

Besides their utility for new product positioning and design, the process of computing family resemblance scores revealed some insights into why consumers perceived existing products as more or less prototypical of a category. For example, subjects ranked apples as a rather typical snack food--more prototypical than other fruits and vegetables such as carrots or salad. Inspection of the brand by attribute matrix used to compute the family resemblance scores revealed some possible reasons for this outcome. Apples appear to share attributes with traditional snack foods like popcorn, potato chips and peanuts. Like these snacks, apples are crunchy, easy to prepare, appropriate for many occasions, liked by most people, and easy-to-eat "finger foods". Subjects also noted that apples are "roundish" like traditional snack foods, divisible into small pieces, have many varieties and flavors, and go well with many other foods. Apples were perceived as like popcorn in certain ways including low in calories, and a good source of roughage. Overall, then, apples were very prototypical of the snack food category.

For the marketer who wishes to persuade consumers that a product is a member of another category or appropriate for some use or occasion, the concept of family resemblance offers interesting insights. Efforts to convince consumers the product is similar to members of the target category on commonly occurring characteristics could be effective. For example, a marketer who wished to encourage consumers to think of apples as snack foods could create promotions emphasizing the characteristics that apples share with very prototypical snack foods like popcorn, potato chips and peanuts.

Application to Consumer Inferential Reasoning and Advertising

The measurement of family resemblance may be useful in the study of consumers' inferential reasoning about the members of a product category. Rips (1975) found that people tend to generalize new information about a product category asymmetrically. In reasoning about products, consumers may be more likely to generalize new information about more prototypical products to less prototypical products than vice versa. For example, if consumers perceive McDonald's hamburgers as prototypical and hear the rumor that McDonald's hamburger contains red worm meat, they may be more likely to generalize the suspicion to other fast food hamburgers than if they heard the same rumor about a less prototypical burger.

These insights into the effect of family resemblance on inferential processes have implications for advertisers, particularly comparative advertisers. A more prototypical product may benefit less from point-by-point comparative advertising or advertising that focuses on specific features of the product than its competitors

TABLE 3

Commonly Shared Attributes of Snack Food

Number of Snack Foods to which Attribute Applied	Attribute
14	Different varieties and flavors.
13	Good with other foods.
12	Easy to prepare.
12	Tastes good.
11	Easy to eat finger food.
10	Can eat anytime of day.
10	Versatile--Can be used for many occasions.
9	Can buy anywhere.
9	Good food to serve at parties.
9	Appeals to kids.
8	High in calories.
8	Liked by most people.
8	Many ways of preparing the food.

because consumers may tend to infer less prototypical products have the attributes of more prototypical products. In actual practice, many dominant, well-known brands like McDonald's avoid the use of point-by-point comparative advertising. Additional research should be useful to clarify these issues and their marketing applications.

Correlated Attributes

Natural categories appear to reflect the correlational structure of the environment. That is, items in a natural category have attributes that tend to occur in correlated clusters. Thus if a consumer classifies a food as a snack food, he or she is likely to infer the food possesses a set of correlated attributes such as "different varieties," "good with other foods," "easy to prepare," "easy to eat finger food," and "appeals to kids" (Table 3). The consumer may be most confident, in a probabilistic sense, that the food has more typical attributes of snack foods since these occur among snack foods with the greatest frequency.

If a consumer classifies a product as a member of a category with correlated structure, then notes the product has a particular attribute like "different flavors" (perhaps emblazoned on the package) then he or she is likely to infer the product also has attributes highly correlated with the attribute initially known. For example, if a product is promoted as having many varieties, consumers might infer it has high calories if these two attributes tend to co-occur in a particular category. This tendency could lead consumers to make unexpected inferences in response to a promotion stressing a particular feature.

The measurement of family resemblance affords insight into the correlational structure of a category. Such insight may provide marketers with clues to the inferences consumers make as a result of categorizing a product or crediting it with a particular attribute.

RETRIEVAL PROCESSES IN CONSUMER EVALUATIVE
JUDGMENT MAKING: THE ROLE OF ELABORATIVE
PROCESSING, CONTEXT, AND RETRIEVAL GOALS¹

Alain d'Astous, Université de Sherbrooke
Marc Dubuc, National Bank of Canada

Abstract

A stage model specifying the processes occurring over time between the acquisition of information and its use in judgment/choice consumer situations is discussed and three factors believed to have a significant impact on memory retrieval are singled out. An experiment where the factors are manipulated is presented. The results support the proposition that elaborative processing enhances recall and the likelihood of information utilization.

Introduction

The issue of how consumers arrive at evaluative judgments and choices has always been central to consumer research. Until recently however the role played by memory processes in these types of situations has been somewhat neglected. This is unfortunate since simple introspection suggests that judgment and choice processes always rely on both information retrieved from memory and information externally available. For instance, consider the case where information about a brand's position on several relevant dimensions or attributes is provided. Even in such a stimulus-based context, consumers may have to search their memory to find information about the relative weights that should be applied to the various attributes in order to generate an evaluative judgment or to make a choice.

As Lynch and Srull (1982) and others have pointed out, a consideration of retrieval processes is fundamental to consumer research. There is a vast literature in cognitive psychology that has been concerned with this problem. Over the years, a number of general principles of information retrieval, based on various experimental findings, have emerged (see e.g. Glass, Holyoak and Santa 1979). In general however, cognitive psychologists have limited their focus on retrieval per se, without worrying too much about information utilization. While it may be of interest to inquire about the process of accessing information in memory, it must be recognized that in most natural situations information is retrieved in order to be used. Thus, consumers generally do not search their memory for facts simply to comply to someone's request; most of the time they do so in order to use the retrieved information in typical tasks such as making choices, evaluative judgments, inferences, communications, etc. Therefore, it seems important to look at the problem of consumer information retrieval within the perspective of the utilization of recalled knowledge for achieving specific objectives.

This paper discusses aspects of information retrieval in consumer judgment/choice situations and presents an experiment designed to provide answers to some research questions that seem of relevance to this area.

Background Discussion

Stage Analysis

An understanding of the factors that may impact on one's ability to access a given piece of information in memory and use it for some purposes is contingent upon an understanding of the processes that occur prior to the retrieval attempt. For instance, failure to access the information may simply be due to its unavailability, in which

case an examination of the conditions prevailing at the encoding stage is warranted. It may also be due to the utilization of an inappropriate search path, in which case the compatibility between the retrieval specifications and the contextual elements surrounding the needed record must be investigated. Therefore, it seems useful to consider the problem of information retrieval and use in the context of a framework that specifies which processes occur over time between the acquisition of some target information and its use. Although simplistic in nature, this stage analysis (Crowder 1976, see also Hastie and Carlston 1980, Tulving 1976) provides some structure upon which various research questions can be formulated.

A stage model is presented in Figure 1. Briefly, the process begins with the individual's initial goals. These will eventually influence the way the target information is encoded. Once encoded, that information is stored and retained for a given period of time until it is retrieved and used for the purpose of making a judgment or a choice. Some issues related to this model are now discussed in more detail.

FIGURE 1

A Stage Model for Examining Issues in
Information Retrieval for Consumer Judgment and Choice

Goals

There is research evidence that one's objectives (e.g. to make an evaluative judgment, to select an alternative, to learn some information) will influence the strategies used to process incoming information and consequently the nature of the information subsequently available in memory (see e.g. Biehal and Chakravarti 1982, 1983, Cohen and Ebbesen 1979, Johnson and Russo 1981). Individuals differing initially with respect to their goals may exhibit quite different remembrances after having been exposed to the same set of stimuli. Ultimately however, all other things being equal, any disparity in recollection follows from the performance of qualitatively and/or quantitatively different mental operations at the encoding stage (Glass, Holyoak and Santa 1979); differences in goals are likely to have an effect on resulting memory structures to the extent that processing strategies are affected accordingly. For example, Biehal and Chakravarti (1982) have shown that directed learning of product information versus learning incidental to a choice task lead to different retrieval processes. In the first case, retrieval operations (as inferred from free-recall protocols) were predominantly brand-based whereas in the other case higher levels of attribute-based processing were observed. According to the authors, the learning goals had a different effect on memory structure because they led to different processing activities during encoding.

¹The authors would like to thank Dipankar Chakravarti for helpful comments on an earlier draft of this paper. This research was supported by a grant from Marketix Inc.

Encoding

At some point, information presented to the individual is encoded, i.e. put in a form that is comprehensible to the human information processing system (Klatzky 1980). Actually, the encoding stage, as it is conceptualized here, involves more than a transformation process but refers to the total interpretation that is taking place (see also Wyer and Srull 1980). Several implications for retrieval follow from an examination of what can happen during this stage.

Encoding. A trivial observation but one that has rather serious implications is that the to-be-retrieved information might not get encoded. The consequences for retrieval need not be elaborated in great detail. From a methodological standpoint however, this suggests the necessity of making sure that the individual allocates some time to information processing.

Prior knowledge. A well-documented result in memory research is that the outcomes of the encoding process are partially determined by what one already knows about the stimulus information (e.g. Bransford 1979, chapter 5). In addition to providing some initial structure that will allow the system to prime those stored concepts that may facilitate comprehension (especially when dealing with ambiguous material), prior knowledge triggers inference making processes. Of the many inferences that are made, one of particular concern here has to do with the believability of a target information. The "S said X is 0 versus X is 0" belief distinction (Fishbein and Ajzen 1975) is crucial as far as retrieving information for making judgments or choices is concerned. Two strategies for enhancing the believability of communicated information appears possible. One is to minimize the effect of prior knowledge by selecting a somewhat unfamiliar experimental topic. The other is to attribute the information to a credible source. Both strategies are implemented in the present study.

Mental operations. The type of mental operations performed at encoding is likely to make a difference at retrieval time. If the allocation of processing capacity to the target information is low, the resulting memory traces are less likely to become associated with potential retrieval cues. Mental activities such as rehearsal and elaborative processing (e.g. making relations with prior knowledge, associating the information with other facts) have been repeatedly shown to substantially improve one's memory. The usual explanation is that it increases the number of retrieval paths and consequently the likelihood of accessing the elaborated upon information (Anderson 1980).

Retrieval Specification

The search for the target information may be initiated and pursued with the help of cues coming from the environment, the retrieval goals (e.g. instructions, task objectives) or memory (Norman and Bobrow 1979). Each of these information suppliers is briefly discussed below.

Environmental cues. In many instances the environment may offer indications that can be helpful for locating information in memory. Consider the example of a consumer in a store trying to remember which of two brands was rated as being of higher quality in a recently read Consumer Reports article. Examining the packages may remind him of attributes that the article mentioned as being particularly important in the quality rating, allowing him/her to recover the name of the winning brand.

Often, the mere fact that the encoding and retrieval environments are the same will suffice to significantly increase the probability of retrieval. An experiment conducted by Godden and Baddely (1975) illustrates the phenomenon. Divers were asked to learn a list of unrelated words either twenty feet under the sea or on the shore. They were subsequently tested in the same environment or in the other one, resulting in completely crossed 2 X 2 factorial design. As expected, the interaction effect

between learning and recall environment was significant, i.e. recall in the same environment (dry or wet) was superior to recall in the different environment. These results can be taken as one manifestation of the principle of encoding specificity (Tulving and Thomson 1973) which asserts that the representation stored in memory is a function of the information present at encoding. Therefore, according to this position, in order to be effective, retrieval cues must be compatible with encoding inputs.

Retrieval goals. Clearly, one's objectives play a prominent role in guiding the retrieval process. They can be specific, as when one is asked "Who's Canada's prime minister?". But, in many cases, the individual's goals are broad, sometimes vague and necessitate his accessing different types of information of which the target information may only be a small subset. As an example relevant to this study, suppose one is asked to evaluate the goodness/badness of a set of profiles systematically defined using specific orthogonal dimensions, like in conjoint analysis (see Green and Srinivasan 1978), and that the research interest is in finding if some previously presented (target) information on the relative importance of these dimensions is retrieved and used by the individual to accomplish this task. The overall goal here is well defined, but the person has to come up by him/herself with some strategies to attain it and these in turn imply the formation of various retrieval goals, one of them being related to the weights that should be mentally assigned to the dimensions when the evaluative judgments are made. The degree of freedom enjoyed by the individual to perform this task makes it difficult to predict if the target information will be retrieved at all. But, if the goal is further specified, e.g. by cuing the person on the utility of considering the relative importance of the dimensions, one can be more confident that the relevant memories will be accessed and utilized.

Information from memory. Frequently, retrieval does not proceed directly. Rather, on the basis of some initial specification, memory is searched and the outcomes serve as inputs for further search until a match is obtained or a decision is made to stop. Memory then supplies itself with informational cues that constantly provide more specification to the retrieval process.

Research Propositions

Some summary statements about information retrieval in judgment and choice situations can now be made.

- (1) The direct retrievability of some specific information relevant to some judgment or choice is contingent upon its availability in memory¹.
- (2) Previously encoded information pertaining to some judgment or choice may be retrieved but will be used only if the individual agrees with the conclusions implied by this information.
- (3) Elaborative activities performed on some target information at the encoding stage will increase the likelihood that it will be retrieved and used.
- (4) The more similar the retrieval conditions are to the encoding conditions, the better the chances of recovering the target information and using it.

¹Obviously there are situations where a piece of information is not available in memory, but can be deduced from other elements. Such would not be a case of direct fact retrieval, however. For example, it is probable that the results of dividing the number 207 by 36.2 is not available in most people's mind. Yet, it can be computed with appropriate procedural knowledge.

- (5) The level of retrieval specification, i.e. the preciseness of the incitation to search for the target information, is an important determinant of retrievability; the more specified is the retrieval goal, the better the chances of accessing the information and using it.

Method

Overview

The experiment basically follows the sequence of events displayed in the stage model of Figure 1. Subjects were presented with some target information of relevance for an evaluative judgment, namely which attribute a credible source considered to be the most important aspect in the evaluation of a given consumer product. After a retention period of one week, they were given the opportunity to retrieve that information and use it in the context of a judgment task.

Preliminary Study

Prior to the experimental phase of the research a small scale study was conducted in order to identify a consumer product with which subjects would have minimal familiarity in terms of the dimensions to use for evaluation and their relative importance. In addition, it had to be possible to adequately predict subjects' evaluative judgments with a few non-interactive and approximately equally weighted attributes. A group of business students took part in a conjoint analysis study involving three products: binoculars, smoke detectors and stereo headphones. For each product a set of 18 profiles varying according to three attributes in a 3 X 3 X 2 complete factorial arrangement was constructed. Students rated the profiles on nine-point good buy-poor buy scales. After the task, they also reported how knowledgeable they were about the importance of the attributes. For this latter measure, the lowest mean was obtained with binoculars. Furthermore, the statistical analysis of the conjoint ratings for binoculars showed no interactions between attributes and very comparable magnitudes of main effects. Results for the other two products were much less interesting (some interactions, large differences between magnitudes of main effects). Thus, on the basis of these results, binoculars were chosen as experimental product.

Exposure Stage

Subjects were undergraduate business students at the University of Sherbrooke. In the first stage of the experiment, they participated in a study of "reading comprehension", supposedly conducted by a graduate student in psychology. Their task consisted in reading and answering various questions about three excerpts from recently published magazine articles. One excerpt was presented as coming from Consumer Reports and contained the target information. It mentioned that consumers in the process of looking at market offerings of binoculars should give more importance to one attribute: field of view. The choice of this attribute was based on a real article published in Consumer Reports (CR).

Elaboration manipulation. One of the research propositions considered earlier asserts that elaborative processing of incoming information helps memory by the fact that it allows the creation of additional useful retrieval routes. A two-level between-subjects factor is incorporated in this experiment. In the elaboration condition, the interaction with the target information was as follows. First, a four-minute delay was given to read the 150-word CR excerpt and answer four general questions about it (e.g. what title would you give to this excerpt?). Then a paragraph from the excerpt in which the target information appeared was made available for a period of ninety seconds during which subjects had to answer four questions related to the information (What product? What attributes? Which is most important? Why?). After this elaboration task, subjects were handed a blank sheet and given two minutes to write down the paragraph as they recalled it. In the no

elaboration condition, the experimental sequence was identical except that subjects were not asked any questions during the ninety-second presentation of the paragraph.

Judgment Stage

One week after having been in what they thought was a study of reading comprehension, subjects participated in a "decision making" experiment conducted by a different researcher². The experiment consisted in going through conjoint analysis tasks with the same consumer products employed in the preliminary study. Within-subjects evaluative judgments of profiles constructed by considering all possible combinations of the attributes associated with the products were collected. Table 1 displays the attributes and levels defining the profiles of binoculars. In addition, subjects were asked to rank the binoculars profiles in order of preference and provide ratings and rank orders of perceived importance for all attributes.

TABLE 1
Attributes and Levels of Binoculars

Attributes	Levels
Magnification	Average (power = 7) High (power = 8) Very high (power = 9)
Brightness	Average Very good Excellent
Field of View	Average (400 feet) Wide (350 feet)

Environmental context manipulation. Reviving the environmental encoding context has been shown to facilitate recall in many memory experiments (see Smith, Glenberg and Bjork 1978 for a review). Consistent with the principle of encoding specificity, reinstatement of the encoding context at the retrieval stage makes it easier to trace the needed information by maximizing the congruence between the retrieval and the previously encoded cues. In this experiment, context effects were investigated by having subjects provide the conjoint ratings either in the room where the reading comprehension study took place or in another room. The rooms were chosen so as to be distinctive, i.e. either a large lecture room with windows, blackboards, etc. or a small seminar room with a few chairs around a large table and no windows. The assignment of subjects to either type of room and experimental condition was random.

As Bettman (1979) has indicated, environmental context effects have been neglected in consumer research; yet, their relevance to marketing situations seems non negligible. For example, matching information context in ads with the in-store context:

"... advertisements present information in a particular context which very often does not match the in-store context. Perhaps information usage, usage of particular attributes as criteria, or even recognition of brands is influenced by the degree to which the context posed in the ad is present in the actual choice situation" (Bettman 1979, p. 46, underlining added).

In this study, the context manipulation was meant to simulate the same type of situation described above, although advertising issues were not of particular concern.

Retrieval specification manipulation. It was suggested earlier that broad goals such as forming an evaluation of a product do not insure that information potentially relevant to the attainment of that goal will be retrieved and

²There is no general rule as to how long a retention period should be, although a one-week delay is common (see e.g. Bradshaw and Anderson 1982, Wyer and Hartwick 1984).

utilized. What is needed to direct the system to some specific information are specific retrieval goals. Therefore, one additional manipulation in this study involved informing half of the subjects of the usefulness of making a priori decisions about the relative importance of the attributes that composed the profiles to be evaluated. This retrieval specification was made orally by the experimenter immediately before proceeding with the conjoint task.

Control group. In order to provide a basis upon which to compare the experimental results, an additional group of subjects provided the conjoint and attribute importance data. These respondents did not participate in the reading comprehension study and were not subjected to either the environmental context or the retrieval specification manipulations.

Experimental Camouflage

One concern with this study was that subjects might see a link between the exposure and judgment stages. In order to minimize the likelihood of subjects guessing that the experiments were in any way related, they were first contacted by the researcher supposedly in charge of the second experiment (judgment stage). Two or three days later, the other researcher, acting as if he had learned by chance that they had agreed to participate in some experiment, asked for another commitment to a study taking place one week earlier. This simple trick was meant to prevent subjects from making causal inferences regarding the relationship between the experiments too easily. Subjects were paid three dollars for their participation in the first study.

Postexperimental Survey

A few days after the judgment stage, subjects were contacted individually for a postexperimental interview. The objectives were to make some checks on the success of the retrieval specification manipulation and to verify if they had perceived a link between the two experiments. Those interviews confirmed that none of the subjects made connections between the studies.

Results

Manipulation Checks

Retrieval specification. During the postexperimental interview, all subjects were asked if they recalled having been told by the experimenter to think about the importance of the attributes composing the conjoint profiles before proceeding with the task. Twenty-nine of the thirty-one subjects in the retrieval specification (i.e. 90.6 percent) recalled the experimenter's intervention. Only one of the thirty-three subjects in the no retrieval specification condition thought he had heard the retrieval verbal incitation.

Elaboration. To verify the success of the elaboration manipulation, subjects' performance on the memory test given immediately after the exposure to the target information can be examined in both elaboration treatment conditions. The proportion of subjects having written down properly the target information on the provided sheet is 0.64 in the no elaboration condition as compared to 0.84 in the other condition. The difference is statistically significant ($Z = 1.83$, $p = 0.0336$, one-tailed test).

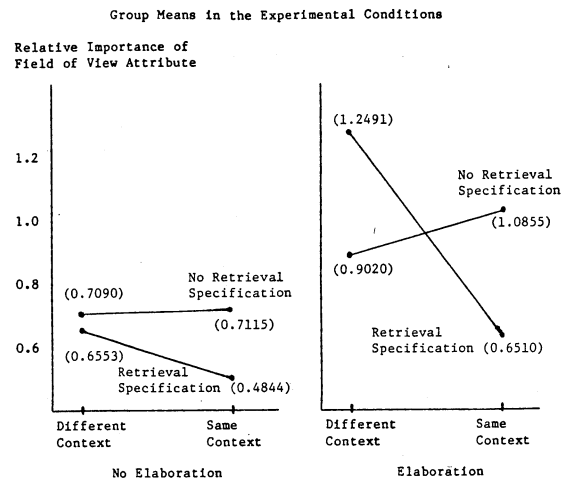

Dependent Variable

In this study, the interest is in finding if the target information was retrieved and used at judgment time and in determining the impact of elaboration, context and retrieval specification on the process. As shown in Figure 1, it is assumed that use of the target information will quite automatically follow its retrieval from memory. To assess subjects' use of the target information during the evaluative processing of the binoculars, a measure of relative importance of the field of view attribute must be

considered. The following analysis strategy was adopted. For each subject, the conjoint data (ratings and rankings) pertaining to binoculars were analyzed through ordinary least-squares methods in order to verify that an additive model was appropriate and that, consequently, the importance of the field of view attribute could be measured independently of the other attributes. The minimum proportion of total variation explained by additive effects only was arbitrarily fixed at 0.70 as a cut-off for inclusion in the final sample. Only one subject had more than thirty percent of the variation in his data explained by interactions and, as a result, was excluded. Overall, the mean proportion of variation due to interactions was very low (about 0.10).

For each subject in the final sample two measures of the relative importance of field of view were computed: (1) mean square associated with the field of view main effect over the sum of the mean squares of all three attributes, and (2) absolute difference between the marginal means of the field of view attribute over the sum of these differences for all attributes. These scores were obtained with both ratings and ranking data and the final dependent variable was defined as the sum of the four scores³.

FIGURE 2

Design and Analysis

The experimental design is a 2^3 between-subjects factorial arrangement with one control group where the two-level factors are elaboration, context and retrieval specification. The field of view relative importance group means are plotted in Figure 2. Since the seventy-four subjects composing the final sample are distributed unevenly across the experimental conditions (seven, eight or ten subjects per treatment condition), the factorial design is unbalanced. Accordingly, Appelbaum and Cramer's (1974) general linear model approach was applied in the computation of the different sums of squares. By using this model comparisons procedure neither the three-way nor any of the two-way interactions are statistically significant by usual scientific standards (i.e. $p < .05$). The only interaction effect which stands out is that involving the retrieval specification and context factors with a p-value of 0.1371; on a descriptive basis, retrieval specification leads to greater weight given to the field of view attribute when the retrieval context is different from the encoding context and lower weight when both contexts are the same. As Table 2 reports, the only statistically significant main effect is associated with the elaboration factor; subjects who engaged in elaborative activities at the encoding stage gave more importance to the field of view

³Other ways of operationalizing the dependent variable were also considered (e.g. absolute mean squares and utility ranges), but the pattern of results has remained essentially the same.

attribute at judgment time than subjects who did not. The differences in marginal means for the other independent variables are in the wrong predicted direction and not statistically significant. A comparison between the control group and the eight experimental groups as a whole confirmed that exposure to the target information leads to more importance attributed to field of view during the conjoint task ($t = 1.96, p = 0.0273, 65 \text{ df}, \text{two-tailed test}$).

Discussion

The only statistically significant results of this study are those associated with the elaboration manipulation. The results support the proposition that elaborative processing of stimulus information leads to better memory and, consequently, better chances of later retrieving that information and using it in some evaluative judgment task. It must be noted, however, that the elaboration manipulation, as operationalized in this experimental study, involved a question that required subjects to retrieve the target information specifically, viz. "Which attribute is most important?". This form of manipulation might then be more appropriately termed *elaborative rehearsal*, since it did not directly incite subjects to create new memory associations. The superior memory performance of elaboration subjects for the target information observed during the interpolated memory test suggests however that these associations were nevertheless created.

Although it did not reach statistical significance, the observed cross-over interaction between the retrieval specification and room context factors (see Figure 1) warrants some discussion, given the small sample sizes and the resulting low statistical power. It seems interesting to speculate about what may have caused this interaction. As indicated earlier, when encoding and retrieval room contexts differ, the retrieval specification manipulation leads to greater weight given to the target attribute. When contexts match, the effect of retrieval specification is opposite. As Figure 2 shows, the interaction seems to be concentrated in the conditions where the target information was elaborated upon. One explanation for the interaction is that the conjunction of retrieval specification and identical environmental context led subjects to question the validity of the target information, thereby reducing the importance given to the field of view attribute in the evaluation of the binoculars. Perhaps these two facilitating conditions occurring at the same time resulted in the retrieval of additional information that cast doubt upon the truth of the target belief, while each condition taken separately was less likely to activate this information. This argument is best conveyed using a spreading-activation memory network representation (e.g. Anderson 1980). Such a representation in the context of this study is depicted in Figure 3. As shown, the target information is assumed to be associated with the room context, the concept "Binoculars Attribute Importance", and some additional information processed during the encoding stage. Examples of additional informational units are the experimental research situation in which the target

information was learned, the CR excerpt context, the other attributes that were mentioned in the excerpt, the pro- and counter-arguments generated during the learning episode, and so on.

FIGURE 3

Network Representation of Subjects' Associative Memory Structure

Now, assuming only the room context mode is activated, accessing the target information should be easier since, contrary to other related information, it has been elaborated upon and the experimental procedures have made it more distinctive. Similarly, assuming only the "Binoculars Attribute Importance" concept node is activated (e.g. using retrieval specification), accessing the target information should be easier for the same reasons. Note that these two scenarios are consistent with the observed interaction. In Figure 3, the greater potency for memory access to the target information is represented by the wider paths connecting the nodes.

Consider the case where both nodes are activated (corresponding to the retrieval specification-same context experimental condition); again the target information should be easily accessed. However, the chances of accessing the other informational units should increase since activation now emanates from two concept nodes. Thus, for example, subjects might come to think about the research study context or the attributes mentioned in the CR excerpt or even self-generated counter-arguments. Such thoughts could have a significant impact on the decision to make use of the target information during the evaluation task. One possible consequence could be a decrease in the importance given to the target attribute.

Obviously, the above discussion has been highly speculative and other explanatory schemes could be proposed. One interesting aspect of this discussion though is that it stresses the distinction between information retrieval and information use and suggests that retrieval of some particular information does not necessarily lead to an unqualified utilization in some subsequent task (see also Gardner 1983).

Conclusion

Information retrieved from memory plays a significant role in the inference making process. Therefore, research on the conditions under which memory retrieval is facilitated must be extended to judgment or choice situations. The results presented in this paper suggest that engaging in elaborative mental activities at the encoding stage may increase the likelihood of retrieving and using the encoded information in a subsequent consumer judgment task. Although the positive impact of elaboration on memory is a well-documented finding in cognitive psychology, its extension to information utilization appears to have been neglected so far. Hopefully, the present study will have stimulated research into extending similarly other cognitive psychology findings.

THE RELATIONSHIP OF MISCOMPREHENSION TO DECEPTIVENESS IN FTC CASES

Ivan L. Preston, University of Wisconsin
Jef I. Richards, University of Wisconsin¹

Abstract

Jacoby, Hoyer and Sheluga have interpreted their findings on miscomprehension as implying that much of what government regulators identify as advertising deceptiveness should properly be recognized only as normal levels of miscomprehension. An analysis is offered which questions this interpretation, for two reasons. The first reason is that the Jacoby group omitted studying one of the significant types of deceptiveness prosecuted by the FTC. The second is that, for the type of deceptiveness the researchers did study, the concept of "induced miscomprehension" suggests it is reasonable to interpret miscomprehension as evidence of deceptiveness.

Introduction

This is an assessment of the work of Jacoby, Hoyer & Sheluga (1980; Jacoby & Hoyer, 1982a, 1982b) on the topic of miscomprehension of message content. While other assessments of this work (Ford and Yalch 1982; Mizerski 1982) have focussed on methodological matters, this one focusses on the legal applicability of the findings for their intended use as evidence pertaining to deceptiveness in Federal Trade Commission advertising cases.

The Jacoby work was funded by the Educational Foundation of the American Association of Advertising Agencies, whose notice inviting research proposals explained how the work was to be applied to the deceptiveness topic: "In the past few years various regulatory bodies have charged certain advertisers with having produced 'misleading' advertising. Regulators have interpreted fairly modest levels of consumers misperception as evidence that a particular advertisement is 'misleading.' This may simply reflect the difficulty in distinguishing between deception and small levels of misperception which may be inherent in the process of mass communications" (A.A.A.A. 1978).

The immediate goal of the Jacoby et al. project was "to provide objective evidence of the extent and nature of consumers' perceptions and misperceptions of various forms of communication, including advertising" (with comment appended that "as the study developed 'misperception' was more properly defined as 'miscomprehension'") (Bartos 1980).

The principal result of the project was the finding that a substantial amount of miscomprehension by consumers occurred. An implication of this finding was stated to be that "just because there is a demonstrable degree of miscomprehension associated with a particular advertisement does not necessarily mean that the particular advertising contains something out of the ordinary to provoke said miscomprehension...[because]...a certain proportion of miscomprehension may simply reflect a natural error rate associated with all types of televised communication" (Jacoby et al. 1980, p. 97). Further, "the authors... would find completely unreasonable any attempt to use 'zero-based miscomprehension' as the criterion for evaluating advertising" (p. 98).

Although little more is stated explicitly, certain additional conclusions can reasonably be drawn as to what the researchers and their sponsors meant to communicate about the relationship of miscomprehension to deceptiveness.

There appears to have been an underlying assumption that government regulators investigate advertising by measuring consumer miscomprehension of it, and then prosecute advertisers on the belief that such demonstration of miscomprehension amounts to a demonstration of deceptiveness.

Contrarily Jacoby et al. urge the belief that miscomprehension, because it occurs in response to all advertising and indeed to all mass communication, should not be interpreted as evidence of deceptiveness. It represents only the natural tendency of human beings to have a certain level of error in their processing of message content, a phenomenon that should be attributable only to the consumer and not to the advertiser.

Only when the observed level of error exceeds the base level of miscomprehension should deceptiveness properly be assumed to exist. Should people typically err in 30% of instances, which is the average figure the researchers observed, then deceptiveness should properly be attributed only to messages for which the observed miscomprehension figure is higher than 30%. If the figure were say, 40%, then only the last 10% could be defined as deceptiveness. This would mean that a great many ads would have no deceptiveness at all, and that the 40% ad would have attributed to it only 10% deceptiveness rather than the full 40%.

Examination of FTC cases gives little reason to accept the A.A.A.A. assumption, at least for recent years, that the FTC frequently prosecutes advertisers on the basis of very small amounts of deception. The present authors, however, forego arguments based on such matter, in order to take up the issue of the theoretical relationship between the concepts of miscomprehension and deceptiveness.

Comparing Miscomprehension and Deceptiveness

We turn to assessing the arguments made by Jacoby et al. about what the occurrence of miscomprehension properly tells us about the occurrence of deceptiveness. The first step is to compare the two phenomena conceptually and empirically. The Jacoby report does not examine deceptiveness empirically, and by standing moot on this topic it may have the capacity to imply a closer relationship between deceptiveness and miscomprehension than is actually the case.

The report does discuss deceptiveness conceptually (p. 40), along with the concept of misleadingness as attributed to the FDA. The present discussion chooses to focus on deceptiveness, because the role of the FDA with respect to advertising is negligible compared to that of the FTC. In any event, there is not nearly so much difference between the two concepts as the report implies. The authors hold that deceptiveness involves a deliberate attempt to produce a false belief, while misleadingness does not necessarily do so (p. 40). Actually, neither do; it is fully established in advertising law that violations may be found in the absence of any evidence of intention to deceive (Preston 1976). Further, deceptiveness and misleadingness are not so clearly the province of separate federal agencies as the authors imply. Rather, the FTC's legislation prohibits misleading as well as deceptive advertising; its practice has been to use the terms interchangeably for conceptual purposes (Preston 1976).

Turning to measurement procedures, although the Jacoby report acknowledges a difference between miscomprehension and deceptiveness (p. 40), it does not discuss the latter enough that the differences as well as similarities may be fully seen. Both concepts involve the understanding about the advertised object that has been conveyed to the consumer. To assess miscomprehension, this conveyed

¹Professor of Advertising and Ph.D. candidate, School of Journalism and Mass Communication, U.W., Madison, 53706.

meaning is identified as being the same as, or different from, the literal message about the object. If the conveyed meaning is different from that stated or logically implied in the ad, miscomprehension exists.

To assess deceptiveness, the FTC first determines the conveyed meaning about the advertised object. It then examines the facts about that object, and finds deceptiveness to occur when the conveyed meaning is false with respect to those facts. Deceptiveness is a function of that relationship without regard for whether the literal advertising message is true or false.

The difference, then, is that the miscomprehension researcher is concerned with whether the conveyed meaning accurately reflects the literal message, without concern for the facts, whereas the FTC is concerned with whether the conveyed meaning accurately reflects the facts, without concern for the literal message. Assuming properly that the literal message's truth with respect to the facts is independent of the conveyed statement's truth the relationship between deceptiveness and miscomprehension is as shown in Figure 1.

FIGURE 1
RELATIONSHIPS AMONG LITERAL AND CONVEYED MESSAGES

	A	B	C	D	E
Literal Message	T	T	F	F	F
Conveyed Message	T	F	F	F	T
Miscomprehension	No	Yes	No	Yes	Yes
Deceptiveness	No	Yes	Yes	Yes	No

The number of combinations of truth and falsity is five rather than four because when both literal and conveyed message are false they may involve the same or different falsities. Miscomprehension is shown where the conveyed message is discrepant from the literal message, and deceptiveness is shown where the conveyed meaning is false.

The most important result found in Figure 1 is that miscomprehension and deceptiveness are independent of each other. Although the Jacoby group recognized this (p. 40), they failed to incorporate the range of outcomes needed to fully demonstrate this phenomenon. They examined only two of the five possible outcomes, Columns A and B in Figure 1, those two being the ones where deceptiveness and miscomprehension are correlated. Such a limitation does not permit the independence of the two concepts to be recognized.

The limitation occurred through the researchers' decision to "accept as given (but not objectively demonstrated) that each of our ads provides a correct representation of Product X" (p. 35). Thus, in their work the literal message was never false. Consequently, they assessed the truth of the conveyed message only by comparing it to the literal message. This was really a measure of correspondence or noncorrespondence of the conveyed message to the literal message, but the researchers referred to it as truth or falsity.

If the conveyed message corresponded to the literal message, either explicitly or by logical relationship, then it was assumed to be true. And, because the literal message was assumed to be true with respect to the facts, the conveyed message therefore must be true with respect to the facts. Under such conditions, both comprehension and nondeceptiveness existed simultaneously.

If the conveyed message failed to correspond to the literal message, then it was assumed to be false with respect to both the literal message and to the facts, and under such conditions both miscomprehension and deceptiveness occurred simultaneously.

It is not surprising that the researchers so equated miscomprehension and deceptiveness, given their enabling assumption. Such assumption, however, is simply wrong.

The literal message may of course be false with respect to the facts. And the FTC certainly is prone to consider prosecutions in such instances.

How often has the literal message been found by the FTC to be false? The present authors analyzed its cases in eight most recent published volumes (FTC 1980-83). The fifty relevant cases contained 330 instances in which a charge of a false conveyed message was made on the basis of a literal statement in an ad. In 164 of these cases the conveyed message was the same as the literal statement, which means that the literal statement was charged by the FTC to be false. In 166 instances the conveyed statement was found to be implied by a literal statement, which means not precisely that the literal statement was found to be true, but rather that it was not challenged as false and therefore was conceded for legal purposes to be not false. If we assume that the unchallenged literal statements were in fact true, the results show that the 330 statements were divided almost exactly evenly between true and false. The Jacoby researchers thus failed to incorporate into their design a type of advertising message reflecting half of the volume of actual FTC activity.

Summing up our assessment to this point, the argument has been made that the Jacoby project failed to study the full range of relationships between deceptiveness and miscomprehension. This criticism does not in itself, of course, amount to a refutation of the suggestion that miscomprehension may in some cases (i.e., Column B in Figure 1) be properly interpreted as the equivalent of deceptiveness. We turn now to a direct assessment of that topic.

Interpreting Miscomprehension as Deceptiveness

The present authors offer no disagreement with the Jacoby researchers' assertion that the FTC has in many important cases sought to determine deceptiveness by utilizing empirical data that can be interpreted as measuring miscomprehension. The real issue lies elsewhere, as will be seen.

There are two kinds of deceptiveness, and the Jacoby group is quite right in associating one of them with miscomprehension. The kind of deceptiveness found in Columns C and D of Figure 1 is based on the literal message. It may be accompanied by miscomprehension (as in Col. D), but the deceptiveness is independent of the miscomprehension. In most such cases the FTC uses no empirical data, asserting a capacity to deceive simply from the message's falsity.

The deceptiveness indicated in Col. B is based on miscomprehension. In most cases the Commission makes no empirical determination of such deceptiveness, and when it does it typically uses different kinds of measures from case to case. However, there was one instance (Sun Oil 1974) of an FTC measurement of deceptiveness that was extremely like the Jacoby group's measurement of miscomprehension.

That particular measurement and the Jacoby measurement have a common forebear, the work of Preston & Scharbach (1971). The latter determined what meaning an advertisement conveyed to consumers by having experimental subjects respond to a number of prepared statements about that ad's content. The prepared statements might be directly true or false in the sense that they would directly express either some content found in the ad about the product or else the opposite of such content. Other prepared statements expressed things about the product that were either logically implied by what the ad literally stated, or else were illogically implied to anyone who responded on the basis of common logical fallacies. Finally a fifth kind of statement said something about the product that was irrelevant to anything the ad had said; it had none of the four previously specified relationships. Five statements, one of each kind, were used for each ad.

The subjects were asked to specify by checkmark whether each statement was an "accurate" or "inaccurate" restatement or paraphrase of what the ad stated or implied. The

instructions emphasized that a specification of "accurate" did not require that the exact words be used, but only that the same meaning be conveyed. Accordingly, subjects would be answering correctly if they specified "accurate" for the statements that were either true or logically implied or "inaccurate" for those that were false, illogically implied, or irrelevant.

The Jacoby measurement of miscomprehension was reported to be "patterned after Preston and Scharbach" (p. 53). Alterations included the use of only the first four of the five types of statements, and for each ad or other type of communication the use of two each of the false (called "inaccurate fact") and the illogically implied (called "inaccurate inference") statements, making a total of six. The instructions required the subjects to indicate whether each statement was "true" or "false," and this was to be based upon what they felt was both stated or implied in the communication (p. 53). Because of the latter qualification, "true" and "false" probably had the same meaning as did "accurate" and "inaccurate" as used by Preston and Scharbach.

In the Sun Oil case the conveyed meanings challenged as false were not the literal advertising statements; the latter thus were conceded to be true, and so were of the sort studied in the Jacoby project. In the case, Preston supported his testimony on conveyance of meanings by introducing a survey that used three of the five types of statements seen in Preston and Scharbach, along with the same instructions. Of eleven prepared statements three were true, two were false, and five were illogically implied. The latter five had been alleged by the FTC to be conveyed to the public and to be false. By showing a strong tendency to indicate that these statements were accurate references when in fact they were inaccurate, the experimental subjects confirmed the FTC in its decision that such content was indeed conveyed by the advertising.

Accordingly, a showing of what the Jacoby report calls miscomprehension was used by the FTC as evidence of deceptiveness. The specific process was that of miscomprehending by drawing invalid implications--that is, by committing common fallacies through drawing conclusions not justified by proper application of logical analysis (Preston 1967; Preston & Scharbach 1971).

The Jacoby report stresses the point that the cause of miscomprehension is in the consumer and thus not in the advertiser. Miscomprehension is shown to occur in approximately equal degrees across a variety of communications. Nonadvertising sources would presumably have no interest in creating deceptiveness, yet their communications produce the same rate of miscomprehension. Therefore, it appears reasonable to argue that normal levels of miscomprehension may be attributed generally to the recipient of the message rather than to the source.

We have now arrived at the real issue--not whether the observed phenomenon is miscomprehension, but whether miscomprehension should be recognized as deceptiveness. The Jacoby researchers (and presumably their AAAA sponsors) say it should not because to label the phenomenon miscomprehension is to conclude that it is created by the consumer and not by the advertiser. Thus it cannot be deceptiveness and the advertiser should not be prohibited from producing it.

The FTC, although not having commented specifically on the term as used by the Jacoby group, says in effect that miscomprehension often amounts to deceptiveness and so in such instances should be prohibited.

No doubt many observers will consider it unconscionable as a matter of public policy for the government to attack, place blame on, and restrict the activities of an advertiser who has not been proved to be the party responsible for the conveyed message. The legal position on this point, however, is the longstanding principle that messages harmful to consumers should be subject to prohibition regardless of the advertiser's intent to produce them.

The advertiser has created a message that has the capacity to deceive; that is enough. The goal of the law is elimination of harm, and lack of intent to harm is irrelevant if harm is created. Further, intent is usually impossible to prove, thus to impose such a requirement would mean that virtually no harm would be eliminated (Preston 1975).

Furthermore, the advertiser is not being prosecuted. The attack, and the prohibition, technically are made against the message alone, not against the advertiser. The message must cease; the advertiser is not punished. The criminal law which the FTC legislation supplanted allowed for sanctions against persons, but the civil law under which the Commission was created does not (FTC Act 1914).

The outcome of this analysis is that the Jacoby report has not revealed anything that the FTC doesn't already assume. The advertiser should not be punished for causing what is not his fault; the FTC knows that. Miscomprehension is not necessarily the fault of the advertiser in the sense of conscious intent; the FTC knows that. Miscomprehension occurs and is interpreted as constituting deceptiveness; the FTC knows that, too. The Jacoby report simply does not supply anything that technically makes any difference.

Possible Informal Impact on FTC Attitudes

Let us turn, however, to consider the impact the Jacoby report might make, despite the technicalities just discussed, on the basis of the simple common sense it exudes. The report raises issues of fairness toward which many observers will be sympathetic. And there appears to be a way in which the FTC might be influenced by such issues.

The approach would be to raise the issue of an advertiser's apparent lack of intent to deceive, not as a legal technicality but rather as a factor that might influence the FTC to dismiss a case for not being of sufficient public interest. In cases, for example, where the commission is straddling the fence on the question of whether a false conveyed message posed a sufficient threat of harm to the public, the realization that the advertiser was believed not to have intended any deception (along with, perhaps, a clean record on such matters in the past) might turn the tide in favor of dismissing. In its recent statement regarding its advertising substantiation program (FTC 1983), the Commission cited "competing demands on the Commission's resources" as a reason why it might sometimes "decline to initiate a law enforcement proceeding." Perhaps in a parallel way it might also decline where an advertiser could reasonably be thought to have no intent to deceive.

Before we assume that possibility, however, some comment is offered on the Jacoby group's apparent assumption that any consumer response recognized as miscomprehension should also be recognized as involving no intent to deceive. In Preston (1967) the possibility was raised that consumers' inaccurate perception of ad claims might favor the advertisers by enabling them to convey claims they could not state explicitly without risking prosecution. This suggests that advertisers might look favorably on the possibility of such miscomprehension occurring, because it would enable them in apparent innocence to convey messages deliberately that they otherwise could not get into the consumer's head. "We can't say it," an advertiser might observe, "but we can get our readers to think it---and that's what matters!"

An example given in Preston (1967) was that Bayer would have been unable to say truthfully that doctors recommend for colds and flu that people should 1) Rest in bed; 2) Drink fluids; and 3) Take Bayer aspirin. The Bayer ad had made a statement that was the same except for excluding the word "Bayer." Twenty-six out of 30 subjects showed miscomprehension by indicating that the test statement, worded as above with "Bayer" included, was an "accurate" expression of what the ad had stated.

The Jacoby report expresses, at least implicitly, the opinion that miscomprehension is uniformly bad and that all parties wish to eliminate it. It is not difficult, however, to appreciate that Bayer might not have wanted to eliminate a miscomprehension that would result in attributing a strong claim to its product. Nor is it difficult to imagine that the creators of the Bayer advertising might have been fully aware of how the phenomenon would operate. The Preston study was based on common logical fallacies, and the very concept of "fallacy" implies the realization that many people predictably will commit it.

What this analysis suggests, then, is a phenomenon that might be called "induced miscomprehension." It is miscomprehension that the message creator predicts will happen, and knows will produce a favorable result, and therefore utilizes deliberately. If it states something falsely about the product, then it will amount to deceiving in the way that the Jacoby report interprets that term---as involving intent. Certainly it will dispel the notion that miscomprehension is always unintended and innocent.

Preston (1967) included some evidence on the difference that "induced miscomprehension" might make. The overall rate of miscomprehension in his study was 29.2%, remarkably similar to that of the Jacoby research. It is possible by additional unreported analysis, however, to measure the miscomprehension rate separately for those test statements that would be favorable to the advertised product if properly comprehended and those that would be favorable only if miscomprehended.

The statements that were "true," "false," and "logically implied" would be favorable to the advertiser if properly comprehended. The "illogically implied" statements, called "inaccurate inferences" by Jacoby, would be favorable to the advertiser if miscomprehended. The independent statements, made up out of thin air and thus having no logical relationship to the ad content, were sometimes favorable to the advertiser but typically were neutral.

The reanalysis, eliminating the independent statements, shows that where accurate comprehension of the test statement would be favorable to the advertiser, the rate of miscomprehension was only 20%, well below the average. Where the miscomprehension of the test statement would be favorable to the advertiser, the rate of miscomprehension was 65%, very much above the average. The reason suggested was that consumers expect ads to say favorable things, and expect them not to say unfavorable things. The outcome certainly suggests that advertisers can benefit from miscomprehension and so could have an interest in inducing its occurrence.

A similar result occurred in the Sun Oil case. None of the representations alleged by the FTC to be conveyed and to be false were stated explicitly in the advertising; they could only have been conveyed by false implication and thus by miscomprehension. Several of the prepared test statements reflected these alleged representations, although other statements were included for masking purposes. For the three statements for which miscomprehension would be unfavorable to the advertiser, the miscomprehension rate was 12%. For the eight statements for which miscomprehension would be favorable, the rate was 67%.

Clearly miscomprehension occurred more to the advertiser's advantage than detriment in consumer response to the Sun Oil ads. And it was that miscomprehension that was interpreted as constituting a violation. Had the miscomprehension rate for the group of eight statements, most of which paraphrased the misrepresentations alleged in the complaint, been as low as for the group of three statements, the findings would have constituted far less support for the finding of a violation.

The Preston (1967) and the Sun Oil data provided comparison points by measuring miscomprehension under differing conditions, favorable or unfavorable to the

advertiser. This suggests that a benchmark can be identified for determining how much "induced miscomprehension" occurs over and above the occurrence of the miscomprehension that may be innocent. The Jacoby report stated that a zero-based assessment of miscomprehension would be unacceptable (p. 98). Had the FTC in Sun Oil considered such an argument, it might also have considered that the 12% miscomprehension rate found in the survey data could serve as a base for evaluating the 67% rate (and the same for the 20% and 65% rates in the Preston (1967) data). The result obviously would be that the challenged conveyed meanings would demonstrate amounts of miscomprehension well above the baseline.

We have been discussing the possibility that the omnipresence of miscomprehension might sway the FTC into dropping some prosecutions of deceptiveness for a lack of public interest. The analysis, however, suggests that this would be unlikely to happen unless the possibility of induced miscomprehension was ruled out. Induced miscomprehension can occur in cases where the false message is conveyed by implication, and data cited earlier suggests that this happened in half of the FTC's recent charges (see also Preston (1977) for analysis of cases in earlier years). We are not suggesting that the FTC is likely to make charges of, or collect data concerning, the concept of induced miscomprehension. The point is only that the perceived possibility of induced miscomprehension makes it unlikely that the FTC will accept the Jacoby report's urging that evidence of miscomprehension should be interpreted as implying the nonexistence of deceptiveness.

Value of Jacoby Report

A debt is owed to the Jacoby group for observing that what the FTC calls deceptiveness often occurs through the process of consumer miscomprehension. Nothing in this paper is intended to deny that advertisers may sometimes have been held responsible for misunderstandings for which consumers more reasonably ought to be held responsible. What is needed is the more precise specification of those situations under which the existence of miscomprehension may be held to imply the absence of deceptiveness.

A possible way to proceed would be to think in terms of defining the level of miscomprehension that cannot be eradicated. An advertiser's plea of not having intended to create a certain false impression could be vulnerable where the possibility exists of rewriting the message so that a more accurate impression will be conveyed. The advertiser, would be on firmer ground where he could argue that the message was written as clearly as humanly possible and that no alternative construction could possibly produce a lower level of miscomprehension. The latter advertiser would have a better case for claiming an exemption from the law's challenges.

Perhaps involved in such an analysis would be a distinction between miscomprehension of explicit and implied messages. More generally, there might be developed measures of the amounts of miscomprehension produced by structurally different types of messages. Certainly the Jacoby group will agree that more can be learned about miscomprehension as a follow-up to their innovative introduction.

Summary

We have proposed two ways in which to question the notion that what is challenged as deceptiveness is actually only miscomprehension. The first involves instances in which the literal message of the advertisement was false, and for which miscomprehension and deceptiveness do not occur concomitantly. The Jacoby research did not study such situations and therefore cannot be regarded as having any pertinence to them. The second involves instances studied by Jacoby in which the literal message is true and in which deceptiveness and miscomprehension are either present or absent concomitantly. For these situations the phenomenon of induced miscomprehension has been offered

as a reason why the FTC might choose to interpret evidence of miscomprehension as constituting evidence of deceptiveness.

MEASURING MISCOMPREHENSION: A COMPARISON OF ALTERNATE FORMATS

Fliece R. Gates, The University of Texas at Austin
Wayne D. Hoyer, The University of Texas at Austin

Abstract

The performance of two question formats for measuring miscomprehension, i.e. true-false and multiple choice, was examined. Immediately following exposure to one of six stimuli (TV ads), subjects answered a set of questions in either true-false or multiple choice form. Results indicate a high rate of miscomprehension for both question formats. However, there was some indication that the true-false questions were more difficult for subjects to answer correctly. Differences between the two formats were most pronounced for questions dealing with inferences (as opposed to facts).

Introduction

In recent years, the miscomprehension of communications has become an important subject of research in a variety of fields. This is evidenced by the fact that an increasing number of studies in the marketing, communication, broadcasting, and journalism disciplines have attempted to assess factors such as rates of miscomprehension and characteristics of viewing audiences that contribute to the misunderstanding of messages. Yet, in spite of this increasing interest, a number of key issues need to be resolved. One of these issues focuses on the measurement of miscomprehension. The purpose of the present study is to provide additional data related to the measurement of this important construct.

Previous Research on Miscomprehension

As mentioned, a number of different studies across a variety of fields have examined the subject of miscomprehension. In the broadcast journalism area, Katz, Adoni, and Parness (1977) found that adding a picture to audio messages did not affect comprehension either positively or negatively, though the picture did improve memory for newscasts. Edwardson, Grooms, and Proudlove (1981) obtained an overall miscomprehension rate of 37.7% using newscasts as stimuli and a multiple choice quiz for measurement. They also found that interesting video (in contrast to talking heads) resulted in a greater proportion of correct answers, and that comprehension levels were higher for persons under 40 years of age. Robinson (1982), using newscasts and an unaided recall measure, obtained a similar finding in that individuals between the ages of 25 and 54 evidenced greater comprehension. Robinson also found that comprehension of the news increases as education and income levels increase, and that men tend to comprehend more than women. Finally, a 1981 study by Sahin, Davis, and Robinson revealed that viewers who know more to begin with (i.e. have a higher level of general knowledge) comprehend the televised news to a greater extent, and vice versa.

In the marketing area, a large-scale study conducted by Jacoby, Hoyer, and Sheluga (1980) (also reported in Jacoby and Hoyer, 1982) revealed an average miscomprehension rate of 29.6%. The stimuli used in this study included 30-second advertisements, brief program segments, and public affairs announcements. A nation-wide sample was employed and miscomprehension was assessed using a 6-item true-false quiz administered immediately after viewing. Among Jacoby, Hoyer, and Sheluga's findings were that: miscomprehension occurred for all types of communications to a significant degree, both younger and older viewers has a slightly greater tendency to miscomprehend, and miscomprehension appears to be inversely related to amount of formal education to a slight degree. These findings are in general agreement with those found by the researchers in the broadcasting and journalism areas. In a related study, Hoyer and Jacoby (1985) obtained an average miscom-

prehension rate of 33.7% for public affairs program.

Using a set of communications for Jacoby and Hoyer (1982), Jacoby, Hoyer, and Zimmer (1982) examined the levels of miscomprehension across three different types of mass media (TV, audio, and print). Results indicated that printed messages were least miscomprehended and audio-only messages led to the greatest degree of miscomprehension. More importantly, the overall mean miscomprehension rate was 22%. While this figure is somewhat lower than in the earlier investigation, the sample was composed of students and, thus, was upscale in terms of education.

An identical modality effect was evidenced by Chaiken and Eagly (1976). While the main focus of the study was examining the persuasive impact of complex legal information, miscomprehension was included as a major dependent variable. Even in this entirely different context, a normative miscomprehension rate of 38% was in evidence.

Other studies using entirely different stimuli and alternative measurement techniques have produced similar findings. In a study by Lipstein (1980), 32% of advertising content was miscomprehended. Jacoby, Nelson, and Hoyer (1982) experienced miscomprehension rates as high as 50% in the case of corrective advertising claims. Finally, Schmittlein and Morrison (1983) reanalyzed the estimates obtained from the initial study (Jacoby and Hoyer, 1982) in order to account for the effects of guessing and yeasaying with true-false items. Their major conclusion was that a more accurate estimate of the miscomprehension rate would be 46% (as opposed to 29.6%).

An important implication of the studies previously reviewed is that comprehension of televised messages should not be assumed or taken for granted by those in broadcasting, advertising, and communications research, though this has commonly occurred in practice (Sahin, Davis, and Robinson 1981). Several factors contribute to the continued importance of comprehension as a research topic. For one thing, research concerned with the effects of advertising on the formation of consumer attitudes and purchase intentions has generally assumed that these processes occur after the message has been comprehended (Jacoby, Hoyer, and Sheluga 1980). In other words, a number of advertising models are predicated on the assumption that comprehension has occurred, which, as has been demonstrated, may be a questionable assumption. In addition, public policy topics such as whether or not an ad is deceptive or misleading and/or whether corrective advertising should be required of a sponsor center on issues of comprehension (Jacoby and Hoyer 1982).

Purpose of the Present Study

One topic which has generated some controversy is that of measuring miscomprehension among viewers. It is apparent from the previous review of recent studies that researchers have used aided and unaided recall measures, true-false quizzes, and multiple choice quizzes to assess miscomprehension, and that various rates have been obtained. Due to its important public policy implications, the Jacoby, Hoyer, and Sheluga (1980) study sparked specific criticisms from Ford and Yalch (1982) and Mizerski (1982) on the issue of measurement. Ford and Yalch (1982) suggested, among other things, that "a multiple choice quiz may have been a better alternative than their true-false quiz because it can be designed to discourage guessing and would assess alternative interpretations of the message that might be considered 'acceptable'" (P. 30). Mizerski (1982), in supporting his claim that the Jacoby and Hoyer (1982) findings were "measurement bound", referred to results of an FTC commercial copy test in which measures of

aided recall, unaided recall, and recognition (multiple choice) were taken. Miscomprehension rates of literal ad claims in that study alone ranged from 2% to 40%, depending on the measure used.

Again, in light of the importance these suggestions have for public policy issues, the purpose of the present study is to explore these criticisms and to investigate the performance of alternate types of recognition measures, specifically true-false item format versus multiple choice format, in assessing miscomprehension. We have chosen to focus on recognition measures for several reasons. First, Ortony (1978) and Woodall, Davis, and Sahin (1983) have pointed out that comprehension of a stimulus and memory for the stimulus may well be separate and distinct phenomena which need to be recognized and treated as such in the study of human information processing. While recognition measures probably do confound memory with comprehension to some degree, they are clearly not as dependent on storage of the stimulus in memory as are recall measures. Another reason for studying recognition measures specifically is that recall measures are quite different to code reliably, and need, at the very least, to be supplemented by more objective quiz items. Finally, as noted in a rejoinder by Jacoby and Hoyer (1982) to criticisms of their original study, miscomprehension rates ranging from 2% to 38% have been obtained in various studies depending on whether true-false or multiple choice questions were used as the recognition measure.

Hypotheses

Competing hypotheses can be generated regarding the expected performance of true-false versus multiple choice questions. One perspective is that expressed by Ford and Yalch (1982), i.e., that subjects have a better chance of guessing correctly on true-false questions, which should result in lower rates of miscomprehension for true-false tests. The chance of guessing correctly on a true-false item is obviously 50%, whereas the chance percentage is reduced to 25% when a four-item multiple choice format is used. An alternative hypothesis is suggested by researchers in the educational measurement area. Frisbie (1973) noted that a multiple choice item "limits the universe of comparisons that the individual must make" (p. 303), meaning that the problem of searching for counterexamples that would falsify a statement is narrowed down for the subject when a question is asked in multiple choice form. A true-false question, in contrast, does not provide the subject with a neat set of four possibilities, with the result that a more extensive memory search is necessary in order for the subject to generate counterexamples. According to this line of reasoning, true-false items would be associated with a higher miscomprehension rate. The following study was designed to explore these hypotheses.

Method

Sample

One hundred sixty eight college undergraduates participated in the study. This represents a convenience sample of sophomores and juniors enrolled in a promotion strategy class. The authors feel justified in utilizing this type of sample since the goal of the research is to explore the internal validity of the measures employed. There will be no attempt to generalize our findings concerning miscomprehension rates to the television viewing population as a whole.

Stimuli

Six 30-second advertisements were chosen from the original Jacoby, Hoyer, and Sheluga (1980) study for use as stimuli in this study. Ads were initially chosen by Jacoby, et al. (1980) to represent the most heavily advertised product categories. The sponsors agreed to participate in the original study on the condition that they not be identified in the results, so only the products advertised in the ads chosen for this particular study can be identified. They were a laundry detergent, a brand of beer, small appli-

ances, a skin care product, a breakfast cereal, and a cough/cold remedy. These ads were chosen to represent the spectrum of miscomprehension scores obtained by Jacoby, Hoyer, and Sheluga (1980) (i.e. from high to low).

Dependent Variables

True-False Quizzes. For purposes of comparison, the exact 6-item true-false quizzes used by Jacoby, Hoyer, and Sheluga (1980) were also used in this study. Half of the questions were based on factual material in the ad, while the other half were based on inferences which might reasonably be drawn from the ad. In each quiz, two items were accurate and four items were inaccurate. In sum, each quiz consisted of one true fact, one true inference, two false facts, and two false inferences. In order to construct the original true-false quizzes (Jacoby, Hoyer, and Sheluga 1980), each 30 second advertisement was analyzed for product or product equivalent information in both audio and visual form. This product relevant information provided the basis for quiz construction. It was determined by the authors at that time that six quiz items exhausted the range of suitable information for miscomprehension testing. The original quizzes were subjected to a series of pretests to assure that they properly sampled the information in the ads and that they were understandable to study participants.

Multiple Choice Quizzes. The multiple choice quizzes in the present study also contained six items each, which were written so as to match the true-false items in content. It was presumed that Jacoby, Hoyer, and Sheluga (1980) had adequately dealt with the issue of sampling the relevant information contained in the ads. It has been suggested (Anderson 1972) that paraphrases can be used to assess comprehension. A paraphrase captures the meaning of the original message, but differs with respect to the shape or sound of the specific words. Comprehension is presumably required for a person to answer a paraphrase question correctly (Anderson 1972). Jacoby, Hoyer, and Sheluga (1980) employed paraphrase to construct their original true-false quizzes, and that tradition was followed in writing multiple choice quizzes for the present study.

The task in composing the multiple choice items was to create an item "stem" and alternative answer categories that would correspond to Jacoby, Hoyer, and Sheluga's (1980) true-false items. It has been suggested in the educational measurement literature that the paraphrase be contained in the stem (Anderson 1972) and that the stem contain the essence of the topic being measured (Mehrens and Lehman 1975). Following these guidelines, the topic of the original true-false item was used in its original wording as the multiple choice item stem. Several options are possible for writing distractor answers for multiple choice items, including: (1) judgmental determination of plausible distractors; (2) administration of a completion test and use of the most commonly occurring errors as distractors; and (3) use of the errors (from a completion test) that best discriminate among high and low scorers (Mehrens and Lehman 1975). It has been demonstrated (Frisbie 1971, Owens, Hanna, and Coppedge 1970) that method of constructing multiple choice alternatives has no significant effect on test validity (Mehrens and Lehman 1975). Therefore, for the present study, one multiple choice option corresponded exactly to the comparable true-false item, and the three additional answer possibilities were constructed on a judgmental basis to represent reasonable alternatives which might have been stated or implied in the ad.

Procedure

Subjects were tested as a group. A 30-second ad was presented over television monitors distributed around the classroom. Immediately after viewing a particular ad, the subjects completed a true-false or multiple choice quiz pertaining to the ad. When the subjects had completed the questions for one ad, the next ad was shown. The quiz for each stimulus was contained on one page of the questionnaire, and subjects were requested not to read ahead in their questionnaires. Subjects appeared to cooperate with

this request not to turn their pages until instructed to do so.

Results

Overall Miscomprehension Scores

Table 1 presents a comparison of overall miscomprehension for both the true-false and the multiple choice formats with the scores obtained in the original study (Jacoby, Hoyer, and Sheluga 1980). As would be expected, a highly educated student sample exhibited significantly lower levels of miscomprehension than the general population across all six stimuli. It is important to note, however, that there is a strong degree of consistency in terms of the order of miscomprehension scores. In other words, the stimuli exhibiting the lowest, medium, and highest levels of miscomprehension in the original study were in the same order in the present study. This order was reproduced exactly in the true-false format ($r=1.00$) and very closely in the multiple choice format ($r=.94$). Thus, while statements regarding absolute levels of miscomprehension cannot be made from present data, conclusions regarding relative levels appear justified.

TABLE 1
OVERALL MISCOMPREHENSION SCORES

Ad	Jacoby, Hoyer, Sheluga (1980)	True-False	Multiple Choice	Significance
Detergent	19%	12%	7%	.04
Skin Care Product	21%	14%	8%	.001
Cough/Cold Remedy	28%	15%	15%	N.S.
Beer	33%	17%	18%	N.S.
Small Appliances	34%	26%	32%	.03
Breakfast Cereal	40%	36%	30%	.03

The most important findings from Table 1 concern the comparisons of the two measurement formats. It can be seen from the table that, for three of the stimuli, miscomprehension was higher for the true-false format.¹ In two cases, differences were non-significant, and in the last instance, miscomprehension was higher for the multiple choice format. Thus, there appears to be slight support for the hypothesis that true-false items require more cognitive elaboration and, thus, are more difficult items to answer. It should be noted, however, that the magnitude of these differences is not large, and substantial miscomprehension occurs with both formats.

Miscomprehension of Facts and Inferences

A major distinction in the Jacoby, Hoyer, and Sheluga (1980) study was the ability to comprehend factual and inferential material. Accordingly, overall miscomprehension levels were broken down into scores representing factual and inferential miscomprehension levels. Table 2 presents a summary of this analysis across the six stimuli.

It can be seen from the table that most of the differences between the two formats occur in the case of inferential items. In two cases, greater miscomprehension was

¹Item total correlations were computed in order to examine the pattern of item difficulties for the true-false and multiple choice items. Results of this analysis indicated a fairly consistent pattern of item difficulties across the two formats.

TABLE 2

MISCOMPREHENSION OF FACTS AND INFERENCE

Ad	Facts			Inferences		
	True-False	Multiple Choice	Significance	True-False	Multiple Choice	Significance
Detergent	10%	5%	.006	2%	2%	N.S.
Skin Care Product	3%	5%	N.S.	11%	3%	.001
Cough/Cold Remedy	8%	7%	N.S.	7%	8%	N.S.
Beer	8%	6%	N.S.	9%	12%	N.S.
Small Appliances	14%	14%	N.S.	12%	18%	.003
Breakfast Cereal	18%	21%	N.S.	18%	9%	.001

evidenced for true-false items; in one instance, more miscomprehension occurred for the multiple choice format; and, in the remaining three instances, there were no differences.

For factual items, there were no significant differences between items in five of the six cases. In only one instance, the true-false format exhibited higher levels of miscomprehension than did the multiple choice format.

Thus, it may be concluded that differences in miscomprehension scores due to item format occur largely for inferential items. In this case, true-false items appear to be slightly more difficult. However, again, it must be noted that the differences are not large and a significant degree of miscomprehension occurs for both types of items in both formats.

Discussion

Results of the present study appear to support, to some degree, the hypothesis that true-false questions are more difficult for subjects to answer correctly. The reasoning for this finding, as explained in an earlier section, is that true-false questions require more cognitive effort on the part of subjects in that subjects must generate alternatives and counterexamples on their own, rather than having them provided in the question (as they are when the multiple choice format is used.) One practical implication of this general finding is that, in future studies, researchers might find it fruitful to determine at the pretest stage if systematic misunderstandings can be identified for a stimulus and, if so, use them as multiple choice alternatives. This would permit a more precise determination of miscomprehension due to specific types of information or alternative interpretations of this information. In other words, if miscomprehension is hypothesized to be a function of certain types of belief, statements related to these beliefs can be included as response alternatives to more accurately pinpoint the cause of miscomprehension.

The findings of this study contradict the implication by Ford and Yalch (1982) that guessing by subjects on true-false questions resulted in an inflated measure of miscomprehension in the original Jacoby, Hoyer, and Sheluga (1980) study. If guessing on true-false items led to inflated miscomprehension scores, one would have expected miscomprehension to be significantly lower when assessed with multiple choice items. Results did not, however, indicate definitive superiority of one question format over the other.

It is important to note that substantial miscomprehension occurred with both the true-false and the multiple choice formats. From a practical standpoint, the differences between measures are not large, and the results of the present study do not invalidate the use of the true-false format in prior studies, such as Jacoby, Hoyer, and Sheluga

(1980). Thus, the key conclusion that substantial amounts of miscomprehension occur across the different types of televised communication does not appear to be invalidated by the type of question format employed.

The most notable differences in miscomprehension rates using true-false versus multiple choice format occurred with inference questions. There appeared to be a slight tendency for subjects to miscomprehend true-false inferential items to a greater degree than multiple choice inferential items. This finding can be viewed as consistent with the generation of counterexamples hypothesis since questions pertaining to inferences would require the generation of a greater number of counterexamples than would factual items. Thus, true-false inferential items would be more difficult than similar items for factual material. This finding needs to be replicated in future studies. However, on a practical level, future attempts to assess miscomprehension should keep this distinction in mind.

It is important to note that the present study possesses some important limitations. The first involves the nature of the sample employed. Obviously, a college sample would be more intelligent and more highly educated than the population at large, and, thus, generalizations regarding the absolute levels of miscomprehension cannot be made. However, it is important to reemphasize that the rank ordering of miscomprehension scores (from lowest to highest) for the true-false format was exactly reproduced in the present study (as compared to Jacoby, Hoyer, and Sheluga 1980). Thus, it may be possible to make at least relative statements regarding the internal consistency of the data. Nevertheless, future research is needed to replicate findings such as these on a more representative sample.

A second limitation is that the ads were tested in one order at one point in time, and order effects may have threatened the internal validity of the findings. This problem appears not to be great, however, since, as mentioned above, there was a high correspondence between the ordering of scores in the original study and the present study.

A third limitation is that the manner of composing multiple choice questions could have influenced results. It may be preferable, when using multiple choice questions, to determine alternative answer categories through use of a completion test at the pre-test stage, as discussed in the methods section.

In conclusion, the results of this study suggest that work remains to be done on the issue of how to best measure miscomprehension. Given the importance of this construct for communication and advertising effectiveness, future studies which systematically compare other question formats would be particularly helpful. One obvious comparison would be between recognition measures, such as those employed in the present study, and recall measures, which have been collected in a number of the studies referred to previously. Exploring this type of measurement issue is one avenue that might be pursued in trying to specify the role(s) of memory in comprehension. In addition, future studies might consider possible interactions between ad characteristics and question format. The effects of question format in the present study differed depending on whether the question concerned a fact or an inference. Ad characteristics, e.g. cognitive vs. affective appeal, or one-sided vs. two-sided message, might also reasonably be expected to affect question format performance.

THE ROLE OF KNOWLEDGE
IN THE EFFECTS OF TELEVISION ADVERTISING ON CHILDREN

Henriette Sanft, Carnegie-Mellon University

Abstract

Previous research on the effects of television advertising on children has focused on age as the important explanatory variable. This study looks at another variable, that of the child's knowledge about advertising, as the important factor. Specifically, this study looks at memory differences between those children who have knowledge about the purpose of advertising and those who do not. Results indicate that those children who have knowledge about advertising remember more product-related information from commercials. These results bring a new theoretical interpretation to the effects found by past researchers and have implications for public policy issues concerning misleading advertising.

Most children between the ages of 5 and 12 watch at least six hours of television each week. During each of these viewing hours, the child is exposed to approximately 15 commercial messages (Barcus 1980). What effect do these television advertisements have on children? This issue has been a focus of research and theory for at least the past 15 years. However, there is still no definitive answer. The purpose of this paper is to review our current knowledge of the effects of television advertising on children, and to suggest a new theoretical interpretation of these effects.

Previous research in the area of children and television advertising has looked at the following questions:

- Do children understand the purpose of advertising?
- Do children pay more attention to commercials than programs?
- Are children persuaded to want the advertised product?
- What do children remember about T.V. commercials?

While these questions have independently received partial answers, we still do not know how television advertising works with children. However, in each of these areas, age emerges as an important mediating variable. Taken as a whole, studies in the area demonstrate that children become more sophisticated in dealing with advertising as they grow older (Adler et al 1980). These age mediated effects have been explained in terms of Piaget's theory of cognitive development. Piaget's theory is often interpreted as essentially a theory of deficits; children of a certain age and cognitive stage are seen as being unable to perform mental operations characteristic of another, later stage. Early, lower stages of reasoning are more concrete, literal and undifferentiated, while higher stages are more complex and show more differentiation and integration of perception and cognition (Blatt, Spencer & Ward 1972). Research in the area of children and advertising has developed with this kind of deficit emphasis (Wartella et al 1979).

Piaget's theory guides research by providing rough age guidelines to follow in designing research (Wackman and Wartella 1977). However, biologically based cognitive stages do not really provide an adequate explanation of children's information processing. What they essentially do is to indicate limits on children's capacity to process information (Calder, Robertson & Rossiter 1975).

¹Funding for this research was provided by the Graduate School of Industrial Administration, Carnegie-Mellon University. The author thanks Eric J. Johnson for his helpful comments, Joanne Chu for her assistance in conducting the study and the Gymkhana school for their cooperation.

They are useful because they explain what children cannot do, but are limited because they do not tell us what children can do. The notion of cognitive stages is most often used in an explanatory, rather than predictive, fashion. Thus, Piaget's stage dependent view of children's performance has gained rapid acceptance among those interested in explaining the effects of television advertising on children. It represents a convenient mechanism for predicting what children are and are not able to do within a given stage (Chestnut 1979).

There has been a recent shift in the field of developmental psychology away from Piaget's theory of cognitive development towards the role of a child's knowledge base as a factor in memory development. By a child's knowledge base we mean the child's knowledge of a specific domain. Changes in such knowledge of specific content domains may underlie changes previously attributed to the growth of capacities or strategies (Siegler 1981). Siegler suggests several points about the child's knowledge base. First, knowledge influences the recall of newly presented material. Second, memorial performance improves during periods of development in which there is little improvement in strategies but substantial improvement in content knowledge. Third, age-related differences in measures of basic capacities and strategies may be attributable to changes in the knowledge base. Finally, under some circumstances, differences in content knowledge outweigh all other age-related differences. Memory development can be viewed as the increment of more content knowledge and a growth in the knowledge base with age can account for learning and improved memory performance (Chi 1981). Thus, according to this view, a younger child can behave like an older child, given the same knowledge base.

It is this relationship between a child's prior knowledge and subsequent performance that this paper is concerned with. Specifically, we want to show that the knowledge that children possess about television advertising, and not age, is the important factor in the effects of television advertising on children. Knowledge and understanding of the purpose of television advertising will affect how children are persuaded by commercials, and subsequent memory for commercial information. The model proposed for this relationship is presented in Figure 1. This model suggests that knowledge about the purpose of advertising will have an effect on the encoding of commercials. This in turn will effect the amount of product related information and non-product related information remembered from the commercial, and recognition of the advertised product. Preference for the advertised product will be affected by three things: 1) recognition of the advertised product, 2) non-product related recall and 3) product related recall. The major findings from previous research for each of the components in the model follow.

FIGURE 1
MODEL

Children's Understanding of the Purpose of Advertising

Age has been found to be directly related to the child's understanding of the purpose of advertising (Blatt, Spencer & Ward 1972; Ward 1972; Ward, Reale & Levinson 1972; Ward, Wackman & Wartella 1977; Adler 1978; Ratner 1978). Children age 5-7 are confused and unaware of the selling motive. Children age 8-12 have some understanding that commercials are intended to sell. By the time children are twelve years old they have a clear recognition of selling motives, and an emerging understanding of the techniques advertisers use in constructing commercials.

Attention to Commercials

In order to process a stimulus, it must first be attended to. Attention is necessary for any memory and comprehension that does occur (Anderson & Lorch 1983). For this reason, children's actual looking behavior or attention to television commercials has been studied. Television advertising to children uses many attention-getting devices such as repetition, unusual sound or visual effects, animation, magic and fantasy (Barcus 1980). What is the effect of these devices on children's attention to commercials? Children 5-10 pay greater attention to commercials and programming than children age 11-12 (Ward, Levinson & Wackman 1972), and the younger the child the greater the influence of perceptual characteristics of commercials on his attention (Ward, Wackman & Wartella 1977). In general, the paying of full attention to commercials decreases with age (Ward 1972).

Children's Preferences for Advertised Products

Several studies have looked at children's preferences for advertised products as a measure of persuasion (Goldberg & Gorn 1974; Robertson & Rossiter 1974, 1976, 1977; Goldberg, Gorn & Gibson, 1978; Rossiter 1979, 1981; Gorn & Goldberg 1982). Exposure to advertising increases desire for, requests for, and consumption of advertised products (Barry 1977; Atkin 1980). This is especially true of brand-name sugared products (Ratner 1978). There are inconsistent findings in terms of developmental differences in this area of research. However, children younger than 8 years old seem to be more likely to request products, and may be more strongly influenced to desire and request television advertised products after watching commercials (Wartella 1980).

Children's Memory for Commercial and Product Claims

As children grow older recall of commercials becomes more differentiated and complex (Ward 1972, 1974; Ward, Wackman & Wartella 1977; Ratner 1978). With both recall and recognition measures memory for commercials increases as a function of age (Blatt, Spencer & Ward 1972; Ward, Reale & Levinson 1972; Wartella 1980; Stoneman & Brody 1983). Young children do not recall the content or purpose of advertising and only recall a single element in a commercial or several elements but in a random fashion. Older children recall more features and relate these features in the proper sequence to represent the story told in the commercial; the commercial message is the focus of recall, not the elements. The major increases in memory seem to occur between the ages of 5 and 8. Again, this focus on age has led researchers to ignore other factors that might influence a child's memory for commercial messages. Roedder (1981) describes these age differences within an information-processing framework. In this perspective, younger children experience difficulty in processing the central persuasive arguments advanced in television commercials and only process information that is peripheral to the commercial content. Roedder concludes by saying that children's abilities to process information can be enhanced by "...affecting the processing of incoming commercial content and previously stored information relevant to evaluating commercial claims" (page 150). It is this relationship between a child's previously stored information about commercials and the child's subsequent memory of commercials that is investigated in this paper.

In summary, research in the area of children and television advertising has shown that age is the best explanatory variable for the effects found. However, the acceptance of this explanatory variable has led to the lack of any investigation of the possible underlying causes. Could it be that a child's knowledge about the purpose of television advertising is the mediating variable?

Experiment

Although the components of children's understanding and knowledge has been investigated, such as children's attention to commercials, memory for commercials, and product preferences, the relationship between these measures has not. The cognitive perspective suggests that there may be strong relationships between them. For example, prior knowledge will effect the recall of newly presented material (Siegler 1981). Thus, we might suspect that knowing that commercials are intended to sell products should have an effect on what is remembered from the commercials. Young children have been found to recall mostly non-product related information from commercials. If young children know the purpose of commercials (to sell products), it should lead to better recall of product related information.

This experiment looks at recall differences between those children who have knowledge about commercials and those children who do not have knowledge about commercials. It is expected that recall of product related information in commercials will be better for those subjects who possess the prior knowledge and understanding of television advertising. This is consistent with prior studies. We know, for example, that children above the age of 11 are able to recall the commercial message, and a separate study shows that this same age group is also able to distinguish between commercials and programming and to understand the purpose of advertising (what a commercial is). Our purpose then, is to minimize age differences by making younger children as knowledgeable as their older counterparts.

In addition, this experiment investigates two explanatory hypotheses. One is the relationship between attention to commercials and overall recall of commercial information. It is expected that knowing about the purpose of advertising will lead to greater attention to the commercials. This greater attention should lead to better memory for both product and non-product related information. The second is the relationship between memory for the commercial and preference for the advertised product. Recall of product related information will be higher for those subjects who know the purpose of advertising. It is expected that this better memory for product-related information will be positively related to preference for the advertised product. This is expected because the more a child remembers about an advertised product, the more salient the product will be when the child is asked to indicate a preference.

Hypotheses

The following hypotheses are proposed:

- Hypothesis 1: Recall of product related information will be better for those children who know the purpose of commercials.
- Hypothesis 2: Recall of non-product related information will be the same for all children regardless of the knowledge they possess about commercials.
- Hypothesis 3: Recognition of the advertised product will be the same for all children.
- Hypothesis 4: For those children who know the purpose of commercials, greater attention to the commercial will lead to better memory for both product and non-product related information.
- Hypothesis 5: For those children who know the purpose of commercials, better memory for product related information will be positively related to preference for the advertised product.

Method

Subjects. Nineteen children, between the ages of 5 and 6 years, (mean age 5.6 years), participated in the study. The children were enrolled in a pre-school gymnastic program in the Pittsburgh area. Children were recruited from two classes at the gymnastic school. Letters were sent out to the parents describing the study, and consent sheets were sent back in the mail. All children were from upper middle class, well educated families. Children were given a small toy at the completion of the experiment for their participation.

Design. The experiment included two groups of subjects who were exposed to four commercials in a trial sequence. Knowledge about the purpose of advertising was manipulated by instructing subjects about commercials. Accordingly, one group (n=10) was instructed about the purpose of commercials while the other group (n=9) was not. All subjects participated in 2 sessions, a week apart from each other.

Materials. The experimental materials consisted of a commercial questionnaire, four cereal commercials and eight cereal boxes (used for the preference and recognition measures). The commercial questionnaire consisted of six questions which measured children's knowledge about the persuasive intent of commercials.

Cereal commercials were chosen because they account for at least 34% of all ads broadcast on children's television programs (Barcus, 1980). The four cereal commercials were for the following brands: Lucky Charms, Cookie Crisp, Cinnamon Life and Cheerios. Each commercial was 30 seconds long. Commercials were obtained from companies and advertising agencies. Although the cereals in the commercials are available in the Pittsburgh area, the commercials were not currently being shown on television. Four different orders for viewing the commercials were used in order to counterbalance the four commercials across trials.

The eight cereal boxes included the four advertised cereals plus four other distractor cereals. The cereals were chosen so that two of them were of the sweetened variety (comparable to Lucky Charms and Cookie Crisp) and two were of the non-sweetened variety (comparable to Life and Cheerios). The four cereals were: Cap'n Crunch, Super Sugar Crisp, Golden Grahams and Kix.

Apparatus. Children viewed the commercials on a 19" color TV. A home video cassette recorder was used to play the commercials. Verbal responses were recorded on a cassette tape recorder. Looking time was measured with a digital stopwatch.

Procedure. The experiment was conducted in two sessions, each a week apart. Two different experimenters were used for each session. All subjects were tested individually.

Session 1: All children were asked questions about television commercials. These questions were imbedded in other questions concerning television in general (i.e. What is your favorite cartoon?) and questions about cereal (i.e. What kind of cereal do you eat for breakfast?).

Following these questions, subjects were randomly assigned to either the instructed or non-instructed condition. The non-instructed subjects were dismissed and told to return next week at the same time. The instructed subjects were told: "Now I want to talk to you about commercials. When you watch television I am sure you see a lot of commercials. Commercials are those short things on TV between programs that show you things to buy. The commercials show things like candy, toys, games and food. Commercials are shown on TV so that you will buy something. The people who make these toys and games put commercials on TV to get you to buy them" (adapted from Shamir, 1979; Wackman et al, 1979).

After these instructions were given, subjects were shown

a videotape of two commercials from Saturday morning cartoons. While viewing these commercials (for bubble gum and cookies) the experimenter pointed out aspects of the commercials that were talked about in the instructions. After viewing the example commercials, subjects were re-asked the commercial questions (as a manipulation check). Subjects were then dismissed and told to return next week at the same time.

Session 2: This session was the same for both groups of subjects. Children viewed the four commercials in a trial sequence. The first commercial was shown and then subjects were asked to tell the experimenter what they just saw on TV. Similarly, the next 3 commercials were shown one at a time with the children recalling after each commercial. Looking time at each commercial was measured by the experimenter with a digital stopwatch.

Following these 4 recall trials subjects were given 4 preference tests. The order of the cereals was the same as that in the commercial viewing. Each preference trial consisted of the 1 advertised brand and the 2 comparable distractor brands. (For example, if subjects saw the Life cereal first, they were shown the Life cereal box along with the Kix and Golden Graham cereal boxes). Children were asked: "If you could take one of these cereals home with you to eat for breakfast tomorrow, which one would you want?". Subjects were told to point to the cereal that they would want. This was repeated 3 more times. Each time, the child was shown the 1 advertised cereal along with 2 distractor brands.

Following the preference measure a series of recognition tests were given. These recognition trials were in the same format as the preference trials. Here, children were asked to point to the cereal they just saw on TV.

At the completion of the experiment all subjects were again asked the commercial questions.

Results

Commercial Questionnaire. Results are presented in Table 1. As can be seen, less than half of all subjects (prior to instructions) could answer appropriately to questions concerning the persuasive intent of commercials. The results for the session 1 manipulation check for the instructed condition subjects show that prior to instructions, the question "What do commercials want you to do?" was responded to correctly by only 20% of the subjects. After the instructions were given, 70% of the subjects could answer the question correctly. As can be seen, the manipulation was successful for all but 3 subjects. Results from the questions asked at the conclusion of the experiment indicate that the instructional manipulation held over the two week period.

TABLE I
QUESTIONNAIRE RESULTS

	SESSION 1		SESSION 2	
	INSTRUCTED Before	UNINSTRUCTED After	INSTRUCTED	UNINSTRUCTED
What is a TV commercial?				
interrupts show	20%	30%	22%	0%
sells you something	0%	20%	22%	10%
don't know	80%	50%	56%	90%
Why are commercials shown on TV?				
to sell or buy things	20%	60%	33%	60%
to tell you things	10%	0%	11%	20%
don't know	70%	40%	56%	20%
What do commercials try to do?				
get you to buy things	30%	60%	56%	70%
don't know	70%	40%	44%	30%
What do commercials want you to do?				
buy things	20%	70%	56%	60%
don't know	80%	30%	44%	40%

Looking Time. Means for looking time are close to ceiling (average looking time is 28.44 seconds for a 30 second commercial). In a 2 (condition) X 4 (commercial order) X 4 (trials) repeated measures ANOVA, a significant effect was found for trials, $F(3.33) = 5.31, p < .01$. A Tukey test for the comparison of means revealed a significant increase in attention up to trial 3, but not beyond. These results indicate that in both conditions children were paying the same amount of attention to the commercial.

Recall. Recall items were coded as product related or non-product related information. Product related information consisted of the cereal brand name, any of the cereal attributes (e.g. marshmallows, low in sugar, etc.) and the character related with the cereal. Non-product related information consisted of any people appearing in the commercial or any events that happened in the commercial (e.g. the little boy just woke up). Results were analyzed separately for product related recall and non-product related recall.

Product Related Recall. In a 2 (condition) X 4 (commercial order) X 4 (trials) repeated measures ANOVA, a significant effect was found for condition, $F(1.11) = 10.50, p < .01$. When recall was analyzed in a 2 (condition) X 4 (specific commercial) repeated measures ANOVA, a significant effect was also found for commercial, $F(3.51) = 3.31, p < .05$ (see Figure 2).

Non-Product Related Recall. In a 2 (condition) X 4 (Commercial) X 4 (trials) repeated measures ANOVA, no significant effect was found for condition, $F(1.11) < 1$. As in product related recall, when non-product related recall was analyzed in a 2 (condition) X 4 (specific commercial) repeated measures ANOVA, a significant effect was found for commercial, $F(3.51) = 5.31, p < .01$ (see Figure 3).

NON-PRODUCT RECALL FOR COMMERCIAL

Preference. For the analysis of variance, preference for the advertised product was summed across trials. Means are presented in Table 2. In a 2 (condition) X 4 (commercial order) ANOVA, no significant differences were found. If children know the purpose of advertising, one would expect them to be less persuaded by commercials. While the means are in this direction, it could be that the lack of any significant effect is due to the small number of data points for each subject.

Recognition. As with the preference measure, for the analysis of variance, recognition of the advertised product was summed across trials. Means are presented in Table 2. In a 2 (condition) X 4 (commercial order) ANOVA, no significant differences were found. Advertised products are recognized equally well by both groups of subjects.

Correlations for All Measures. Correlation tables for all subjects, instructed subjects, and uninstructed subjects are presented in Table 3. For all subjects, the correlation between recognition and product recall ($r=.594$) was significant, $p < .01$. This correlation was also significant for the instructed condition subjects ($r=.736$), $p < .01$. However, it was not significant for the uninstructed condition subjects. This suggests that recalling the product name is related to recognizing the product at some later time. The correlation between recognition and preference for the instructed condition subjects was also significant ($r=.553$) $p < .05$. For the uninstructed condition subjects the only significant correlation was between attention to the commercials and recognition of the advertised product ($r=.596$), $p < .05$.

Tests for differences between the correlations for the instructed condition and the uninstructed condition were also done. The only comparison that was significant ($p < .05$) was the correlation between preference and recognition, (instructed condition $r=.554$, uninstructed condition $r=.381$). This suggests that preference for the advertised product and recognition of the advertised product are related only for the subjects that knew the purpose of television advertising.

For the instructed condition subjects, it was expected that attention and recall of the commercial would be positively correlated. However, given that the attention measures were close to ceiling for both the instructed and non-instructed conditions, it is not surprising that the hypothesized relationship was not found. In addition, for the instructed condition subjects it was expected that recall of product related information and preference would be positively correlated. As can be seen, the hypothesized relationship (although nonsignificant) was found. This suggests that the better memory for product related information found in the instructed condition subjects is related to preference for the advertised product.

Discussion and Implications

The experiment has provided support for the three major hypotheses. As predicted, recall of product related information from the commercials was greater for those subjects who knew the purpose of advertising. Also as predicted, recall of non-product information and recognition of the advertised product were the same for all subjects, regardless of the knowledge they possess about commer-

cial. These findings bring a new perspective to the issue of children and the effects of advertising. They show that young children's failure to recall product related information from commercials is not brought about by the mere fact that they are young, but by the fact that they do not understand that commercials are any different from programs. The lack of any differences in non-product related recall lends further support to this notion. Children without the knowledge of commercials only recall what they understand.

The relationship between recall of commercials and attention to commercials is still unclear. Better attention measures would probably help in shedding some light on this issue, along with varying the amount of attention getting devices in the commercials.

Preference for the advertised product appears to be related to only one measure, recognition of the advertised product. This suggests in some way that young children's preferences are not based on any product attributes themselves, but on the mere fact that they are able to recognize the product. However, a weak positive relationship between recall of product information and preference for the advertised product was found for the instructed condition subjects. This finding suggests that remembering more about the specific product influences the child's preference for that product. The extent of this influence needs to be specified through further research.

This study provides a new theoretical explanation of the results that have been found in previous studies. Mainly, that of the child's knowledge about advertising being the determining factor in his/her encoding of commercials,

memory for advertised products, and the extent to which the child is persuaded to want the advertised product. Although there were a small number of subjects in the study the results are encouraging. Further research is being conducted to extend the findings reported here.

This study also has implications for public policy issues concerning children and television advertising. In the past ten years, consumer advocacy groups and the Federal Trade Commission have argued that it is unfair to advertise to young children (Possiter, 1981). One issue, in particular, is whether advertising to children is deceptive. Deception is defined in terms of the child's beliefs about the product. An advertising claim may be factually true yet result in consumer beliefs that are factually false. Of concern here is whether advertisements directed at children result in beliefs about the product that are untrue. Prior research has helped shape public policy to date. Specifically, research has been instrumental in supporting or refuting allegations of misleading advertising (Rossiter, 1981). How can this study contribute to this issue?

In terms of children's recall of television commercials, research findings have suggested that children recall information that is peripheral to the product, and young children in particular, recall very little product relevant information. This learning of information that is peripheral to the product may be one factor involved in misleading advertising. For example, in a toy commercial, much information may be given about the toy itself. However, information peripheral to the toy, such as children playing with it and laughing, may lead to a possibly false belief that the toy will make a child happy. Due to the lack of any remembering about the product itself, the child is left with a false belief that the product will make him/her happy. If young children have the relevant knowledge about advertising (e.g. knowledge about the purpose of advertising, knowledge about the product being advertised or knowledge about the product class in general) to process product-relevant information and young children are able to recall this information, this should lead to less false beliefs about the product. Therefore, this research has much to contribute to policy issues involving misleading advertising to children. Specifically, it can be shown that when young children have the knowledge that is necessary to process the information, they are able to recall more product-relevant information.

Abstract

A further examination of the availability-valence hypothesis found that illustrations added to advertising copy enhanced belief formation and attitude toward the product. The results illustrate the value of taking as much care in the choice of dependent measures as is taken in choosing the manipulations to test the hypotheses.

Introduction

In a recent study, Kisielius and Sternthal (1984) undertook an examination of what they call the "availability-valence hypothesis." Their findings that instructions to image and the presence of story-board illustrations reduced subjects' judgments about a fictitious brand of shampoo were explained by the following set of propositions:

- 1) people process new information about an object by relating it to available information in memory,
- 2) the affective valence of information brought to mind by external stimuli in turn determines the favorableness rating of the external stimuli,
- 3) the picture analogs (illustrations) used in their research and their instructions to image advertising copy enhances cognitive elaboration that makes available in memory information that is less favorable to the advocated message position and, consequently,
- 4) adding illustrations to advertising copy may result in a decrement in favorable brand attitudes.

In the Marketing Teleconference Consortium organized by the Oklahoma State University on November 28, 1984 entitled "Assessing the Black Box: When is a Duck a Duck," scholars from different institutions raised concerns as to whether Kisielius and Sternthal (K&S) had considered and eliminated alternative explanations for the major effects observed in their study. It was suggested that a research approach employing manipulation check measures and measures of moderating beliefs associated with specific claims made in the advertising copy might have helped eliminate competing explanations and led to a better test of theory. In accordance with this philosophy, the research reported here replicates K&S's study, incorporating additional measures which we believed would help further explain the judgmental effects of pictures.

The K&S results were surprising in view of the literature which has shown pictures to frequently have a favorable effect on learning (i.e., recall). Childers and Houston (1984) examined the role of interactive pictorial stimuli in which verbally presented brand names were accompanied by pictures that directly portrayed the brand name. They found that pairing pictures with verbal brand names enhanced brand name recall when people were engaged in sensory but not semantic processing. However, picture conditions yielded better recall than verbal conditions in both sensory and semantic processing groups after a two day delay. Lutz and Lutz (1977) have also found interactive pictures to enhance recall. This was not the case for non-interactive pictures (i.e., pictures that were separated from the brand name) which generated recall levels equivalent to those obtained in the verbal only condition. In a recent partial replication of the Lutz and Lutz study, Biron and McKelvie (1984) found that picture conditions resulted in superior recall to verbal conditions even when the illustration and verbal portions were separated.

K&S's pictorial stimuli were large drawings with the verbal claim appearing at the bottom of the page in small

standard one-eighth inch type. Each verbal claim was about a sentence long. In the research reported here, their verbal and pictorial conditions are replicated. A second pictorial condition is added that is designed to draw greater attention to the verbal claim. In this condition, the verbal claim appears in large black lettering at the top of the page. If K&S's results are due to subjects' paying insufficient attention to the verbal claims, we would expect the negative effect of the picture condition to be eliminated in the large print picture condition.

An alternative possibility that could account for their results is that the illustrations employed in the picture conditions may have adversely affected the evaluation of the advertisements, and this negative evaluation may have generalized to the product. The pictures employed by K&S were black line drawings or sketches on white paper. They were not at all like finished advertisements. Examination of differences in stimulus evaluations between verbal and pictorial advertisement conditions would address this issue. We, therefore, asked subjects to evaluate each of the 13 story-board pages in the advertisement on good-bad, desirable-undesirable and pleasant-unpleasant scales.

A third possibility is that their illustrations may have been irrelevant to their verbal claims. Pictures appear to facilitate learning when they are relevant to the verbal material, but have a detrimental effect on learning when they are irrelevant (Wollen, Weber and Lowry 1972; Wollen and Lowry 1971). Manipulation check questions included in our study permit an examination of this possibility.

A fourth consideration is that K&S had people rate the shampoo on three attributes after seeing all 13 pages. Yet it is likely that the effects of pictures on acceptance of each page's verbal claim will vary from page to page. Therefore, in addition to asking for summary evaluations of the shampoo, we assess subjects' beliefs about each of the claims made in the advertising stimuli to which they were exposed. We expect that some of these beliefs will be affected by the picture manipulation and that others will not be affected by this manipulation.

Relatively little is known about what differentiates effective and ineffective or counterproductive pictures. Whether or not pictures are interactive with verbal material, whether they are relevant to that material, whether people are engaged in semantic or sensory processing and whether they have sufficient time to fully process the stimuli have been shown to be important moderating variables. It is likely that other variables are also important. For example, message titles and pictures that help the reader better understand the meaning of the verbal material have been found to increase the cognitive effort employed in the comprehension of that material (Britton, Holdredge, Curry and Westbrook 1979) and the recall that results (Bransford and Johnson 1972, Dooling and Lachman 1971). Some of these variables will be explored in this research by examining differences in subjects' ratings between effective and ineffective pictorial ads. While we recognize the post hoc nature of this kind of data investigation, we believe it is a fruitful precursor to future research.

A final concern is methodological in nature and focuses on the particular manner in which K&S assessed subjects' attitude toward the shampoo. Their attitude measure, reproduced in Table 2, consisted of three semantic differential scales. As can be seen, the first two scales

appear to tap subjects' beliefs or cognitive attitude rather than their affective attitude. Consequently, it is debatable whether K&S even tested the effect of elaboration valence on affective attitude toward the target object. If this is a valid concern, then the K&S findings should be interpreted using a cognitive based theory rather than an affect transfer theory.

The following study is an attempt to replicate and extend the K&S findings by exploring competing explanations for observed moderating effects of illustrations on advertising copy. The findings should therefore be of interest to three audiences: advertising practitioners, information processing theorists, and those interested in continuing the philosophy of science debate on the most appropriate methods for testing theory and advancing knowledge.

Method

Subjects and Procedures

A total of 555 students enrolled in a massive undergraduate marketing course participated in the study. In order to maximize comparability with the K&S study, we employed the same copy, pictures and dependent measures.¹ Only the instructions were altered slightly to reflect that the product was being considered for introduction into the Columbus market rather than the Chicago area.

A booklet containing the advertising stimuli was distributed to subjects during class under the supervision of eight experimenters. Subjects were directed to examine each of the 13 pages that contained the phrases comprising the advertising copy (see Table 1 for the 13 phrases). They were exposed to each page for five seconds. After the directed page by page study of the advertisement, subjects responded to a series of measures described below.

TABLE 1

THE ADVERTISING COPY

1. Does your hair get tangled and limp? Could be your shampoo.
2. Now there is Celebrate, designed especially for you.
3. It cleans your hair .. squeaky clean.
4. And it leaves your hair smooth, soft and full.
5. Celebrate contains no harsh detergents.
6. It doesn't have those sweet perfume or soapy scents that are found in most shampoos.
7. And Celebrate comes in three formulas -- for fine, thick and normal hair -- one just right for you.
8. Even Celebrate's new plastic bottle was designed with you in mind.
9. It has a handle built into the side of the bottle so that it won't slip out of your hands.
10. And it has a measuring dispenser that regulates just the right amount of shampoo for one washing.
11. Even though Celebrate costs about a dollar more than other leading shampoos..
12. You'll want to buy the shampoo that does the most for you.
13. So, why not Celebrate!

At the end of the exercise we also verbally instructed subjects to reread the initial instructions and place an "x" on the back of the booklet if they had not conscientiously followed the instructions or if they had answered any or all of the questions flipantly. Fifty nine participants did so and were excluded from the analysis. A further 50 subjects were dropped from the analysis because of missing data or clearly inconsistent responses to the K&S and attitude measures that indicated a lack of

¹We would like to thank Jolita Kisielius and Brian Sternthal for their generous cooperation in supplying us with the experimental materials from their study.

care and/or effort.

Independent Variables

The experiment involved a 2x3x2 between-subjects factorial design. The first factor manipulated the presence or absence of the following paragraph in the initial instructions:

"To compensate for the unfinished form of the ad, we would like you to view the ad in a particular way so as to get a good feel for the product. As you are presented with the ad, please try to construct a mental picture or image of the product as it is being described. For example, if an ad about a dishwashing liquid stated that it had high sudsing value, you might imagine a sink full of dishes covered with soap bubbles. Certain characteristics of a product may seem hard to picture in your mind. Nevertheless you should attempt to create some sort of image."

The second manipulation involved three story-board formats. The first (verbal only) presented the reader with a type written phrase at the bottom of each of the 13 pages. The rest of the page was conspicuously blank. In the second condition (picture-words), the K&S illustrations were added. We also explored the framing effect of the words on the picture (rather than vice versa) by creating a word-picture condition. This involved placing the phrase at the top rather than the bottom of each page in very bold printed letters some 4-5 times larger than in the second condition.

The third factor was a blocking on sex. The female students received a pink booklet with female illustrations, the males a blue booklet with male illustrations.

Measures

Upon completion of the advertising message, subjects first responded to the three bipolar scales used by K&S (see Table 2). Our study went further by having subjects

TABLE 2

RATING SCALES EMPLOYED IN THIS RESEARCH

The Kisielius and Sternthal Scale

CELEBRATE shampoo is:

Gentle _____ Harsh
 Difficult to handle _____ Easy to handle
 Good for your hair _____ Bad for your hair

Our Attitude Scale

CELEBRATE shampoo is:

Superior _____ Inferior
 Undesirable _____ Desirable
 Pleasant _____ Unpleasant
 Bad _____ Good
 Worthless _____ Valuable

Example Belief Measures

	SD	N	SA
Celebrate leaves hair smooth, soft and full.....	1	2	3 4 5 6 7
Celebrate does not have a sweet perfume.....	1	2	3 4 5 6 7
Celebrate contains no harsh detergents.....	1	2	3 4 5 6 7
Celebrate costs a dollar more than other shampoos.....	1	2	3 4 5 6 7
Celebrate's bottle has a non skid bottom.....	1	2	3 4 5 6 7

respond to (1) five evaluative semantic differential attitude scales (see Table 2), (2) 11 general belief statements about Celebrate, (3) 16 very specific belief judgments using the words from the advertising copy but including three false product claims, and (4) questions that evaluated each of the 13 story-board pages. The last set of measures consisted of again presenting each of the 13 stimulus pages on the left facing page. The right facing page contained measures asking subjects to rate the

stimulus page on three evaluative scales, followed by three scales assessing the ease of understanding, ease of relating to, and meaningfulness of the page. The next three questions measured how favorably disposed the subject was toward the entire page, the words alone, and the illustration alone (in the conditions where illustrations were presented). For the illustration conditions, the final four measures captured the extent to which each picture was perceived to be consistent with the accompanying words, similar to the words, related to the words, and whether it was perceived to clearly illustrate the specific point or feature made by the text (e.g., "The picture clearly illustrates that Celebrate has a handle built into the side of the bottle so it won't slip out of the hands"). For the verbal only condition, however, the final four measures assessed subjects' perceptions of the ease in which images could be formed for the words (consisting of two measures) and the words could be related to subjects' actual shampoo experiences, as well as their agreement with the statement "Nothing comes to mind when I read these words."

Subjects answered these questions after studying each story-board page for as long as they desired. These measures, although taken some time after the initial paced exposure to the advertisement, enabled us to explore the impact of specific word-picture combinations on related specific and general beliefs as well as the impact of the entire set of 13 pages of text and illustrations on overall attitude toward the product.

Hypotheses

For the purposes of this paper we have chosen to only present a number of preliminary findings that address the following hypotheses:

- H1: The imaging instructions will reduce affective evaluation of the advertised product (shampoo).
- H2: The presence of illustrations accompanying the advertising copy will reduce affective evaluation of the product.
- H3: Framing the pictures with the copy by presenting the words at the top of the page in very large printed letters will moderate the detrimental effect of the illustrations on attitudes.

These three hypotheses are derived from availability-valence hypothesis. The first two are directly implied from the propositions presented above. The third hypothesis is based on the theory that external contextual information as well as internal available information will shape the interpretation of the distal cues. This implies that the pictures may well influence interpretation of the copy and vice versa. If the words are presented boldly at the top of the page rather than at the bottom of the page, then the subject may be more likely to read the copy first before studying the pictures. This will result in less picture interference with the words and an interpretation of the picture more consistent with the copy. It may also reduce the impact of relevant and (perhaps more importantly) irrelevant information on the interpretation and assimilation process which is likely to occur if the subject is first exposed to the illustrations and then reads the relevant copy (see Edell and Staelin 1983).

We anticipate that the effect of imaging and the effect of the illustrations on attitudes will be accompanied by similar effects on beliefs about product claims made in the copy. However, we expect that the effect of adding each of the 13 different story-board illustrations to each of the phrases will vary and depend on the picture-word consistency.

Results

Findings for K&S Measure

The scores on the three item K&S measure were summed for

each individual. It yielded a coefficient alpha of .47 ($n = 446$) which is lower than the alpha of .60 ($n = 43$) reported by K&S. The second scale (easy/difficult to handle) was problematic as reflected by a corrected item-total correlation of only .17. Indeed, alpha rose to .63 if this item was deleted. The K&S scale was then submitted to a $2 \times 3 \times 2$ factorial analysis of variance. Contrary to K&S's findings, neither the imaging nor pictorial manipulations had a significant effect. The only significant main or interaction effect was that females rated Celebrate higher ($p < .004$) than did males.

Findings for Our Attitude Measure

The above analyses were then replicated for our five item attitude measure. This measure received a coefficient alpha of .85. Our attitude measure also responded to the experimental manipulations quite differently than the K&S scale with the exception of the imaging instructions again failing to have a significant effect. Thus, H1 was not supported.

Contrary to K&S's findings, pictures had a significant ($p < .04$) positive effect on attitude. The mean score across the five scale items was 4.98 in the verbal only condition, 5.25 in the picture-small print condition, and 5.26 in the picture-large print condition. Differences between the verbal only condition and each of the picture conditions were significant ($p < .05$). However, H2 was not supported as the pictures increased rather than decreased affect toward the product. H3 was also not supported, as affect was constant across the two picture conditions. Other than the effect stemming from the pictorial manipulation, none of the remaining main or interaction effects were significant ($p > .1$). Consequently, we collapsed the design into a simple single factor design consisting of two groups: the verbal only subjects versus the picture subjects (including both picture versions). Unless otherwise noted, subsequent analyses are based on a comparison of these two conditions.

The above results raise questions about the tenability of the availability-valence hypothesis as presented and tested by K&S. First, the validity and the consistency of the three item K&S measure can be questioned. Second, we were not able to replicate the previous findings using the K&S measure. Third, and of greatest concern, the illustrations enhanced affective attitudes toward the product. Granted the effect explained very little of the overall variance, but it was still statistically significant in the wrong direction!

To explore whether the illustrations contributed to the formation of stronger beliefs about the product, which in turn influenced attitude, we examined the impact of pictures on specific beliefs. It should be noted that the availability-valence hypothesis does not explicitly propose that illustrations influence learning and acceptance of the verbal claims which in turn influence attitude. Rather, it proposes a direct transfer of valence from internally generated available thoughts to the target object.

Effect of Illustrations on Beliefs

Comparisons of product-related beliefs between picture and verbal only conditions revealed a number of significant ($p < .05$) differences and several that approached significance (see Table 3). It is reassuring that some, but not all, beliefs were influenced by the message manipulation. This finding eliminates the possible contention that subjects employed an evaluative inferential process in responding to the measures. Only if all (or at least most) beliefs varied in sympathy with the attitude measures across the message conditions would such an argument seem plausible.

For those beliefs affected by the manipulation, pictures enhanced subjects' beliefs about the product. For all but one of these beliefs, higher belief scores reflect greater processing accuracy and/or acceptance of the claim.

TABLE 3
RESULTS FOR SELECTED BELIEFS

Belief Statement	Verbal Only	Picture Conditions	p*
1. Celebrate is a good buy	3.34	3.64	.066
2. A lot of thought was put into designing Celebrate's plastic bottle	4.96	5.36	.013
3. Celebrate's plastic bottle is designed with me in mind	4.56	5.32	.000
4. Celebrate has a special dispensing device that gives you the right amount of shampoo	5.98	6.29	.055
5. Celebrate's bottle has a non slip handle	5.61	6.03	.021
6. Celebrate leaves hair smooth, soft and full	5.10	5.39	.035
7. Celebrate's cap is attached to the plastic bottle	4.10	4.38	.059
8. Celebrate is designed especially for me	4.05	4.49	.009
9. Celebrate comes in four special formulas	2.42	3.28	.000

*Significance level for the message main effect.

Note: Scale ranged from "strongly disagree" (1) to "strongly agree" (7).

This was not the case for the statement "Celebrate comes in four special formulas" as the advertisement states it comes in three special formulas. For this incorrect product claim, subjects in the pictorial conditions had less accurate perceptions although they did on average disagree with the statement. But this result is understandable when one appreciates that the illustration accompanying this claim depicts five people. This inconsistency between the pictorial and semantic stimuli apparently had a detrimental impact on the picture condition subjects' accuracy.

An important question at this juncture is whether message impact on affect was driven by the above differences in cognition. If the message influences affect through beliefs, then one should expect that controlling these beliefs should eliminate the message impact on attitude. Accordingly, various sets of beliefs were covaried to test their ability to mediate the influence of pictures on affect. The first set of covariates were the beliefs associated with the bottle design (beliefs 2-5, 7 and 8 in Table 3). These covariates completely eliminated ($p > .3$) the impact of pictures on attitude. The second set of covariates consisted of beliefs focusing on hair treatment (beliefs 6, 8, 9). Again the effect of pictures was eliminated ($p > .1$) although the beliefs pertaining to number of formulas was not a significant ($p > .7$) covariate. The final covariance analysis used the single remaining belief (belief 1 in Table 3). Although this belief was a significant ($p < .001$) covariate, it did not completely mediate the impact of pictures ($p < .05$). In sum, these analyses suggest that pictures influenced particular product beliefs (especially the beliefs about bottle design) which in turn impacted on product attitude.

An important question that arises at this point is why do some pictures enhance associated beliefs while others do not? To address this concern, we compared those stimulus pages which did ($p < .05$) versus did not ($p > .1$) have a significant effect on product beliefs. The pages where the effect approached significance were omitted.² These comparisons were performed on various measures assessing favorability toward stimulus elements, ease of understanding, meaningfulness, and consistency. The results are

²The page presenting the potentially conflicting picture-word information about the number of formulas was also omitted.

summarized in Table 4.

TABLE 4
RATINGS OF EFFECTIVE AND INEFFECTIVE PICTURES

Measure	Effective	Ineffective	p
Page is good/bad	4.96	4.47	.000
Page is desirable/undesirable	4.94	4.34	.000
Page is pleasant/unpleasant	5.04	4.40	.000
Page is easy/hard to understand	5.47	5.47	.988
Page is easy/hard to relate to	5.24	5.21	.540
Page is meaningful/meaningless	4.98	5.00	.571
Page makes me feel favorable/unfavorable about Celebrate	4.93	4.35	.000
Words make me feel favorable/unfavorable about Celebrate	5.20	4.58	.000
Picture makes me feel favorable/unfavorable about Celebrate	4.68	4.15	.000
Picture is consistent/inconsistent with words	4.96	4.82	.004
Picture is similar to/different from the words	4.95	4.78	.001
Easy to relate picture to words	4.79	4.67	.019
Picture clearly illustrates the product claim	4.24	4.12	.041

Effective represents those stimulus pages producing a significant ($p < .05$) picture effect on relevant beliefs while ineffective represents those stimulus pages not having a significant ($p > .1$) picture effect on relevant beliefs.

As can be seen, these two groups differed across nearly all of the measures except for those representing the meaningfulness and ease of understanding and relating to the page. Pages which influenced product beliefs generated more favorable responses than pages failing to influence beliefs. The presence of such differences must be cautiously interpreted, however, as evidence for a variable's role as an antecedent of the picture effect. For example, although illustrations were rated more favorably for pages having an effect on belief, further data analysis suggest that subjects' favorability toward the illustration was unrelated to the pictorial effects observed here. In particular, comparisons between the picture and verbal only conditions for those pages generating stronger beliefs revealed that subjects had a more favorable ($p < .05$) evaluation of the page in the verbal only condition. If these page evaluations were responsible for the impact of pictures on beliefs, then the verbal only condition should have enhanced beliefs. That the verbal only condition produced more favorable page evaluation but weaker beliefs suggests that subjects' evaluative reactions to the illustration were not responsible for the effect of pictures on beliefs. Indeed, covarying these page evaluations did not eliminate the impact of the picture manipulation on beliefs.

Discussion

K&S summarized their findings by pointing out that "on four occasions, verbal information presented alone was shown to induce more message-consistent judgments than verbal information accompanied by pictorial analogs" (p. 61). They argue that this effect is due to the "pictorial analogs" inducing greater elaboration of information that is less favorable than that elicited by the verbal claims. The results reported here present a dramatic contrast to their findings. Using their stimuli and procedures, verbal information accompanied by pictures produced a more favorable response than did verbal information alone. One could interpret this effect as also being consistent with the availability-valence hypothesis by arguing that in our study the pictures induced elaboration of information that was more favorable than the information available in memory for subjects in the verbal only condition. However, the same theory would then be employed to explain two diametrically opposed effects obtained following the same procedure and using the same stimuli. This points out a serious weakness in the availability-valence hypothesis. In a very real sense it is nonfalsifiable. No matter what effects are obtained on attitude, it can always be argued that they are consistent with the valence

of information available in memory. The theory does not permit us to predict on an a priori basis whether pictures or other stimuli will have a favorable or an unfavorable effect on the valence of available information.

This research went beyond the use of a multi-item attitudinal scale as a single dependent variable. Subjects also reported their level of agreement with statements made in the verbal claims. Significant belief effects emerged for six of the thirteen verbal claims made in the K&S stimuli. These belief scores show more agreement with the claim in the pictorial conditions than in the verbal only condition. When these beliefs were employed as covariates in separate analyses of variance, they eliminated the effect of message on attitude.

These findings appear to be inconsistent with implications of the availability-valence hypothesis. K&S state as a general proposition that "pictorial analogs" should enhance elaboration. The resulting effect depends on the valence associated with this elaboration. They argue that "the richness of cues in the picture condition was likely to have enhanced the availability of idiosyncratic information" (p. 56). If this idiosyncratic information were the cause of the obtained effect on attitude, then covarying for the belief scores obtained on ratings of the verbal claims should not eliminate the effect of pictures on attitude. The finding that covarying for these beliefs did eliminate the effect on attitude suggests that the obtained effect of pictures on attitude was not due to elaboration of idiosyncratic information.

If we assume as they do that pictures enhance "elaboration of message relevant information" (p. 61), we should expect to find a consistently greater level of learning in the picture condition across their stimuli. That is, if presenting the claim with a picture increases stimulus relevant elaboration we should obtain significant belief strength effects for each of the verbal claims. The finding that only some of the beliefs were significant suggests that the effect on learning may depend upon the type of picture employed or upon the relationship between the picture and the accompanying verbal claim.

In a general sense, these findings also support the usefulness and importance of carefully examining obtained effects on a series of dependent variables. Without the belief measures discussed above, we would have been unable to address alternative explanations for the obtained effects on attitude. On the other hand, in hindsight, we feel that our dependent measures of attitude toward each page and picture-word inconsistency were weak because of the manner in which this data was collected. It is questionable whether the responses to these measures fully reflected the processing that occurred during the initial paced exposure to the advertisement.

It should be acknowledged that the effects observed in this research did not account for a large proportion of the variance in the data. We did not obtain a significant effect on the imaging manipulation, and the manipulation of the order and visual dominance of the verbal claim over the illustration was not effective. We followed K&S by administering our study in a classroom, and this may have adversely affected precision. While the distractions and loss of control that are common in classroom exercises may well have added error, there is no reason to believe that classroom administration would have a biasing effect on our results. This is particularly true here because Kisielius and Sternthal also employed classroom administration. We recommend that future experimental research: reduces the number of pages and claims in the advertisement, manipulates time of exposure by a greater amount, manipulates the attractiveness and the consistency of specific picture-word combinations within the advertisement, and is administered in small groups or individually. The value of using appropriate measures of affect and beliefs has been demonstrated in the above study.

VISUAL INFORMATION PROCESSING OF TELEVISION
COMMERCIALS: COGNITIVE EFFECTS

Thomas D. Jensen, University of Arkansas
Larry W. Rottmeyer, University of Arkansas

Abstract

Advertisers have utilized various techniques for assessing the effectiveness of television commercials. The present manuscript describes a theory and methodology for examining viewers' chunking of ongoing visual information when viewing commercials. In an exploratory study, viewers indicated the number of chunks of information in television commercials while being exposed to either the visual stimuli or to both the audio and visual stimuli. It was hypothesized that the number of boundaries of information chunks (breakpoints) indicated by observers would affect information processing and, subsequently, output measures of advertising effectiveness (i.e., attitudes & beliefs). Results consistent with this process perspective were found.

Introduction

A variety of research techniques and measures have been proposed and developed for assessing the effectiveness of television commercials. These techniques include memorial measures (e.g., recall, & recognition), physiological measures (e.g., eye movements, tachistoscope, galvanic skin responses, pupil dilations, & electroencephalograms), and cognitive measures (e.g., cognitive rehearsals, free associations, attitudes, beliefs, & intentions) as well as more behaviorally oriented measures (e.g., sales following test markets, inquiries via reader cards, calls to toll-free telephone numbers requesting additional information). Although all of these techniques have advantages and disadvantages (see Engel, Warshaw, & Kinnear 1983), with the exception of the physiological measures, the majority of the measurement techniques do not allow the simultaneous collection of data during consumer viewing of the commercials and, hence, are post hoc. Consequently, these measures fail to acknowledge that the manner in which the stimuli are processed may affect subsequent cognitive measures and behaviors (i.e., purchase). For the physiological measurement techniques, mixed results have been found and, hence, have had little practical implications for the development of commercials (Watson & Gatchel 1979; Hensel 1970).

Previous research in the field of advertising has concentrated on the stimuli inputs and cognitive outputs related to television commercials such as the attention properties of the commercial and recall of these attention points. However, little or no attention has been given to the processing (what & how) involved during the actual viewing of the commercial. When information processing has been addressed, it has almost exclusively been conducted on auditory as opposed to visual stimuli.

Although there is an absence of research addressing visual information processing of television commercials, some research does exist examining the processing of visual stimuli for print advertisements (i.e., pictures vs. text). Generally, these studies have found that pictures are more easily recalled than accompanying text or text containing the same basic information as the pictures, and that print advertisements influence product related attitudes and beliefs, both negatively and positively. In one of the few studies to actually examine the effects on consumers of print advertising from a process perspective, Edell & Staelin (1983) found differences in the processing of text and pictures based upon the relevancy between the two components as well as for subsequent cognitions (e.g., attitudes). Specifically, these authors found differential effects of the ad structure (relevancy of pictures and text) and ad

content (objective versus subjective) on the processing of information and subsequent measures of cognitive responses, beliefs, attitudes, and intentions. These dependent measures were found to be hierarchical whereby the activation of one process variable impacted upon subsequent variables.

The present process conceptualization for television commercials parallels that of Edell and Staelin's (1983) conceptualization for the processing of print advertisements with one major exception: the present study examines the manner in which the consumers process the visual information contained within the commercial as opposed to any content differences between commercials per se. In this regard, the present conceptualization suggests that the stimuli are not necessarily the sole key to what material is processed and how the material is processed. Rather, the conceptualization suggests an interactive process of the advertisement, information processing, and cognitive activity. In the case of television advertisements, the processing of audio material should be similar to the processing of text material in print advertisements and, hence, similar to output measures from text material. For visual material, however, the motion inherent in television commercials forces viewers to process a series of "pictures" or "frames"; each "picture" potentially having the property of conveying information to the viewer and interacting with the audio portion as well as with viewer processing variables. This perspective suggests that consumers may segment the visual stimuli into chunks. The chunking of the visual portion of commercials and related variables represents the major thrust of the present study. The number of chunks of visual information that is perceived by a viewer should impact upon various output measures of beliefs and attitudes. In this regard, a theoretical perspective and methodological technique for examining the visual information process are warranted. The feature change hypothesis and breakpoint analyses serve this purpose.

Feature Change Hypothesis & Breakpoint Analyses. Darrin Newtonson and his colleagues (Newtonson 1973, 1976; Newtonson & Engquist 1976; Newtonson, Engquist, & Bois 1977; Newtonson, Rinder, Miller, & LaCross 1978) have demonstrated that observers of an action sequence tend to divide the action into meaningful segments for the purpose of extracting information. The number of segments indicated by observers has been shown to be affected by the instructional set provided to the observers (virtually all studies in this area), the predictability of the action sequence (Newtonson 1973; Newtonson et al. 1978; Wilder 1978a, 1978b; Jensen & Schroeder 1982), the sex-type of the observer (Deaux & Majors 1977), and by the number of actors (Jensen 1983, 1984). The indication of the boundaries for a segment are termed breakpoints. What is important for information processing, however, is not the actual breakpoints but, rather, the change or action between two successive breakpoints. This contention, termed the feature change hypothesis, has received considerable empirical support (e.g., Newtonson et al. 1977; Newtonson et al. 1978).

The feature change hypothesis postulates that stimuli factors such as movement, rate of movement, changes in the rate of movement, predictability, and changes in the relationship between two objects could alter an individual's segmentation strategy when observing ongoing action. Viewer factors such as attention, the sex-type, personality, and previous exposure to the material or related material may also affect the degree of perceptual analysis of an action sequence. Furthermore, this

hypothesis suggests that stimulus and viewer factors may interact in affecting the processing of visual information and subsequent cognitions. The research methodology in most of the studies have had observers view a videotape or movie while indicating "meaningful actions" (breakpoints) by either pressing a button connected to a continuous event recorder, pressing a button connected to a high speed computer, or by indicating tally marks on a piece of paper.

The present study was not designed to be a direct test of the feature change hypothesis but, rather, was designed to test the relationship between the chunking of visual information in commercials and the subsequent impact upon cognitions. However, in testing this relationship, ancillary evidence for the feature change hypothesis may be gleaned. In the present study, it was predicted that individuals viewing television commercials would segment television commercials into chunks when provided with differential instructions utilizing a breakpoint methodology and that the number of breakpoints indicated would be related to subsequent cognitive output variables (e.g., attitudes & beliefs). First, it was predicted that individuals instructed to indicate the more detailed or "smaller" actions in the commercial that were meaningful to them would indicate more breakpoints than individuals instructed to indicate the "larger" actions. More importantly, it was predicted that a positive relationship would be found between the number of breakpoints indicated by individuals and subsequent cognitive output measures (i.e., attitudes & beliefs). Previous research has indicated a positive relationship between the number of breakpoints and attributions (i.e., Newton 1973; Newton & Rindner 1979; Wilder 1978a) and affect (i.e., Lassiter & Stone 1983) concerning the actor(s) in stimulus materials.

The above predictions and previous research findings are based upon the premise that an increase in the number of chunks of visual information results in more positive cognitions. However, it is feasible that with an increase in the number of chunks of information, an individual would simply process more information to confirm pre-viewing cognitions. In other words, individuals who were initially positive toward the brand, commercial, or actors within the commercial could become more positive after more detailed processing while individuals who were initially negative could become more negative. In this regard, following the viewing of a commercial, individuals' cognitions could become more extreme or increase in magnitude in either a positive or negative direction. Hence, it was predicted that individuals indicating a finer unit of perceptual analysis would hold more extreme cognitions.

Finally, it was predicted that the presence versus absence of the audio portion of the commercials would affect the number of breakpoint indicated, hence, lending support to the interactive perspective of the stimulus material and viewer visual information processing. No specific predictions were made about the direction of the influence when both audio and visual stimuli of a commercial were provided to viewers as opposed to only the visual stimuli.

Methodology

Subjects & Procedures

A total of 209 students (96 males & 113 females) enrolled in either a consumer behavior course or a principles of marketing course volunteered to participate in the study for extra course credit. The 2 to 5 subjects who attended each session were instructed that the study addressed the manner in which individuals extracted information from television commercials. The experimenter explained to the subjects that previous research had indicated that people segment action sequences into meaningful segments or units and provided the subjects with a brief example of how an action sequence could be

segmented into either small or large segments. The subjects were informed that they would be making judgments of meaningful actions in commercials by pressing a hand-held metal tally register whenever, in their judgment, one meaningful action ended and another action began.

Approximately one fourth of the subjects were instructed to press the tally register for the smallest (fine unitization instructions) meaningful actions, one fourth of the subjects for the largest (gross unitization instructions), and one fourth of the the subjects for the most natural (natural unitization instructions). For example, individuals provided with fine unitization instructions were asked to "indicate their judgments of the smallest meaningful behaviors or actions portrayed in the commercial by pressing the tally register." The remaining one fourth of the subjects were not provided with any information or instructions concerning the segmentation of action (no unitization instructions): they were informed that the study dealt with the manner in which individuals processed information from commercials and that following the viewing of some commercials they would be requested to complete a questionnaire concerning their impressions of the commercials.

One half of the subjects were shown the commercials with the audio turned off (visual condition). The remaining subjects were provided with both the visual and audio portions of the commercials (audio/visual conditions). Hence, the factorial combination of instructions (fine, natural, gross, or none) and stimuli (visual or audio/visual) resulted in eight conditions that were conducted according to a block randomized schedule.

For those individuals provided with unitization instructions, between each of the six commercials the experimenter recorded the number of breakpoints indicated by each subject for that commercial. Following the presentation of the commercials, all of the subjects completed a questionnaire concerning their impressions of the commercials. When the subjects had completed the questionnaire the experimenter collected the booklets and thoroughly debriefed the subjects.

Stimulus Materials: Commercials & Questionnaire

Television commercials were recorded on a 1/2" VCR color television recorder using two major criterion: the commercial must contain ongoing action sequences and the primary emphasis other than brand must be the actor and the relationship between the actor and the brand. Using these criterion, 66 commercials were selected for further consideration, of which six were utilized in the present study based upon the clarity of the picture, length (30 seconds), the advertised product being a relatively frequently purchased nondurable good, and the presence of visual information. In order to reduce any order effects, two randomly ordered presentations were developed with approximately one half of the subjects receiving each of the two different orders of presentation.

The questionnaire requested subjects to indicate their beliefs about the primary actor/actress (13 items), commercial (11 items), and brand (7 items) for each of the six commercials. Subjects were also requested to indicate their attitude (liking) toward the actor/actress, commercial, and brand for each of the six commercials. All belief and attitude measures were collected on seven point semantic differential scales with the positive and negative poles randomly determined both within and between commercials. However, for all of the analyses presented below the scales have been transformed such that 7 represents the positive pole. Finally, a series of demographic items, the frequency of previous purchases of the brands and exposure to the commercials, and future purchase intentions were collected.

Results

The effects of the instructions (fine, natural, gross,

or none) and stimuli (visual only or audio/visual) on the various dependent measures were tested utilizing multivariate analysis of variance (MANOVA) across commercials where the main effects of instructions and stimuli as well as the interaction served as predictor variables. The results of these analyses for all dependent variables are reported in Table 1. As a manipulation check of the assignment of individuals to conditions, two analyses were conducted utilizing the individual's self-reported frequency of exposure to the commercials and pre-experimental purchase patterns of the advertised brands. None of the F values approached statistical significance for these dependent variables, verifying the random assignment procedure.

Actors	1.55 ^b (18,495)	1.08 ^c (6,175)	1.37 ^c (18,495)

^a $p < .05$
^b $p < .10$
^c $p > .10$

Breakpoints

The analyses conducted on the number of breakpoints indicated for the commercials revealed, as predicted, significant main effects of instructions and stimuli. Collapsing across commercials, individuals given fine unitization instructions indicated more breakpoints ($X = 9.08$) than individuals given natural unitization in-

structions ($X = 7.41$) with individuals given gross unitization instructions indicating a number of breakpoints between the two extremes ($X = 8.58$). Individuals receiving only the visual stimuli indicated more breakpoints ($X = 9.32$) than individuals receiving both the audio and visual portions of the commercial ($X = 7.36$). The interaction of these two factors did not approach significance.

Purchase Intentions

Analyses conducted on purchase intentions for the advertised brands revealed no differences between conditions.

Attitudes

Commercial. The F values associated with the effects of instructions and stimuli on attitudes towards the commercials revealed a significant F value for instructions. Individuals provided with fine unitization instructions indicated greater liking for the commercials ($X = 4.85$) than did individuals who were not provided with any unitization instructions ($X = 4.51$). Individuals provided with gross or natural unitization instructions indicated a degree of liking for the commercials somewhere in between those individuals in the other two conditions ($X = 4.66$ and $X = 4.62$, respectively). The F values for stimuli and the interaction of instructions X stimuli did not approach statistical significance.

Brand. Analyses conducted for participants' liking of the brand revealed only a significant effect of stimuli. Individuals receiving both the audio and visual portions of the commercials indicated a greater liking for the brand ($X = 4.67$) than individuals receiving only the visual stimuli ($X = 4.51$). The main effect of instructions and the interaction of instructions X stimuli did not approach significance.

Actors. Analyses conducted on individuals' attitudes toward the actors revealed a marginally significant F value, $p = .11$, for the main effect of instructions. This finding was due to individuals receiving the fine unitization instructions ($X = 4.95$) or no unitization instructions ($X = 4.83$) indicating a more positive attitude toward the actors than individuals receiving either gross ($X = 4.72$) or natural unitization instructions ($X = 4.74$).

Attitude Extremity

In order to assess whether the attitude extremity was affected by the experimental manipulations as opposed to the direction and strength of the attitude as in previous studies, the scales were collapsed about the midpoint. Hence, attitude extremity measures ranged from 0 to 3 with 0 indicating neutral and 3 indicating a more extreme attitude regardless of direction (e.g., favorable versus unfavorable).

Commercial. The analyses conducted on the attitude extremity for the commercial revealed significant main effects for instructions and stimuli as well as a significant instructions X stimuli interaction. Basically, individuals provided with natural unitization instructions held more extreme attitudes ($X = 1.81$) than individuals provided with no unitization instructions ($X = 1.67$), gross unitization instructions ($X = 1.63$) or fine unitization instructions ($X = 1.58$). Although the MANOVA revealed a main effect of instructions, this finding was due to individuals indicating a more extreme attitude when presented with both the audio and visual stimuli ($X = 1.79$) as compared to only the visual stimuli ($X = 1.55$) for two of the commercials while for the other four commercials this trend was reversed (visual = 1.73, audio/visual = 1.61), qualifying the overall significance when collapsing across all six commercials ($X = 1.67$). The significant interaction was due to individuals given fine unitization instructions indicating more extreme attitudes when receiving only the visual stimuli

($X = 1.65$) as compared to both the audio and visual stimuli ($X = 1.51$) while for the other instructional conditions no significant difference was found (audio/visual = 1.73, visual (1.68).

Brand. Analyses conducted for attitude extremity in reference to the brands advertised did not reveal any significant differences.

Actors. Although not revealing any significant main effects, this analysis revealed a significant instruction X stimuli interaction. Individuals receiving only the visual stimuli indicated more extreme attitudes when provided with natural unitization instructions ($X = 1.68$) than when provided with either fine ($X = 1.56$), gross ($X = 1.56$), or no ($X = 1.53$) unitization instructions. For individuals receiving audio and visual stimuli, however, more extreme attitudes were found for natural unitization instructions ($X = 1.76$) than for gross ($X = 1.58$) or no ($X = 1.50$) unitization instructions, which in turn were more extreme than for fine unitization instructions ($X = 1.37$).

Beliefs

In order to examine the participants' beliefs, all items used in tapping the beliefs were reassigned such that 7 was the positive pole and 1 represented the negative pole. In the case of items that did not possess easily discernible positive and negative poles (e.g., traditional versus contemporary), the scales were transformed when necessary such that the poles were labeled consistently (e.g., traditional = 1). The items tapping subjects' beliefs were then summed for beliefs about the commercial (11 items), brand (7 items), and actors/actresses (13 items). Hence, neutral beliefs would be indicated by scores of 44, 28, and 52 for commercial, brand, and actors/actresses, respectively. Collapsing across commercials, Cronbach's alphas were .81 for commercial beliefs, .56 for brand beliefs, and .78 for actor beliefs.

Commercial. A significant effect of instructions for participants beliefs about the commercial was revealed. Individuals provided with unitization instructions tended to have slightly more positive beliefs (fine = 49.76, gross = 48.99, & natural = 49.18) than individuals not receiving any unitization instructions ($X = 48.07$).

Brand. This analysis did not reveal any significant main effects nor interactions.

Actors. Individuals receiving different instructions held differential beliefs about the actors. As with commercial beliefs, individuals receiving unitization instructions had more positive beliefs about the actors (fine = 59.51, gross = 59.07, & natural = 58.75) than individuals not receiving any unitization instructions (none = 57.98).

Belief Extremity

As with attitudes, the possibility exists that the experimental manipulations utilized in the present study may have affected the extremeness of beliefs as opposed to or in addition to beliefs *per se*. In this respect, the instructional manipulations may have caused individuals to attend closer to the details contained within the commercial itself. This increased attention could result in the individuals observing some aspect of the commercial which, in turn, could justify their existing beliefs and, subsequently, increase the magnitude or extremity of those beliefs. In order to test this proposition, individuals' belief scores were collapsed about the neutral midpoint for commercial, brand, and actor beliefs. In this regard, a zero belief extremity score represents a neutral or very weakly held belief for the commercial, brand, or actor. Scores of 33, 21, and 39 represent extreme beliefs, either positive or negative, concerning the commercial, brand, and actor, respectively.

Commercial. Analyses conducted for extremity of beliefs about the commercial did not reveal any significant effects.

Brand. The F values for extremity of brand beliefs were not significant.

Actors. Analyses conducted for the extremity of beliefs regarding the actors in the commercials revealed a significant main effect of instructions. Individuals receiving gross ($X = 11.36$) or natural ($X = 11.49$) instructions indicated held more extreme beliefs when compared to individuals not receiving any unitization instructions ($X = 9.78$) while individuals receiving fine unitization instructions possessed beliefs somewhere between the two extremes ($X = 10.61$). No other significant effects were found.

Discussion

In the present study, individuals directed to attend to the finer details of the action in a commercial perceive more meaningful behaviors than individuals provided with alternative instructional sets. The fact that individuals indicated more breakpoints when provided with "gross" as opposed to "natural" unit instructions is inconsistent with previous studies examining the unitization of ongoing action sequences: most research has found that, although not necessarily statistically significant, individuals indicate more breakpoints when provided with natural as opposed to gross unitization instructions. Two possibilities for this discrepancy exist. First, under "natural" unitization instructions observers may have believed that the semantic context of natural could be interpreted to imply "as if you were watching the commercials at home." In this regard, individuals may have reacted by not paying as close of attention to the commercial as they did under "gross" unitization instructions and, hence, passively processed the incoming visual and auditory information. Second, in a similar semantic vein, individuals may have interpreted the "natural" in the instructions as referring to "common everyday occurrences" rather than "naturally meaningful" actions. Given the uniqueness of the actions contained within the commercials and the propensity for these actions to attract attention, individuals may have viewed the commercials as containing few actions or behaviors that they might engage in or that they might view others exhibiting. Also, some combination of the above two reasons may have been responsible for the difference between gross and natural unitization instructions.

The finding in the present study that individuals indicated more breakpoints when provided with only the visual portion of the commercials as contrasted to both the audio and visual portions of the commercials is, although unique in the present context (e.g., commercials), consistent with previous studies requesting individuals to focus on either the visual or the verbal behaviors of two actors having a conversation (e.g., Strenta & Kleck 1984). At least three explanations for this finding are feasible. First, it is possible that the audio stimuli interfered with the processing of the visual information. The inclusion of the audio portion in the present study may have caused individuals to engage in more "gross" processing of visual information due to the interference/distraction of the auditory stimuli. Second, the audio message may have caused the individual to shift toward a "gross" unitization strategy of the visual information, either actively or passively, in order to capture both sensory inputs. This explanation suggests a change (reduction) in visual information processing with the increase in information. Third, individuals may lack the attention capacity to process both stimuli and may therefore switch attention between the audio and visual, resulting in the appearance of a "gross" visual analysis.

All of the above explanations, although not exhaustive, assume a limited capacity input channel. Individuals

may have had to allot processing time to the audio stimuli in order to capture both sets of information. In this regard, visual messages may not be adequately processed, not as deeply processed, processed in less detail, and/or processed in larger chunks when presented with audio messages. Hence, one would predict that more complex and/or distracting audio messages would result in poorer visual information processing and have a subsequent impact upon memory for the components (cf., Bither & Wright 1973). Likewise, under conditions of the same audio message, complex visual messages would not be processed to the same extent nor in the same manner as simple visual messages. These explanations are also consistent with the work of Posner and Snyder (1975a, 1975b) who have shown that if attention is attracted to one modality, information from another modality is not processed to the same extent as if it were presented separately and with Edell and Staelin's (1983) findings that the consistency between the messages presented in the pictures and text of print advertisements affects memory and cognitions. Furthermore, these interpretations are also consistent with Jensen and Schroeder's (1982) findings that an increase in the number of actors does not result in a corresponding increase in the number of breakpoints.

The relationship between the visual information processing as operationally defined by the number of breakpoints and subsequent measures of cognitive processes revealed some interesting findings. As expected, individuals' cognitions about the commercial were more affected by the extent of visual information processing than individuals' cognitions about either the actors or brands. This finding is not surprising when one acknowledges that the extent or magnitude of processing manipulation involved attention properties as well as an interaction of attention and cognitive activities (see Newton 1980). Individuals may be more prone to cognitive change concerning an object that they have had relatively little experience, such as the commercial, whereas individuals may possess relatively strong attitudes and beliefs regarding the brand. Also, a strongly held cognition would be relatively difficult to alter following a single exposure. For cognitions about the actor, individuals would be unlikely to form attitudes since the observer would not foresee interacting with the actor or making any decisions involving the actor. However, individuals should be able to form beliefs about the actors, assigning them various characteristics or attributes (e.g., talent). These attributes, in turn, should be related to the attention an individual pays to the actors and, hence, as found in the present study, to the extent or magnitude of processing. This finding is consistent with previous studies examining the segmentation of ongoing behavior and subsequent causal and ability attributions (e.g., Newton 1973; Newton & Rindner 1979; Wilder 1978a). Also, for both cognitions regarding the commercial and actors, the positive relationship between the extent of processing (i.e., number of breakpoints) and attitudes or beliefs is consistent with earlier studies of affect (e.g., Lassiter & Stone 1983).

An interesting finding concerning cognitions and measures of cognitive extremity was found for attitudes and beliefs about the commercial and beliefs about the actors. Given the random assignment of individuals to conditions and subsequent manipulation checks, the amount of processing affected cognitive change in a positive direction which, in turn, was inversely related to measures of cognitive extremity. Individuals provided with instructions invoking a finer level of analysis were more likely to change their attitudes and beliefs in a favorable direction but, subsequently, appeared less sure or confident of those attitudes and beliefs. The possibility, strongly suggested in the present study, that cognitive change is inversely related to subsequent measures of extremity, confidence, or strength following persuasive communications warrants additional research.

Potential limitations of the present study are similar to those associated with other exploratory studies and the need for more sophisticated attention in future research efforts. First, the results of the present study for either the breakpoints, cognitions, or both measures may be due to demand characteristics. The plausibility of demand characteristics causing the individuals to respond in some set manner is weakened, however, when one notes the consistency of the present results with previous studies, findings from other studies examining the motion between successive breakpoints as opposed to non-breakpoints, and similarities in memory for individuals provided with natural as compared to no unitization instructions in recognizing breakpoints and nonbreak points (for example, see Newton et al. 1977). For the measures of cognitions, it also seems unlikely that demand characteristics could account for the more positive actor and commercial related cognitions while not also impacting upon brand related cognitions. Nonetheless, additional studies may need to develop appropriate methodologies to examine the possibility of demand characteristics in spuriously producing the obtained results.

Second, one can always question the generalizability of the findings in a laboratory situation to more "real world" settings. Individuals in the present study knew they were involved in a study examining the "effectiveness" of various commercials. The possibility exists that some of the findings may have been due to the artificial situation imposed upon the participants.

Third, individuals in the present study were exposed to only a single presentation of each commercial. Given that most individuals had some previous exposure to the commercials, questions arise about the effects of multiple exposures and novelty of the commercials on visual information processing and subsequent cognitions.

Fourth, the present study did not examine the relationship between visual information processing and cognitive responses nor memorial factors (e.g., Edell & Staelin 1983). Studies are justified which examine the simultaneous information processing of television commercials, cognitive responses, and recall as well as recognition. Furthermore, the present study measured cognitions immediately following the viewing of the commercials. Future research should examine the persistence of some of the findings (e.g., attitude change) following differential processing as well as probe for new findings following the passage of time (e.g., changes in confidence).

Fifth, the present study examined commercials for relatively frequently bought products, some of which may not have been especially relevant for all of the participants. Other studies examining visual versus auditory (e.g., Bither & Wright 1973) or pictorial versus textual (Edell & Staelin 1983) have concentrated their efforts on less frequently purchased, higher ticket products (e.g., automobiles). Investigators may need to consider the degree of involvement of the observers for the advertised products.

In conclusion, echoing and elaborating upon the call by Jensen and Schroeder (1982), the ultimate veracity of the segmentation of ongoing action rests in the identification of related psychological processes (e.g., cognitions) and the resulting impact upon behavior. Furthermore, future research should be concerned with the identification of the conditions likely to induce the various levels of processing. For example, Newton (1973) and Wilder (1978a; 1978b) have shown that the predictability of the action affects the unitization rate. Marketing research efforts designed to identify the characteristics needed in television commercials to invoke fine or gross levels of visual information processing should prove to be valuable both from theoretical and applied perspectives.

MEASURING EMOTIONAL RESPONSES TO ADVERTISING

Ronald P. Hill, The American University
Michael B. Mazis, The American University

Abstract

Traditional measures of cognitive response, attitude toward the ad, and attitude toward the brand fail to include adequate emotional measures of consumer response. Emotional responses to ads can be assessed by coding verbal protocols for positive and negative affect. Also, the emotional component of attitude toward the ad (ATT_A) and toward the brand (ATT_B) can be measured through "emotional" attitude scales. The current study shows that emotional measures of cognitive response, ATT_A, and ATT_B are needed to evaluate the effects of emotional advertising.

Introduction

Until recently, consumer behavior researchers have relied on cognitive information processing models of consumer decision making and have neglected the emotional side of human behavior (Holbrook and Hirschman 1982, Rook and Levy 1983, Zajonc and Markus 1982). This "man-as-computer" perspective regards consumer behavior as a series of rational decisions through which the buyer processes attribute information to make a purchase decision from available alternatives (Holbrook 1984).

Although cognitively-based models have been useful in the prediction of consumer behavior, they have been unable to completely explain the processes underlying advertising effects. This may be due, in part, to the failure to include "emotional" variables in these models. If emotion is considered at all, it is usually operationalized as a simple affect measure that deals with only one emotional dimension (e.g. like-dislike). This perspective ignores the multidimensional nature of emotion (i.e., love, hate, anger or joy).

The purpose of this paper is to identify and to discuss the role of emotion in the sequence of steps that intervene between exposure to an advertising message and eventual purchase of a product. The study presented is an attempt to improve understanding of the measurement of emotional advertising effects.

Background

The Traditional Approach

The traditional model of consumer decision making has its roots in Plato's original distinction among cognition, affect and behavior (Holbrook 1984). This paradigm was first introduced in the marketing literature as the hierarchy-of-effects concept (Lavidge and Steiner 1961). This perspective, consisting of a causal flow from cognition (C) to affect (A) to behavior (B), dominated subsequent attitude research.

Recent research has suggested that the C-A-B sequence of decision stages may not always take place. For instance, Zajonc and Markus (1982) have conducted extensive research which concludes that affective judgements may be independent of, and precede in time, cognitive operations.

Changes in the traditional C-A-B approach are also based on evidence which suggests that a consumer's level of involvement in a particular advertising message may influence his or her processing strategy (Krugman 1965, Rothchild 1979, Vaughn 1980).

Petty, Cacioppo and Schumann (1983) have expanded the level of involvement approach through the development and testing of their "two routes" theory. Following this theory, Shimp (1981) has suggested that most ads use one of two possible

approaches that he terms "ATT_B" and "ATT_A." Under the ATT_B (attitude toward the brand) approach, purchase behavior is influenced by developing favorable consumer attitudes toward the advertised brand. This is accomplished by structuring ads to influence consumers' beliefs and evaluations regarding the favorable consequences of purchasing a particular brand. This approach is consistent with the high involvement/central route perspective (Petty, Cacioppo and Schumann 1983).

Under the ATT_A (attitude toward the ad) approach, a message is not directed at specific product attributes or benefits. Instead, the purpose of the advertisement is to create a favorable attitude toward the ad by leaving the viewer/listener/reader in a positive emotional state after processing the ad. The assumption underlying this concept is that consumers are hedonistically motivated by the desire to feel good. This approach is consistent with the low involvement/peripheral route perspective (Petty, Cacioppo and Schumann 1983).

The Attitude Toward the Ad Perspective

The ATT_A perspective described by Shimp (1981) has led to a recent emphasis in the marketing literature on studies involving attitude toward the ad (Holbrook 1978, Lutz, Mackenzie and Belch 1983, Mackenzie and Lutz 1983, Mitchell and Olson 1981). Typically, this construct is treated as an intervening variable that mediates the effects of the advertising message on brand attitudes and preferences (Edell and Burke 1984, Holbrook and O'Shaughnessy 1984). Further, ATT_A is believed to consist of two distinct components, one cognitive and the other emotional (Shimp 1981). The former dimension is determined by consumers' conscious response to the advertising execution. For instance, consumers may prefer certain ads due to a credible source or a convincing product demonstration. The latter dimension is composed of consumers' emotional responses to advertisements. These responses may include feelings of love, joy, patriotism and nostalgia.

Measurement of ATT_A

One of the most common methods used to measure consumers' reactions to advertisements is through verbal protocols. Although interest in ATT_A has increased, the cognitive response categories used to code verbal protocols have remained similar to those developed by Wright (1973). These categories include support arguments, counterarguments and source derogations. In recent years, researchers have added categories such as simple affirmations and disaffirmations (Berber 1975), neutral and irrelevant thoughts (Cacioppo and Petty 1979), and source bolstering and repetition related thoughts (Belch and Lutz 1982). Further, Lutz, Mackenzie and Belch (1983) divided responses according to whether they were evaluatively positive or negative.

Consumer responses also may include emotional reactions to the moods created by the ads. For example, Golden and Johnson (1983) have conducted research suggesting that factual and emotional ads produce differential communication responses. Therefore, the most appropriate coding scheme for cognitive responses should include categories that capture consumers' reactions to product information, ad execution style, and the emotions elicited by the ad.

Besides cognitive responses, bipolar scales have been used to measure ATT_A. For example, Mitchell and Olson (1981)

measured attitude toward the ad through four scales (good-bad; like-dislike; irritating-not irritating; and interesting-uninteresting). The mean of these four evaluative measures was interpreted as ATT_A .

Although this approach provides a good overall measure of ATT_A , it may not capture the multidimensional nature of this construct. Which, if any, of these scales measures emotional response? One investigation did attempt to estimate consumers' emotional reactions to ads with the scale "positive-negative" (Moore and Hutchinson 1983). It is doubtful that this one scale is capable of capturing the richness of possible emotional responses (i.e., happiness, sadness, love and joy).

In an attempt to break from this tradition, Gresham and Shimp (1985) used seven affective items to measure their emotional reactions. Although their results were somewhat disappointing, they did attempt to partition potential emotional reactions into soothing, warm-hearted, sorry, sad, affectionate, happy and elated categories. Therefore, consistent with the discussion involving cognitive responses, it is recommended that researchers using bipolar scales to measure ATT_A select scales that capture the emotional responses as well as the "utilitarian" response.

Measurement of ATT_B

Measures of ATT_B are even less likely to contain an emotional component. For example, Mitchell and Olson (1981) measure ATT_B through mean values on four five-point scales (e.g. good-bad and dislike very much-like very much).

The use of these procedures is somewhat peculiar given the widely discussed classical conditioning hypothesis. This position conjectures that ATT_A may directly influence ATT_B through classical conditioning (Edell and Burke 1984). Under this hypothesis, ATT_A 's direct effect on ATT_B occurs since emotional reactions elicited by the ad get transferred to the brand. Thus, the emotional element of the ad acts as the unconditioned stimulus and the brand becomes the conditioned stimulus, eventually generating the same affective response as the ad. Given this perspective, it is essential that measures of ATT_B include both cognitive and affective components that capture the full range of meanings of these variables.

Objectives

The current study is designed to determine whether affective measures that assess emotional responses to advertisements are needed to measure the impact of emotional advertising. In the case of advertising that is primarily factual, traditional cognitive response measures--support argument, counterargument, source bolstering and source derogation--should be sufficient to assess consumer responses to advertising. Emotional measures--positive affect and negative affect--are unlikely to assist in the measurement of factual ad effects. On the other hand, emotional measures of cognitive response are likely to be important in examining the impact of emotional ads.

In addition, traditional bipolar evaluative adjective scales--good-bad; like-dislike; irritating-not irritating; interesting-uninteresting--are unlikely to discriminate between the effects of factual and emotional ads. It is predicted that these ATT_A measures are inadequate to capture the impact of emotional ads. The "sensual" factor (Leavitt 1970) consisting of adjectives that capture the emotional mood of the television commercial (lovely, beautiful, gentle, serene, tender and sensitive) should be more effective in measuring emotional ad effects.

Finally, traditional ATT_B measures (e.g., good-bad and like-dislike) should be adequate for determining the impact of factual advertising. However, to discriminate between the effects of factual and emotional ads, affective ATT_B measures are needed. Bipolar adjective scales that measure consumer emotion (e.g., pleasant-unpleasant; sociable-unsociable; nice-awful) regarding individual brands are likely to be more effective than traditional measures when

emotional ads are being tested.

Method

The study was conducted at a private university in the eastern United States. Student subjects voluntarily participated in the experiment and received additional course credit for their participation. Subjects were randomly assigned to the two experimental treatments--exposure to emotional or factual advertising. Approximately 25 subjects participated in each of four experimental sessions. Overall, 48 and 51 subjects were in the emotional and factual advertising treatments, respectively.

Subjects were led to believe that the study was designed to examine the impact of television programming on their attitudes and beliefs. This guise was successful since all subjects stated that the program was the central focus of this investigation in response to a study-purpose question placed at the end of the study. All subjects watched three separate segments of a movie that had not yet appeared on network television. The movie was interrupted for three commercial breaks to simulate actual exposure to a television program.

All subjects were exposed to one television ad at each commercial break. Subjects viewed commercials for a bank, telephone service and a camera. Commercials were matched so that emotional and factual versions were the same length (either 30- or 60-seconds). The ads for the telephone service and camera were for the same brands while the bank ads contained different organizations. However, the use of different firms in the bank ads was not expected to impact on the results since both banks were unknown to subjects. A panel of judges familiar with advertising campaigns un-announcedly concluded that the advertisements used were either predominantly factual or emotional in execution.

After viewing the advertisement during the commercial break, subjects were asked to generate verbal response protocols by providing any and all response to the ad they had just seen. They were given four minutes to complete this task. After the television program was concluded (including commercials), respondents were asked to provide written protocols in response to the television program they had just seen (distractor task).

Written protocols were coded independently by two judges who were given operational definitions of the response categories and were trained in the application of the definitions. In cases where there was no agreement between the judges (approximately 10% of all responses), the researchers served to make the coding decisions.

The cognitive response categories were support argument, counterargument and source derogation (Wright 1973). In addition, a source bolstering category was also used to provide the positive counterpart of source derogation (Belch 1981). Two other cognitive response categories--positive and negative affect--were used in order to capture respondents' emotional responses to the messages (Batra 1984). One example of a positive affect response is "I felt good when I saw this ad". On the other hand, a negative affect response might be "This ad made me angry". A series of 45 adjectives were taken from Leavitt's (1970) factor analytic study that identified eight factors--amusing, authoritative, dislike, energetic, familiar, novel, personal relevance and sensual--to rate television commercials. Each factor consisted of six adjectives having the highest loadings on that factor with the exception of the "familiar" factor that contained only three adjectives. Respondents were asked to judge on a five point-scale whether each of the adjectives described the commercial "extremely well" (5) to "not very well at all" (1). Scores for adjectives were summed to develop eight ad rating variables (factors).

Following the advertising ratings for a given commercial, respondents were asked to provide their overall evaluation

(ATT_A) of the advertisements on four bipolar adjective scales (good-bad ; like-dislike; irritating-not irritating; interesting-uninteresting). These are the four attitude scales commonly used to measure ATT_A (Gardner 1983; Mitchell and Olson 1977). Scores on the four attitude scales were summed to develop a single overall ad evaluation measure.

After the three commercials were shown and were evaluated, respondents were asked to provide their attitudes toward specific brands of cameras, telephone services and banks. ATT_A measures were taken on four sets of bipolar adjective scales--overall evaluation (good-bad; like-dislike; positive-negative); emotional (pleasant-umpleasant; sociable-unsociable; nice-awful); savory (sensitive-insensitive; interesting-boring; tasteful-tasteless); authoritative (useful-useless; important-unimportant; intelligent-unintelligent). These attitude scales were taken from analytic work of Osgood, Tannenbaum & Suci (1957) and Batra (1984).

Results

Cognitive Response Measures

The data in Table 1 indicate that arguments advanced, message factors and affect measures were important variables in discriminating between the effects of emotional and factual commercials. For the bank advertisements, there were few support or counterarguments for either the emotional or factual advertisements. However, the factual ad generated significantly more source bolstering statements, on the average, than did the emotional ad (2.04 vs. .92). The factual ad used animation and apparently this technique was liked by respondents. The emotional bank ad generated more positive affect responses than did the factual ad (.54 vs. .02).

TABLE 1
COGNITIVE RESPONSE MEASURES
EMOTIONAL VS. FACTUAL ADVERTISEMENTS

	Mean Scores		t-value
	Emotional Ad	Factual Ad	
<u>Bank Ads</u>			
Support Arguments	.23	.22	.89
Counter Arguments	.02	.06	.34

Negative Affect	.33	.02	2.50 ^b

^a p < .05

^b p < .01

^c p < .001

In the case of the two telephone ads, the factual ad produced more support arguments, on the average, than the emotional ad (.63 vs. .29). The mean number of counterarguments generated for the factual ad was also higher than for the emotional ad (.27 vs. .04). On the other hand, the mean number of source bolstering responses was higher for the

emotional ad (1.23 vs. .67), but the mean number of source derogations was higher for the factual ad (.96 vs. .15). The emotional telephone ad generated significantly more positive affect responses than the factual ad (.90 vs. .00). Neither message produced any significant volume of negative affect statements.

Finally, the factual camera commercial produced significantly more counterarguments, on the average, than did the emotional commercial (.51 vs. .02). The factual ad also generated significantly more source bolstering responses than did the emotional camera ad (1.49 vs. .71). The mean number of positive and negative affect responses generated was greater for the emotional ad than for the factual ad (.40 vs. .00; .33 vs. .02).

These findings suggest that when there are differences in the number of support arguments or counterarguments generated that factual ads will produce a higher number of these responses than will emotional ads. For the telephone ads, the factual ad resulted in significantly more support and counterarguments than the emotional ad. This finding was also observed for the camera ads; the mean number of counterarguments was higher for the factual ad than for the emotional ad. In no case did emotional ads produce a higher level of support or counterarguments than did the factual ads.

As expected, there was no consistent pattern of differences in source bolstering or source derogation responses produced by emotional and factual commercials. In one case (telephone ad), the emotional ad produced more source bolstering responses; in three cases, the factual ads produced more source bolstering or source derogation responses. The particular execution used is likely to be responsible for source related responses. There is no inherent liking or disliking of emotional or factual executions.

When there were differences in the number of affective responses generated, emotional ads always produced higher mean levels than did factual ads. For all three advertising treatments, there were more positive affect statements when the emotional ad was aired in contrast to when the factual ad was aired. In one case (camera ad), the emotional ad also resulted in a greater number of negative affect responses.

Table 2 shows the relative contribution of message arguments (support arguments-counterarguments), source statements (source bolsterings-source derogations) and affective responses (positive affect-negative affect) in predicting consumers' overall ad evaluations. For these three cognitive response measures, the number of negative responses was subtracted from the number of positive responses for each individual. The four ad evaluation scales (good--bad; like--dislike; irritating--not irritating; interesting-uninteresting) were summed up to produce an overall ad evaluation measure. Stepwise multiple regression analysis was employed by "forcing" the three independent variables in the following order: (1) message arguments (SA-SD); (2) source statements (SB-SD); and (3) affective response (PA-NA).

The stepwise multiple regression analysis indicates that affective responses (PA-NA) did not produce any significant amount of incremental explained variance for the three factual ads. In each case, the message arguments and source statements accounted for all of the variance explained in the overall ad evaluation measure used in the factual ads. For the emotional ads, however, affective responses accounted for a significant amount of incremental explained variation in ad evaluation for both the bank and telephone commercials. In both of these conditions, affective measures (PA-NA) had more explanatory power (highest simple correlation coefficients) than either the message argument or source statement variables.

Advertising Ratings

The data reveal that the overall evaluation measures (good--bad; like-dislike; irritating--not irritating; interesting-uninteresting) used in most ATT_A research did not distinguish

between the impact of emotional and factual ads. Statistically significant differences between emotional and factual ads. Statistically significant differences between emotional and factual ads were observed in only one case (telephones).

PA-NA	.59	.15	.61	-.13

The set of eight factors developed by Leavitt (1970) and Wells, Leavitt and McConville (1971) appear to better discriminate between the effects of emotional and factual ads than do the traditional evaluative measures. Three factors related to ad execution--the "energetic" factor (lively, exhilarated, vigorous, enthusiastic, energetic and excited), the "amusing" factor (merry, jolly, playful, joyful, amusing and humorous), and the "novel" factor (original, unique, imaginative, novel, ingenious, and creative)--vary significantly across emotional and factual ad treatments. In the case of the banks and cameras, the factual commercials received higher scores (more descriptive) on these three factors; for the telephone ad the emotional ad received a higher score on the three execution factors.

As hypothesized, respondents rated the emotional ads as being higher on the sensual factor (lovely, beautiful, gentle, serene, tender and sensitive). For each of the three commercials, statistically significant differences were observed for the sensual factor (Table 3).

Brand Ratings

The data in Table 4 indicate that respondents tended to express a more positive attitude toward the brand under the emotional ad conditions as compared with the factual ad

conditions (lower numbers in the table are more positive). These differences were particularly strong in the case of the factors that were hypothesized to distinguish between emotional and factual ads. In the case of the "savory" factor (sensitive-insensitive, interesting-boring, and tasteful-tasteless) and the "emotional" factor (pleasant-unpleasant, sociable-unsociable, and nice-awful), there were significant differences between factual and emotional treatments across all three commercials.

The overall brand evaluation factor (ATT_B) (good-bad, like-dislike, and positive-negative), which has been used in most studies employing an ATT_B measure, was slightly less useful; it discriminated between emotional and factual treatments for only two of three ads. The "utilitarian" factor (useful-useless, important-unimportant, and intelligent-unintelligent) was significant in the case of the telephone ad only.

Therefore, affective brand evaluation measures appear to be slightly more sensitive in discriminating between the effects of emotional and factual ads than are traditional evaluation measures.

Discussion

This paper takes the position that "traditional" approaches to measuring three key dependent variables in advertising research--cognitive responses, ATT_A and ATT_B--are inadequate for assessing the impact of emotional advertising. Zielske (1982) previously reported that traditional day-after-recall measures "penalize" emotional ads since consumers are unlikely to play back specific ad elements in "feeling" ads. He recommends, therefore, that advertising researchers use recognition techniques, which are better able to detect the impact of emotional ads.

The current research extends Zielske's view to three other dependent variables used in advertising studies. Following the theoretical work of Batra (1984), affective cognitive responses were coded in addition to the traditional cognitive response categories--support arguments, counterarguments, source bolstering and derogations. The affective responses were useful in assessing the impact of emotional advertisements. Future researchers should consider using coding schemes that incorporate affective cognitive responses, as well as the traditional cognitive response measures.

This study also suggests that traditional ATT_A measures are inadequate for measuring the impact of emotional ads. The ad rating factors developed by Leavitt and Wells were more effective than the traditional evaluative measures for measuring the emotional ad effects. The "sensual" factor (lovely, beautiful, gentle, serene, tender and sensitive) appears to offer the most promise in future studies involving

emotional advertising. Other ATTA measures specifically focused on the affective component might be developed in subsequent research studies.

Finally, several previous researchers (Bagozzi 1982; Batra 1984; Burnkrant and Page, 1982) have attempted to isolate cognitive and affective components of brand attitudes. These efforts have met with only limited success. Generally, a positive "halo" effect has been found to operate. Respondents do not discriminate between cognitive and affective measures; their responses are strongly influenced by their overall attitude toward the brand. The current study found some differences between cognitive and affective components. However, even though the "savory" and "emotional" factors distinguished between emotional and factual ad effects, the overall evaluation measures "worked" reasonably well also. Therefore, additional research is needed to develop affective brand attitude measures.

A DEVELOPMENTAL STUDY OF FAMILY FINANCIAL MANAGEMENT PRACTICES

Donald H. Granbois, Indiana University
Dennis L. Rosen, University of Kansas
Franklin Acito, Indiana University

Abstract

Family financial management and control practices have received little attention. Yet they are increasingly important, due to changes in the financial environment such as deregulation of the banking industry and the increasing number of dual income families. This paper reports on a pilot study relating demographic variables, measures of sex role, and locus of control to five variables thought to be indicators of the family's financial management and control tendencies. An overall financial management scale is constructed and its relationship to the independent variables is discussed.

Introduction

Although seldom explicitly acknowledged in consumer research studies, normative assumptions about consumers' pre-purchase behaviors are strongly emphasized in the consumer economics and family management literatures (Deacon and Firebaugh 1975; Maynes 1976). Writers in these disciplines tend not to conduct empirical studies of how consumers actually do behave. However, research in marketing has provided data on numerous measures of what one researcher has labeled "good consumership" (Hill 1963). Reviews of these studies document wide variability in pre-purchase behavior, and various interpretations and tentative profiles of "good consumers" have been offered (Granbois 1977; Granbois and Braden 1976; McNeil 1974; Newman 1977; Olshavsky and Granbois 1979).

A second normative theme in family management and consumer economics -- that consumers "should" devise and utilize appropriate financial planning and control procedures regarding spending and saving -- has not been subjected to much empirical testing (Beutler and Sahlberg 1980; Ferber 1973). Ferber (1973) reports few studies and fewer generalizations about how families handle financial tasks and decisions regarding budgets, bill payment, or saving.

The underlying rationale for prescribing specific financial practices seems to be that families engaging in such practices are expected to be more effective in achieving goals and in getting the greatest possible utility from their income. One writer refers to these behaviors as "... family competences which differentiate families who make the most of their resources in getting where they wish to go from families who lag in this respect" (Hill 1963, p. 425). A clear statement of the predicted link between financial management and goal achievement is provided by Deacon and Firebaugh (1975), who note:

The expected outcome of financial management is to meet demands (whether long-term goals, short-term goals, or events) by effective use of the resources available to each managerial unit. A major output is the achieved level of living and the related sense of fulfillment of goals. (p. 287)

Recent changes in the financial environment make this process more important. Consumers today are faced with many more savings options as the line blurs between savings and investments. Taking advantage of these options generally requires better management than was true for the traditional passbook savings account because restrictions or penalties may be applied to deposits and withdrawals. The dual incomes of many families may also require better financial management to take advantage of increased opportunities. Differences among families in the extent and pattern of financial planning and control

practices may be useful for defining segments that will respond differently to financial institutions' strategies.

An ultimate theoretical justification for the empirical study of consumers' financial management practices appears to be the need to verify that "good managers" will make more effective use of resources in meeting goals. Presumably, both objective measures of level of living, household net worth, etc. and subjective measures of perceived achievement and satisfaction should be affected by consumers' financial management practices. Before such predictions can be tested, though, it is necessary to identify the nature of consumers' financial management practices, devise measures for determining performance, and determine characteristics and situations associated with their use.

This paper reports on an exploratory study of five aspects of the financial management practices reported by married couples. The topics were suggested by a literature review and by our earlier developmental research involving unstructured depth interviews with married couples. Our findings on husband-wife role structures with respect to these financial management behaviors have been reported elsewhere (Rosen and Granbois 1983). Our emphasis here is on the extent to which our pilot study respondents used the management practices investigated, the testing of tentative hypotheses about family characteristics that may predict which families use the practices, and the development of a composite scale measuring financial management behavior with the family.

Development of Variables and Hypotheses

Financial Management Variables

Ferber (1973) divides the domain of family economic decision making into four segments: money management, saving behavior, asset management, and spending behavior. We confined our discussion of family financial management to money management and saving behavior because asset management is complex and specialized and perhaps best studied by experts in consumer finance and investments.

Five primary measures of family financial management were suggested by our literature review and developmental depth interviews:

Budget: whether a budget is determined at the beginning of a spending period;

Savings Policy: whether savings are added to on a regular (periodic) basis;

Surplus Funds Policy: whether pre-planning occurs for funds left over after the payment of bills and other obligations;

Special Accounts: whether special savings accounts are used to facilitate saving for specific purposes;

Credit Transactions Analysis: whether credit card transactions are sorted to study spending patterns.

Using each of these strategies would be consistent with a normative view of how family financial affairs might "best" be handled. However, we did not expect all five behaviors to appear with equal frequency across families. We did suspect that the five varied in importance in contributing to effective family financial control, and

they were hypothesized to be ranked in importance in the order listed above.

Budgeting was viewed as most important because it includes all aspects of using household funds. While budgets tend to be prepared for each pay period, regular budget preparation has implications for long-run control of spending and saving. Thus, both short-run and long-run consequences of budgeting may be realized. Regular saving is similarly both a short-run and long-run practice, but covers disposition of only that part of the household income that is not spent. Planning for surplus funds and use of special accounts are both subsidiary practices facilitating the larger savings function. Finally, credit card sorting was visualized as an occasional aid used to track expenditures. It was thought that credit transaction sorting could occur in the absence of budgeting. Also, it was felt that planning for the use of surplus funds and having special accounts did not necessarily imply regular saving. Each of the five behaviors was therefore considered to be a possible independent component of a larger syndrome of planning and controlling the disposition of the family's income.

Independent Variables

As measures of independent variables we included several dimensions suggested in the literature on family decision making. Recent researchers and commentators on contemporary families have suggested wife's working status and motives for work, life cycle stage, and husbands' and wives' sex-role attitudes as potentially important variables for explaining differences among families. (See Rosen and Granbois 1983 for a brief review.) Since control is a central element in budgeting behavior, a personality variable, locus of control, (Rotter 1966) appeared to be especially likely to be related to family financial management. Individuals classified as "internals" on the locus-of-control variable tend to believe they are more in control of events that affect their lives while "externals" tend to believe that such events are not in their control.

Demographic variables, including education of both husband and wife, number of years married, and household income have been found in earlier studies to have some relationship to family financial management, although the exact nature of these relationships has not been clearly established (Ferber 1973). In a recent study of the extent to which families engage in three activities specified by a formal financial management system model (recording expenditures, reviewing and evaluating expenditures, and making formal spending plans), formal planning was negatively related to age of household head and life cycle stage and positively associated with number of children and education of household head (Beutler and Sahlberg 1980). We could find no support in the literature for directional hypotheses relating sex-role attitudes or wife's work status and motives to the performance of the five measures of family financial management behavior.

In summary, based on past research and judgment we expected that the five financial management behaviors would be more likely to occur among the more highly educated, those with an internal locus of control, families in the middle life cycle stages, and those with higher incomes. We also explored the relationship of sex-role attitudes and wife's work status and motives to our defined family financial management activities.

Method

The city directory in a Midwestern university community identified 82 couples balanced as equally as possible between families with working and nonworking wives and upper and lower income families. (See Rosen and Granbois 1983 for details and rationale.) Usable data were obtained from 76 couples. The interviewer read questions dealing with each of the five behaviors; husband and wife responded jointly. Each respondent separately completed Rotter's (1966) Locus of Control Scale and the Osmond and

Martin (1975) Sex-Role Attitude Scale.

Respondents were found to be uniformly distributed across life cycle stages and across income groups, and were almost equally divided on wife's working status. As is often true in college towns, both husbands and wives were more likely to have graduated from college or to have earned an advanced degree than would be the case in other research settings. This heavy emphasis toward better-educated respondents may have tended to overstate somewhat the incidence of financial management practices, although our analysis revealed virtually no evidence of a relationship between level of education and use of these practices.

Sex-role attitude responses for the total sample showed husbands to be significantly more traditional than wives (means of 74.2 and 69.4, respectively; $t = 2.82$, $df = 69$, $p < .01$), and husbands' and wives' scores to be moderately correlated ($R = .63$). Wives showed a significantly more external locus of control than their husbands (means of 9.21 and 7.34, respectively; $t = 3.40$, $df = 69$, $p = .001$); locus of control scores were only modestly correlated within families ($R = .32$).

Results

Individual Financial Management Behaviors

As we expected, the five financial management practices studied were not employed with equal frequency by our respondents. The rank of frequency of use differed slightly from our predicted rank of importance, as shown in Table 1.

TABLE 1
INCIDENCE OF FIVE FINANCIAL
MANAGEMENT PRACTICES FOR 76 FAMILIES

Practice	Percent Using
Preparing a budget (written or not written)	64.5
Saving regularly	73.7
Planning for surplus funds	34.2
Using special accounts	38.2
Sorting credit card transactions	31.8 ^a

^aCalculated for those using credit cards (66 couples).

A higher proportion of our respondents reported regular savings patterns than has been found in earlier research, which reports a range of 15 to 40 percent (Olander and Seipel 1970). We have no comparable data from earlier studies against which we can compare the level of incidence we found for the remaining four measures.

Intercorrelations among the five measures were very low, as shown in Table 2.

TABLE 2
INTERCORRELATIONS AMONG FIVE
FINANCIAL MANAGEMENT PRACTICES

	Budgeting	Saving Regularly	Planning Surplus Funds	Using Special Accounts
Saving Regularly	-.00			
Planning Surplus Funds	-.21	.18		
Using Special Accounts	.19	.04	-.11	
Sorting Credit Transactions	.09	-.04	.10	.16

The modest negative correlation between formal budgeting and planning for surplus funds suggests a reasonable pattern. Those who do not use overall budgets nonetheless have prior planning procedures for the part of their income left over after paying bills and obligations; those who plan and budget may find planning for "left overs" unnecessary if an adequate budgeting procedure is devised to start with.

We found little evidence that the independent variables included in our study can help predict the incidence of our five financial management practices; one variable appeared to have an effect opposite to that hypothesized. The results of our chi-square analysis of categorical independent variables and t-test analysis of continuous variables can be summarized as follows:

- (1) Family life cycle stage was significantly related to the reported use of a written or unwritten budget ($X^2 = 12.19$, $df = 5$, $p < .05$). Those in the earlier stages of the family life cycle made greater use of budgeting.
- (2) Income was weakly related to the use of written or unwritten budgets with greater use occurring at lower income levels ($X^2 = 6.16$, $df = 3$, $p = .10$).
- (3) Conflicting results were obtained for locus of control. Wives in families that budget were more external than those in families that did not budget ($t = 2.31$, $df = 44$, $p < .05$). However, husbands' in families employing special accounts were significantly more internal than were husbands in families that did not employ special accounts ($t = 2.28$, $df = 60$, $p < .05$).
- (4) Wife's sex role was weakly related to planning for surplus funds with planners more traditional than nonplanners ($t = 1.77$, $df = 43$, $p < .10$). Husbands' sex-role attitude was not related to any of the practices.
- (5) Neither wife's working status nor the motivation of working wives appeared to be related to any of the five financial practices.

Composite Scale Development and Relationship to Independent Variables

We felt justified in assuming that each of the five financial management practices contributed positively to the family's overall financial management behavior. However, since each of the individual families reported different subsets of the five practices, any effort to assess the relative financial management behavior of individual families required that a scale value be associated with each item. Scale values also could be used to confirm the a priori judgment of importance ordering of the five practices that has been previously described. The scale values for each practice were obtained from an ad hoc panel of expert judges. Included were the author of a text on consumer management, professors teaching courses on personal finance and family studies, and others with special expertise in related subjects.

Conjoint analysis was used as an assessment tool. The judges were given a set of profiles of the financial management activities and asked to rank them in order of degree of financial management evident. The budgeting factor was offered at three levels -- no budget, unwritten budget, and written budget. The other four factors were specified at two levels each. This yields $3 \times 2^4 = 48$ combinations. An orthogonal array (Addelman 1962) of 25 combinations was used to reduce the set. Several of the combinations were duplicates, so a unique set of 20 profiles was finally developed. The 20 profiles were typed on 4" x 6" cards with the order of the financial management activities systematically varied across sets of cards (that is, each set of 20 cards used a single ordering of the factors, but this order was different for each judge.)

Eight judges evaluated the financial management profiles. The judges were simply asked to rank the profiles (ties permitted) according to the degree of family financial management indicated by each. The profile rankings submitted by the eight judges were analyzed at the group level using LINMAP (Shocker and Srinivasan 1973). The single set of part-worth values that was obtained is shown in Table 3. LINMAP converted the ranked data to 190 paired comparisons for the eight judges. One element in a pair is considered higher in management behavior if five or more judges ranked the element higher.

The overall fit of the derived conjoint data was indicated by a Kendall's Tau of .83. Of the 190 paired comparisons, 165 were strictly satisfied, 17 were neither violated nor satisfied (due to ties), and 8 were violated. Overall, these results indicated a good fit of the additive conjoint model to the expert judgments. The weights shown in Table 3 were used to assign a scale value on financial management to each respondent in the study. By determining which activities a family conducted, a suitable score was derived, with higher scores representing higher degrees of financial management behavior.

Also shown in Table 3 are the relative importance of the attributes in contributing to management behavior scores. This importance is a simple function of the range of weights on each attribute. The expert judges' ordering was consistent with our hypotheses.

TABLE 3

ATTRIBUTE WEIGHTS FROM CONJOINT ANALYSIS OF EXPERT JUDGMENTS FOR FAMILY FINANCIAL MANAGEMENT ACTIVITIES

Attribute	Level	Part-Worth ^a	Attribute Importance
Budgeting:	None	-46.7	.42
	Yes, not written	- 6.7	
	Yes, written	53.3	
Adding to Savings Regularly:	No	-30.0	.25
	Yes	+30.0	
Planning to Surplus Funds:	No	-20.0	.17
	Yes	+20.0	
Using Special Accounts:	No	-10.0	.08
	Yes	+10.0	
Sorting Credit Cards:	No	-10.0	.08
	Yes	+10.0	

^aFor families that did not use credit cards, weights for the first four activities were adjusted slightly, and a 0.00 weight was given for the last activity, thus enabling a comparable composite scale value.

The composite score for a family was the simple sum of the part-worth weighting it received for each of the five activities. The distribution of our respondent families' scores on the composite financial management scale is shown in Figure 1.

Relationships among the couple's composite management scale values and the independent variables were sought through multiple regression analysis. No association was found between the independent variables and composite scale scores.

Discussion

We were reasonably confident that our exploratory interviews and literature review had uncovered relevant and important measures of financial management practices for investigation, and our analysis of results seems to

FIGURE 1

DISTRIBUTION OF COMPOSITE SCALE SCORES

confirm this assessment. All five practices were used by a significant number of respondents, and we sensed no feelings on the part of respondents who did not use these practices that their use was inappropriate or unexpected. Not all practices were used with equal frequency, so the idea of forming a scale with importance weights assigned to each element seemed reasonable. Our expert judges found our measures to be realistic elements of family financial management and confirmed our a priori ranking of their relative importance. Inter-judge agreement was high and standard tests supported strong confidence in the importance weights devised from conjoint analysis.

The set of demographic variables and sex-role attitude measures used as independent variables were strongly suggested as important determinants of family behavior by other researchers and commentators on contemporary family structure and behavior. Finally, locus of control seemed to have strong intuitive relevance and had been found useful in scattered earlier consumer research and in decision-making studies in other disciplines.

Given the methods employed, the general lack of significant findings for the relationship between the independent variables and financial management behavior is surprising. Although our sample was small and was confined to a single small city, we selected respondents in a very carefully planned and controlled fashion so that our responding couples were distributed over age, income, family life cycle, and wife work status categories. Husbands' and wives' sex-role attitude and locus of control scores differed from each other in predicted ways, and average scores were well within ranges predicted by earlier administration of the instruments as reported by their developers (Osmond and Martin 1975; Rotter 1966). The only obvious flaw in the distributions of our respondents' characteristics was the over-representation of more highly educated persons.

The small size of our sample may have limited our ability to discover significant associations that might be revealed in a larger study. We plan to include these variables in a more extensive future study. Further, there may be additional family or individual respondent characteristics that determine whether our five practices are implemented. The lack of relevant theory hampers identification of these possible determinants, and we welcome other researchers' suggestions of variables for inclusion in our next study.

We find it interesting that the strongest relationships, though inconsistent, were found for locus of control. One finding was the opposite of that predicted with greater indications of the budgeting behavior when wives had a more external orientation. This finding may indicate that internals have confidence in their ability to control finances without the help of such devices as budgets and

special accounts. Externals may see such devices as ways of imposing controls, or protecting their financial status from otherwise uncontrollable external forces and influences. This view is contrary to our hypothesis concerning locus of control, but it is supported by Mueller (1966), who notes:

Budgeting is usually intended to insure that some money is available for major acquisitions or for savings. Various (unsuccessful) attempts to talk to people about their budgeting procedures have led us to the tentative conclusion that determination is a more effective control device than a plan or system developed on paper. Indeed it appears that people who resort to formal budgets may do so because their determination or self-control has not proven sufficient. (p. 33)

The significant findings for locus of control suggests that other personality variables may show a stronger relationship than standard demographics. Further research using personality and lifestyle measures may find that they prove to be more fruitful indicators of financial management behavior.

In addition to theoretical importance, an understanding of the variables most strongly related to family financial management practices should have applied relevance for financial institutions. Deregulation of the banking industry has led these institutions to provide an ever-increasing array of financial planning and management services in an effort to remain competitive in their new environment. Conventional wisdom suggests that demographic variables such as income and education should be related to the use of such financial management and savings options. However, to the extent that the five financial management practices we studied affect the family's interest in or ability to use such services, our findings suggest that conventional wisdom may be incorrect.

Future Research

This study represents a first step in a larger research effort. We hope to investigate appropriate measures of effective consumer performance and satisfaction, which may then be studied as possible outcomes or consequences of applying financial management practices in handling household spending and saving. Our experience with simple satisfaction scales administered for each aspect of respondents' financial practices has been that such scales fail to reveal much variability across respondents or across the various financial practices. Further developmental work in this area is clearly needed.

We intend to explore the possibility that income variability and frequency may be determinants of our budget and savings regularity variables. This follows the tentative suggestion by Deacon and Firebaugh (1975, p. 282 p. 282) that both budgeting and saving may be more important when household income is unstable and received less frequently. A simple measure of income stability included in the present study failed to reveal much variability across responding families, thus indicating the need for additional development of an adequate measure.

Finally, we intend to investigate role structure as a determinant of financial management and control behavior. The literature does not suggest hypotheses in this area, but it seems plausible that formal budgets and savings plans will be more likely if husband and wife tend to exhibit a syncretic (joint) decision-making style.

AN ANALYSIS OF THE PRESENCE, STABILITY, AN ANTECEDENTS OF HUSBAND AND WIFE PURCHASE DECISION MAKING INFLUENCE ASSESSMENT AGREEMENT AND DISAGREEMENT

Alvin C. Burns, Louisiana State University
Jo Anne Hopper, Southeastern Louisiana University

Abstract

Noting the absence of empirical study of husband and wife over- and underestimation of purchase decision making influence assessments, the authors utilize Davis and Rigaux's (1974) and Burns' (1977) conceptualizations. Results confirm presence of a wide variety of disagreement as well as agreement groupings of couples who differ greatly from overall husbands and wives group averages. Some generalized tendencies for stability of agreement and disagreement predispositions across influence dimensions is apparent for one product (family automobile) and financial decisions across two products. Antecedent variable analyses imply differential sensitivity to resource theory with wives overestimating their influence when they make greater contributions and underestimating if they do not. Implications for future research and decision making dynamics are discussed.

Introduction

Researchers working with husbands and wives perceptions of their relative purchase decision making influence have long acknowledged that while influence assessments usually agree in the aggregate, there is often a lack of agreement on the individual couple level. Davis (1976), Burns and Granbois (1979), and Safillios-Rothschild (1969) all point out the need for research which clarifies the nature and reasons for these reporting discrepancies. Thus far, however, scant attention has been given to this problem, and empirical research is almost nonexistent.

In addition to the above authors' comments, some preliminary conceptual thinking has been devoted to the problem. For instance, Heer (1962) and Granbois and Willett (1970) have noted over- and underestimation occurrences. Davis and Rigaux (1974) noted "vanity" and "modesty" in matched spouses and alluded to the need for further research to identify, isolate, and study couples with these perceptual biases. A more detailed model of the comparison of husbands to wives influence assessments has been proposed by Burns (1977) who identified nine different types of outcomes possible in a comparison of husband to wife influence assessments. Both of these conceptualizations serve as frameworks for the research reported in this paper.

Objectives of this Study

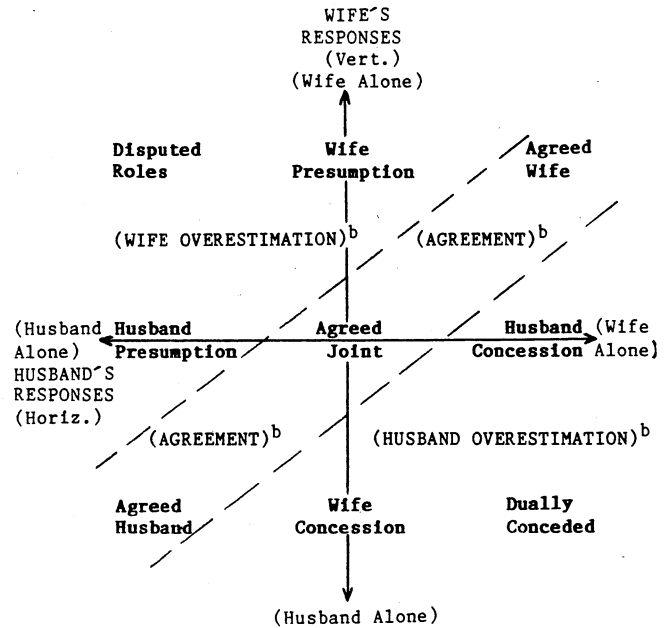

The primary purpose of this study was to investigate instances of spousal agreement and disagreement in purchase decision making influence assessments. In particular, the intent was to assess the efficacy of Burns' (1977) and Davis and Rigaux's (1974) notions as paradigms in identifying the presence and persistence of agreement and disagreement. Four specific research questions served as the objectives of the study.

1. Can groupings of couples be identified who are similar in agreement or disagreement yet dissimilar from others and the aggregate?
2. If so, do couples maintain stable agreement and disagreement dispositions across independent influence dimensions?
3. What, if any, are the antecedent variables associated with certain matched influence assessment predispositions?

The rationale for this study stems from corroborated findings in husband and wife influence assessment

FIGURE 1

AGREEMENT AND DISAGREEMENT REGIONS FROM MATCHED HUSBAND AND WIFE RESPONSES^a

^aAdapted from Burns (1977)

^bAdapted from Davis and Rigaux (1974)

research (Davis, 1976). Namely, purchase influence distribution between husbands and wives varies as a function of personal attributes, product-specificity, and type of decision. It seems reasonable to expect that disagreements may obey some regularities as well, and if determined empirically, future research will be better equipped to separate out or otherwise adjust for systematic perceptual differences.

The Davis and Rigaux (1974) and Burns (1977) models are not competing; they simply differ in detail. Davis and Rigaux suggest that three groups can be found: (1) those in agreement; (2) husbands overestimating relative to their wives; and (3) wives overestimating relative to their husbands. In contrast, the Burns model compares a husband's to his wife's assessments of decision making influence in a consensus-nonconsensus framework mapped onto a two-dimensional grid. In the instance of a three-point response scale ("husband," "joint," or "wife"), the comparison generates nine cells, each of which is assigned a descriptive label. Figure 1 relates both models applied to a 100% influence scaled-response measure. The dotted lines define Davis and Rigaux's agreement area and two disagreement areas. Also, it can be seen that Burns has identified the three different "regions" within each of Davis and Rigaux's areas. These two models constitute basic paradigms for this study.

Method: Sample and Instrument

Data was collected as part of a larger study using a convenience sample of 85 married couples living in Baton Rouge, Louisiana. Respondents were asked to take part in a study on how husbands and wives make purchase decisions. The study involved filling out a series of questionnaires at home with an administrator present to give the questionnaires and provide instructions. Husbands and wives were prevented from comparing answers in two ways: (1) questionnaire segments were administered randomly to each spouse, and (2) the administrator, ostensibly involved in administration paperwork, remained with respondents throughout the session.

Respondents were asked to estimate the amount of influence of each spouse, defined as "...the amount of persuasion..." on a 100-point constant sum scale. This scale was chosen as it has been claimed by Jenkins (1978) to be more reliable and valid than other scale types. The spouses were told to consider the purchase of two major durable products: (1) the family automobile and (2) family room furniture. These products were selected as they are customarily used in husband and wife purchase decision making influence studies (Burns and Granbois, 1979) and both are products in which over- and underestimates have been reported. For each product, several subdecisions were specified: (1) price to pay; (2) where to buy; (3) model/brand; (4) how to pay; (5) style; and (6) when to purchase. Each subdecision was separated into a search for information stage and a final decision stage as influence differences have been found across stages in the purchase decision (Davis and Rigaux, 1974). A final item pertaining to initial recognition and suggestion to replace the old product completed the set of thirteen response items for each product.

The sample exhibited a profile similar to those often reported in husband and wife purchase decision making studies: it was upscale in terms of education and income. Husbands and wives averaged 5 years and 4 years of schooling beyond high school, respectively. Forty percent of the husbands earned more than \$35,000 per year. Husbands were 40 years old, and wives were 38 years old, on the average. Marriage length averaged 15 years.

Analysis and Findings

Determination of Influence Dimensions

The raw data was comprised of 170 spouses' influence distribution responses to each of thirteen subdecision items for each of two products. For convenience, it was decided to analyze the influence attributed to the wife. (Since a constant sum scale was used, husband influence was the complement.) As it was highly probable that multicollinearity existed in the responses, a principal components factor analysis was applied for each product to determine the dimensionality of influence perceived by husbands and wives. The eigenvalue "equal to or greater than one" rule was used to determine the number of factors, and varimax rotation was applied to assist in interpretation. Both the automobile and furniture influence assessments yielded two factors which were quite similar. In particular, for each product one factor defined Financial considerations (price, how to pay, when to buy) and the other pertained to Nonfinancial considerations (where, brand/model, style, and suggesting the need to buy). Rotated factor loadings for items associated with each factor were .60 or higher. Cumulative variance explained was 79% and 82% for Family Room Furniture and Family Automobile, respectively.

Cronbach's alphas were computed to assess the internal consistency of the items loading on each factor, and these were determined to be as follows: Automobile Financial (.93); Automobile Nonfinancial, (.96); Furniture Financial, (.83); and Furniture Nonfinancial (.97). These values indicated that sufficient reliability of measurement had been attained to warrant further analysis. Next, Pearson product moment correlation coefficients were computed on the sum scores of the items for each factor to confirm that the dimensions were independent. The highest correlation was found to be .64 for husbands Financial to Nonfinancial Automobile sum scores and .61 for wives in the same pairing. All other correlations ranged from -.18 to .54, signifying little covariation was present across the four perceived influence dimensions.

Identification of Agreement and Disagreement Groupings

Comparison of the husbands group and wives group means corroborated previous findings of agreement in the aggregate. These means are presented as part of Table 1, signified as "TOTAL" for each Influence Dimension, where the greatest difference between the husbands group and the wives group means was 2.8% in the case of the Furniture Financial decision.

^aStandard Deviations in Parentheses
^bBased on Burns (1977)

The next phase of the analysis was the application of cluster analysis to matched husbands-to-wife responses. Although not without its critics and problems, cluster analysis does reveal the presence of heterogeneous subgroups within a sample based on the ratio of within-group to between-group variance and seemed the most appropriate numerical taxonomy procedure available under the objectives of the research (Punj and Stewart, 1983). A technique with the potential to identify widely differing subgroups was especially desirable in light of Burns' model which presupposes several types of agreement and disagreement couples.

A separate cluster analysis was run for each of the four purchase influence dimensions. Ward's method was used, and the cubic clustering criterion (CCC) was graphed against cluster steps to determine the final number of clusters (SAS Institute, 1982, p. 420). Inspection revealed that the CCC peaked at 8 clusters for Nonfinancial decisions for both products and at 9 clusters for Financial decisions in both instances. Figure 2 presents graphs of the cluster centroid locations while Table 1 compares their descriptive statistics. Table 1 also contains designations of the Burns' model regions they occupy. Unfortunately, neither Davis and Rigaux (1974) nor Burns (1977) indicated a relevant criterion to judge the separation of agreement and disagreement, so we adopted the rule that any difference between husbands' and wives' cluster centroid means of 10% or greater constituted disagreement. In addition, it was necessary to define range limits for agreed wife-, joint-, and husband-influence regions. We decided on limits of 61%-100%; 40%-60%; and 0%-39%, respectively.

^aStandard Deviations in Parentheses
^bBased on Burns (1977)

The figures and Table 1 reveal the great degree to which the aggregate-level means mask disagreement as well as other forms of agreement. For instance, in the case of Automobile Nonfinancial decision, determined as an Agreed Husband influence area in the aggregate, only 2 of the 8 cluster centroids fell into this region, while 2 were found in the Agreed Joint Region. In other words, only 29% of the sample fell into clusters consistent with the aggregate result designation. Presumption and Concession by both spouses were also apparent. A great variety of agreement and disagreement groups was evident across all four of the purchase influence agreement dimensions.

Investigation of the Stability of Agreement and Disagreement

These independent descriptive result comparisons were insufficient, however, as they did not address the stability of couples across cluster results. If couples exhibit stable dispositions, they should be in similar regions from influence dimension to influence dimension. If stability is not found, the phenomena of agreement and disagreement are either random variables or highly specific to the influence dimensions studied. Consequently, an attempt was made to determine the degree of stability of couples across influence dimensions.

Since cluster membership is a nominal variable, the Chi Square test for independence was appropriate. It became apparent at this point that the 8- and 9-cluster solutions could not be used due to the small sample size relative to the number of cells. Consequently, it was decided to use collapsed cluster analysis results in the forms of 4-cluster solutions to overcome the Chi Square cell-size problem. Table 2 reports these results and reveals that with the exception of Furniture Nonfinancial decisions, over- or underestimation disagreements were still prevalent.

Chi Square results determined significant associations between Automobile Nonfinancial and Financial decisions (Chi Square = 66.5; df = 9; prob. = .0001) and between Automobile Financial and Furniture Financial decisions (Chi Square = 19.2; df = 9; prob. = .02). Inspection of these two crosstabulation tables revealed that agreement, overestimation and underestimation was relatively stable except in the case of wife overestimation relative to the husband for Financial decisions. Approximately one-third of the couples remained in agreement that the decision would be jointly decided in both comparisons. Another five percent agreed on husband autonomy in both Automobile influence dimensions. Other subsets of couples exhibited stable disagreement predispositions across the Family Automobile purchase. Fourteen percent maintained a posture of wife overestimation while nine percent retained a husband overestimation disposition. Husband overestimation of the wife's influence also held for nine percent of the sample in the Financial decision area across both products. Although seemingly inconsequential percentages, when compared to the relatively small cluster sizes for disagreement couples, these value take on more significance.

Associations of Antecedent Variables

The final analysis undertaken addressed the question of antecedent variables which might assist in identifying and/or understanding agreement or disagreement between spouses' purchase influence assessments. Two reasons compelled this analysis. First, Punj and Stewart (1983) contend that a gauge of the usefulness of cluster analysis is the demonstration that the clusters are meaningfully related to variables other than those used to generate them.

The second reason stemmed from prior research which has relied on demographic, work status, and attitudinal variables as determinants of husband-wife role structure. Findings have supported the notion that wives tend to assume greater decision making influence as a function of greater resource contributions to the family. Also, more liberal sex role attitudes held by either spouse are often associated with more wife influence (Davis, 1976; Burns and Granbois, 1979).

Consequently, several demographic variables were selected with the expectations that agreed wife influence and wife overestimation relative to the husband would be positively associated with her work status, education, or liberal attitudes. In the latter case, the Brogan-Kutner sex role orientation scale (1976) was used. Cronbach alphas were found to be .71 for husbands and .67 for wives. Correlations between the several candidate variables revealed the highest to be .38 between years married and husband income level, revealing overall low multicollinearity.

Table 3 presents the results of significance tests performed using the 4-cluster groupings. Individual ANOVA's were performed rather than MANOVA's due to low correlations. Duncan's multiple range analysis was the post hoc test applied to the cases of significant ($p < .10$) computed F values. These are not presented to conserve space, but two patterns were clearly evident. First, corroboration of past findings of agreement occurred. That is, agreed joint decision making was associated with shorter marriages and more liberal wife sex role orientation attitudes for both spouses. Similarly, agreed decision making autonomy for either spouse was associated with longer marriages, higher income, and more traditional wife sex role orientations for both spouses.

The second pattern concerned spouses disagreeing on relative purchase decision making influence. Wife overestimation of her influence relative to the husband's assessment was associated with greater: (1) wife education level; (2) wife income; and (3) wife hours worked per week. Husband overestimation of the wife's influence relative to her assessment was associated with less: (1) wife income; (2) wife hours worked; and (3) husband education. Interestingly, with the single exception of husband education, the significant antecedent variables for disagreement were all wife attributes. They were also largely specific to the Furniture Financial dimension. The implication here is that both spouses credit amounts of decision making influence to the wife as a function of two factors: (1) the product under consideration, and (2) her personal characteristics which are related to her contributions to the family socioeconomic status. However, the wife is seemingly more sensitized to these factors than is the husband.

Discussion

This study sought to clarify the nature, stability, and antecedents of agreement, over- and underestimation of husband and wife purchase decision making influence assessments. A brief summary of the findings is in order here. As predicted by the conceptualizations of Davis and Rigaux (1974) and Burns (1977), a substantial proportion of the sample of husbands and wives did not agree.

TABLE 3
RESULTS OF SIGNIFICANCE TESTS FOR ANTECEDENT VARIABLES^a

^aF-values from 4-group analysis of variance; all df=3
^bProbability $\leq .10$

Moreover, there was a great variety of disagreement and agreement groupings for any single influence assessment dimension. Within certain couples, there appeared to be a generalized tendency for spouses to maintain agreement, over- or underestimation postures across decisions for the family automobile purchase and to some extent for financial considerations across products. As noted in other studies, agreement was related to length of marriage and sex role attitudes. On the other hand, resource contributions appeared to figure into wives' overstatements of wife decision influence relative to their husbands. At the same time, a reverse effect could be seen operating for wives with less resource contributions, for they tended to understate their influence. These occurrences were concentrated in the financial decision of furniture purchase.

There are two sets of implications evident from the results which require brief discussion. The first is methodological, and the second is specific to husband and wife purchase decision making dynamics. In the first case, this study has demonstrated that a comprehensive paradigm such as the one suggested by Burns (1977) is a viable means of separating out agreeing as well as disagreeing couples. The relatively stable predispositions found make clear that perceptual differences are not random variables and must be explicitly taken into account in future husband and wife purchase decision making research. The paradigms used in this research can assist in separating out individual differences, and the antecedent variable associations suggest covariate relationships which should be considered.

The second set of implications concerns the impact of wife resources on the decision making process. Resource theory interpretation of husband and wife decision making implicitly assumes that spouses perceive these contributions equally. However, the findings of significant associations of wife resource characteristics with wife overestimation point to the conclusion that she views her contributions more extremely than does her husband. Assuming that resource theory underlies husband and wife decision making, the differences between spouses' sensitivities to the wife's contributions provide ample opportunity for spirited interaction over financial decisions for certain household durables. This interaction might be especially interesting to study in couples where the wife has recently entered the workforce, acquired more education, or received a pay increase. Subsequent research would be well advised to consider these perceptual differences in resource contributions as possible determinants of influence strategies, distributions, and outcomes.

TELEVISION ADVERTISING AND INTERPERSONAL INFLUENCES ON
TEENAGERS' PARTICIPATION IN FAMILY CONSUMER DECISIONS

George P. Moschis, Georgia State University
Linda G. Mitchell, Georgia State University

Abstract

This paper presents the results of a study designed to test the effects of television advertising and interpersonal communications on the teenager's consumer behavior. Unlike previous studies, however, the effects of such communication processes on teens are evaluated in the context of household decision making. Specifically, the research examines the effects of television advertising, family and peer communications about consumption on the child's participation in household decision making.

Introduction

Previous research on the effects of communications has focused either on the youth's consumer behavior and socialization or on second-order consequences. The first type of research usually deals with the effects of interpersonal communication and advertising on the youth's consumption-related cognitions, attitudes, and behaviors (e.g., Adler 1977). The second deals with subsequent effects of these communications on others and their behaviors. For example, research has examined the effects of advertising on the child's product requests from parents and parental yielding as a result of these requests (Adler 1977; Henderson et al. 1980; Ward and Wackman 1972). Considerably less attention has been devoted to the examination of second-order consequences of commercial communications on family decision making. The limited research on the effects of second-order consequences of commercial communications focuses on the outcomes of parental denial (e.g., parent-child conflict, child's disappointment) rather than on family decision-making processes.

Although critics charge advertising with creating "selling agents" within the home by persuading the child to request products s/he sees advertised, little evidence exists to support the contention that such second-order influence extends to household consumer decisions. Studies of household decision making are usually confined to spousal influence (e.g., Kollat and Blackwell 1983). Although some studies have investigated the influence of children in household decisions (e.g., Szybillo et al. 1977), such influence has not been investigated as a second-order consequence of the child's exposure to persuasive communications and other influences outside the home. Studies of advertising effects on the child's requests and parental yielding, on the other hand, are mostly confined to products consumed by the child rather than products consumed by the entire family (e.g., Henderson et al. 1980; Ward and Wackman 1972).

Conceptual Framework

Research on the effects of communications on the consumer behavior of the youth has been based primarily on conceptual and theoretical models of socialization. For example, communication researchers have examined the effects of cognitive development of the child's evaluation of advertising messages (Adler 1977). Similarly, consumer behavior researchers have investigated the effects of mass media interpersonal communications on the development of consumer behaviors (e.g., Moschis and Moore 1982; Ward and Wackman 1971).

When consumer behavior of the youth is approached from a socialization perspective, the emphasis is placed upon sources of consumer information--often known as

"socialization agents"--influencing the development of the individual's values, norms, and behaviors. Such development or learning often occurs in various social settings defined by the person's socio-demographic environment.

Although the outcomes of socialization may include changes in or the development of values, attitudes, and behaviors, several aspects of such learning have consequences on the youth's family (Riesman and Roseborough 1955). Specifically, results of learning effects from socialization agents on the youth's family may be in the form of product requests, information seeking, or even influence and eventual modification of parental behaviors. In the context of household decision making, the influence of children may conceivably be at the stages of need recognition, information seeking, product evaluation, and/or actual purchase.

The general research hypothesis in this study is that the extent of the child's influence on the family decision process is conditioned by selected socialization processes and antecedent variables defining the child's social environment.

Hypotheses

Research in consumer socialization suggests three important agents: family, television, and peers (e.g., Moschis 1981; Ward 1974).

Television

Television advertising effects are often assessed either at the individual level or at the interpersonal or group level. With respect to the first type, one finds studies of TV advertising effects on perception, attitudes, and actual behavior of the viewer. TV advertising effects have also been studied in terms of how they may affect the behavior of individuals other than those exposed to advertisements. For example, research has examined television advertising effects in a two-step flow of communication/influence; and more recently, research on children and adolescents examined children's influence attempts as well as parental mediating role of television advertising (e.g., Adler 1977; Moschis and Moore 1982).

If advertising plays an important role in family decision making by influencing the child who, in turn, influences household decision making, one would expect the youth's exposure to advertising messages to be reflected in his/her greater participation and influence at various stages in the decision making process:

H1: Television advertising viewing is positively related to the youth's propensity to play a more influential role than his/her parents in: (a) mentioning the need for products, (b) discussing purchase of products, (c) deciding what should be purchased, and (d) actually buying products.

Family. Family influences on the consumer behavior of young people is often viewed in the context of interpersonal communications. These communications include learning processes such as reinforcement (positive and negative), modeling, and social interaction which often incorporates both reinforcement and modeling. Most of the studies of consumer socialization have used the social interaction mechanism in the form of parent-child communication about consumption (Moschis 1985).

While the frequency of family communication about consumption often fails to predict the expected outcome, measures of communication structures and patterns of interaction were found to be good predictors of the youth's consumer behavior (Moschis 1985). Analysis of family communications about consumption and other matters has consistently found two relatively uncorrelated dimensions of communication structure (McLeod and Chaffee 1972). The first (which is analogous to the types of social power) is called socio-oriented, the type of communication that is designed to produce deference and to foster harmonious and pleasant social relationships at home. The child in homes characterized by such a communication structure may be taught to avoid controversy and to repress his/her feelings on extrapersonal topics, for example, by not arguing with adults and giving in on arguments rather than risk offending others.

The second type of communication structure is called concept-oriented, a pattern that focuses on positive constraints in helping the child to develop his/her own views about the world. The parents may, for example, encourage the child to weigh all alternatives before making a decision or may expose him to controversy -- either by differing openly on an issue or by discussing it with guests at home (McLeod and Chaffee 1972).

Extensive research evidence has lead researchers to assume that such family communication processes help guide the individual in coping with various situations he encounters outside the immediate family context--for instance, situations in relation to public affairs issues and mass media use (e.g., Chaffee, McLeod, and Atkin 1971; Chaffee, McLeod, and Wackman 1966; McLeod and Chaffee 1972). In addition, the evidence suggests that "the influence of family communication, as generalized to other situations, persists well into adulthood; it appears to become part of the developing individual's personality that he carries outside the home" (Chaffee et al. 1971, p. 331).

In the context of household decision making, previous research suggests that concept-oriented family communication structures will foster greater participation in such decisions, while socio-oriented structures will deter participation (Moschis 1985). Specifically, the child's influence as result of these family communication structures can be hypothesized as follows:

- H2: Concept-orientated family communication structure is positively related to the youth's propensity to play a more influential role than his/her parents in: (a) mentioning the need for products, (b) seeking information, (c) deciding what should be purchased, and (d) actually purchasing products.
- H3: Socio-oriented family communication structure is negatively related to the youth's propensity to play a more influential role than his/her parents in: (a) mentioning the need for products, (b) seeking information, (c) deciding what should be purchased, and (d) actually purchasing products.

Peers

Peer influence appears to be important in early life, especially during adolescence. The youth's desire to conform to peer norms is often exemplified in terms of product ownership, making the child more likely to purchase or to request the purchase of such products. Thus, it is not surprising to find evidence indicating that young people who frequently interact with peers about consumption matters are likely to get ideas from peers regarding the products they should own (Caron and Ward 1975); they are likely to discuss peer consumption behavior with their parents (Churchill and Moschis 1979); they are likely to play an important role

regarding the kinds of products and brands they or their family should buy (e.g., Moschis et al. 1983); and they are actively involved in the purchasing process (Moschis et al. 1977). Thus, it is hypothesized that:

- H4: The youth's frequency of communication with peers about consumption will be associated with greater influence in the family decision making process by increasing his/her likelihood of (a) mentioning the need for products, (b) discussing products with parents, (c) deciding to purchase products, and (d) actually purchasing products.

Antecedent Variables

Previous research suggests that several antecedent variables affect consumer learning. Some of these are related to the child's characteristics (such as age, sex, and social class) (Moschis 1981; Ward 1974).

In this research it is expected that age, available money, sex, and social class will affect the child's involvement in, and influence on, family decision making. Specifically, with increasing age, the child's competence as a consumer increases (e.g., Moschis and Moore 1979), and s/he may assume greater responsibility in purchasing products both for individual as well as for family use. Also, with increasing age, youngsters are likely to find alternate sources of income (e.g., work), thus decreasing his/her financial dependence upon parents for purchases of products (Sanders et al. 1973).

- H5: Age is positively related to the adolescent's propensity to play a more influential role than his/her parents in (a) mentioning the need for products, (b) discussing consumption with parents, (c) deciding whether to buy certain products, and (d) independently purchasing products.
- H6: With increasing money earned outside the home, young people are less likely than their parents to (a) mention the need for products, (b) discuss the purchase of products, (c) decide whether to buy certain products, and (d) independently purchase products for individual or family use.

Furthermore, research shows that male adolescents are more likely to obtain independence in the consumption process than their female counterparts (Moschis et al. 1977). Such independence may be reflected in terms of lower participation in the decision making process involving the youth and his family. Finally, research suggests that youths from lower socioeconomic backgrounds are more likely than their upper socioeconomic counterparts to contribute to the family's income (Sanders et al. 1973). This may indeed increase their influence in consumer decisions. The preceding discussion suggests the following hypotheses:

- H7: Female adolescents are more likely than their male counterparts to have influence over his/her parents in (a) mentioning the need for products, (b) discussing purchase of products, (c) deciding what should be purchased, and (d) actually buying products.
- H8: Lower socioeconomic status adolescents are more likely than their counterparts to have influence over his/her parents in (a) mentioning the need for products, (b) discussing purchase of products, (c) deciding what should be purchased, and (d) actually buying products.

Method

Sample

Adolescents from several cities and towns in five counties in urban, suburban, semi-rural, and rural Georgia in junior and senior high schools were asked to complete anonymous self-administered questionnaires. Specific schools were selected after personal interviews with school officials to ascertain schools demographically representative of their respective regions.

Respondents were also given a questionnaire to take home to their parents. This questionnaire was addressed to the child's mother. Specifically, the questionnaire asked the mother to indicate demographic characteristics of the child who brought the questionnaire to her, including his/her birthday, sex, grade in school and name of school attended by the child. This information was used to match the parent's anonymous questionnaire responses to anonymous responses given by the child at school, using primarily the child's birthdate and, whenever necessary, other demographic characteristics.

While most previous research in this area has used responses solicited either from the child or from the mother, this study solicited responses from both. Specifically, measures of the independent variables (e.g., television viewing, family and peer communication about consumption) were obtained from adolescents, whereas measures of dependent variables were solicited from the child's mother. The rationale for using this method, instead of surveying only parents or children, was based on the assumption that the youngster is in a better position to provide accurate information on his/her interaction with TV, peers, and family and motives for such interactions while the mother is in a better position to assess the child's influence on the outcome of various types of consumer decisions over which she is expected to exercise control and authority.

A total of 161 parent-child pairs were obtained from this effort. The "nonrespondents" were adolescents who did not deliver the questionnaire to their parents, and parents who did not respond to questionnaires for several reasons (e.g., "household without mothers"), but the specification of nonresponse rates in these groups was not possible. The sample, however, was representative with respect to the adolescent's sex, age, race, and socioeconomic status.

Definition and Measurement of Variables

The dependent measures addressed several aspects of the role(s) a person can play in the decision making process within the family. These included measures of the roles of (a) purchase initiator, (b) influencer, (c) decider, and (d) purchaser of the product. This conceptualization produced respective measures. Specifically, relative parent-child measures were obtained by asking mothers to indicate the person(s) who usually (a) mention(s) the need, (b) discuss(es) buying, (c) decide(s) what/whether to buy, and (d) actually buy(s) eight products. The products were soft drinks, child's clothing, shampoo, school supplies, auto repairs, kitchen appliances, records for the child, and grooming products for the child's use. These products were selected to represent various levels of relevance to the child's vis-a-vis family's consumption or use, providing several opportunities for parent and child involvement; in addition, the products cover the complete spectrum of consumer goods classifications -- convenience, shopping, and specialty goods. The response alternatives were "parent(s)", "child" (who brought the questionnaire home), or "both parent(s) and child," with these alternatives treated as nominal scales. Thus, the dependent variables are (a) the extent to which the child mentions the need, (b) discusses buying, (c) decides, and (d) actually purchases products for child's and family's use in relation to other family members.

The child's role as purchase initiator refers to the adolescent's relative propensity to mention the need for a product. It was measured by summing responses to those products the mother indicated the child usually mentions the need for. The alpha reliability coefficient of this 0 to 8 point scale was .67.

The child's role as influencer refers to the adolescent's relative propensity to "discuss buying" a product with others. It was similarly measured by summing responses to those products the mother indicated the child usually discusses buying. The alpha coefficient of this 0 to 8 point scale was .58.

The child's role as decider refers to the adolescent's relative propensity to decide what/whether to buy. It was measured by summing responses to those products the mother indicated the child usually decides what/whether to buy. The reliability coefficient of this 0 to 8 point scale was .69.

Finally, the child's role as purchaser refers to the adolescent's relative propensity to buy products. It was measured by summing responses to those products the mother indicated the child usually actually buys. The reliability coefficient of this 0 to 8 scale was .71.

Following the rationale presented in a previous study (Moschis and Moore 1982), television advertising viewing was a direct measure of the adolescent's frequency of viewing TV commercials for the purpose of gathering information for consumer decision making as well as information about life styles and behaviors associated with consumer products. Respondents were asked to indicate on a four-point "very often-never" scale the extent to which they watched television ads for seven reasons such as "to find out about things to buy to impress others" and "to find out how good a product is." Responses were summed across the seven items to form a 7-to-28 point index, which had a reliability coefficient of .80.

Peer Communication about consumption was operationally defined as overt peer interaction concerning goods and services (e.g., Churchill and Moschis 1978). It was measured by summing responses to eight items such as "My friends and I talk about buying things," on a five-point "very often" (5) to "never" (1) scale; the alpha reliability coefficient of this 8 to 40 point scale was .76.

Concept-oriented and socio-oriented family communication structures were measured in line with previous research (e.g., Moschis and Moore 1978; Moschis et al. 1983) by asking the adolescent to indicate how often certain types of parent-child communications occur; six items were designed to measure each communication structure. The reliability coefficients of these 6 to 30 point scales were .72 and .51, respectively.

Results

Table 1 shows relationships among dependent and independent variables. The two measures of family communications are unrelated, as expected. Age is negatively associated with television advertising viewing and family communications; it is positively associated with peer communication. These relationships are in line with previous theory and research (Moschis 1985).

Table 2 shows partial correlations between measures of child's participation in consumer decisions and the independent variables. Contrary to our expectations, advertising viewing frequency is not associated with any one of the four measures of the child's participation in consumer decisions, providing little support for Hypothesis 1.

In addition, concept-oriented family communication structure was not significantly related to any of the

dependent measures, providing no support for Hypothesis 2. Socio-oriented family communication structure, on the other hand, was negatively associated with the child's propensity to decide what products to buy ($r=-.13$, $p<.05$) (Hypothesis 3c) and actual purchase of these products ($r=-.20$, $p<.01$) (Hypothesis 3d), as posited.

Peer communication about consumption was positively related to most dependent measures. Specifically, the more frequently the adolescent interacts with his/her peers about consumption matters, the more likely s/he is to play a major role in mentioning the need for products ($r=.20$, $p<.01$), discussing purchase ($r=.14$, $p<.05$); peer communication was not significantly associated with actual purchase ($r=.07$, n.s.). These results provide support for Hypotheses 4a, 4b, and 4c; they do not support Hypothesis 4d.

Age was positively associated with all four dependent measures, as posited. Specifically, the older the adolescent is, the more likely s/he is to play a major role in mentioning the need for products ($r=.20$, $p<.01$), discussing purchase ($r=.15$, $p<.05$), making the purchasing decision ($r=.31$, $p<.001$), and actually buying products ($r=.21$, $p<.01$). These data offer support for Hypothesis 5. The data also offer partial support for Hypothesis 6, showing that with more money available adolescents have more say in consumer decisions. Although they are not necessarily more likely to mention need for products ($r=.02$, n.s.) (Hypothesis 6a), discuss purchases ($r=.05$, n.s.) (Hypothesis 6b), or participate in product decisions ($r=.09$, n.s.) (Hypothesis 6c), with increasing money availability adolescents are more likely to have greater purchasing independence ($r=.21$, $p<.01$) (Hypothesis 6d).

The data also provided support for Hypothesis 7 concerning the effects of sex. Specifically, female adolescents appear to be more likely than their male counterparts to mention need for products ($r=.24$, $p<.05$), discuss purchase ($r=.27$, $p<.001$), make product decisions ($r=.26$, $p<.001$), and actually purchase such products ($r=.16$, $p<.05$), offering support for Hypotheses 7a, 7b, 7c, and 7d, respectively.

The effects of socioeconomic status on the teenager's participation in consumer decisions were generally weak, with only one significant positive relationship (opposite those expected) shown between social class and the youth's propensity to mention need for products ($r=.13$, $p<.05$). Thus, hypothesis 8 was not supported.

Discussion

Television advertising viewing was not associated with any dependent measure of the child's relative participation and influence in consumer decisions. Although previous studies have shown television advertising effects on the youth's cognitions, attitudes, and behaviors, the results of the present study suggest that TV advertising viewing has no effect on household consumer decisions. If, indeed, the adolescents acted as a "selling agent" for the seller of advertised products, our data should have shown significant relationships between the frequency of viewing of such ads and measures of the youth's relative participation in consumer decisions. Thus, the second-order consequences of television advertising effects found in previous studies (e.g., Adler 1977) may only apply to young children and/or products for child's use (e.g., toys, candy). The findings appear in line with the results of a study by Henderson et al. (1980).

A number of reasons can account for the inconsistency in the present results with those of previous studies. First, previous research exploring second-order consequences of television advertising effects dealt almost exclusively with children and not with adolescents. Since requests have been found to decline with age among

children (Ward and Wackman 1972), it is possible that adolescents make fewer attempts to influence family decisions. Second, previous studies evaluated advertising consequences in the context of the child's consumption behavior rather than household decision making. Third, measures of advertising effects in the majority of previous studies were based on self-reported influences rather than on correlational evidence; and they based on samples of either parents or children. Fourth, previous research has focused on relatively few types of product categories. Fifth, measures of advertising exposure have normally used amount of time spent viewing TV, rather than time and motivations for viewing TV ads. Finally, measures of the child's influence in previous studies were absolute--i.e., the extent to which the child requested the advertised product; the measures in this research were relative--i.e., the child's influence in relation to parental influence.

The adolescent's involvement in consumer decisions appears to be a function of social processes, with the effects of social interactions with parents and peers playing an important role. When parents discourage (constrain) the child's involvement in the world of ideas (socio-oriented family communication structure), they may also discourage the child's participation in consumer decisions. However, encouragement (concept-oriented communication structure) does not necessarily lead to greater participation in the form of autonomous decision making. Thus, although other studies have shown significant effects of family communication structures on the youth's cognitions (Moschis et al. 1983), the results of this study suggest that such effects may not be carried to behavioral levels defining the youth's participation in family consumer decisions.

The adolescent's frequency of interaction with his/her peers about consumption matters was a fairly good predictor of involvement in the early stages of consumer decisions. Such influence, however, declines with movement toward actual purchase, suggesting that parents may mediate the effects of peer influence.

With increasing age, adolescents show greater participation in consumer decisions. This may be due to their increasing knowledge of the marketplace, to the removal of factors constraining their ability to purchase (e.g., ability to drive), or to increasing responsibility granted by their parents. With increasing money, however, adolescents appear to acquire independence in consumer decisions from their parents, since they are more likely to actually purchase products without prior consultation with them.

Finally, female adolescents appear to be more likely to be involved in consumer decisions than male adolescents. This is possibly due to the early learning of sex roles associated with gender and/or to parental encouragement.

THE ROLE OF RADICAL BEHAVIORISM IN
THE EXPLANATION OF CONSUMER CHOICE

Gordon R. Foxall, Cranfield Institute of Technology¹

Abstract

Insofar as the psychodynamic assumptions which currently dominate consumer research exclude alternative explanations they impede scientific progress. In line with Feyerabend's advocacy of the proliferation of tenaciously-held, incommensurable theories as essential to progress, this paper maintains that an important role of radical behaviorism in consumer research is the provision of a critical stance, a counterpoint to the prevailing paradigm. Radical behaviorism exposes the taken-for-granted assumptions that underpin current explanations and suggests an alternative interpretation based on different assumptions.

Introduction

The theory-ladenness of observation raises problems for theoretical and scientific progress (Peter and Olson 1983; Popper 1980). A theory ultimately has meaning and explanatory significance only within the paradigm wherein it is derived and there is no consensus on how theories belonging to separate paradigms might be compared or how competing paradigms can be comparatively evaluated (Borger and Cioffi 1970). Neither the view that paradigms are successively established (Kuhn 1970) nor the suggestion that research programs can be systematically compared (Lakatos 1970) appears appropriate for the social sciences. The approach to scientific progress adopted here owes more to the 'epistemological anarchy' of Feyerabend (1975). He argues that scientific progress depends on the deliberate proliferation of competing explanations, engendering an 'active interplay of tenaciously held views', forcing into open articulation the taken-for-granted assumptions which underlie conventional wisdoms, and thus stimulating critical comparison and debate. Contradictory, even incommensurable perspectives are thus to be welcomed since the evidence required to test one may not be generated but for another. The alternative approach, in which one paradigm assumes a preeminent status, encourages adherence to fixed viewpoints and methodologies; it is inimical to progress because it restricts the scope of intellectual enterprise. The resulting 'anything goes' approach involves the purposeful development of novel explanations and the resuscitation of those which appear outmoded and even irrational. Complete knowledge requires that nothing be excluded.

This paper is intended to contribute to the progress of consumer theory by considering (i) an analysis of choice which accords explanatory power exclusively to environmental consequences of behavior, denying causative significance to intrapersonal events: radical behaviorism; and (ii) the relationship between that analysis and the prevailing paradigm for consumer research which derives principally from the cognitive psychology of human information processing. The focal point of recent interest in radical behaviorism's potential role in marketing has been the search for novel prescriptions for managerial action, notably the more effective exploitation of promotional stimuli based on operant conditioning principles. Whether radical behaviorism can play a significant role in improving managerial practice or modeling consumer choice remains an unanswered empirical question. Behavior modification through operant conditioning has been most demonstrable in small, manageable situations and with individuals - in therapeutic and training communities, for example. The manager or researcher has little control over purchase and consumption which are governed by many competing stimuli. The import of this paper is that radical

behaviorism has much to offer the explanation, rather than the manipulation of consumer choice.

The Prevailing Paradigm

The prevailing approach to the explanation of consumer behavior may be characterized as teleological (in that its explananda are assumed to exhibit purpose and design) and psychodynamic (in that the predominant sources of explanation are found in antecedent mental events and processes). This stance assumes two types of concepts: those which relate to an observable realm of consumer behavior from which explananda are derived, and those which relate to an unobservable mental or conceptual realm of prebehavioral, intrapersonal events in terms of which the explicans is couched.

The comprehensive models of consumer choice are firmly founded on this duality, taking for granted that cognitive processes determine consumer choice. The explanation of consumer choice in terms of information processing and its outcomes extends beyond these models, however, and includes the near-ubiquitous assumption that cognitions and cognitive changes are inevitable precursors of behavior and behavioral change.

The philosophical stance offered by this psychodynamic paradigm is often uncritically accepted despite mounting contrary evidence. In the twenty years of comprehensive modeling which has formed the backbone of the paradigm, several intellectual challenges have arisen which might have led to a thorough reassessment of its fundamental assumptions. For instance: models have been extensively criticized, notably for their lacking correspondence rules necessary for empirical testing (Bagozzi 1984); where empirical testing has been possible, it has produced fragmentary and disappointingly weak support (Holbrook 1974); empirical investigations in social psychology generally as well as consumer research reveal low correlational consistency between measures of the central, prebehavioral components of those models (attitudes, intentions) and overt choice (Foxall 1984); some research points unambiguously to the prior explanatory significance of behavioral measures over cognitive intermediaries (Fredericks and Dossett (1983); it has been persuasively argued that consumers make smaller and less rational use of information than the paradigm assumes and the whole notion of consumer decision making has been called into question (Olshavsky and Granbois 1976); the assumption that consumers are ego-involved while purchasing and consuming has also been queried (Krugman 1965); and sequences other than cognition-affect-conation have been shown to describe more accurately the consumer choice process (Ray 1973).

Some limited change has been accommodated within the paradigm but its assumptions have remained intact. Models have been revised without deviating from their basic philosophical stance and even the potentially subversive concept of low involvement consumer behavior has been integrated into the existing framework and explained in terms of cognitive mediation (Engel and Blackwell 1982). The possibility that low involvement might be represented as the direct result of environmental stimuli has been overlooked or ignored by modelers and textbook writers.

The dominant status of the paradigm is evident above all from its adherents' response to the intellectual challenge of alternative paradigms based on antithetical assumptions about the explanation of behavior, eg. radical behaviorism. Writers who have seriously employed this paradigm (e.g. Berry and Kunkel 1970) have been largely ignored.

¹Cranfield School of Management, Bedford, England.

Recent advocates of behavior-based perspectives (Nord and Peter 1980; Peter and Nord 1982; Rothschild and Gaidis 1981) have avoided commitment to radical behaviorism itself, opting for social learning theories (e.g. Bandura 1977) which admit cognitive mediation; their principal quest has, in any case, been for managerial prescriptions rather than explicative systems. Authors who have discussed radical behaviorism have distorted its character by failing to emphasize the rejection of mentalistic causation demanded by its philosophical stance: some consciously or unconsciously blend cognitive concepts such as needs and attitudes with their accounts of operant conditioning; some misdefine and confuse basic concepts such as negative reinforcement and punishment; some appear to think that operant behavior is under conscious control yet claim that radical behaviorism fails to consider internal states (see variously Engel and Blackwell 1982; Hawkins et al. 1983; Loudon and Della Bitta 1983; Markin and Narayana 1976; Nord and Peter 1980; Schiffman and Kanuk 1983).

This state of affairs constrains and impedes scientific advance which depends on paradigms responding to, rather than absorbing intellectual challenges. The psychodynamic paradigm which now provides the normal science component of consumer research avoids effective confrontation with alternative philosophies. The first stage in the constructive criticism of that paradigm is the clear statement of the nature of an alternative explanatory mode such as radical behaviorism.

Radical Behaviorism

The experimental analysis of behavior comprises three separable elements: operant conditioning (the influence of environmental factors on behavior); a single subject research strategy (which proceeds inductively through the intensive study of individuals); and a philosophical stance, radical behaviorism (which explains responses by reference to their contingent consequences) (Blackman 1983). Radical behaviorism thus presents a philosophical base which is antithetical to the psychodynamism of the prevailing paradigm and thus a standpoint from which the assumption of the current models of consumer behavior can be exposed and subjected to criticism in the manner suggested by Feyerabend. Social behaviorism (Bandura 1977) assumes the reciprocal determinism of individual and environment and is thus less parsimonious and more complex in its approach to explanation. Because it includes the cognitive mediation of behavior, social behaviorism does not provide so unambiguous a yardstick. Second, radical behaviorism has certain advantages over methodological behaviorism and the classical conditioning on which it rests experimentally. Radical behaviorism does not exclude intrapersonal events but reinterprets them as responses rather than as causes of behavior. It also makes central explanatory use of the concept of reinforcement and is thus of greater relevance than other behaviorisms to the analysis of consumer choice which is usefully explained in the marketing context by reference to its consequences.

Radical behaviorism proceeds from the assumption that once the environmental factors which affect the rate at which behavior occurs have been identified the behavior in question has been explained (Skinner 1950). Notions of intrapersonal causes may have provided useful 'mental way stations' before the establishment of a behavioral analysis, but the latter can now replace cognitive hypotheses with statements which link the performance of behavioral responses to their contingent consequences; as the contingencies investigated have become more complex they have taken over 'the explanatory functions previously assigned to personalities, states of mind, feelings, traits of character, purposes and intentions' (Skinner 1972, p.18). When the probability of a response's being repeated under similar conditions increases, its contingent consequences are termed 'reinforcers' and the response is known as an 'operant'. Reinforcement refers always to the strengthening of a response, i.e. to an increase in the probability of its being repeated. A contingent consequence which is followed by a decrease in the frequency of

response is a 'punisher'. Operants and reinforcers/punishers are, therefore, defined in mutually dependent ways: responses are not operants unless their rate of emission is influenced by their consequences; and no event is a reinforcer or punisher unless it consistently affects the rate of emission of a preceding response. Since reinforcers/punishers are functionally related to operants in this way, it is incorrect to speak of them as having intrinsically rewarding, pleasant or painful properties.

The contingencies of reinforcement which provide the basis of radical behaviorist explanation comprise the behavior in question, the setting conditions or situation in which it occurs, and those of its consequences which affect the rate at which it is subsequently performed. Skinner (1953) defines a three term contingency in which the action of the reinforcing stimulus (Sr) is contingent on the emission of a response (R). Any element of a situation in the presence of which that response has previously been reinforced may come to signal the availability of reinforcement in future; such an element or setting condition is known as a discriminative stimulus (Sd). The individual performs the response only in its presence, discriminating behaviorally between situations in which it is present and others. The three term contingency, usually depicted as $Sd \rightarrow R \rightarrow Sr$, summarises the paradigm.

It is important to emphasise that the explanation of behavior in terms of contingencies of reinforcement is distinct from that based on classical conditioning (McSweeney and Bierley 1984). In classical conditioning, the pairing of two antecedent stimuli results in each separately having the ability to elicit a given response, whereas previously only one did so. By contrast, in operant conditioning, 'Behavior is shaped and maintained by its consequences' (Skinner 1972, p.18). More technically, the rate of emission of a response is explained in terms of reinforcement contingencies. While, within the radical behaviorist framework, behavior may be described as coming under stimulus control when responses are differentially reinforced in the presence of separate antecedent stimuli, the relationship between a discriminative stimulus and an operant does not involve automatic elicitation of reflex behavior as is the case in classical conditioning. Rather, the discriminative stimulus is represented as increasing the probability of an individual's emitting the operant. If the accompanying reinforcing stimulus is withdrawn, the response will cease (extinguish).

Because operant behavior is said to be emitted by the individual rather than elicited by a preceding stimulus, it is sometimes said to be 'voluntary' but (pace Nord and Peter 1980, p. 38) this does not imply that it is under conscious control. When the other variables which control behavior (notably succeeding reinforcers) are known, that behavior can be fully explained in terms of environmental factors. Like the involuntary behavior which is elicited in the course of classical conditioning, operant responses are externally controlled; in neither case is consciousness involved in the explanation of behavioral causation and the only difference is in the sort of external control assumed (Skinner 1953, p. 112). While radical behaviorism rejects explanation in terms of unobservables, it is not accurate to depict it as failing to consider (pace Nord and Peter 1980, p. 36) covert and private processes within the individual. It interprets feelings and sensations as aspects of the physical body, responses which are subject, like their publicly ascertainable and verifiable counterparts, to environmental control (Skinner 1974).

Some radical behaviorists have argued for a clearer statement of their paradigm. Terms such as 'discriminative stimulus' and 'punishment' are both emotive and open to misinterpretation (as attempts at delineating the paradigm in the marketing literature show only too well). Blackman (1980) introduces a less elaborate formulation of the three-term contingency: A:B:C, in which A=antecedent conditions (the setting in which behavior occurs), B=behavior, and C=consequences. Of greater importance than the simpler terminology is the novel relationship between

behavior and consequences proposed. The colons denote a correlational relationship in each case, the first fully-supported in Skinner's (1953) statement, the second additional to it. The import of the second colon is to relax the assumption of automaticity found in most accounts of radical behaviorism.

Because operant responses and reinforcing/punishing stimuli are traditionally functionally defined, radical behaviorists have often been accused of circular reasoning in their explanations. Blackman points out that reinforcing or punishing consequences may follow behavior only occasionally or after delay; they may fail to reinforce behavior or decrease rather than increase its rate of emission. The formulation of reinforcement contingencies presented earlier in terms of Sd, R and Sr is simply a subset of Blackman's A:B:C, that in which the antecedent conditions act as discriminative stimuli and in which the consequences of behaviour reinforce it. The import of this reasoning is to stress that behavior and its consequences are related in a correlative rather than contiguous way (Baum 1973).

Radical Behaviorism and Consumer Choice

Theory in Radical Behaviorism

Radical behaviorism does not avoid theory as long as it is couched in similar terms to those in which observations are described. But it denies emphatically that explanations of observed behavior in terms derived from another realm of discourse or understanding are necessary. It rules out mental, neural or conceptual explanations on two grounds. First, while apparently explaining observed behavior, they simply raise the necessity of explaining the neural or mental event in terms of which the explanation itself proceeds. Second, they encourage wasteful research since they are based upon 'explanatory fictions', mental events which are simply inferred from the behaviors they purport to explain, thereby precluding investigation of more directly available (environmental) determinants of action (Skinner 1950, 1963).

These general criticisms could well be applied by radical behaviorists to consumer research. The comprehensive models exclude the possibility of explaining behavior by direct reference to the effects of environmental factors: having accepted from the start the assumption that causation is mental, they apparently obviate the necessity of looking for other possible sources of influence. Such models are replete with abstract unobservables which, according to a behavioral analysis, add nothing to observation but simply redescribe it. Herein lies the danger of the prevailing paradigm and the source of its impediment to theoretical development. Once its psychodynamic assumption has been accepted, ready-made 'explanations' of any observed behavior can be effortlessly found in alleged intrapersonal causes conveniently inferred from the behavior itself. As Skinner (1963, p. 957) comments, 'It is too easy to say that someone does something "because he likes to do it", or that he does one thing rather than another "because he has made a choice".'

Consumer Decisions

Some of the implications of this perspective for explaining consumer choice are apparent from consideration of its treatment of two central building blocks of the comprehensive models, information and choice. Advertising and other persuasive/informative messages embody discriminative stimuli which signal the availability of reinforcement contingent upon the operant performance of specified purchase and consumption behaviors. Such discriminative stimuli take the form of rules, norms, promises, prompts and various additional verbal and nonverbal descriptions of contingencies. Although these antecedent stimuli exert partial control over behavior, the contingent consequences of operant responses are the principle source of behavioral control since, in their absence, the response will extinguish. Thus, the individual must have some tendency to behave in the advocated manner before the stimuli

contained in the message can exert any control by marking the occasion for reinforcement. The individual's unique reinforcement history determines whether a message's discriminative stimuli signal reinforcing, punishing or neutral contingencies and, unless the appropriate behavioral discriminations have already been learned, advertising cannot alter behavior.

There is thus no need to posit unobservable mental processes to explain consumer choice. In contrast to cognitive psychology in which the formation of attitudes and intentions is a necessary mechanism of prebehavioral choice, behaviorism has no place for concepts of underlying or true mental processes which consistently mediate verbal statements of attitude and intention as well as overt behavior. The problem of attitudinal-behavioral relationships thus disappears in a behavioral analysis: behaviors which belong to different classes, such as the consumer's verbal responses to an attitude questionnaire and his actual purchasing, will be consistent only when the contingencies applicable in each situation are functionally equivalent (DeFleur and Westie 1963).

Nor need choice itself be conceived as an outcome of internal cognitive deliberation or decision making. It is simply a behavior, the only way of acting in a given set of circumstances defined by the prevailing contingencies. Situations in which individuals report that they have to make choices are those in which several responses are equally probable. Since such situations are usually aversive, any behavior which is followed by the strengthening of one response or another is reinforced (Skinner 1974, p. 22-23). Freedom thus consists in the avoidance of aversive consequences (Skinner 1972).

Consumer Innovativeness

The radical behaviorist critique of psychodynamic approaches can be further illustrated by reference to Midgley and Dowling's (1978) conceptualization of consumer innovativeness. These authors argue that the various measures of consumer innovativeness and their apparent relationships to distinct definitions of this construct (Robertson and Myers 1969; Summers 1971) indicate degrees of innovativeness: each extent of innovative behavior measured requires explanation in terms of successively more abstract constructions of a personality trait, 'innovativeness'. At the observational level, 'actualized innovativeness' is adequately represented by the idea of the relative time of adoption (Rogers 1983, p. 22). The adoption of several innovations within a product category (Robertson and Myers 1969) must be explained by a deeper and more abstract construct of innovativeness. Consumer innovation across several product fields (Summers 1971) necessitates a third, yet more abstract construct, 'innate innovativeness'.

Innate innovativeness is 'the degree to which an individual makes innovation decisions independently of the communicated experience of others', where 'decision-making' is an unobservable, a prebehavioral event not accessible to measurements of overt behavior, yet it is assumed to be possessed to a degree by all individuals.

As noted, radical behaviorism objects to theory of this kind on the grounds that it raises new problems of explanation which are usually not pursued and that it leads to wasteful research which ignores the controllable determinants of behavior. How is 'innate innovativeness' itself explained? Midgley and Dowling (1978, p. 235) say only that it is 'plausible to view it as a function of a number of (yet to be specified) dimensions of the human personality'. Yet the belief that behavior has been explained by this device can easily direct attention from other interpretations, explicative variables and the environmental factors that control the extent of new product purchasing.

Radical behaviorism would draw attention to the external antecedents and consequences of consumer choice, the contingencies of reinforcement, rather than to conceptual

traits of character. Complex innovative behavior does not suddenly appear. It is shaped as successive approximations to the terminal response of new product purchasing are differentially reinforced. A consumer who appears suddenly to purchase a wardrobe of fashionable clothes does not do so spontaneously but as the endpoint in a process in which increasingly similar behavior has been successively reinforced. The investigator would look for a pattern of responses (say, the purchase of fashionable shoes, a trend-setting suit, and so on), a pattern of antecedent discriminative stimuli and succeeding reinforcing stimuli, to explain and predict the purchase of new clothes.

Managers actively use shaping in order to increase the likelihood of a final response by such means as the distribution of free samples. Their expectation is that the consequences of usage will increase the probability of subsequent purchases. Initial purchase of newly-marketed products is also differentially reinforced by means of coupons, offers and other promotional deals; consumer behavior is thereby shaped, as the terminal response - purchase of the brand at the full retail price - becomes more likely. Complex behavior, which appears innovative to on-lookers who are not familiar with the individual consumer's reinforcement history, may also be explained as the final link in a chain of reinforced responses which culminate in the observed response; the chain is created and maintained as discriminative stimuli come to function as conditioned reinforcers (Skinner 1953, p. 91; cf. Kazdin 1980, p. 39).

The endpoint of either shaping or chaining might be the purchase of one or more products in one range or more. The extent of purchasing can also be viewed in terms of the extent to which discriminative and reinforcing stimuli determine the generalization of responses. Studies of operant conditioning have drawn attention for several decades to the tendency for humans to discriminate and generalize in their behavior. A response may only ever be performed in the presence of a specific Sd (discrimination) as when an employee works hard only when his boss is there. Another response having been reinforced in the presence of one Sd may subsequently be performed in the presence of similar stimuli even though immediate reinforcement is not available (stimulus generalization): a child who is praised for singing by a teacher may do so in the presence of any adult. Sometimes several similar responses, one of which has been reinforced in the presence of an Sd, may be emitted when that stimulus is available (response generalization): a neighbor whose wave is returned may smile and chat when next we see him (Kazdin 1980).

The extent to which consumers' purchases of recently-launched products comes under stimulus control, and the circumstances in which discrimination and generalization occur with respect to such items is unknown and is likely to remain so as long as consumer researchers are satisfied that innovative behavior is explained by innate traits. How many consumers only buy specific new products from one store, or when a given person is present? How often is a new product bought from a range of stores and what element of the buying situation is similar in each case? Under what circumstances do consumers who have purchased a new product at a store return to talk about, try on or try out and/or buy similar new items? In each case, what are the stimuli which control discrimination and generalization? Only the adoption of an alternative perspective is likely to generate research which makes the environmental control of purchasing intelligible.

The adoption of that perspective offers other insights into the interpretation of observed buyer behavior. The radical behaviorist analysis of consumer new product purchasing suggests a reevaluation of the concept of innovativeness. If the purchase of recently-launched products within and across product ranges can be explained in terms of the generalization of existing responses, the whole notion of innovative behavior is called into question. If 'new' patterns of purchasing consist in whole or part of

existing behavioral elements, in what sense are they new? Radical behaviorism tends to play down the whole idea of innovation because its explanation stresses the continuity which results from a relatively stable controlling environment. In the case of discontinuous products, novel responses may be learned accidentally in a process akin to that of the evolutionary development of the species (Skinner 1974, p. 114). But there is little discontinuity in practice. Most products permit trial in which the consequences of purchase and consumption become apparent before adoption or rejection occurs.

The analysis of new product purchasing in terms of its environmental consequences anchors the researcher's frame of reference more closely to observable behavior than does analysis in terms of inborn personality traits. The authors cited by Midgley and Dowling actually disconfirm the hypothesis that personality variables strongly influence purchase behavior and draw attention to the need to investigate situational influences. Midgley and Dowling's own quest for the situational factors that influence consumer behavior appears to have lost out to the attempt to explain innovation by reference to innovativeness.

Conclusion

The existence of a well-defined paradigm providing the normal component of scientific inquiry has had advantages for the development of consumer research. Yet the very success of the psychodynamic paradigm now threatens to impede theoretical progress. New bases of explanation are required which offer a standpoint from which to conduct a critique of the taken-for-granted assumptions on which psychodynamic explanation rests. Models derived within alternative paradigms should be amenable to the rigorous empirical testing which has often proved elusive in the case of the comprehensive models. It is important, therefore, that unobservables have greater empirical content than hitherto and that any core of theoretical assumption which cannot be directly subjected to empirical test should be logically evaluated by reference to competing explanations.

The most obvious contribution that radical behavioral analysis can make to the development of empirically-testable consumer theory stems from the relative closeness of its explanations to observed behavior. It promises to be a source of hypotheses which are amendable to relatively straightforward and unambiguous empirical test, e.g. with respect to the comparative efficacy of primary vs. secondary, and immediate vs. delayed reinforcers (Rothschild and Gaidis 1981). Its lesson is that theoretical development does not necessarily require high levels of abstraction: whatever unobservables are necessary for explanation should not be treated as immutable but so constructed as to allow their critical evaluation. Unobservables are a convenience to researchers and ought not to be used to reify currently-fashionable modes of explanation. If this is recognized, then radical behaviorism may provide a more direct route to understanding than paradigms which rely excessively on untestable hypothetical constructs.

The usefulness of radical behaviorism in consumer research depends, however, on researchers' capacity to recognize the totally different nature of its philosophical stance from that generally employed. In every instance in which cognitive and trait psychologists speak of changing behavior by acting on states of mind, the radical behaviorist speaks of changing the probabilities of action through the manipulation of reinforcement contingencies. As a result, many of the familiar analytical terms disappear and are replaced with concepts more closely related to observation (Skinner 1972, p. 94).

This is not to argue that radical behaviorism be pursued to the exclusion of other perspectives. First, like any way of seeing, radical behaviorism involves ways of not seeing; it rests like any paradigm, on an incomplete model of man. It offers explanation of a particular aspect of behavior, the rate at which responses are emitted; the

extrapolation from simple to complex actions on which its explanations of human conduct often rely involves extensive theory-dependency and, therefore, limitation. Second, insofar as scientific progress requires a proliferation of competing views, other paradigms will undoubtedly be needed to express fully the diverse nature of consumer choice. Methodological and social behaviorism have a role here. Nor has the paper argued against psychodynamic explanation per se. Apparent human capacities - for self-consciousness, for verbalizing the attention given to contingencies of reinforcement, and for modifying those contingencies to produce specific behaviors - encourage teleological explanation.

But, while so much consumer research is marked by an uncritical psychologistic reasoning, based on the automatic assumption that overt behavior implies intrapersonal causation, it will be necessary to prescribe an antidote. Just as radical behaviorism has provided a counterpoint to the 'loose mentalism' sometimes apparent in general psychology (Valentine 1982), so it now offers to play a similarly constructive role in consumer research.

THE OPPOSITE OF SATIATION: MOTIVATIONAL PRIMING AS AN
AFTEREFFECT OF A PLEASURABLE CONSUMPTION EXPERIENCE¹

Peter J. DePaulo, University of Missouri-St. Louis

Abstract

A recent focus of interest in consumer research has been on satiation, the process by which consuming a product leads to a temporary decrease in the person's desire to consume the same product again. This paper explores the possibility that there are circumstances under which consumption can have the opposite aftereffect -- a transient increase in motivation to continue consumption.

Introduction

In contrast to the traditional emphasis on information processing, a recent focus of consumer research has been on non-cognitive aspects of consumption, such as emotions and experiences (Hirschman and Holbrook 1982; Holbrook and Hirschman 1982). One example of this interest is a series of articles on satiation (McAlister 1979, 1982) and related constructs such as variety seeking (Faison 1977; McAlister and Pessemier 1982), novelty seeking (Hirschman 1980), and optimal stimulation level (Raju 1980).

Satiation can be described as a process by which consumption of a product results in a temporary reduction in motivation to consume the product again. The decrease in motivation may generalize to an entire product class (e.g., finishing a big meal suppresses desire for all kinds of foods), or, as in McAlister's models, the effect may be specific to particular attributes (e.g., the regular cola drinker chooses the "Uncola" as a change of pace).

Satiation effects appear to be noncognitive and nonassociative in the sense that they require neither information acquisition nor instrumental learning nor classical conditioning. For example, food-satiated persons stop eating even if they have not acquired any new, unfavorable information about the food (cognitive learning). Likewise, satiation occurs even if eating has not had any punishing consequence (instrumental learning), and did not happen to occur at the same time as some unpleasant external event (classical conditioning). Instead, the satiation is simply the result of the direct physiological consequences of eating a certain amount within a certain period of time. Furthermore, since satiation does not depend on either information acquisition or conditioning, it should be independent of the consumer's level of involvement with the product.

The concept of satiation seems to be especially applicable to products which provide hedonic experiences, such as foods, movies, and games. This paper explores the possibility that consuming these kinds of products can have a noncognitive effect that is in the opposite direction -- an increase in motivation to consume the product again. Consider, for example, the common-sense idea that if one wants to avoid eating too many potato chips at a party, one should not eat any at all. The rationale for this idea seems to be that eating a small amount of chips induces a "taste craving" (Solomon 1977b), i.e., arousal of one's desire to eat more of them. In the words of an old potato chip commercial, "I bet you can't eat just one." In experimental psychology, the term "priming" has been given to the enhancement effect of exposure to a reinforcer on operant behavior motivated by that same reinforcer (for a review see Eiserer and Ramsay 1981).

Analogous priming effects, though in dramatically different form, appear in drug addiction. Sufficient exposure to pharmacologically addictive substances such as opiates results in physical dependence, as evident in the withdrawal syndrome. The symptoms of withdrawal, which appear soon after the "high" from the last dose of the drug is gone, are extremely unpleasant but they can be eliminated by taking another dose of the drug (Jaffe 1980). Hence, it is assumed that the withdrawal state motivates the addict to use the drug again. Another illustration is the advice commonly given to recovering alcoholics: to abstain from alcoholic beverages entirely instead of trying to become "social drinkers" (Miller 1983). This advice presupposes that even a small amount of alcohol might make it hard for the individual to resist taking another drink, thus initiating a vicious cycle that could reinstate problem drinking. These considerations imply that, for the addicted individual, the immediate effect of a drug dose is priming rather than satiation.

This is not to imply that motivation to eat potato chips should have the same intensity or the same physiological substrates as motivation to consume pharmacologically addictive drugs. Nonetheless, snack foods and addictive drugs both can function as reinforcers, and it is reasonable to hypothesize that they can engender some analogous patterns of behavior. Further, within the past decade, researchers in the behavioral and biological sciences have begun to examine seriously the possibility of important similarities among phenomena as diverse as opiate addiction, alcoholism, obesity, compulsive gambling, and the habitual consumption of coffee and cigarettes (Levison, Gerstein, and Maloff 1983).

Moreover, some commonalities found among drug and nondrug habits actually are physiological. One example is the recent discovery that the brain contains naturally occurring, opiate-like substances (for a review see Adler 1980). These neurochemicals, called endorphins, may mediate a variety of habitual behaviors such as opiate use, social attachment (Herman and Panksepp 1978), and exercising (Dearman and Francis 1983). Another example is the development of physical dependence and withdrawal symptoms in people whose diets contain too much of a specific food (Randolf 1978).

In the 2 x 2 classification in Table 1, the effects of consumption on subsequent motivation to consume the same product are categorized according to the direction and nature of the effect. The two top panels represent processes which can be considered associative. On a cognitive level, the consumption experience permits the individual to acquire information about the product's attributes. Whether subsequent motivation is increased or decreased depends on the extent to which the attributes that the individual associates with the product are or are not satisfying. From the perspective of behavioral learning theory, consuming a product permits operant and classical conditioning to occur. Although operant and classical conditioning need not involve cognition (Hull 1951), both can be viewed as associative processes (Mackintosh 1974). For example, the response of using a product may become associated with a pleasurable consequence through operant conditioning. Likewise, through classical conditioning, an otherwise neutral stimulus such as a package can become a conditioned stimulus through association with unconditioned stimuli (UCSs) such as food within the package or the presence of companions with whom the product is consumed. The direction of the conditioning effects would depend on whether the consequences or UCSs correlated with consumption are reinforcing (rewarding) or punishing (aversive).

¹The video game experiment reported in this article was funded by a Summer Research Fellowship from the University of Missouri-St. Louis.

TABLE 1
CLASSIFICATION OF EFFECTS OF CONSUMPTION
ON MOTIVATION TO RESUME CONSUMPTION

NATURE OF THE EFFECT	DIRECTION OF THE EFFECT	
	Increase	Decrease
Associative Learning, Relatively Permanent	cognitive learning (satisfying attributes)	cognitive learning (unsatisfying attributes)
	operant conditioning (reinforcement)	operant conditioning (punishment)
	classical conditioning (rewarding UCS)	classical conditioning (aversive UCS)
Nonassociative, Transient	priming	satiation

In contrast, the effects in the two bottom panels of Table 1 appear to be nonassociative. Eating enough of a food at one sitting eventually will satiate the individual, whether or not any new associations involving the food are acquired during the meal. The party-goer fears that eating one potato chip will prime him (i.e., reduce his "will power" to avoid eating too many potato chips), even though he may be so familiar with that brand of chips that he is unlikely to learn anything new about them.

A second way in which conditioning and information acquisition may differ from satiation and priming is in the duration of the effects. Whereas learned associations seem to be able to persist for years in long-term memory, priming and satiation seem to dissipate within a relatively short time. For example, some priming effects can dissipate in a matter of minutes (DePaulo and Hoffman 1980). Some may last much longer: withdrawal symptoms of an opiate addict undergoing "cold turkey" treatment may persist more than a week (Jaffe 1980), but even that parameter is short compared to how long the addict can be expected to remember what the drug states were like. Hence, learning theorists typically postulate that relative duration is one variable that separates true learning from other experienced-based behavioral changes, such as satiation and fatigue (Hilgard and Bower 1981).

Theories of Priming

Opponent-Process Theory

One theoretical approach that deals explicitly with addiction and priming is the opponent-process theory of motivation and emotion (Solomon 1977a, 1977b, 1980; Solomon and Corbit 1973; Hoffman and Solomon 1974). The theory assumes that functionally similar physiological processes underlie virtually all emotional reactions. These processes ensure that when a pleasurable experience is repeated with sufficient intensity or frequency it will have an unpleasant motivational aftereffect. For example, the pleasurable sensations from drug "highs," tasty foods, and companionship are assumed to be followed by aversive states that can be called drug cravings, taste cravings, and loneliness, respectively. The aftereffect is assumed to motivate the person because the unpleasant feeling can be eliminated by resuming contact with the pleasurable stimulation (e.g., re-dosing with the drug). The theory also assumes that unpleasant experiences can produce pleasurable aftereffects.

A full description of opponent-process theory is beyond the scope of this paper, but two key assumptions will be noted here because of their special relevance to the study of priming and habitual consumption. One is that prior experience with the emotion-arousing stimulus strengthens the aftereffect so that it is more intense and longer lasting. Thus, the first few times a person takes an addictive drug, each "high" is followed by only a slight, short-lived craving to consume it again. However, after the individual has had the drug often enough, then the end of a high is followed by the long, intense craving known as the withdrawal syndrome (unless, of course, the addict avoids or stops the withdrawal syndrome by re-dosing).

The second key assumption is that the motivational aftereffect can be classically conditioned to environmental stimuli that are present when the emotion-arousing stimulus is experienced. Opiate addicts who have gone through withdrawal and have abstained from opiates for extended periods seem to experience withdrawal symptoms when they enter places where they have consumed the drugs in the past, and when they encounter companions who had been present during prior drug use (Wikler 1971).

Opponent-Process theory has been introduced to the marketing literature by Oliver (1980), in his analysis of affective reactions of consumers to disconfirmation of expectations in retail settings. In basic research, the theory has been examined in a variety of laboratory and field studies involving both human and animal subjects (e.g., Benton, Banks, and Vogler 1982; Craig and Siegel 1980; DePaulo and Hoffman 1980; Solomon 1980; Piliavin, Callero, and Evans 1982). Generally these studies have supported the model.

Consumption-Induced Moods

A second theoretical approach that may help in explaining priming is the analysis of consumers' moods (for a review see Gardner and Vandersteel 1984). In a typical mood-induction study, subjects are observed immediately after an experience that might affect mood, such as receiving cookies (Isen and Levin 1972) and winning a computer game (Isen et al. 1978). Since leisure experiences may alter one's mood (Mannell 1980), and since moods, like other emotions, can be expected to have motivational dimensions (Young 1973), it is reasonable to hypothesize that consuming a pleasurable product could result in a mood change that motivates continued consumption of the same product. In other words, using a product might put the individual "in the mood" to keep using it. However, it is also logically possible that a mood change resulting from consuming a product might motivate the person to do something else -- an effect which would be in the direction of satiation. Thus, mood analysis does not make specific predictions about whether the effect of consumption will be satiation or priming. Nevertheless, as will be explained below, mood concepts may be useful tools for description and measurement.

Opponent-process theory can be combined with mood analysis in the study of priming. Specifically, the unpleasant state which opponent-process theory postulates as the aftereffect of a pleasurable experience may be characterized as a mood. Thus, techniques developed to measure moods may be helpful in the empirical investigation of priming. In fact, mood measures have been used to test the prediction of opponent-process theory that unpleasant experiences have pleasant emotional aftereffects (Piliavin et al. 1982).

Empirical Data on Priming

Non-Experimental Data on Product Samples

Evidence of food priming in a marketing context is provided by Steinberg and Yalch (1978). In their field study, obese supermarket patrons who took a free sample of a doughnut while shopping were found to overspend (exceed their planned total purchase for the store visit)

by a greater amount than obese patrons who did not take a sample. The authors' interpretation was consistent with priming: "...eating food heightens its taste salience and this motivates obese persons to go shopping and buy more than intended." However, a satiation effect (less overspending after taking a sample) was observed for nonobese shoppers.

Video Game Experiment

The author has collected laboratory data which suggest that playing a video game can generate both priming and satiation effects. The study described here has been reported in detail elsewhere (DePaulo 1985).

In this experiment, college students who had prior experience with the "Pac-Man" video game were randomly assigned to two groups, and were run individually in a controlled-length session during which they played Pac-Man continuously. Subjects in the "10-minute" group played Pac-Man until at least 9 minutes had elapsed. The experimenter waited until the subject completed the game that was in progress at the end of 9 minutes, then stopped the session. Since a single game of Pac-Man typically lasted 1-3 minutes, the average session length for this group was approximately 10 minutes. In the other condition (the "3-minute" group), subjects played Pac-Man until the end of the game that was in progress after two minutes had elapsed.

Immediately before and immediately after the game session the subjects rated their current desire to play Pac-Man on a Likert scale. Over the next 18 minutes, the subjects completed a lengthy questionnaire, ostensibly to determine their "state of mind" during the game session. Actually, this questionnaire served as a filler activity to keep the subjects occupied for at least 18 minutes. While working on this task, the subjects were interrupted every two minutes and again asked to rate their desire to resume playing Pac-Man.

FIGURE 1
EFFECT OF SHORT VS. LONG GAME-PLAYING
SESSIONS ON DESIRE TO RESUME PLAYING
PAC-MAN (FROM DEPAULO 1985)

Figure 1 shows the mean ratings. The groups did not differ statistically on pre-game desire to play Pac-Man, but the 3-minute group mean was significantly higher than the 10-minute group mean on the first post-game rating, and significantly higher than the pre-game mean for the 3-minute group. The figure also shows the gradual dissipation of the enhancement effect in the 3-minute group, as confirmed by a statistically reliable interaction of Groups by Time in the data from the 10 post-game ratings.

The effect of the 3-minute game session seems to have been a temporary increase in desire to play Pac-Man. This finding is consistent with a priming model. However, the finding that desire to play was lower immediately after the long session than after the short session is

consistent with a satiation model, because more satiation of desire to play should occur in a longer session.

How can these two findings, which might seem conflicting at first glance, be explained? As proposed by Solomon (1977b) in his analysis of motivational aspects of eating, it is possible that both priming and satiation could be operating during the same consumption experience; the effect that is manifest in the subject's behavior would be the one that happens to be stronger under the circumstances of the observation. This possibility can be illustrated with the intuitive example of eating potato chips. Eating just a very small amount of potato chips seems to be sufficient for inducing a taste craving, but if much more of them are consumed in the same sitting, then satiation becomes strong enough to overwhelm the taste craving and cause the person to stop eating.

Why, then, was taking the doughnut sample followed by a priming effect for some shoppers (those classified as "obese") and a satiation effect for the other, nonobese shoppers? One possible reason is that the doughnut sample was a relatively small amount for an obese person but, for the nonobese, the same size sample was enough to produce more satiation than priming. Another possibility, suggested by Steinberg and Yaich (1978), is that nonobese people are simply not as sensitive to the taste of a food; this would imply that any amount of a food is less likely to produce a "taste craving" (observable priming effect) in a nonobese person.

The results of the video game experiment are consistent with the hypothesis that a priming effect will be manifest in behavior after a small amount of consumption, while satiation will be evident after a larger amount. Hence, playing Pac-Man for three minutes may have been like eating one potato chip at a party -- it induces more priming than satiation. Playing Pac-Man for 10 minutes may have been like eating just enough potato chips so that there was about as much satiation as priming -- there was no significant difference in the pre- and post-game ratings for this group. This analysis simply assumes that a small amount of consumption produces more priming than satiation, while a large amount of consumption produces more satiation than priming.

Basic Research on Operant Reinforcement

Experimental studies of animal behavior have revealed priming effects with a variety of species and reinforcers (for a review see Eiserer and Ramsay 1981). With food or water as reinforcers, the dual priming-satiation effects suggested above are clear. That is, giving the animal "free" (noncontingent) food or water instigates the animal to perform an operant response that it already has been trained to perform, if the free amount is small. Giving the animal a larger noncontingent amount suppresses subsequent operant responding.

However, there are other reinforcers that generate strong priming effects with little or no satiation. These include presentation of an "imprinting stimulus" to a duckling (Eiserer and Hoffman 1973) and electrical stimulation of so-called "pleasure centers" in the brain (Gallistel 1973; Katz 1979). With these reinforcers, a larger amount results not in satiation but in an even stronger priming effect. A related consideration is the observation that depriving the animal of contact with these reinforcers does not increase motivation to consume them (DePaulo and Hoffman 1980); in contrast, very strong effects of deprivation are obtained with reinforcement by food and water. Thus, priming and satiation seem to be mediated by separate physiological systems. Whether a particular reinforcer engenders priming, satiation, or both would depend on the extent to which each system operates when that reinforcer is encountered.

In the case of foods and other products for which the desire to consume is increased by deprivation, how would priming and satiation be affected by the amount of prior deprivation? The simplest possibility is that depriva-

tion raises the baseline level of motivation and that priming and satiation raise and lower (respectively) this level. In other words, deprivation may produce a main effect on motivation without interacting with priming or satiation. However, it is possible that some interactions will occur due to floor and ceiling effects as illustrated in Figure 2.

FIGURE 2

HYPOTHETICAL INTERACTION OF PRIOR DEPRIVATION WITH PRIMING AND SATIATION

At a high level of deprivation (top curve), the priming effect of a large amount of food may be hard to observe empirically because of a ceiling effect (motivation is already high and cannot be increased much further). This is consistent with a finding obtained by Steinberg and Yalch (1978) when they compared data from obese shoppers who were "deprived" (said that they had not eaten within four hours before entering the store) with data from nondeprived obese shoppers. The increase in overspending associated with eating the food sample (priming effect) was smaller for the deprived than for the nondeprived obese shoppers. At the other extreme (bottom curve in Figure 2), there would be room for a priming effect but not for a satiation effect, since a non-deprived person's motivation to eat is already very low. This suggestion is consistent with another finding by Steinberg and Yalch: the decrease in overspending among nonobese shoppers who took a food sample (satiation effect) was observed only among those nonobese shoppers who were deprived. Thus, it should be easiest to observe both priming and satiation effects at an intermediate level of deprivation (middle curve).

This interpretation of the Steinberg and Yalch (1978) findings rests on post-hoc assumptions. Further research is needed to test the ceiling and floor effects hypothesized here.

Limitations

The aim of this paper is to encourage consumer researchers to investigate the possibility that motivational aftereffects of product use can involve priming as well as satiation. However, there may be difficulties in empirically isolating the effects of priming from associative learning. When subjects' motivation to resume consumption is enhanced as a result of prior consumption, there is always the possibility that they actually did learn something new during the observed or manipulated consumption episode, even if they have had substantial prior experience with the product. Of course, if the observed post-consumption increase in motivation seems very short-lived, one might feel confident in assuming that the effect was due to priming rather than associative learning, but this begs the question: how rapid must the decline in the effect be in order to conclude that this represents the dissipation of a motivational state

rather than the forgetting of a learned association?

It should be noted that this same confounding can occur in studies of satiation. Specifically, if consumption leads to a decrease in motivation to consume the product, it is possible that subjects learned something unfavorable about the product during the consumption episode, and that the recovery of subjects' desire to resume consumption represents the forgetting of the unfavorable association instead of the dissipation of satiation.

Isolating Priming Effects in Experimentation

Three steps could be taken to minimize the confounding of associative and nonassociative effects in experiments on priming and satiation. First, the subject pool could be limited to people who have already had considerable experience with the product under study and are very familiar with its features so that little or no additional learning is likely to occur during the experiment. Second, an attempt should be made to show both priming and satiation in the same experiment by having subjects consume both smaller and larger amounts. It would seem unlikely that subjects discovered something good about the product when they consumed a little of it and then discovered something bad about it when they consumed more of it, especially if the subjects were experienced users of the product. Under these circumstances the nonassociative interpretations (priming and satiation) would be more plausible. Third, an attempt could be made to measure associative effects directly through, say, attitude or perception measures. For example, if consumption during the experiment does not change subjects' ratings of the product's quality but does change their momentary desire to resume consumption, then the effect would appear to be priming or satiation, not associative learning.

Directions for Future Research

A basic objective of further investigation should be to arrive at a better understanding of when the immediate aftereffect of consumption is an increase in motivation to consume again (priming) and when it is a decrease (satiation). Based on the research reviewed in this paper, four factors can be hypothesized.

First, the amount consumed appears to be critical. The greater the amount consumed, the more likely it is that satiation rather than priming would be observed. Second, the animal behavior experiments indicate that the relative strength of priming vs. satiation depends on the type of reinforcer. By analogy this indicates that the type of product may be a determinant. More specifically, the animal studies imply that priming should be evident under a narrower range of conditions for products that replenish biological deficits (e.g., food) than for products that seem unrelated to survival needs (e.g., video games). Replenishing a biological deficit results in satiation, which could mask evidence of priming. Third, opponent-process theory postulates that prior consumption experience increases the strength of priming processes (as in the development of drug addiction). Fourth, the Steinberg and Yalch findings point to personal characteristics such as obesity.

In summary, prior research provides suggestions on what some of the regularities may be, but a more comprehensive model is needed.

Priming and the Satisfaction of Wants

The most favorable view of marketing is that firms which achieve success are those that offer products which satisfy consumers' wants. Implicit in this view is the assumption that, if consumers' use of a product increases their desire to use the product again, then the product must have satisfied some pre-existing want. This assumption implies that the increase in desire to use the product again must be an associative effect, i.e., the consumer learns that the product has want-satisfying capabilities. Galbraith's (1958) classic criticism of

this benevolent view of marketing is that the wants satisfied by products are not necessarily pre-existing but are created by marketers through advertising.

This paper does not take a stand on Galbraith's contention that advertising creates new wants. However, the possibility of priming as an aftereffect of consumption suggests another way, besides advertising, in which a want can be created. Specifically, consumption by itself may generate a type of motivation (the enhanced desire to consume the same product again) that did not exist before the product was first consumed.

To be precise, we need to distinguish between two sources of a person's total desire to resume consumption of the product: motivation that is independent of the product and motivation that is a result of exposure to the product. For example, a person may start playing a video game out of boredom (motivation independent of the product, or "pre-existing"). After playing for a short time some boredom might still exist, but the person's desire to resume playing may be greater than his or her original desire to start playing (as in the 2-minute group in the video game experiment); a priming process has increased the person's total desire to resume playing. Hence, the person plays the game longer than is necessary for boredom to be relieved, since priming alone can motivate extended playing on that occasion.

The only role that marketing may play in creating this kind of want is indirect: a promotion or some other marketing effort may instigate trial of the product on a particular occasion, and the initial bout of consumption, in turn, instigates prolonged consumption through a priming process. This is in contrast to Galbraith's view that advertising creates new wants directly.

Priming and Compulsive Consumption

As explained above, a priming process can cause a person to consume a product beyond the point where the pre-existing want which initiated the bout of consumption is satisfied. This situation is very clear in drug addiction. Frustration, social pressure, thrill-seeking, or some other drug-independent factor may motivate initial use of drug, but in the addicted individual repeated drug use can be motivated by the aftereffects of drug use itself, i.e., the withdrawal syndrome. Analogously, hunger may motivate a person to start a meal, but priming (taste craving) may be responsible for some overeating.

Thus, a major application of the concept of priming should be in the analysis of consumption which is so compulsive that it is a serious problem. Examples of such phenomena include not only drug abuse but also leisure pursuits that ordinarily seem harmless, such as playing video games and exercising. Arcade video games seem to be so involving that some communities, concerned about truancy, have enacted ordinances to restrict access to arcades by adolescents (Newsweek 1981). Avid joggers, in extreme cases, choose to run even when they have injuries that make running painful, and their "exercise addiction" seems to disrupt their interpersonal relations (Morgan 1979). Several scholars recently have called for consumer researchers to address such problems (Bloch and Bruce 1984; Shimp and Dyer 1979). Priming processes, which can motivate consumers to continue consumption beyond the point where pre-existing wants are satisfied, may play a key role in compulsive consumption.

What can a person do to avoid this kind of excessive consumption? One solution lies in the fact that a priming effect is relatively transient. Thus, if a person can just refrain from further consumption for a relatively short time, the priming aftereffect should dissipate and no longer motivate resumption of consumption on that occasion. This solution is consistent with advice typically given to dieters on how to avoid eating too much at one meal: walk away from the table after you have eaten your caloric allocation for that meal and stay away from food. It is assumed that within minutes you will feel

less hungry than you did immediately after you stopped eating. However, while this tactic may be relatively easy for the dieter, it can be agonizing for the opiate user, for whom the "cold turkey" cessation of drug intake initiates a withdrawal syndrome that can last for days.

Conclusions

Certain conditions exist under which consumption of a pleasurable product temporarily increases motivation to consume it again (priming) instead of decreasing the motivation (satiation). This proposition is supported by intuitive considerations as well as by experimental and nonexperimental data from both human and animal studies. Priming cannot be understood with reference to the concepts of cognition and information processing that traditionally have been the dominant focus of the consumer behavior literature, nor can it be attributed to classical or operant conditioning. However, priming can be studied through two theoretical approaches which have recently attracted the attention of consumer researchers: opponent-process theory and mood analysis. Since priming can motivate prolonged or repeated consumption on a particular occasion, this kind of process may underlie compulsive consumption habits. More research is needed to identify the conditions under which the immediate aftereffect of consumption is priming rather than satiation.

CLASSICAL CONDITIONING EFFECTS IN PRODUCT/CHARACTER PAIRINGS PRESENTED TO CHILDREN

M. Carole Macklin, University of Cincinnati

Abstract

An experiment was designed to test for effects of classical conditioning in children's product preferences. Eighty-four children participated in one of six conditions. The color of a pencil (orange or yellow) was presented with a picture of Smurf in one of three temporal arrangements. The preschoolers saw the pictures of the pencil and Smurf together (simultaneous condition), sequenced separately (forward condition) or unpaired (control). Results indicated no behavioral choice impact. However, a measure indicating cognitive activity resulted in statistical differences among the conditions. Children in the forward conditions were less likely to trade the pencil selected for a sticker. Implications to the classical conditioning framework and to children's advertising are discussed.

Introduction

A basic principle of learning, classical conditioning, has received increased attention in the marketing literature (Nord and Peter 1980; Gorn 1982; McSweeney and Bierley 1984; Gresham and Shimp 1985; Allen and Madden, forthcoming). As Nord and Peter (1980) pointed out, advertisers appear to make frequent use of the principles of classical conditioning when repeatedly pairing exciting or sexy voices, music, etc. with a product.

Pavlov's (1927) work stands as the basic paradigm for classical conditioning. Pavlov arbitrarily selected a stimulus, a metronome, to be presented to a hungry dog. The metronome, labeled the conditioned stimulus (CS), was then followed by food, the unconditioned stimulus (US). The US, the food, automatically caused the dog to salivate, the unconditioned response (UR). With pairings of the metronome (CS) with the food (US), the dog responded to the metronome (CS) by salivating, now called the conditioned response (CR), even in the absence of food. The events are illustrated as follows:

CS(metronome)/US (food) ----- UR (salivation)
CS(metronome)-----CR (salivation).

The above ordering is referred to as forward or traditional conditioning. The CS and US can be presented together (simultaneous conditioning), or the US can precede the CS (backward conditioning).

McSweeney and Bierley (1984) presented an excellent review of recent developments in classical conditioning. They reported changes in assumptions about the form of the CR and the temporal arrangement of the CS and US needed to establish a CR. In terms of form, the CR does not have to resemble the UR. Second, the sequencing of the CS and US is less restrictive. The traditional, temporal priority view suggested that a CS must precede a US in time for conditioning to occur. That is, the metronome must precede the food or a product must precede the music in an ad (forward conditioning). Rescorla (1967) argued for a predictiveness view suggesting that the CS (the metronome) must predict the US (the food), but the CS must not necessarily precede the US in time. His reformulation requires the use of a control group to ascertain whether true conditioning has occurred as distinct from CS or US familiarity or interaction. [The reader is referred to McSweeney and Bierley (1984) or Moore and Gormezano (1977) for a fuller explanation.]

McSweeney and Bierley (1984) cautioned consumer researchers against assuming that people respond like

rats. They argued that consumers behave in more complicated settings than do animals in the laboratory. Many studies are needed before "translations" from the laboratory work with animals, upon which this literature is built, are made to consumer behavior.

The potential usefulness to consumer behavior of the classical conditioning paradigm appears encouraging by the work of Staats and Staats (1957, 1958, 1959) who suggested that the learning paradigm is applicable to humans. The Staats' work resulted in evaluative meaning being successfully conditioned. For example, Staats and Staats (1957) associated visually presented nonsense syllables with auditorily presented evaluative adjectives over a number of trials. They reported that the nonsense syllables that had been paired with positive meaning (e.g., happy) were considered more pleasant than those nonsense syllables paired with negative evaluation (e.g., ugly). Their work offers promise that the underlying mechanisms for automatic transfer are applicable to human settings that involve stimuli more approximate to advertising applications.

Empirical work on the classical conditioning paradigm in a marketing context is in the pioneering stage. Gorn's (1982) offered support for the usefulness of the classical conditioning paradigm. He reported two experiments testing whether the framework could account for the impact of music, a background feature, on product choice. Subjects saw a slide of either a blue or beige pen and listened to one minute of either pleasant or unpleasant music. They were asked to select a pen "for their help." Gorn reported a clear-cut impact of the music (pleasant or unpleasant) affecting the selection of the pen. Those subjects who heard the pleasant music were more likely to select the color of pen they saw on the slide, while those listening to the unpleasant music selected more often the color they had not seen. In the second experiment, Gorn (1982) manipulated the decision-making context and argued that classical conditioning accounted for choice behavior when the decision-making context was uninvolved.

Allen and Madden (forthcoming) questioned whether Gorn's findings would be replicated with a stronger experimental design. While acknowledging Gorn's important introduction of the neglected topic to the marketing literature, Allen and Madden (forthcoming) suggested that Gorn's processing of subjects in groups in a classroom setting could have resulted in either group interaction and/or awareness of other experimental conditions. Allen and Madden (forthcoming) designed an experiment to be administered on an individual basis in which pleasant or unpleasant humor was paired with a color slide of a pen (green or black). They did not find support for the classical conditioning paradigm. In both the pleasant and unpleasant treatment groups, a majority ended up selecting the color viewed on the screen.

Allen and Madden (forthcoming) extended the theoretical inquiry by designing a clever buy-back procedure to assess whether a conditioned response, affect, would manifest itself in a decision that engaged more active cognitive processes. A statistically significant difference appeared between the pleasant and unpleasant humor groups with a greater percentage of pens sold back by those who listened to the unpleasant humor. They explained the results by suggesting that humor created feeling states in which those in pleasant humor condition were more likely to generate positive thoughts. Thus, they were more resistant to the buy-back attempt. Although no direct measures of the thought processes were taken, Allen and Madden (forthcoming) interpreted their finding as congruent

with the "mood" literature (cf., Bower 1981; Clark and Isen 1982) suggesting that an affective state can influence people's judgments and behaviors indirectly by prompting and biasing cognitive activity.

Therefore, the two empirical efforts in a marketing context, both involving simultaneous conditioning, provide contradictory indications for the applicability of the classical conditioning framework to marketing phenomenon. Gorn's (1982) work with music offered strong support. However, Allen and Madden (forthcoming) reported none. In fact, the results from their buy-back measure, which may have produced a mood that biased cognitive activity, advised that no automatic responses occurred as expected under the classical conditioning paradigm.

The current research to be described consisted of another effort to witness conditioning effects. Both forward (or traditioning) conditioning and simultaneous conditioning were tested. An advantage of the present study was the use of young children as subjects. A major problem for consumer researchers to consider is subject awareness (Allen and Madden, forthcoming). Because young children are less likely to intuit a researcher's purpose, concern for this potential demand artifact is minimized.

Research Hypotheses

An experiment was designed to assess whether a favorable source paired with a product would directly affect children's product preferences. Two temporal arrangements between the CS and US were tested. First, it was hypothesized that children who saw a picture of a pencil together with a picture of a favorable character (simultaneous conditioning) would not evidence choice preference based on the simultaneous pairing. The second hypothesis predicted, however, that children who first saw a picture of the pencil followed by a picture of the favorable character (forward conditioning) would be more likely to select the pencil "advertised."

The rationale for the two hypotheses is as follows. The research literature grounding the first hypothesis is contradictory in terms of anticipated results. In general, laboratory work with animals suggests that simultaneous conditioning does not provide optimal conditioning (Smith, Coleman, and Gormezano 1969). Moore and Gormezano (1977) asserted that instances of simultaneous conditioning that have appeared have failed to include proper controls or have employed stimuli of too long a duration.

In terms of human conditioning, Gorn's (1982) work indicated success. As discussed, Allen and Madden (forthcoming) did not find effects. Thus, the first hypothesis is stated in a fashion consistent with the work based on animals and with Allen and Madden's (forthcoming) failure to find an effect with people.

In terms of the second hypothesis, effects from the forward conditions were predicted in accord with the literature based on animal literature. None of the human studies have included forward conditions, although Staats and Staats (1957, 1958, 1959) found effects from forward delay conditioning of adult subjects. As discussed in the introduction to this paper, Rescorla (1967) argued for a "predictiveness" view rather than just a temporally-based one. It is generally agreed that both views dictate the use of a control group to ascertain true conditioning. It should be noted that the issue of what constitutes an appropriate control has received considerable attention. An unpaired control group procedure assumes randomized sequencing of CS (alone) and US (alone) presentations at intervals larger than that of the conditioning group(s). Rescorla (1967) argued for a truly random control procedure in which CS and US were independently programmed so that the US would have equal probabilities of occurring

in the presence or absence of the CS. Gormezano and Kehoe (1975) pointed out both empirical and theoretical difficulties with the truly random control procedure. In recognition of the problems (Holland and Rescorla 1975), the more traditional, unpaired control has once again become favored. Procedures will be described in the next section of this paper that incorporated an unpaired control for the current study.

It should be noted that designing an acceptable control procedure is particularly challenging when dealing with human subjects who may find unpaired or truly random exposures absurd and/or who may intuit the researcher's purpose. Subject awareness, or lack thereof, is a major consideration for the researcher. As discussed in the introduction of this paper, one advantage of working with preschoolers is that they are probably less likely to determine the researcher's purpose as compared to college students who may become "sophisticated" in their participation in projects.

Method

A 3 x 2 factor design was created to test for evidence of classical conditioning effects on children. Three levels of the first factor, temporal condition, were as follows: 1) simultaneous conditioning, CS and US presented together, 2) forward conditioning, CS presented sequentially followed by US, and 3) unpaired control, CS and US presented alone, randomly and in a long interval in relation to each other. The reader will notice that the forward conditioning reflects the traditional view of temporal spacing between the CS and US.

The second factor consisted of two levels of color of the product: 1) an orange pencil and 2) a yellow pencil. This factor was included to mock Gorn's (1982) and Allen and Madden's (forthcoming) behavioral measure of a pen selection.

Therefore, the six groups were as follows: 1) simultaneous conditioning - orange pencil, 2) simultaneous conditioning - yellow pencil, 3) forward conditioning - orange pencil, 4) forward conditioning - yellow pencil, 5) unpaired control - orange pencil, and 6) unpaired control - yellow pencil.

Subjects

Arrangements were made with the directors of a daycare center and a preschool in two adjacent suburban communities of a large, Midwestern city. Eighty-four subjects were recruited and randomly assigned to the conditions. The subjects were 4 and 5 years old (44 were four years, 40 were 5 years; mean age = 58.1 months). Boys and girls were approximately equal (43 boys, 41 females), and they were mostly white (77 white, 7 black). The subjects could best be described as coming from suburban, middle to upper-middle income homes surrounding an outerbelt highway of the city.

Stimuli

Brightly colored pencils were selected as the CS. Fifteen preschoolers, from similar socioeconomic backgrounds as the test children, compared four colors (black, blue, yellow, and orange) in side-by-side tests of actual pencils (the four colors were narrowed down from an original pool of eight). Orange and yellow were decided from the pairwise comparisons on an equal preference basis (53.3% preferred orange and 46.6% preferred yellow).

The source for pairing was also pretested. The same fifteen children rated nine characters on a four-point interval felt board illustrating smiling to frowning faces. The source rating task was systematically rotated with the pencil comparisons.

A picture of Smurf was clearly favored (n = 15, mean rating = 4.0 on a 1 to 4 scale). Indeed, the ceiling score indicated strong popularity. Other characters evaluated included Cabbage Patch's Otis, Cabbage Jack, Care Bear, Gargamel, Pink Panther, Prune Face, A Big Bad Wolf, and Pie Man who received the lowest score of 1.8.

Pictures of Smurf and the pencils (color photocopies of the actual pencils) were transferred to individual 9" by 12" laminated posters. Multiple copies were made for ease of administration of the three exposures included for each child in each condition.

Procedure

Individuals were randomly assigned to one of the six treatment groups. Each child saw the poster of Smurf associated with a poster of either an orange or yellow pencil. As described earlier, the three temporal arrangements of the associations were either simultaneous, forward, or unpaired (control). Three exposures were included to strengthen the manipulation and were consistent with previous efforts in psychology (McSweeney and Bierly 1984). All interviews were conducted on an individual basis.

Children were told that they would be asked to answer some questions and play a game with the experimenter. In fact, the three exposures to the CS and US were buried in another study about children's understanding of advertising. At intervals appropriate to the conditioning treatment, children were asked to look at some pictures the experimenter "brought along." The subjects in the simultaneous conditions viewed the posters held side-by-side. The three exposures were approximately equally spaced during the 20 minute session. Children in the forward conditions saw the poster of the pencil immediately followed by the poster of Smurf, once again, at intervals approximately equally spaced. Children in the unpaired control condition saw one poster at six different breaks (approximately equal) in the 20 minute session. The six posters used in the unpaired control conditions were shuffled before each child entered the test room. The length of exposures, five seconds, was held constant across all conditions.

Each child rated his/her liking for Smurf on a four-point interval faces scale at the end of his/her session. Smiling to frowning faces were illustrated on a felt board which had also been used for the pretest. In addition, each child answered how good he/she thought Smurf was, and how good a feeling Smurf gave him/her. A four-point interval scale was vertically displayed on a board with the following anchors **GOOD** **good** **bad** **BAD**. Each child received at least two practice trials. The experimenter asked the child to "try the boards out" by indicating answers about such other familiar characters as Santa Claus, Strawberry Shortcake, Luke Skywalker, Pie Man, and so forth. The experimenter asked about Smurf after she judged the child to be proficient in the use of the boards.

The key measure for the study was taken at the very end of the session. The experimenter said that she wanted to thank the child for being in the study. She showed the child a yellow and orange pencil held side by side and asked the child to select one. (Pretests of the procedures indicated the importance of presenting the pencils precisely side by side. During one pretest session, the experimenter asked the child why he picked a particular color. He responded, "because it is longer." The experimenter was careful to hold the pencils directly next to one another.)

A buy-back procedure was modified from Allen and Madden (forthcoming). The experimenter said to the child after his/her selection, "I can only give you one thing, but I want to be sure you get something you like--the pencil is yours now. But, would you like to trade me for a

sticker?" The experimenter then opened a small box filled with a variety of stickers that were very popular during the time of the study.

This "buy back" procedure was included with the rationale provided by Allen and Madden (forthcoming). Whereas the choice between an orange and yellow pencil (that were equally desirable as based on a pretest) would probably not stimulate much cognitive activity, a decision to trade for a sticker would probably evoke some thought.

The experimenter placed each child's selection in an envelope that was sealed in his/her presence noting, "so it won't be lost." Thus, the child's selection was kept out of view from the other children. The child then returned to his/her classroom and joined in the ongoing activities. Teachers were asked not to discuss the study with the children but to listen for comments. Few comments were relayed; however, teachers reported such as the following, "it's fun to talk to the lady; you get to play a game, etc." No teacher reported children's awareness of the study's purpose; indeed, few comments were expressed by the children.

Results

Pencil color selection

The data were analyzed in a fashion consistent with prior work in marketing (Gorn 1982; Allen and Madden (forthcoming). As can be seen in Tables 1 and 2, the treatments did not yield statistical differences in color selection.

The results depicted in Table 1 suggest that there may have been an overall color preference for orange. Of the 14 control subjects who saw yellow, 10 selected the orange pencil. However, only 6 out of the 14 orange control group picked orange.

TABLE 1
ANALYSIS OF SUBJECTS' PENCIL COLOR CHOICES
SIMULTANEOUS VERSUS FORWARD VERSUS CONTROL

	Simultaneous		Forward		Unpaired Control	
Color Chosen	Color Subject Saw	Color Subject Saw	Color Subject Saw	Color Subject Saw	Color Subject Saw	Color Subject Saw
	Orange	Yellow	Orange	Yellow	Orange	Yellow
Orange	8	10	18	7	8	15
Yellow	6	4	10	7	6	13
	14	14	28	14	14	28
	$\chi^2 = .62, df=1$		$\chi^2 = .144, df=1$		$\chi^2 = 2.33, df=1$	
	sign. = .43		sign. = .71		sign. = .13	

More importantly, Table 2 illustrates the data in Gorn's (1982) fashion. The key concern is not what color was picked per se, but whether the source influenced the choice based on the color paired. Table 2 displays a crosstabulation of the pencil selected ("advertised" versus "nonadvertised") by condition. No statistically significant difference appeared ($\chi^2 = .686, df = 2, n.s.$).

Thus, the first hypothesis received support. Children who viewed Smurf simultaneously with the pencil evidenced no choice preference based on the pairing (simultaneous condition). The second hypothesis did not receive support, however. It will be remembered that children who first saw the pencil then viewed Smurf were

predicted to show choice preference for the "advertised" pencil (forward condition). The data offered no support. Therefore, the form of conditioning, simultaneous or forward, provided for no statistical differences from the control group who saw Smurf and the pencil in an unpaired fashion.

TABLE 2
ANALYSIS OF SUBJECTS' ADVERTISED/NONADVERTISED CHOICES AND CONDITION

Condition	Pencil selected		
	"Advertised" pencil	"Nonadvertised" pencil	
Simultaneous	12	16	28
Forward	13	15	28
Control	10	18	28
	35	49	84

$$X^2 = .686, df = 2, n.s.$$

In short, no support was indicated for automatic behavioral responses to a favorable character, Smurf, being associated with a product. This finding is consistent with Allen and Madden's (forthcoming) failure to establish a simultaneous conditioning effect with adult females. It is inconsistent with Gorn's (1982) results in favor of the simultaneous conditioning hypothesis.

The trading results

Allen and Madden's (forthcoming) buy back procedure was mocked in that children were provided the opportunity to trade the pencil selected for a sticker. This measure was included to gauge whether Smurf would create a positive feeling state that would bias the cognitive evaluation of the pencils. In the procedure section of this paper, it was argued that a trade for a popular item would be more likely to stimulate thought as compared to a choice between two pencils that varied only in color.

The percentages who traded the sticker for a pencil were compared among the simultaneous, forward, and control groups. The following trades were made: simultaneous group, 82.1% (23 out of 28); forward group, 60.2% (17 out of 28); and control subjects, 89.3% (25 out of 28). The difference between the forward group and the control group ($z = -2.18, p < .05$) was statistically significant, and the one between the traditional and the simultaneous group ($z = -1.53, p < .07$) was nearly so at the traditional .05 level. Nearly the same percentage of the simultaneous (82.1%) and control subjects (89.3%) traded, $z = -.71, n.s.$ Therefore, the treatments yielded one statistical difference in the children's willingness to trade. Apparently, the children who saw the pencil, then Smurf, were more reluctant to trade the selected pencil for a sticker. It will be argued that this procedure biased positive evaluations. Although no direct measures of thought processes were taken, children in the forward group appeared more resistant to trade.

At first glance, the trading results seem to lend support to the conditioning mechanism. As one would anticipate with conditioning, children in the forward group appeared more resistant to trade. For this interpretation to hold, however, one would expect that within the forward group, those children who selected the color of pencil paired with Smurf (consistent selectors), would have been more resistant to trade as compared to those children who selected the color they had not seen paired. Yet, within the forward group, 8 (61.5%) traded of the 13 who appeared consistent with their exposure, while 9 (60%) traded of the 15 who picked the color that they had not been shown. Thus,

the difference in percentages of traders was not statistically significant ($z = .06, n.s.$), as one would expect with a true conditioning result. In addition, differences within the other groups were statistically insignificant [simultaneous ($z = -.74, n.s.$): 9 (75%) traded of 12 consistent selectors versus 14 (87.5%) traded of the 16 inconsistent selectors; control ($z = -.95, n.s.$): 8 (80%) traded of the 10 consistent selectors versus 17 (94.7%) traded of the 18 inconsistent selectors. Therefore, the color selected in terms of its exposure did not appear to relate to the trading variable.

The interpretation for cognitive activity is consistent with Allen and Madden's (forthcoming) finding with adults. They reported that pleasant humor, simultaneously presented with a slide of a pen, resulted in subjects' reluctance to accept money for the pen selected. Allen and Madden (forthcoming) argued that their finding was bolstered from indications from the "mood" literature. Humor resulted in an affective state that had an impact on subjects' judgments and behaviors indirectly by biasing cognitive evaluations of the pens.

The same argument is relevant to the current finding. However, only children who saw the items in a traditional temporal arrangement (CS before US) were cognitively stimulated. The procedure used in the current study may have precluded a "cognitive" result from those in the simultaneous condition. It will be remembered that all exposures were held constant at five seconds. Therefore, the children who saw the pencil and Smurf held together had less time, as compared to children in other conditions, to view the stimuli. If they had been provided a longer exposure, then a trading result may have been significant. On the other hand, as compared to the control children, the ones in the forward group appeared more reluctant to trade. The length of exposure during the control and forward conditions was equivalent. Nevertheless, the trading results are best viewed as offering no support for conditioning in absence of a difference within the forward group in terms of resistance to trade and consistency of selection. In short, children who selected a color consistent with their exposure should have been more reluctant to trade, but were not. Thus, no support is offered for a conditioning result in absence of such a difference to trade within the forward group.

Discussion

The research findings offered no support for automatic responses to classical conditioning manipulations on children. In fact, results from an offer to trade suggested that cognitive activity may have been biased among children who saw a traditional, forward pairing. Limitations on the confidence of this interpretation include several methodological concerns in addition to the length of exposure already discussed.

First, it should be stressed that the current study contributes only one small piece of evidence on conditioning effects, or more precisely, the lack thereof. Many empirical studies are needed. Cell sizes of fourteen in the current study are not large. Moreover, children completed this exercise during a twenty minute session. Although the procedures probably minimized awareness, fatigue may have occurred (other tasks across subjects were held constant, however). Therefore, as is wise when interpreting any findings from one experimental setting, caution is warranted.

In addition, a US pre-exposure effect may have occurred. Familiarity has been found to decrease the effectiveness of the stimulus as a US (Mis and Moore 1973; Rescorla 1973). Smurf was not only familiar to the children but highly liked (pretest subjects' mean = 4.0, all experimental subjects mean = 3.8; 4-point scale). One could argue that an unfamiliar character should be paired before concluding a failure of conditioning. On the

other hand, findings from the trade measure indicated that a forward pairing did have an effect--on cognitive evaluation, which is the antithesis of an anticipated automatic response. Therefore, an interpretation for a pre-exposure effect is questionable.

The current research provides some implications for those interested in issues of children's advertising. Little empirical work has been conducted on source effects. Yet, critics of television advertising allege that the use of characters takes unfair advantage of the younger viewer. Rossiter (1980) presented an excellent overview and research agenda on source effects in children's advertising. He pointed out that NAB restrictions on endorsements to children can be interpreted as a reflection of concern for the allegedly negative effects.

The current research findings cannot be interpreted as support for the critics' concern. Children in the traditional, forward conditioning group were more reluctant to trade; however, one can argue that Smurf stimulated positive evaluations through active thought processing. Based on the data, one cannot argue for children's automatic responses to Smurf. Thus, a passive view of children's viewing, which is reflected in critics' concern, received no support.

Until recently, attention to television has been conceptualized as reactive in nature with the child being passively controlled by the medium. More recent work in children's television viewing does not lend support to this passive view. Instead, children appear to be active processors (c.f. Anderson and Lorch 1983; Wright and Houston 1981). It should be stressed, however, that the current research addresses these broader issues in only a most peripheral way. The present study consisted of a limited manipulation of sequencing of posters with likenesses of pencils and Smurf. Needless to say, television advertising consists of vastly more complex stimuli.

Nevertheless, the current findings lead to future research questions. Audiovisual manipulations of source effects are needed to decipher critics' concerns. The classical conditioning framework provides one path of inquiry to study whether children's responses are automatic or more active in nature.

To conclude, no empirical support was indicated for behavioral effects when pictures of pencils were paired with Smurf in three temporal arrangements (simultaneous, forward, and unpaired control). Simultaneous effects were not predicted (first hypothesis); however, children in the forward conditions were predicted to exhibit automatic responses (second hypothesis). Results from a trade-back measure were more equivocal. This study contributes just one small piece of evidence in an area of research worthy of attention. Future research efforts should include manipulations of media, background features, temporal arrangements, and research settings. Hopefully, evidence will accumulate on the viability of the classical conditioning framework in a marketing context including its application, or lack thereof, to issues of children's advertising.

SEX-LINKED TRAIT INDEXES AMONG BABY-BOOMERS AND PRE-BOOMERS:
A RESEARCH NOTE

Benny Barak, Hofstra University
Barbara Stern, Kean College of New Jersey

Abstract

This paper presents an examination of sex traits in two female age cohorts: Baby-Boomers and Pre-Boomers. Relationships between variables and trait indexes past research considered sex-linked were assessed. Findings indicate that the past interpretations of femininity still hold true. However, current perception of masculinity traits seems socially redefined to self-assurance and to incorporate femininity as well, which may explain much contradiction in prior sex research. Indications are that the two cohorts do interpret sex role traits differently.

Introduction

The relationship of sex traits, sex roles and sex-linked characteristics has long been of interest in multidisciplinary research. Within the past decade, these topics have surfaced in marketing literature; while the relationship of sexual identity and consumer behavior has been investigated to some extent, much more remains to be discovered. This paper presents a reexamination of sex traits in an age-related social context.

Sex traits are treated in two ways: one, as simple unidimensional self-descriptions--either "feminine" or "masculine"; two, as multi-trait indexes of self-linked identity--FEMININITY or MASCULINITY.

The currently accepted sex role categories of Feminine, Masculine, and Androgynous, all based on combinations of these FEMININITY and MASCULINITY trait indexes (Bem 1974), have not been especially useful to consumer behaviorists. We felt that a reexamination of the uncombined indexes might provide more practical results than the combined typology has done so far. Additionally, since the central changes in society concerning appropriate role stereotyping have occurred since World War II, and have mainly impacted on the roles of women, we also felt that concepts of FEMININITY and MASCULINITY might very well be associated with the dimensions of age in women consumers.

We thus decided to conduct an exploratory study to examine the way selected demographic, psychographic, and behavioral variables relate to self-perceived sex traits in two female age cohorts: Baby-Boomers (25-39) and Pre-Boomers (40-64).

Sex Role Research

Pre-1970's sex role research assumed that "healthy" individuals adopted the sex role appropriate to their gender, and demonstrated only those traits judged desirable for that gender by society (Robinson and Green 1981). Traditional sex role theories, however, were unable to accommodate the dynamic changes in America's cultural milieu dating from the late 1960's (Bem 1974, 1975, 1977; Bem and Lenney 1976; Robinson and Green 1981). The shattering of cultural stereotypes in the wake of the women's liberation movement forced the conclusion that sex roles and biological gender are not necessarily the same.

Self-Perceived Sex Concepts

The theoretical framework for measuring combinations of feminine and masculine traits to determine sex role concepts is the Bem Sex Role Inventory (BSRI; Bem 1974). The BSRI is a self-descriptive survey instrument relying on a 7-point true-untrue scale to measure respondents' identification with 60 characteristic qualities. Independent panels of judges in the early 1970's established these attributes as either feminine, masculine, or non-gender

related--for example, helpful or happy. Each of the BSRI role typologies is measured by 20 of the attributes; a respondent's identification with these qualities provides insight about his/her self-perception as feminine or masculine.

BSRI research has been used to assign individuals to four categories: Feminine, Androgynous, Masculine, and Undifferentiated. This categorization relies on various combinations of the femininity and masculinity scores, minus the non-gender subscale. Most of the BSRI based sex research (e.g., Bem 1974, 1977; Bem et al 1976; Robinson and Green 1981) is concerned with the Androgynous sex role--high scores in both femininity and masculinity--and its difference from the Feminine role--high femininity and low masculinity scores. Few differences have been found between Androgyny and either the Masculine--low femininity, and high masculinity--or Undifferentiated--low femininity and low masculinity--sex roles. Bem's widely used research has led to the reevaluation of femininity and masculinity as separate and blendable constructs, not bipolar opposites.

There has been growing marketing interest in the sexual revolution's impact on the American woman's interpretation of femininity and masculinity (e.g., Caffetera 1984; Kanter and Wortzel 1985; Kilbourne 1984). Some consumer studies have been done on product and brand usage (e.g., Allison et al. 1980; Gentry et al. 1978). Marketers have also examined sex roles and stereotypes on the mass media, with particular emphasis in advertising portrayals (Coughlin and O'Connor 1985). Past research emphasis, when the BSRI was employed, has been almost exclusively on combinations of traits, especially the Androgynous. Results, however, have been disappointing: the Androgynous role, like the 1960's Unisex one, seems to be a fad (Caffetera 1984).

The Study

We felt that a reexamination of the sex traits of femininity and masculinity in the light of a woman consumer's age might be especially useful. The role changes concerning education, employment, and sexuality seemed likely to affect the Baby-Boom woman differently from the Pre-Boomer woman. We thus conducted an exploratory study to investigate the way sex traits, measured by BSRI items, correlate with a number of variables in the two female populations.

Variables Selected

Multidisciplinary sex-role research has established sets of variables associated with self-perceived sexual roles measured in various ways. Contradictory evidence has characterized such research, perhaps caused in part by differences in sampling procedures and populations studied. Even when contradictory findings occur, however, certain variables often show significant relationship to sex traits. Tested relationships are listed in Tables 1 and 2; where male and female populations were analyzed separately, only female ones are shown.

In addition, one other hitherto untested potential correlate was also selected on the basis of logic: Opinion Leadership in grooming and cosmetic products.

Research Methodology

From 1982/84, a convenience sample of 698 women in the New York Metropolitan area completed a ten page, 30-45 minute self-report questionnaire. Marketing students trained in

LEISURE TIME AND ITS RELATION TO SEX ROLE*

LEISURE TIME ACTIVITIES	FEMINISTS	MODERATES	TRADITIONALISTS
Outdoor sports	+		
Engage in sports in free time	+		
Leisure activities	+	+	

* Venkatesh (1980) categorizes women into "Feminists," "Moderates," and "Traditionalists" and reports on associations with leisure activities as shown here. Other researchers (Gentry et al 1978) report on associations between femininity and masculinity factors with leisure time activities, but they do not provide clear findings.

survey techniques distributed and collected the questionnaires. An age quota sampling procedure ensured a representative population of women 25 to 64, with a median age of 40. The total population sample was edited down to 280 Baby-Boomers (25-39) with a mean age of 31.25, and 334 Pre-Boomers (40-64) with a mean age of 50.88, who completed the BSRI. The questionnaire, used for other purposes as well, incorporated numerous variables.

Survey Instrument (Questionnaire)

Sex Traits. Four sex traits are employed in this study. Two of these are sex-linked trait indexes, FEMININITY and MASCULINITY, the dependent study variables. Varimax rotated factor analysis of feminine and masculine BSRI (Bem 1974) characteristics--a common technique in such research (e.g., Gaudreau 1977; Whetten and Swindells 1977)--led to the selection of items with a loading of .55 or higher for either a FEMININE or a MASCULINE trait index. Appendix A shows the 20 specific items identified by factor analysis as having sufficiently high loadings to be included in these indexes. Scoring relies on a simple summation of the ten factor-loaded feminine items for FEMINITY, and the ten masculine items for MASCULINITY. There are two additional sex-traits measured: self-ascribed "feminine" and "masculine," single items on the BSRI scale (factor loadings < .55), scored from 1 to 7 by the respondent.

Age Variables. Four age measures were selected.

(1) Chronological Age, measured directly in years;
(2) Identity Age (Cutler 1982), measured by a respondent's self-perception as "young" (score=0) or "middle-aged" (score=1); (3) Cognitive Age (Barak and Gould 1985) measured by a respondent's assessment of personal age identity

in terms of four age dimensions (Feel/Age, Look/Age, Do/Age, and Interest/Age) expressed in years; and (4) Ideal Age (Barak and Gould 1985), measured by a respondent's answer to the question, "What do you consider to be a person's IDEAL age?" in years.

Demographics. Five demographic variables were selected. These were scaled dichotomously to avoid empty cells. (1) Education, scored in years; (2) Occupation scored as a dummy variable, with "professional" or "executive" = 1, all others = 0; (3) Employment outside the home also a dummy variable, "fully-employed" = 1, "not fully employed" = 0; (4) Income, with personal income under \$20,000 = 0, \$20,000+ = 1; and (5) Health Status, measured by the question, "How would you describe the state of your health?" Scoring was "Excellent and Good" = 1, "So-So, Bad and Terrible" = 0.

Family Measures. Three variables concerning household and offspring were selected. (1) Marital Status, with "marrieds" = 1, "widowed, separated, divorced, and singles" = 0; (2) Household Size, based on the question, "How many persons are presently in your household, including yourself?" and (3) Number of Children, based on a straightforward question: "How many children do you have?" Both (2) and (3) were scored numerically.

Psychographics. Each of the two scales employed, (1) Self-Confidence (Reynolds and Darden 1971) and (2) Morale (Barak and Gould 1985), is based on four Likert summation items to which respondents indicated agreement/disagreement. Responses were then factor analyzed to establish the specific AIO scales employed (see Wells 1975). A typical Self-Confidence scale statement is, "I think I have a lot of personal ability." Morale measures a condition of well-being, particularly happiness with one's age-status, as indicated by a statement such as "These are the best years of my life."

Social Traits. Three social traits were selected. (1) Perceived Risk (Error-Tolerance; Schiffman 1972) differentiates between respondents who, when shopping in a supermarket, prefer to try a new brand of product when it first comes out, and those who prefer to wait and learn how good a product is before trial. Perceived risk is thus a dummy variable: error-tolerant who try products first = 1, others = 0. (2) Opinion Leadership (Katz and Lazarsfeld 1955); another dummy measure was scored dichotomously, since the "not-sures" and non-opinion leaders are distinct from those who identify themselves as opinion leaders. This measure thus scores respondents who agree that "friends and neighbors often ask my advice about grooming and cosmetic products" = 1, all others = 0; (3) Risk Inclination scores respondents 1 to 7 according to their degree of self-perception as "willing to take risks."

Leisure Time Behaviors. Four leisure time variables were selected. Respondents are scored numerically in terms of their answers to "How many times did you engage in the following activities in the last three months?" (1) Running, (2) Swimming, (3) Dancing, and (4) Going to a Bar.

Propositions

We decided to investigate the following Propositions in both age cohorts:

Proposition I - All sex-related traits are significantly interrelated.

On the basis of variables assessed for relationship with sex roles/traits (see Tables 1 and 2), Propositions II and III were set forth:

Proposition II - Femininity will correlate negatively with: Chronological Age, Education, Employment Status, Occupation, Income, Health, Marital Status, Perceived Risk, and Risk Inclination. Femininity will correlate positively with: Number of Children, Self-Confidence and Morale. Femininity will not significantly correlate with Self-Perceived Age, Leisure Time Activities and Ideal Age.

Proposition III - Masculinity will correlate negatively with: Chronological Age, Self-Perceived Age, and Number of Children. Masculinity will correlate positively with: Education, Occupation, Employment Status, Income, Health, Marital Status, Self-Confidence, Morale, Perceived Risk, Risk Inclination, and Leisure Time Activities. Masculinity will not significantly correlate with Ideal Age.

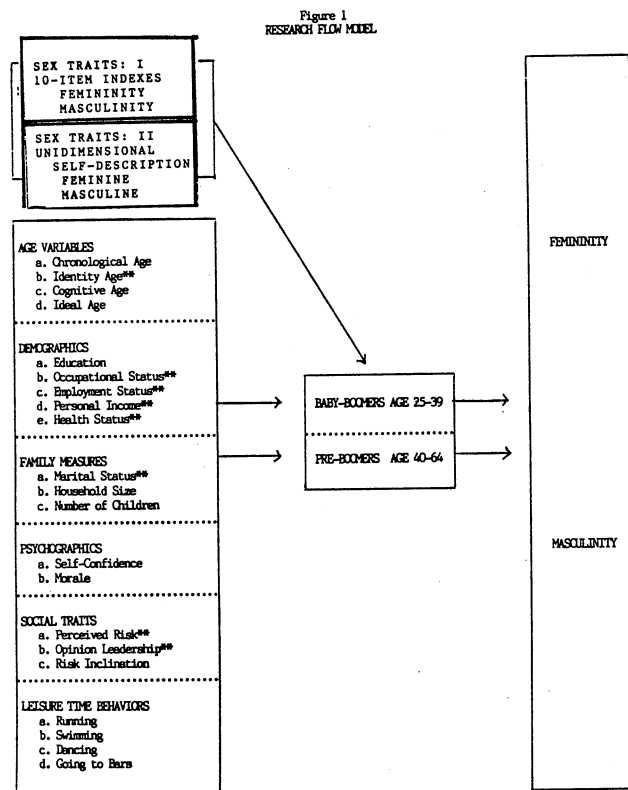

On the basis of logical association with sex roles/traits, Proposition IV was set forth:

Proposition IV - Femininity will not correlate significantly, and Masculinity will correlate significantly with Opinion Leadership.

Since the relationship between sex traits and other consumer variables has not previously been considered in an age cohort context, the study also set out to compare and contrast relationships found in both age groups.

Research Procedures and Results

All statistical procedures relied on the Statistical Package for the Social Sciences (SPSS--Nie et al. 1975; Hull and Nie 1981). The first procedure, reliability tests, showed all multiple-item scales in the study to be sufficiently reliable: only measures with a coefficient ALPHA >.5 were included. The research flow model tested is shown in Figure 1.

* Independent research variables considered WITHOUT as well as WITH sex traits.
** Dummy Variables (scored 0/1).

Correlation and Regression Procedures

To assess the propositions, three separate stages of investigation took place. The first stage, testing Proposition I, used Pearson correlations between the four types of sex traits. The results of this intercorrelation are in Table 3.

Table 3
CORRELATION MATRIX SEX TRAITS

SEX TRAITS	BABY-BOOMERS AGE 25-39				PRE-BOOMERS AGE 40-64			
	FEM (r)	MASC (r)	Feminine (r)	Masculine (r)	FEM (r)	MASC (r)	Feminine (r)	Masculine (r)
FEMININITY	1.00	+.27***	+.47***	-.26***	1.00	+.27***	+.52***	-.21***
MASCULINITY		1.00	+.14*	---	1.00	+.19***	+.12*	---
Feminine (self ascribed)			1.00	-.55***		1.00	-.28***	---
Masculine (self ascribed)				1.00			1.00	---

* p (.05)
** p (.01)
*** p (.001)

Part of Proposition I must be rejected for the Baby-Boomer cohort: no significant relationship was established between MASCULINITY and self-ascribed "masculine." One surprising finding was that in the two cohorts the correlation between both FEMININITY and self-ascribed "feminine" vis-a-vis MASCULINITY was positive: we expected these relationships to work in opposite directions. All other relationships were in logical directions.

The second stage, testing Propositions II, III and IV, used Pearson and Bi-Serial (dummy variable) correlations between the two trait-indexes and the independent variables. The resulting correlates shown in Table 4 establish the independent variables for which Propositions II, III and IV were accepted.

Table 4

** p (.01)
*** p (.001)

**** Dummy variables for which the correlational analysis is Bi-Serial.

The third stage, to confirm the Propositions and compare findings in both cohorts, used Forward Stepwise Regression. A total of eight multiple regressions were performed, four in each cohort. The collinearity index (Chapman and Staelin 1982) was <.05 for all eight functions.

Table 5 presents the FEMININITY functions in both cohorts, WITHOUT (Functions I and II), and then WITH sex traits (Functions III and IV). MASCULINITY functions are presented in the same order: WITHOUT (Functions V and VI) and WITH sex traits (Functions VII and VIII). Function VII was developed without self-ascribed "masculine," since that was not a MASCULINITY correlate.

Discussion of Results

Functions I and II show that when FEMININITY is developed without the sex traits, the variance explained is rather limited: R square = .08 for I, and R Square = .09 for II. Furthermore, the variables in both Functions differ totally.

Functions III and IV show that when sex traits enter the regressions, the first step in both cohorts is "feminine," and the second step, MASCULINITY. The variance explained in both cases increases nearly fourfold: R Square = .31 for III and R Square = .33 for IV. The other independent variables remain basically the same, except that Opinion Leadership drops out in the Baby-Boom cohort. The entry of "feminine" and MASCULINITY in III and IV shows that FEMININITY indeed measures a sex-related dimension. The strength of the relationship between "feminine" and FEMININITY is shown by the relatively high correlation between the two, and first step entry. MASCULINITY also shows correlations of similar strength in both cohorts. Moreover, III and IV show not only a significant relationship

between FEMININITY and MASCULINITY--step 2 in both--but also a positive one.

Functions V and VI show that when MASCULINITY is developed without the sex traits, a fair amount of variance is explained: R Square = .45 for V, and R Square = .34 for VI. In both functions, Self-Confidence and Risk Inclination form the first steps. The fourth step is also similar, in each case a form of self-perceived age. The major difference between the functions is in step 3: in the Baby-Boomer cohort, Dancing, and in the Pre-Boomers, Professional and Executive status occupy this step.

Functions VII and VIII show that when sex traits enter the regressions, the first two steps are again Self-Confidence and Risk Inclination, which confirms these variables as the main determinants of the MASCULINITY trait index. The third step in both functions is FEMININITY, again a positive association. The entry of FEMININITY raises the variance explained in the Baby-Boomer cohort: R Square = .51 for VII. The addition of sex traits in the Pre-Boomers also helps raise the variance explained: R Square = .39 for VIII. In VIII, both "masculine" and "feminine" enter, as steps 5 and 7. All three sex traits thus show a positive relationship. This implies that the MASCULINITY trait index is still slightly associated with the sex-linked masculine dimension in the minds of respondents 40+.

Implications

It is clear that when MASCULINITY is the dependent variable all of the independent variables (except Number of Children as step 6, Function VIII) reflect a form of SELF-ASSURANCE. The ten items that form this trait index (Appendix A) are all traits characteristic of a highly self-assured woman. We thus suspect that this trait index is NOT sex-linked as originally thought, but, rather, a NON-SEX related self-concept measure. These ten traits might have been considered stereotypically masculine in the early 1970's, but the sexual revolution seems to have wrought a shift in perception. We therefore suggest the reinterpretation of the MASCULINITY index as SELF-ASSUREDNESS.

As the correlations and regressions show, many more useful consumer-related variables emerge for the new SELF ASSURANCE trait index than for FEMININITY. FEMININITY alone seems to have few such correlates: it shows both small explained variance and only a few different correlates in both cohorts. On the other hand, the MASCULINITY index, reconsidered as SELF-ASSURANCE, even without sex traits, is quite relevant to consumer behavior because of the high variance explained and many correlates.

Past sex role research, in the light of the study findings, can now be viewed from a different perspective. Bem's typologies used in a consumer behavior context seem inapplicable. The difference between FEMININE (high femininity and low masculinity scores) and ANDROGYNY (high femininity and high masculinity) simply boils down to the difference in Self-Assurance scores. The difference between ANDROGYNY and MASCULINE (low femininity and high masculinity) depends mainly on femininity scoring. Since FEMININITY is relatively independent of consumer behavior variables, it is not surprising that few differences between the Androgynous and Masculine types have been reported.

Our findings seem to shed light on the problems associated with interpretation of Androgyny. If Androgyny really means a mix of high FEMININITY and high SELF-ASSURANCE, then it is not a true sex-role self-concept, as Bem's original research implies. The differences between FEMININITY and ANDROGYNY might be differences in self-assurance rather than sex-role, and the lack of differences between MASCULINITY and ANDROGYNY might reflect limited differences between high and low FEMININITY trait index scores.

Another implication is that unlike the FEMININITY trait-index which, though appealing, is not useful for marketing purposes, the new measure of SELF-ASSURANCE shows great promise. It has high reliability ($\text{ALPHA} > .88$), and can be used to identify potential innovators in the marketplace.

While full implications of the self-assurance measure require further study, some current fashion trends provide an example of the self-assured woman who considers herself feminine. The apparent paradox of the declining interest in mannish styles and fabrics at the same time as women are increasingly entering the formerly purely masculine world of career commitment makes sense, if one reinterprets self-assuredness as incorporating, rather than denying, femininity. The trend away from "menswear styling" (*Harper's Bazaar*, July 1985, p. 160), in fact, seems to be spreading in the mid-1980's from the innovative few to the masses. Liz Claiborne often considered the most important designer for the large middle-class and middle-price market, proposes to take women out of "neat little suits that erase the fact that they're women" in Fall 1985 (*Harper's Bazaar*, June 1985, p. 129).

The creators of promotional appeals might thus take note of the feminized self-assured woman: images of confident women can, for example, be shown in highly romantic settings.

Thus social changes have culminated in reevaluation as feminine of "Self-Assuredness" traits which a decade ago were judged masculine. This shift explains why positive relationships between FEMININITY and SELF-ASSURANCE traits have been so clearly established in this study. It also explains why the Baby-Boomer cohort shows no correlation between SELF-ASSURANCE and self-ascribed "masculine." To some extent, this study confirms that the sexual revolution has won a major battle: women who are aggressive, forceful, competitive, and ambitious view themselves as not losing one bit of their femininity!

Appendix A
FACTOR ANALYSIS OF BSRI TRAITS: FORMING SEX-LINKED INDEXES*

BSRI TRAIT ITEMS	item number in BSRI	FEMININITY (factor loadings)	MASCULINITY (factor loadings)
AFFECTIONATE	11	.59	.21
ASSERTIVE	13	.14	.69
STRONG PERSONALITY	16	.26	.69

SEX ROLES AND CONSUMER PERCEPTIONS OF PROMOTIONS, PRODUCTS, AND SELF:
WHAT DO WE KNOW AND WHERE SHOULD WE BE HEADED?

Kathleen Debevec, University of Massachusetts
Easwar Iyer, University of Massachusetts

Abstract

Sex roles have been a focus of attention in Consumer Behavior because they are believed to have an impact on individual and family decision-making and ultimately the purchase of consumer goods and services. Of special interest to marketers is their effect on perceptions of promotions and products. The present paper examines the influence of culturally prescribed sex roles on individuals' reactions to sex role characterizations in promotions, the gendering of products, and one's self-concept (which purportedly underlies sex role stereotypic perceptions). Avenues for further research which complement and integrate the above streams are suggested.

Introduction

The growing number of women entering the workforce in recent years has triggered a change in sex roles for both men and women. The effect of these changing roles has been studied primarily in terms of how family decision-making has been influenced (Scanzoni 1977; Park and Iyer 1981). Dual-earning families have been a target of investigation because of the increased time pressures felt by "working wives" (Strober and Weinberg 1980) and its expected effect on convenience-oriented consumption such as the purchase of time-saving durables (like a microwave oven), food requiring less preparation (frozen foods), and services. The cause and effect relationships expected were often not found because they were based on demographic characteristics of families (working vs. nonworking wives) rather than perceptual variation of the woman's working status such as the degree of her labor force attachment (Maret-Havens 1977) and professional status in the workplace (Schaninger and Allen 1981).

The importance of understanding consumers' perceptions as they relate to changing sex roles should not be underestimated because of their potential impact on the effectiveness of marketing strategies. As men and women assume different roles, they would be expected to view themselves differently and this change in self-concept would likely influence their perceptions of marketing strategies, in particular, promotional strategies and product positioning. This paper reviews research investigating the influence of changing sex roles on individuals' perceptions of (1) promotions, (2) products, and (3) themselves. Each of the three areas is reviewed individually and future research is proposed in each section which would enhance our understanding of each area and the relationships between the perceptual constructs such that effective marketing strategies may be developed.

Sex Roles as Portrayed in Advertising

Research focusing on sex roles in advertising has arisen from societal as well as marketing concerns. Societal criticisms have centered primarily on women's stereotypical roles in ads and their effect on the socialization of children and the perpetuation of women's "place" in society. Critics contend that women's roles are changing but that advertisers are not keeping pace with these changes or depicting women realistically. Consequently, researchers have attempted to document women's roles in TV commercials (Courtney and Whipple 1974; Dominick and Rauch 1971; McArthur and Resko 1975; Scheibe 1979; Schneider and Schneider 1979; Sharits and Lammers 1983) and print ads (Belkaoui and Belkaoui 1976; Courtney and Lockeretz 1971; Wagner and Banos 1973) to determine the extent to which the criticisms are justified. In the earlier studies, women were found to be portrayed in stereotypically feminine roles, whether in the home or on the job (Courtney

and Whipple 1974; Courtney and Lockeretz 1971; Wagner and Banos 1973; Dominick and Rauch 1972) whereas, more recently, their image relative to that of men seems to have improved (Scheibe 1979; Sharits and Lammers 1983). Men's roles in advertising have also been a target of criticism. Men often serve as announcers or demonstrators of products, and when they are shown "using" a household product, they tend to be depicted as helpless and dependent on a woman for instructions (Scheibe 1979). For example, in a commercial for Aunt Jemima waffles, the father is portrayed as helpless while preparing breakfast in order to promote the product's ease of preparation. Such a stereotypical representation (of men or women); while unflattering, may effectively serve the purpose of emphasizing a specific product attribute.

Marketers' concerns revolve around the effectiveness of traditional versus progressive sex role portrayals in advertising and individuals' preferences for one type of portrayal over another. Most published research focuses on the latter. Lull, Hanson, and Marx (1977) found that women were more sensitive and critical of the sex role stereotyping of females than were men and that their responses were somewhat related to the extent to which they agreed with the sentiment of women's liberations. Other studies indicate that younger and more highly educated women are most critical of such stereotypic portrayals (Lundstrom and Sciglimpaglia 1977; Venkatesh 1980; Witkowski 1977). Some women are so critical of such stereotypical portrayals that they stop using a product. In one of the author's experience, a woman claimed that she stopped using Wisk laundry detergent because the portrayal of women in the commercial was "very demeaning." Bettinger and Dawson (1979), however, did not find traditional roles offensive to women but did find more liberated depictions offensive (women pictured in masculine occupations). An ad for Pittsburgh National Bank in which a woman promoting the bank was featured as a construction worker may be an example of such a "liberated" portrayal and may attract criticism for that very reason.

Wortzel and Frisbie (1974) measured individual preferences for women's role portrayals in ads by having women construct print ads for a variety of products. The women were instructed to match pictures of products with pictures of women who were portrayed in family roles, fashion roles, sex object roles, and career roles. None of the role portrayals were consistently preferred. Instead, subjects matched the product to a role portrayal based on the product's function. For example, family role portrayals were preferred for products used by the family. Similarly, Buchanan and Reid (1977) created ads depicting women in traditional and nontraditional occupations (housewife, teacher, cabdriver, PhD) for a variety of products (instant breakfast drink, bath cleaner, golf clubs, blood bank) and found no one portrayal was evaluated most favorably over all products. Perhaps advertisers are best off depicting women who balance the responsibilities of career and family. Ads for Enjoli perfume portray the user of the product as a housewife and career woman.

Studies examining the effects of sex role modern and traditional women in advertising are generally lacking and additional research is warranted. Future inquiries should focus not only on preferences for each type of portrayal, but on various measures of effectiveness (Debevec and Allen 1984) such as that portrayed in McGuire's (1978) information processing model, Colley's (1961) DAGMAR model or the Lavidge and Steiner (1961) model. Each of these models suggests a hierarchy of communication effects ranging from some type of awareness through an evaluation process to purchase. In particular, McGuire's model

includes attention, comprehension, yielding, retention, and behavior. In the context of this research, it might be suggested that ads featuring women in progressive roles may be more likely to generate attention than ads depicting women in traditional roles because they may be unexpected and different from the norm. Will these ads be better comprehended, however, and lead to purchase intention more often than the traditional ads?

The research to date on sex roles is also limited in that women have been the primary focus of investigation. While their role changes may be the most noticeable because of their increased participation in the work force, men's roles have also begun to change in response. Men to some degree have begun accepting nontraditional household responsibilities (e.g., food shopping and preparing meals) because of time constraints experienced by both members of dual career families. Men also acquire nontraditional household and consumer skills as they delay marriage or remain single (Roberts 1981). Consequently, should we not question the manner in which men are portrayed in advertising? Can men effectively represent household products on their own without the aid of women as supporters? Future research should focus on men's roles as well as women's roles.

Attention should also be directed to the type of product promoted and individual difference variables as they relate to traditional and progressive role portrayals for men and women. These variables have received some preliminary attention in the previous studies cited, however, their relevance will become evident in the forthcoming discussion.

Gendering of Products and its Role in Promotion

The notion that products possess symbolic images is not a new one (Levy 1959). These images are of concern to marketers because consumers not only purchase a product for its functional benefits but they purchase the image they perceive the product to have, whether real or imagined. Several studies have investigated recently the extent to which various types of products possess gender images (Allison, Golden, Mullet, and Coogan 1979; Alreck, Settle, and Belch 1982; Golden, Allison, and Cleo 1977). Products found to have masculine images include a pocket knife, tool kit, shaving cream, cuff links, and a briefcase, to name a few (Allison et al.). Products with feminine images include a scarf, baby oil, hand lotion, bedroom slippers, gloves, and sandals.

Although consumers commonly hold gender images of products, the basis of those gender images is not completely understood. Allison et al. speculate that products may be sex-typed based on the gender of the group most likely to use the product. In addition, cultural norms relating to sex roles may dictate the types of products most appropriate for men and women to use (Morris and Cundiff 1971), implicating a circular relationship. This relationship between a product's use and its gender image is intuitively logical but has yet to be tested.

Marketers have attempted, as well, to form gender images for products and brands. Advertisements for cosmetics and diet soda have traditionally been aimed at women; however, in an attempt to expand the market for these products, ads have more recently been directed at men. The Pepsi Cola Company is positioning its Diet Pepsi brand to a male market by enlisting the aid of two well-known male athletes to promote the product. Not surprisingly, they are depicted in a brand choice, usage situation thus providing support for the previous assertion. Can a stereotypically feminine product be perceived as acceptable for men as a result of two men promoting the product? To what extent can marketers alter the gender image of a product, whether it is one they have created or one which has been culturally determined? In the maturity stage of a product's life cycle, marketers often try to "ungenderize" a product or brand. The Lowenbrau beer campaign with its "Here's to good friends" slogan may be an example of this strategy. Beer has traditionally been positioned as a masculine product, but Lowenbrau has developed ads featuring men and

women in neutral social situations supposedly consuming the product. Do consumers weigh promotional cues on an equal footing with usage cues in forming gender images for products? We would hypothesize that usage cues are critical and the effectiveness of promotions could be enhanced by featuring the targeted gender in a "usage" situation. Are there other variables not mentioned which may influence a product's image, such as the gender of the person most likely to purchase the product? These inquiries should be subject to empirical testing.

Although a product's gender image up to this point has been characterized as either masculine or feminine, this dichotomous distinction has been questioned and tested (Allison, Golden, Mullet, and Coogan 1979). Earlier studies conceptualized a product's gender as a bipolar construct (Aiken 1963; Fry 1971; Morris and Cundiff 1971; Vitz and Johnson 1965) while later studies began treating the masculinity and femininity of products as separate dimensions, prompted somewhat by Bem's (1974) research on sex roles (Gentry, Doering, and O'Brien 1977; Golden, Allison, and Cleo 1977).

Bem was interested in classifying individuals according to their sex role orientation as masculine, feminine, androgynous, or undifferentiated. Individuals rate themselves on a series of masculine, feminine, and neutral trait dimensions and are subsequently categorized as high masculine, low feminine (a masculine orientation), high feminine, low masculine (a feminine orientation), high masculine, high feminine (androgynous), and low masculine, low feminine (undifferentiated).

The logic then followed that if people could be classified along these dimensions based on their sex role orientation, so too may products be perceived along these dimensions. Allison, et al. tested this assertion by having subjects rate 24 products on two separate 9-point scales, one tapping the products' perceived femininity and the other tapping the products' perceived masculinity. They hypothesized that if masculinity/femininity is a dichotomous construct, the scores for each product should sum to ten (e.g., a product rated as a 7 on the masculine scale should be rated as a 3 on the feminine scale). The majority of products did not satisfy this unidimensional criteria and they concluded that masculinity and femininity are two separate constructs. These findings therefore suggest that products may be perceived as androgynous (high masculine, high feminine) and undifferentiated (low feminine, low masculine). Androgynous products may be those which are "used" equally by men and women while undifferentiated products may simply be those which have not yet established a gender image. When attempting to classify products along these dimensions, Golden, Allison, and Cleo (1977) found that none of the products they tested could be labeled as androgynous or undifferentiated. They formed three product groups instead, high masculine--low feminine, medium masculine--medium feminine, and low masculine--high feminine.

Additional evidence supporting the gender classification of products is desirable. Potentially, marketers may be able to draw up a typology of products along gender dimensions which may provide insight into how classes of products may be characterized. Exploring the roles men and women play in society, trait characteristics commonly assigned to men and women, and potential usage situations (Dickson 1980) may provide a starting point in such a classification scheme. For example, "household cleaning" products may be perceived as highly feminine because of women's traditional role as homemaker. "Financial services" may be considered as masculine because of men's perceived knowledge or expertise in handling financial matters and their traditional assumption of this role. "High technology" products may be perceived as masculine following similar logic. Groups of individuals may differ with respect to such gender stereotyping because of their own set of past experiences. College students and dual career couples may be less likely than those residing in a traditional family structure to assign clearcut gender images to such products and services because of their own personal exposure to household

maintenance, budgeting, and/or computers. Such a classification scheme based on individuals' perceived roles, personal characteristics, and possible usage situations may provide marketers with some generalizable yardsticks upon which they may begin to make strategy decisions.

As mentioned earlier, product gendering has become an issue in developing promotional strategies. Marketers have taken an active stance in gendering products in an effort to target new groups of customers and develop new market segments. Altering the gender of a product or service, however, is not undertaken without some degree of risk. While opening up new market segments, promoters risk alienating their established market. The question arises as to what degree men and women can be credible spokespersons for cross-gender products, given that product usage by men or women (as depicted in such ads) is likely related to the product's overall gender image. This concern is especially critical given the general sensitivity of males to using products with a feminine image (Morris and Cundiff 1971). Can a woman credibly and effectively promote an Individual Retirement Account or a bank charge card? Will the ad for VISA which depicts a woman receiving her own "classic" card and breaking it in by inviting her male friend to dinner be as effective as the one in which the roles are reversed? Since these are "products" which both men and women can certainly buy into, it is critical that the spokesperson not alienate target consumers. Will a woman be effective promoting a personal computer to business people? This product has primarily been promoted by men, whether targeted for the workplace or to parents in the home. Are there certain "types" of masculine products a woman can endorse effectively? Are there certain "types" of feminine products a man can endorse effectively? Will a man be a credible spokesperson promoting dishwashing liquid or laundry detergent, without the presence of a woman? Insights into these questions may be enhanced by considering situational variables, as suggested earlier.

Gender Perceptions of Source Characteristics in Promotions

Are there definable source characteristics which may lend credibility to cross-gender promotions? Some recent work in social psychology may provide partial insight. An individual's appearance in terms of their physical attractiveness, grooming, and physique have been found to affect perceptions of their masculinity and femininity. Gillen (1981) found that individuals are sex-typed based on their physical attractiveness. Attractive women are perceived as more masculine than unattractive women while attractive men were perceived as more masculine than unattractive men. In a followup study, Cash, Gillen, and Burns (1977) conducted further research to determine if attractiveness would be a detriment to women in the workplace, especially relative to stereotypically male occupations (where masculine traits would likely be important for success). They found that highly attractive women were less apt to be recommended for nonmanagerial jobs. For men, however, attractiveness was always an advantage, whether they were being recommended for managerial or nonmanagerial jobs.

Given the link between attractiveness and sex-typing, it might be expected that attractive women will be less effective than unattractive or average-looking women in promoting products with a masculine image because the unattractive women are perceived as relatively masculine. Unattractive men may be more effective than attractive men in promoting products with a female image (since attractive men are perceived as more masculine). This latter suggestion may be faulty, however, given other research which has found that attractiveness is always an advantage for men, regardless of sex-typing (Cash and Janda 1984).

In addition, there is some evidence that an individual's grooming and physique influence perceptions of their masculinity and femininity (Cash and Janda 1984; Deaux and Lewis 1984). Women groomed in a relatively masculine fashion (short hair, little makeup, clothed in a suit) were perceived as more competent and were more likely to be judged as potential managers than women groomed in a "feminized"

style. Individuals who are perceived as tall, strong, and broadshouldered (whether male or female) are judged to have masculine personality traits and thought to be employed in a masculine-type occupation. Even though the "pure" masculine or feminine appearance may be beneficial in the context of promoting certain gender-stereotyped products, on other occasions, the androgynous appearance proves to be particularly successful. It has been argued by some that one of the reasons for Michael Jackson's dizzy success lies in "the high-pitched voice, the androgynous good looks, and the dangling forelock" (Davis and Allen 1985).

Future research should investigate the extent to which these "image" variables interact with the gender of a model and reflect on their perceived masculinity and femininity, thus influencing the model's effectiveness in promoting "gendered" products. We have little, if any, evidence whether a female model can enhance her credibility in promoting a "masculine" product by wearing a business suit rather than a dress or by altering other aspects of her appearance. Studies on impression management suggest that props (such as the suit) and appearance variables (hair, makeup, etc.) can effect impressions formed of others (Schlenker 1980). The use of masculine props may enhance the effectiveness of a woman promoting a product with an otherwise masculine image.

It might also be questioned whether these image variables are more effective with certain classes of products. Given women's entry into the business environment in professional/managerial positions, she may be an effective promoter of business-type products or even financial services (possibly reflective of her financial independence). These categories of products/services may be more malleable in terms of their sex-typed image than others which may be linked to roles women have not assumed in great numbers (e.g., lawncare--lawnmower, repair work--wrench). Similarly, there may be certain types of "feminine" products a man can or cannot endorse effectively (hairspray, over cleaner) and these too may be related to tasks which men have or have not begun to assume in the household. Also of interest would be the extent to which individual personality factors (or one's self-concept) influence acceptance or rejection of the aforementioned traditional and progressive role portrayals. This latter variable will be subsequently addressed.

Self-Schema and Sex Roles

In an attempt to understand individuals' evaluations of and reactions to products and promotions, researchers have tried to identify individual "personality" variables related to sex roles likely to influence their perceptions (Allison, Golden, Mullet, and Coogan 1979; Alreck, Settle, and Belch 1982; Gentry and Doering 1977; Gentry, Doering, and O'Brien 1978; Golden, Allison, and Clew; Morris and Cundiff 1971). These personality variables have been generally referred to as an individual's sex-role orientation or sex-role self-concept and were subsequently measured using a variety of instruments, including Gough's (1952) California Psychological Inventory (CPI) Fe-scale (Aiken 1963; Fry 1971; Gentry and Doering 1977; Gentry, Doering, and O'Brien 1978; Morris and Cundiff 1971; Vitz and Johnston 1965), Spence's et al. (1974) Personality Attributes Questionnaire (PAQ) (Gentry and Doering 1977; Gentry, Doering, and O'Brien 1978; Gentry and Haley 1984), and Bem's (1974) Sex-Role Inventory (Allison, Golden, Mullet, and Coogan 1979; Golden, Allison, and Clew 1977).

Gough's CPI Fe-scale examines masculinity and femininity on a continuum using 38 true-false items. The PAQ treats masculinity and femininity as two separate dimensions and individuals can be classified as masculine, feminine, androgynous (those receiving high scores on both the masculinity and femininity scales), or low-masculine, low-feminine. Bem's Sex Role Inventory, as described earlier, is similar to the PAQ in terms of its separate masculinity and femininity scales but it differs primarily in its measurement of these dimensions. The use of one scale or another appears to have been a choice of individual preference in the studies previously cited. The choice of a scale, however,

should be directed by whether or not masculinity/femininity is unidimensional or multidimensional in nature.

Early studies attempted to relate an individual's masculinity and femininity to their product choices and found positive associations. Individuals classified as masculine (feminine) were likely to smoke cigarettes with a masculine (feminine) image (Fry 1971; Vitz and Johnston 1965). Based on these findings, more recent studies explored the relationship between a person's masculinity-femininity and perceptions of products (Allison, Golden, Mullet, and Coogan 1979; Alreck, Settle and Belch 1982; Gentry and Doering 1977; Gentry, Doering, and O'Brien 1978; Gentry and Haley 1984; Golden, Allison, and Clee 1977), activities (Gentry and Doering 1977; Gentry, Doering, and O'Brien 1978), brands (Gentry and Doering 1977), and promotions (Alreck, Settle, and Belch 1982; Gentry and Haley 1984). The relationship between an individual's sex-role orientation and their attitudes, perceptions, or usage patterns is not yet clearly understood. Some researchers have found that gender is at least as important as an individual's sex-role self-concept in affecting perceptions of products (Allison, Golden, Mullet, and Coogan 1979; Golden, Allison, and Clee 1977) and more important in predicting attitudes and behavior (Gentry and Doering 1977; Gentry, Doering, and O'Brien 1978). Others provide evidence that an individual's gender schema affects recall of gendered ads (Gentry and Haley 1984). Gender schema in this study was operationalized with Markus' et al. (1982) categorization scheme in which individuals are classified as feminine schematics, masculine schematics, or aschematic. Markus (1977) defines self-schema as "cognitive generalizations about self, derived from past experience, that organize and guide the processing of self-related information contained in the individual's social experiences" (p. 64). It is predicted that feminine (masculine) schematics will favor feminine (masculine) stimuli in their processing of incoming information (Markus et al. 1982). Gentry and Haley (1984) exposed subjects to ads featuring masculine, feminine, and neutral products and varied the gender of the model for each product to create sex-role congruent and incongruent ads. They found that masculine females were more apt to recall ads for masculine products than their feminine counterpart, although their results were not statistically significant. They suggest that their results warrant additional research into the effect of one's gender orientation in the processing of advertising information.

The Gentry and Haley study is useful in that it begins to address the interaction between a product's gender and a model's gender but it appears to be limited in two respects. First it focused only on one measure of advertising effectiveness--recall. As mentioned earlier, other measures of advertising effectiveness also warrant attention. In addition, it might be useful to operationalize sex-role traditional and modern portrayals in a more blatant fashion. Print ads featuring a male and female model with masculine and feminine products may not be stimulating enough to evoke sex-role congruent or incongruent images, especially when the accompanying wording focuses only on the features of each product. The models may have been perceived as decorative and functionless. Future studies might depict men and women delivering testimonials for the gendered products, thus linking the model and product in terms of a usage situation. This latter inquiry would be in line with the contention of previous researchers who have suggested that a product's gender image is related to the gender of individuals most likely to use the product. Such portrayals may draw greater attention and be evaluated in a manner consistent with gender schema theory.

Conclusion

Researchers have made considerable progress in broadening our understanding of the effects of changing sex roles on consumers' perceptions of products and promotions. It is clear, however, that marketers are in need of additional information regarding promotional strategies, product positioning strategies, and with respect to individuals to whom their strategies are aimed. An integrated research

effort which examines the synergistic effect of these variables should be undertaken if we are to deepen our understanding of how individuals respond to changing sex roles.

SEGMENTATION OF WOMEN'S MARKET BASED ON
PERSONAL VALUES AND THE MEANS-END CHAIN MODEL:
A FRAMEWORK FOR ADVERTISING STRATEGY

Ved Prakash, Florida International University

Abstract

The purpose of this paper is to examine the various bases for segmentation of women's market. Thereafter a conceptual framework is presented for the application of personal values (Rokeach Value Survey) and means-end chain model for identification of an advertising strategy. For hypothetical purposes Bartos' (1977, 1978) classification of women's market is used as the basis for segmentation. As a result of the hypothetical application of the means-end model for two products i.e. fashion clothing and automobiles, relevant benefits of the two products are identified. Suggestions for advertising strategy are offered; limitations of the study and directions for further research are provided.

Background

Marketers need to identify segmentation variables based on changing demographics, lifestyles, values and expectations of women (Joyce and Gultinan 1978; Lazer and Smallwood 1977). An examination of literature on women's market shows that only in recent years have the consumer researchers begun to conduct detailed examination of the basis of segmentation. Since the 1970s increasing attention has been paid to women's career orientation. The literature on women's segment can be classified into three categories. The earlier studies only compared working women with non-working women. Examples of this category include Anderson (1972), McCall (1977), and Joyce and Gultinan (1978). McCall (1977) compared working and non-working women and found differences with respect to a number of buyer behavior activities. Joyce and Gultinan (1978) conceptualized three categories of women i.e. housewives, non-professional working women and professional working women, and found significant differences with respect to retailing activities.

The second category of studies looked at the attitudinal (political) orientation of women. Douglas and Urban (1977) classified women on two lines i.e. traditionalist versus liberated and found significant differences between the U.S. and France. Reynolds, Crask and Wells (1977) divided women into Modern vs. Traditional lines and found Modern women to be more independent and pragmatic. Venkatesh (1980) divided women into three categories based on Arnott's (1972) Feminism Scale i.e. Feminists, Moderates and Traditionalists. He found significant differences in life style and magazine readership. The major problem with this type of segmentation is that it overlooks the employment status of women and motivation for work.

The third category of studies takes into account the employment status and motivation. Bartos (1977, 1978) went beyond the simple division of working wife vs. non-working wife. She presented a four-way classification: Stay at Home (29%), Plan to Work (20%), Just a Job (32%), and Career-oriented (19%). This classification was based on Yankelevich Monitor Survey at the time and Bartos found significant differences among the four groups with respect to travel, financial and shopping activities. Schaninger and Allen (1981) developed a three-way classification: Non-working Wife, Low Occupational Status and High Occupational Status. This classification is similar to Bartos' in that Low Occupational Status corresponds to the Just a Job type and High Occupational Status corresponds to Career-oriented women. Schaninger and Allen could predict differences among these groups with respect to food, beverage and alcohol consumption, make-up usage, clothing purchases, shopping behavior, media proneness, media wage,

major and minor appliances. Nickols and Fox (1983) posited that income was a better predictor than occupational status for time-saving strategies. Stroeber and Weinberg (1977) and Weinberg and Winer (1983) found wife's employment status to be not related to family's time saving durables. Joag, Gentry and Hopper (1985) maintain that occupational status of the wife is insufficient for prediction of buyer behavior; consequently it is important to consider the work overload and motivation to work. These authors added another dimension i.e. homeward orientation vs. outward orientation to the classification suggested by Schaninger and Allen. Joag et. al. have not presented any empirical evidence for their scheme.

Research Gaps

There is no one best classification of Women's segment and many gaps remain in the area. First, none of the studies have examined various occupations of women i.e. sales, technical, managerial, academics and explored the differences in personal values. Secondly, except for the self-reports on attitudinal survey, there is no objective method of identifying segments. Thirdly, even for the segmentation schemes offered so far no effort has been made to explore the personal value structure on the lines suggested by Rokeach (1973); it is important to study the value structure in order to study the goals of employment. Finally, no attempt has yet been made to develop an advertising strategy based on personal values and means-end model (Gutman 1982).

Women's Segment, Value Structure and Means-End Approach: A Conceptualization

Personal values can be an important basis for segmentation; Personal Values can differ due to age, income, education, sex and social class (Rokeach 1973). Rokeach Value Survey (RVS) a popular methodology, consists of eighteen Terminal Values and eighteen Instrumental Values. Terminal Values e.g. Happiness, Sense of Accomplishment, Comfortable Life are enduring desired modes of existence. Instrumental Values e.g. being Capable, Forgiving, Broad-minded are modes of behavior and are susceptible to change because of the socialization process. It is also possible that differences due to social class, income, education and self-concept would create differences in priorities placed on values by different women.

Just as personal values have antecedents they also have consequences e.g. impact on brand evaluation and choice criteria (Howard and Woodside 1984). Values also impact problem recognition, search for information, brand belief and ultimately brand preference. The impact of values can be visualized as follows:

Values impact choice criteria and are instrumental in determining benefit segmentation (Pitts and Woodside 1984) 1984). Empirically it has been shown that due to the differences in values, ethnic groups differ in product attribute perception of fashion clothing and automobile (Prakash 1984).

We can now draw on Gutman's (1982) means-end chain model.

According to this model, ends are the valued states e.g. Comfortable Life, Exciting Life and products are the means to satisfy those values. In the context of women's market, it may be hypothesized that a study of the personal values can help in the development of an advertising campaign. We will first review the segments suggested by Bartos and hypothetically identify the value structure for each segment. This will be followed by a review of the means-end-chain model and its application for fashion clothing and cars.

Women's Segment and Value Structure¹

The reasons for picking Bartos' (1977, 1978) Segmentation Scheme, i.e. stay at home, plan to work, just a job and career-oriented are as follows. First, this scheme combines occupational status with motivation to work and consequently it can be tied to the value structure. Secondly, this scheme is intuitively appealing from female perspective is our conclusion based on indepth focus group discussions. This scheme is also similar to Schaninger and Allen (1983) and Joag et al (1985) classification. The disadvantages of Bartos' classification are as follows. There is no objective method of measurement of the segments. The classification is based on attitudinal self-reports. Secondly, this scheme ignores income as a criteria; according to Nickols and Fox (1983) income is an important variable for time saving devices. Thirdly, the category of career-orientation is too broad; there could be further segmentation based on various types of careers. Bartos' scheme is selected because of simplicity, convenience and presentation of a hypothetical application of means-end model. The following identification of values is hypothetical based on focus group interviews. In an empirical study the respondents would have been asked to rank 18 terminal values and 18 instrumental values from the Rokeach Value Survey. Thereafter some type of cluster analysis would be performed to examine segmentation differences. Alternatively, one could look at the rank scores and perform analysis of variance to evaluate the differences.

The following is a hypothetical composite of the demographics of each segment along with values extrapolated from the Rokeach Value Survey.

Stay at Home

Even though these women have no intention of working, they may at one time have been in the workforce, either before marriage or thereafter. They have no desire to change their life patterns, but some of them perceive it to be fairly limited. They are the oldest segment with more than half of them being over 50 years. This segment makes up approximately two-thirds of the total housewife segment.

This segment (based on age and social class) is likely to have less than high school education. It predominantly belongs to lower or working class (Coleman 1983). The life-style of this group is mainly traditional. Their lives are primarily bound by family and children. They have a somewhat lower self-concept and a defeatist attitude. They may sometimes long to be in the working woman's shoes in order to achieve self-fulfillment, may envy the latter's wardrobe, stimulating life and independence. On the other hand, they may perceive working women to be neglecting children and housework. They may describe themselves as kind, sociable, below the average in dominance, intelligence, broadmindedness and a sense of humor. Their buying style does not permit much advance planning. They are cautious and brand loyal. They have a mild interest in style and admit being persuasible. They are found to be far less involved in financial activities than the other segments. They are the heaviest viewers of daytime TV, second to "plan to work" in primetime viewing and listen to very little radio.

Based on the preceding description, the following Rokeach values were identified by the focus group to be important for this segment.

¹The discussion in this section is mainly based on Bartos (1977,1978,1981), Rokeach (1973) and Coleman (1983).

Terminal Values

- Family Security
- Comfortable Life
- Self-Respect
- Salvation
- True Friendship
- National Security
- Inner Harmony

Instrumental Values

- Loving
- Self-Controlled
- Cheerful
- Forgiving
- Obedient
- Helpful
- Polite

Plan to Work

Some of the 'plan to work' housewives find that being a homemaker is personally rewarding. They are committed to their role as housewives but they also like to earn money. The plan of the working housewife carries some characteristics of the career woman. They make up the youngest segment with a median age of 32 mostly in the range of 25-24 years of age. They are probably similar to Venkatesh's liberated group with few of the traditional/moderate values thrown in.

The educational profile of plan-to-work women is similar to just-a-job and career-oriented segments. They are slightly more likely to have graduated from college and to have completed high school education than just-a-job women. Assuming that most marriages take place into the same social class, because of the educational characteristics, it may be assumed that this group of women would mainly belong to middle and upper middle classes.

Women in this segment are athletic, cultured and energetic. They also allocate time for personal gratification and future career development. Their sense of the self is expressed in wanting to appear neat and attractive for self-pride. These women are a little more impulsive than "stay at homes". They are involved in financial activities similar to career women but to a lesser degree. They take an active role in shared decisions in the purchase of big ticket items such as cars. They are the heaviest viewers of primetime television and second heaviest readers of magazines (next to career women). This group is second behind career women in the purchase of convenience and time saving appliances.

Based on the above stated description from Bartos (1981), Venkatech (1981), and Coleman (1983), the following Rokeach Values were identified by the focus group for this segment.

Terminal Values

- Comfortable Life
- Exciting Life
- Social Recognition
- Family Security
- Self-Respect
- Sense of Accomplishment
- Equality

Instrumental Values

- Broadminded
- Responsible
- Ambitious
- Loving
- Capable
- Imaginative
- Intellectual
- Forgiving

Just a Job

This group makes up about 60% of the working women. They are not terribly involved with their jobs, but either enjoy the social aspect of self-fulfillment of working, or work due to economic necessity. They usually finish high school and possibly some college, although to a lesser degree than plan to work or career women. The median age of this group is about 36, but a high ratio fall into ages below 25 and over 50, indicating a trend toward remaining at home during the child-rearing years which is confirmed by Yankelovich's claim that there is a movement from "plan to work" to the "just a job" category. Just a job women fall below career women in household income, but based on education/occupation factors, we may expect them to be found mainly in the working and middle classes. They correspond to low-occupational status category of Schaninger and Allen (1981).

This group appears to be split between traditional/moderate and liberated viewpoints. The just a job woman may be described as trustworthy, kind, refined, stubborn,

broadminded and affectionate. They are more concerned than career women with economy but are the least brand loyal and most experimental. They are responsive to new products and competitive promotional campaigns. They along with career women are likely to buy on impulse. They make an average use of financial services except investments where they are below average. They are independent decision makers in the purchase of large ticket items such as cars. Just a job women are a captive market for those using radio as an advertising medium.

Based on this information, the following Rokeach Values were identified by the focus group for this segment.

<u>Terminable Values</u>	<u>Instrumental Values</u>
-Comfortable Life	-Broadminded
-Exciting Life	-Cheerful
-Sense of Accomplishment	-Self-Controlled
-Social Recognition	-Independent
-National Security	-Responsible
-True Friendship	-Polite
	-Forgiving
	-Honest
	-Loving

Career-Oriented Women

They are professionally or technically trained women with a future in their career. Over 55% of them have attended or graduated from college. The median age of this segment is the same as that of "just a job" but they are more likely to be between 25 and 34 years of age. The implied viewpoint of this segment is likely to be liberated/moderate under the Venkatesh study. This group is the most affluent with 60% of those married to the most achieving men. It may be assumed that they are found in the middle, upper middle and lower upper classes (Coleman 1983). This group corresponds to high occupational category of Schaninger and Allen (1981) and Joag et al (1985).

Career women enjoy home surroundings a characteristic of the higher social classes and are brought up with the expectation of living in an orderly fashion. They usually purchase items that allow for convenience without loss of quality. The career women plan their shopping (more so on big ticket items) probably due to time constraints and are cautious and brand loyal. They do impulse shopping in order to reward themselves. They take a strong interest in grooming and style, mostly to maintain a social image. They are athletic and health conscious and are principal consumers of natural cereals.

Career women are the most active users of financial services and are the most likely to have purchased themselves the big ticket items such as a car. They are a prime target for travel both for business and pleasure. They are not heavy viewers of television. They are the heaviest readers of magazines and newspapers, the most active listeners of radio and heavy viewers of outdoor advertising. They may describe themselves as having a strong self-image, trustworthy, kind, refined, broadminded, efficient, intelligent, frank, self-assured, relaxed and creative.

Based on the above stated description, the following Rokeach Values were identified by the focus group for this segment.

<u>Terminable Values</u>	<u>Instrumental Values</u>
-Comfortable Life	-Imaginative
-Exciting Life	-Intellectual
-Sense of Accomplishment	-Independent
-Self Respect	-Ambitious
-Social Recognition	-Broadminded
-Inner Harmony	-Capable
-Mature Love	-Honest
-Wisdom	-Loving
-World of Beauty	-Self-Controlled
-Freedom	-Responsible

The means-end chain model establishes a framework to explain how products are the means to consumers' achievement of desired values. This model offers marketers a method of positioning products by associating product attributes (means) with benefits (consequences) that lead to the satisfaction of values (ends).

The means-end model developed by Gutman (1982) has four underlying assumptions:

1. values are dominant factors in the purchase pattern of consumers
2. consumers group products based on function to satisfy values
3. all actions have consequences (desirable or undesirable)
4. there is a link between consequences and product attributes

Gutman's model is developed on the premise that there are two major links in a consumer's cognitive map:

1. values are linked to consequences since consequences are given positive or negative valence depending on values
2. consequences are directly connected to product attributes since consumers will purchase the products they perceive will produce desirable benefits (consequences)

The linkages when combined have a common terminus i.e. values. Therefore, the basis of the model becomes the product attribute→consequence→value construct.

Based on the preceding model, we propose that the grouping of Rokeach Values within each of the four Bartos' segments would allow concentration on the centerpiece of the model i.e. consequences, in the development of advertising strategy for the target segments. Values, having been predetermined for a segment, become known variables with consequences and attributes being unknown. By utilizing techniques such as repertory grid (Kelly 1955), laddering (Gutman and Reynolds 1979), and product categorization (Gutman and Reynolds 1977, 1979), marketers can focus on the desirable consequences resulting from appropriate product attributes. The advertising message can emphasize the attributes that will help achieve valued end-states and ultimately lead to customer satisfaction.

Illustration of the Means-End Chain Model

To illustrate the model incorporating the previously mentioned value groupings by segments for women's market, two products have been chosen: fashion clothing and automobiles. The set of matrices included at the end of this paper should be referenced to facilitate an understanding of the following analysis.

Fashion Clothing

To draw out the differences among the segments based on the grouping of values, consequences were held constant for the four segments. Values were taken from each segment based on a subjective association with the product class. Assuming that respondents were subjected to a method such as the repertory grid to ascertain level distinctions, a set of consequences similar to those in the attached matrices would be developed. A +1 or -1 is assigned to show the relationship between consequences and values.

In the case of fashion clothing, the following consequences were developed based on a focus group discussion: self-expressive, feel unique, easy care, affordable, personal comfort, practical/lifestyle and classic. These consequences were related to the respective values for each segment. A perusal of this set of matrices shows that for the stay at home segment, the highest consequence is that of easy care which is related to the values of comfortable life, self-respect and inner harmony. The other minor

consequence is affordable which is related to the values of comfortable life and self-control. The "plan to work" segment is high in the consequences of feeling unique and being self-expressive; these consequences are tied to the values of an exciting life and self recognition. The "just a job" group also prefers the consequences of feeling unique and self-expressive. However, the strongest link is with the value of an exciting life. The "career" segment puts a high emphasis on enjoying a classic look, feeling unique and being self-expressive due to the values of being intellectual, imaginative and having an exciting life.

For this product, situations had to be considered as inputs into the system due to the different occasions for which one may purchase fashion clothing. Therefore, the second set of matrices (one for each segment) ties consequences to the situations. Some situations for which women may purchase fashion clothing are listed at the top of the second set of matrices; these are: leisure, sports, in the home, entertaining, appointments, party, evening and meeting. In the matrices the consequences are listed with the algebraic sign determined in the first set of matrices. To indicate the consequences that are relevant to specific situations a 1 is placed in the corresponding square. The column for the situation of interest to the marketer is transferred to the top headings of the third set of matrices which connects the consequences (benefits) to the relevant product attributes. Assuming that a marketer were interested in gearing an advertising message to the "stay at home" segment for fashion clothing to be worn in the home situation, the product attributes to be stressed would be wash and wear, without detailed design and be flexible (i.e. can clean in, lounge in) connecting to the consequences (benefits) of easy care, personal comfort and practical lifestyle. An advertising strategy geared to the "plan to work" segment for fashion clothing to be purchased for a party situation should emphasize the attributes of separate garment, pieces to mix and match tying to the benefit of feeling unique; and also highlight new colors and wash and wear for consequences of self-expression and easy care respectively.

For the situation of entertaining, the "just a job" group is interested in receiving the same benefits as the "plan to work" group is for the party situation. However, the relevant benefits (consequences) have been ranked differently, exhibiting a difference in priority. Therefore, the advertising strategy for fashion clothing aimed at the "just a job" segment would first emphasize new colors, then wash and wear, followed by separates for entertaining. Using the example of an evening out situation for the "career" category, a marketer would target this segment best by featuring product attributes of high styling, followed by current fad and new colors, tying to the benefits of classic, feeling trendy and self-expressive.

Automobiles

For the product category of automobiles it was necessary to construct two matrices for each of the four segments. The first matrix focuses on the values and consequences level to determine what the product class can do for the consumer. The second matrix (for each segment) focuses on the group level to uncover product attributes. The purchase of an automobile is not affected by situations but rather by economic status, social class and life cycle. Therefore, situations as inputs into the system are not used. To draw out differences among the segments based on grouping of values, consequences were held constant for the four segments. The following consequences were identified for cars with the help of focus group interviews: feeling safe, economical, affordable, feel stylish, personal comfort, and practical/lifestyle.

A look at the first set of matrices shows that the "stay at home" puts high importance on feeling safe, being economical and enjoying personal comfort consequences. These benefits relate to the values of family security, comfortable life and inner harmony. The "plan to work" group enjoys an automobile that is practical for their lifestyle,

economical and safe relating to the values of comfortable life, family security and responsibility. The "just a job" segment would prefer the characteristic consequences of sporty, stylish and economical which ties to the values of independence, a sense of accomplishment and social recognition. In comparison the "career" woman ranks high on feeling sporty, stylish and enjoying personal options connecting to the values of intellectual, independence, sense of accomplishment and social recognition.

Transferring the highest ranked consequences to the second set of matrices for each segment, the relevant consequences are related to product attributes. Based on these matrices, the "stay at home" group would receive the greatest benefits from a medium sized car that has low maintenance, high mileage and is sturdy. These are the attributes to be stressed in an advertising message aimed at "stay at home" women. If the advertisers were interested in attracting "plan to work" women, they would gear advertising to emphasize compact yet plenty of room, sturdy, low maintenance but high gas mileage cars. To capture the "just a job" market, the marketers should advertise the qualities of compact, low maintenance, high gas mileage and a sleek design. The "career" oriented women would prefer luxury and sleekness in either a compact or a large car.

Implications for Advertising Strategy

Reynolds and Gutman (1984) show the importance of means-end model for promotional strategy. Basically the identification of values, situations and benefits helps in the development of ad campaign and slogans. For example, for the stay at home segment the important values are family security, comfortable life and self-respect. The plan to work woman values comfortable life, exciting life and social recognition. To the just a job segment important values are comfortable life, exciting life, and sense of accomplishment. Similar values are important to the career women as well. In product attributes stay at home enjoys personal comfort, feeling safe, being practical and economical in clothing. Plan to work desires to feel unique and self-expressive in fashion clothing and enjoying personal comfort in car. The "just a job" wants a sporty car a self-expressive fashion clothing in linking to an exciting life. The "career" woman desires a stylish sporty/luxury car and fashion clothing that is classic and trendy, which connects to the values of sense of accomplishment and exciting life.

This approach also helps decision on media, budget allocation and communication objectives. Through the process of laddering (i.e. hierarchical ordering of consequences and benefits) one can try to improve involvement for low involvement products (Gutman 1982). Finally this methodology helps in the development of marketing mix.

Here it is appropriate to compare the method described with some other methods of benefit segmentation (Myers 1976). In other methods of benefit segmentation multi-dimensional scaling or cluster analysis is performed on product attributes preferences. Those approaches are more quantitative and scientific. On the other hand the main characteristic of the means-end model is its qualitative approach giving freedom to management in decision making; the analysts in this approach moves slowly toward a hierarchical ranking of consequences in situations and establishing priorities. The means-end approach is simpler. The main disadvantage of this approach being relative lack of quantitative data. Of course, the major limitation of the present paper is that it is a conceptual study and no data is presented. This paper, however, provides guidelines for a future empirical study and we are in the process of implementation and data collection. A set of matrices is presented below as an illustration of the technique.

Abstract

There are a number of marketing problems which have emotional aspects, such as product scares, ad affect, etc. In order to enhance the understanding of such problems, the present study investigates the role of subjective feeling states on a person's judgments within the theoretical framework of associative network model of memory. The influence of experimental manipulation of affect induced by a product scare story on evaluations of various products is examined. The results are consistent with a memory based model of affect.

Effects of Affect on Judgment About Products

There are a number of pervasive marketing problems that are neither well studied nor understood. One such problem is product scares like McDonald's worms rumor (Tybout, Calder, and Sternthal, 1981) and the Tylenol scare. We do not know whether or when the negativity generated about product X will influence only that product or generalize to other products, such as Burger King or Anacin.

A similar problematic area arises with advertising issues such as ad placement, and emotion in advertising. How and when the mood created by a prior program segment, a prior commercial, or affective context of a commercial will influence the response to the critical message are questions that are not well understood.

The problems mentioned above have something in common: an emotional aspect. However, until recently there has not been much research interest in emotions. Relying on cognitive psychology, which has attended to its narrower task of explaining 'cool' thinking" (Simon 1982, p. 342), may fail to provide sufficient explanation for marketing issues with emotional aspects. Therefore, we need research on these marketing problems which are not well understood. Furthermore, a theoretical framework is needed to enhance understanding of why and how affective states influence responses and hence to provide useful knowledge about managerial implications. The present study addresses this need for a basic understanding of how affect is processed and how it affects judgment.

Theoretical Issue

The purpose of the present study is to investigate the role of feeling states on a person's judgment within a theoretical framework. The construct of interest is defined as "immediate affective state." Affect is used as a generic term here. A definition that is modified from Simon (1982) is: affect, emotion, and moods designate states and processes in the cognitive system, autonomic nervous system, and the endocrine system. Mood or feeling refer to affect that provides context for ongoing thought processes without noticeably interrupting them. This subtle affective state is the construct of interest here.

To investigate the role of affective states on judgment, a number of questions need to be addressed: 1) How are feeling states represented? and 2) What is the process by which affect influences judgment? Some recent theoretical views have emerged in the last few years concerning these questions.

I wish to thank Bobby Calder and Brian Sternthal for resources and thoughtful comments.

Two approaches are discussed below. One is the "common processes" view (Clark and Isen 1982; Bower 1981; Bower and Cohen 1982). According to this view, affective and cognitive systems involve common processes, and are similarly represented in memory. Feeling states interact with and operate within the organization of thoughts. This approach argues that affective and cognitive systems are interdependent and provides a specification of how the two systems interact. Common processes view is based on "accessibility hypothesis": an affective state can function like an organizing unit as a cue to prime related cognitive material. This hypothesis implies that affective tone may be an important dimension of cognitive organization. Different models of accessibility, derived from different models of memory (network models of Collins and Quillian 1969; Collins and Loftus 1975; and distributed memory models of Eich, 1985; Murdock, 1983; Smith, et al. 1974; Tversky 1977 where items are represented as ordered sets of features) may provide explanations for how affect functions as a retrieval cue. Among these models of accessibility, a widely accepted one is "spreading activation in an associative network." Although there are many other models of retrieval, spreading activation is the example chosen here because of its prevalence in the literature.

According to the network model of memory, concepts are interconnected by associations. The associative network is a large connection of nodes, which are independent units. The spreading activation process, in the associative network, makes particular portions of the net selectively accessible for recall. When a concept is attended to, a node is stimulated. Activation spreads out along portions of the network associated with that node, in a decreasing gradient (Anderson and Bower 1973; Collins and Loftus 1975). In a recent version of this theory (Anderson 1983) spreading activation defines working memory. Spreading activation identifies and favors the processing of information most related to the immediate context or sources of activation.

Various nodes or elements—an element that encodes an environmental stimulus and a goal element serve as sources of activation. For example, the instructions of an experiment define a goal for the subject. Retrieval process involves refocusing which refers to selecting a subnode of a concept for focus of activation and focusing on a subset of facts about that concept. The notion of goal as a source of activation as well as the mechanism of refocusing on subnodes enable Anderson's ACT* model to activate almost any portion of the network selectively. Thus, modern spreading activation models are consistent with many patterns of activation, both specific and global.

Some nodes in the associative network represent feeling tones (Bower 1981). An aroused emotion spreads out activation, priming related concepts, words, and inference rules. An emotion becomes associated to coincident events and can later act like a retrieval cue. Research evidence that feeling states can cue retrieval of material in memory is provided by a number of studies (Fisher and Marrow 1934; Weingartner, et al. 1977; Isen, et al. 1978; Bower, et al. 1978; Teasdale and Fogarty 1979; Laird, et al. 1982).

Whereas Bower (1981) argues that affect is a node in the associative network, there is another way to view emotion that is prominent in the literature. It is termed "functional independence." According to this view affective and cognitive systems are represented differently, and affective states may be independent of

cognitions (Zajonc 1980; Zajonc and Marcus 1982, 1984; Zajonc, Pietromonaco and Bargh 1982). The motor system can represent information independently of other forms of mental representations.

Functional independence approach represents the "somatic" view of emotions: discretely different patterns of neurophysiological activity, independent of cognitive appraisal, is capable of generating emotions (Izard 1982 and Leventhal 1979). This view is concerned more with the somatic expression of emotion, and suggests that emotion is an experience which has immediate meaning for the person.

Wilson (1979) offers impressive evidence for a functional independence view. He reports that melodies presented five times were liked better than melodies never heard, even though subjects could not discriminate the former from the latter for familiarity. Although this effect appears congenial to a functional independence position it should be noted that a compelling explanation for why familiarity or exposure increases preferences has not been provided: "We have never been sure why exposure has positive effects" (Zajonc and Marcus 1982, p. 125).

A recent study addressed these opposing views in an attempt to test the spreading activation hypothesis (Johnson and Tversky 1983). They report that experimental manipulation of affect induced by a brief story of a tragic event produced a pervasive increase in the respondent's estimates of frequency of risks. This effect was independent of the similarity between the story and the estimated risk such that all estimates, not necessarily related to the mood inducing experience were mood congruent. For example, reading a story about a person dying from homicide not only influenced estimates of deaths from homicide but also estimates of deaths from floods. Johnson and Tversky (1983) suggest that a local (only the risk that matches the story topic being influenced) or a gradient effect (risks closely linked to the story being affected more than unrelated risks) would have indicated that the mood effect was dependent on memorial associations. They argue that the finding of global effects (all responses, unrelated and related to mood producing event are influenced by the mood), in the absence of specific effects (local or gradient mood effects) is supportive of the functional independence view. However, several alternative explanations for their findings can be provided.

There are a number of methodological and theoretical problems in the Johnson and Tversky study. One problem pertains to the plausibility of a demand characteristics explanation. If some intervention influences non-treatment variables as well as treatment variables, then a suspicion for demand emerges. The subjects might just be reacting to the demand of the situation and not to the intended intervention. Another methodological problem is the operationalization of the dependent measures: open ended frequency estimates may involve a very large within-group variance which may mask between-group differences.

A major theoretical problem is the limited variety of the risk estimates. The span of risks does not provide enough range for a fair test of the spreading activation hypothesis. Another theoretical problem is with regards to data interpretation. Johnson and Tversky's results can be interpreted within the spreading activation framework: the story activates a general emotion node which is strongly linked to fatalities and different causes of death. When the feeling node is activated all the associations with that node are also activated. A homicide story activates a "depressed" node which is connected also to the "flood" node. So, "flood" thoughts as well as other death thoughts are activated. In addition to the emotion node as a source of activation, goal element and other contextual cues may refocus activation on a number of elements such as superordinate nodes or specific subnodes. For example, giving a number

of risk estimates before a particular one activates many nodes all of which are linked to "fatalities." The goal of estimating fatalities also activates the set of all events linked to the "fatalities" node. Estimating frequency of deaths due to a particular event, "flood", refocuses the goal element on both "fatality" node and "flood" subnode, and elements of these structures become sources of activation. Frequency estimates of "flood" would be biased by what is in the working memory: mood congruent flood episodes and other fatal events including homicide. Thus all estimates will be influenced by the homicide story, resulting in a global mood effect. Specific effects could have been obtained if homicide-flood link were very weak or not focused on or if the goal element were mainly focused on "flood."

Hence, both global and specific effects appear to be consistent with the spreading activation mechanism because of context dependent sources of activation and the process of refocusing for further activation. The present view involves inclusion of emotion nodes in a network of associations where an Andersonian (1983) selective, context dependent activation mechanism operates. According to this interpretation, lack of a specific effect in Johnson and Tversky's study does not necessarily imply that the impact of mood was independent of the strength of association between story and risks and does not falsify the "common processes" view of affect. Especially in light of the difficulties involved in testing for global versus specific effects it seems premature to reject the spreading activation view. Thus, another study is needed to test the spreading activation notion. The current study investigates whether activation from a feeling node spreads along portions of the network of associations with that node, in a decreasing gradient. Specifically, the question of whether mood will influence all the judgments, even judgments unrelated to the cause of the mood (global effect) or only the judgments associated with the cause of the mood (specific effect) is examined. Common process view would predict a specific effect (local or gradient) whereas the functional independence view would predict a global effect.

Overview of the Experiment

This study investigated the influence of affective states on judgments about products. The stimuli and measurement were designed to alleviate three problems identified with Johnson and Tversky's paradigm: 1) Numerous products were chosen to provide a wide range of associations for a fair test of the gradient hypothesis, 2) To reduce demand, cover stories attempted to conceal the relationship between mood induction and judgment task, and 3) To eliminate high within group variance that existed in risk perception and thus to improve statistical power, scaled measurements were used.

To induce affect, brief stories about lethal effects of a toxic residue in a specific beverage were constructed. Three possible effects of exposure to a mood-evoking story on evaluations of various products (discussed below) were considered: compared to control group baseline, 1) a local decrease—for only the focal beverage in the story, 2) a generalization gradient—decreased evaluations of beverages related to the focal one, and 3) a global decrease for all product (beverage and non-beverage) evaluations.

Stimuli

Stories

Two affective stories were written and pretested to be credible and worry/fear provoking. To maintain information content constant, the stories were exactly the same except for the product they referred to: bottled orange juice or wine. The neutral story was about test marketing for Citrus Hill orange juice; it had

appeared in Advertising Age. All stories were about the same length, type-set, and presented as if they were clipped from a newspaper.

The Set of Products

Four groups of products were chosen to tap different associations with the target beverage. One set includes objects of different similarity with, and in the same category as the focal products—orange juice and wine, namely six beverages. Bottled orange juice, grapefruit juice, instant coffee, bottled cola, beer and wine, in that order of proximity, were the beverages selected based on the results of cluster analysis and multidimensional scaling performed on beverage similarity data. However, category relationship is not the only type of association that may be retrieved. Thoughts evoked by the story may also be associated with nonbeverages. The second set of products included nine foods that either were ingredients of or complemented orange juice or wine.

The third set included four products that had no cognitive association to the target beverages but had an emotional relationship, i.e., they were products (such as household insecticide) that make people worried. The fourth set consisted of fillers, completely unrelated to the target beverages.

These products have different implications in terms of the hypotheses. If mood effects are local, only the evaluation of focal beverages should be influenced. Evaluation of beverages of differing degrees of proximity provides a test of the gradient notion within the object category. Second and third sets of products provide a test of the extended gradient notion; and the fourth set provides a test of global effects.

Sample

Forty five male and female students at Northwestern's Graduate School of Management served as subjects. They were paid \$5.00, each, for their participation. They were processed individually or in groups of two or three.

Design and Procedure

When the subjects arrived at the laboratory they were told that they would participate in two surveys: one conducted for a newspaper to investigate readership and interest in different types of journalism, and the second to find out product opinions as a part of a market research. These instructions were intended to reduce demand characteristics.

Subjects were given a questionnaire entitled "Newspaper Reporting Study." Affect manipulation was introduced by varying the story subjects read in this questionnaire. Subjects were randomly assigned to one of the three story conditions: fear evoking story about orange juice or wine and neutral story. Filler questions about readership (presented before the story) and story ratings with respect to interest and quality of writing were also included. Subjects indicated how involved the story makes the reader (not at all: 1/very: 7), and were asked to list five adjectives to describe how the story made the reader feel. The last two questions served as manipulation checks.

Following the completion of this questionnaire, subjects were presented with a second questionnaire entitled "Marketing Research Survey," containing the dependent measures. Participants were asked to evaluate each of the randomly ordered products on five seven-point semantic differential items: good/bad, reputable/disreputable, valuable/worthless, pleasant/unpleasant, something I would be willing/unwilling to buy. Finally, subjects indicated their gender and frequency of target beverage usage (never: 0/everyday: 4).

Thus, the experiment involved two independent variables: affect (between-subjects factor) and degree of proximity of products (within-subjects factor). Fifteen participants were assigned randomly to each of the three story conditions. Product evaluation served as the dependent variable.

Manipulation check

The adjectives listed to describe feelings were classified by a scheme generated from Plutchik's (1970) categorization of emotions. Once they were coded, the number of adjectives indicative of fear, worry, and apprehension were recorded. χ^2 tests indicated that experimental groups listed more fear/worry adjectives than the control group. 26.7%/86.7% of the subjects who read the orange juice scare story and 40%/73.3% of those who read the wine scare story indicated that they felt afraid/concerned or apprehensive whereas nobody/6.7% of those in the control group felt so: $\chi^2(2)=7.2$, $p=0.03/\chi^2(2)=22.3$, $p=0.0$. Control subjects mostly responded with adjectives like informed, aware, indifferent, and bored.

T-tests indicated that subjects who read orange juice scare and wine scare stories felt more involved ($\bar{X}=5.07$ and 5.00, respectively) than the control group ($\bar{X}=3.07$): $T(28)=4.19$, $p=0.0$, and $T(28)=3.85$, $p=0.001$, respectively.

Thus, the number of fear/worry adjectives and the responses given to the involvement question revealed that the stories effectively induced the intended emotion.

Results

Affective state did not have any effect on the evaluations of three sets of products: foods, emotionally related objects, or fillers. Hence, analyses of their ratings will not be discussed. The evaluative scales, composed of five items for each beverage, were reliable (Cronbach's α 's were 0.79, 0.80, 0.80, 0.88, 0.89, 0.92). Mean of each subject's response on the five items was used as an evaluation score. Means and standard deviations of evaluative scores of each beverage, categorized by treatment, are shown in Table 1.

TABLE 1

MEANS AND STANDARD DEVIATIONS FOR BEVERAGE EVALUATIONS CATEGORIZED BY THE TYPE OF STORY

Evaluations	Story					
	Orange Juice Scare Story		Wine Scare Story		Neutral Story	
	Mean*	Standard Deviation	Mean	Standard Deviation	Mean	Standard Deviation
Bottled Orange Juice	2.11	0.63	2.11	0.97	2.45	0.96
Bottled Grapefruit Juice	2.63	0.90	2.96	1.27	3.85	1.34
Instant Coffee	4.45	1.79	3.29	1.45	4.95	1.36
Bottled Cola	3.37	1.07	2.77	0.95	3.13	1.29
Bottled Beer	3.27	1.45	3.87	1.78	3.44	1.95
Bottled Wine	2.31	0.75	3.01	1.47	2.32	1.24

*Smaller numbers indicate more favorable responses.

A profile analysis treating beverage evaluations as an ordered within-subjects factor and type of story as between-subjects factor indicated a multivariate interaction between beverages and story: $F(10,78)=1.84$, $p=0.068$ / $F(10,210)=2.37$, $p=0.01$, with averaged test of significance using sequential sums of squares. This analysis suggested that affective state induced by a story did not influence ratings of all the objects, rather its effect depended on the type of beverage evaluated.

Separate analysis of variances of beverage evaluations revealed story effects only for grapefruit juice ($F(2,42)=4.29$, $p=0.02$) and coffee ($F(2,42)=4.51$, $p=0.017$). A priori contrasts indicated that subjects who had read either an orange juice scare or a wine scare story rated grapefruit juice more favorably than the control group: $F(1,42)=8.02$, $p=0.007$; and $F(1,42)=4.26$, respectively. Coffee evaluations were more positive in the wine scare story condition than in either orange juice scare story $F(1,42)=4.21$, $p=0.046$) or control ($F(1,42)=8.56$, $p=0.006$) groups. Thus, a respondent worried about wine evaluated grapefruit juice and coffee more favorably, and one worried about orange juice rated grapefruit juice more positively than a control subject.

Individual differences in consumption habits for the beverage in the story may mediate subjects' evaluative responses. Hence, frequency of drinking the target beverage was used as a covariate. Analysis of covariance did not significantly change the results for the beverage evaluations except for wine. Hence, analyses of the other dependent variables will not be discussed. When the effect of frequency of consumption of the focal beverage was partialled out, a story main effect was obtained on wine evaluations: $F(2,41)=3.97$, $p=0.027$. A priori contrasts indicated that subjects who read a wine scare story rated wine less favorable (adjusted $\bar{X}=3.17$) than the control group (adjusted $\bar{X}=2.0$): $F(1,41)=7.62$, $p=0.009$. Thus, when the effect of individual differences in consumption habits on wine ratings was removed statistically, a subject feeling apprehension towards wine (having read a wine scare story) evaluated wine less favorably than a respondent in a neutral state. This finding suggests a local mood effect.

Discussion

This study failed to replicate Johnson and Tversky: a global effect was not obtained. Mood induction did not affect all the responses of a subject indiscriminately; evaluations of only three products that were in the same category as the target object were influenced. Category membership implies cognitive relationships. Thus, the results suggest that mood effects were somehow dependent on the association between the responses and the cause of the affective state. The existence of a story by beverage interaction supports this suggestion too.

The findings that the treatment influenced evaluations of only three products, and that of those three two were in the opposite of the expected direction, rule out a demand explanation.

However, the overall pattern of the results were puzzling. First, a local effect was obtained only for wine but not for orange juice ratings. Orange juice may be a product towards which there are strong positive attitudes. In another study very favorable evaluations were detected; some subjects even described it as an "all American drink." A speculation may be that in the absence of any negative thoughts stored about orange juice, retrieval primed by a temporary negative affective state could not have made any mood congruent associations available.

Second, a gradient effect was not obtained. If structural proximity were the association which carried activation, orange juice scare/wine scare story should have made grapefruit juice/beer ratings less favorable

than a neutral story but did not.

On the other hand, the story by beverage interaction, the local effect on wine evaluations, as well as the reverse effects on grapefruit juice and coffee suggest that mood effect is dependent on relationship between the target and the evaluated object, but that the nature of this relationship may be something other than categorical proximity. Characteristics of grapefruit juice and coffee suggest two types of association between the target and the evaluated object. One possible relationship may be that of substitutability. Even though coffee was not the closest beverage to wine in pre-experimental similarity analyses, both are mature, adult drinks that have an acquired taste (Levy 1984).

An alternative interpretation is also plausible. The data indicated that grapefruit juice and coffee were the beverages most negatively rated by the control group. A post hoc comparison, using Scheffe 0.95 confidence interval revealed that evaluations of these drinks were less favorable than the aggregated ratings of the other beverages. Thus, the relationship may be evaluative similarity to affect congruent target object thoughts. Then the subject might deliberately disregard, for example, bitter taste, and consider relative benefits of coffee over lethal wine. This may be done with an experimental goal of alleviating a negative state so that he could give objective product ratings.

Why were Johnson and Tversky's (1983) global effects not obtained here? It cannot easily be attributed to the differences in mood induction because any stable phenomenon should persist despite method variation. Besides, the induced moods were probably very similar: 1) both studies used stories, with exactly the same cover, only the topics varied, and 2) both inductions seem to have lead to worry and fear. If at all, a slight difference may be in apprehension aspects in the present study versus depressive aspects in Johnson and Tversky's. To account for the discrepant results, one would have to argue that even slightly different moods are processed differently—a possible but nonparsimonious explanation.

Two other explanations seem more likely. One may be the greater likelihood of demand characteristics in Johnson and Tversky's study than in the present one. And the second is the existence of some unknown mediator, such as structure, levels, and kinds of associations in the memory.

Hence, it appears that global mood effects are not so reliable or stable. Mood can also have other effects, such as the local effect obtained here. Lack of a pervasive global effect leads to rejection of the functional independence view of affect. Although the results do not provide conclusive support for the common process view-memory-based model of affect, the findings of local mood effect on wine evaluation and story by beverage interaction are congenial with this view.

The results also suggests a more complicated process than was predicted. Further studies are needed to specify the underlying knowledge structure as a mediator, and provide stronger tests of the spreading activation mechanism. Goals and refocusing can be manipulated to create conditions under which specific versus global effects would be obtained. Furthermore, network models have mostly been tested in simple recognition or recall tasks. There may be a need to use different types of research paradigms to test these models for affective nodes and in judgment tasks.

James A. Muncy, Texas Tech University

Abstract

Two competing theories have developed which relate to the nature of affect. The present paper discusses some of the consumer behavior implications of the evidence presented by the proponents of these two competing theories. These implications relate to the storage of affect, the role of affect in memory, and the relationship between affect and physiology.

Introduction

One of the primary topics of interest to consumer researchers is that of consumer preferences. Much of the research in consumer behavior focuses on how preferences develop and how these preferences affect the consumer choice process. Almost by definition, these preferences have been assumed to be affectively based. Although few would deny that there exists a relationship between affect and preference, there has recently developed a major debate in the literature (particularly in psychology) as to the nature of affect. Historically, it has been assumed that affect is "post-cognitive." This means that affect occurs as a result of (and therefore after) cognition. In 1980, Zajonc proposed a "separate systems" view of affect which challenged this basic assumption. Thus, two competing theories have developed which differentially explain the nature of affect: the traditional or "post-cognitive" theory of affect and the more recent "separate systems" view of affect (some key articles in this debate are Baars 1981; Birnbaum 1981; Lazarus 1981, 1982, 1984; Mellers 1981; Rachman 1981; Slife 1981; Watts 1983; Zajonc 1980, 1981, 1984; and Zajonc and Markus 1982).

Zajonc's separate systems perspective of affect and cognition is based on three primary propositions.¹ The first is that affect and cognitions are controlled by two separate systems in the brain. Though these two systems can affect one another, they are generally believed to operate independently. The second proposition is that affect is not necessarily post-cognitive. This does not imply that affect cannot result from cognitive processing (no one denies that affect can be post-cognitive). It simply states that affect can result from causes other than cognitive processing. The third proposition (one that can be refuted without the whole theory being rejected) is that affect is primary. This implies that a person's primary reaction in a situation where affect and cognitions come into conflict is the affective reaction. This can be seen in the dilemma often faced when one states "my thinking tells me do one thing but my feelings tell me to do something else." In such a situation, the person's typical problem is to stifle his or her primary reaction (i.e., do what he or she "feels") so that he or she can do the "rationale thing" (i.e., what he or she thinks).

As stated earlier, this separate systems view is opposed to the more traditional view which assumes that affect is always preceded by and occurs as a result of cognitive processing. Most consumer behavior models fall into this post-cognitive tradition. The only consumer behavior models which could be found that explicitly allow affect to either parallel or precede cognition were Ray's (1973) dissonance attribution hierarchy and Bagozzi's (1983) affect response, parallel response, and social response models.

The exact mechanics of these post-cognitive models of affect vary but they are typically decompositional. By

¹Zajonc actually presents several propositions regarding affect. The three selected seem to be the ones which are central to the debate and germane to the field of consumer behavior. Thus, only these three are discussed.

being decompositional, they typically divide an idea or object into component attributes. By somehow utilizing a set of beliefs that pertain to the object or idea being evaluated (which are cognitive in nature), a person derives an affective reaction to that object or idea². The most researched decompositional models in consumer behavior are the multiattribute models of attitude (for a review of this class of models, see Lynch 1985).

It is unlikely that this debate will soon be resolved. First, there are definitional barriers to its resolution. As pointed out by Izard, Kagan, and Zajonc (1984) there is no generally accepted definition of either affect or cognition. One could solve this debate by simply defining affect and cognition in such a way that they either are or are not, by definition, related. However, as Izard, Kagan, and Zajonc point out, this does little to advance our understanding of either affect or cognition. If one does not simply define away this problem, there are many complex definitional issues which must be addressed before any viable solution can be proposed. Secondly, there are several complex operational issues that must be addressed in this area. Presently, one cannot unequivocally show the absence of cognitions. Without doing so, it is impossible to refute the traditional theory of affect. Thus, it does not appear as though an acceptable resolution of this debate is in the immediate horizon. Even without such a resolution, however, some issues have surfaced in this debate which should be of interest to consumer researchers. The present paper discusses some of these issues. But before this is done, it is necessary to look in greater depth at what is meant by the term "affect."

Defining "Affect"

As indicated earlier, there is no universal agreement as to a definition of affect. However, any discussion of the relation of affect to consumer behavior must be clearly rooted in an explicit definition of affect. Since the present discussion focuses on the evidence presented in the debate surrounding Zajonc's separate systems view of affect and cognition, it seems fruitful to define affect in a way consistent with his conceptualization. One problem in doing this is that Zajonc does not explicitly define affect. One must infer such a definition from what Zajonc does say.

Though Zajonc does not explicitly define affect, he does make a clear statement as to what types of "feelings" he wishes to explore and what types of "feelings" he wishes to ignore. He states:

The class of feelings considered here is that involved in the general quality of behavior that underlies the approach/avoidance distinction. Thus for the present purpose, other emotions such as surprise, anger, guilt, or shame which have been identified in the literature and extensively analyzed by Tomkins (1962, 1963), Izard (1977), and others are ignored. (p. 152)

From this brief quote, two implications can be drawn as to what Zajonc means by the term "affect." First, it appears as though Zajonc views affect as a type of human emotion. Secondly, it is clear that he does not wish to include all

²It must be noted that not all cognitive models fall into this decompositional mold. In fact, Lazarus' (1981, 1982, 1984) arguments against Zajonc's separate systems view of affect are based, to a large extent, on his position that these types of models do not accurately represent cognitive processing.

human emotions under his discussion of affect; he is interested only in those that explicitly (and perhaps exclusively) relate to approaching or avoiding an object or idea.

Since Zajonc appears to view affect as a form of emotion, it seems reasonable to conclude that it would possess the characteristics of an emotion. Izard, Kagan, and Zajonc (1984) state that it is generally agreed that three components of emotion are "neurophysiological/biochemical, motor or behavior expressive, and subjective/experiential" (p. 3). Thus affect, as discussed by Zajonc should have some physiological basis, be expressed in behavior, and be individualistic and evaluative in nature.

To come up with a definition of affect with which to evaluate the separate systems view, these three components must then be incorporated with the approach/avoidance distinction. This approach/avoidance distinction adds two additional elements to a definition of affect: 1) it appears as though affect is object or idea specific (i.e., the object or idea that is being approached or avoided) and 2) affect appears to have a valence component (i.e., the tendency to move towards or away from an object or idea).

With all of this in mind, a working definition with which to evaluate the claims of the two theories of cognition and affect would be as follows:

Affect is an individualistic, physiological based predisposition to behave either positively or negatively towards an objective or idea.

It is interesting to note that this definition of affect does not deviate substantially from definitions of attitudes present in the literature (e.g., Fishbein and Ajzen 1975). The difference between the current definition of affect and previous definitions of attitudes is two-fold. First, the current definition does not require affect to be "learned" (though it does not say that affect is not "learned"). Secondly, it states that affect is physiologically based (thus, introducing the distinction between "hot" and "cold" cognitions). Since the study of attitudes has become a key topic in consumer behavior, it appears as though affect, as defined here, should also be of interest to consumer researchers.

Looking at the Evidence Without a Verdict

With this working definition of affect, the present paper is now ready to investigate some of the implications of the affect/cognition debate for consumer behavior thought. The three particular issues addressed by the present paper are: 1) the role of memory in affect, 2) the role of familiarity in affect, and 3) the relationship between affect and physiology.

Affect and Memory

Much of the research in this area would indicate that affect and cognitions are stored separately in the brain (for an excellent presentation of this position, see Fiske and Taylor 1984, pp. 35-36). An example of how this might occur can be seen in the field of social cognition. When two people meet and interact, usually an affective based evaluation is formed (i.e., the people develop some feelings of liking or disliking for each other). At some later point in time, either person can probably state if he or she liked the other person (i.e., the affective reaction), regardless of whether or not he or she can remember the specifics of the interaction (i.e., the basis for the affective reaction).

If it is true that affect and cognitions are stored separately, then a corollary to this proposition is that affect can develop at the time of encoding and not just at the time of decoding. Most cognitive based models of consumer behavior seem to assume, at least implicitly, that affect occurs at the time of decoding. Figure 1 illustrates this difference. The first model presents the typical consumer behavior approach. It assumes that consumers search for information and store that information

in memory. At the point of the decision, the consumer retrieves from memory (via internal information search) this information. This information is then used to form a preference. The second model presents an alternative interpretation of this process. It shows that affect is developed (perhaps as a result of cognitive processing) and then stored in memory (separate from the basis of this affect). At some later point, when the person is forced to behave based on the preference, the feelings are recovered from memory (not necessarily with the basis of these feelings).

The differences between the models presented in Figure 1 are not trivial. The traditional model would imply that there should be a close correspondence between information in memory and evaluations that are presumably made based on this information. As Lichtenstein and Srull (1985) point out, most psychological theories of persuasion make such an assumption. However, they also point out that the empirical evidence to date has not supported such an assumption. People do not always have access to the basis for their evaluative judgment. This finding is problematic for the traditional model presented in Figure 1; however, it creates no problem for the alternative model.

FIGURE 1

Two Competing Models of Affective Storage and Usage

Model A (The Traditional Model)

Model B (An Alternative Model)

Here it is interesting to note that models have developed which propose that presented information is stored separately from interpreted information (see Beattie and Mitchell 1985). Such models assume that the presented information is stored in episodic form and the interpreted information is stored by fitting it into the existing semantic structure. In such cases, the interpreted information (which is integrated) should be retained much longer than the original information (which is stored episodically). Both models presented in Figure 1 imply that the affective based evaluations occur as a result of interpreting incoming information. However, the second model would imply that the evaluations and the information on which the evaluations are made are both stored in memory. If the models of memory discussed by Beattie and Mitchell are accurate, then one would expect affective judgments (stored in memory through integration) to remain in memory longer than the information (stored episodically) which caused these judgments.

The above discussion implies that it is likely that a consumer may have strong affective based judgments stored in memory even when he or she is not able to remember the

basis for the evaluation. This, of course, presents a major obstacle when studying such evaluations. There may be reasons for assuming that, even when consumers want to, they often cannot tell a researcher why they prefer one store or brand over another.

Another implication of the alternative model presented in Figure 1 relates specifically to the role of memory in the consumer choice process. The term used in consumer behavior for the process by which a person retrieves something from memory is "internal information search" (e.g., Bettman 1979). The implication is that the consumer is searching memory for "information" (which has definite cognitive overtones). In fact, the consumer may be searching his or her memory for feelings and not cognitions. The implication is that consumers engage in memory searches and these are not necessarily "information" searches.

Familiarity and Affect

One of the primary empirical arguments presented by Zajonc for his separate systems view of affect is that mere exposure can cause an affective reaction. This newly formed affect is usually positive and is present even when there is no detectable change in the person's ability to remember the exposure (Harrison 1977; Kunst-Wilson and Zajonc 1980; Moreland and Zanjoc 1977, 1979; Wilson 1979; Zanjoc 1968).³ Though this mere exposure effect may not prove that affect and cognitions are indeed separate systems (see Birnbaum 1981; Birnbaum and Mellers 1979a, 1979b; Gordon and Holyoak 1983; Mellers 1981; Mandler and Shebo 1983; and Obermiller 1985), it does have interesting implications for consumer behavior.

Many advertising campaigns appear to be very effective in altering consumers' preferences, even when they have little if any relevant information content. The research cited by Zajonc would indicate that people form preferences (e.g., a brand preference) simply on the basis of familiarity. If this does occur, then it makes sense for an advertiser, in the absence of real product differences, to affect preferences through exposure. This certainly does not explain all of advertising's effect, but it does deserve further research.

Familiarity has been investigated in consumer behavior. The type of familiarity typically discussed refers to the amount of prior experience with or knowledge about a product or product class (for a discussion of common definitions and operationalizations of familiarity, see Sirgy 1981). The present discussion centers on a different meaning of the word "familiarity." The familiarity discussed here is more akin to the idea of recognition. Copeland in his classic 1923 article hypothesized a relationship between this type of familiarity and consumer buying habits. He hypothesized that, in the absence of perceived brand differences, the consumer will make a choice on the basis of "consumer recognition" which he defined as "an acquaintance with the general standing of the brand" (p. 287). The evidence presented by Zajonc seems to support the reasoning of Copeland.

Affect and Physiology

The major difference between the definition of affect presented earlier and common definitions of attitudes (e.g., Fishbein and Ajzen 1975, p. 6) is that affect is "physiologically based." It is obvious that the simple statement that affective preferences are "physiologically based" is inadequate since even cold cognitions certainly have a physiological bases somewhere in the central nervous systems. If this definition is to be adequate, there must be some way of differentiating the physiological

³It should be noted that the mere exposure effect does not appear to be as simple or as universal as one might conclude from reading Zanjoc (1980). There have been attempts that have failed to replicate the mere exposure effect under similar but not identical conditions (see Mandler and Shebo 1983 and Obermiller 1985).

basis for "cold cognitions" from the physiological basis for affective preferences. The present section briefly discusses the unique physiological aspects of emotion and a few implications of the physiological nature of emotion.

The most compelling arguments for a separate systems view of cognition and affect come from studies in physiological psychology. Izard (1984) notes that:

The case for considering emotions as a separate system seems fairly well established at the neuro-physiological-biochemical level. At this level, it is well known that some brain structures, neural pathways, and neuro-transmitters are relatively more involved than others with emotion expression, emotion experience or feelings, and emotion related behavior. (p. 19)

It is well established that emotions (one of which would be affect as defined earlier) have a strong physiological component. One need only look at the synonym for emotions -- "feelings" -- to see this connection. The term feelings implies that something is occurring in the persons physiological system. Any adequate theory of affect must address this physiological basis of emotion.

Much of the work on the physiological aspects of emotion has focused on its interaction with the autonomic nervous system. The autonomic nervous system is that portion of the nervous system that controls survival functions. The autonomic nervous system has historically been divided into two parts: the sympathetic nervous system which is primarily responsible for heightened activity levels and the parasympathetic nervous system which is responsible for maintenance, repair, and resource conservation (Bruce 1977). Generally it has been the sympathetic division of the autonomic nervous system that has been implicated in emotional behavior (for easy to read reviews of this interrelationship between the autonomic nervous system and emotion, see Sigg 1975 or Lang, Rice, and Sternbach 1972).

It is interesting that the strongest physiological effects of affect seem to occur either in the autonomic nervous system or in the bodily organs which are controlled by the autonomic nervous system. This becomes important when one notes that most of the work on classical conditioning has focused on unconditioned and conditioned responses which are also controlled by the autonomic nervous system. Though classical conditioning is not exclusively tied to the autonomic nervous system (McSweeney and Bierley 1984), the majority of evidence in this area shows that classical conditioning also has its strongest and most significant effects on those aspects of the body which are controlled by the autonomic nervous system. Since the autonomic nervous system seems to be a common ground for both affect and classical conditioning, then it is possible that affect might often have its bases in classical conditioning.

The idea of emotions being classically conditioned is not totally new. In 1947, Mower described emotions (with particular emphasis on fear) in terms of conditioned responses. Recently, researchers have begun to further investigate the role of classical conditioning in emotion. For example, Grings (1983) argued that "the conditioned stimulus is not so much a signal of what is to come as it is a new stimulus with a modified affective tone" (p. 205). Though all of the evidence is not in, it is likely that classical conditioning can be at the root of a wide range of human feelings--including consumer preferences. At this point in time, there is evidence to suggest that affect may result from classical conditioning (which, it could be argued, is not cognitive in nature). Since this is only speculative at this point, the need definitely exists for more research in this area.

Another implication of the link between affect and physiology relates to the idea of consumer drives. Many consumer drives are physiologically based (e.g., the drives associated with food products). If affect is interrelated with physiological events, then it is likely that preferences may change as physiological changes occur in the

consumer's system. It is well documented that nutrition deficiency can dramatically alter an animal's food preference (for reviews of this phenomenon know as "specific hungers", see Overman 1976 and Rozin and Kalat 1971). In consumer behavior, this type of effect can be seen in the advice that a person should never go grocery shopping when he or she is hungry. The danger is that the hunger drives could distort the consumer's preferences for certain foods. There may be a conflict between thinking and feeling and the feeling may win out. This is one example of how consumer preferences for some products (e.g., food products) could possibly vacillate because of physiological changes. Empirical work is needed which would investigate changes in preferences as a function of physiological changes, both in the realm of primary needs (e.g., food) and in the realm of secondary needs (such as love or companionship).

Summary and Conclusion

One of the most significant debates in contemporary psychology centers around the relationship between affect and cognition. The present paper discussed some of the most obvious implications of this debate. This debate has raised some intriguing issues for consumer researchers. As a starting for research in this area, the present paper has poisted a set of specific hypotheses that can be derived from the evidence presented in his debate. In proper form, these hypotheses can be stated as follows:

- H1: A stimulus will affect a consumer's preference at the time of encoding and at the time of decoding;
- H2: Under certain conditions, the bases for consumer preference formation will be inaccessible even when the preferences themselves are readily accessible;
- H3: Under certain conditions, consumer preferences can result from simple familiarity with an object;
- H4: Under certain conditions, consumer, preferences can occur simply as a result of classical conditioning;
- H5: Under some conditions, consumer preferences can change as a result of physiological changes.

These hypotheses provide specific direction for future research. It is clear that research is needed that will show that these hypotheses either possess or lack validity. In addition, the "under some conditions" clauses of these hypotheses need to be addressed. The key question here is "under what conditions?"

It is hoped that this paper will encourage researchers to take a closer look at the relationship between cognition, affect, and consumer preferences. Though it may be premature to conclude either that affect is always post-cognitive or that affect can occur independently of cognitive processing, consumer researchers should address some of the issues which have recently emerged in the debate surround the relationship between affect and cognition. The role of affect in consumer preferences is probably much more significant and much more varied than contemporary consumer behavior theories would suggest.

CONSUMER RESPONSE TO MARKETING STIMULI:
THE RELATIONSHIP BETWEEN AFFECT, COGNITION, AND BEHAVIOR

Carol Pluzinski, The University of Michigan¹
William J. Qualls, The University of Michigan²

Abstract

This paper presents a dynamic framework for consumer response models that focuses on 1) the relationship between the constructs of interest (i.e., cognition, affect, behavior), and 2) the systemic properties of such an organization. The framework is an attempt to reconcile at the theoretical level the seemingly incompatible research positions currently held at the empirical level of analysis.

Introduction

The tripartite construal of psychological experience has dominated consumer research for more than three decades. Based upon three components of cognition (thinking), affect (feeling), and conation (behavior) this conceptualization has formed the foundation of several consumer behavior and communication response models used in marketing (Colley 1961, Lavidge and Steiner 1961, Krugman 1962, Howard and Sheth 1969, Ray 1973, Smith and Swinyard 1982). While most researchers will agree with a tripartite division of consumer psychological experience, an on-going debate regarding the order in which the three components are arranged continues to surface in the research literature (Zajonc and Markus 1982, Van Raaij 1984, Sternthal 1984).

We propose that this research problem cannot be resolved by remaining at the empirical level of analysis. Rather we must now consider the theoretical meaning of the disparate empirical results by abstracting the essence of the problem to a higher level of analysis. This requires framing the problem conceptually rather than empirically. Therefore a more dynamic framework will be presented under which previous models can be subsumed, and which focuses on the nature of the relationship between the components rather than addressing the perfunctory question of temporal order.

This relationship will be described in terms of three general properties: iteration, parallelism, and complementarity. These properties are actually processes which will serve to define the boundaries of the framework. The present paper presents a framework which argues for a process orientation, rather than an outcome oriented model of consumer response.

First, a brief overview of consumer response models which addresses the difficulty in establishing their validity at the empirical level will be presented. Next an alternative, more global conceptualization of cognition, affect and conation will be developed, the rationale for which will be provided by the New Physics. Finally, the implications of such a framework for consumer research will be discussed.

Consumer Response Models

Traditionally, most models of consumer behavior have assumed some awareness or cognitive state prior to an affective or behavioral response (Engel and Blackwell

¹ Doctoral Candidate, The University of Michigan, The graduate School of Business Administration, Ann Arbor, Michigan 48109.

² Assistant Professor of Marketing, The University of Michigan, The graduate School of Business Administration, Ann Arbor, Michigan 48109.

1982, Howard and Sheth 1969, Lavidge and Steiner 1961, Ray 1973, 1982). This cognitive dominated paradigm of consumer response holds that response order is based upon COGNITION--->AFFECT--->CONATION. However, many researchers have begun to question the appropriateness of such an approach for understanding all types of consumer behavior (Kassarjian 1978, Olshavsky and Granbois 1983, Isen 1984).

Alternatively, a growing body of research argues and presents evidence suggesting that AFFECT, which is activated first, influences thought processes (COGNITION) which subsequently direct an individual's behavior (CONATION) (Zajonc and Markus 1982, Van Raaij 1984). Finally a third stream of research contends that behavior precedes both affect and cognition. This implies that individuals often exhibit behavior in response to marketing stimuli without actually thinking or considering their feelings (Nord and Peter 1980). Although empirical support exists for each of the alternative configurations, researchers continue to debate the "correct" order of response (particularly with regard to the affect/cognition primacy question).

Yet further progress or resolution is inhibited because the proponents of each response sequence ordering subscribe to vastly different paradigms, or world views, which cannot be reconciled at the empirical level (Kuhn 1962). Perhaps the investigation of the relationship between these components would be more fruitful. Hence the study of the nature of the interaction process among the three components requires a higher level of analysis and a broader framework from which to understand the relationships.

Consumer response models suffer from the following problems which make them seem incompatible at the empirical level. First, the models conceptualized and tested in the literature are essentially variations of the same hierarchy-of-effects process (Colley 1961, Lavidge and Steiner 1961, Krugman 1965, Ray 1973). In this way they are unidirectional and static, reflecting a serial processing bias which implies that consumers are passive rather than active in response to their environment. Second, the temporal relationship of cognition, affect, and conation has never been fully explicated. As such, the dominance of the observed effect may be an artifact of the experimental design. Details regarding this point will be presented later in the paper.

Most models have operated under a cognitive activated paradigm; that is, cognition serves as the primary activator and moderator in the consumer response process. Recently, such cognitive models have come under attack and have been severely criticized for failing to recognize a more important role for both affect and behavior. Finally, an additional weakness with respect to consumer response models arises as a result of past research failing to develop standardized conceptualizations and operationalizations of the models' components. As a result researchers must still resolve such issues as whether or not there is a difference between recall and comprehension, and whether behavioral intentions or executed actions should be employed as the measure of behavior. Even more confusing has been the variation in the manner in which affect has been conceptualized, both as an attitude (which itself is comprised of affect, cognition, and conation, c.f. Fishbein and Azjen 1975) and as an evaluative judgment or a feeling state.

To help shed some light on these issues, we suggest a more global framework of consumer response incorporating

systemic properties of how the components are related, as well as the theoretical boundaries which set the limits of the process. Thus the framework attempts to explicate the components' boundaries, as well as to provide a more definitive conceptualization of the relationships between the model's components. This framework allows iterative steps as well as parallel processing, alleviating the dependence upon a sequential single component activated paradigm. After providing philosophic support, the remainder of this paper will elaborate on the characteristics and systemic properties of the proposed framework. Further justification for such a framework will be based upon evidence that has been presented in the literature.

In Support of Broader Framework

Since affect, cognition, and behavioral intention are unobservable variables, we may do well to follow the methodology of the New Physics (c.f. Zukav 1979). For example, subatomic particles are not only unobservable, they are not really particles at all in a material sense; and in this way they are much like the latent constructs we analyze as consumer researchers. The New Physics recognizes the subjective nature of our perceptual experience, as well as the notion that we cannot observe something without changing it. The problem of how to measure a particle is an illustrative example. A subatomic particle can be characterized by both position and momentum, but the two properties cannot be accurately measured at the same time. We can choose to measure both, but in doing so we sacrifice accuracy; or we can choose to measure one property precisely, at the expense of knowing nothing about the other (Heisenberg's Uncertainty Principle).

Zukav (1979) explains that because it is the nature of things that we can know either the momentum of a particle or its position, but not both, and because we must choose which of the properties we want to measure, we are actually creating certain properties by the very act of choosing to measure them. Similarly, the measurement of a consumer's response is influenced by the point at which the researcher chooses to close the system and determine the initial point of response. If reality is defined by the nature of the researcher's experimental design, then the component order which results becomes a mere experimental artifact. For example, if we define cognition as including the prerequisite processing stages of transducing sense data into information, then by definition cognition precedes an affective response and behavior. On the other hand, if affect is defined as a primary visceral response that we experience before we consciously know how to label it, then affect precedes cognition and behavior.

In order to execute an empirical investigation we must close the system, holding some variables constant while others are chosen to vary. Thus reality is dictated by methodology and our results have meaning only within the specific system for which they were constructed. If we accept the argument that temporal order is experimenter-induced, we are now left with the task of "making sense" of the data. Olson and Peter (1984) suggest that researchers must question the theoretical meaning of their results. In this way we move from a narrow empirical level to a broader conceptual level of analysis. Because concrete effects (at the empirical level) have very little intrinsic meaning, we should seek to develop abstract theoretical meanings so as to enhance the generality of those meanings and thus their usefulness (Olson and Peter 1984). Thus the framework presented here is consistent with contemporary philosophic views in that it accounts for the subjectivity of empirical findings, yet provides a unifying conceptual analysis in order to promote a consistent research program.

A Dynamic Communication Response Framework

The framework proposed here differs from earlier models in that the process of consumer response can be activated within the system at one or multiple points, and move

throughout the tripartite process in either direction. We propose that three processes best describe the way in which the (cognitive affective and conative) response components are related to each other. In particular, the framework which is proposed postulates that iterative, parallel, and complementary processes function alternately in linking the response model's components. An individual does not necessarily have to complete connections with each of the components, but in fact may just cross between two components in an iterative process. For example, when deliberating about a product decision, a consumer may cycle between a thinking state (cognition) and a feeling state (affect). This may be the typical for consumers who cannot make a decision because they are torn between what they consider rational behavior and the way they actually feel (i.e., the household that needs a family car although the husband really wants a Corvette).

FIGURE 1
A DYNAMIC COMMUNICATION RESPONSE FRAMEWORK

Conversely, two components may simultaneously activate a third component as the result of parallel processing that has occurred. Such is the case of a purchaser whose thoughts (cognition) place him/her behind the wheel of the Corvette while he/she is physically in the process of signing the purchase contract (behavior), which brings a joyous smile to his/her face (affect).

Similarly, two components can complement each other in their impact upon a third component. For instance, the strength of our feelings (affect) may determine how we think (cognition); how we think may strengthen how we feel, thereby inducing a stronger behavioral response. These scenarios presented above represent only three of the possible ways in which affect, cognition, and conation may be related. Examples such as these clearly point out the need for a more robust framework if researchers are to understand and explain the dynamic phenomena of consumer response to marketing stimuli.

Theorizing does not take place in a vacuum. Rather our theories, methods, and results are based upon unstated assumptions about how we think the world works. As argued by Bristor (1984) these underlying assumptions are often inadvertently incommensurate, and so meaning becomes obscured. Thus, in order to help clarify the nature of the construct order debate, we will first discuss the theoretical boundaries of the three constructs.

Cognition, Affect, and Conation

Over the years, the components of the tripartite model have taken on varying definitions, with affect being the most ambiguously defined. Affect has been conceptualized variously as feeling, emotion, preference, and attitude. Interestingly, a dominant school of thought regarding attitude uses the entire tripartite, defining attitude as a combination of affect, cognition, and conation (Fishbein and Azjen 1975). In the present framework, affect is considered as evoking a form of experiential feeling or emotional response. Affect is intended to represent a more global measure of evaluation and is not meant to reflect specific affective responses. Recent research

into the conceptualization of affect suggests that it may be composed of primarily perceptual reactions to external stimuli occurring without awareness or interpretation (Leventhal 1979, 1980, Zajonc 1980, Zajonc and Markus 1982). Advertisers have long held that, at the very least, advertising messages impact the way consumers feel rather than the way they think or behave.

Conversely, cognition has been construed as thoughts, beliefs, or any of a number of brain-related activities associated with perception, memory, and/or learning. While earlier communication response models have made a distinction between conscious (attentive) and preconscious (perceptual pre-attentive) cognitive activity, the present framework accommodates both conscious and preconscious cognitions.

The third component, conation or behavior, is possibly the easiest to understand as it is defined as purposive action. A classic example is operant conditioning which suggests that the probability that a behavioral response will occur which can be influenced by reinforcement directly following the behavior (c.f. Skinner 1966). With respect to consumer responses, the behavior of interest is typically purchase and decision behavior. While these constructs have been shown or hypothesized to be related via a consumer response model of behavior, a unifying framework has failed to emerge.

Systemic Properties

As noted above, three properties which influence the relationships in the consumer response process include: 1) iteration, 2) parallelism, and 3) complementarity. These properties serve as rules of correspondence and as the theoretical boundaries for the relationships between affect, cognition, and conation. Based on a more holistic approach, these systemic properties define the interaction between the consumer response components (interconstruct), as well as the processing that might occur within each of the constructs (intraconstruct). Hence, when a property occurs between affect, cognition, and/or conation, it represents an interconstruct process. When a property occurs within any of the constructs, it represents an intraconstruct process. Each of these properties is discussed in turn below.

Iterative Processing. We define an iterative property as one which allows for repetitive sequential processing. For example, a script (Abelson, 1976) may be thought of as a sequence of repetitive interaction between expectations (cognitions) of behavior as well as the actual execution of behavior (interconstruct). Processing within the cognitive component (cognitive intraconstruct) is evidenced by the very nature of consumer memory itself as it is based on the notion of hierarchical interaction among the various structural forms of knowledge (c.f. Anderson and Bower 1973; Klatzky 1980, Loftus and Loftus 1976). Research in the area of information processing and long-term memory provides an excellent example of how iterative properties of cognition might relate to consumer responses. Bettman (1979) contends that consumers use information stored in memory to aid in perceiving and translating incoming marketing stimuli. Described as a process by which semantic concepts, visual images, and auditory messages are associated by way of a series of interactions, it has been suggested that such a mapping process forms the basis of all cognitive activity (Holyoak and Gick 1980).

Parallel Processing. Parallel processing assumes that two or more constructs may be activated simultaneously. That is, separate processes may occur at the same time. For example, Zajonc (1980) argues that one can have an initial emotional response to a stimulus which is paralleled by an associated behavioral (motor) response. With respect to consumer response behavior, affect and cognition may act parallel to each other without impacting either upon each other or upon the behavior. For example when a consumer hears a particular jingle or responds to a particular advertising stimulus (McDonald's Arches),

the stimulus serves as a cue for memory retrieval, while at the same time evoking the particular feeling or mood which was present when the stimulus was originally stored. We have all remembered some event and the feelings we had which are triggered by a favorite song or melody. Thus parallel processing offers another solution to the continuing debate as to whether affect precedes cognition, i.e., they may occur simultaneously.

Perceptual processing (cognitive intraconstruct) often occurs in parallel. When executing a visual search during a pattern recognition task, an advertising stimulus could be compared to many internal perceptual codes at the same time. Bettman (1979) proposes that within a choice task, the decision maker works through several different goals, not necessarily one at a time. He states, "although goals may have some natural sequencing, progress can often be made on several goals simultaneously" (p. 21). If researchers accept the argument that affective as well as cognitive operations are performed when one acquires new information, it would appear that they both could occur simultaneously, through parallel processing.

Complementary Processing. Complementarity refers to the activation of two constructs as one means to the same end. With complementary processing, one phenomena serves to strengthen the other in its impact upon a third. For example affect and cognition may act as complements to each other to then influence behavior. Empirical evidence in a series of studies by Bower (1980) demonstrates that the affective mood state at the time of encoding may influence behavior only in conjunction with information retrieved from memory.

An example of the property of complementarity in action may be found in today's innovative advertising research. When consumers are asked to view television advertising commercials, multiple measurements are made of the perceptions--one affective and the other cognitive. The cognitive measure may consist of a series of aided or unaided recall and recognition tests, while the affective measure may be based on a galvanic skin response test or pupil dilation test. In response to the ad, cognitions serve to strengthen the affective response or vice-versa.

Intraconstruct complementarity may be illustrated with an example based upon the nature of memory. It is now generally accepted that there exists two conceptually distinct types of memory--episodic and semantic (Loftus and Loftus 1976, Klatzky 1980). Tulving (1972) was the first to propose a distinction between episodic and semantic memory. Loftus and Loftus summarize this difference as: "episodic memory refers to our memory for personal experiences and their temporal relations, whereas semantic memory includes the organized knowledge we have about words and other verbal symbols, their meaning, and referents; about relationships among them; and about rules for manipulating them" (p. 120). Thus even though they are distinct, it seems clear that episodic and semantic memory must work in synergy under the auspices of the same overall memory structure and information processing system. Interestingly, this distinction between semantic and episodic memory may be of import for our understanding the relationship between cognitive and affective processes. Zajonc suggests that it may be possible to "store" affect in some way (Zajonc 1980, Zajonc and Markus 1982). This would require that affect possess some mnemonic properties. Yet, rather than ascribing to affect the properties of a totally independent processing system as Zajonc suggests, perhaps it would be better to view affect and cognition as being associated with different types of memory. Isen (1984) provides justification for this view by arguing that "affect is an experience--it feels like an experience, and its role in memory feels like that of place or time, which are also experiential" (p. 224).

Summary

This paper has attempted to describe a broader, more dynamic, framework of consumer response to marketing stimuli. The framework focuses on the functional relationships that may exist between its constituent constructs of cognition, affect, and behavior. Three systemic properties are proposed as rules of correspondence between these constructs, and the implications of these relationships associated with both interconstruct and intraconstruct processing have been discussed. Moreover, the framework emphasizes the need to abstract the current empirical problem to the theoretical level of analysis.

Justified by epistemic assumptions from the New Physics, the present conceptualization provides an organizing framework which may serve to: 1) imbue more theoretical meaning to existing empirical observations; 2) provide a foundation for a consistent program of research.

A MODEL TO EXPLAIN CHARITABLE DONATION -
HEALTH CARE CONSUMER BEHAVIOR

Jerry A. Rosenblatt, Concordia University
Alain J. Cusson, University of Sherbrooke
Lee McGown, Concordia University

Abstract

This paper deals with the choice process of individuals for making charitable donations to non-profit organizations. Specifically, a Donating Behavior Model (DBM) is proposed, to assess the criteria with which consumers base their decisions concerning giving to one non-profit organization as opposed to another. The focus of the paper is on validating the antecedent and consequent variables proposed in the model of charitable donations in the case of limited donation budgets. The results indicate that severity, involvement, predominance and alleviation are good predictors of importance, and that importance in turn is a good predictor of donating behavior.

Introduction

Charitable donations are an important issue in our society. The increasing number of non-profit organizations which conduct annual or periodic fund raising campaigns have made it difficult for the consumer to allocate his donations. As consumers do not have unlimited budgets, they must use decision strategies not unlike those required in a product choice situation. Dichter (1972) concluded that a major motivating factor for blood donors is the belief that they are probably helping themselves. It can be considered that the act of giving to any non-profit organization partly constitutes an act wherein the donor is either purchasing 'personal insurance', is attempting to alleviate personal guilt or is obtaining some other such personal benefit. Kotler (1975) posited that consumers expect an exchange process in a social marketing context similar to the exchange process implied in the classical definition of marketing (AMA 1960). The act of donating viewed in this light can clearly be viewed as an exchange process.

The present research considers that the act of contributing to any non-profit organization, and in particular to a fund raising campaign, corresponds to the act of buying. The altruistic feeling of helping others, or the feeling of security, hoping that one day the individual will benefit from the contribution, are considered potential motivators (eg. the belief that contributions to cancer research could help in the finding of a cure that could one day save that individual's life). The act of donating funds is then considered as a purchase, in that a consumer is investing in some security. It is argued that the perceived risk toward the cause defended by the non-profit organization would be very important in triggering the behavior. Perceived risk would not inhibit the buying situation, but would instead initiate the process by which the consumer would eventually make his/her decision. The contribution could then have the effect of lowering the perceived risk for that particular cause.

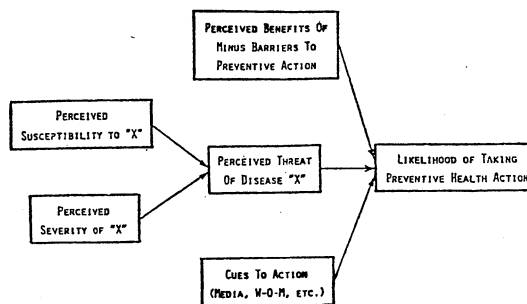

This paper proposes a Donating Behavior Model (DBM) partly based on the Health Belief Model (HBM - Becker 1974; Rosenstock 1966) and the Behavior Intentions Model (BIM - Fishbein 1967). The present model is similar to HBM in that even if the service is not performed immediately, the act of giving for a social cause implies the act of buying a service more preventative than compulsory. The HBM is thus adapted to render it more suitable to any type of non-profit organization's fund raising. It is suggested that the model could be generalized to all cases where

charitable donations (i.e. financial contributions or volunteer aid) are made to non-profit organizations.

Health Belief Model (HBM)

Rosenstock (1966) first proposed the Health Belief Model. It was derived from a value-expectancy framework in the attempt to predict the probability of an individual engaging in a preventative health care action. It was argued that three factors contributed to this decision: 1) a benefits-barriers analysis of the advantages and disadvantages of the health prevention activity; 2) the perceived threat associated with the condition or illness; and 3) various cues-to-action which include both mass media and interpersonal communications. The complete model is depicted in Figure 1.

FIGURE 1
THE HEALTH BELIEF MODEL

Oliver and Berger (1979) have noted that while this model is widely accepted among medical sociologists there are a number of problems that have not been resolved, including: a) the HBM is more a collection of variables than a formal theory or model; and b) there are serious measurement problems - it is not uncommon to find identical constructs operationalized totally differently from study to study with the same disease under consideration.

Behavioral Intentions Model

Fishbein (1967) proposed the behavioral intentions model which stated that behavior is a function of the intention to perform that behavior. Intentions are then posited to be best predicted by two components: the attitude toward the act, and a subjective norm. The complete Fishbein Behavioral Intentions Model is depicted in Figure 2.

FIGURE 2
BEHAVIORAL INTENTIONS MODEL

Oliver and Berger (1979) note that the Fishbein model has been used sparingly in the field of health care, although it has been argued that it is a good alternative to the HBM (Jaccard 1975). Results using the BIM in the field of health care have been demonstrated its usefulness. Jaccard and Davidson (1975) reported that the BIM was a valid predictive framework and more parsimonious than others. Schlegel, Crawford and Sanborn (1977) found that the addition of 33 variables exogenous to the BIM resulted in only a seven percent increase in explained variance.

The Proposed Donating Behavior Model (DBM)

Referring to the HBM and BIM, Oliver and Berger (1979) argued that,

...both models explained a statistically significant portion of the variance in behavioral intention... Consequently, practitioners can, with some degree of confidence, apply concepts in the models to the decision-making process used by their organization... In addition, researchers concerned with the most complete determination of health care decisions (eg. when an epidemic is imminent) may wish to combine further improve prediction (p.120).

This paper reports a first attempt to build a better health care/donating behavior model using variables from both the HBM and BIM as well as additional variables. The variables included from the previous models are behavioral intention, perceived severity and perceived threat. It is suggested that examining other variables including involvement, perceived possibility of alleviating the condition, perceived predominance (visibility) of the condition, and the importance for the individual of giving to a particular non-profit organization, is essential for the understanding of donating behavior. Specifically, the variables of the proposed model are:

Involvement: Valence (1981) has argued that perceived risk can be synonymous with involvement. Valence points out 6 similarity criteria with respect to involvement and perceived risk. The DBM considers an individual perceiving a certain risk associated with a particular situation to be more highly involved than an individual who perceives no risk of being affected by the situation.

Alleviation: This refers to the perceived possibility of alleviating the condition or situation with the health care action. Incorporating Dichter's (1972) belief concerning the reasons why individuals donate blood, and Kotler's notion of an exchange process, it is herein accepted that individuals attempt to maximize the utility of their health care actions (eg. donations, volunteer work). Thus, an individual would like to believe that his contribution of money or effort will in some way alleviate the actual situation as he perceives it. This construct is similar to the perceived benefits proposed by Zaltman and Vertinsky (1971).

Perceived Severity: Zaltman and Vertinsky (1971) and Becker and Maimon (1975) proposed a measure of perceived seriousness or severity of the cause. The construct is herein used in a broader sense, measuring how an individual perceives the serious of any social cause.

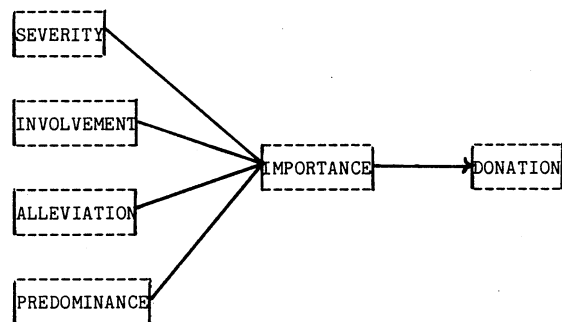

Perceived Predominance: Similar to the cues-to-action in the HBM, predominance is a way of measuring the visibility of the situation defended by the non-profit organization. It is suggested that more visible situations act as a reminder of the cause. For example, not all consumers perceive diseases or starvation as equally visible. Among diseases, some are more visible than others. The recent example of African famine is an excellent example. It appears that with the tremendously

increased activities concerning the famine in Africa, individuals are starting to act.

Importance of Giving: As in the BIM, it is important to measure the extent to which consumers want to contribute. In the HBM, only the probability of contributing is measured. The inclusion of the measure of importance makes it possible to know whether or not the consumer would contribute if they were not given easy access. In the case of charitable donations, consumers must be given the opportunity to contribute, as in regular buying situations. There is probably an inverse relationship between the importance of giving and the required level of easy access.

The entire model is depicted in Figure 3. As shown, it is believed that importance is an intermediate variable between the donation (or any health care act) and the other four predictor variables. Importance of giving is hypothesized to be determined by the severity of the situation, the predominance of the condition, the possibility of alleviating the situation and consumer involvement (as measured by perceived risk). Importance of giving, in turn, is hypothesized to be the best predictor of the health care act, in this particular situation, the amount of the charitable donation.

FIGURE 3
THE DONATING BEHAVIOR MODEL (DBM)

The importance construct is defined as the perceived necessity for a specific consumer to contribute to a non-profit organization. A consumer may consider it to be very important to contribute to cancer research, and may also consider it important (but less important) to contribute to his church. It is suggested that more of his budget would be spent on cancer research. Thus, it is proposed that consumers facing a donation choice, would rank the organization according to their perceived importance, and their donations would reflect this ranking.

It is suggested that this model is not only applicable to actual financial donations but could be generalized to giving behavior of all types and for all kinds of non-profit organizations.

Relationships Among the Variables

The relationships between the variables indicate that a consumer considers the perceived severity of a situation (eg. the severity of an illness or disease, the size of the local orchestra's deficit); the degree to which the disease or issue affects his personal life (involvement - dying from heart disease, losing the opportunity to attend live music concerts); the predominance of the situation, or the extent to which the problem is highly visible (wheel chairs, muscular problems as opposed to high blood pressure, also media visibility); and the potential to alleviate the problem with his donation (eg. feeding one child for a year in Africa with a \$25 contribution).

Given these variables, a consumer rates all possible alternatives in terms of the necessity for him to contribute. This rating then serves as the basis for the donor to divide his available budget for charitable donations.

The following section reports the results of a pilot study to test the model using financial donations to charitable organizations as the dependent measure.

Objectives of the Research

The objectives of this pilot study were three-fold:

- 1) to validate the proposed DBM;
- 2) to demonstrate that importance of giving is a good predictor of behavioral intention; and
- 3) to generalize a model that could be applied to any type of non-profit organization's fund raising campaign.

Research Method

The study was conducted in the months of February and March, 1985 in the Province of Quebec. A questionnaire was distributed to 100 individuals who were asked to complete the questionnaire in the presence of the researcher. Of the 100 questionnaires handed out, 86 were considered usable. The sample consisted of 43 males and 43 females, with an average age of 35 years, family income of over 20,000 per annum. Most were married with an average of one child.

The Questionnaire

The questionnaire was structured and contained three parts. The first section contained questions concerning previous donations. In addition, the respondent was placed in a situation wherein he/she was "given" \$100 and asked to distribute the funds among 10 charitable organizations. The respondent was told to allocate the funds in any way, and that it was not necessary to contribute to all organizations. The list of organizations is as follows:

- * Research on cancer.....\$ _____
- * Local hospital foundation.....\$ _____
- * Research on lung disease.....\$ _____
- * Research on child disease.....\$ _____
- * Local Church charity.....\$ _____
- * United Way.....\$ _____
- * Research on cardio-vascular disease.....\$ _____
- * Help for alcoholics.....\$ _____
- * Help for Third-World Countries.....\$ _____
- * Half-Way houses for women/young offenders....\$ _____

The second part of the questionnaire contained a number of questions measuring the five independent variables in the DBM. In all cases, 7-point semantic differential scales were utilized (eg. It is "very important" - "very unimportant" for me to support research into cardio-vascular disease, etc.). Other variables not related to the present study were also measured. The third part of the questionnaire contained the demographic variables previously reported.

Data Analysis

The dependent variables in the study are the amounts given to each of the non-profit organizations. Every respondent indicated the amount he/she would contribute to each of the ten charities. In addition each individual responded to the five independent measures (i.e. severity, involvement, alleviation, predominance and importance).

In order to validate the model a multiple linear regression was first used with all five independent

measures and the level of donation as the dependent measure. Next, a multiple linear regression was utilized using the four independent measures that were hypothesized to predict importance, and a simple regression using importance as the independent measure and donations as the dependent measure. Finally, a partial correlation was computed for donation with respect to the four independent measures (i.e. severity, alleviation, predominance and involvement) controlling for importance. A significant fall in the correlation coefficients would then indicate that importance would depend on the four independent variables, and that it in turn, is related to the amount of the charitable donation.

Path Analysis Procedure

A path analysis procedure is used to evaluate the model. Importance is regressed on the four proposed antecedents using ordinary least squares regression (Duncan, 1975; Wright, 1934) to determine if the independent variables account for the variance in importance. Evans (1978) and Oliver and Berger (1979) applied path analysis to BIM and HBM respectively. This technique appears to be an ideal procedure for testing the proposed model. In functional form, the investigated relationships appear in Table 1.

TABLE 1
PATH ANALYSIS FUNCTIONS

Donating Behavior Model (DBM)

$$\text{IMPORTANCE} = f(\text{Severity, Involvement, Predominance, Alleviation})$$

$$\text{BEHAVIOR} = f(\text{Importance, Involvement, Severity, Predominance, Alleviation})$$

Behavioral Intention Model (BIM)

$$\text{A-act} = f(\text{Ebiei, Enbjmcj})$$

$$\text{SN} = f(\text{Ebiei, Enbjmcj})$$

$$\text{INTENTION} = f(\text{Ebiei, Enbjmcj, A-act, SN})$$

$$\text{BEHAVIOR} = f(\text{Ebiei, Enbjmcj, A-act, SN, Intention})$$

Health Belief Model (HBM)

$$\text{THREAT} = f(\text{Susceptibility, Severity})$$

$$\text{INTENTION} = f(\text{Susceptibility, Severity, Threat, Benefits/Barriers, Cues-to-Action})$$

$$\text{BEHAVIOR} = f(\text{Susceptibility, Severity, Threat, Benefits/Barriers, Cues-to-Action, Intention})$$

Results/Interpretation

The results of the multiple regressions and the path coefficients obtained with the variables suggested by DBM are presented in Table 2.

The results indicate that the level of donation can in part be explained by these variables. All regression equations are significant at $p < .05$ with the exception of cancer research and heart research. The percentage of explained variance (for the significant equations) varies from .10 to 20.

The path coefficients clearly indicate that the importance of a specific cause is the single best predictor of donating behavior. Further, the results suggest that it is much easier to predict importance than behavior.

The results indicate that the four independent variables explain a significant amount of the variance of the importance variable. All eleven regression equations are significant at $p < .01$, with R-SQUARE ranging from .16 to .50. These results are highly significant and support the intermediary positioning of the importance variable in the model.

a= p .05 a= p .10

The results indicate that importance explains a significant amount of the variance of the level of donation for 8 of the 10 charitable organizations (again, the results for cancer research and heart research do not support the model). All other regression equations are significant at $p < .10$, with R-SQUARE ranging from .03 to .16.

The final step in the initial testing of the model is to determine whether or not importance can be considered an intermediate variable. The method is to use partial correlations between the five independent variables and the level of donations to control for importance. A fall in the correlation between the zero-order correlations and the first-order partial correlations would indicate that importance is an intermediate variable between the four prior independent variables and the level of donation.

Tables 4 and 5 present the correlations between the independent and dependent variables. Table 4 presents the zero-order correlations and Table 5 presents the first-order partial correlations.

The results of the correlation analysis reveal that almost all zero-order correlations fall significantly when the first-order partials are applied, indicating support for the hypothesized relationships in the proposed model.

Conclusions

The model and pilot study reported in this paper are an initial attempt to develop a better understanding of the way individuals behave in a non-profit marketing context. Specifically, this paper has suggested a new model for understanding and predicting charitable donation/health care consumer behavior. It is believed that the model is not specific to certain types of non-profit organizations, but rather, can be generalized to all or most non-profit situations.

Past research (eg. Oliver and Berger 1979) has indicated that some variables in the HBM and BIM models have more immediate effects on one's intention and behavior decisions. Thus, research similar to that proposed herein is useful when one is interested in prediction, resulting in a more parsimonious model consisting of antecedent and consequent variables. From a practical standpoint, given that our model suggests that importance is consequent to severity, involvement, predominance and alleviation, it may be more meaningful for the non-profit organization to deal with these four specific variables before attempting to "sell" an individual on how important the cause is.

There are a number of limitations in the current research. Firstly, the sample is quite small and relatively unique and may not be representative of any relevant donating universe. Secondly, the research reported herein describes and utilizes a very limited number of variables, and thus the external validity of the model and research must be investigated further.

Future research should attempt to validate the proposed model in a more formal and extensive research setting, correcting some of the above-mentioned limitations. In addition, other factors such as perceptions of the method of collecting donations, the differences in individuals propensities to give, concentrated versus dispersed giving, the differences between the various charitable organizations, peer pressure, etc. should be thoroughly investigated.

UNDERSTANDING DONOR BEHAVIOR: A CLASSIFICATION PARADIGM

Jane R. Ziegler Sojka
The Wichita State University

Abstract

The "business" of donating to non-profit institutions is a multi-million dollar enterprise yet, relatively little quantifiable research has been done on the topic. This paper investigates motivations behind monetary donations to non-profit organizations by examining related research on altruism, socially conscious behavior, social status behavior, and non-altruism within the gift-giving context. What emerges is a proposed paradigm categorizing donors on the basis of their internal values and overt behavior.

Introduction

Monetary donations to nonprofit organizations result in a substantial amount of money. According to American Association of Fund-Raising Counsel's recent figures, over \$60.39 billion is donated to nonprofit organizations annually. In terms of financial clout, nonprofit organizations in the U.S. are indeed, big business and therefore totally appropriate as topics within the marketing and consumer behavior field.

This paper's purpose is to examine the phenomenon of individual donations to nonprofit institutions. Because so very little previous research has been applied directly to the fund-raising discipline, it is first necessary to provide a theoretical basis for explaining its consumers' behavior. As a result of examining the related topics of altruism, socially conscious behavior, social status behavior, and what could be termed non-altruism, or hedonic, self-satisfying responses, as well as related research on gift-giving behavior and attendance at non-profit entertainment events, a theoretical framework for explaining the phenomenon of donor behavior will be presented. Possible hypotheses suitable for empirical testing will be suggested for further research.

Previous Research

Despite the substantial size and potential market of philanthropy in the United States, relatively little empirical research has been conducted in this area. (Desruisseaux 1985) As Sherry (1983) notes, "Gift exchange between the individual and the corporate group is less frequently described and less perfectly understood than other types of giving; research into philanthropy is still in its infancy." Some of the reasons for this lack of research may be purely pragmatic. Sherry attributes the slow growth in this area to the inability to access data. (Sherry 1983). Harmful public relations could result from an institution using contributed funds to research how to raise even more money rather than utilizing the funds for their intended purpose. Father Flanagan's Boys Town, for example, has long been acknowledged for raising money more successfully than for raising boys. (Shapiro 1973)

From a broader perspective, Smith (1979) suggests the lack of research stems from nonprofit organizations not being traditionally considered as business enterprises and therefore not applicable to marketing and consumer behavior analysis. Probably the most outspoken advocate of expanding the marketing realm to include a variety of non-business organizations such as social services and nonprofit organizations is Kotler (1975, Fox and Kotler 1980), who views the study of donors to non-profit institutions as having potential for eventually shedding light on their motivation for giving.

Lastly, the oversight of non-profit organizations in marketing research may, in fact, be the unique nature of the product and consumer process. As Holbrook (1980) points

out, the majority of marketing research is directed towards products such as "corn flakes and frozen orange juice and potato chips that nobody spends very much time seeking information about, that nobody wastes much time deliberating over, and that nobody exerts much effort shopping for, because, frankly, these are products about which consumers really just don't give a damn." Note the sharp contrast between his description of non-durable consumer products with the potential emotion, attitudes, and decision processes (Clarke and Belk 1976) that an individual may go through in the gift-giving process.

Insufficient research on consumer behavior within the donation context, makes it necessary to examine the literature on gift-giving to devise some parallel situations. Initial research into the gift-giving dynamics indicates that the process comprises a unique sub-category of consumer behavior. Belk's research on the gift-giving process led him to conclude that "there can be little doubt that gift-giving is a pervasive experience in human life and consumer behavior." Compared to more routine consumer purchases, gift selection is a very deliberate and highly involving type of consumer choice: frequently entailing a much greater expenditure of time and money than a purchase to used by the buyer. (Belk, 1976, 1981) Furthermore, the situation or occasion surrounding the gift presentation and consumption (such as the relationship between the buyer and receiver) may play a major role in the importance placed on the decision process. (Belk 1975) Hence, in order to accurately examine gift-giving behavior, it is necessary to review situational and motivational effects as well as cultural and social pressure.

Existing Frameworks

In spite of the overall dearth of information on donor behavior, several interesting and viable frameworks for understanding the field have been proposed. Banks (1979) suggests a gift-giving paradigm that outlines the stages of consumer behavior in the gift-giving context. The consumer moves through four stages--the purchase stage, the inter-action/exchange stage, the consumption stage, and the communication/ feedback stage--in her conception of the gift-giving process. While her paradigm represents the gift-exchange process, it does not explain the process of donor behavior. Although the selection of the gift and its consumption play a significant part in the gift-exchange process, in most nonprofit organizations, however, these two variables play minor roles. For example, a donor may merely write a check, not shop and select a particular gift. In addition, most small donations are merely mailed to the organization without any elaborate exchange process. Furthermore, the consumption stage, where the receiver uses the gift, can only be imagined by the typical university donor; the results of a \$20.00 donation can be literally imperceptible. Thus Banks' paradigm sheds little light on the particular situation of donor behavior.

Assuming reciprocity towards balanced giving in the long-run, Belk (1976) proposes a balanced digraph between the giver, the receiver, the gift, and the giver's self-concept. If the giver likes the receiver as well as the gift and has a positive self-perception, then the gift exchange will be satisfying. While strict reciprocity in the donor setting is difficult to conceptualize, nonetheless, the balance notion that Belk proposes coupled with the concept of cognitive consistency could be applicable to the proposed paradigm. For an altruistic person to want his name to appear in a directory of donors so that he could be recognized in the community comprises behavior clearly at conflict with altruistic motives. To the ex-

tent that the internal and external donor behavior must be consistent or balanced, the Belk model can be somewhat applicable to the donor process.

Scott Smith (1979) offers one of the few consumer behavior models dealing directly with charitable donations. Somewhat comparable to the proposed model, Smith suggests a range of donor behavior on a continuum from altruistic to what he terms hedonic. He sees charitable giving as a developmental process leading to the internalization of beliefs about charitable donations. Hence individuals may move through a series of stages related to giving to a specific organization. If considered as a steady state, his paradigm is reasonable and his suggested market strategies have valuable implications for fund-raisers. Yet, the actual movement of people through a "developmental process" which "increases the degree of internalization of attitude" as he terms it, is difficult to substantiate both in theory and research.

The beliefs, according to Fishbein (1975), essential to forming attitudes inherent in altruistic and non-altruistic behavior, share no compatibility according to existing research. Hence, Smith does not propose a simple strengthening and reinforcement of an individual's affect toward donations, but rather suggests a total shift in the individual's value structure and attitude towards charitable contributions. As Smith and Swinyard (1983) demonstrated, it is extremely difficult, even perhaps impossible to change attitudes by advertising alone. Likewise, it is difficult to conceptualize why a non-altruistic person, perfectly content in his hedonic satisfaction and status recognition, would have any motivation to suddenly become altruistic. Furthermore, the organization soliciting his donation should be relatively unconcerned with altering his reason for donating as long as the donation is consistent; hence there is little motivation on the institution's part, contrary to Smith's hypothesis, to move donors from the non-altruistic mode to an altruistic behavior unless a substantial difference in the size or consistency of the donation exists.

Although professional fund-raisers frequently work under Smith's premise that donors can be moved along a continuum, initial research indicates that donor patterns do not substantiate this thesis. In their study of consumer dynamics in nonprofit organizations, Ryans and Weinberg (1978) hypothesized an entry pattern divided into stages: first the individual would start as a single ticket holder, then he would purchase several tickets in a season, and finally, he would become a season ticket holder. This is much the same pattern of donations suggested by Smith. In reality, what Ryans and Weinberg found were three basic categories of subscribers: continual subscribers (32%), gradual subscribers following the hypothesized pattern (31%), and an almost equally large category of sudden subscribers (36%) who suddenly subscribed without any prior attendance or who exhibited a miscellaneous attendance pattern. Perhaps the different categories of behavior merely represent behavior pattern segments based on the proposed altruistic/non-altruistic model.

Altruism

Although each of the existing frameworks shed light on the subject from various perspectives, each is incomplete with regard to a more narrow focus on donation behavior within the context of nonprofit development. Hence, it becomes necessary to review literature from a variety of academic disciplines to enrich and enlarge the research currently in existence.

On the most positive side, gift-giving can be perceived as purely altruistic in nature. According to Krebs (1970) most behavioral research skirts the problem of defining altruism by employing operational definitions. Leeds (1963) defines altruistic behavior as: an end in itself, not directed at gain; emitted voluntarily; and doing good. Sherry, (1983) however, defines altruistic behavior as the donor's "attempt to maximize the pleasure of the recipient." Within the context of this paper, altruism shall

be defined as a donor's voluntary act which benefits the recipient. Note that there is no indication of "self" in this definition: the emphasis is on the intention to please the exchange partner.

Most of the altruistic behavior research has been within psychology theory and has largely investigated the link between altruism and personality. Krebs (1970) saw altruism as an important personality attribute in that people reacted differently to individuals who were considered altruistic as opposed to those who were considered selfish.

As Kassarian (1971) points out, analysts do not agree on any general definition of the term 'personality' except to somehow relate it to the concept of consistent responses of the individual to the surrounding environment. The definition controversy comprises just the tip of the iceberg in terms of problems with personality research. Methodologically, perhaps consumers do not tell us about themselves as they really are, but rather as an ideal, as Wells (1966) suggests. In addition, Kassarian (1971) theorizes that personality researchers ignore the many interrelated influences on the consumer process such as pricing, packaging, group influences, and learned responses. He cautions personality researchers that "to expect the influence of personality variables to account for a large portion of the variance is most certainly asking too much." Indeed, Pessemier, Bemmar, and Hanssens (1977) could substantiate only a weak correlation between personality variables and the likelihood that an individual will donate body parts.

Furthermore, it is difficult to justify altruistic behavior in terms of the majority of psychological theory. Freud's psychoanalytic theory contends that children are basically selfish. In addition, both Pavlov's classical learning theory and Skinner's stimulus response theory are based on the individual receiving some type of reward for behavior. While rewards may certainly play an important role in the sociological and cultural theories of gift-giving, the extreme sense of altruism as defined with the context of this paper, specifically negates the behavior for the sake of a reward.

Perhaps the lack of altruistic behavior inherent in psychological theory stems from preliminary research on animals. Rats, for example, press a bar less when it served to terminate a companion rat's pain than when it did not. Furthermore, rats exposed to a shocked companion crouched in fear at the other end of their cages leading Krebs (1970) to conclude that rats supply "no real support for altruism." Perhaps Campbell's (1975) research on conflicts between biological and social evolution offers the best explanation for the apparent lack of altruism in human nature. He sees "human urban social complexity" as a product of social evolution which has had to "counter with inhibitory moral norms the biological selfishness which genetic competition has continually selected." He concludes that the effects of society have encouraged altruistic behavior: not inherent personal characteristics.

Socially Conscious Behavior

Closely related to altruism but with an awareness of societal needs is a category of behavior directed towards society at large and exemplified by the "socially conscious consumer." Definitions of the socially conscious consumer vary according to researcher. Nonetheless, they all generally accept that this type of behavior is enacted in an effort to help others or bring about presumably beneficial social changes. Webster (1983) defines the socially conscious consumer as one "who takes into account the public consequences of his or her private consumption or who attempts to use his or her purchasing power to bring about social change." Similarly, Brooker (1976) defines socially conscious consumers to be "the group whose actions lead the way to an improving quality of life in society." Finally, Anderson and Cunningham (1972) use the operational definition of the Berkowitz and Daniels

Social Responsibility Scale to define socially conscious as "the willingness of an individual to help other persons even when there is nothing to be gained for himself." For the purposes of this paper, a socially conscious consumer will be defined as one whose actions are directed towards benefiting society. Types of behavior exhibited by socially conscious individuals include financial contributions to religious and educational institutions, active participation in community, church, or other organizations, and intense interest in politics.

It is very important to note, however, a few subtle differences between supposedly altruistic behavior and socially conscious behavior. First of all, the very term, socially conscious, suggests the influence of social awareness. While this may be perceived as either social pressure or a need for social change, socially conscious individuals remain very sensitive to their social surroundings: a variable totally excluded in the consideration of altruistic behavior. In addition, while socially conscious behavior may appear to be motivated by purely unselfish desires, since the society benefits which includes the individual, the individual will also benefit. Hence, socially conscious behavior may, in fact, be somewhat motivated by simultaneous self-interest as well as social interest.

Similar to the limited research on altruism, the research on socially conscious consumers also suggests that demographics compose a poor predictor variable. Anderson and Cunningham (1972) and Kinnear, Taylor, and Ahmed (1974) determined socio-psychological variables to be most effective when attempting to differentiate between low and high socially conscious consumers. They describe the high social responsibility group as more cosmopolitan, less alienated, less dogmatic, less status conscious, and less personally competent than the group exhibiting low social consciousness. Webster (1975) differentiates socially conscious consumers as individuals willing to engage in purchase behavior that may or may not be popularly accepted but which is consistent with his or her own standards of responsibility. Socially conscious consumers may be considered members of the upper middle class counter culture, but, according to Webster's research, they "operate at a rather low key."

The psychological theory that may best account for socially conscious behavior is Maslow's (1970) self-actualizing theory of personality; the closer one becomes to being self-actualizing, the freer one becomes of selfish, neurotic self-concerns. Self-actualizing individuals, while not negating their own concerns, will nevertheless consider the needs of others. Note that Maslow does not describe altruistic behavior as I have defined it: the very fact that self-actualized individuals take their own needs into account indicated non-altruism.

Maslow's theory is more applicable to socially conscious behavior than the majority of psychological theories were to altruism, yet several aspects exist where the research and the theory do not seem to coincide. While Maslow's self-actualized individuals seem to be totally oblivious to societal needs, socially conscious consumers appear to be very aware of societal expectations and the fact that they may be exhibiting nonconforming behavior. While socially conscious consumers may not be affected by social pressures such as conforming to societal expectations, they remain keenly aware that those social pressures exist.

Social Status Behavior

Social influences can play still another significant role in the gift-giving process. Previous research suggests that gift-giving behavior represents an individual's response to peer pressure in the effort to maintain a social role or image. Belk (1975) believes that one of the most influential situational variables is the social situation: the group's structure and the role requirements surrounding the gift-giving behavior. Goodenough (1969) labels Belk's "role requirements" as statuses: "what legal

theorists call rights, duties, privileges, powers, liabilities and immunities." Hence social status behavior can be defined as an individual's actions to maintain or establish a status position within a self-selected group of people. Gift-giving in this context becomes a form of maintaining one's position or status within one's peer group.

How is status maintained? Levy (1959) hypothesizes that there are many symbols of social participation. "Most goods say something about the social world of the people who consume them." He goes on to assert that cars "say prominent things about their owners," and that the possessions "are partly chosen to attest to their social positions." Levy (1981) believes the effect of peer influence to be so overwhelming that "individual choice behavior is almost irrelevant." Hence, according to this stream of research, status can be maintained and publicly displayed through an individual's purchases.

Perhaps the clearest example of social influence is clothing (T. Smith 1974, Holman 1980). In her study of the formation of aesthetic criteria through social structures and social institutions, Wallendorf (1979) found that the determination of "what's in fashion" is largely determined by the individual's peer group. Smith (1979) found similarly that the effects of peer influence not only influence the individual's decision, but also "reduce the amount of information individuals require to make a judgment of others." Belk, Bahn, and Mayer (1982) found that even grade school children could identify certain products with a particular social class thus implying the extent to which consumption symbolism recognition occurs in our society.

Preliminary research indicates the effects of social influence on consumer behavior may be substantial. This research coupled with the previously cited studies on the importance of situational variables (such as the relationship of the gift-giver and receiver, and the status of people who will be present when the gift will be received and consumed) suggests that an individual's social status and image may have a profound effect on the selection, presentation, consumption, and reciprocity of the gift-exchange process. It is important to note that social role behavior dealing with interpersonal relationships is entirely separate and distinct from the socially conscious, altruistic behavior directed towards society at large.

Non-Altruism

Completely opposite from altruism is a gift-giving behavior that could be generally classified as non-altruistic. As the name implies, non-altruism comprises beliefs and values purely hedonic and self-satisfying in nature: totally contradictory to the self-less nature of altruistic behavior. Hirschman and Holbrook, (1982) and Day (1983) define hedonism as an individual's ego-involvement with the fantasy and emotive aspects of the product. Sherry (1983) identifies non-altruism as agnostic behavior in which the donor attempts to maximize personal satisfaction. For the purposes of this paper, non-altruism is defined as an individual's actions designed to reward himself with self-satisfaction and pleasure.

The preeminent expert on gift-giving behavior in this context is the French anthropologist sociologist Marcel Mauss. His theory on gift-giving, specifically the exchange of gifts in a cultural context, centers around the principle of reciprocity and obligation. Mauss (1954) suggests that while a gift is generously offered, the accompanying behavior is formal pretence and social deception; in fact, the transaction itself is based on obligation and economic self-interest.

Mauss's description of gift-giving behavior sounds like the typical American lament of overly commercialized Christmases, Easters, and other sacred holidays. However, this potentially "selfish" phenomenon is by no means limited to our culture. Ruth Benedict (1934) discovered

an elaborate exchange system in the culture of the Northwest coast Indians who inhabited the narrow strip by the Pacific from Alaska to Puget Sound. Their potlatch, according to Levi-Strauss, (1971) involves a triple function of returning gifts formerly received with proper interest, establishing the public claim of a family's title or status, and surpassing a rival in generosity. Mauss (1954) found similar evidence of a rivalry where contracting parties rival each other with gifts. The French, for example, compete with each other in their ceremonial gifts, parties, weddings, and invitations, and feel bound to reciprocate with a more lavish ceremony.

The purpose of the gift in a non-altruistic context may serve a variety of intentions. Schwartz (1967) perceives the gift as an extension of the self that plays a role in the establishment and maintenance of an individual's status. The public display of "I gave" stickers on doors, and "blood donor" pins publicizes the individual's donations. Social rankings are also reflected in and maintained by the gift. The list of donors published in an arts program or sports program with people delineated into different "categories" depending upon the size of their donation provides a classic example. Levi-Strauss (1971) places the gift-giving process in an even more self-aggrandizing context by discussing gifts as mere instruments for power in a skillful game of exchange complete with a complexity of maneuvers, "to gain security, and to fortify one's self against risks incurred through alliances and rivalry." Hubert and Mauss (1964) postulate that the sacrificial nature of gift-giving exists primarily to alleviate guilt. Finally, Belk (1976) suggests the obligation to give is based on moral, religious imperatives, recognition and maintenance of a status hierarchy, or the expectation of reciprocal giving.

Inherent in the non-altruistic view of giving is the concept of reciprocity. The purpose of many gift exchanges is to receive an equivalent gift immediately or at a later date. Gift exchanges at Christmas and on birthdays illustrate the former and the later. Belk's (1976) signed digraph of gift-giving represents a model based on the premise of reciprocal balance between the giver, receiver, gift, and giver's self-concept.

Proposed Paradigm

What emerges as a result of examining the various philosophies about the gift-giving process is a descriptive paradigm (see figure 1) classifying donor behavior into two basic categories: altruistic and non-altruistic.

The paradigm was originally conceived as representing monetary donations to non-profit organizations; however, with modifications, it could be applicable to donations of time or goods. The relationship between the donor and the recipient organization is specifically left nebulous. In some cases, an interpersonal relationship may exist, such as in the case of an alumnus donating to his/her alma mater in memory of a favorite professor, but in other cases, the relationship is less specific. For example, many people who donate to higher education athletic departments who have no connection to the school other than their enjoyment of the sporting events.

Within each category, two separate distinctions can be made between internal processes and the external manifestation of these processes. The altruistic giver's chief concern is taking care of, or pleasing, the gift receiver; behavior manifested in a variety of observable behavior patterns which illustrate the altruistic's concern for his

fellow man. Overt behavior expected of a person exhibiting altruistic tendencies approximates that of the socially conscious consumer; making financial contributions to a variety of religious, social, and educational institutions, volunteering time, or offering blood donations would be consistent with expected behavior.

Since the internal motivation for non-altruistic donors is primarily hedonistic in nature, their overt behavior would be entirely different from that observed from altruistic types. For example, peer pressure and the maintenance of a status position figures prominently into non-altruistic behavior. Thus, a great deal of recognized group behavior would be expected. Non-altruistic donors to a nonprofit theatrical event, for example, would likely desire their name in a program to be read by others attending the event. For university athletic donors, a special parking place close to the stadium would indicate that they are significant donors. Attendance at sporting events, membership in alumni associations, and the wearing of clothing items proudly bearing the school's insignia are external "symbols" of the individual's status.

The proposed paradigm has value to both researchers and practitioners in the field. It aids researchers by focusing the subject area into somewhat more manageable proportions. The diversity between altruistic and non-altruistic behavior provides fertile ground for separate, in-depth analysis of these segments: thus allowing the researcher to concentrate on one type of behavior in much greater detail.

This paradigm also suggests a possible segmentation of the practitioner's audience allowing a manipulation of marketing mix variables to more effectively target potential donors. It would be extremely difficult to obtain accurate information on donor's feelings towards altruism or non-altruism: very few people would be willing to admit to hedonistic or status maintenance impulses. In addition, non-profit organizations do not like to "bother" their constituents with potentially controversial surveys. Yet it may be possible to identify these segments by the overt behavior hypothesized by the proposed paradigm. Hence this paradigm could result in more effective fund raising for practitioners in the field.

Testing The Proposed Paradigm

The proposed model generates several empirically testable hypotheses.

H1: Donors can be divided into two groups--altruistic or non-altruistic--depending upon their motivation for giving.

The appropriate methodology--a combination survey examining overt behavior such as donations to other charitable causes, volunteer activities, membership in alumni or sports clubs, public display of school symbols such as hats, t-shirts, bumper stickers combined with the administration of a psychological test such as the Berkowitz and Daniels Social Responsibility Scale could assist in empirically validating the two groups.

H2: A larger percentage of donors are motivated by non-altruistic motivations than altruistic motives.

Using research methods similar to those proposed for H1, it would be relatively easy to determine membership ratios between the two groups. Once validated, one could determine if any differences between the size of donation or consistency of donations over time existed between the two groups and adjust marketing mix variables accordingly.

H3: Donors motivated by non-altruistic reasons are more likely to be influenced by the tangible benefits produced by their donations than their altruistic counterparts.

Tangible benefits, somewhat similar to conspicuous consumption, are symbolic products signifying the individual's attachment to, or status within, the recipient

organization. Typical tangible benefits that might be derived from donating to a non-profit organization include: being named as a patron in an event program, receiving special seats or a special parking place for athletic events, or even naming a building after the donor.

H4: The gift-giving principle of reciprocity is also prevalent in non-profit donations through tangible as well as intangible means.

Although the lines of reciprocity are much more clear-cut in gift-giving situations where an individual is expected to exchange Christmas gifts with his/her siblings, it is hypothesized that a similar exchange occurs during a donation in a less concrete form. For example, the tangible benefits that a donor receives from a nonprofit organization can also be translated into non-tangible benefits that satisfy an individual's particular need for affiliation, status, or perpetuity.

The testing of these and related hypotheses would help the development organization segment their constituents for more efficient solicitation. In addition, they can provide valuable insight to direct further research in this area.

Study Limitations

The limitations of this initial research must be noted. The lack of literature quoted on the donation process, indicates this research represents the beginning of what Hunt (1983) would call the discovery stage in the scientific process of understanding, describing and ultimately predicting donor behavior. Classifying donors into one of two categories grossly oversimplifies the nonprofit donation phenomenon, but is totally necessary given the current stage of research.

The proposed paradigm only suggests a correlation between observed behavior and an individual's internal values and does not attempt to establish a cause or effect relationship between the two. Additional research would be necessary to investigate and explain this relationship.

Suggestions For Additional Research

As illustrated by the diverse and eclectic collection of relevant theories borrowed from other disciplines, like much of consumer behavior theory, development theory also lacks an unified approach. Although part of this diversification is due to the lack of research in the area and will undoubtedly become more cohesive in time, nonetheless, before this research can move out of the exploratory stage and become a bonafide theory by Hunt's (1983) definition, a consensus overview must be reached.

From this brief review of various disciplines appropriate to the study on donor behavior, perhaps the literature on gift-giving and gift exchanges is most appropriate and should be pursued in greater detail. While the research on altruism--from the psychological, sociological, as well as anthropological viewpoints--is intriguing and complimentary to the human species, there are several problems with the concept. First of all, while definitions are frequently not agreed upon by researchers within a field, the definition of altruism is a particularly sticky issue. Within the confines of this paper, a very narrow definition of altruism, totally negating any feelings for "self" was used. The very fact that it is a self-less act may raise an individual's self-worth, thereby producing a personal gain. Hence, one could effectively argue that true altruism in the narrow definition of a totally self-less act, does not exist. Defining altruistic behavior then becomes an even grayer area--is behavior that is simultaneously beneficial to recipient and donor considered altruistic? How would the cut-off between altruistic and non-altruistic behavior be established? In addition, the lack of quantifiable observable behavior in animals, and the connection between donor behavior and personality, another nebulous term with its own methodolo-

gical problems and concerns, tends to indicate that altruistic research should not be of primary concern during the initial stages of donor-behavior research.

In examining non-altruistic behavior in greater detail, several areas need to be addressed. First of all, in the context of gift-giving behavior, the concept of reciprocity is of primary importance. The question of reciprocity and the role that it plays in donor behavior must be addressed in greater detail. I strongly suspect that reciprocity between donor and recipient occurs, but on a much more symbolic, intangible level than that which happens during a gift exchange or potlatch.

Relating to the reciprocity question is the concept of the symbolic product that is exchanged in the donation process. Status, a sense of affiliation, increased self-worth as well as other psychological needs could be satisfied by an individual's donation. Understanding these key issues would undoubtedly enhance the research currently underway.

Methodologically, research into development activities desperately needs quantifiable data subjected to rigorous statistical analysis to support or refute proposed hypotheses. As previously stated, data on donors are difficult to obtain, yet as this stream of research progresses and as practitioners become more aware of the value of research, perhaps data will become more readily available. Quantifiable research accurately accessing the predictability of demographic data, which is predominately used in development organizations, as well as accessing other variables that might prove to be more accurate predictors of donor participation would be extremely beneficial to both practitioners and academicians. In addition, just as 95% of a company's sales are frequently derived from only 5% of its customers, so too runs development donations. Hence, it would be extremely important to differentiate between large and small donors so that development resources may be efficiently utilized.

Conclusions

This preliminary research helps to shed some light on the donation phenomenon. Yet, the need for additional research concerning donor behavior as well as gift-giving behavior can not be overstressed. As a result of examining the literature from a variety of appropriate disciplines, a donor categorization paradigm based on donor intentions and observed behavior is proposed. Not only will further investigation in this area be welcomed by practitioners in the field, but it may also help in the overall understanding of consumer behavior.

TOWARD A THEORY OF COLLEGE SELECTION: A MODEL OF COLLEGE SEARCH AND CHOICE BEHAVIOR¹

Randall G. Chapman, University of Alberta

Abstract

A behavioral theory of how students select a college is posited in this paper. This theory integrates aspects of search and choice into a comprehensive college selection theory. A menu of research questions is derived from the theory. These questions provide an extensive research agenda for the study of buyer behavior in the college selection domain.

Introduction

This paper proposes and describes a behavioral theory of how students select a college. Implicit in this theory is the notion that college selection may be viewed as a process which consists of a sequence of interrelated stages. It is posited that students move through this series of stages as they search for desirable colleges, search for and process information about colleges, and ultimately choose a specific college. This theory is also useful in establishing a framework within which past and current research efforts in the college selection domain may be classified. An immediate consequence of this theory is the development of a set of major research questions. These questions identify the central issues and dimensions of the college selection process, as well as providing a research agenda in this field.

The next section develops the details of the proposed behavioral theory of college selection. Then, the status of research on aspects of the college selection process is reviewed and assessed. Some concluding remarks complete this paper.

A Behavioral Model of the College Selection Process

The five components of the college selection process model describe the stages through which students move along the path toward the ultimate selection of a college. Figure 1 contains a schematic diagram of the model. The stages are labeled as follows: Pre-Search Behavior; Search Behavior; Application Decision; Choice Decision; and, Matriculation Decision.

The premise upon which this model is based is that college selection consists of search and choice components. Thus, it is important to define clearly the terms "search" and "choice" as used throughout this modeling effort.

Search refers to searching for the attribute values which characterize colleges. Relevant college attributes might include cost, academic quality, future career prospects and opportunities (upon graduation), quality of life while a student at the college, and related considerations that might be of interest to students in the ultimate college choice decision.

The search phase concludes with the application decision, when a student decides on the set of colleges to which formal applications for admission will be submitted. As noted below, some search activity is inevitable during the choice phase as well.

Choice refers to choosing among the colleges which have admitted a student. Search and choice are distinct but interrelated phases of the college selection process. However, it is useful to recognize the distinctiveness of these two stages in analyzing student behavior because

different considerations arise at the search and choice stages.

A detailed description of each of the five stages of the college selection process follows.

Pre-Search

Pre-search behavior begins when a student first recognizes the possible need and desirability of a college-level education. Parental influences may lead to such a realization on the part of the student well before the high school years. Thus, the pre-search stage may be very extended, covering many years. This length of time plus the difficulty in assessing when pre-search behavior actually first begins make this stage of the college selection process the most difficult to research.

Pre-search activities presumably involve an assessment of the costs and benefits associated with attending college in general (and perhaps certain college types, in particular), plus a corresponding assessment of the costs and benefits of alternative non-college post-high school options.

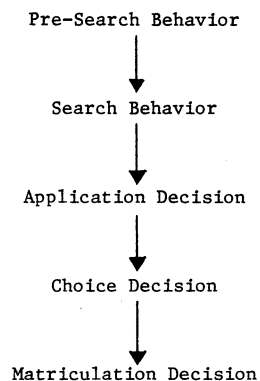

Given the recognition of the possible need for a college-level education, a student implicitly and perhaps continuously scans a range of possible information sources to learn about the availability of information sources, their content, and some information about various college options and perhaps even specific colleges.

Research on pre-search behavior would focus primarily on the college-going decision of students: the decision of whether higher education should be pursued at all. The subsequent stage in the college selection process, search, addresses issues related to the initial phases of choosing a particular college option.

College-going behavior might be studied by examining higher education participation rates of various market sub-groups. A range of demographic variables (for example, parental education and income levels, socio-economic status, gender, ethnic group membership, religious affiliation, and the like) might be useful predictors of college-going behavior. However, empirical evidence in the marketing segmentation area suggests that other things -- such as personal attitudes and values toward higher education correlates -- would be even

FIGURE 1

A MODEL OF THE COLLEGE SELECTION PROCESS

¹The helpful comments of Larry H. Litten, Associate Director, Consortium On Financing Higher Education, and the referees are most gratefully acknowledged. The author is responsible for all remaining errors.

stronger predictors of college-going tendencies.

Key research questions with regard to the pre-search phase include the following:

- (PS1) When does pre-search begin? When does a student first come to realize the possible value of a college-level education?
- (PS2) Who is consulted about educational and career options, with what frequency and what effect?
- (PS3) To what extent do family circumstances, lifestyle, personal values, and culture influence a student's perceptions of the value of a college education in general, and of the value of specific college options (either colleges or types of colleges [e.g., public vs. private]) in particular?

Due to the difficulty in assessing when pre-search begins, research on pre-search may be limited to attempting to measure the extent to which factors such as family circumstances, lifestyle, personal values, and culture influence subsequent stages of the college selection process. The assumption that these fundamental determinants of college selection behavior are exogenously determined for the purposes of studying the rest of the college selection process implies that they are beyond the immediate influence of any particular college.

Search Behavior

For a student to reach the search behavior phase of the college selection process, the pursuit of a college-level education must have been concluded to be a viable and desirable step. Search behavior presumably begins in earnest sometime during a student's high school years.

The search behavior stage is characterized by extensive and active acquisition of information about possible college alternatives. Knowledgeable "others" are presumably consulted with great frequency and in depth. Knowledgeable "others" might include high school teachers, high school guidance counselors, family members and relatives, family friends, college alumni, and acquaintances attending particular colleges. Students typically write to a number of colleges to request descriptive information, such as college catalogs and relevant brochures. Students receive unsolicited direct mail from individual colleges. Some actual visits to colleges occur. The search phase involves active search, rather than the relatively passive search-related activities that might be found in most consumer non-durable goods settings. College selection is an important milestone in a student's life, and extensive high-involvement search efforts are to be expected.

It is postulated that information search efforts are directed toward determining the attributes possessed by various college alternatives. Students are presumably interested in learning about a college's costs and benefits. Among the relevant benefits are the college's academic dimensions, future career prospects and opportunities (upon graduation), and its quality of life. Chapman and Litten (1984) describe these as consumption and investment benefits. A variety of information sources are tapped by students so that they may form a belief about what life would be like at specific colleges. A potentially wide range of college alternatives are presumably examined during the search phase, although the number of colleges given serious consideration may be only a relative handful.

Search may also entail learning about and identifying the "right" attributes to consider. (The "right" attributes are not expected to be the same for all students, although some attributes are likely to be commonly seen as relevant to many students.) This possibility introduces considerable complexity into efforts to model the college selection process. The typical assumptions of stable and known weights (in a multiattribute utility model context), weights "known" to the individual student (but "unknown"

to the researcher), thus, may not be tenable in the college selection process.

Thus, the search stage involves considerable complexity for the student -- extensive (generating college alternatives) and intensive (assessing where specific colleges lie in an attribute-space sense) search efforts are required (Chapman and Litten 1984), as well as efforts directed to identifying the salient attributes.

At some point, search stops and the student chooses a set of colleges to which applications are to be submitted. Search terminates presumably because the cost of further search (in terms of time, money, and effort) is not thought to materially reduce the uncertainty with regard to where the colleges' attributes really lie, or to identify any significantly more promising college alternatives than are already known to the student.

Some relevant research questions associated with the search phase include the following:

- (S1) How extensive is search? How many colleges are considered at various times during the search process? How many colleges are given serious consideration? How do personal circumstances, attitudes, values, and demographics of the student (and his/her parents) influence the extent of search?
- (S2) What information sources are consulted, with what frequency and what influence, and in what order? What is the content of the information received from various sources? How do these information sources vary with a student's personal circumstances, attitudes, values, and academic area of interest? Are sources used for different purposes? Are sources viewed with different degrees of credibility with regard to specific information dimensions?
- (S3) What activities occur during search? How much literature is accumulated? What kinds of students tend to make actual campus visits? What happens during campus visits? How do campus visits influence a student's perceptions about a college?
- (S4) What college attributes are viewed as being salient at the beginning of search? What college attributes are viewed as being salient at the end of the search process? How can changes in attribute saliency be accounted for?
- (S5) What are the specific indicators that students use in order to judge colleges on the attributes of importance?
- (S6) What colleges are students aware of at the beginning of search? Why are students aware of such colleges? What additional colleges do students become aware of as search progresses? What accounts for these "new" colleges entering the awareness set?
- (S7) Do perceptions about college attributes become more precise as search progresses? Do "halo" effects exist? If so, across which attribute subsets do "halo" effects exist?
- (S8) What forms of decision rules are used by students to evaluate specific college alternatives? To what extent are trade-offs recognized and dealt with? To what extent are simple cut-off rules (heuristics) used to simplify the decision making task, and to reduce the complexity of the search process by focusing attention (and associated information processing and search efforts) on a manageable number of college alternatives?

An ideal research program to study search behavior would be longitudinal in nature. Students would be contacted at several points during the search process, near the beginning and at the end, at a minimum. This research design would allow for questions related to changes in

attitudes, values, knowledge, awareness, preferences, and perceptions about individual college options to be assessed. A one-shot retrospective study, presumably conducted at or near the end of the search process, would have considerable difficulty in achieving reliable answers to all of these research questions due to inevitable lapses in memory, faulty recall, perceptual distortions, self-rationalizations, and halo effects.

Application Decision

Search behavior ends when a student decides to apply to a set of colleges. By definition, the application set consists of those colleges to which a student submits an application for admission. At this point, the pursuit of a college-level education is serious and the number of college alternatives has been narrowed down to a few.

Students are most likely to apply to colleges in which they are interested and to which they are likely to be admitted. Thus, a student's expectations as to the probability of admission are relevant here. In addition, it is presumed that only colleges viewed as being at least minimally acceptable on all major dimensions are included in the application set. One area in which students lack full information at the application decision stage is financial aid. Thus, students may apply to colleges which might be too expensive for them, unless sufficient aid is ultimately forthcoming with the offer of admission.

The notion of a "safe" or "backup" college merits special attention. Students may apply to a fairly low preference but perceived high-probability-of-admission college (often the local public institution) just to ensure that at least one positive admission decision is forthcoming.

The key research questions with regard to the application phase of the college selection process include:

- (A1) To what extent do expectations as to admissions probabilities enter into students' decisions as to which colleges will be included in the application set?
- (A2) How large are application sets? What factors (demographic, attitudinal, and other) account for variations in the size of application sets?
- (A3) To what extent is "portfolio decision making" (involving attempts to reduce and diversify risk) evident in the formation of college application sets? To what extent do students apply to "safe" or "backup" colleges, colleges in which there is a high probability of being admitted, so that they are assured of admission to at least one college?
- (A4) What more-or-less binding constraints (monetary, geographical, and "buying jointness" [having someone else to consider]) exist that influence the application set formation decision?
- (A5) Which colleges were actively considered at the search stage but not ultimately included in the application set? Why?
- (A6) What are the determining factors in a student's initial preference ranking/rating of colleges to which applications have been submitted?
- (A7) How do students perceive the standing of each of their college application set alternatives on each of the relevant dimensions? To what extent are these perceptions consistent with the actual (objectively determined) characteristics of the colleges? How can the differences between perceived and actual characteristics be accounted for?

Research on the application decision can be conducted by contacting students at any time after this stage has been reached. Ideally, contact would be made after the application decision has been made by the student, but before any of the colleges in the student's application set have made their admissions and financial aid

decisions.

After a student submits applications, the colleges must then make their admissions and financial aid decisions. Subsequently, the outcome of these decisions must be communicated to the students.

Choice Decision

By definition, the choice set consists of all those colleges to which a student is admitted. Note that this is another point where some uncertainty enters into the college selection process -- namely, the uncertainty with regard to whether a student will be admitted to a college. Students may form expectations about the probability of admission to particular colleges, but they cannot be certain of admission. This is especially true for selective colleges where the number of applications from minimally qualified students may exceed the number of available freshmen slots by factors of two to five. Indeed, some highly selective colleges receive more applications from straight-A students than there are available slots!

At the choice decision phase, the student is presumed to possess relatively complete information on all relevant college attributes, since the student is informed of the availability of financial aid amounts and mix (the allocation of financial aid between grants/scholarships, loans, and part-time jobs). However, there may be some further extended search along the "determinant attributes" (Alpert 1971), those college attributes which will really make a difference in the college choice process. This may involve campus visits, for example. Search activity during this stage is intensive only, being concerned with improving a student's information stockpile as to where the colleges in the choice set lie in an attribute-space sense.

The choice process presumably involves a trade-off among the multiattribute college alternatives in the choice set. (Cut-off heuristics may also be used to simplify the choice process, especially for students with large choice sets. Such heuristics presumably are of greater usefulness during the search phase, to reduce the universe of all possible colleges down to a manageable number, from information search and processing perspectives.) The need for trade-offs exist because any single college may not be dominant on each of the student's relevant attributes. Also, the homogenizing nature of the application decision -- which suggests that all colleges to which applications are submitted must be judged (implicitly, at least) to be minimally satisfactory on all major dimensions -- suggests that modeling the student decision maker as weighing the relative merits of each college alternative, in a compensatory fashion, would be a reasonable approach.

The choice decision phase normally ends with the selection of a specific college to attend. However, some students will end the choice decision stage by deciding to defer admission to a later time, perhaps because the student was not admitted to a highly preferred first choice college, or because financial considerations or some other change (since the application decision stage) in the student's personal life makes it impossible to pursue a college education at this point in time.

Key research questions with regard to the choice decision phase include the following:

- (C1) How do students perceive the standing of each of their college choice set alternatives on each of the relevant dimensions? To what extent are these perceptions consistent with the actual (objectively determined) characteristics of the colleges? How can the differences between perceived and actual characteristics be accounted for?
- (C2) What are the relative importances of various factors in the choice process? How do these relative importances vary across students? Are

there systematic differences in the relative importances that may be explainable by personal circumstances, attitudes, values, and demographic characteristics of the student (and his/her parents)?

- (C3) To what extent are students' expectations as to financial aid awards met? How accurate are students at predicting financial aid packages?
- (C4) What search behavior occurs after the choice set is formed? Do campus visits occur? If yes, with what effect?
- (C5) How consistent are a student's final preference ranking/rating of colleges and the original preference ranking/rating at the application formation set decision stage? How can changes in these two rankings/ratings be explained?
- (C6) What more-or-less binding constraints (monetary, geographical, and "buying jointness" [having someone else to consider]) exist that influence the college choice decision?

Although not strictly a college selection behavior phenomenon, an additional research question related to how specific colleges (and college types) make admissions and financial aid decisions might be noted.

Many of these research questions are answerable with a one-shot post-choice decision survey. However, issues related to perceptions and expectations require two-stage research efforts, involving questioning at the later part of the search stage (or after the application decision has been made) and again after the choice decision has been made. Significant distortions in reports of perceptions and expectations may occur, however, in a one-shot post-choice survey. It is crucial that the post-choice survey research effort be conducted well before the actual matriculation point, both to reduce memory losses and also to avoid major problems associated with self-reported rationalizations of past actions.

Matriculation Decision

For most students, the college choice decision will be made late in the Spring, with actual matriculation to the chosen college not occurring until the Fall. For some students, the initial college selected in the Spring will not be the college actually attended in the Fall. Changed family or personal circumstances (such as significant changes in financial situation) and unexpected events may alter the original choice decision. A student who was wait-listed with a highly preferred college may renege on the initial college selected if the highly preferred college subsequently admits the student.

This "no-show" problem creates considerable problems for colleges, as it can easily cascade down from highly selective to successively less selective institutions, as the colleges tap their wait-list pools to fill their respective classes. Standard institutional practice in admissions is to require a deposit along with the acceptance of admission. However, these deposits are normally not substantial (a \$100-\$200 range is common), so the cost of forfeiting such a deposit to attend a much more preferred college alternative is not a major hurdle for many students.

Relevant research questions with regard to the matriculation decision include the following:

- (M1) How large is the "now-show" problem?
- (M2) Why do some students become "no-shows"? To what extent is being offered late admission (i.e., coming off a wait-list) by a preferred college a contributing factor to the "now-show" problem? To what extent are changes in financial aid packages a contributing factor to the "no-show" problem?
- (M3) To what extent can students predict the likelihood of their being "no-shows"? Is "no-

show" behavior planned at the time of the original college choice decision?

The investigation of this "no-show" problem is only possible with a survey of students after they have actually physically enrolled in colleges in the Fall.

The Current Status of Research on College Selection Decision Making

Existing published research on the college selection process has focused largely on the college choice stage. Major studies of college choice behavior include Chapman (1979, 1985), Chapman and Staelin (1982), Manski and Wise (1983), Punj and Staelin (1978), Radner and Miller (1975), and Tierney (1980).

While less plentiful, some empirical research exists in the other areas, although it primarily focuses on student demographics as determinants of behavior. In the pre-search area, studies of college-going behavior based on students' demographic backgrounds are relatively numerous. For example, see Anderson, Bowman, and Tinto (1972), Christensen, Melder, and Weisbrod (1975), Manski and Wise (1983), and Radner and Miller (1975). In the search behavior area, see Litten and Brodigan (1982) for an example of the sources of information that students report they use. Spies (1973) focused some attention on application decision behavior. Hise and Smith (1977) report the results of an experiment to attempt to reduce "no-show" behavior.

The disproportionate emphasis that researchers have placed on studying the college choice phase is no doubt due to the relatively low costs with which such research efforts may be conducted. A one-shot post-choice retrospective survey is typically employed in college choice studies. Also, in studying choice, the population may be defined conveniently to include only students who have already applied to a particular college, thus yielding large savings on survey administration costs. (Of course, such a choice-based sample will have associated with it some restrictions regarding the possibilities of generalization beyond the college's applicant pool.)

While retrospective studies of choice may represent reasonable compromises between cost and data accuracy/generalization considerations, search behavior cannot be studied successfully with retrospective study designs. Also, the study of search would require a much larger population of students. The search behavior stage can potentially encompass a wide range of activities occurring over many months. A single survey research questionnaire administered to students well after the search stage is over will be ineffective and quite possibly misleading due to students' faulty recall, halo effects, cognitive dissonance, and selective perception and retention. The study of search behavior requires intervention during the search process, ideally at several points with a longitudinal research design.

Unfortunately, much has already happened by the time students have reached the application decision stage. Researchers and, by inference, college admissions decision makers could be misled by focusing only on the application and choice behavior of students. For example, students who perceive a college to be too expensive will not presumably apply to such a college in the first instance. Much of the substance of the college selection process is still hidden behind/before the application decision.

It is, of course, not surprising that initial research efforts would focus on the relatively easier-to-investigate choice behavior stage. However, the large research gains in the future seem likely to occur only with sustained efforts devoted to the search and pre-search behavior phases of the college selection process, perhaps in combination with analyzing application and choice decisions of students simultaneously.

Concluding Remarks

The model proposed in this paper represents a starting point to the complete study of college selection. In addition to attempting to organize the college selection process into a series of researchable stages, the research questions developed provide an extensive research agenda for buyer behavior scholars and applied researchers interested in buyer behavior in higher education. Marketing scientists may find the college selection process to be especially interesting due to its inherent complexity and its high stakes nature. There are few other buying processes where the stakes are higher; this is an extreme example of high involvement buying decision making.

This model is proposed as an organizing framework for the study of college selection. The model has a certain rigidity to it, in that it suggests that every student progresses through the specified stages in a "top-down" fashion. This is, of course, consistent with the underlying premise that college selection is a high stakes high involvement buying process. Naturally, the worth of this model of college selection can only be gauged with extensive empirical testing. Certainly, not every student will go through all of the proposed stages. (Some may have "inherited" application sets, for example, corresponding to parents' colleges.) Indeed, those students who do not follow the form of this model may be especially interesting. Alternative models no doubt exist, but this stagewise buying model appears to be a useful starting point for the study of the complete process of college selection.

In addition to academic research interest, the research questions developed in this paper are of paramount importance to the relevant managers in higher educational institutions. Admissions, financial aid, and college planning officials need answers to these questions to cope with the increasingly competitive nature of the college selection process. Thus, these research questions appear to have both scholarly and managerial interest.

THE FRAMING OF THE INSURANCE PURCHASE DECISION

Joshua L. Wiener, Oklahoma State University
James W. Gentry, Oklahoma State University
Ronald K. Miller, Oklahoma State University

Abstract

Previous research (Hershey and Schoemaker 1980; Tversky and Kahneman 1981) has shown that choice is dependent upon the manner in which the decision is framed. If framed in the asset domain (as is assumed by Utility Theory), the purchase of insurance would seem to be a realistic alternative. On the other hand, if the insurance purchase is framed in the loss domain as suggested by Prospect Theory (Kahneman and Tversky 1979), then it would appear that the purchase would be much less likely. An extensive pilot study of the decision to purchase flood insurance finds some tentative support for the greater likelihood to purchase insurance when the respondent is using an asset decision frame.

Introduction

An individual's behavior is influenced by the task encountered, the individual's characteristics, and their interaction (Punj and Stewart 1983). The influence of the task environment is so strong that Dawes (1975) has argued that many behavioral theories test well because they are actually models of the tasks which the subjects are performing.

One of the most powerful task environment elements is how the task is presented to the subject. The manner in which the task is presented can directly influence how an individual forms his or her decision frame (Tversky and Kahneman 1981). A decision frame is the individual's perception of the decision problem being faced. It includes the perceived alternatives, consequences derived from selecting an alternative, and likelihood of particular consequences occurring. The developers of the decision frame concept, Tversky and Kahneman (1981), emphasize that a single decision may be framed in multiple ways. In other words, how a communicator presents the objective information to an individual (*i.e.*, frames the problem) can influence how the receiver perceives the problem (*i.e.*, forms the decision frame).

Dawes' (1975) suggestion that behavioral models are task environment specific provides a method for the a priori identification of how decision formulation manipulations will influence behavior. If different behavioral models predict different responses to the same objective situation, then behavior can be influenced by encouraging the use of a particular model. The use of a particular model can be encouraged by presenting the task so that it better fits the model's decision frame.

To illustrate how the presentation format's influence upon behavior can be predicted by use of the decision frame construct, a study of decision making in an insurance purchase situation was conducted. Both economists and decision theorists have investigated the insurance purchase decision. Although there is considerable variation within each research framework, there are two fundamental differences which delineate the frameworks. Both expected utility theory and the decision theory frameworks, such as prospect theory (Kahneman & Tversky 1979), explicitly postulate different framings of the uncertainty decision, and make different predictions. In particular, they make opposite predictions about an individual's willingness to purchase flood insurance (Kunreuther 1978).

Decision theory frameworks postulate that an individual frames a decision in terms of the immediate gains or losses he or she may incur. For example, if one

consequence of a bet is losing \$17.00, an individual will frame this consequence as a \$17.00 loss. On the other hand, economic theories generally postulate that an individual frames a decision in terms of changes in his or her assets. In other words, it is assumed that the immediate loss or gain is combined with the current level of assets to produce a net asset level. For example, if an individual's assets are worth \$3,000, then the consequence of losing a \$17.00 bet is framed as a reduction in wealth from \$3,000 to \$2,983.

Decision theory and economic frameworks make opposite predictions about the choice an individual will make when faced with the following decision. The decision is to choose between a situation with a small certain loss and a situation in which the two alternatives are a large loss or no gain. Economic theory predicts that most individuals will select the situation with the small certain loss. The decision theory framework predicts that most individuals will select the uncertain prospects over the certain loss. This prediction is made if the individual's aspiration level of wealth is his or her current level, and the loss is not ruinous (Payne, Laughunn, and Crum 1980).

Prospect theory predicts that the uncertain prospect will be selected over the sure loss, unless the probability associated with the sure loss is very small. Prospect theory postulates that individuals make risky decisions by acting as if they used a two stage process. In the first stage they edit the problem. An outcome is viewed as either a gain or loss. A value is assigned to the outcome. The function that assigns values to outcomes is convex for losses and concave for gains. The function is steeper for losses. A second important feature of the editing process is that probabilities are translated into decision weights. Most decision weights are lower than their corresponding probabilities. The exception is that very low probabilities are associated with relatively higher weights (Kahneman & Tversky 1979). The majority of the experimental studies discussed in Hershey, Kunreuther, and Schoemaker (1982) support this conclusion.

The insurance purchase situation, stripped of its nonmonetary aspects, fits the structure of the problem discussed above. If insurance is purchased, a small certain loss (the premium) is incurred. If insurance is not purchased, then a situation exists which includes the likelihood of a large loss (the flood, fire, accident, or robbery) and the likelihood of no gain.

The analogy to the insurance decision provides a framework for evaluating the respective approaches. A number of recent studies of decision making under uncertainty have used a flood insurance framework (Slovic and Kunreuther 1974, Slovic et al. 1977, Kunreuther 1978). Flood insurance provides a particularly useful framework because some of the nonmonetary dimensions, such as moral hazard and enforced legal requirements to buy, are minimal. Moreover, the propensity of individuals to purchase flood insurance is a matter of major public concern (Taft 1972, Kunreuther 1978).

Flood Insurance

The most salient fact about flood insurance is that the vast majority of flood-plain homeowners in the United States do not own any flood insurance. Only one in four homes in 100 year flood plains are covered by flood

insurance (Barton 1985).¹ Although virtually no homes in 500 year flood plains have flood insurance, 40% of all flood damage (measured in dollars) occurs in these areas (Barton, 1985). The number of homeowners residing in flood-plains who are not insured for the peril of flood is startling. As White and Haas (1975, p. 255) pointed out, "Nearly every community in the nation has some kind of flood problem, chiefly resulting from inadequate drainage systems for runoff water produced by heavy rainfall from storms." For example, 97.5% (2483 out of 2547) of the communities in Pennsylvania have been identified as being flood prone (Luloff and Wilkinson 1979). The Federal Insurance Administration estimates that one of every ten Americans resides in locations where flooding is likely to occur (Kunrueher 1978).

Survey research by Kunrueher et al. (1978) has identified three key reasons why individuals fail to purchase flood insurance. They may be unaware of it; they may miscomprehend it; or they may not want it. A critical finding of this study was that when the survey respondents' subjective assessments of the likelihood of a natural disaster, the monetary damage caused by such disasters, and premium rates were incorporated into expected utility analysis, between 30 and 40 percent of their insurance decisions violated the predictions of expected utility theory.

The finding that insurance purchase decisions violate the predictions of expected utility theory has been replicated in experimental situations (Slovic et al. 1974, 1977).

Theoretical Review

Expected utility theory, as originated by Bernoulli (1954), and axiomatized by Von Neumann and Morgenstern (1947), predicts that most individuals who fully comprehend the flood insurance purchase decision will buy flood insurance. This prediction is due to the assumption that individuals are risk averse with respect to changes in their wealth. In contrast, the results of a series of experiments reviewed by Hershey et al. (1982) generally support the postulate that individuals are risk takers in the domain of losses. Slovic et al. (1977) argue that this postulate implies that individuals who fully comprehend the flood insurance purchase decision will not buy flood insurance unless the nonmonetary dimensions compensate for the monetary dimensions.

Numerous experiments investigating the validity of expected utility theory have been conducted since 1948. A common element of their design is that information is presented to subjects in the form of a win or lose gamble. A common finding is that individuals are risk preferring in the domain of large losses. The finding is integral to prospect theory (Kahneman and Tversky 1979) and supported by the findings of Slovic et al. (1977), Payne, Laughhun and Crum (1980), Hershey and Schomaker (1980), and Hershey et al. (1982).

A key difference between the two approaches is that the direct consequences of the action are not integrated with the individual's existing wealth in the decision theory framework. Although the two equations are isomorphic (both can be derived from the same rationality axioms, Borch (1972)), they may represent very different mental framings of the insurance decision. In the former case purchasing insurance is associated with a sure positive consequence, in the latter purchasing insurance is associated with a pure negative consequence. This sign difference is potentially significant since individuals appear to be risk averse in the positive domain of gains (Tversky and Kahneman 1979) but risk takers in the negative domain.

Both economists and decision theorists explicitly recognize that insurance provides more than simply monetary protection. There are both normative reasons for

¹Homes in a 100 year flood plain have a .01 likelihood of being flooded within a given year.

buying insurance, e.g., it is the socially right thing to do, and self interest reasons, e.g., it permits one to take less care. Studies by Hershey and Schomaker (1980) and Hershey et al. (1982) support these arguments. They find that individuals are more likely to select the small certain loss alternative when it is labeled "buying insurance."

Methodology

The alternative of purchasing flood insurance was presented to subjects in five forms. Two decision frames were used (asset and loss) and each frame was presented in two ways (tabular format and lottery format). Also, one form of the advertisement was used as a control group and did not present the decision in either a loss or asset frame. Thus the experiment involved a two x two with control group design. The subjects were college students from a variety of courses.

Advertisements. The students were asked to role play the following situation:

The year is 1990 and you have just purchased a \$100,000 home (with an 80% mortgage) in a large midwestern city. You have received the following information in the mail.

All subjects were shown the advertising content shown in Figure 1. Those subjects in the control group were shown only the information in Figure 1.

1. How likely is it that MY home will be flooded?

You live in a 100 year flood plain. This means that there is a one in 100 chance that your home will be flooded this year, a three in 100 chance that it will be flooded in three years, and about a one in 10 chance that it will be flooded within a decade. It does not mean a flood comes every 100 years.

2. Does my homeowner policy provide flood insurance?

No! The standard home owner policy does not cover floods.

3. How much damage will a flood cause?

The damage a flood causes depends on many factors. The most important is the value of your home and its contents. Assuming that your home is worth \$100,000 and its contents \$33,000, the average flood would cause about \$38,800 in damage.

4. What can I do?

Flood insurance can protect you from the loss a flood would cause.

5. How much will it cost?

Like all insurance, your cost depends on how much you insure and the deductible you select. Unlike other insurance, the federal government helps pay the costs of providing the insurance. This means that your cost is about \$20 plus one-hundredth (.01) the expected loss insured if there is a flood. This is a fair price--for you--because every year there is a one in 100 chance you will be flooded. For your home, the cost will be \$388 for a policy that has a \$500 deductible.

The loss and asset frames were manipulated as shown in Figures 2 and 3. The loss frames contrasted the possible loss of a large amount of money with the sure loss of a smaller amount of money (the premium). The asset frames discussed a possible large reduction in assets as opposed to a sure small reduction in assets. The tabular format was developed because it is the most comprehensive means of showing what happens in all circumstances. The lottery format was used also because most previous work with decision frames has used gambling tasks expressed as lotteries (for example, Hershey and Schoemaker 1980; Tversky and Kahneman 1981).

FIGURE 2

LOSS FRAME MANIPULATIONS

TABULAR LOSS MANIPULATION

6. Is it worth it?

An easy way for you to answer this question is to compare how you will feel if you buy insurance to how you will feel if you don't. The chart below will help you decide--the numbers are based on a policy which has a \$500 deductible. In other words, if your home is flooded, you would be reimbursed for all damage except \$500 worth.

The chart below describes the amount of money you will lose under four conditions.

- flood--no insurance
- flood--you have insurance
- no flood--no insurance
- no flood--you have insurance

Ask yourself whether the small loss due to paying the premium is worth the chance of a big loss if there is a flood.

How Much Is Lost?

Home value of \$100,000 with contents of \$33,000:

	Flood	No Flood
Insurance	\$888	\$388
No insurance	\$38,800	\$0

LOTTERY LOSS MANIPULATION

6. Is it worth it?

An easy way for you to answer this question is to compare how you will feel if you buy insurance to how you will feel if you don't. The two options below will help you decide. They assume that the flood insurance policy would have a \$500 deductible; in other words, if your home is flooded, you would be reimbursed for all damage except \$500 worth.

Option 1: Buy flood insurance for \$388. All flood damage would be reimbursed except for the \$500 deductible.

Option 2: Take a one in one hundred chance that you will suffer a loss of \$38,800.

Subjects. The use of student subjects presents serious problems, since few of them have faced the issue of whether to insure their home from flood damage. Consequently, the role playing scenario was required. Factors which made the scenario somewhat realistic were (1) a large number of the students planned to obtain employment after graduation in the city mentioned in the scenario, and (2) this city had suffered serious flood damage within the past year.

While college students are homogeneous in many ways (age,

FIGURE 3

ASSET FRAME MANIPULATIONS

6. Is it worth it?

An easy way for you to answer this question is to compare how you will feel if you buy insurance to how you will feel if you don't. The chart below will help you decide--the numbers are based on a policy which has a \$500 deductible. In other words, if your home is flooded, you would be reimbursed for all damage except \$500 worth.

The chart below describes the amount of money you will lose under four conditions.

- flood--no insurance
- flood--you have insurance
- no flood--no insurance
- no flood--you have insurance

The dollar values are for a family which owns its home's contents outright, but has a mortgage equal to about 80% of the home's value. For example, a family that lives in a \$100,000 home would have a \$80,000 mortgage.

Ask yourself whether the small reduction in your investment's value due to paying the premiums is worth the chance of a large reduction in your investment's value if there is a flood.

Amount of Equity Left In Your Home and Its Contents

Home value of \$100,000 with contents of \$33,000:

	Flood	No Flood
Insurance	\$52,112	\$52,612
No insurance	\$14,200	\$53,000

LOTTERY ASSET MANIPULATION

6. Is it worth it?

An easy way for you to answer this question is to compare how you will feel if you buy insurance to how you will feel if you don't. The two options below will help you decide. They assume that the flood insurance policy would have a \$500 deductible; in other words, if your home's flooded, you would be reimbursed for all damage except \$500 deductible.

Option 1: Your total assets would change from \$53,000 to \$52,612. You would be insured for all possible flood damage, except for the \$500 deductible.

Option 2: You take a one in one hundred chance that your total assets change from \$53,000 to \$14,200.

for example), we attempted to investigate diverse groups of students. The insurance classes were included, as it was expected that they would be most familiar (among student groups) with the content areas of the study. Similarly, undergraduate decision theory classes and an MBA class were included with the expectation that these students would have more expertise with the cognitive aspects involved in the decision making. At the other end of the spectrum, sophomore level business law students were included with the expectation that they had little understanding of the insurance decision in general and little training in systematic decision making processes. Finally, several senior-level marketing courses were surveyed, with the expectation that these students would fall somewhere in between the sophomores and the other students.

The students provided information on their (and their family's) experience with floods and with insurance purchases (car, life, health, and property). Also, personal information (age, family income, and sex) was obtained.

Manipulation Checks. Previous decision frame research manipulated the loss and asset perspectives, but did not use any manipulation checks. Given the different risk propensities found in the gambling scenarios, it can be inferred that the manipulations were successful. The translation of the positive and negative quadrant frames from gambling to applied decision-making situations is not straightforward. While the manipulations shown in Figures 2 and 3 may well be criticized, they are enormous improvements over the first advertising appeals we developed. Given the applied nature of the decision setting, we used manipulation checks (shown in Figure 4) to investigate the success of our attempts. Further, their use should provide insight into the perspective that subjects bring into the insurance purchase, as the control group received neither the loss nor asset manipulations.

Dependent Variables. The subjects responded to three items about their intentions to purchase flood insurance and to two items dealing with their beliefs about flood insurance. One intention measure was the subject's assessment of how likely (7 point scale) s/he would be to buy insurance for \$388. The other four measures are also shown in Figure 4. The eight Likert-type items shown in that figure were ordered randomly in the survey completed by the subjects.

FIGURE 4

DEPENDENT VARIABLES AND MANIPULATION CHECKS

Intention Measures

I will buy flood insurance for my home.
I would investigate flood insurance further.

Belief Measures

Flood insurance makes sense to me.
The government should continue the national flood insurance program.

Manipulation Checks

Loss Frame

Thinking about buying insurance is like thinking about a situation where the best you can do is break even, and the worst you can do is lose lots of money.

I don't like to think about insurance because what you think about is losing money.

Asset Frame

I don't mind thinking about insurance because what you think about is how much you are worth,.

Thinking about buying insurance is like thinking about a situation where the best you can do is to keep your current wealth and the worst you can do is to have your current wealth driven down.

Results

The profile of the 541 respondents is shown in Table 1. Only 8% of the sample had ever owned a home, indicating that the role-playing was somewhat irrelevant to most of the subjects. The vast majority of respondents were covered by some form of insurance, although many of them had it purchased for them by their parents. About 9% had experienced flood damage themselves and 17% had family members who had experienced flood damage.

Manipulation Checks. Unlike previous studies

investigating the impact of decision frames, this study used manipulation checks to see if the treatments would affect one's perception of the decision frame. The results presented in Table 2 show that the asset manipulations were successful for one of the two checks. For that check, those who received the asset manipulation were more likely to agree that buying insurance either allows you to keep your current wealth or reduce your wealth slightly than were those in the control group. The control group was more likely to agree than those who received the loss manipulations. The loss treatments did not elicit more agreement with statements viewing insurance in the loss domain than did the asset treatments or the absence of a treatment.

Impact of Decision Frame on Intention and Attitudes.

Table 2 also presents the mean responses for the intention to purchase and the attitude measures. One point to note is the highly positive mean responses to all five items (between 5.0 and 6.0 on a seven-point scale). Given the low acceptance of flood insurance among the general population as a whole (as discussed earlier), these results either indicate the wonders of advertising or that demand characteristics are present. The second explanation will be investigated in more detail later.

The decision frames showed no differential impact on intentions or attitudes. The presence of advertising information (whether framed in the asset or in the loss domain) resulted in higher intentions to purchase than did the control.² It had been hypothesized that the asset decision frame would result in higher intentions to buy. There is a slight trend in this direction, but the differences are not significant at all ($p > .25$).

It may be that people are predisposed to view the insurance purchase situation in either a loss or an asset

²This was not found for the third intention measure (wanting to seek more information about flood insurance). However, this is to be expected since the control group's treatment presented the smallest amount of information.

decisions frame. Further, it appears that our treatments did not manipulate that decision frame significantly (especially for losses). Consequently, we attempted to categorized subjects as to having a loss decision frame, an asset decision frame, or neither. In order to operationalize these constructs, we assumed that our manipulation checks are capturing the concepts adequately. Those agreeing with the loss checks more than the asset checks were classified as having a loss frame, and vice versa.

When the intention and attitude measures for these groups are investigated (as shown in Table 3), we find that the direction of the mean responses is consistent with our theory for all five measures. Further, the means are significantly different for two of the measures, marginally significant for two others, and non-significant for only the "investigate further" intention (which received the uniformly favorable response, possibly due to demand characteristics).

Impact of Context on Intentions and Attitudes. Previous studies of decision frames have presented the alternatives in the form of lotteries. Since lotteries would seem to be more appropriate for gambling situations than for the purchase of insurance, it was believed that the use of a

two x two table would present the possible consequences of the insurance purchase in a more systematic manner. While we can see no reason to expect differential effectiveness for the two modes of presentation; past research (Dawes 1975; Hershey and Schoemaker 1980) would suggest that context effects might occur. However, the mean responses to the tabular presentations were not different from the mean responses to the lottery presentations for any of the dependent variables.

Evaluation of the Nature of the Subjects. As this study represents a first attempt to investigate decision framing in the context of a specific purchase situation (as well as the first attempt to measure the decision frame through the manipulation checks), student subjects were used as a pilot study. As acknowledged earlier, students are far from ideal in this scenario (92% in this study have not experienced home ownership). In our defense, it can be noted that previous research on decision frames has used student subjects almost exclusively. This section will attempt to investigate the nature of this limitation.

Even though we must acknowledge that our student sample is largely homogeneous, we did attempt to vary the familiarity with insurance and with decision making processes by using subjects from a variety of classes. No differences in the intention and attitude responses were noted for the five class groupings, but differences were noted ($p < .05$) for two of the decision frame measures ("insurance is like thinking about losing money" and "insurance makes you think about how much you are worth"). Students in the insurance classes were the most likely to disagree with the former item and to agree with the latter item, while the MBAs were the most likely to have the opposite views.

The intention and attitude measures were related directly to the demographic, insurance-experience, and flood-experience variables using Chi square analysis. For ease of interpretation and because most previous decision framing studies (Hershey and Schoemaker 1980) had used a dichotomous dependent variable, we dichotomized the dependent variables by coding the three positive scale responses (for example, "extremely likely," "very likely," and "likely") as "yes" and the other responses as "no".

The majority of cross tabulations were not significantly related, but the pattern of significant findings is insightful. Previous family experience with flood damage was directly related to the intention to buy flood insurance (for the first two intention measures). Ownership of property and health insurance was directly related to the willingness to investigate flood insurance further.

The rest of the results point out the weaknesses of using a student sample. Females, those who do not buy their own car insurance, and younger respondents were more likely to intend to purchase and to hold positive attitudes toward flood insurance. Further, those who do not own their own homes were more willing to seek further information about flood insurance. These results indicate that it is likely that a survey of homeowners would result in much lower intentions to purchase. Whether the different decision frames have a differential impact on those intentions remains to be investigated.

DISCUSSION

This study represents an attempt to investigate the impact of decision framing on one's intention to purchase flood insurance. A case is made for the expectations that people viewing the purchase from an asset perspective will be more likely to buy than those viewing it from a loss perspective. Subjects were asked to role play a situation in which flood insurance might be a relevant alternative. They were presented with information, including a manipulation of the decision frame.

Contrary to the expectations, subjects receiving the asset frame did not express greater intention to purchase. However, further analysis did find that those viewing insurance in the asset domain expressed greater intentions than those viewing insurance as being in the loss domain.

The study suffered from several limitations. One, the use of student subjects, received much discussion. It seems clear that students are prone to the demand characteristic to say that they will purchase flood insurance. A study of homeowners will undoubtedly find a lower level of intentions being expressed. Whether the decision frames will have greater impact remains to be seen.

Recently, Peterson, Albaum, and Beltramini (1985) reported that the use of both student subjects (as opposed to nonstudents) and intentional (as opposed to behavioral) response variables decrease the size of treatment effects by 42% and 85% respectively (ω^2 being the effect size measure). By analogy, this study's use of students and intention measures may have contributed to the failure of the manipulations to have any significant effect.

Another limitation lies in the asset and loss manipulations. The failure to find significant manipulation checks indicates the need to develop better treatments, especially for the loss decision frame. There appears to be little difference in the effectiveness of a lottery or tabular presentation of the information.

Part of the problem with the insignificant manipulation checks may be due to the construction of the manipulation checks themselves. As noted earlier, previous studies have not attempted to measure subjects' decision frames. One reason may be that this is less than a straightforward process. Clearly improvement is needed in the manipulation checks used.

Thus our conclusion is that there is sufficient evidence to support a recommendation that more research in this area is needed.

SOME CAN, SOME CAN'T, AND SOME DON'T KNOW HOW THEY DID IT:
A DIRECT TEST OF THE UTILITY MAXIMIZATION HYPOTHESIS

Peter R. Dickson, The Ohio State University
Joel E. Urbany, University of South Carolina
Paul W. Miniard, The Ohio State University

Abstract

A direct test of whether relatively knowledgeable students can maximize utility in a very simple investment choice task was undertaken. Although a pretest of an on-going, larger study, the results suggest that many can, particularly for the task that involved a simpler optimizing rule. Further manipulations and dependent measures are needed to determine whether the poor performance of some subjects is primarily an ability or a motivational problem. It appears to be an ability problem.

Recent years have seen a growing interest in the developing interface between marketing and economics (see, for example, Mitchell 1978, *Journal of Business* special issues 1980, 1984). Economists have shown greater concern over how well their "laws" of the marketplace actually describe observed behavior (Gilad et al 1984), while marketing researchers are increasingly interested in the application of economic theory to marketing problems (Nagle 1984). This paper attempts to make a contribution to the merger of the two fields by developing a direct test of the classic economic proposition that buyers maximize utility relative to price. We first describe the concepts of utility maximization, and the current discontent with the neo-classical theory in economics. We then present results from a preliminary study designed to directly test whether student consumers make simple investment decisions in a way consistent with the maximization hypothesis. A more extensive experiment is now in progress.

Utility Maximization

The neoclassical economic model of demand proposes that consumers spread their disposable income across purchases by equating the marginal utility/price ratio for each category of goods (Waud 1980, Monroe 1979). According to the theory, a change in price for one good is compensated for by a shift in expenditures among all goods so that the ratios remain equal. When applied to a specific consumer purchase choice decision, the maximization hypothesis suggests that the buyer will select the alternative with the largest marginal utility per dollar cost.

While some economists have long questioned the adequacy of the utility maximization hypothesis (UMH) (see Becker 1962 for a discussion of criticisms), the hypothesis has come under particularly severe criticism recently. Nobel laureate Herbert Simon, who long ago discarded the UMH in proposing his theory of "bounded rationality" (Simon 1957), laid the groundwork for a developing "behavioral" school of economic thought. More recently, Gilad, Kaish, and Loeb (1984) have described the "platforms" of a new school of thought, foremost among which is the notion that economic theory be consistent with observed fact. The primary basis for criticism of the UMH is that behavior observed in the laboratory and the marketplace has frequently differed from what we would expect if participants were maximizing utility by applying sound economic and statistical logic. For example, the experimental observations that subjects are not consistent in their preferences for gambles (preference reversal - Lichtenstein and Slovic 1971) and that the way decision alternatives are framed (phrased) affects preference (Tversky and Kahneman 1984) are inconsistent with the proposition of a "maximizing" decision maker. Kunreuther's (1978) study of consumer aversion to low cost flood insurance and Arrow's (1982) observation of how investors overweight current information (relative to baseline information) lead to the same conclusion. These studies do not directly test the utility maximization hypothesis, however, because they introduce the added

complication of outcome uncertainty and the possibility that each decision maker has a unique conception of risk which changes depending on the decision context and their interpretation of different information cues.

While disenchantment with the UMH has grown in economics, there appears to be no direct evidence regarding whether buyers have the natural tools and instincts to maximize utility. Setting aside the important criticism that decision-makers are too limited in their information gathering and processing abilities to be maximizers (Simon 1978, 1979), more basic questions can be raised: given perfect information about simple decision alternative payoffs and costs (thus avoiding the complication of outcome uncertainty as noted above) and a clear maximization objective, do buyers naturally apply and can buyers naturally apply the rules necessary for utility maximization? These questions have not only been untested in the literature, the conventional wisdom in economics seems to be that they cannot be addressed empirically. Even when economists argue about philosophy of science applied to economics they agree that the maximization hypothesis is untestable (Boland 1982, Caldwell 1983). The problem appears to be to construct a convincing case for supporting or refuting what amounts to a paradigm as any indirect test based on inference can be shown to be suspect (Boland 1982). This research represents a first step in an attempt to directly test the utility maximization hypothesis. The fundamental issue is not whether the decision maker will maximize but whether he or she can maximize when rewarded for doing so.

Marketing and Utility

Understanding how buyers place utility or value on product/brand alternatives is central to research in marketing. Much research addresses how people derive their judgments of product utility or value (e.g., Cox 1967, Olson 1977). Two other major areas which deal explicitly with the measurements of product utility or value include multiattribute models (e.g., Wilkie and Pessemier 1974) and conjoint analysis (Green and Srinivasan 1978). Note that an underlying rationale for research in the above areas is that marketers want to present products (and/or product cues) which provide maximum net value or utility to buyers. According to Sheluga, Jaccard, and Jacoby (1979), this is appropriate because "the best prediction of which product will be chosen... is the product alternative having the most positive overall evaluation." (p. 166). The logic of the UMH, then, is often reflected in the study of consumer choice behavior.

The same logic is also reflected in our pricing literature. Monroe (1979, 1984) has contended that buyers make purchase decisions by selecting the alternative which has the highest "perceived value (utility) for the money." The "value for the money" construct is commonly measured in pricing studies (see Zeithaml 1984). Note that this decision criterion is equivalent to the marginal return/price decision rule presented in the classic economic theory.

The marketing relevance of studying the UMH is not to call into question the work cited above, but to extend our understanding of buyers' abilities to "rationally" approach and solve decision problems. Whether decision-makers satisfy or optimize in consumption decisions has come under the category of "choice rule" research. A consistent finding from this literature is that consumers, when confronted with a complex decision, initially use a satisficing rule to "weed out" unwanted alternatives and then use a more thorough rule to evaluate the remaining alternatives (Lusier and Olshavsky 1979). The current research differs

from such choice rule research in that (1) it uses an objective measure of decision-makers' ability to maximize and (2) it does not have an information acquisition confounding problem because it provides subjects with all the information they need to make their very simple decisions. The following research involves a test of buyers' natural abilities to maximize their outcomes. It is relatively unencumbered by the problems of incomplete information, information overload and optimizing ambiguity that have troubled other studies.

The Experiment and Hypotheses

The present study examined subjects' ability to maximize their decision outcomes for two different optimization rules. The decision context consisted of subjects choosing the one of three investment alternatives which yielded the greatest return. To illustrate, consider the following example:

Investment Alternatives	Dollar Return (per unit)	Dollar Cost (per unit)	Return minus Cost	Return divided by Cost
1	\$30	\$15	\$15	2.0
2	\$25	\$10	\$15	2.5
3	\$40	\$20	\$20	2.0

Some subjects were required to invest \$1000 in one of the three investment alternatives. For this decision, subjects should select the alternative with the largest "return/cost" ratio (hereafter referred to as the Ratio rule) in order to maximize their return. In the above example, the second alternative is the optimal choice. The remaining subjects were constrained to purchasing only one unit of the chosen investment. In this situation, subjects should choose the alternative with the largest "return minus cost" difference (referred to as the Diff rule). Thus, the third alternative is the optimal selection.

The first hypothesis tests whether the subjects come from a population where the mean score on the tasks is 18/20 (relaxed maximization assumption). This test is directional in that the alternative hypothesis is that the subjects' mean performance is less than 18/20. The null hypothesis is:

H₁: The subjects come from a population with an average maximization performance of 18 correct out of 20 (90%).

We anticipated that subjects' ability to maximize their decisions would depend on the rule required for outcome optimization. Assuming that subjects find the mathematical operations required for ratio estimation appreciably more difficult than those involved in difference estimation, the Diff rule should be easier to implement than the Ratio rule. Therefore, the following hypothesis is offered:

H₂: Subjects who purchase a single unit of their selected investment will more often make optimal investment decisions than will those who invest \$1000 in their selected investment.

A second experimental factor involved the presence or absence of the information in the last two columns of the prior example. These two columns present the mathematical calculations relevant to the Diff and Ratio optimization rules respectively. This information may affect decision accuracy in one of two ways. First, its presence may serve as a cue to subjects, helping them to recognize the appropriate decision rule (see Russo 1977). A third hypothesis, then, is:

H₃: Subjects who are provided the return-cost difference return/cost ratio information will make better decisions than those not provided such information.

The presence of this information may also be beneficial by assisting subjects in their mathematical calculations. That is, it should help eliminate simple mathematical

errors. However, because the mathematical calculation required by the Diff rule is relatively straightforward, we expected the facilitating effect of the information to emerge only for the relatively more complex Ratio rule. Accordingly, the following interaction is proposed:

H₄: Providing subjects with the mathematical information should improve their accuracy only when making \$1000 investment decisions.

Finally, we examined the possibility of a learning effect. Subjects were given a replication of the 20 tasks in the same order. It was expected that this practice would enable some subjects to discover and execute the correct optimizing rule. This learning effect is proposed in the following hypothesis:

H₅: Subjects will more often make optimal decisions later in their investment tasks than earlier.

In summary, the major issues addressed are whether subjects (1) can achieve a 90% correct choice performance level, (2) are equally adept at making decisions in terms of the gain/cost ratio or "value for the money" rule compared to the "return minus cost" rule in the appropriate situations, (3) are affected by information about relevant mathematical calculations, and (4) improve their decision accuracy with practice.

Method

Procedure

This preliminary study involved a series of "investment" decisions made by 48 junior and senior marketing undergraduates at a major university. All had taken a required accounting or finance course. The subjects were told that the study was intended to evaluate the information presentation format of a new investment guide published by Standard and Poors. The research took place in a personal computer laboratory and required subjects to make 40 investment decisions. Their decisions were preceded by an introduction to the exercise, three practice investment decisions, and three "check-up" problems to make sure they understood the consequences of their decisions. After finishing the investment task, the subjects completed a paper and pencil questionnaire, were compensated for their participation, and left the lab.

Subject Compensation

Subjects' compensation was based directly on their investment "performance" in order to heighten task involvement and effort. After each decision, subjects received a return based on their investment choice. This return was then added to a "bank balance" appearing at the top of their computer screens. Upon completion of the experiment, subjects were paid a percentage of their bank balance. The payments ranged from \$3.79 to \$4.75. Subjects were paid with a check which had been stapled to her/his handout on which the subject had identified her/himself as "payee" at the beginning of the hour. This procedure was intended to heighten awareness of the subjects' rewards for making the best decisions. Their objective, clearly, was to maximize their ending bank balances. The average post-test agreement score of subjects with the statement "I tried to make the best decision for every decision I had to make" was 6.3, with the statement "The instructions were very clear" 6.4 and with the statement "The game was interesting" 5.4 (1 = strongly disagree, 7 = strongly agree).

Research Design

The experimental design was a 2 (Investment Task) by 2 (Information Set) design with replication of the 20 tasks within subjects. The different conditions of the Investment Task factor will be referred to as the "single unit purchase" and "\$1000 investment" conditions. The Information Set conditions will be referred to as the "limited" and "full" information conditions. Both independent factors were described in the hypotheses section.

It should be noted that the second 20 problems given to subjects were an exact repeat of the first 20 problems. This allowed for a more precise analysis of the learning effect (H4). Informal discussion with some subjects after the experiment indicated that they did not recognize that the problem set had been repeated. This is understandable as the replications were separated by 19 tasks with very different cost and return profiles.

Dependent Variables

Overall choice accuracy was assessed by the number of times subjects selected the optimal alternative for each of the 20 decisions in the first and second problem sets. For each decision, subjects received a score of one for an optimal choice and a zero for a suboptimal choice. A set of post-task measures were included to identify the self-reported rule that was used during decision making, whether the rule changed during the exercise, self-reported understanding of economic maxims, and self-reported ability to do arithmetic, make investments and play video games. A number of the measures checked the subjects' understanding of the task, level of effort and beliefs about the purpose of the study.

It should be noted that the methodology used here was developed to maximize subjects' involvement in the research. Toward this end, subjects were provided with a clear objective in the research, a clear monetary reward which dominated their choice behavior during the experiment and a reward that was clearly tied to their performance and not one else's. Grether and Wilde (1984) have described a set of four conditions that research addressing microeconomic issues should meet. Their conditions appear to be met by the current methodology.

Results

Post-Task Measures

We first consider subjects' responses to the 7-point agree (7) - disagree (1) scales involving their reactions to the experimental task. Subjects strongly agreed that the instructions were very clear ($M = 6.4$). They perceived the "game" as interesting ($M = 5.35$) and disagreed that the game was tedious and boring ($M = 2.52$). Subjects also disagreed ($M = 2.48$) that the choices were very difficult. Concerning self-reported effort, subjects strongly agreed ($M = 6.3$) that they tried to make the best decision for every choice, although subjects in the \$1000 investment-limited information condition reported significantly ($p < .05$) less agreement ($M = 5.5$) than subjects in the remaining conditions. Subjects disagreed ($M = 2.3$) that they exerted less effort in decision making later in the game. Interestingly, subjects differed in their feelings that they had maximized their ending bank balance. Subjects in the full information conditions agreed ($M = 5.5$) more strongly ($p < .05$) with the statement than those in the limited information conditions ($M = 4.3$).

Given our expectation that the \$1000 investment task is more difficult than the single unit purchase because the former requires the more mathematically complex optimization rule, we asked subjects whether a calculator would have made their decision making easier and more accurate. Although subjects in the single unit condition disagreed ($M = 2.3$) that a calculator would have made the task easier, subjects in the \$1000 investment condition had a different perception ($M = 4.7$, $p < .01$). Similarly, subjects in the limited information condition ($M = 3.9$) differed ($p < .05$) from those in the full information condition ($M = 2.9$). In addition to these main effects, a significant ($p < .01$) interaction also arose such that subjects in the \$1000 investment - limited information condition reported the greatest support ($M = 5.7$) for the calculator's potential to make their choices easier. Although these same patterns emerged for subjects' perceptions about making more accurate choices with the calculator, only the difference between the \$1000 investment ($M = 4.3$) and single unit purchase ($M = 2.2$) conditions attained statistical significance ($p < .01$).

A disturbing finding concerns the existence of significant differences on measures of individual characteristics that should not differ across experimental conditions. For example, subjects in the \$1000 investment - full information and single unit - limited information conditions significantly ($p < .05$) differed from subjects in the remaining conditions on reported mental arithmetic and financial abilities, understanding of expected value, present value, and marginal utility concepts, and their experience and skill with computer games. These unexpected differences suggest that the assumptions underlying random assignment of subjects to experimental conditions may not hold, and thus represent a serious threat to the internal validity of this study. A correlation and factor analysis revealed that none of the post-task belief measures were strongly related to performance. The highest correlation was between agreement with the statement "I am good at playing computer games" and subjects score on the second replication ($r = 0.29$). Most of the correlations were below 0.10 with only a few above 0.2. But because of a concern over our ability to control for extraneous between subject effects through randomization (because of our small cell sizes), we ran several covariance analyses adjusting for self-reported involvement and effort, self-reported arithmetic ability and self-reported knowledge of economics and finance. Interestingly, only the first covariance analysis had a material effect on our findings.

Decision Accuracy

On the whole, subjects displayed considerable skill in making the optimal decision. Thirteen of the 48 subjects had a perfect score across the 40 decisions. A total of thirty subjects had an accuracy rate of 90% or more. Only seven subjects failed to make the optimal choice more than half the time. The average accuracy rate was 80 percent. A within cell test of the first hypothesis lead to its rejection only in the investment task condition (where the ratio rule had to be applied) where the subjects were not provided with the difference and ratio calculations for each of the three choices (see Table 1 for the mean scores and standard deviations for each cell). This result should be qualified by the low statistical power afforded by the experiment.

An interesting question is whether the poor performance was due to either a lack of ability and/or motivation to optimize. A comparison of subjects scoring 75% accuracy or better versus those less accurate on key post-task measures was therefore undertaken. Subjects high and low in accuracy equally agreed ($p = .9$) that they tried to make the best decision for each choice. Nor did they differ in their understanding ($p = .8$) of the task. While there was a tendency for the less accurate to perceive that a calculator would have been useful, this difference was not statistically ($p = .14$) significant. This latter result may in part stem from limited statistical power given that the less accurate group consisted of 14 subjects.

Impact of Experimental Manipulations

Table 1 summarizes the cell means for decision accuracy. The pattern of these data is very consistent with the research hypotheses. There is a tendency for subjects to make better decisions (1) when the Diff rule is the appropriate optimization rule, (2) under full information conditions involving only the Ratio rule, and (3) with practice. The results of a 2 (Investment Task) X 2 (Information Set) X 2 (Replication) ANOVA consisting of both between-subjects (the first and second manipulations) and within-subjects (Replication) factors are presented in Table 2.

As can be seen, none of the experimental manipulations attained statistical significance, although both the Investment Task and Replication factors approached significance ($p = .11$). Thus, we are unable to support most of the research hypotheses. This lack of support suggests that the research hypotheses are incorrect. However, we believe such a conclusion would be premature for several reasons.

First, as discussed above, the pattern of cell means,

although statistically insignificant, it very consistent with the research hypotheses (as well as many of the findings involving the post-task measures). Second, the power of the statistical tests may be unduly constrained by a relatively small sample size. In this regard, we should note that a sample with the same pattern of mean responses and variability as in the current sample but triple the size would have produced statistically significant main effects for Investment Task and Replication and a significant Investment Task by Information Set interaction effect.

Third, the apparent "breakdown" of random assignment procedures may have introduced an unfortunate bias in the results. A set of six measures of task involvement and effort introduced as covariates was reduced to three that explained a statistically significant amount of performance variance. The resulting covariance analysis resulted in a significant effect of task that supported our second hypothesis (see Table 2). Table 1 reports the adjusted cell means. Finally, the decision sets may have been too easy, as reflected by the high degree of choice accuracy. Obviously, it will be quite difficult to demonstrate a learning effect when subjects are "perfect" initially. A separate analysis that included only the subjects who scored less than 20 on the first replication resulted in a significant directional replication effect ($p < .05$). This set of 31 subjects were significantly more accurate in their second effort ($M1 = 13.4$, $M2 = 14.5$), thus supporting H5.

Self-Reported Rule Usage

Subjects were asked to select from a series of statements (see Table 3) the one which described how they made their investment choices. None of the subjects selected the "random" decision rule, while six selected the "other" option. Examination of these six subjects' descriptions of their decision making process revealed that they had in fact used a strategy consistent with one of those described in Table 3, but had simply failed to recognize this fact. We compared the recognition rule choice and self-described use of the different possible choice rules across the experimental conditions and then examined whether self-reported use of the optimal choice rule was related to performance. In the single unit purchase task condition 76% reported using the correct Diff rule when presented with the options in Table 3. An analysis of the written descriptions (open ended) revealed that 80% of the subjects confronted with this choice task used the correct Diff rule. The results were very different for the \$1000 investment task. In the full information - \$1000 Investment task condition, 80% reported using the correct ratio rule from the list presented in Table 3 but none of the subjects in the limited information - \$1000 investment task reported using the appropriate rule.

In short, there was a significant task/information interaction effect on the self-reported use of the correct rule ($p < .05$). This suggests that a major reason why the subjects in the \$1000 investment - limited information condition did not do as well was because they did not use the correct rule. However, upon examination of the self-described rules that the subjects used it became clear that 5 of the 13 subjects in this condition did indeed use a ratio rule - they simply did not recognize it as such when presented with the choices in Table 3. For example, the following two subjects described their choice rules thus: "I took the cost of investment decision and divided it into \$1000. For example, $1000/10 = 100$ units. I then multiplied that amount (100 units) by the return. This was done for all three choices. I then selected the choice with the highest return." Both were not able to recognize that they had, in effect, used the ratio rule more simply described in Table 3. In both task conditions self-reported use of the correct rule (either using the recognition or described measures) significantly increased performance ($p < .0001$).

Of further interest is that the subjects who reported changing their rule did not improve their performance in the second replication. Four out of five in the single

unit purchase task who reported switching, switched to the correct rule but only one significantly improved performance. In the \$1000 investment task condition, nine reported switching (6/13 in the limited information condition switched) with only four reporting switching to the correct rule and none of the four improved their performance significantly as a result of the switch. It seems that the learning effect that we observed was not the result of rule switching but the result of improvement in application or execution of the correct rule.

TABLE 3
DECISION RULES

Rule	Statement
Random	"I made my choices randomly without using the information or doing any calculations."
Return	"I chose the investment with the biggest monetary return."
Cost	"I chose the investment with the lowest monetary cost."
Diff	"I chose the investment with the biggest difference between its return and cost."
Ratio	"I chose the investment with the biggest return divided by its cost ratio."
Other	Other (please describe on the back of this page).

Discussion

The present study indicates that while some subjects were either unable and/or unwilling to optimize their decision making, the majority of them were in fact able to maximize their decision outcomes. Unfortunately, in this pretest we were unable to clearly discriminate between the motivational and ability explanation for suboptimizers, an issue clearly for future investigation. Even so, we were able to provide direct evidence that many subjects can and do make decisions which maximize utility. The results are also suggestive that for the task where subjects have to assess the return to cost ratio in an information condition where the computation is not done for them, they are not able to consistently optimize even when motivated to do so. If replicated in later studies, this is an important result as this situation comes closest to the typical real world circumstance where the decision maker has to allocate and optimize using marginal utility divided by price. The experimental task the subjects faced was much more straightforward than choice decisions in the real world. Utility and costs were provided in the same units and with no uncertainty. Consequently, it can be expected that subjects will be even less capable of optimizing in the real world.

The lack of evidence supporting some of the experimental manipulations is, of course, disappointing. We believe, however, that refinements in the task setting (e.g., more difficult tasks) and increased sample size (for both power and random assignment reasons) will permit a more appropriate test of the research hypotheses. We are currently pursuing an experiment that studies differences in decision time as well as accuracy. Time spent making the choice along with some other post-task measures should help us tease out whether poor performance is because of a lack of motivation or a lack of ability. The latest experiment also examines the impact of changing the decision task and hence optimizing rule between the replications. This will permit some insight into subjects' rigidity in their application of choice strategies (i.e., ability to adapt). In our follow-up study we also are examining the framing effects of only providing either the net return computation or value for money calculations in both tasks.

Abstract

The relationship of household attitudes to the major consumption-saving decision of homeownership is addressed. Findings of logit models of ownership are reviewed and the joint dependency between ownership and expected mobility is noted.

This joint dependency is then modeled in a conditional logit specification with attitude factors as explanatory variables. Results of the model estimation support hypotheses on direct and indirect influences of attitudes on ownership. The potential policy relevance of the findings is discussed.

Introduction

The relevance of attitudes to major household consumption decisions has been discussed in studies that now span several decades (e.g., Katona 1951; Pickering 1981). There is, however, limited empirical support for relationships hypothesized in these studies. The present study will consider the relationship between attitudes and the consumption-savings decision of homeownership. This decision is generally discussed as choice of ownership or contract rent forms of housing tenure and is among the most important household decisions in the consumption of housing services and the management of household financial assets.

The mainstay of existing studies estimate single equation logit or probit models of homeownership. Results of these studies have indicated income, the relative price of ownership and rental forms of tenure, family size, and age and sex of the household to be significant explanatory variables (e.g., Kain and Quigley 1975; Li 1977; Struyk 1978). The influence of explanatory variables other than income and price is generally interpreted in terms of institutional effects such as discrimination in housing and financial markets and taste differences. Tastes are, however, never explicit variables in these specifications.

This study instead proposes that the choice of ownership or rental tenure is influenced by socially learned normative orientations of the household in which attitudes are important elements. We consider the relationship between homeownership and household attitudes in a framework of household production theory (e.g., Becker 1976) where households do not consume goods and services they acquire in market transactions but enter them into the production of higher order social commodities such as "health status" or "prestige."

Following several generations of social research, we argue that the utility households derive from social commodities depends on its values and attitudes. Given this dependence of utility on attitudes, the derived demand for goods and services will also include attitudes as relevant explanatory variables. In the case of homeownership, we may model demand as discrete choice between ownership and rental tenure, and specify a "random utility" model of choice (e.g., McFadden 1974) which under certain independence and distributional assumptions is estimable in simple logit form.

Recent studies have taken up critical interdependencies between choice of housing tenure and other household decisions such as mobility (Boehm 1981; Krumm 1984) and the quantity of housing services consumed (Gillingham and Hagemann 1983). Within the framework of the present study, we believe that modeling the joint dependency between tenure choice and expected mobility can contribute to the explanation of effects of attitudes on choice.

The joint dependency between homeownership and mobility arises because search and transactions costs of changing residences are greater for owners than for renters. The cost of mobility will therefore depend on the households type of tenure. Similarly, the cost of a tenure type to the household will depend on its mobility.

We have previously hypothesized direct effects of attitudes on choice of housing tenure. Relationships between attitudes, career aspirations and occupational mobility rates (e.g., Sewell et al, 1973) also suggest direct effects of attitudes on expected mobility. If attitudes affect expected mobility, the joint mobility-ownership dependency leads us to hypothesize that attitudes also have indirect effects on tenure through mobility.

If in modeling, the joint dependency between ownership and expected mobility, we specify their reciprocal influence in an interaction term then the indirect effect of attitudes on ownership should be evidenced in this term. From previous discussion, we expect the interaction between ownership and expected mobility to be negative (i.e., expected mobility should decrease the probability of ownership and vice versa). If attitudes increase expected mobility as hypothesized, we would expect the inclusion of these explanatory variable to significantly increase the hypothesized negative interaction between the probability of ownership and expected mobility.

In the next section, we will test this hypothesis in the estimation of a conditional logit specification (e.g., McFadden 1974; Nerlove and Press 1973) of the joint dependency between choice of tenure and expected mobility. Boehm (1981) develops a similar specification and we take up some differences in testing the significance of the interaction term.

Conditional Logit Model of Tenure Choice and Expected Mobility. We begin by specifying both choice of tenure and expected mobility as binary endogeneous variables, and further assume "random utility" models of both tenure choice and expected mobility are applicable.

We can then write the following simultaneous equations for the joint dependency between tenure choice and expected mobility.

$$(1.1) \quad \Pr (T_i = 1, EM_i = 1) = (e^{B_1'X_i})/K$$

$$(1.2) \quad \Pr (T_i = 1, EM_i = 0) = (e^{B_2'X_i})/K$$

$$(1.3) \quad \Pr(T_i = 0, EM_i = 1) = (e^{B'_1 X_i})/K$$

$$(1.4) \quad \Pr(T_i = 0, EM_i = 0) = 1/K$$

where

T_i = the tenure choice alternative of i^{th} household:
 $T_i = 1$ if the i^{th} household chooses to own and
 $T_i = 0$ if this household chooses to rent;

EM_i = the expected mobility alternative of the i^{th} household:
 $EM_i = 1$ if the household expects to move in the next few years and $EM_i = 0$ if the household does not expect to move within the next few years;

X_i = a vector of the i^{th} household's sociodemographic characteristics and attitude factors which affect its tenure choice and/or expected mobility;

and

$$K = 1 + \sum_{j=1}^3 e^{B'_j X_i}$$

From equations (1.1) to (1.4), we can derive the following structural equations for tenure choice and mobility.

$$(2.1) \quad \Pr(T_i = 1 | EM_i) = \frac{e^{B'_1 X_i + \alpha_1 EM_i}}{1 + e^{B'_1 X_i + \alpha_1 EM_i}}$$

$$(2.2) \quad \Pr(EM_i = 1 | T_i) = \frac{e^{B'_3 X_i + \alpha_1 T_i}}{1 + e^{\alpha_1 T_i + B'_3 X_i}}$$

where

$$\alpha_1 = (B_1 - B_2 - B_3)' X_i.$$

Since the parameter α_1 , as defined above, equals the log odds ratio between tenure choice and expected mobility, we use it as a measure of the strength of¹ the interaction between tenure choice and expected

From equation (2.1) we observe that if $\alpha < 0$, $\Pr(T_i=1|EM_i=1)$ is less than $\Pr(T_i=1|EM_i=0)$. This is consistent with previous discussion which maintained that expected mobility should decrease the probability of ownership. Thus, we predict the sign of the estimated value of α_1 to be negative.

We derive estimates of the logit coefficients B_1 , B_2 and B_3 from maximum likelihood estimation of equations (2.1) and (2.2).

¹From (1.1) to (1.4)

$$\alpha_1 = \log \frac{[\Pr(T_i=1, EM_i=1)/\Pr(T_i=0, EM_i=1)]}{[\Pr(T_i=1, EM_i=0)/\Pr(T_i=0, EM_i=0)]}.$$

Thus, α_1 can be interpreted as the logarithm of the ratio of the odds of a household owning given it expects to move to the odds of a household owning given that it does not expect to move.

The Data Sets

The observations used in the estimation of logit model of tenure choice were drawn from the Panel Study for Income Dynamics (PSID) for the year 1968 to 1972 (cf., Survey Research Center 1972). Since the PSID was initially based on a conceptual model relating attitudes to a household's income relative to its needs, a range of attitude and behavior items were included with income and expenditure data on participant households.

Measures of Attitudes in the PSID. To specify attitude measures in the PSID, eight items were selected from the original survey on the basis of their judged relatedness to social class and the household's utility for social commodities.²

A principal components analysis of the attitude items yielded a three-factor solution accounting for 54 percent of the total item variance. The first attitude factor, goal setting (GS), includes educational items of expectations for children, preferred task difficulty level, and the frequency of implementing and completing plans. The second factor, future orientation (FO), is based on frequency of thinking about the future, planning ahead, and preference for saving rather than immediate consumption items. The task persistence factor (TP) includes general satisfaction/dissatisfaction and frequency of implementing and completing plans.

The dimensions of these attitude factors have been related to social class membership by a number of researchers (e.g., Blau and Duncan 1967; Cofer and Appley 1964; Keller and Zavalloni 1964). The relationship between these attitude factors and social class was directly investigated by regressing an assigned household Socio-Economic Index (SEI; Duncan 1961) scores³ on the attitude factors. These factors were found to account for 14 percent of the variation in SEI scores across household.

Measures of Income, Price and Sociodemographic Variables. The PSID reports annual household income over the years 1967-1971 and identifies household residence by county. This allows well-specified income and price variables to be constructed for each household.

We define 1968 permanent income as a four-year unweighted average of measured income before taxes in constant 1968 dollars plus the imputed rental value of owner-occupied housing for the years 1967 to 1970.

The relative price of own and rent tenure was defined as

$$P_{o/r} = \frac{P_o}{P_r} (1 - st)$$

²While these items include judgments of one's own past behavior as well as attitudes, we identify the items and derived factors as attitude measures for consistency with the Survey Research Center's grouping and simplicity in exposition.

³A procedure implemented by Featherman, Sobel and Dickens (1975) was used to approximate SEI scores on occupational prestige from standard Bureau of Labor Statistics codes of occupation, industry of employment, and the sex, race and age of the household head.

where P_o and P_r are BLS indices of the costs of owning and renting a home, respectively, for a family of four at a moderate living standard in the household is residence county (cf., U.S. Bureau of Labor Statistics 1972), s = the percentage of each dollar spent on housing services which is deductible from taxable income during the year and t = the marginal tax rate of the household in the year (c.f., Rosen 1979).

We also include the age, education (ed), race, and veteran status (vet) of the household head, family size, and categorical measures of whether young children are present (ch<18), and wealth (non-wage income: NWY (1) and (2)) in the joint tenure-mobility equations.

Finally, a set of variables that are hypothesized to influence expected mobility are included. These are expected change in family size (ECFS (1) and (2)), expected change in job (ECJ), and whether or not the household is on speaking terms with half of the neighbors or has relatives within walking distance (NT). The specification of the joint tenure-mobility equations to be estimated is

$$P(T,EM) = f(Yp, Po/r, ed, age, GS, FO, TP, famsiz, ch<18, NWY(1), NWY(2), NT, ECJ, ECFS(1), ECFS(2), Vet, Caucas, married)$$

Results and Discussion

Logit coefficients and asymptotic "t" statistics obtained from the estimation of equations (2.1) to (2.2) are presented in Table 1.⁴ Our discussion of the effects of independent variables in the joint tenure equations will concentrate on the B_2 and B_3 columns of the logit coefficients and the difference $B_1-B_2-B_3$.

From equations (2.1) and (2.2) of the previous section, we observe that B_2 and B_3 represent the direct effects of independent variables on $\Pr(T_1 = 1|EM_1)$, tenure choice given expected mobility, and $\Pr(EM_1 = 1|T_1)$, expected mobility given tenure choice, respectively. Correspondingly, $B_1-B_2-B_3$ represents the contribution of the independent variables to the interaction of tenure choice and expected mobility.

Considering the coefficients of the conditional tenure choice function (B_2) first, we observe that income, price, the presence of young children, non-wage income, attitude factors of goal setting and future orientation, and the age, race and marital status of the household head are significant. Results for the sociodemographic variables are generally consistent with previous studies (see, for example, Li 1978) and for reasons of brevity are not discussed here.

Although signs of all three attitude factors are positive in the conditional tenure choice equation, only coefficients of the goal setting and future orientation factors are significant. Constituent items of both these attitude factors have clear links to social class and relevant value orientations.

The conditional tenure choice equation was also estimated with coefficients of the attitude factors set to zero. Comparisons of the log likelihood values for

⁴Since some variables were included in the JTE because of their singular influence on either tenure choice or expected mobility, not all variables in Table 1 have predicted signs for both tenure choice and expected mobility.

* $p < .01$

** $p < .05$

this estimation and the fully parametrized tenure choice equation in Table 1 indicate that attitude factors significantly ($p < .01$) increase model fit to the data.

Turning next to the conditional expected mobility function, $\Pr(EM_1=1|T_1)$, coefficients for income, education, age, neighborhood ties and attitude factors of goal setting and task persistence are significant in Table 1.

Among attitude factors, goal setting and task persistence have different influences on expected mobility. Goal setting has an expected positive effect on expected mobility which may result from its hypothesized influence on occupational aspirations. Task persistence evidences a negative effect on expected mobility. The high frequencies of planning ahead and completing plans that define this factor may result in less frequent but more carefully planned adjustments to consumption through moving.

Finally, in considering the interaction between tenure choice and mobility, we observe that permanent income, non-wage income over \$500, and the goal setting attitude factor have significant influences on the magnitude of this interaction ($B_1-B_2-B_3$ in Table 1). The significant contribution of goal setting to the interaction of tenure choice and expected mobility is consistent with study hypotheses. In addition to the direct effects of the goal setting factor on tenure choice, this attitude factor apparently has an indirect effect on choice through its effect on expected mobility.

The coefficient of the interaction parameter, α , evaluated at population means of sociodemographic characteristics (X), has the predicted negative sign in $P(T_1 = 1 | EM_1)$ and is significantly different from zero ($\alpha = -2.2$, $p < .05$). This was tested by a t statistic that differs from the one Boehm (1981) has used in a similar model specification.⁵ We define the test statistic as

$$t_\alpha = \bar{\alpha} / \left(\frac{M}{N} \sum_{i,j} \bar{x}_i \bar{x}_j A_{ij} \right)^{1/2}$$

where M is the number of variables in the joint tenure mobility equation,

N is the number of observations in the sample,

$\bar{x}_i \bar{x}_j$ is the sample mean of the i th or j th component of X ;

$i, j = 1, 2, \dots, M$

$$\bar{\alpha} = \frac{1}{N} \sum \alpha_i$$

$$A_{ij} = \text{Cov}(B_{i1} - B_{i2} - B_{i3}, B_{j1} - B_{j2} - B_{j3})$$

where B_{i1}, B_{i2}, B_{i3} is the logit coefficient corresponding to the i th component of X

The goal of this research was to demonstrate the relationship between household attitudes and the major consumption-saving decision of homeownership. Estimation of a conditional logit model in which tenure choice and expected mobility were endogeneous variables indicated positive effects of goal setting and future

⁵We suggest the denominator of Boehm's test statistic must be multiplied by $(1/N)^{1/2}$ to be defined as a " t ".

However, Boehm's (1981) definition of t_α also assumes the B coefficients are known with certainty and the elements of X are random. This definition does not take the variability of the estimated B s into account. We consider a more appropriate assumption for the definition of t to be that the elements of X (sociodemographic characteristics of households) are fixed and the B coefficients are random, and therefore define the " t " as above.

orientation attitude factors on the probability of homeownership. Indirect effects of goal setting on homeownership through expected mobility were also obtained. These results support hypotheses on the interrelatedness of attitudes, expectations and consumption.

While earlier work on attitudes and consumption provides a foundation for the present inquiry, we believe that we now benefit from more definitive product or service class specific modeling of complex demand effects of attitudes.

Finally, we briefly note potential policy applications of this research. Since 1968, a major end of federal housing policy has been to increase homeownership among disadvantaged households as a means of increasing their housing quality and improving neighborhood quality in urban areas. These programs have focused on affecting the relative price of owning and renting largely through direct grants and subsidies. While income and price are major influences on the probability of ownership in our results, ownership is also found to be significantly affected by attitudes and expectations. More definitive investigation of the influence of these latter variables may yield policy methods to augment or guide constrained grant programs in increasing homeownership. For example, it may be that when households are grouped by attitude factors, income grants are efficient policy in some, while subsidies to the stability of neighborhoods which decrease expected mobility are efficient in others. These policy issues would be best considered in data with measurement instruments specifically designed for the investigation.

NEW EVIDENCE CONCERNING CONSUMER PRICE LIMITS

Anthony D. Cox, Georgia State University

Abstract

The idea that consumers have upper and lower price limits in choosing a brand has both intuitive appeal and empirical support. Several studies have attempted to measure these limits, but few have explored factors which may influence them. This study examines factors which may influence buyers' price limits. The results indicate that these limits are strongly correlated with prices buyers have paid in the past, and that at least lower limits may be shifted by the current range of prices presented to a consumer. These findings have implications both for price setters, and for consumer theorists -- suggesting how buyers' decision criteria may be shifted as they interact with the marketplace.

Introduction

Over the past 30 years, a variety of consumer researchers have suggested that a buyer possesses two price "limits" with respect to a given product category: a maximum expenditure he would be willing to make for such a product, and a minimum price below which he would have prohibitive doubts about the product's quality. (Emery 1970; Gabor and Granger 1966; Monroe 1971; Monroe and Venkatesan 1969; Sherif 1963; Stoetzel 1970). Not only has the concept of upper and lower price limits appealed intuitively to these researchers, but it is consistent with two other bodies of consumer research: the price-perceived quality literature (see e.g. Olson 1977) and studies revealing the importance of non-compensatory rules -- particularly the "conjunctive" rule -- in consumer brand choice (see e.g. Grether and Wilde 1984).

Almost all previous empirical research on consumer price limits has focused on measurement -- assessing individual consumers' price limits, and estimating market-wide frequency distributions of such price limits within specific product categories. Several researchers (e.g. Adam 1970; Monroe 1971) have suggested that the knowledge of such distributions could be a useful tool in managerial price setting. Beyond the issue of measurement, however, another important question regarding price limits has remained largely unexplored: How are these limits formed?

One interesting hypothesis is that a buyer does not bring rigidly formed price limits into the market place, but that these limits are to some extent shaped or shifted by the very range of prices he finds when he gets there. If this hypothesis were true, it would have significant managerial implications, suggesting a firm might be able to shift its customers' price constraints by altering its product assortment or price levels. Such a finding would also alter the interpretation of previous price limits research, particularly those studies (e.g. Monroe 1971; Monroe, Della Bitta and Downey 1977) which have assessed buyers' price limits by having them sort a particular range of prices selected by the researcher.

The purpose of this paper is to explore the hypothesis that consumers' price limits are shaped by the particular prices they encounter in the marketplace. First, relevant research findings from both marketing and psychology will be discussed. Next, the results of an experiment conducted by the author will be reported. Finally, the implications of the findings, both for marketing managers and consumer researchers, will be discussed.

Literature Review and Hypotheses

One indirect piece of evidence regarding the above hypothesis comes from the price-recall literature. Studies have shown that buyers typically have a poor memory for prices

previously paid for products, even frequently purchased products (see e.g. Dietrich 1977). Such uncertain recall might cause buyers to rely heavily on the immediate range of prices when judging what constitutes a reasonable or typical price. This effort might be accentuated in inflationary times; even if buyers can recall previous prices, a high inflation rate may make this information seem obsolete, causing them to rely on present prices as a more relevant guide to what is "normal."

Some evidence regarding the formation of price limits can also be found in the literature on human psychophysical judgement. The psychologist Helson (1947) posited that when a subject is asked to judge the magnitude of a stimulus (e.g. the height of another person) his frame of reference or "adaptation level" is partially determined by the average magnitude of the "focal stimuli" (e.g. the heights of the other people currently being judged). This hypothesis has since found considerable empirical support in the work of Parducci and his associates (Parducci 1954, 1956; Parducci and Hohle 1957; Engel and Parducci 1961; Parducci and Perrett 1971; Marsh and Parducci 1977.) It should be noted that Parducci's subjects have usually been asked to judge objects for which they have no meaningful prior experience or frame of reference (e.g. the size of black cardboard squares) and that they have been asked to rate these objects on inherently relativistic semantic differential scales (e.g. "very large," "very small," etc.) It seems likely that these factors would increase subjects' reliance on the current range as a frame of reference. Still, this research has interesting implications concerning the formation of buyers' price limits.

Two studies have extended the Helson/Parducci research stream into the domain of price judgements. Della Bitta and Monroe (1974) presented subjects with a series of prices in either ascending or descending order and asked them to rate each price on a semantic differential scale ("very expensive," "very cheap," etc.) They found that subjects shown the ascending series tended to rate a given price as more expensive, apparently because it contrasted against the preceding lower prices. Nwokoye (1975) presented subjects with either a high or low price range, and asked them to semantically rate each price in that range. He found that the average dollar value of prices designated "medium" was higher among subjects shown the higher range. While these results are interesting, their generalizability to the formation of price limits is limited by the fact these subjects, like Parducci's, gave purely semantic ratings of prices. Since terms like "very expensive" are inherently relative, a subject may examine the range of stimulus prices as a cue regarding what the researcher considers "very expensive." This does not necessarily mean that this range would alter the price the subject would pay for the hypothetical product.

Most pertinent to the present topic are two studies which have examined the effect of the stimulus range on buyers' self-reported price limits. Sherif (1963) presented subjects with price cards representing prices for hypothetical winter coats, and asked subjects to sort them into categories of "acceptable," "too expensive," and "too cheap." Subjects were given a set of prices ranging either from \$5 to \$54 or from \$5 to \$104. Sherif found that subjects' upper and lower price limits were both significantly higher in the group presented with the higher price range. However, the apparent shift in the upper limit is impossible to interpret, since by the nature of the task, sorters of the short series were unable to indicate an upper limit higher

than \$54. In fact, Sherif mentions that many of the subjects sorting the short range did not even use the "too expensive" category, suggesting they would have specified upper limits higher than \$54, had they been able to.

Monroe, Della Bitta and Downey (1977) replicated Sherif's experiment. Unlike Sherif, they found no significant price range effect on subjects' lower price limits. There was a statistically significant change in subjects' upper limit; however its theoretical significance was muddled by the fact that their subjects too were constrained in their ability to specify an upper limit.

In summary, while there is considerable indirect research evidence that buyers' price limits may be influenced by the prevailing range of prices, those studies which have directly addressed this issue offer conflicting results and contain methodological limitations which harm their internal validity.

To shed additional light on this phenomenon, the author conducted an experiment designed to overcome some of the methodological limitations of previous research. The research hypotheses guiding the study were as follows:

Hypothesis 1a

Subjects asked to evaluate a series of relatively high prices will specify a higher bottom price limit than subjects asked to evaluate a series of relatively low prices.

Hypothesis 1b

Subjects asked to evaluate a series of relatively high prices will specify a higher upper price limit than subjects asked to evaluate a series of relatively low prices.

The rationales for hypotheses 1a and 1b are discussed extensively above.

Hypothesis 2a

Subjects' lower price limits will be positively associated with the prices they have previously paid for similar merchandise.

Hypothesis 2b

Subjects' upper price limits will be positively associated with the prices they have previously paid for similar merchandise.

These hypotheses are consistent with the contention of Fouille (1970) that buyers' price limits may be based in part on past prices paid. More generally, it is consistent with the research findings of Parducci, et al. that subjects' judgements concerning stimuli are partially anchored by their previous experience with similar stimuli.

Hypothesis 3a

The level of the stimulus price range will exert a stronger influence on the lower price limits of those subjects who have not recently made a purchase in this product category than on those subjects who have made a recent purchase.

Hypothesis 3b

The level of the stimulus price range will exert a stronger influence on the upper price limits of those subjects who have not recently made a purchase in this product category than on those

subjects who have made a recent purchase.

These hypotheses are based upon the supposition that subjects who have not purchased the product recently will tend to have less certain recall of the prices to which they were exposed at the time of purchase. Therefore, they may rely more heavily on the current range of prices as a frame of reference.

The Experiment

Ninety-seven subjects were selected from four undergraduate business classes at a large midwestern university. A product type was chosen for the experiment (dress slacks) which had been purchased by the large majority of the subjects, male and female. Each subject was given a large envelope. Inside that envelope was a set of price tags (in random order), three smaller envelopes labeled "too expensive," "too cheap," or "acceptable," and a short questionnaire. The use of three categories is consistent with the majority of previous research in this area (e.g., Emery 1970; Gabor and Granger 1966; Stoetzel 1970).

S's were asked to turn the questionnaire face down, and to arrange the small envelopes with the labels facing up. They were then asked to unclip the price tags, and sort through them as if they were prices for pairs of slacks. They were told that they were not required to use all of the categories (labeled envelopes) provided for them, or to have an equal number of tags in every category. When the S's were finished sorting, they were asked to place the tags in the appropriate envelopes. In order to avoid the problems of the Sherif and Monroe experiments, the S's were then told that if they had not placed any price tags in the "too expensive" envelope, to write on the front of that envelope the highest price they would pay for a pair of slacks. They were given similar instructions regarding the "too cheap" envelope. When this was completed, they were told to fill out the questionnaire (in which they were asked to state when they last purchased a pair of dress slacks, and what price they paid), place all materials back into the large envelope, and hand it forward.

Half of the envelopes contained prices ranging from \$2 to \$46, at two dollar intervals, and the other half contained prices from \$16 to \$60, at two dollar intervals. The two price ranges were randomly assigned to subjects (by shuffling the envelopes before they were handed out). Both ranges of prices contained the pricepoints most frequently purchased by this subject population (according to a telephone survey of local merchants ranging from K Mart to expensive specialty stores). The subjects showed little interest in the experimental materials received by their neighbors, and there was no evidence that they knew there were two different sets of prices distributed.

Results

The data were analyzed in an analysis of covariance, with "stimulus price range" and "recency of purchase" entered as dichotomous factors (the latter variable was split at the sample median) and "price last paid" entered as a metric covariate. The unadjusted cell means are shown in the table.

The analysis of subjects' lower price limits supported Hypothesis 1a: Subjects presented with the higher range of prices specified an average lower price limit of \$19.53, whereas those presented with the lower range indicated a mean lower limit of \$16.21. This difference was significant at well beyond the .01 level ($F[1,92] = 10.08$). Thus it appears that the subjects did tend to use the stimulus prices as a frame of reference when deciding what was an unacceptably low price. This finding is consistent with that of Sherif (1963), but inconsistent with that of Monroe (1977), who found no stimulus-range effect on subjects' lower price limits.

TABLE
CELL MEANS FOR BUYERS' REPORTED
PRICE LIMITS

	High Price Range		Low Price Range	
	Recently Purchased	Not Recently Purchased	Recently Purchased	Not Recently Purchased
Lower Price Limits	19.8	19.32	16.48	16.0
Upper Price Limits	37.64	34.68	35.11	32.15

Such conflicting experimental results generally lead researchers to look for contingency factors, or variables which may moderate the treatment's effect. One potential moderator (recency of purchase) was addressed in this study in the form of Hypothesis 3a. Unfortunately, this hypothesis was not supported by the analysis. The interaction of recency of purchase and price range on lower limits was not statistically significant at even the .25 level ($F[1,92] = .608$), nor was there a significant main effect of recency of purchase ($F[1,92] = .123$).

Hypothesis 2a was strongly supported by the analysis. The price last paid accounted for 32% of the squared variance in subjects' lower price limits, statistically significant at the .001 level ($F[1,92] = 48.54$). This confirms the work in both consumer behavior and in psychophysics concerning the effects of past experience with similar stimuli on subjects' judgements.

A comparable set of analyses were performed on subjects' upper price limits. Hypothesis 1b was not confirmed; the effect of the stimulus price range on subjects' upper price limits was not statistically significant ($F[1,92] = 1.8$). However, it should be noted that the sample difference was in the predicted direction. Subjects presented with the series of high prices specified a mean upper price limit of \$35.96, while those shown the low series indicated an average upper limit of \$33.43. It is interesting to note that there was considerably more total variance in subjects' upper price limits than in their lower limits (the standard deviations were \$7.62 and \$5.62, respectively). This tended to inflate the denominator of the F ratios, possibly masking real effects of the treatments. It would be useful in future studies to try to discover variables which might explain for some of this variance. Such correlates would not only be interesting in their own right, but they could be used as covariates to increase the power of statistical tests examining the effects of the stimulus price range on subjects' upper price limits.

As was the case with lower price limits, the hypothesized interaction of recency of purchase and price range on upper limits was not even weakly supported, ($F[1,92] = .047$) nor was there a significant main effect of purchase recency ($F[1,92] = 1.1$). However, the analysis did strongly support Hypothesis 2b, indicating once again that buyers' price limits are closely related to the prices they recall having paid in the past ($F[1,92] = 52.62$, $p < .001$).

Conclusion

An understanding of consumer price limits is important both to those who must set prices, and those who wish to better understand the process of consumer choice. This paper has tried to offer some insight into how consumers form these limits. The experimental results reported above suggest two variables which may be important: The

prices consumers have paid in the past, and (though the evidence on this is less consistent) the range of products' prices at the point of purchase. The role of the latter variable is of particular interest, for at least two reasons. If the range of prices subjects are asked to judge can influence their price limits, this suggests that studies which have measured price limits by having subjects sort a particular range of prices (e.g. Monroe 1971) may have inadvertently altered that which they set out to measure. A practical implication of this result is that marketing managers may be able to shift consumers' price limits by altering their product assortment or prices. For example, a retailer might add a \$500 suit to its assortment in order to make a \$400 suit appear less extravagant to its customers (or perhaps to discourage them from buying \$100 suits). However, this effect needs to be examined in a more naturalistic setting.

There are several directions which future research should take. Future studies should test the generalizability of these findings, by examining other subject populations and product classes, and by increasing the realism of the task - presenting subjects with actual products, asking them to make actual purchase commitments, and so forth.

There are also other factors whose effects on consumers' price limits might be examined. One such factor is consumers' involvement - both with the particular product class, and with prices in general. Research in social psychology (see Sherif and Hovland 1961, p. 129; Fishbein and Ajzen 1975, p. 457) has indicated that subjects who are highly involved with a class of stimuli are likely to consider a much narrower latitude of stimuli as "acceptable." This suggests that product involvement may have a main effect on price limits (narrowing the range of acceptable prices) and also may interact with the prevailing price range (highly product-involved subjects might be less susceptible to price-range influences in forming their judgments). Both of these effects are worthy of future investigation. It is also possible that there may be demographic (e.g., gender) and behavioral (e.g., type of stores patronized) factors which are either directly or indirectly related to consumers' price limits.

In summary, this study generates more questions than it answers. However, the phenomenon of consumer price limits is sufficiently interesting, both managerially and theoretically, to justify future research directed at answering these questions. The author is currently engaged in such research.

THE EFFECTS OF SAMPLING AND INFORMATION ON BRAND CHOICE
WHEN BELIEFS IN QUALITY DIFFERENCES ARE AMBIGUOUS

George Brooker, University of Puget Sound
John J. Wheatley, University of Washington
John S. Y. Chiu, University of Washington

Abstract

Extant research has suggested or demonstrated that when consumers believe large quality differences exist among brands in a product class there is a tendency for consumers to choose the higher priced alternative. These studies have failed to answer a number of important questions. For example, what is the relative effectiveness of information and sampling in affecting preference and can monetarily constrained choice be influenced when beliefs about quality differences among brands in a product category are ambiguous.

Introduction

Prior beliefs about large quality differences among brands in a product category with a tendency for consumers to prefer the higher priced alternative in such circumstances has been suggested or demonstrated by a number of researchers. (Leavitt 1954, Tull Boring and Gonsior 1964, Lambert 1972, Obermiller and Wheatley 1984). However, the earlier studies did not attempt to measure preference when money was involved and the more recent study, while imposing a monetary constraint on choice behavior failed to answer a number of important questions.

First, the work by Obermiller and Wheatley (1984) on price effects indicated that individuals changed beliefs and behaviors consistent with self-perceptions of evidence given them about products. The nature of the evidence given was a taste test of (identical) brands and information about the brands. The information given was either "perfect" (indicating no essential differences existed between brands) or irrelevant (sales figures, usage data, user demographics). All participants in the study got both a taste of the brands and one of the information treatments in a before-after between-subjects design. From the perspective of the marketing change-agent, there is some uncertainty regarding which of the treatments (taste and information) was influential in causing the changes that were reported. Although there is little reported research on the relative effectiveness of sampling versus advertising, possibly because both are typically used simultaneously in promotional efforts, the former is generally regarded as the more effective method of persuading consumers to choose a product (Kotler 1984, p. 663). Product trial is thought to generate stronger attitudes than advertising at least in part because, unlike advertising, there is little risk of source derogation, discounting and counterarguing (Smith and Swinyard 1983). Preferences based on sensory experience with products are viewed by consumers as valid and usually unquestioned (Bem 1970). Therefore, we hypothesize that sampling will be more influential than information in determining choice behavior.

Pre-measures and post-measures of beliefs about brand differences and strengths of those beliefs were taken by Obermiller and Wheatley. These beliefs along with changes in perceptions of quality differences were used to assess switching patterns between low and high priced brands. While switching patterns were consistent with beliefs, some of the patterns were inconsistent (e.g., people initially choosing a low priced brand, subsequently changed to a high priced brand). A second question which arises from these results deals with the nature of the beliefs that are changed (leading to changes in preference). Some beliefs are stronger than others, and more difficult to change. Rokeach (1969) has discussed the sources of beliefs as one reason for difficulty in changing them. Generally, beliefs

emanating from personal experience are most difficult to change; beliefs arising from an authority figure will be somewhat less resistant to change, changing when the authority changes; inconsequential beliefs, such as those developed by advertising are easiest to change. From this perspective, it would be expected that individuals whose beliefs about products are based on personal experience are less likely to change those beliefs (and consequent behavior) in response to marketer activities than would those whose beliefs are less resistant to change as, for example, advertising based beliefs.

The third question, and perhaps the most important, has to do with the types of products chosen by Obermiller and Wheatley to demonstrate the effect of prior beliefs on brand preference. The product categories, colas and pop corn, were ones that consumers believed contained either large (cola) or negligible (popcorn) quality differences, among brands. In reality, a large number, if not most product categories are believed to include brands that are quite similar in terms of quality. The issue of how consumers utilize price as an indicator of quality in such circumstances was not addressed. If the hypothesis that individual differences, such as prior beliefs about the presence or absence of quality differences among brands in a product category, determines whether consumers utilize price as a quality cue is true, we should anticipate ambiguous results in the case of product groups that are viewed as consisting of brands that, while not alike in terms of quality, are not very different from one another. An appropriate choice of products should offer an opportunity to demonstrate discriminant validity.

Consequently, this research has four major objectives: (1) to determine the relative effects of sensory (taste) and cognitive (informational) experience on quality assessments and behavior, (2) to ascertain the relationship between the source and strength of beliefs and subsequent effects on perceptions of quality and behavior and (3) to infer the effects of price on quality perceptions and choice when neither very large nor very small quality differences are thought to exist among brands. A fourth objective was to verify the generalizability of previous results to adult consumers, since the work by Obermiller and Wheatley was done primarily on student populations.

Methodology - Exploratory Research

A pretest was performed on twenty-two products to select those appropriate for the subsequent experiment. The products studied were food products that could be used in a taste-test procedure.

Products were separated into four groups for the pretest. Convenience samples of 32-35 people rated the products (on a seven point scale) in each group for quality differences among brands in the product class. Selection for the experiment was based on a reasonably uniform distribution of ratings across the entire scale and a mean close to the scale midpoint. The products chosen for the research from the pretest were potato chips and frozen orange juice.

Methodology - Causal Research

Two separate 2x2x2 split plot factorial designs were used. For each of the two products, two information conditions (relevant or irrelevant) and two sample conditions (taste or no taste) were created between subjects. The two price conditions were within subjects, that is, all subjects were exposed to the high and low

prices then prevailing in the marketplace for potato chips and frozen orange juice.

Data collection was performed at two different sites (grocery stores in a medium-sized Northwestern city). One product was studied at each research site to minimize the potential for cross-product contamination by reusing respondents. The research sites were about ten miles apart. Only one person was run in the experiment at one time to minimize respondent suspicion regarding the sample condition. (Having one person sample the product while a second was not allowed to sample at the same time has the potential to create questions regarding the procedure in the minds of respondents.) Individuals were randomly assigned to experimental conditions at each site.

In the procedure, individuals were screened to be sure they used the products. Then they were asked about their beliefs regarding differences among brands of the product and about the strength of these beliefs. This was followed by three questions on possible sources for their beliefs: personal experience, knowledge gained from advertising, and expert opinion. The remainder of the experiment was completed by the respondent, with the experimental treatment and all remaining measures contained in a booklet.

Experimental treatments were couched as information drawn from articles in Consumer Reports. In the relevant information conditions, it was stated that there were no essential differences between brands of the product and a blind taste test panel could not tell the brands apart. In the irrelevant information conditions, no mention was made of brand differences. The various treatments are presented in Appendix A.

Following the presentation of the information condition, individuals were shown samples of the (identical) product with "brand names" Xb and Wt attached. (Xb and Wt have been demonstrated to be neutral "brands.") Retail prices of higher priced and lower priced brands were included as part of the "brand" information. (The higher priced brand was Xb.) In the taste condition, people were given samples of each "brand" at this time. Individuals then rated the quality of both brands on a five-point scale, after which they made a choice between the brands.

By way of introducing a monetary constraint, the choice was presented as the prize the individual would win if selected in a drawing. If the lower priced brand were chosen, the individual would receive that brand plus the cash difference between the lower and higher priced brand. If the higher priced brand were chosen, the individual would receive only the product.

After the choice was made, individuals were asked about the reasons for making their choice; views on Consumer Reports and manipulation checks were taken; demographics were collected and individuals were asked their beliefs regarding the purpose of the experiment. Upon completing the booklet, the people were thanked for their participation and were given a folded and stapled sheet of paper which they were asked to open and read when they got home. This sheet debriefed the subjects; it explained that some of the information given was not correct, and related it to the general purpose of the experiment.

Results¹

The profiles of the groups participating in the two studies were quite similar except for income. In the orange juice experiment, 74 people participated: 23 males, 50 females, and one was unreported. Median age was 34.1 years; 69% had more than a high school education

¹ We wish to acknowledge the assistance of Ms. J.M. Morris in the computer analysis of the data generated in this experiment.

and the median income was \$19,615. In the potato chips study, 77 people participated: 23 males, 53 females and one unreported. Median age was 34.8; 75% were educated beyond high school and median income was \$29,999.

Manipulation checks focused on the relevant and irrelevant information treatments. The checks measured on a five point scale the strength of agreement by respondents with factual statements about the information given to them "from Consumer Reports." The groups compared, on an individual product basis, were those receiving the relevant and those receiving the irrelevant information treatments. T-tests were used to make the comparisons. For potato chips, those receiving the relevant information agreed more strongly ($p < .05$) that there were "no essential differences between brands," and those receiving the irrelevant information agreed more strongly ($p < .05$) with a factual statement about the consumption of the product in the U.S. For orange juice, the irrelevant treatment check (about consumption) produced a significant ($p < .05$) and parallel difference between groups. The relevant treatment check was not significant ($p < .30$), but the group means showed that the relevant information group was in greater agreement with the "no difference" statement. Therefore, it was concluded that the treatments were effective.

T-tests between information treatment groups on their views of the factualness of Consumer Reports did not yield significant differences for either product. Similarly a question about the usefulness of the information from Consumer Reports in helping respondents choose between brands produced no significant (or substantial) differences.

Responses to the two product studies were analyzed separately. Table One presents the results of the treatment effects on choice behavior in the orange juice experiment. As hypothesized, the effect of sampling the product had a significant effect on the choice made, with those receiving the sample tending to choose the lower-priced (Wt) brand. (Table Two shows the proportions of those in the sampling conditions choosing each brand.) Information did not affect choice, and the interaction effect was insignificant.² The inferred price effect was also weak, as anticipated.²

TABLE 1

ORANGE JUICE: ANOVA ON CHOICE USING UNIQUE SUMS OF SQUARES, SAMPLING AND INFORMATION AS DUMMY VARIABLES³

Treatment	df	F	Signif.
Price (Constant)	1	<1	ns
Sample (S)	1	4.328	.041
Information (I)	1	1.858	.177
S x I	1	1.858	.177
Residual	70		

² This method of analysis may be unfamiliar to the reader. Briefly, the vertical axis in the ANOVA, which is cast in a regression mode, ranges from 0 to 1 and represent the probability of purchase of the expensive brand. Non-random choice behavior would differ significantly from .5 in either direction. The intercept in this case was .536 with a standard error of .055. Thus the inferred lack of significance of "price."

³ The response function involving a binary dependent variable is essentially linear in the middle range. Therefore, the logit transformation was not necessary here. (See graph, page 329, Neter and Wasserman 1974.)

TABLE 2

ORANGE JUICE: Sample Condition	PROPORTIONS CHOOSING BRANDS BASED ON SAMPLING CONDITIONS		
	Chose Xb	Chose Wt	Total
No Sample	64%	36%	100%
Sampled	40%	60%	100%

Analysis of Covariance using initial beliefs in brand differences, strength of those initial beliefs, belief difference x belief strength and confidence in the factualness of Consumer Reports as covariates did not change the pattern of significance shown in Table One. None of these covariates was significantly associated with brand choice.

In the belief that absolute quality ratings of each of the brands were not meaningful in themselves, a variable was created to reflect the differences in relative quality ratings given to the brands by each person in the study. This was done by subtracting the quality rating given to Wt from the quality rating given to Xb. An ANOVA performed on this variable indicated that differences in relative quality ratings were not affected by the information and sampling treatments in the orange juice experiment. The inferred effect of price was, however, marginally significant ($p < .068$) as indicated in Table 3. The relative quality ratings apparently were the result of the price cue being utilized by the subjects to perceive quality differences where, objectively speaking, none existed. (In this ANOVA, we infer the price effect from the intercept; the ordinal axis is scaled to reflect differences in the quality ratings of the expensive and inexpensive "brands.") The same concomitant variables used to examine the choice process also yielded nothing of statistical significance in connection with the relative quality ratings of the two brands.

TABLE 3

ORANGE JUICE

ANOVA on the Difference in Quality Ratings Between Brands Using Unique Sums of Squares, Sampling and Information as Dummy Variables

Source of Variation	df	F	Signif.
Price (constant)	1	3.441	.068
Information (I)	1	< 1	ns
Sampling (S)	1	< 1	ns
S x I	1	< 1	ns
Residual	70		

In the potato chip experiment, ANOVA revealed no significant effects of sampling or information on brand choice or on differences in quality ratings. The price variable was, however, significant for quality ratings as indicated in Table 4. Once again, none of the concomitant variables were significant nor did they alter the results of ANOVA.

TABLE 4

POTATO CHIPS

Residual	73		

Discussion

Sources of beliefs had negligible effects in both experiments. Unfortunately, responses to the questions on sources of beliefs were highly skewed, with a preponderance of people reporting personal experience as the basis for their beliefs and only a few reporting advertising or reliance on other knowledgeable people as the sources of their beliefs. Thus, we were unable to deal with the research hypotheses having to do with sources and strength of belief and choice. In retrospect, it seems plausible to suggest that the products chosen for this experiment may have contributed to this outcome. If orange juice and potato chips were regarded as relatively low involvement - low risk products, that alone could account for the large number of experimental subjects who said that personal experience was the source of their beliefs.

Nevertheless, this research was partially successful in clarifying the results of the previous research by Obermiller and Wheatley. As anticipated, sampling is more powerful than "limited" advertising in affecting preference. In the orange juice study at least, the effects of sampling resulted in choice differences; information effects were non-significant. However, neither of these treatment effects were significant in the potato chips study. Price, on the other hand, was significant in affecting quality ratings for both potato chips and orange juice. In assessing quality, adult consumers apparently still use price as a cue even when they believe that quality differences among brands in a product category are not large. This is a significant finding because it strongly suggests that the quality of a large proportion of the products available in the marketplace may be judged on the basis of price information, i.e., the price-quality relationship may not be restricted to the smaller number of product categories in which large differences among brands are believed to exist. As long as product differences are not negligible, e.g. salt, popcorn or sugar, prices seem to matter; they create a price-quality perceptual bias. Additional and different types of products should be tested to confirm this conjecture. On the other hand, consumers may not feel strongly enough about this difference in quality to make a price constrained choice of the more expensive brand. This is consistent with the earlier observation by Wheatley et. al. (1980) "a price-quality perceptual bias may not necessarily affect choice behavior."

These research results may also be product specific. The pattern of results is somewhat different between the two products. However, aside from product form, there is no obvious difference between the products that would cause dissimilar results and there is no obvious reason why product form should affect the way beliefs influence quality assessments and brand choice. It may be that there is a difference in the decision process used to choose among brands in these product classes, but this observation is merely speculative.

One of the interesting, though understandable, outcomes of this project is the lack of impact of the information treatment. The manipulation checks indicated the information treatments were perceived accurately and retained. Few, if any, students of the communication process would suggest supplying information to change beliefs, attitudes, or behaviors is a hopeless task. It is more likely that the effects of information require more than a single exposure to be reflected in the types of measurement used here. Counter arguments and negative thoughts about the message may also have played a role. In addition, as mentioned before, in this experiment most of the participants beliefs were found to be based on personal experience. Such beliefs are strongly held and difficult to change. They will limit what will be accepted and remembered about a message because a message recipient relies more heavily on his or her evaluative response to the content of a message than on the content of the message itself (Wright 1973).

The effects of sampling are equally intriguing. Only in the orange juice experiment was an impact found on choice behavior; no such finding was observed in the potato chips experiment. Here we see a marketer behavior (sampling) affecting sensory experience (taste) in turn affecting choice behavior by demonstrating that the samples were indistinguishable. This is similar to an effect reported by Steinberg and Yalch (1976), who found sampling had an effect on the purchase behavior of obese people. This suggests that sensations may beget behaviors in some circumstances. This is a notion which ought to be explored to define the conditions under which it holds true.

While we have inferred that quality difference ratings were attributable to price differences, it is possible that they were the result of demand characteristics inherent in the experiment. Most consumers like to feel that they can notice differences between brands of a product. Advertisers certainly do their best to encourage such sentiments. The two samples presented to the respondents were identified as being different brands having different prices. Thus, the shoppers were encouraged to believe that differences existed. Fully half the sample, however, was led to believe that the samples were identical. The emergence of an inferred price effect, in such circumstances, tends to lend credence to the interpretations we have given, and attenuates the alternative explanation of a demand artifact.

The failure to find effects based on the sources of beliefs probably is due, in part, to the lack of control over the belief sources in the research. The skewed responses, problems with recall, and confounding of multiple sources could be overcome if source of belief were manipulable. Although it was not the focus of the study, manipulation of sources has been tried with undergraduate students in a study by Obermiller and Wheatley (1985). That approach could be adapted for use with different populations. The Rokeach typology of beliefs is relatively untested in consumer research in spite of the fact that beliefs and belief change have been studied for years. The typology may represent an opportunity to develop greater understanding of the problems of changing or maintaining beliefs with a research design adapted to test it.

Another interesting step would be to determine what proportion of consumer products are in each of the three product categories discussed in this paper, i.e., product groups in which consumers believe that there are large, intermediate or very small differences among brands. It would also be worthwhile to learn what fraction of consumers believe strongly in these characterizations. This work would have obvious implications for the development of pricing strategies on the part of sellers.

APPENDIX A - The Information Treatments

A study by Consumer Reports states:

Most Americans start their day with a glass of some sort of juice. By far, the most popular juice consumed is orange juice. Orange juice basically contributes vitamin C and sugar to the diet. The sugar in orange juice - a combination of sucrose, fructose, and glucose - contributes most of the 70 or so calories per glass. Orange juice is available in several forms - freshly squeezed, frozen, refrigerated, and canned. More recent variations are the imitation juices made from powder which is mixed with water. All forms are available in local supermarkets. (Orange Juice - Irrelevant)

A study by Consumer Reports states:

Orange juice basically contributes vitamin C and sugar to the diet. Different kinds of orange juice don't differ significantly in vitamin C or in calories. The big difference is in what processing does to the flavor. Frozen orange juice is the least processed of the supermarket juices. It's basically fresh juice with most of the water removed. If the juice isn't defrosted and

refrozen, all frozen orange juices will taste pretty close to freshly squeezed juice after they are reconstituted. A scientifically conducted experiment with a large sample of frozen orange juice users found it was impossible to tell the brands apart in a blind taste test. (Orange Juice - relevant)

A study by Consumer Reports states:

The potato is an important staple in the American diet. On average, every American eats 123 pounds of potatoes a year - 58 pounds fresh and 65 pounds processed. Processed potatoes include frozen french fries, instant dehydrated potatoes, and potato chips. (Potato Chips - Irrelevant)

A study by Consumer Report states:

The content of all commercially available potato chips in this country is the same, except for flavorings such as barbecue, hickory smoke, or cheese, that may be added. Differences in color, fat content, moisture content, preservatives and salt were found to be very small. Since potato chips are all made with similar raw materials and utilize almost identical manufacturing processes, our researchers were not surprised to discover that a scientifically conducted experiment with a large sample of potato chip users revealed that it was impossible for consumers to tell any of the various brands of unflavored chips apart in a blind taste test. (Potato Chips - Relevant)

AN EXAMINATION OF CONSISTENCY IN COUPON USAGE BY HOUSEHOLDS
ACROSS PRODUCT CLASSES

Kapil Bawa, New York University
Robert W. Shoemaker, New York University

Abstract

This study examines whether households behave consistently in their level of coupon usage in different product classes. It also examines whether the degree of store loyalty is consistently high or low for these households. Several interesting empirical results are found. First, households are considerably more consistent in their purchasing than would be expected by chance. Second, there exists a significant segment of households with above average coupon usage for most product classes and low store loyalty for most products. The managerial implications of these findings are discussed.

Introduction

In recent years, a number of studies have been conducted on the growing use of coupons, the profitability of coupon promotions and the level of coupon redemption rates. While these studies have addressed a number of important couponing issues, it appears that no studies have examined whether households are consistent in their level of coupon usage across different product classes. For example, if a household uses coupons to an above average extent in one product class, does it also use coupons to an above average extent for its purchases in other product classes? If it does, it can be considered a "consistently" heavy user of coupons.

When examining coupon usage across product classes, it appears desirable to consider the extent of store loyalty as well. A household that is consistently store loyal and a heavy coupon user is likely to be responsive to manufacturers' coupons for products that are not available in its favorite store, and much less responsive to store coupons offered by other stores. On the other hand, a household that follows a store-switching strategy for most product classes and is a heavy user of coupons is likely to respond favorably to both manufacturer and store coupons.

This study therefore examines consistency across product classes in terms of both coupon usage and store loyalty. The major questions addressed here are:

1. To what extent are households consistent in their use of coupons across product classes? (i.e. to what extent do they consistently use an above average percent of coupons in all classes or to what extent do they consistently use a below average percent of coupons across product classes?)
2. To what extent are households consistent in their store loyalty across product classes? (i.e. if they are store loyal for one class, are they also loyal for other classes?)
3. What is the relationship, if any, between a household's degree of consistency in coupon usage and its degree of consistency in store loyalty?

Prior Research On Consistency In Purchasing Behavior
Across Product Classes

While no previous studies have examined the consistency of

coupon usage across products, a number of authors have examined the general question of whether households utilize similar buying strategies across product classes.

Cunningham (1956) studied households' loyalty to their favorite brand (measured as the share of purchases devoted to the favorite brand) in seven product classes. He computed pairwise rank correlation coefficients for each of the 21 possible pairs and found only 2 of the pairs to be significant. He concluded that "...loyalty proneness (across product classes) does not exist to a significant degree." This conclusion was later echoed by Massy, Frank and Lodahl (1968) who conducted a similar analysis using purchase data for beer, coffee and tea.

A third analysis covering 38 product classes was conducted by Wind and Frank (1969). The two variables they observed were brand loyalty (measured as the market share of the favorite brand) and private brand proneness (market share of private label purchases). As in earlier studies, they correlated each measure between all possible pairs of product classes and concluded that "on the average, only an extremely small percentage of the variation from household to household in loyalty to brands in one product class is associated with variation in brand loyalty in another class."

A more recent study of buying consistency across product classes was conducted by Blattberg, Peacock and Sen (1976). In their analysis, heavy buyers were classified into one of sixteen "purchase strategy" categories such as "Loyal Buyers of National Brands" or "Deal Oriented Buyers of Private Label Brands." They then measured the extent to which buyers utilized the same buying strategy across 2 pairs of product classes.

They found that 35% of the households (n=108) used the same buying strategy for aluminum foil and waxed paper, while the corresponding figure for liquid detergent and facial tissue was 13% (n=235). They also examined the extent to which buyers used similar but not identical buying strategies for the two pairs of products. In general, the authors found greater consistency in buying strategies than the earlier studies. However, the level of consistent behavior across product classes was still not high.

The purpose of the current analysis is to extend prior research in several ways. First, the study focuses on a new variable, namely the consistency of a household's coupon usage across product classes. Second, this study simultaneously analyzes consistency across four different product classes. While prior studies considered data from several product classes, the analyses were based on comparing only two product classes at a time. Finally, statistical tests are used to test the hypothesis that usage of coupons or degree of store loyalty is decided independently for each of the four product classes. "Independence" in this study refers to statistical independence; that is, if the joint probability of observing similar behavior (such as above average coupon usage) in different product classes is statistically no different from the product of the unconditional probabilities of observing such behavior in each of these product classes, the behavior is considered independent across the classes.

Hypotheses

It is assumed that households gain utility when they use coupons in any product class, in the form of savings re-

sulting from the lower prices paid. However, there are certain costs associated with coupon usage as well. These consist of (a) a fixed cost, which must be incurred if one wishes to use any coupons at all, and which includes the opportunity cost of scanning newspapers or direct mail, reading coupon inserts, and organizing the coupons for future use, and (b) variable costs for each coupon used, arising from the opportunity cost of cutting, sorting, and redeeming individual coupons.

Thus an individual household's coupon usage is assumed to be a function of the savings obtained relative to the costs associated with coupon usage. The notion of a "fixed cost" of coupon usage suggests, moreover, that if a household uses coupons at all, it is in the household's interest to use coupons in many product classes in order that the total benefits from coupon usage exceed the fixed cost. Thus if the household is able to redeem enough coupons such that the total savings exceed the total costs of coupon usage, it will tend to be a relatively "heavy" user of coupons for most product classes. However, if the total savings are always less than the total costs, it will tend to be a light or non-user of coupons for most product classes.

In either case, the level of coupon usage by individual households is likely to be highly correlated across product classes—that is, they will be relatively consistent in their use of coupons across classes, rather than deciding on their coupon usage independently for each product class. This reasoning leads to the following hypothesis on coupon usage:

H1: More households will consistently make an above (or below) average share of their purchases with a coupon in several product classes than would be expected if coupon usage was decided independently for each product class.

For store loyalty too, one would expect to find consistently high (or low) levels across product classes. Here it is assumed that if a household buys in several different stores for one product class, it can then buy in several stores for most product classes at little or no additional cost. This leads to the following hypothesis:

H2: More households will consistently shop in different stores (exhibit low store loyalty) or primarily in one store (exhibit high store loyalty) in several product classes than would be expected if store loyalty was independent from one product class to another.

The Data

The panel data used to test the hypotheses were obtained by NPD Research. The panel consisted of over 4,000 households. The data analyzed cover four product classes: ready-to-eat cereal, facial tissue, shampoo, and deodorants and anti-perspirants. The period analyzed covers the 12 months of 1975.

In order to provide an adequate basis for classifying households, the analysis was based on all households who made at least five purchases in each of the four product classes. This yielded a sample of 385 households.

A brief summary of the data is presented in Table 1. The first row of the table shows the average number of purchases in each of the four product classes. It ranges from 10 for shampoo and deodorants to 46 for cereal. Row two shows the average percent of volume purchased with a coupon (e.g. on average 9.8% of all facial tissue purchases for this sample were made with either a manufacturer or store coupon). Row three shows the percent of households whose fraction of volume was above the average for all households. The corresponding figures for store loyalty are shown in rows four and five.

TABLE 1

SUMMARY STATISTICS ON COUPON USAGE AND STORE LOYALTY BY PRODUCT CLASS^a

	Product Class			
	Cereal	Facial Tissue	Deodorant	Shampoo
1. Average Number of Purchases per Household in one year	46	17	10	10
2. Average Proportion of Volume Purchased with a Coupon	12.2%	9.8%	9.5%	8.1%
3. Percent of Households whose fraction of Volume with a coupon was above the average	36%	33%	29%	28%
4. Average Proportion of Purchases Made at Favorite Store for this Product Class	76.1%	68.9%	62.3%	60.3%
5. Percent of Households whose fraction of Transactions at their favorite store was above the average	54%	49%	45%	41%

^a Based on 385 families who made 5 or more purchases in each product class during a twelve month period.

Method Of Analysis

As a household purchases each product class over an extended period, such as a year, the household makes some percent of its purchases with a coupon. Let $PC_{i,c}$ denote household i 's percent of purchase volume that is made with a coupon in product class c . The percent of volume purchased with a coupon is used rather than the total volume of coupon purchases since households differ widely in their total volume of purchases in each product class, and a light user household might otherwise be classified as a light coupon user. The average of $PC_{i,c}$ over all households is denoted by APC_c . If $PC_{i,c}$ exceeds APC_c the household is considered to be a "heavy" user of coupons for this product class¹.

Similarly, let $PS_{i,c}$ denote household i 's percent of purchases for product class c that are made in household i 's favorite store for this product class. This is a measure of store loyalty for product class c . The "favorite" store is defined as the one in which the household shops most frequently for that product class. The average of $PS_{i,c}$ over all households is denoted by APS_c . If $PS_{i,c}$ exceeds APS_c the household is considered to be relatively store loyal for product class c .

Households are considered to be relatively consistent in their coupon usage behavior across product classes to the extent that they are consistently above or below the average for each of the 4 product classes. Similarly, they are considered consistent in their store loyalty across classes to the extent that their store loyalty is uniformly higher or lower than the average for each class. Thus "consistency" in purchase behavior is used here in the sense of systematic repetition in behavior across product classes. Table 2 contains hypothetical values of $PC_{i,c}$ and $PS_{i,c}$ for four households in each of four product classes. This illustrates how households might vary in their coupon usage and store loyalty across

¹ While it was possible to split the sample into more than two groups, for instance into "heavy," "medium" and "light" coupon users, this would reduce the sample size in each of the groups and thus might invalidate the statistical procedures used subsequently.

product classes. For household 1, $PC_{i,c}$ is above the average (APC_c) for all classes. That is, the percent of volume purchased with a coupon for this household is consistently greater than the average percent of volume purchased with a coupon for each of the four classes. This household is also above average in store loyalty for all four product classes. Thus household 1 is considered to be highly consistent both in terms of its coupon usage and store loyalty. Household 2, on the other hand, is consistently store loyal across classes but is not consistent in its coupon usage; it exhibits lower than average coupon usage for 2 of 4 classes.

TABLE 2

EXAMPLES OF POSSIBLE PURCHASING PATTERNS FOR ONE YEAR

Household Number	Percent of Volume Purchased With A coupon in Product Class:				Percent of Purchases Made at Favorite Store in Product Class:				Consistent Behavior With Respect to	
	A	B	C	D	A	B	C	D	Coupons	Store Loyalty
1	20%	18%	20%	12%	74%	72%	85%	70%	Yes	Yes
2	10	12	10	9	70	68	75	50	No	Yes
3	10	2	4	4	74	68	83	57	Yes	No
4	20	8	14	7	70	72	77	63	No	No
Average Over Households	15%	10%	12%	8%	72%	70%	80%	60%		

Let $DC_{i,c}$ and $DS_{i,c}$ denote dummy variables which represent above average coupon usage and store loyalty, respectively, in household i 's purchases of product class c . That is,

$DC_{i,c} = 1$ if $PC_{i,c} > APC_c$ and $= 0$ otherwise.

$DS_{i,c} = 1$ if $PS_{i,c} > APS_c$ and $= 0$ otherwise.

While some information is lost by using dummy variables rather than the original percentages, this procedure allows us to use certain statistical tests (such as the chi-square test) which would not be possible otherwise, and captures the phenomena of interest—households' coupon usage and store loyalty relative to the average for the product class.

Let $n(CU)_i$ and $n(SL)_i$ be the sums, respectively, of $DC_{i,c}$ and $DS_{i,c}$ across the product classes:

$$n(CU)_i = \sum_c DC_{i,c}$$

and

$$n(SL)_i = \sum_c DS_{i,c}$$

The variables $n(CU)_i$ and $n(SL)_i$ are measures of consistency in coupon usage and store loyalty across product classes. Note that consistency is greater to the extent that $n(CU)_i$ and $n(SL)_i$ take on extreme values. Thus, for $c=1, \dots, 4$, $n(CU)_i$ varies from 0 to 4, with high consistency in coupon usage indicated by values of either 0 (the household is consistently below average in its coupon usage across product classes) or 4 (above average in coupon usage for all classes). Similarly, $n(SL)_i$ equals 4 if a household is consistently store loyal and equals 0 if the household is consistently below average in loyalty.

The values for $n(CU)_i$ and $n(SL)_i$ for the four families in Table 2 are shown in Table 3.

TABLE 3

CHARACTERIZING HOUSEHOLDS' CONSISTENCY ACROSS PRODUCT CLASSES (BASED ON DATA SHOWN IN TABLE 2)^a

Household Number	Variable $DC_{i,c}$ for Product Class:				Variable $DS_{i,c}$ for Product Class:			Consistency Vector	
	A	B	C	D	A	B	C	$n(CU)_i$	$n(SL)_i$
1	1	1	1	1	1	1	1	4	4
2	0	1	0	1	0	0	0	2	0
3	0	0	0	0	1	0	1	0	2
4	1	0	1	0	0	1	0	2	2

^a $DC_{i,c} = 1$ indicates above average coupon usage. $DS_{i,c} = 1$ indicates above average store loyalty. $n(CU)_i$ and $n(SL)_i$ are the sums of $DC_{i,c}$ and $DS_{i,c}$ across classes.

Each household can thus be characterized by the vector $[n(CU)_i, n(SL)_i]$. For the 4-product-class case, each of the 2 elements in the vector can have 5 values. The 25 possible outcomes can be represented as cells in a 5x5 matrix as shown in Table 4. In this matrix, the corner cells $[0,0]$, $[0,4]$, $[4,0]$ and $[4,4]$ represent highly consistent behavior; households which fall into these cells are consistently below or above average in both their coupon usage and store loyalty. On the other hand, households which fall into cells along the borders of the matrix (where either $n(CU)_i=0$ or 4 and $0 < n(SL)_i < 4$, or $n(SL)_i=0$ or 4 and $0 < n(CU)_i < 4$) are consistent on one variable but not the other. Finally, households which fall into the interior cells (where $0 < n(CU)_i, n(SL)_i < 4$) have little or no detectable consistency across product classes.

TABLE 4

JOINT DISTRIBUTION OF 385 HOUSEHOLDS BY CONSISTENCY OF COUPON USAGE AND CONSISTENCY OF STORE LOYALTY ACROSS FOUR PRODUCT CLASSES^a

Number of Product Categories With Above Average Store Loyalty $[n(SL)_i]$

Number of Product Categories With Above Average Coupon Usage $[n(CU)_i]$	Number of Product Categories With Above Average Store Loyalty $[n(SL)_i]$				
	0	1	2	3	4
0	22 (4.7)	36 (20.0)	27 (31.6)	35 (21.9)	36 (5.6)
1	15 (11.0)	12 (62.2)	18 (59.1)	14 (35.8)	10 (7.9)
2	18 (9.6)	21 (32.7)	23 (40.4)	12 (21.4)	15 (4.1)
3	11 (3.7)	12 (11.0)	10 (11.9)	8 (5.5)	3 (0.9)
4	13 (0.5)	6 (1.4)	4 (1.3)	4 (0.5)	0 (0.1)

^a Numbers in parentheses are the expected frequency under the hypothesis of independence across product classes.

Each of the households in the sample was assigned to one of the cells in the matrix on the basis of its observed $n(CU)_i$ and $n(SL)_i$ values. The resulting distribution of households across cells is shown in Table 4, along with the expected frequencies for the cells under the assumption of independence in purchase behavior across product classes.

The expected frequency for each cell was computed by considering all the possible combinations of $DC_{i,c}$ and $DS_{i,c}$ that would result in that particular $[n(CU)_i, n(SL)_i]$ vector, computing the joint probability of each such combination as the product of the observed proportions for each product class, and multiplying the sum of these joint probabilities by the total sample size.

For example, the only possible combination that can result in the cell [0,0] is $DC_{i,c}=0$ and $DS_{i,c}=0$ for all c . Thus the expected frequency for that cell, denoted $E_{0,0}$, is computed as:

$$E_{0,0} = N \cdot \text{prob}[\text{observing } DC_{i,c}=DS_{i,c}=0 \text{ for } c=1,\dots,4] \\ = N \cdot P_{1,00} \cdot P_{2,00} \cdot P_{2,00} \cdot P_{3,00} \cdot P_{4,00}$$

where N = the total number of households in the sample, and

$P_{c,rs}$ = the overall proportion of households with $DC_{i,c}=r$ and $DS_{i,c}=s$, where $c=1,\dots,4$, $r=0,1$ and $s=0,1$.

Similarly, there are four combinations of $DC_{i,c}$ and $DS_{i,c}$ values that can result in the cell [0,1] since there are four product classes and $DS_{i,c}$ can equal 1 for each of them in turn. The probability of each combination is computed from the appropriate $P_{c,rs}$ values and summed to yield the probability for the cell [0,1]. Probabilities for the other cells in the matrix are computed using the same procedure.

Note that we are treating $p_{c,rs}$ as the "guessing" distribution for households across c , r and s . That is, if a household is drawn at random from the sample, the probability that it will have $DC_{i,c}=r$ and $DS_{i,c}=s$ for a given product class c is $P_{c,rs}$. By computing the joint probability of observing a specific combination of $DC_{i,c}$ and $DS_{i,c}$ values for each class as the product of the $P_{c,rs}$ values, we are making the assumption that the "guessing" distributions are independent across classes. Thus if the distributions are not in fact independent, the theoretical probabilities computed in this manner will differ from the proportions observed in the data.

Results

As Table 4 shows, the observed frequency of households in the cells along the borders of the matrix (i.e. where $n(CU)_i=0$ or 4, and/or $n(SL)_i=0$ or 4) is much higher than the expected frequency. This suggests that households are more consistent in their coupon usage and store loyalty across product classes than would be expected by chance. In other words, for the households in this sample, information about the extent of coupon usage and store loyalty for one product class can be a useful predictor of these variables for the other product classes.

We first consider the presence of consistency in coupon usage alone. Table 5 shows the observed and expected frequencies of households for different values of $n(CU)_i$ (these are simply the row totals from Table 4). A chi-square test revealed that the two were significantly different at the .001 level, thereby rejecting the null hypothesis that coupon usage was independent across product classes. As can be seen, the actual frequency was much higher than expected for extreme values of $n(CU)_i$. For $n(CU)_i=0$, the observed frequency was nearly twice that expected (41% of the sample versus 22%), while for $n(CU)_i=4$, the observed was nearly seven times as large (7% versus 1%). Thus 48% of the households in the sample were consistently above or below average in their coupon usage for all 4 classes.

A similar pattern was observed for store loyalty. Table 6 shows the distribution of households for different values of $n(SL)_i$, along with the expected distribution if store loyalty was independent across classes (these are the column totals from Table 4.) Again, the chi-square test rejected the hypothesis of independence at the .001 level. Of the 385 households in the sample, 21% were below average in store loyalty for all 4 classes (compared to an expected value of 8%), while 17% were consistently above average in store loyalty for all 4 classes (compared to 5% expected). Taking the two together, 37% of the households were consistent in their degree of store loyalty across product classes.

TABLE 5
FREQUENCY OF HOUSEHOLDS WHO MADE AN ABOVE AVERAGE PERCENT OF THEIR PURCHASES WITH A COUPON IN n PRODUCT CLASSES

n	Observed Frequency	Expected Frequency ^a	Percent of sample (observed)	Percent of sample (expected) ^a
0	156	84	40.5%	21.8%
1	69	156	17.9	40.5
2	89	108	23.1	28.1

4	64	19	16.6	4.8
	385	385	100.0%	100.0%

$$x^2(4 \text{ d.f.})=218.7$$

^a assuming independence in store loyalty across product classes.

Finally, in order to examine the interaction between consistency in coupon usage and in store loyalty, we considered the frequency of households that were either below or above average in coupon usage for 3 or more classes ($n(CU)_i=0,1,3,4$), and below or above average in store loyalty for 3 or more classes ($n(SL)_i=0,1,3,4$).² These households, therefore, were those that exhibited moderate to high consistency in both coupon usage and store loyalty. Table 7 shows the frequency of households under this classification scheme.

Of the households that were below average in store loyalty, nearly a third were above average in coupon usage (Cell C in Table 7). At the same time, among those households that were above average in store loyalty, less than a sixth were above average in coupon usage as well (Cell D). These results suggest the presence of a strong interaction effect between coupon usage and store loyalty for households that are relatively consistent in their purchase behavior across classes. Those who are consistently below average in store loyalty are more likely to be above average in coupon usage than those who are consistently store loyal, and

²The cells were defined in this manner to ensure that the sample size in each was large enough to permit the use of the chi-square test.

TABLE 7

DISTRIBUTION OF HOUSEHOLDS ABOVE OR BELOW AVERAGE IN COUPON USAGE AND STORE LOYALTY FOR 3 OR MORE PRODUCT CLASSES

		Store Loyalty ^a		Row Total
		Below Average in 3 or more classes	Above Average in 3 or more classes	
Coupon Usage ^a	Below Average in 3 or more classes	(A) 85 (22%)	(B) 95 (25%)	180
	Above Average in 3 or more classes	(C) 42 (11%)	(D) 15 (4%)	57
Column Total		127	110	

$$\chi^2 (1 \text{ d.f.}) = 11.3$$

^a numbers in parentheses are percentages of total sample of 385 households.

vice-versa. A chi-square test of independence showed the interaction to be significant at the .001 level.

Two cells in Table 7 are of particular interest. The households in Cell C are consistently heavy users of coupons and exhibit low store loyalty for most product classes. This group, which might be described as "activist shoppers", constituted 11% of the entire sample. The household in Cell B are quite the opposite. These households (25% of the sample) are consistently store loyal and consistently below average in coupon usage. They might be labeled "inert" shoppers.

The above analyses were repeated for households that made 2 or more purchases over the 12-month period. Similar results were obtained for this larger sample of 1247 households.

Conclusions

The major finding is that more households are consistent in their usage of coupons and their degree of store loyalty across product classes than would be expected by chance. The finding concerning consistency in coupon usage is an important one, both from a theoretical and a managerial perspective, since it indicates that knowledge about households' purchase behavior in one product class can be a useful predictor of behavior in other classes. Thus managers may be able to predict the effectiveness of coupon promotions in a given product class based on information about coupon redemptions in other product classes in the past.

The fact that households tend to be relatively consistent in their store loyalty also has important implications for retailers. In particular, it indicates that if consumers can be induced to shop in one store for a given product class (for example, by providing a large selection of brands and frequent "specials" for that product class), they will tend to make their purchases of other product classes in that store as well, thus increasing total revenues for that retailer.

One can also identify an "activist" segment consisting of households that are both high in coupon usage and low in store loyalty (see Cell C in Table 7). From a managerial standpoint this is an important segment to study since their response elasticity to coupons and other promotions is probably the highest. Future research may be able to profile this segment in terms of its demographic descriptors and media habits, which would allow managers to target their promotional activities more efficiently. Another possibility is to determine if this group would

still redeem coupons even if they were for lower face values or were harder to collect.

There is also a larger than expected segment of households that is above average in store loyalty and below average in coupon redemption (Cell B, Table 7). If one is to promote to this "inert" segment, one might consider alternatives to coupons, such as free samples. Alternatively, one might decide that it is not profitable to promote to this group at all.

Yet another possibility is to focus on households that consistently use an above average level of coupons for several product classes (see Table 5). These households are likely to be more responsive to multiple brand coupons (coupons which are redeemable only if two or more brands are purchased). Again, demographics and media habits could be studied for this group and used to reach it more efficiently.

Abstract

Considerable research has focused on the role of product attributes in consumer preferences. Many approaches present the subjects with a set of attributes on which to rate available choices. This study contends that such a presentation heightens the salience of the attributes. An alternative procedure is presented where the subject is given a set of choices, but the underlying attributes under investigation are not made explicit. The nonstated attributes are orthogonally arrayed which allows for simple estimation of their partworths.

Introduction

A critical issue in marketing is the determination of the importance of characteristics to consumers in their evaluation of choice alternatives. From such information, product and advertising decisions can be directed towards improving consumer's judgments of the products being offered by a firm. The task facing researchers in this field has been the measurement of the consumer importances associated with the product attributes. In this paper we present an alternative method for measuring product attribute importances without distorting the salience of the attributes through the data collection instrument.

Literature Review

Multi-Attribute Attitude Models

Throughout the late sixties and early seventies the marketing literature was filled with studies which focused on the evaluation of choices along a set of product attributes, and the assessment of their importance in forming an overall attitude or preference toward the choices. The origin of such work is often associated with Fishbein (1967) and Rosenberg (1956). Such efforts, founded in psychology, quickly evolved in the marketing literature, and were well reviewed by Wilkie and Pessemier (1973).

The underlying theory in this literature was that a consumer had an attitude toward an object which was based upon the object's intrinsic characteristics. The issue was then one of identifying the characteristics, evaluating the choices on these characteristics, weighting the characteristics, and then aggregating them (usually through some linear additive model) into an overall attitude or preference towards the object. The measurement task usually entailed the tedious respondent evaluation of each of the objects across each of the characteristics.

Aside from possible consumer fatigue, several possible problems arose (Wilkie and Pessemier, 1973). First was the identification of the correct set of underlying characteristics which led to overall choice. It was generally believed that this was best accomplished through management judgment and a pretest of consumers where the attributes were elicited. This presumed that the managers or the consumers would be aware of which characteristics were critical in leading to choice. Any unconscious attributes that were part of the evaluation would be overlooked by the method.

A second problem was termed "halo effects" (Wilkie, McCann and Reibstein, 1973; Beckwith and Lehmann, 1975). "Halo effects" refer to the respondents mapping their

preferences back onto the attribute evaluations, thereby rating each of the favored choices highly on each of the attributes, and the disfavored choices poorly on each of the attributes, beyond their true levels. This implied that it was the affect which drove the beliefs and not the reverse. Such response made the importance weights associated with the attributes difficult to assess.

The initial process for evaluating the attribute importances was through a direct evaluation of the attributes (Lehmann, 1969). This, too, was problematic because a) consumers may be incapable of evaluating the true importance of a characteristic in their overall evaluation, b) consumers may be unwilling to confess the true weights because they may feel their process was irrational, i.e., the use of color in their assessment, c) they may not remember what characteristics were instrumental in their initial evaluation, d) there may be socially desirable answers which could make their answer "look better", i.e., fuel efficiency in their evaluation of automobiles, or e) the attribute may be salient, although not determinant, because of minimal variance across the choice alternatives.

This difficulty led Bass and Wilkie (1977) to recommend deriving the importance weights via regression based on the preferences (the dependent measure) and the attribute beliefs (the independent measure).

Conjoint Measurement

An alternative approach, with the same underlying theory, evolved and gained in popularity throughout the mid to late seventies and into the eighties. This approach was conjoint measurement. Although not specifically designed for these purposes, conjoint measurement answered many of the problems in multi-attribute attitude models.

Again, the approach was to describe choices along a set of attributes and ask the respondent to rate, rank or choose between two choices based on these characteristics. (See Green and Srinivasan (1978) for a thorough review of conjoint measurement.) However, in conjoint, no consumer beliefs were measured, only the overall choice evaluation or preference. With a carefully balanced design of choice attributes, it was possible to assess the impact of each attribute on the ultimate evaluation using analysis of variance (either MONANOVA or ordinary least squares). The belief still remained that the overall evaluation was based on the underlying choice characteristics.

A major possible problem with this approach is the cueing of respondents created by the data collection approach. The respondents are explicitly told to evaluate the choices based on these characteristics. Generally, the products are nonidentified, or, more likely, hypothetical. Hence, the respondent can only evaluate the choices based on these characteristics. The respondent is usually told to ignore all other characteristics or to treat the choices as if they are equal on all nonstated attributes.

All that can be measured from a conjoint study is the relative importances of the attributes included in the exercise. It is unrealistic to expect to have included all of the relevant attributes. A method for measuring whether the relevant attributes have been included is to look at the individual model's fit or, if OLS is used, R^2 . A low degree of fit would indicate either that the respondent is inconsistent or that the model is

misspecified, i.e., some relevant attributes have been excluded. The inconsistency may even be the result of the truly determinant attributes being excluded.

Alternatively, in many conjoint studies the model's fit may be quite high; unfortunately, this may be the result of heightening the salience of the attributes on which the choices are described. This heightened salience may distort the natural process of evaluation.

Holistic Evaluation

An alternative procedure, which we propose, is to present the choices to the subject, where the attributes are orthogonally arrayed, but the attributes are not directly explicated to the subject. The subject makes evaluative judgments about the choices from which the attribute importances or partworths can be described.

Holistic judgments are not new. One of the distinguishing characteristics about multidimensional scaling (MDS) techniques is that they are based on holistic or gestalt evaluations, from which the underlying dimensions can be derived.

Unlike MDS where the relevant dimensions are not known by the researcher until after the data are collected, in our approach the attributes will be known by the researcher, but not the subject. This is very similar to the economic technique of hedonic regression, or to psychophysical research. There are also several examples in the marketing literature.

Huber (1975) gave subjects iced tea to drink, compare, and evaluate. Presented in a full factorial design, the various iced teas differed in amounts of tea and sugar. Based on subject judgments, he was able to determine the ideal levels of sugar and tea and their importance in forming preference. Holbrook (1981) analyzed both perceptions and affect, in an integrative model of evaluative judgments, for presentation of a piece of classical music. Each presentation differed in tempo, rhythm, dynamics, and phrasing. Buchanan and Morrison (1984) have analyzed holistic judgments where subjects make judgments in blind taste tests, either in pairs or triplets, and select either which choice is preferred or different. From this they can test on individual's ability to discriminate, although they do not relate the judgments to the underlying attributes.

The Study

In many cases it is difficult, sometimes even impossible, to ask subjects to evaluate choices without describing the choices along some set of attributes. This is particularly true when one is dealing with hypothetical products which could neither be shown or even described by brand name. In such cases, the only alternative may be to use a conjoint design. However, in other cases, it is possible to present the choices either physically, visually, or verbally without making it explicit which attributes are under investigation.

We selected food products which could be presented to consumers without making the basic ingredients explicit. In particular, we were interested in the role of basic nutrients in food choice and preference formation. In this case, the respondents would have a low level of awareness of different nutrients, might not know how the nutrients influence their food preference, or, if aware, would know what is socially designated as appropriate behavior. There has been a considerable amount of publicity on "eating right." All of these conditions would make it extremely difficult for a respondent to assess the importance of various food nutrients or to rank/rate their choice of foods described on a set of nutrients.

Hence, the subjects were given pairs of meals from which they would have to select their preferred meal. The meals were described in terms of the foods, not their

underlying nutritional content.

Each respondent had to rate sixteen pairs of meals (32 meals in total). The pairs were constructed, with the help of a nutritionist, to represent an orthogonal array of six basic nutrients — protein, carbohydrates, fiber, fat, sodium, and cholesterol.

Respondents were handed a deck of sixteen cards, each containing one pair of meals. They were first asked to go through the deck, one card at a time, and to indicate which of the two meals they would personally prefer to eat on an individual taste basis. They then were asked to repeat the task with respect to which meal they would be most likely to eat at home, considering cost, time, etc. They repeated the task a third time, but this time they were to choose the meal that they thought was the most healthful. The three measures were intended to indicate preference, behavioral intentions, and nutritional perception or knowledge.

The study was conducted with a national probability sample of 700 consumers — participating in an on-going research project funded by the United States Department of Agriculture in a grant to the Marketing Science Institute (Schmalensee, et al., 1982). Subjects were selected as the "primary food purchaser and preparer in the home" and were 93% female. Each subject was interviewed in the home and also completed a lengthy leave-behind questionnaire.

Results

Individual regression analyses were performed for each of the three dependent measures. Unlike a conjoint study or the Huber (1975) study, it was not necessary to dummy-variable code the individual factors, since they were on a continuous scale. Each observation was choice "A" meals, coded either a zero (if rejected) or a one (if selected), and the independent variables were the actual differences (grams, milligrams) between the meal pairs on each of the six nutrients. The "B" choices were excluded since they would simply provide redundant (mirrored images) information.

The choices for "prefer" and "prepare" were most similar, with a Pearson correlation coefficient of .70, while "nutritious" and "prefer" were least correlated with a correlation coefficient of .47.

As an example of the results, one individual's regressions are shown in Table 1, in this case, we may assume she "prefers" meals with higher fat content, with none of the other partworths being significant at the $P < .10$ level. However, when asked which meal she is actually likely to prepare at home for her family, a different selection pattern begins to emerge. It appears this person is more likely to "prepare" meals higher in protein ($P < .01$) and sodium ($p < .01$) and lower in carbohydrates ($P < .01$), fiber ($p < .05$) and cholesterol ($p < .10$). Her assessment of what she considers most nutritious is quite different. It should be noted that for this individual the R^2 is significant for both the "prepare" and "nutritious" models.

Given that the respondents are not cued as to the underlying attributes, it would be expected that for many individuals the models would not be significant. This is different than what one generally finds for traditional conjoint models, where the subjects are specifically directed to make choices based on the dimensions of the models. The average R^2 for the three models across the population was .41 for preference, .42 for "prepare" or behavioral intention, and .46 for "nutritious," with the variance of the R^2 's equal to .17 for each model.

The average coefficients (partworths) for each of the three models are shown in Table 2. The mean values and the standard deviations across the population are shown in the first two columns. The next column is the

percentage of individuals that had the coefficient significant ($P < .10$).

TABLE 2
SUMMARY STATISTICS ON THE
DIRECTION AND STRENGTH OF B's
(n=700)

TABLE 1
SIGN AND SIGNIFICANCE LEVELS
FROM INDIVIDUAL REGRESSIONS
SUBJECT 1

	$P <$	Prefer	Prepare	Nutritious
PROT		+ .20	+ .01	+ .05
CARBO		- .20	- .01	- .10
FIBER		+ .30	- .05	+ .01
FAT		+ .05	- .40	- .01
SODIUM		+ .30	+ .01	- .01
CHOLESTEROL		+ .30	- .10	+ .50
		R^2	$p <$	
Prefer		.22	.40	
Prepare		.61	.00	
Nutrition		.66	.00	

Independent Variables	Mean B	Standard Deviation	% Respondents Significant ($p < .10$)
<u>Preference</u>			
Protein	.12	.33	10.4
Sodium	-.06	.33	9.3
Fat	-.06	.32	11.6
Cholesterol	.10	.30	12.7
Fiber	.02	.27	9.1
Carbohydrate	-.05	.25	7.3
<u>Preparation</u>			
Protein	.13	.34	8.9
Sodium	-.06	.33	9.7
Fat	-.10	.31	10.6
Cholesterol	.09	.32	12.7
Fiber	.01	.27	10.3
Carbohydrate	-.06	.25	10.3
<u>Nutritious</u>			
Protein	.16	.33	11.1
Sodium	-.11	.32	11.1
Fat	-.20	.30	10.3
Cholesterol	.11	.31	15.3
Fiber	.17	.26	11.7
Carbohydrate	-.09	.23	9.3

As can be seen, the percentage is relatively small for any one attribute. In fact, only 15.2% of the sample had two or more significant factors. This implies either that a) respondents base their evaluations on a particular nutrient, b) that the stimuli set (sixteen cards) was not large enough to detect underlying nutritional preferences without undue distortion by specific food likes and dislikes, or c) that there are a number of other factors which are not included in the model; that is, the respondents make their choices relying on a number of factors other than nutrients. This is totally realistic, and this approach does not force the evaluations to be based on the factors which are included.

It should be noted from Table 2 that the two attributes which are most commonly positive for the preference and behavioral intention models are protein and cholesterol, while fat, sodium and carbohydrate are negative. There apparently is some nutritional knowledge, as in the third model, the fiber dimension grows in importance. It would appear that consumers know fiber is good for them, they just don't like it nor intend to eat it. The results for cholesterol are also illuminating, as it appears to be a consistently positive predictor of all three dependent variables. This positive effect would be unlikely if consumers are specifically cued to cholesterol content. It would appear that consumers are either unable to detect high cholesterol foods or have natural tastes for such foods. This finding would be obscured in a traditional conjoint design.

In many cases it is essential that we identify which characteristics are important to consumers in their choice process. The question facing researchers is one of how to measure these importances. In some cases, it is difficult for respondents to indicate directly what is important to them. It may even be difficult for them to indicate not just the degree of importance, but even which attributes are used in their choice process. Describing choices along a set of dimensions may overly cue the respondents to give added weight to the selected dimensions.

We have presented a methodology which should ameliorate this problem. Rather than listing the attributes for product evaluation, the holistic choices themselves are presented. From these choices, the respondents make their selections. This provides the information from which the partworths can be derived.

In many cases the proposed approach would not be logical. When the product category has numerous potential/hypothetical products it would be impossible to present the subjects with the actual choices. Alternatively, a product category may contain far too few alternatives to allow the model to be specified. In many cases, however, the researcher is interested in the role of specific attributes which play a significant role, but may not be directly recognizable to the respondent. The example we chose was a nutritionist's concern about the role of basic nutrients — general characteristics unknown to the subject.

The potential with food products should be clear, but the opportunities are also apparent in other product categories. In the context of verbal v. pictorial presentation, Holbrook and Moore (1981) note that holistic evaluations may be appropriate if evaluative judgments depend on aesthetics, taste, symbolic meaning, or sensory experience. For example, fashion designers may be concerned about the influence of specific designs, fabrics colors, and patterns. Rather than describing alternative apparel which vary on these dimensions, thereby heightening their salience, specific pictorial or actual choices could be presented.

Future Direction

The next step in this research is to collect direct importance measures in a conjoint design which would

allow weights to be derived. These weights could then be compared with weights derived from a holistic conjoint. This would allow one to determine if the weights were different, but would not serve as a basis for determining which set of weights were true.

What clearly remains, for all procedures, is the need to determine the validity of the various alternative measures. Future research needs to collect behavioral data with real stimuli that can be compared with responses predicted by sets of conjoint weights.

PROCESSING COMPLEXITY IN MAGNITUDE VERSUS CATEGORY SCALING

Bruno Neibecker, University of the Saarland (Fed. Rep. of Germany)

Abstract

This study supplements previous research on measurement qualities of magnitude versus rating scales. Its primary purpose is to determine the complexity in cognitive processing between these two scaling methods on responding to advertisements and erotic pictures. Secondly, it is to ascertain the conceptualization of collative properties of stimuli (e. g. the complexity and novelty of an object) as a more cognitive judgment compared to affective responses. The results suggest that magnitude scaling allows for fewer cognitively controlled responses and the conceptualization of collative responses as a cognitive judgment which could be empirically supported.

Background

The effects of affective factors in consumer behavior are now gaining closer attention. A splendid overview about the importance of consumers' moods and emotions on their behavior is given in the 1984 ACR-Proceedings (Vol. XI, pp. 525-547). Let me summarize the main thoughts of the mood debate as far as the research conducted here is concerned. In emotion psychology at least two trends can be distinguished. On the one side, it is assumed that affect and cognition are under the control of separate and partially independent systems that may influence each other in a variety of ways (e.g. Zajonc 1980). This position is supported, at least partially, by research on hemispheric specialization of affective processes (Tucker 1981; Bryden and Ley 1983) and research on the biological determinants of human behavior, called "human ethology" (Eibl-Eibesfeldt 1980).

On the other side, it is argued that thought is a necessary condition of emotion (e. g. Lazarus 1982). This position is based on the concept of cognitive appraisal which means that the way one interprets one's own state at any given moment is a crucial determinant of the emotional response.

Since humans have the ability for autonomic discrimination without awareness, it is even reasonable to assume that perceptions can be global rather than built up sequentially of structural elements. Therefore, emotionally relevant meanings could be triggered by inputs, denotations of which had not been achieved completely.

However, the crucial question of this debate, whether the original affective reactions themselves - on which evaluative judgments are presumably based - must also contain cognitive components cannot be answered empirically given the current state of knowledge and research technology (Zajonc and Markus 1982, p. 124).

Of central interest for our further argumentation is the assumption, which may rely on both families of emotional theories, that emotional reactions, require a minimum of cognitive participation, at least on the self-report level (Lazarus, 1982). At the same time,

The author wishes to express his gratitude to Professor W. Kroeber-Riel and Professor Jerry Olson for ideas on the subject and helpful editorial comments.
Author's address: Institut für Konsum- und Verhaltensforschung, 6600 Saarbrücken 11, FRG.

there is support that affective reactions are difficult to verbalize and rely much more on nonverbal channels (Zajonc 1980; Ekman and Friesen 1969).

If we consider these two extremes - i.e., affective and cognitive behavior - not as dichotomous types but as ends of a continuum, it is possible to distinguish between different self-report methods along this continuum.

Recently, the validity of an alternative direct scaling procedure, called magnitude scaling or "new" psychophysics has been shown for emotional stimuli (Neibecker 1984; see also Stevens 1975; Marks 1974). In this paper it will be argued along with others (Kroeber-Riel 1984; 1985) that magnitude scaling allows for responses which are less cognitively controlled because subjects can express the magnitude of their sensory experiences on nonverbal continua, such as the length of a line, the duration of pressing a button, the loudness of a tone, etc. These analogue and nonverbal response modalities are quite different from the conventional rating-scale/category task, where subjects are asked to express their impressions of sensation intensities by choosing among a limited number of categories labelled with such cues as agree/disagree.

A second point of interest relevant for this research is derived from environmental and emotional psychology. The dimension theorists in emotional psychology have conceptualized a small set of independent dimensions that best describe the differences in emotional behavior (Mehrabian and Russell 1974; overview by Ekman et al. 1982). The most widely accepted dimensions are pleasantness-unpleasantness and activation or arousal. In addition, Ward and Russell (1981) discuss the collative properties of stimuli. This construct is based on research of Berlyne (1974) and Mehrabian and Russell (1974) and more generally known as the "information rate-arousal hypothesis". Collative properties of stimulus patterns are structural or formal characteristics measured with items like familiar-novel, simple-complex, expected-surprising etc. Ward and Russell (1981) have conceptualized this collative construct as a cognitive judgment about the complexity and novelty of an object.

The usefulness of the collative dimension is supported by research on TV-commercials (e. g. Aaker and Bruzzone 1981). But this prior research in consumer behavior lacks a clear theoretical foundation and uses the novelty component only as an empirically derived construct. The psychological background given here helps to interpret the different sets of adjectives developed to measure consumers reactions to advertising.

Hypotheses

Based on these theoretical considerations, two hypotheses were formulated. One concerned the measurement qualities of magnitude scaling as a more nonreflective and spontaneous measurement tool compared to rating scales. The second concerned the collative properties of stimuli which postulates that this construct is accompanied by more cognitive processing than the affective dimensions pleasantness and activation.

It was hypothesized that:

- H₁: Nonverbal responses (e.g. magnitude scaling) allow for less cognitively controlled responses than verbal responses (e.g. rating scales) when measuring emotions.
- H₂: Judgments about collative properties require more extensive cognitive processing than do affective responses.

Method

The experimental data reported herein were supplied by an extensive laboratory experiment conducted at the Institute for Consumer and Behavioral Research, University of the Saarland, FRG. The study was performed on a random sample of 136 persons with a quota sampling of 50 per cent students, the remainder being adult men and women aged 25 to 54 (non-students). Four stimuli were chosen, including advertisements and erotic pictures. The ads were selected from current image ad campaigns of two leading German chemical enterprises. Pictures 1 and 4 were erotic pictures showing a woman with little clothing; picture 2 was an ad with a woman's and a man's hand touching in an affectionate manner with a small amount of copy below; picture 3 was an ad showing three children sitting in a small pasteboard house with copy below. Because of time limitations, subjects were divided into two groups, one consisting of 69 subjects evaluating pictures 1 and 2 using category and magnitude scales and the other made up of 67 subjects evaluating pictures 3 and 4 using category and magnitude scales.

To reduce the time needed to collect and process data and reduce method-dependent artifacts, magnitude scaling was integrated into a computer-controlled questionnaire facility. The interview was conducted via a computer-controlled system. Respondents sat directly in front of a cathode ray tube (CRT) terminal and answered questions by pressing keys on the terminal. For our experiment, the following modalities were implemented: visual length (line length), time duration with simultaneous presentation of a white noise, and brightness by a regulated lamp.

First, the subjects received a description on the CRT screen of how to use the apparatus. These instructions included a learning session on how to use the equipment for the magnitude task (about four minutes). Subjects were ascertained initially to make approximate proportional judgments. The first group made their judgments with rating scales and the magnitude modalities line length and brightness for pictures 1 and 2, the second group with rating scales and magnitude modalities line length and duration for pictures 3 and 4.

The rating scales were of the semantic differential type. The typical scale had the following form:

Picture x is
slightly dynamic(1) (2) (3) (4) (5) (6) (7)very dynamic

For magnitude scales, only a mnemonic statement was given. The typical statement for the modality line-length had the following form.

Picture x is
slightly dynamic very dynamic
(short line) (long line)

where the length of the line was under the control of the respondent.

The sequence of the pictures as well as of the items

and methods were rotated randomly by the computer and only one item was shown at a time. To produce a line, the subjects pressed a button on the CRT and the computer started to draw a line on the screen. For the modality duration, subjects pressed a separate button. In addition a white noise was presented. The brightness could be regulated by turning a knob (potentiometer) until the adequate lamp brightness was reached. At the beginning of a response, reaction time was measured unobtrusively (non-reactive) by the computer. This was the time starting with the appearance of the item on the screen until a response was given.

The questionnaire consisted of 10 emotion descriptive adjectives. Convergent and discriminant validity of the arousal measuring items were shown already elsewhere (Neibecker 1984). For this research, items were separated according to these results into three treatment factors: arousal, collative judgments and evaluation. The respective items were: dynamic, lively, tiring, lifeless (for arousal) / common, average (for collative properties) / beautiful, disgusting (for evaluation).

To operationalize the cognitive processes involved in responses the reaction time was measured. The faster responses are given, the fewer cognitive processes are assumed. This is a usual operationalization to determine the relative complexity in cognitive processing (e.g., Mandler and Shebo 1983; Paivio 1978).

Results

For a descriptive overview, the mean reaction times (or response latencies) are given in seconds (see Table 1). Furthermore, they are divided into three different judgment tasks (rating, line length, duration / brightness), three response types (evaluation, collative judgments, activation), and two picture categories (erotic pictures and advertisements).

TABLE 1
RESPONSE TIME IN SECONDS

	Rating	Line Length	Duration/Brightness	
EV	4.2	3.4	3.6	E
COL	4.8	4.0	3.8	r
ACT	4.2	3.8	3.6	o

EV	4.2	3.0	3.4	i
COL	5.4	4.3	4.0	c
ACT	4.7	3.6	3.8	A

EV	4.2	3.4	3.6	d
COL	4.8	4.0	3.8	
ACT	4.2	3.8	3.6	

EV=evaluation; COL=collative judgements; ACT=activation

As can be seen, reaction times for rating scales are longer than those for magnitude measures (in columns). Likewise, response times for collative judgments are longer than those for affective responses (evaluation and activation).

In a further step, two 2 x 3 x 3 analyses of variances were performed. The effects were stimulus x method x judgment task (or dimension). Stimulus was treated as between subjects factor and the others as within subject factors. The raw scores were rescaled according to MacLachlan (1977). By this rescaling procedure,

typical skewness is diminished from 1.30 to about 0.40 (highest skewness 1.17) and typical kurtosis is diminished from 1.70 to about -0.70 to 0.70.

$$ART_{ik} = \frac{\overline{RT}_i}{RT_{ik}}$$

(i = subject; k = item; \overline{RT}_i = mean reaction time of subject i; ART = adjusted reaction time; RT = reaction time)

Results are given in Table 2.

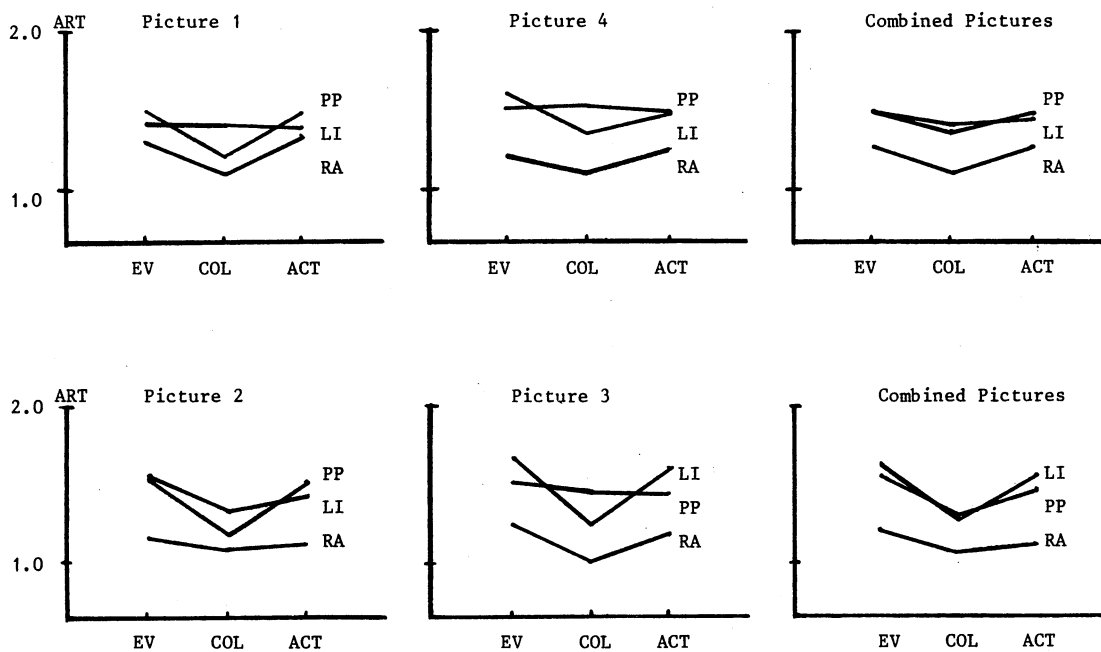

As can be seen, none of the stimulus factors (erotic pictures and advertisements) reached significance showing that no differences exist between the over-all reaction times of the two groups of subjects. In fact, the evaluated pictures in each group resembled each other strongly. The division into these groups was only necessary because of time limitations. Of central interest for our hypotheses are the factors method and judgment task (dimension). Each one of these factors is highly significant reflecting that affective responses are given faster than collative judgments, and non-verbal responses via magnitude scaling are given faster than those with rating scales. Up to now the three-way interactions are difficult to interpret. Figure 1 shows that this is due to the unsystematic deviation of one method in pictures 1, 3 and 4 from the over-all main effects. It reads as follows:

TABLE 2

ANOVA FOR EROTIC PICTURES AND ADVERTISEMENTS

Factor	df	F-Value	Significance
Erotic Pictures	1/130	3.21	0.075
Method	2/260	23.46	0.000
Dimension	2/260	14.67	0.000
Eroticism x Method	2/260	2.86	0.059
Eroticism x Dimension	2/260	1.043	0.354
Method x Dimension	4/520	0.924	0.450
3 x Interaction	4/520	6.077	0.000
Advertisements	1/130	0.343	0.559
Method	2/260	39.035	0.000
Dimension	2/260	39.282	0.000
Ad x Methode	2/260	0.235	0.791
Ad x Dimension	2/260	0.302	0.740
Method x Dimension	4/520	3.342	0.010
3 x Interaction	4/520	9.830	0.000

FIGURE 1
INTERACTIONS

ART=Adjusted Reaction Time; RA=Rating; LI=Line length; PP=Duration or Brightness

The upper left-hand side of Figure 1 represents the plot of the profiles for the Method x Dimension interactions for the two levels of the erotic pictures. On the upper right-hand side, the profiles of the over-all Method x Dimension means are given. These three profiles are parallel, indicating that the Method x Dimension interaction is not significant. Since some profiles for each level of the picture factor are not parallel to the respective profile of the combined picture data the three-way interaction is significant.

For the advertisements, profiles are given at the bottom of Figure 1. Here, the profiles on the right side of the over-all Method x Dimension means are not parallel indicating a significant Method x Dimension interaction. Again, some profiles for each level of the advertisement factor are not parallel to the respective profile of the combined advertisement data. This finding implies a significant three-way interaction.

Conclusions

This research does not claim to answer the opposing question, whether or not there exist two distinct, qualitatively different systems for affect and cognition. Since this question cannot be answered empirically given the current state of knowledge and research technology, we proposed a more pragmatic position. Considering the requirements of the respondents by answering questions, we expected a more or less complex processing in making evaluative judgements. It can be assumed that the usual response situation, in which a questionnaire has to be completed, tends to be as least as complex as simple lexical decision judgements, for example.

On the other side, emotional reactions, even if cognitive mediation should be necessary, could be triggered by inputs whose full-fledged denotations had not yet been achieved. In addition, considering that emotional reactions rely more on non-verbal channels and are difficult to verbalize, we suggest that affective responses be measured more adequately and spontaneously by non-verbal response modalities.

Based on these arguments, it has been shown that magnitude scaling with non-verbal modalities like "length of a line" or "duration of pressing a button" allows for shorter reaction times than category scaling with ratings. Since it is of central interest to measure the first affective reaction, which is not cognitively masked and less influenced by social desirability, quick responses are preferred. Thus, magnitude scaling seems to have a more direct (non-verbal) path to emotional processes which are probably more concentrated in the right hemisphere of the brain.

At the same time, if reaction time is an effective operationalization for the amount of cognitive processing, then our distinction between affective items and information rate items, conceptualized as a cognitive judgement concerning the complexity and novelty of a stimulus, should hold. This distinction could be empirically supported. Thus, with some modification of the prior theorizing of Berlyne (1960), who predicted a direct relationship between collative properties of a stimulus and activation (arousal), the conceptualization of Ward and Russell (1981) was supported.

Unfortunately, the main effects are overlapped by three-way interactions, which are due to a rest of unsystematic variations between methods and dimensions.

Q - TIPS: USING QUALITATIVE AND
QUANTITATIVE TECHNIQUES IN TANDEM
TO ASSURE VALID MANIPULATIONS

Don R. Rahtz, College of William and Mary
David L. Moore, College of William and Mary

Abstract

Multiple Discriminant Analysis (MDA) has received widespread use as a quantitative predictor equation for categorical group membership. Focus groups and other qualitative data generation methods have also been receiving widespread use as preliminary classificatory tools. This paper explores the feasibility of using these techniques in tandem to assure valid experimental manipulations in certain settings. Data were collected via survey questionnaires for a study concerning the product class involvement levels of four different product types.

MDA was then used as a manipulation check on the qualitative involvement classification. The results of the MDA technique's application as a manipulation check seem to suggest a continuing use of the statistical technique when data configurations are compatible.

Introduction

Multiple Discriminant Analysis (MDA) has enjoyed fairly widespread use as a multivariate statistical technique in the marketing discipline (e.g., Wiley and Richard 1974). Dillon and Westin (1982) state that the availability of multiple discriminant analysis procedures in canned computer software packages has made the application of MDA very easy for the marketing practitioner. The use of MDA, however, has apparently been seen as being limited to that of a predictor equation for some given categorical criterion variable. For example, the probability of a given product or service strategy succeeding or failing to induce consumers to buy a product.

The purpose of this paper is to suggest a different application for multiple discriminant analysis. That role is that of a manipulation check technique. Since the MDA procedure is applicable when there is a categorical dependent variable and interval independent variables, many experimental situations created by marketers could lend themselves to data configurations appropriate for the use of MDA in such a context. Such use, under the correct conditions, could provide researchers with greater confidence concerning the success of the manipulation than would a simple t-test of means or similar techniques performed on the data.

Churchill (1979) has advocated the use of qualitative and quantitative techniques in tandem to produce richer constructs. This paper demonstrates an effective combination of a qualitative technique (i.e., the nominal group technique) and a quantitative technique (i.e., MDA). When research involves vague or loosely specified constructs (e.g., involvement), qualitative approaches to construct operationalization can reveal novel and insightful interpretations of the construct. MDA can then be employed, as this study demonstrates, to assess the validity of the resulting operationalizations of construct dimensions.

If marketing research is to be considered scientific, reliability assessment of constructs is essential (Peter 1979). It is also desirable to explore alternative techniques for assessing statistical significance in marketing research (Sawyer and Peter 1983). Clearly, there has been an increased sensitivity to questions surrounding methodological rigor in marketing research.

It is not the intent of this paper to delve into the many statistical issues surrounding the estimation and application of the linear discriminant function (LDF). Rather, the intent here is to suggest a possible expanded role for

the technique in research being conducted in marketing. The remainder of this paper presents an example of the application of MDA as a manipulation check technique for nominal group technique generated construct dimensions.

The Study

In the Spring of 1984 a study was conducted to assess the impact of product class involvement on individual's cognitive consistency. As part of that study, it was necessary to generate four products classes for use in the study. Two of these products classes had to be considered low involvement product types and two had to be considered high involvement product types by the target population.

The samples used throughout this study consisted of undergraduate students at two major mid-Atlantic universities. The use of a student sample was deemed appropriate since the products used were relevant to the population from which the sample was drawn (i.e., students). While some authors (Cunningham, Anderson, and Murphy 1975) question the assumption that students are "real people," others (Lamb and Stem 1980) argue that use of student samples is appropriate given that the students are relevant to the context of a given study. That is, those types of situations where students were not expected to be affected in their behavior by simply being students. Since the products utilized in the study were relevant to the student as a consumer, no threat to the external validity of the results was anticipated from selection-treatment interaction.

In order to provide high and low involvement product classes and brands which were more meaningful and relevant to the subjects used in the broader study's major procedure and hypothesis testing, a valid classification of involvement was crucial. Too often, involvement studies have relied strictly on a researcher's "feeling" that "this" is high involving and "that" is low involving. Manipulations of involvement are sometimes questionable at best, relying on other research from different populations, or post-hoc assignments to classify objects/situations as high or low involving. (See Moore and Rahtz 1984 for a methodological review of involvement studies.)

In the present research, care was taken to provide an involvement classification of product classes based on the population's own feelings, not a single researcher's contention. These initial product classes were later employed to generate relevant brands and product attributes used in purchase decisions by the population under study.

While some authors, (c.f., Lastovicka and Gardner 1978) have developed multi-item scales for measuring involvement, their use in this study was deemed unwarranted for two reasons. First, such scales are of a reactive nature. This could create a demand artifact (Sawyer 1975) in that products rated are selected by the researcher and not the subjects. That is, the product pool from which the specific products are selected is predetermined by the researcher. This then limits the possible responses to the a priori defined set. Second, from a logistical standpoint, the number of responses required (as many as 1,100 per subject for 50 products (22 scale items used by Lastovicka and Gardner, 1978 to define product class involvement \times 50 products = 1100) renders this approach untenable.

Given the unwieldiness and reactive nature of such a quantitative approach, the present study sought to explore an

alternative qualitative approach to generate the needed product information. The qualitative approach chosen was the nominal group technique (NGT) (Huber and Delbecq 1972). The NGT is linked with the family of "brainstorming" groups discussed by Osborn (1957). The NGT operates in a manner such that individual creativity is not hindered by group processes, an often bothersome aspect of interactive groups (Collaros and Anderson 1969; Taylor, et. al., 1958), but enhanced and sharpened (Delbecq, Van de Van, and Gustafson 1975). That is, individual responses can be explained and interpreted more clearly through the group discussion session of NGT, allowing the individual to sharpen the response or make other related corrections to uncover more quality and a greater quantity of ideas. Claxton, Ritchie, and Zaichkowsky (1980) support the method's use in a somewhat similar setting of attribute generation for conjoint studies. In this study, the nominal group technique procedure utilized in obtaining the high and low involvement product classes followed the procedure outlined by Delbecq, et. al. (1975). Tables 1 and 2 summarize the NGT procedures and benefits as adapted for this study.

TABLE 1
NGT PROCEDURES

Step 1: Preliminary Setup

- Procedures: a) Arrangement of classrooms into seating clusters of five chairs (eight clusters)
b) Providing of ten index cards, two sheets of paper and one pencil per seat

Step 2: Introduction

- Procedure: a) Preliminary statement of greeting to subjects including:
1) Cordial welcome;
2) Sense of importance of group's task;
3) Clarification of the importance of each member's contribution;
4) Indication of purpose of meeting's output.

Step 3: Silent Generation of Ideas in Writing

- Procedure: a) Presentation to group of question in written form;
b) Verbal presentation to question to each group;
c) Asking group to work silently and independently;
d) Reminding them to take as long as necessary to exhaust their ideas.

Step 4: Round Robin Recording of Ideas

- Procedure: a) In a round robin manner, the researcher and assistants ask for one idea from each individual. This continues until all ideas are exhausted. Duplicates are scratched during the listing. Respondents are informed they may add any ideas that come to mind to the list during this step. When all ideas are exhausted, the group is then instructed to move to Step 5.

Step 5: Serial Discussion for Clarification

- Procedure: a) Each group is instructed to proceed through the group list of ideas discussing each idea independently;
b) After the group has discussed each idea they are instructed to move on to Step 6.

Step 6: Voting on Item Importance

- Procedure: a) Each member is asked to record their top then choice of ideas independently. Each

of these choices is then recorded on 5 x 7 index cards. They are then asked to rank order their ten choices from 1 (most important) to 10 (least important)

Step 7: Conclusion of NGT

- Procedure: a) All rank ordered cards are then collected by the researcher to be analyzed;
b) Subjects are thanked for their cooperation and debriefed

(Source: Delbecq, Van de Van and Gustafson, 1975)

TABLE 2
NGT BENEFITS

Step 1: Silent Generation of Ideas in Writing

- Benefits: 1) Adequate time for thinking and reflecting
2) Social facilitation (that is, the constructive tension created by observing other group members working hard;
3) Avoidance of interruptions;
4) Avoidance of undue focusing on a particular idea or train of thought;
5) Sufficient time for search and recall;
6) Avoidance of competition, status pressures and conformity pressures;
7) The benefits of remaining problem-centered;
8) Avoidance of choosing between ideas prematurely.

Step 2: Round Robin Recording of Ideas

- Benefits: 1) Equal participation in the presentation of ideas
2) Increase in problem-mindedness;
3) Depersonalization - the separation of ideas from personalities;
4) Increase in the ability to deal with a larger number of ideas;
5) Tolerance of conflicting ideas;
6) Encouragement of hitchhiking;
7) Provision of a written record and a guide.

Step 3: Serial Discussion for Clarification

- Benefits: 1) Avoidance of focusing unduly on any particular idea or subset of ideas;
2) Opportunity for clarification and elimination of misunderstanding;
3) Opportunity to provide the logic behind arguments and disagreements;
4) Recording of differences of opinion without undue argumentation.

Step 4: Vote on Item Importance

- Benefits: 1) Having individual members of the group make independent judgements;
2) Expressing these individual judgements mathematically by rank-ordering and/or rating items;
3) Using the mean (x) value of independent judgements as the group's decision.

(Source: Delbecq, Van de Van, and Gustafson, 1975)

Assessment of Product Class Involvement

Eighty subjects from undergraduate business classes were enlisted to assess product class involvement. Half were assigned to eight NGT groups of five members each to obtain two high involvement product classes. The remaining half were assigned to eight NGT groups of five members each to obtain two low involvement product classes. Assignment to high and low groups was assumed to be random by computer assignment to various sections of the same class. Within these classes, individuals were randomly

assigned to groups. Since Shaw (1981) had pointed out that single sex groups may operate more along conformist lines, thus limiting possible idea generation quality, groups included no more than three members of the same sex.

Students assigned to each involvement group were then instructed to proceed with the NGT process, see Table 1. The question presented to the respondents concerning involvement with the product class was derived from work by Lastovicka (1979a), Cialdini, Levy, Herman, Kozlowski, and Petty (1976), Ray Sawyer, Rothschild, Heeler, Strong, and Reed (1973), Ray and Webb (1976), Lastovicka and Gardner (1978), and DeBruicker (1979) which related involvement to a combination of commitment, importance, perceived product differentiation, and information processing levels (thinking) by the individual.

In order to provide a selection of product classes which would most likely be of high or low involvement to the entire population to be used in the broader study, an additional step was added to the NGT procedure at this stage. The products in both the high and low involvement procedures were rank ordered by the researcher. The procedure for rank ordering was to give ten points for a top ranked product, nine points for the second ranked product, on down to one point for the tenth ranked product for each subject. Those products not receiving a top ten ranking were not awarded any points. The points were then totaled across subjects for each product and the products ranked with respect to their overall point scores. From the top ten for each of the involvement conditions, two products were selected for inclusion in the study for a total of four products. These products were: (1) stereos and (2) clothes (jeans) for high involvement; and (3) bar soap and (4) paper towels for low involvement. Table 3 and Table 4 summarize the results of this ranking procedure.

TABLE 3
TOP TEN PRODUCTS
NGT High Involvement Product Summary

See Table 3 for rating scale

Selection of the products was based on ranking and perceived appropriateness for the broader study's contrived purpose. Participants in the broader study were asked to complete a product advertising survey concerning individual's feelings about randomly selected brands for sale in their area and advertising in general. For example, while a college education is viewed as high involving, it is hard to classify as a tangible "brand". Jeans were chosen as the specific clothing garment since a substantial portion of the clothes listed were jeans or designer jeans. In addition, earlier work by Lastovicka and Gardner (1978) had shown jeans (as well as stereos) were rated as being highly involving for college students.

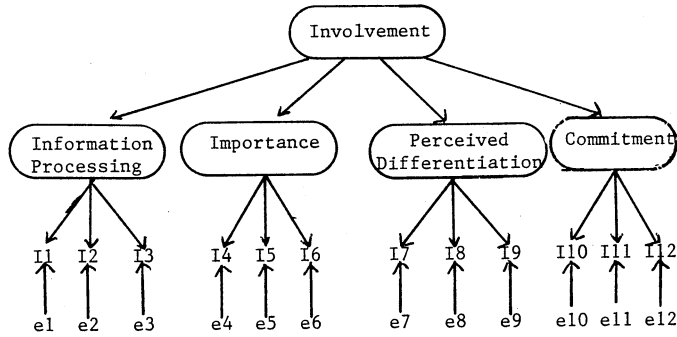

The two low involvement products, paper towels and bar soap were selected on the basis of their rankings. Bar soap was ranked sixth out of ninety products listed. Those products finishing in front of bar soap, as Table 4 shows, were mostly grocery type products, often bought as unbranded or store branded products (e.g., milk, eggs). This was felt to be in conflict with the cover story of the research being concerned with advertising and brands.

The Role of Manipulation Checks

As Bagozzi (1980) points out, a definition of causality relies on a "human agent" being about something while controlling for all other possible effects. In order to actually profess a cause (e.g., involvement) and effect (e.g., cognitive consistency of the individual) relationship, a manipulation check is necessary to control for extraneous interferences by showing the "agent" (e.g., involvement) did in fact cause the effect, or was present at all.

To determine if the product classes used in the study were correctly classified as to their involvement levels (high or low), a number of items in the broader study's scale served as manipulation checks. These items consisted of nine-point semantic differential scale statements (e.g., "strongly agree" to "strongly disagree") measuring four elements of involvement gleaned from the literature. As noted, involvement was operationalized as a combination of four components: (1) information processing levels; (2) importance; (3) differentiation of salient attributes; and (4) commitment. Most studies agree that a high involvement state elicits higher levels of information processing on the part of the individual than does a low involvement state. A majority of the work also alludes (implicitly or explicitly) to importance, whether it be internally or externally instigated. Involvement seemed to be related to the ability of the individual to differentiate relevant (salient) relationships between objects and beliefs. Finally, there is agreement on commitment by the individual. These four components are developed from the work on involvement by Lastovicka (1979a, b), Lastovicka and Gardner (1978), DeBruicker (1979), Mitchell (1981), Petty and Cacioppo (1979, 1981), Kiesler (1971), Robertson (1976), and Ray, Sawyer, Rothschild, Heeler, Strong, and Reed (1973) and others. Figure 1 illustrates the operational measurement model for the involvement indicators used in the multiple discriminant analysis manipulation check.

FIGURE 1
OPERATIONAL MEASUREMENT MODEL
FOR THE MANIPULATION CHECK INDICATORS

Results and Analysis

A reliability analysis was run on the four indicators of product class involvement using the internal consistency measure of Cronbach's Alpha (Cronbach, 1951). Each of the four indicators of product class involvement (importance, commitment, information processing, and perceived differentiation) were operationalized by three items from the main questionnaire. The analysis on each of the sixteen scale combinations (four products X four indicator scales) yielded reliabilities above or near the generally accepted level of 0.8 (Peter 1979). Only one scale, the commitment scale for the low involvement product class of paper towels, yielded questionable results. This scale had had problems for the same product in the pretest and had been modified and retested qualitatively on a small group with no apparent problems. It is speculated, however, that the nature of the product itself may have caused the inconsistency to occur. That is, since paper towels may have been such an obviously low involvement product type, subjects may have not cared to bother with being consistent at all. These results can be seen in Table 5.

TABLE 5
INTERNAL CONSISTENCY MEASURES (ALPHA)
FOR INVOLVEMENT MANIPULATION CHECK SCALES

Scale	Product			
	Stereo	Bar Soap	Paper Towels	Jeans
Importance	.84	.89	.87	.87
Information Processing	.86	.88	.76	.85
Commitment	.78	.84	.60	.80
Perceived Differentiation	.82	.89	.88	.84
Combined Scale Alpha	.86	.88	.82	.80

n = 250

Following this overall reliability analysis, another set of reliabilities was calculated for the involvement indicators. This procedure generated reliabilities for the combined involvement scales for each product class. In the procedure a four item analysis was used with commitment, importance, information processing, and perceived differentiation as the individual items for each product class involvement scale. Once again, the reliabilities were above the 0.8 level. An item analysis conducted on the scales showed that there would be a slight decline in the Alpha if any of the items were removed. There appeared to be significant declines if the commitment or importance items were removed for the jean or paper towel product class involvement scales. These product class involvement scales were four item scales comprised of the four components of involvement presented earlier: (1) importance; (2) commitment; (3) information processing; and (4) perceived differentiation. Each of these scale items was an averaged index of the three items from the questionnaire used to measure each of the product class involvement components. Scale means are an averaged mean of the four items over a scale from zero to one.

Scale means for the four product classes were .60 for jeans, .643 for stereos, .176 for paper towels and .413 for bar soap. These means indicate a higher mean scale involvement for the two preclassified high involvement product classes than for the two low involvement product classes. However, while these results suggest a difference, it was felt further analysis would be beneficial to help verify a correct preclassification of the involvement product classes.

Using MDA

To verify the involvement levels, as high or low, multiple discriminate analysis (MDA) was used. Multiple discriminant analysis is a multivariate extension of the univariate t-test for differences between means under the assumption of equal variances. Since the design was a within design, the procedure was well suited for use here. Maximal separation for the means was accomplished by taking linear combinations of the original variables which maximized the ratio of the between to within group variance.

Multiple discriminate analysis was deemed appropriate in this setting due to the nature of the predetermined nominal groups (i.e., high and low involvement) and the interval type involvement manipulation check scales (Hair, Anderson, Tatham, Grablovsky 1979; Klecka 1980). Using the involvement groups (high and low) as the dummy coded dependent variable and the four scaled item responses to the product class involvement measures as the independent variables; allowed an examination of whether or not the respondents viewed the predetermined involvement levels as correct.

In this procedure, each of the four product measures for each subject was treated as a separate case. By doing so, a sample for analysis of 1000 was created. The use of the two high and the two low involvement products effectively created a preassigned grouping of 500 subjects per involvement category.

It is noted that the artificial inflation of sample size from 250 to 1000 significantly increases the degrees of freedom for the statistical procedure. However, due to the restriction of this analysis to use as a manipulation check, this inflation was not viewed as critical. An additional note is added here concerning the violation of the independence criterion of the observations (see Klecka 1980). Since the 1000 observations are four observations per individual, a possible violation of the statistical assumption of independence exists. However, it was not felt that individuals' responses to one product class would affect their responses to another. Therefore, the violation of the independence assumption was not viewed as crucial to the use of the procedure as a manipulation check. Use of these data beyond simple manipulation check, however, is advised only with clear recognition of their limitations.

The discriminant equation for the analysis was generated by using a sample of ninety-nine subjects from the base sample of 250. Since each of the respondents had generated four distinct product class responses, the actual "cases" used to generate the discriminant equation totaled 396 (four products X ninety-nine subjects). The canonical correlation for the discriminant function was .600736, significant at the p=.00 level. The eigenvalue was .56466. Table 6 summarizes the standardized canonical discriminant function coefficients, structure matrix and canonical discriminant function evaluated as the group centroids (means).

This MDA output provides the researcher with substantive information as to the effectiveness of the manipulation and the explanatory ability of the manipulation check operationalizations. As Table 6 shows a substantial portion of the variance was explained by the discriminant function. It is also possible to assess the magnitude of the influence of each of the operationalized components in the explanation. For example, the commitment portion of the

scale offers the most explanation of the four operationalized elements of involvement.

TABLE 6
SUMMARY OF MDA ANALYSIS

	Std. Canonical	Structure Matrix
	Discriminant Function Coefficients	Pooled Within Group Corr.
Importance	.56120	.52539
Info. Processing	.53214	.70516
Commitment	.73654	.85873
Per. Different.	.39001	.73617

Canonical Discriminant Function at Centroid		
Group	Function 1	
0	-.74954	
1	.74954	

The classification table for this analysis is shown as Table 7. As can be seen in Table 8 the cross-validation MDA procedure using the discriminant functions from the prior sample gave support to the classification of the study's products into their respective involvement categories. Using the remaining 151 respondents to generate 604 "cases", the results in Table 6 show a large proportion of the cases were classified correctly (81.79 percent). Hair, Anderson, Tatham, and Grablovsky (1979) liken this "hit percentage" to a regression procedure's R-square. The MDA results support the contention that the NGT procedures had generated correct classificatory data for use in the main study.

TABLE 7
CLASSIFICATION RESULTS FOR CASES
SELECTED FOR USE IN THE ANALYSIS

Actual Group	No. of Cases	Predicted Group Membership	
		Low	High
Low Involvement	198	148 74.7%	50 25.3%
High Involvement	198	43 21.7%	155 78.3%

Percent of "Grouped" Cases Correctly Classified: 76.52%

TABLE 8
CLASSIFICATION RESULTS FOR CASES
USED FOR CROSS VALIDATION

Actual Group	No. of Cases	Predicted Group Membership	
		Low	High
High Involvement	302	239 79.1%	63 20.9%
High Involvement	302	47 15.6%	255 84.4%

Percent of "Grouped" Cases Correctly Classified: 81.79%

Conclusions

Very often, when manipulations are employed one finds ANOVA's and t-tests being used as the statistical manipulation check technique. The authors are unaware of any studies where MDA has been used. Clearly, in cases where the data is appropriate MDA should be explored as a technique to use.

Often in marketing researchers may be led by the techniques they are familiar with rather than by the technique which may be best suited for the task at hand. It is hoped that this paper has contributed to a greater awareness of a different method (MDA) which may be appropriate for manipulation check techniques under certain data configurations.

In addition, it is hoped that researchers (especially those working in the involvement area) may be more predis-

posed to using combinations of qualitative and quantitative methods to assure valid manipulations. As noted, manipulations may be at times be simply based on a researcher's "notion", not "hard data". The MDA results here indicate that the NGT procedure appears to hold promise for marketers exploring nebulous constructs for which consumers subjective responses are salient to an explanation of the construct.

SELF-MONITORING AND PRODUCT CONSPICUOUSNESS ON
REFERENCE GROUP INFLUENCE

David Brinberg, Baruch College, CUNY
Linda Plimpton, Ohio State University

Abstract

Two facets of product conspicuousness--public/private and luxury/ necessity--and their impact on reference group influence were examined. The self-monitoring orientation of the respondent was included as an individual difference variable that may influence the relation between product conspicuousness and reference group influence. Two dimensions of reference group influence were identified--normative and informational. Products perceived as conspicuous; that is, public and luxury products, were more susceptible to group influence. The self-monitoring orientation of the individual, however, had little impact on the relation between product conspicuousness and reference group influence.

Introduction

Marketers and advertisers have long recognized the apparent influence of reference groups on consumers' decision. Several researchers have demonstrated consumers' susceptibility to reference group influence when making product or brand purchase decisions (Bearden & Etzel 1982; Burnkrant & Cousineau 1975; Park & Lessig 1977; Stafford 1966). The influence of the visibility of the purchase decision, sometimes referred to as the "conspicuousness" of the decision (Bourne 1957), has also been examined extensively as a factor that affects reference group influence on purchase decisions (Bearden & Etzel 1982; Burnkrant & Cousineau 1975; Witt 1969; Witt & Bruce 1970, 1972).

Behavioral theorists differ in explaining how reference groups affect consumer behavior. Several similar underlying dimensions of reference group influence appear in the literature. Deutsch and Gerard (1955) described two types of social or reference group influence. One is informational influence, which facilitates the transfer of information among reference group members. Information, here, could include product evaluations, preferences, or opinions and can occur through either active transfer, i.e., verbal interaction or through observation of group members. The second type of influence identified by Deutsch and Gerard is normative, which includes any influence to conform to group norms or expectations.

Recently, Park and Lessig (1977) used a three dimensional structure to describe reference group influence. By combining the theories of Deutsch and Gerard (1955), Asch (1952), Jahoda (1972), and Kelman (1961), they defined three forms of reference group influence:

(a) Informational reference group influence - information will influence an individual if it is accepted and is perceived as enhancing the individual's knowledge of the environment and/or their ability to cope with some aspect of this environment, e.g., purchasing a product.

(b) Utilitarian reference group influence - is similar to the normative influence (Deutsch and Gerard 1955 and the compliance process (Kelman 1961; Jahoda 1972). In a purchasing decision, an individual will comply with the expectations of a reference group if s/he thinks the group can produce rewards or punishments, if the behavior would be visible or known to the group members, and if the individual is motivated to receive the reward or avoid the punishment (Park and Lessig 1977).

(c) Value-expressive reference group influence - an individual is influenced by the reference group because of a desire to enhance his/her self concept or because of a liking (affect) for the group.

The normative influence described by Deutsch and Gerard (1955) may be viewed as the basis of the value-expressive and the utilitarian influence dimensions. Both reflect the awareness of group norms, accepted practices, and values. Given this potential dual effect of normative influence, one aspect of the current study will examine whether the value-expressive and utilitarian influences are perceived as distinct, across different products, or are both measuring the same underlying normative dimension.

Product Characteristics

Several researchers have noted that reference group influence is affected by the type of product or situation studied. In two separate studies of brand choice, Witt (1969) found that brand decisions vary in their susceptibility to group influence. Subsequently, Witt and Bruce (1970) found that reference group influence is related to the amount of social involvement associated with the product and that influence differs as a function of product characteristics.

Bourne (1957) found a relationship between reference group influence and product conspicuousness; where a product may be conspicuous (or visible) in two senses: (a) it is consumed publicly and (b) it is exclusive in some way. A good consumed publicly would be seen by others and, hence, be more conspicuous than a good consumed privately. Similarly, an exclusive product (i.e., luxury), defined as not commonly owned or used, would be more conspicuous than a product that is a necessity. Bearden and Etzel (1982) operationalized the conspicuousness of the product by creating two factors: (1) a public-private factor and (2) a luxury-necessity factor. They found that "...consistent with Bourne's framework, the luxury-necessity and public-private dimensions were consistently significant" (p. 192). These authors suggest, however, that several issues need to be explored, including individual difference variables that may moderate the relationship between reference group influence and product choice.

Self-Monitoring

One individual difference variable that has received some attention in consumer behavior is self-monitoring (Becherer and Richard 1978). Snyder (1974) postulates that a high self-monitoring individual is one who identifies social cues for appropriate behavior and modifies his/her self-presentation accordingly. A low self-monitoring individual is less sensitive and responsive to these situational cues. Snyder developed a self-monitoring scale to "...discriminate individual differences in concern for social appropriateness, sensitivity to the expression and self-presentation of others in social situations as cues to social appropriateness for self-expression, and use of social cues as guidelines for monitoring and managing self-presentation and expressive behavior" (Snyder 1974, p. 125).

Using Snyder's self-monitoring scale, Becherer and Richard (1978) hypothesized that the behavior of low self-monitoring individuals would be more affected by dispositional factors i.e., personality variables, and that high self-

monitoring individuals would be more affected by situational factors i.e., social cues. These authors found that self-monitoring was useful in identifying "...individuals for which situational or dispositional variables have primary influence" (1978, p. 62). In the present study, self-monitoring was used to examine potential differences in the amount and type of reference group influence among individuals.

In sum, the present study was conducted to examine: (1) the structure underlying the three reference group influence scale items proposed by Park and Lessig (1977), (2) the influence of self-monitoring and product conspicuousness on reference group influence.

Method

We adapted Bearden and Etzel's (1982) procedures to examine three forms of reference group influence (Park & Lessig 1977) and two forms of product use conspicuousness (Bearden & Etzel 1982). In addition, Snyder's (1974) self-monitoring scale was used as a dispositional factor that may influence the relations between product conspicuousness and reference group influence.

Pilot Study

Two factors were used to examine the conspicuousness of the product: (1) a public/private factor and (2) a luxury/necessity factor. A pilot study was conducted to identify those products that best represented the 2 x 2 combination of factors. Ten products were selected initially to represent each of the four conspicuousness combinations, i.e., public luxury (PUL), public necessity (PUN), private luxury (PRL), and PRN (PRN).

A sample of sixty undergraduate students were asked to classify each of the forty products into one of the four categories using the definitions listed below.

1. Public luxury (PUL) - a product that other people are aware you possess and use. If they want to, others can identify the brand of the product with little or no difficulty. This product is not needed for ordinary day-to-day living.
2. Public necessity (PUN) - a product that other people are aware you possess and use. If they want to, others can identify the brand of the product with little or no difficulty. The product is needed for ordinary day-to-day living.
3. Private luxury (PRL) - a product that is used at home or in private. Except for your immediate family, people would be unaware of the brand you own. This product is not needed for ordinary day-to-day living.
4. Private necessity (PRN) - a product that is used at home or in private. Except for your immediate family, people would be unaware of the brand you own. This product is needed for ordinary day-to-day living.

In addition, subjects rated each product placed in one of the four categories, on a seven point Likert scale, ranging from very representative to very unrepresentative.

Based on the classification of the product and the mean representativeness judgments, the following products were selected (the value in the parentheses represent the percent of respondents who placed the product in the appropriate category): golf clubs (73%) and a walkman (73%) for the category of public luxury; record album (77%) and stereo (73%) for the category private luxury; rain coat (65%) and winter coat (81%) for the category of public necessity; and clock (68%) and toothpaste (77%) for the category of private necessity. A two-way ANOVA (luxury/necessity by public/private) was conducted using the re-

presentativeness of the product as the dependent variable. No significant differences were found. The results of the pilot study suggest that no systematic differences exist in the categorization or representativeness of the products.

Dependent Measures

For the main study, a questionnaire, developed by Park and Lessig (1977) and adapted by Bearden and Etzel (1982), was used to measure reference group influence for each of the eight products. The wording of the items was modified slightly from the original Park and Lessig (1977) questionnaire to connote not an evaluation of what "the individual," meaning other consumers, would do, but what "I" would do. This modification of the original questionnaire is important for the present study because the impact of an individual difference variable (self-monitoring) is being investigated. To compare self-monitoring tendency and susceptibility to reference group influence, the reference group items must measure what each subject would do with respect to the product being considered.

A six point bipolar agree (1) - disagree (6) scale was used to measure the reported reference group influence for each of the 14 items in the questionnaire. These items, which represent informational, utilitarian, and value-expressive reference group influence, were repeated for all eight products. The order of both the three types of reference group items as well as the presentation of the products was randomized. Snyder's (1974) 25 item self-monitoring scale was used to measure self-monitoring.

Design

A 2x2x2x2 factorial design was used with public/private, luxury/necessity and two products per category as within subject factors and high/low self monitoring score (derived using a median split of the self-monitoring scale) as a between subject factor.

Subjects and Procedure

A total of 80 undergraduate students participated in the study, resulting in 75 useable respondents. The five respondents were eliminated from further analyses due to substantial missing data. Subjects were scheduled for one-hour sessions in groups of 10 to 15. On entering the lab, subjects were given an instruction sheet that described the basic purpose of the study as well as the types of scales to be used in the study. They were then given several "warm-up" questions to become familiar with the scales.

Results

Structure of Reference Group Items

A principal components analysis with a varimax rotation was used to examine the underlying structure among the reference group items for each product separately. Based on a scree test and the interpretability of the factors, a two factor solution was selected for each product. The median percent of variance accounted for by the two factor solution across the eight products was 57% (range from 50% - 60%). The median correlation of the first factor across the eight products was .87 and for the second factor across the eight products .88. Because the factor structure was highly similar across the eight product categories, only one product is presented to represent the obtained factor structure. Table 1 contains a summary of the factor loadings of the reference group items associated with the toothpaste product.

The two factors were identified as informational and normative. Examination of the factor loadings indicates that the informational items loaded highly on factor 2 whereas the utilitarian and value-expressive items (except item B3) loaded highly on factor 1.

TABLE 1

FACTOR LOADINGS OF REFERENCE GROUP ITEMS FOR TOOTH PASTE

Reference Item	Category	Factor Loadings	
		Factor 1	Factor 2
seeks information from professionals or experts	A	.17	.77
seeks information from salespersons	A	.46	.57
seeks information from friends, relatives, neighbors, or work associates	A	.05	.79
brand choice influenced by approval of independent testing agency	A	.08	.80
brand choice influenced by observations or purchases of experts	A	.27	.79
classmate's brand preferences	B	.86	.02
friend's brand preferences	B	.89	.02
family member's brand preferences	B	.01	.35
satisfy expectations of friends	B	.89	.11
enhance image others have of me	C	.78	.10
those who purchase brand possess the characteristics I would like to have	C	.73	.12
nice to be like person in ads	C	.51	.28
people who purchase brand are admired and respected by others	C	.74	.10
purchase of brand shows others who I am or who I would like to be	C	.86	.06

 B = utilitarian influence
 C = value-expressive influence

Product conspicuousness and self-monitoring

Two influence subscales were developed by summing the items labelled "A" in Table 1 to form an informational subscale and by summing the items labelled "B" and "C" to form a normative subscale. These subscales were then used as the dependent variables in the subsequent ANOVA analysis. We will focus our discussion on the effects of self-monitoring, public/private, and luxury/necessity factors. We will not discuss the impact of the product factor because of its limited theoretical interest.

For the normative subscale, there were significant main effects for the public/private factor ($F=103.49$; $df=1,73$; $p<.01$, $\bar{X}(\text{public}) = 33.2$, $\bar{X}(\text{private}) = 38.1$) and for the luxury/necessity factor ($F=45.62$; $df=1,73$; $p<.01$, $\bar{X}(\text{luxury}) = 34.0$, $\bar{X}(\text{necessity}) = 37.4$). The main effect of the public/private and luxury/necessity factors indicates that products perceived as public (or luxury) had more of an affect on normative influence than private (or necessity) products.

In addition, there was a significant self-monitoring (A) by luxury/necessity (C) interaction ($F=40.05$; $df=1,73$; $p<.01$) and a public/private (B) by luxury/necessity (C) interaction ($F=36.37$; $df=1,73$; $p<.01$). A simple main effects test was conducted to examine these interactions further. For the AxC interaction, high self-monitoring individuals were more affected by normative influence for a product perceived as a luxury ($\bar{X} = 32.9$) than low self-monitoring individuals ($\bar{X} = 34.9$) ($F = 4.09$; $df=1,75$; $p<.05$). For necessity products, however, low self-monitoring individuals were more affected by normative influence ($\bar{X} = 36.3$) than high self-monitoring individuals ($\bar{X} = 38.9$) ($F = 6.91$; $df=1,75$; $p<.05$). For the B X C interaction, a private/necessity product had less of an affect on normative influence ($\bar{X} = 41.3$) than public/necessity product ($\bar{X} = 33.4$) ($F = 63.66$; $df=1,75$; $p<.05$). There was no difference between private/public products for luxury products.

For the information subscale, there was a significant main effect of the public/private factor ($F=40.05$; $df=1,73$; $p<.01$, $\bar{X}(\text{public}) = 13.9$, $\bar{X}(\text{private}) = 15.7$) and for the luxury/necessity factor ($F=8.58$; $df=1,73$; $p<.01$, $\bar{X}(\text{luxury}) = 14.2$, $\bar{X}(\text{necessity}) = 15.3$). In addition, there was a significant public/private (B) by luxury/necessity (C) interaction ($F=9.86$; $df=1,73$; $p<.01$). Public luxury products had more of an affect on informational influences ($\bar{X} = 12.9$) than private/luxury products ($\bar{X} = 15.6$) ($F = 29.52$; $df=1,75$; $p<.05$). In addition, public/necessity products ($\bar{X} = 14.8$) had more of an affect on the informational subscale than private/necessity products ($\bar{X} = 15.8$) ($F = 4.1$; $df=1,75$; $p<.05$).

Discussion

The two factor structure of reference group influence found here suggests that the theory of Deutsch and Gerard (1955) should not be expanded. Only two types of reference group influence were identified--informational and normative. Perhaps, as Kelman (1961) has argued, reference group influence operates through three separate processes, two of which are associated with the normative influence. Burnkrant and Cousineau (1975) relate Deutsch and Gerard's reference group influence types with Kelman's three processes. They suggest that normative reference group influence is accomplished through either the process of compliance (utilitarian influence) or identification (value-expressive influence).

Both utilitarian and value expressive reference group influences motivate behavior based on expectations. Whether one is attempting to identify with a group to enhance one's self image or to comply with its norms and behaviors to avoid chastisement, a desire for some association with the group exists; that is, both forms of influence are derived from normative pressure.

Bourne's (1957) theory of reference group influence on brand decisions for two forms of product conspicuousness was supported for both the normative and informational influence subscales. Both public and luxury products, which represent two features of conspicuousness, had more of an affect on reference group influence than private and necessity products. Further, the significant interactions indicate public/luxury products had more of an affect on reference group influence than private/luxury or necessity products.

An individual's self monitoring orientation had limited relation to reference group influence and brand choice. We may interpret the self-monitoring by luxury/necessity interaction for the normative subscale to suggest that individual's who are likely to attend to social cues will do so when the product is a luxury rather than a necessity. This finding is consistent with the hypothesized impact of self-monitoring; that is, individuals influenced by social cues (high self-monitors) when considering luxury products, are most likely to be susceptible to reference group influence.

In sum, product conspicuousness did impact on the effect of reference group influence. Two rather than three dimensions of group influence were identified--normative and informational. Products perceived as conspicuous were more susceptible to group influence. Finally, the self-monitoring orientation of the individual had little impact on the relation between product conspicuousness and reference group influence.

PEOPLE WHO USE PEOPLE :
THE OTHER SIDE OF OPINION LEADERSHIP

Lawrence F. Feick, University of Pittsburgh
Linda L. Price, University of Pittsburgh
Robin A. Higie, University of Pittsburgh

Abstract

Most consumer research has explored opinion leadership entirely from the viewpoint of the opinion giver in the exchange. This research examines opinion seeking across a broad range of product classes. In contrast to previous research, this research examines the extent to which the opinion seeker is also an opinion leader in the same product class or in other product classes. In addition, this research examines the information seeking, information transmission and demographic profile of the opinion seeker. The results, based on a national study of over 1500 households, suggest a high overlap between opinion giving and seeking. Further, the results indicate that opinion seekers, compared to the rest of our sample, show greater inclination to seek and diffuse market information. Demographically, the profile of opinion seekers is similar to the profile of opinion leaders.

Introduction

The importance of informational interpersonal influence in consumer decision making has been recognized for decades. Considerable research on interpersonal influence has focused on opinion leaders. Primarily because of their product knowledge, opinion leaders influence others in their purchases. It is important to remember, however, that opinion leadership is social communication between opinion givers and opinion seekers. As a consequence, understanding opinion leadership requires an examination of the relationship between opinion givers and opinion seekers. Despite the importance of understanding this relationship, almost all research has focused on the opinion giver in the exchange (Gatignon and Robertson 1985). Specifically, most consumer research has explored opinion leadership entirely from the viewpoint of the self-designated expert and influencer. Further, researchers have restricted their consideration of interpersonal influence to communications about a single product class (or a researcher designated selection of product classes).

The purpose of this research was to examine the second party involved in the interaction -- the opinion seeker. This research explores the opinion seeker across product classes, employing a receiver-based definition of opinion leadership. In contrast to previous research, this research affords an opportunity to examine the extent to which the opinion seeker is also an opinion leader in the same product class or in other product classes. Moreover, it allows examination of the characteristics of the opinion seeker. By contrasting people who seek the opinions of knowledgeable individuals with those who do not, this research sheds new light on informational interpersonal influence and the relationship between opinion givers and opinion seekers.

Background

A variety of research has suggested the pervasive role of interpersonal sources in consumer decision-making (Arndt 1967, Feldman and Spencer 1965, Katz and Lazarsfeld 1955, King and Summers 1970). This research suggests that across a wide range of product classes, interpersonal sources are more likely to influence consumer choice than any other source of information (Assael 1984, Price and Feick 1984). Considerable research has attempted to explore the nature of this influence. Three sources of influence have been identified: (1) the information supplied (informational); (2) Identification with the source (comparative); and (3) pressure to conform (normative). Park and Lessig (1977) suggest that products that are

technologically complex or require objective criteria for selection are most likely to be subject to informational influence. Research has suggested that across product types, informational influence is the most important of these three types (Burnkrant and Cousineau 1975, Hansen 1969, Moschis 1976, Park and Lessig 1977, Price and Feick 1984).

In part because of the importance of informational interpersonal influence in consumer decision-making considerable research has focused on the opinion leader. The definition of an opinion leader is an individual who is regarded by other individuals as having expertise and knowledge on a particular subject (Assael 1984). Because of their knowledge on a particular topic, opinion leaders presumably are then used as information sources by opinion seekers. Research indicates that the distinction between opinion leader and opinion seeker is artificial, however. For example, studies have indicated that individuals most likely to influence others in a particular product category are also most likely to be influenced in their decisions about that product category. This finding has been documented for doctors adopting a new drug (Coleman, Katz and Manzel 1957); and consumer adopters of a stainless steel razor blade (Sheth 1971), a new food product (Arndt 1967), and several other low risk innovations (King and Summers 1967). Thus "a consumer who frequently expresses opinions about sports equipment will also be more likely to listen to others' opinions about such equipment," (Assael 1984, p. 413).

Studying Opinion Giving And Receiving

There are a number of ways to study information exchange. Perhaps the ideal way is to use sociometric analysis and trace the pattern of communication among members of a social system (Arndt 1967, Coleman 1959, Jacoby 1972, Martilla 1971, Schiffman 1971). While sociometric methods allow an examination of interrelationships among participants in the transmission of information about products, the approach is practically limited to applications involving small, closed social systems. Since consumer product influence may extend beyond a single social system, other techniques appear necessary.

The most common method of examining interpersonal influence employs some form of self-designation of the opinion leader (King and Summers 1970, Reynolds and Darden 1971, Rogers and Cartano 1962, Silk 1966). Using this approach, opinion leadership has been based on self-designated product expertise and influence in a prespecified product class. For example, research on opinion leaders in clothing fashions would ask a series of questions to establish whether or not individuals have product expertise and believe they influence others in their choice of clothing. Both expertise and influence are defined by the perceptions of the opinion giver. While this approach allows the research to explore the perceptions, attitudes and characteristics of the opinion giver in some detail, it is a view of information exchange defined entirely from the perspective of the self-designated influencer.

An alternate way of exploring interpersonal information exchange would be from the viewpoint of the opinion seeker. However, almost no research has specifically focused on the consumers' use of knowledgeable others to acquire information (Price and Feick 1984). A focus on the opinion seeker appears to have a number of advantages. First, it provides a means for examining a group that has been ne-

glected in past research. This approach allows the researcher to contrast the information acquisition and transmission patterns and general descriptive characteristics of opinion seekers and other respondents. Second, the focus provides a markedly different point-of-view from which to examine the relationship between opinion givers and seekers. In particular, it should yield a different perspective on the extent to which opinion leaders are used by others and on the overlap between opinion seeking and opinion giving. Finally, a focus on the opinion seeker should redirect attention from opinion leadership as one-way influence in a particular product class toward a view of opinion leadership as social communication to acquire product information (Assael 1984). Self-designation approaches usually focus on communications about a particular product class. They do not address the extent to which an opinion leader in sports equipment trades information with an opinion leader in stereo systems. A focus on the opinion seeker should provide a clearer picture of informational interpersonal influence by emphasizing the social communications aspects of opinion leadership.

Method

Data used in the study were obtained through telephone interviews with 1531 residents of the contiguous states. The interviews, conducted during the middle two weeks of August 1984, averaged eighteen minutes in length. Random digit dialing was used to obtain the sample. Household heads were selected for interviewing by preassignment of sex to the telephone numbers, alternating male and female. Interviewers screened for the pre-assigned household head. If that person did not exist, interviewers talked to the lone household head. If the person was unavailable, a call back was scheduled. At least three call backs were made to individuals who were unavailable and to numbers that were busy or not answered. The response rate (completed interviews as a percentage of completed interviews, refusals and terminations) was 47 percent. The demographics of the sample, with the exception of sex, closely mirrored the 1980 census and relevant 1984 updates from the U.S. Department of Commerce. The sample somewhat overrepresented females compared to our estimate of the proportion of female heads-of-households in the population.

Development of Measures

Opinion Leaders

As noted previously, consumer researchers usually have used self-designation in a predetermined product class to measure opinion leadership. Most have used a modification of the Rogers and Cartano (1962) scale proposed by King and Summers (1970) to identify opinion leaders. Silk (1966) and Reynolds and Darden (1971) have used other self-designation measures.

In this study, opinion leadership was defined to include knowledge and influence and was measured using two self-designation items. First, "Is there a particular type of product that you feel you are very knowledgeable about?" Respondents were encouraged to name all product categories in which they were very knowledgeable. The second item focused on the one product category about which respondents felt they were most knowledgeable. It read: "Do you think that you ever influence other people in their purchase of or opinions about this kind of product?" Respondents who answered yes to both questions were classified as opinion leaders in the product category about which they were most knowledgeable.

In pilot testing, the two-item dichotomous measure of opinion leadership showed a high (.75) correlation with the King and Summers (1970) scale. The use of a self-specified product allowed us to more accurately measure opinion leadership across the sample and across product types. Obviously, using predetermined product classes would tend to underestimate the incidence of opinion leadership.

Opinion Seekers

Opinion seekers have been defined as individuals who sought information or opinions from interpersonal sources in order to find out about and evaluate products, services, current affairs, or other areas of interest (Arndt 1968, Feldman 1966, Sheth 1968, Wright and Cantor 1967). In the past, items used to measure opinion seeking, typically in a predetermined product class, service or activity, have been tailored to the individual researcher's study. Consequently, there has been little consistency among the measures. Feldman (1966), for example, researched non-family interaction dyads, defining opinion seekers as people who used non-family interpersonal sources as their dominant source of influence in selecting a physician. Alternatively, Wright and Cantor (1967) classified as opinion seekers people who had frequent discussions about, asked peers for information about, and knew an opinion leader in a particular predetermined topic area.

Opinion seeking in this study was measured by self-designation and based on our measure of opinion leadership. Respondents indicated their acquaintance with an individual who was knowledgeable in up to three product classes. Then, they specified their use of that person to help find out about or evaluate new brands or models in the product class in which respondents identified the person as being most knowledgeable. Specifically, respondents were asked the following questions: "Do you know someone other than yourself, who is very knowledgeable about a particular product?" If yes, "What product is this person knowledgeable about?" If more than one product was offered, respondents were prompted to specify that one about which the individual was most knowledgeable or had the most expertise. Two seven-point items were used to measure the importance of the opinion leader to the opinion seeker: "How important is this person to you (a) for finding out about new brands or models and (b) in evaluating different brands and models of this type of product?" Respondents who said they knew an opinion leader in a self-specified category and who indicated the person was very important (the top three categories on the seven-point scale) in either finding out about or evaluating brands or models were classified as opinion seekers. The choice of the top three categories is somewhat arbitrary but includes all respondents who fell into categories above the midpoints on either scale.

Results

Incidence of Opinion Leadership and Opinion Seeking

Almost one-half of the total sample (46.2%) were opinion leaders in a self-specified product class. Opinion leadership was most prevalent in food (42.8%) and household goods (19.2%). Incidences of opinion leadership in other product categories are reported in Table 1.

Approximately 42 percent of the total sample were opinion seekers; that is, people who knew one or more knowledgeable individuals who helped them to find out about or evaluate products in some product class. The highest incidence of opinion seeking was also in the food category; one-fourth of opinion seekers were opinion seekers in food. A large percentage of individuals were opinion seekers in major durables, somewhat fewer respondents were opinion seekers on other nondurables. Incidences of opinion seeking in the product categories are also listed in Table 1.

Information Seeking and Diffusion Characteristics of
Opinion Seekers

Opinion seekers, by our definition, use knowledgeable individuals to find out about or evaluate products. The questionnaire also examined general information seeking tendencies using three seven-point items: "I often read advertisements just out of curiosity," "I find out about new products sooner than most other people," and "I read advertisements because they are a good source of information about new products." The results, listed in Table 2, indicate that opinion seekers have a greater inclination to seek general marketplace information than the rest of our sample ($p < .01$).

Although the two step flow model holds that opinion leaders, attending to mass media, provide information to opinion followers (Katz and Lazarsfeld 1955, Lazarsfeld, Berelson and Gaudet 1948, Rogers 1983), results in several studies (Sheth 1971, Arndt 1968) suggest that people influenced by personal sources were themselves likely to transmit information to others. The information transmission characteristics of respondents were measured using these seven-point items: "I like introducing new brands and products to my friends," "I like helping people by providing them with information about many kinds of products," "People ask me for information about products, places to shop or sales," "If someone asked where to get the best buy on several types of products, I could tell him or her where to shop," and "My friends think of me as a good source of information when it comes to new products or sales." The results, listed in Table 3, suggest opinion seekers were more likely to diffuse marketplace information than other respondents. In fact, opinion seekers were significantly higher ($p < .01$) on all items measuring information transmission.

Incidence of Opinion Seeking and Opinion Leadership in
Same Product Category

Our study required respondents to indicate if they were opinion leaders in a self-specified product category and also if they were opinion seekers in a self-specified product category. Therefore, we were able to examine the co-occurrence of opinion giving and seeking in both the same and different product categories.

Approximately two-thirds (64.5%) of opinion seekers were opinion leaders in a product category. The percentage of opinion seekers in a product who were also opinion leaders in that same product category ranged from 54.5 percent in sporting goods to 21.3 percent in home appliances. The highest coincidence of opinion seeking and leadership occurred in more frequently purchased products: food (44.2%), health and beauty products (42.0%), household goods (39.2%), clothing and accessories (30.4%) and non-prescription drugs (22.7%). There was a somewhat smaller coincidence of opinion seeking and leadership in major durables. Table 4 presents these results. Table 4 should be interpreted carefully because of the small numbers in some of the product categories.

TABLE 4

PERCENTAGE AND NUMBER OF OPINION SEEKERS IN A PRODUCT
CATEGORY WHO ARE ALSO OPINION LEADERS IN THAT SAME CATEGORY

PRODUCT CATEGORY	PERCENT	NUMBER
Sporting Goods	54.5	18
Food	44.2	72
Health and Beauty Products	42.0	21
Household Goods	39.2	20
Clothing and Accessories	30.4	14
Electronic Products	25.0	29
Hobbies	24.0	18
Non-prescription Drugs	22.7	10
Automobiles and Related	20.2	17
Home Appliances	19.2	10

Demographic Characteristics

Opinion leaders typically have been characterized as higher education, higher income individuals (Assael 1984, Robertson, Zielinski and Ward 1984). It would seem reasonable to expect opinion leadership to be similarly characterized, given the high coincidence of opinion seeking and opinion leadership. Our results indicate

opinion seekers are more educated than other respondents, an average of 13.9 and 13.1 years of school, respectively ($p < 0.1$). In addition, opinion seekers have higher annual household incomes, \$29,960, compared to \$24,150 for other respondents ($p < 0.1$). Opinion seekers are significantly younger than other respondents, 41.4 and 44.9 years of age, respectively ($p < 0.1$). There were no significant differences between opinion seekers and the rest of our sample on race, marital status, people per household or number of children under 18.

Discussion

The results of this research are interesting in a number of respects. First, the results suggest a relatively high incidence of opinion seekers in the population. Although our measure does not define the extent of opinion seeking (i.e., the number of product experts relied on and the degree of reliance), our results provide evidence on the prevalent use of others as information sources by consumers.

Second, our results suggest that opinion seeking is not restricted to particular types of products, but ranges from non-durable to major durable goods. Specifically, the highest incidence of opinion seeking was in the food category. This result is intriguing since food is unlike the kinds of products for which interpersonal influence has been viewed as most important. Results on opinion seeking across a diversity of kinds of products directs our attention to social communications as a means of acquiring product information, rather than focusing on interpersonal sources as a means of risk-reduction or evaluation of complex products.

Third, in contrast to the often suggested role of the passive seeker or follower, our findings suggest that opinion seekers (like opinion leaders are important links in the flow of market information. In fact, the results suggest the similarity of opinion leaders and opinion seekers. In part, this result occurs because of the coincidence of opinion giving and receiving. The finding that almost two-thirds of opinion seekers also view themselves as opinion leaders in a product category substantiates the belief that opinion leadership is more of an exchange of opinions and information than a one-way flow of influence.

Perhaps the most interesting finding in the research involves the coincidence of opinion giving and seeking. Our research demonstrates that interpersonal information exchanges may occur between opinion leaders in the same product category or different product categories. It is interesting to speculate about the reasons some product categories show a higher coincidence of opinion seeking and leadership than do others. Several interpretations of the degree of overlap are possible. For example, the amount of overlap of opinion seeking and opinion leading is probably affected by the pervasiveness of product use, product complexity, economic incentives for seeking knowledgeable individuals, varying levels of product interest, and the level of aggregation of the product categories.

One possible framework for organizing the degree of overlap might be the combined effects of the pervasiveness of product use and product complexity. First, consider the large overlap in sporting goods, a product category with a relatively low level of product complexity and a lower pervasiveness of use relative to food, clothing, automobiles. The large overlap in this category could be a result of sports buffs having conversations with one another about sports equipment. We can also speculate about the relatively small overlap in major durables. This result could occur because many people purchase automobiles, electronic products, and other major durables and have an incentive to seek a product expert (Price and Feick 1984). A relatively smaller number of individuals, however, are likely to have an enduring involvement or are able to obtain the amount of knowledge necessary to be an expert in more technically complex product classes. Thus we might expect to see, and do find a relatively low coincidence

of opinion seeking and leadership in these categories. One might want to speculate further that products are highly complex and have a low pervasiveness of use, for example special industrial products or professionally related products, might have an even lower coincidence of opinion leading and seeking.

Our results represent only a first attempt at understanding opinion seeking. While we have demonstrated some important findings about opinion seeking across a wide range of product types, research still needs to pursue the relationship between opinion givers and seekers in multiple product categories. Because of space limitations on the questionnaire, we could not examine multiple product opinion seeking for given individual, nor could we examine multiple product influence on the part of a given opinion leader. Clearly, exploring these multiple product situations are needed in order to better understand the relationship between opinion seekers and opinion leaders. In addition, this study was limited to an examination of opinion givers and receivers for products, not for services or other intangibles. The relationship between opinion seekers and leaders in these choices are also important areas for consumer research.

Perhaps most importantly, our results suggest more research attention be directed to the phenomenon of opinion leadership as a form of social communication. Specifically, more research is needed on the comparison of the type of information transmitted in exchanges between opinion leaders in similar product categories and the type of information transmitted between an opinion leader and an individual who is not an opinion leader in the product category.

SOURCE CREDIBILITY: ON THE INDEPENDENT EFFECTS OF TRUST AND EXPERTISE

Joshua L. Wiener, Oklahoma State University
John C. Mowen, Oklahoma State University

Abstract

Marketing researchers and practitioners have tended to assume that a more trustworthy source is more credible than a less trustworthy source. However, previous studies have either confounded trustworthiness with expertise and/or attractiveness, or found that trustworthiness did not influence persuasion. In the 2 x 3 between subjects factorial experiment three levels of source expertise were crossed by two levels of trustworthiness. Careful pre-testing assured that the manipulations did not influence ratings of source attractiveness. The results supported the hypotheses developed from attribution theory that sources perceived to have external reasons for making a persuasive argument will be discounted. In addition, the results revealed that expert sources influenced perceptions of the product's qualities.

Introduction

Marketers have a long held belief that a source with superior intrinsic characteristics is more persuasive. Examples abound of the desire of companies to use intrinsically positive sources and to avoid sources which are perceived as biased. National advertisers pay vast amounts to famous endorsers, such as sports stars, while local advertisers cite favorable evaluations from local customers. Estimates are that one in three television commercials use endorsements (*Business Week* 1978). In fact, companies will go to great lengths to have their products associated with positive sources. For example, the Regina Co. argued in a Federal Appeals court that it had the right to cite in its advertisements a favorable Consumer Union evaluation of its Electricbroom Powerteam. In other instances companies have tried to avoid having sources, which might be perceived as biased, associated with a product or idea. Thus, when dietary manufacturers sponsored advertisements opposing the banning of saccharin, the advertisements were attributed to a third party, "The Calorie Council" [Sturdivant 1981]. Similarly, when the natural gas lobby initiated its direct mail campaign to create grass-roots support for deregulation, the pamphlets were attributed to "The Alliance for Energy Security."

Early research supported the intuitive belief that positive sources enhance persuasion. Generally, the methodology of the studies assessed the immediate attitude change, or the extent of agreement with a message, induced by an intrinsically superior source in comparison to that induced by an intrinsically inferior one. With one critical exception, these studies found that greater immediate agreement or attitude change was induced by the superior source [McGuire 1968]. From these studies emerged the construct of source credibility. A credible source was one who had such intrinsic attributes as trustworthiness, expertness, and attractiveness [e.g., Dholakia and Sternthal 1977, Harmon and Coney 1982].

However, a fundamental problem exists in the way in which both marketing practitioners and marketing researchers conceptualize the effects of source credibility. The presumption that a source is more credible if he or she is more "trustworthy and/or expert" [e.g., Dholakia and Sternthal 1977] is not supported by experimental studies. In their reviews of the source credibility literature, both Anderson & Clevenger (1963) and McGuire (1968) concluded that strong support exists for attractiveness and expertise as components of source credibility, but none for trustworthiness. McGuire argued that the belief that a more trustworthy source is more persuasive is an

example of "bubbapsychology" (i.e., a compendium of psychological principles that one's grandmother knew but which aren't so., p. 183)

The issue of whether or not trustworthiness influences persuasion is of theoretical importance. Sternthal, Phillips, and Dholakia (1978) proposed that source effects could be understood by a framework which integrates cognitive response ideas with attribution theory. Attribution theory predicts that a claim made by a biased source will be discounted (Kelly 1973). In justifying their framework, Sternthal, Phillips, and Dholakia (1978) cited the prototypical example of a biased source's claim being discounted. If McGuire is right, Sternthal et al. (1978) are wrong.

The issue of whether trustworthiness contributes to persuasion also has pragmatic significance. The creation of a seemingly trustworthy source can be costly, as well as unethical. One can argue that it is unethical for a company to create in a self-serving manner a seemingly "trustworthy" organization to act as a "false-front" for the presentation of ideas. Costs can arise if the company is caught in its duplicity. For example, the natural gas lobby created a false front, the "citizen" alliance, to support deregulation of the industry. The major news story produced in response to the creation of the "citizen alliance" was that the organization was comprised of the industry's employees.

The primary purpose of this paper is to further investigate the relationship between the constructs of trust and credibility. Secondly it investigates expertise as a component of the construct of source credibility. It first reviews the literature on source credibility for evidence of the relationship. Next, it presents an experiment in which source trust and expertise are orthogonally manipulated while holding the attractiveness of the source constant.

Source Credibility and Attitude Change

The numerous empirical studies of the relationship between source credibility and attitude change were reviewed by Anderson and Clevenger (1961), McGuire (1968), and Sternthal, et al. (1978). The first two reviews focused upon the issue of whether or not a source's intrinsic characteristics affect the persuasiveness of a message. The reviews reached a common conclusion--a source that was more expert and/or more attractive was more persuasive. The review by Sternthal et al. (1978) focused upon the issue of what situational factors interacted with source credibility to enhance, vitiate, or reverse the persuasiveness of a more credible source. They reached the conclusion that trustworthiness is one of the components of credibility. What is the evidence supportive of Sternthal et al.'s presumption that trustworthiness is a component of source credibility?

Table 1 lists the studies cited by Sternthal et al. (1978) and Dholakia and Sternthal (1977) to support their contention that more trustworthy and/or expert sources induce more immediate attitude change than do sources having less of these attributes. Note that in most of the studies source credibility was manipulated by creating a highly attractive source (e.g., President Eisenhower or genius doctor) versus a high negative source (e.g., Nazi leader or convicted quack). The use of such highly attractive or negative sources tends to confound the concepts of trustworthiness and expertise, which are purported to form the construct of credibility.

TABLE 1

Miller & Basehart (1969)	smoking cigarettes	President Dwight D. Eisenhower	Goerge L. Rockwell (Head, American Nazi Party)
Whittaker & Meade ² (1968)	numerous	high authority	low authority

¹Two low credibility sources were used.

²In a pretest, subjects identified high and low authority sources. In the main test, subjects were provided with the two sources which they identified.

Methodology

The study employed a 2 x 3 between subjects factorial design. Thus, two levels of the trustworthiness independent variable were crossed by three levels of source expertise.

The trustworthiness manipulation was based upon Kelly's (1973) augmenting-discounting ideas. In the study subjects received messages from a mechanic concerning the mechanical condition and value of an automobile. In the high trust conditions, subjects learned that a car mechanic had no relation to a nearby automobile dealership. In the low trust conditions the mechanic was described as part owner of the automobile dealership. Hence, trustworthiness was equated in this study with intrinsic self-interest. Importantly, no normative statements, such as honest or dishonest, were used to describe the source. It was anticipated that in the low trust case, the consumer should discount the message and place less trust in it.

Expertise was manipulated by altering the individual's training, experience, and certification. Certification

was by the National Association of Mechanics. The salient differences are depicted by Table 2.

Two major dependent variables were used: the subjects' perceptions of the automobile's mechanical quality and of its value. Each dependent variable was measured via a seven-point semantic differential scale.

Hypotheses

Two major hypotheses were formulated.

- H₁: Subjects will reveal higher agreement with the claims of the mechanic regarding the car's mechanical condition and value in high trust than in low trust conditions.
- H₂: Subjects will reveal higher agreement with the claims of the mechanic regarding the car's mechanical condition and value in high expertise than in the moderate expertise conditions and more agreement in the moderate than the low expertise conditions.

Hypothesis 1 was based upon Kelly's (1973) discounting principle and is consistent with the arguments of Strenthal, Phillips, and Dholakia (1978). Hypothesis 2 is also derived from the literature on source effects. As various reviewers have noted, highly expert sources have proven to be more persuasive than less expert sources. The contribution of the present study is that the two variables (trust and expertise) are manipulated independently.

TABLE 2
THE EXPERTISE MANIPULATION

Source	Training	Experience	Certification
high	courses in general auto mechanics	2 years evaluating automobiles	yes
moderate	courses in auto air conditioner repair	6 months evaluating automobiles 18 months air conditioner repair, body work	no
low	courses in auto air conditioner repair	2 years air conditioner repair, and body work	no

Procedure

In order to insure the construct validity of the manipulations, the study was divided into two phases--a pretest and a main test. In both the pretest and main test, all subjects were presented with a common situation. The situation was described to the subjects as follows:

You have found a 1979 mid-size American sedan, with am/fm radio but no air-conditioning, at an auto dealership. You are thinking of buying it. You decide that a mechanic should inspect it before you buy it. You take it to a large auto repair center in a nearby mall so that you can eat while they inspect it.

You are especially interested in learning how long you can expect major components, such as the transmission, to last before they will need to be replaced or repaired.

The man who inspects the car is in his mid-twenties, polite, friendly, and well-spoken. He says that he is married, has a daughter, and that his family is going to Yellowstone for their vacation next month.

After high school he joined the Army, received an award for bravery, and several promotions. After being discharged he went to work for his uncle who owns the garage. The mechanic is part owner of the garage. Since the guy who normally does the inspections is sick, he is doing it.

The brief common biography was included in order to create a generally favorable view of the source of information. The goal was to create a source who would be equally attractive to respondents regardless of the trustworthiness or expertise condition. The use of a common biographical sketch is a distinguishing feature of the methodology. For example, Ward and McGinnies (1980) explicitly described the trustworthy source as "honest, sincere, and trustworthy; whereas the untrustworthy source was described as "devious, calculating, and sympathetic to the Nazi party."

In all cases the mechanic made the assertion that:

Because it is in excellent mechanical condition I would say it is worth a lot more than the average automobile of its year and make. In fact I'd say it's worth 10% more than the blue book value.

The automobile example was used because most undergraduates are sufficiently familiar with automobiles to understand questions, but are not so familiar as to hold strong prior beliefs. To check the latter point, data on sex, experience, (buying) selling used cars, and experience with mechanics was collected from respondents.

The manipulations were pretested on a class of 40 undergraduate business students. The manipulations of trust and expertise were pretested independently. The trustworthiness manipulation was assessed via three, seven point semantic differential scales: trustworthy/not trustworthy, partial/not partial and biased/not biased. The expertise manipulation was measured by the scales used previously by Harmon and Coney (1982) and Dholakia and Sternthal (1977), i.e., expert/not expert, trained/not trained, and experienced/not experienced. The two manipulations were successful, i.e., at the .05 α level there was a significant difference between the scale scores of the treatment groups. The scales revealed good internal reliability; Cronbach α scores were .73 for trustworthiness and .89 for expertise. The pretest revealed that the manipulations of inherent self-interest did strongly influence perceptions of trustworthiness. In addition, the variations in source training, experience and certification did influence perceptions of expertise.

Results

In the main study, students were randomly assigned to one of the 6 (2 trustworthiness x 3 expertise conditions). In all conditions the common situation and biography were used. After reading the material they indicated their level of agreement with the source's claim (dependent variables), and then evaluated the source (the manipulation checks).

In the main study, tests were first run to identify any halo or attractiveness effects. Optimally, no significant effects for attractiveness should be found across any of the manipulations. Attractiveness was measured by using the 3 item scale used by Harmon and Coney (1982) and Dholakia and Sternthal (1977); the items are attractive/not attractive, dynamic/not dynamic, aggressive/not aggressive. The Cronbach α levels were .71 for attractiveness, .76 for trustworthiness, and .84 for expertise. Using a .05 α level criterion, attractiveness was not found to be influenced by variations in expertise or trustworthiness. In addition, the expertise manipulations did not influence perceived trustworthiness and the trustworthiness manipulations did not influence perceived expertise.

Tables 3 and 4 present the means and the summary table for the two-way analyses of variance used to analyze the mechanical quality and automobile value claims. The semantic differential scales used to measure persuasions were anchored by excellent mechanical quality/not excellent mechanical quality, and worth a lot more/not worth a lot more. For the dependent variable of mechanical quality, significant main effects occurred for expertise ($p < .01$), and trust ($p < .03$). A Scheffe test of expertise found that (at the .05 level) only the high and low expertise manipulations were associated with different agreement levels. The size of the trustworthiness and expertise effects were measured by omega squares. The variance accounted for was in line with that typically found in social psychological research. It is interesting to note that the expertise measure accounts for more than twice the variance trustworthiness measure (.15 vs. .06). For the dependent variable of automobile value, significant effects were found only across levels of trust ($p < .03$). A significant main effect for value was not found across levels of the expertise independent variable.

Discussion

The results for both the major dependent variables (mechanical quality and automobile value) supported the attribution theory component of Sternthal et al.'s (1978) source credibility framework. In conditions in which one

would expect a source to have a bias (i.e., low trust conditions in which external pressures exist to elicit a particular message), the results revealed that subjects had lower perceptions of the automobile's value.

TABLE 3
MEAN AGREEMENT SCORES FOR DEPENDENT VARIABLES
OF MECHANICAL QUALITY AND AUTOMOBILE VALUE

EXPERTISE	MECHANICAL QUALITY		AUTOMOBILE VALUE	
	Low Trust	High Trust	Low Trust	High Trust
Low	2.75 (12)	3.75 (12)	2.25 (12)	3.75 (12)
Moderate	3.77 (11)	4.27 (10)	2.82 (11)	3.70 (11)
High	4.37 (11)	4.54 (13)	3.28 (11)	3.46 (13)

Note (70) is sample size

The finding that variations in trust influence consumer reactions to messages is important for the understanding of source effects. McGuire (1968) has argued against trustworthiness as a factor influencing persuasiveness. Indeed, the effects of trustworthiness had not been unambiguously demonstrated in the literature heretofore. Previous work tended to confound trust with the expertise of the source.

TABLE 4

ANOVA RESULTS

Source	Mechanical Quality				Value		
	DF	F	$P_r >$	ω^2	F	$P_r >$	ω^2
Trust	1	5.19	.026	.06	8.46	.005	.10
Expertise	2	17.60	.001	.15	.57	.568	--
Trust X Expertise	2	2.04	.402	--	1.73	.185	--

In two previous studies trustworthiness and expertise were investigated. In the Hovland and Mandell (1952) study, variations in trustworthiness were not found to affect persuasion. A possible explanation for their failure to find trustworthiness effects was the overwhelming effects of source expertise. In the present study, a comparison of the mean agreement scores in the highly expert case (see Table 3), supports such a conjecture. The effects of the trustworthiness variable showed signs of being mitigated in the high expertise cases. In other words, the situation may be similar to ones in which evidence is used to overwhelm the source effects (Hunt 1972, Hendrick and Schaffer 1970).

In the second study investigating trustworthiness and expertise, McGinnes and Ward (1980) confounded trustworthiness with attractiveness. In the present study, efforts were made to hold attractiveness constant while manipulating trustworthiness. Results revealed that these efforts were successful. An attractiveness scale was not influenced by levels of trustworthiness. The significant effects found for trustworthiness, therefore, supported the arguments of Sternthal et al. (1978) and removed the construct of trustworthiness from the realm of "bubba-psychology" (McGuire 1968).

The study also found that the level of expertise of the source strongly influenced perceptions of the auto's

mechanical quality. McGinnes and Ward (1980) previously found no evidence for the increased persuasiveness of expert sources. Possibly their extremely strong manipulation of attractiveness/trustworthiness overwhelmed the effects of variations in expertise so that subjects failed to attend to expertise differences. Note, however, that variations in expertise did not influence perceptions of the automobile's value. This outcome may have occurred because perceptions of value were not inferred directly from knowledge of the source's expertise. Instead, expertise may influence value through its influence on the mechanical value perception. Therefore, the likelihood of expertise affecting value perceptions is lowered because of the requirement of a two-step inference process. In this two-step process, observers may first evaluate expertise. Second, they may form beliefs about the mechanical quality of the car from the message and the expertise. After estimating the car's mechanical quality, they would then assign some value to the car. The additional cognitive effort required to engage in such complex reasoning lowers the likelihood that subjects would engage in such a two-step process resulting in variations in expertise failing to influence the value of the car.

From a managerial perspective, the results are straightforwardly applied. When the receiver is being influenced by peripheral cues, such as source characteristics, a message from a source of information, who is perceived to be biased, has less impact than a message from a source not perceived to be biased independent of the source's attractiveness and expertise. Similarly, the greater the perceived expertise of the source, the greater the impact of a message upon technical, but not product value, beliefs independent of the source's attractiveness and perceived level of bias. Based upon these findings, advertisers, public relations officers, and sales managers should carefully consider the extent which prospective target audiences perceive the level of bias and expertise of sources of information.

SATISFACTION AND CONSUMER SERVICES

Donna J. Hill, Indiana University

Abstract

This paper seeks to make a conceptual contribution to the measurement of consumer satisfaction for services. This involves a conceptualization of product evaluation in the services context and a description of the confirmation/disconfirmation paradigm of satisfaction/dissatisfaction. The author proposes that the unique characteristics of services implies different consumer evaluation processes from those used when assessing tangible goods. An effort is made to integrate a taxonomy of "qualities" into the confirmation/disconfirmation model which will account for these differences.

Introduction

While the consumer satisfaction/dissatisfaction literature continues to grow at a substantial rate, comparatively little attention has been paid to consumer satisfaction and dissatisfaction with respect to services (Liechty and Churchill 1979; Zeithaml 1981). Given the escalating significance of services in the economy, it is suggested that satisfaction with these offerings should be a concern to both consumers and businesses. The primary objective of service providers is to develop and provide offerings that satisfy consumer needs, thereby ensuring their own economic survival. To achieve this objective, service providers will need to understand how consumers choose and evaluate their offerings.

The objectives of this paper are threefold. The first is to present a conceptual basis for understanding consumer satisfaction processes. Second, the unique characteristics of services will be identified. Finally some propositions concerning the consequences of these characteristics on expectation formation and perceived performance which, in turn, effect outcome judgments will be presented.

The Disconfirmation Paradigm

The key elements of the satisfaction/dissatisfaction process are: (1) some a priori basis of evaluation (e.g., expectations of product performance); (2) comparison of perceived performance with expectation; and (3) a post-purchase judgment that the experience was noticeably better or worse than anticipated leading to feelings of satisfaction or dissatisfaction. The disconfirmation paradigm is presented graphically in Figure 1.

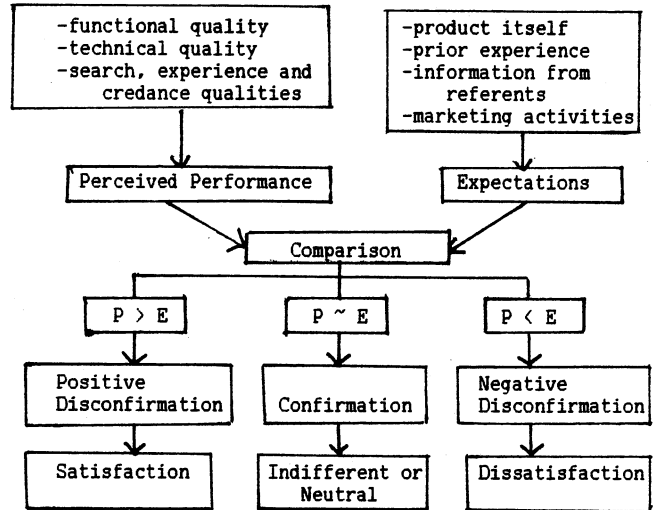

Satisfaction is an evaluation rendered that the (product) experience was at least as good as it was supposed to be (Hunt 1977). Specifically, an individual's expectations are: (1) positively disconfirmed when performance exceeds expectations; (2) negatively disconfirmed when performance is less than expectations; and (3) confirmed when performance is approximately equal to expectations. Satisfaction is related to the size and direction of the disconfirmation experience where disconfirmation is related to the person's initial experience (Churchill and Surprenant 1982). However, the relationship may not be so simple, Woodruff, Cadotte and Jenkins (1983) suggest that the relationship, instead of being monotonic and continuous is rather one of zonal ranges.

Although in the traditional disconfirmation approach to satisfaction/dissatisfaction the exact confirmation of expectations is the definition of satisfaction, it is assumed here that exact confirmation does not produce feelings of either satisfaction or dissatisfaction. Oliver (1980) suggested that one's expectations perform the function of an adaptation level in that they define the baseline or standard against which subsequent performance is judged, i.e., a norm. Woodruff et al. (1983) suggest that expectations are based on experience (product

and brand) and that some interval around a performance norm is likely to be considered equivalent to the norm. They call this interval a "zone of indifference." Positive or negative disconfirmation results when perceived performance is compared with expectations and the resulting evaluation is outside the zone and thus different enough from the norm to be recognized as such.

FIGURE 1

THE DISCONFIRMATION PARADIGM

*P = perceived performance
E = expectations

Weak disconfirmation of expectations whether positive or negative tends to be assimilated away (Olshavsky 1977). Perceptions of performance which are close to expectations are within a latitude of acceptable performance, and are assimilated toward the expectation (Olson and Dover 1977; Olshavsky and Miller 1972). Performance which is above or below the norm, but within the indifference zone, leads to indifference. Positive disconfirmation logically leads to satisfaction which, in turn, may lead to positive responses such as brand or store loyalty, favorable word of mouth, and "complimenting behavior." Negative disconfirmation has the opposite effect. That negative disconfirmation has adverse consequences to the producer, including a tendency for negative word of mouth to occur, is well documented (Richins 1983).

An expectation is the perceived likelihood that a product possesses a certain characteristic or attribute, or will lead to a particular event or outcome (Olson and Dover 1979). In this view expectations are belief probabilities of attribute occurrence. These beliefs perform two functions: (1) they serve to provide the foundation for attitude formation and (2) they serve as an adaptation level for subsequent satisfaction decisions (Oliver 1980).

Expectations are formed based on such factors as: (1) the actual product including prior experience and brand attributes, (2) exposure to marketing activities including advertisements, price and image, and (3) communication from social referents such as word of mouth information or observation of referents usage of the product.

As noted earlier, expectations are compared to perceived performance in order to arrive at an evaluation. Perceived

performance is affected by characteristics of the product and circumstances surrounding its acquisition. Gronroos (1983) suggested that perceived performance is composed of two qualities, functional and technical. Technical quality has to do with what the consumer receives from purchase of the product. Functional quality has to do with how the consumer receives or purchases the product, the events surrounding the acquisition of a product. In general, technical dimensions can be judged in a much more objective manner than can functional quality dimensions which are perceived in a very subjective way.

Nelson (1970) distinguished between two characteristics of products: search qualities, attributes which are very tangible and can be evaluated by examination prior to purchase; and experience qualities, attributes which can only be evaluated during or after consumption. Darby and Karni (1973) added a third dimension, credence qualities, which are characteristics the consumer may find impossible to evaluate even after purchase and consumption.

Perceived performance is a very complex area but it seems evident that it is a function of both technical and functional elements. Consumers are quite capable of having responses to each element that differ from the other. "The food was great, the service poor" are comments often encountered in an evaluation of a restaurant. Secondly, the timing of the performance evaluation and the ability of the consumer to evaluate the product will vary by characteristics of the offerings itself. These characteristics include search, experience and credence qualities. Zeithaml (1981) has proposed a taxonomy based on these last three qualities.

Distinctive Features of Services

There is a growing literature stream which deals with differentiating physical goods from services (Bateson 1977; Eiglier and Langeard 1977; Shostack 1977; Berry 1980). Although not all authors agree that services marketing should develop as a distinct area of marketing theory, (see Wyckham, Fitzroy and Mandy 1975 for another point of view) there is general consensus that services share some unique characteristics that differentiate them from physical goods. The three most frequently mentioned ones are: intangibility, nonstandardization, and simultaneous production and consumption.

A service is mainly immaterial or intangible. Intangible means that the product has no existence except to the degree that it is produced and consumed, the finished product cannot be inventoried. Bateson (1977) states that "services are doubly intangible; they are impalpable" -- they cannot be touched by the consumer -- and they are difficult for the consumer to grasp mentally ("the mental image" of the service is "fuzzy"). Czepiel (1980) poses that services often have a larger number of relevant attributes than physical goods; and that intangibility means a larger proportion of those attributes are not amenable to physical methods of measurement or control. That is, services tend to be high in experience qualities and low in search qualities.

This experience quality implies that services are an activity or a process rather than a physical entity. The service can be consumed only as long as this process continues. This simultaneous production/consumption nature of services implies that the customer has a high degree of involvement in the production of the service. In fact, Eiglier and Langeard (1977a) define a service as the outcome of an interaction between the client, the service personnel, and the physical environment. Two other implications evolve from this characteristic. First, because the service encounter is frequently a dyadic interaction, the abilities of an individual as a consumer are linked inextricably to characteristics of the seller. The ability of the service provider to perform the service is frequently dependent upon the consumer fulfilling certain role behaviors. For instance, in order for the physician to arrive at a correct diagnosis, the patient must correctly describe symptoms. Second, the high involvement of the

consumer means that services are not very standardized, that is, there is a great deal of variability from one service encounter to the next for one individual and between individuals engaging the same service.

Other differentiating factors frequently cited are the complex nature of most services compared to physical products, a higher level of perceived risk (Eiglier 1977), greater search costs in brand switching (Zeithaml 1981), a lack of both pre- and postpurchase evaluative criteria (George, Weinberger and Kelly 1985) and difficulty of the service firm in attempting to differentiate itself from its close competitors (Eiglier and Langeard 1977b). This last characteristic implies that services tend to be grouped by the consumer into product categories rather than being differentiated by brand. This, in turn, implies that product based rather than brand based expectations are more extensively employed in evaluation of services. For instance, expectations concerning performance of a physician will more likely be based upon experience with physicians in general and not one in particular.

Finally, there is really no such thing as a pure physical good or a pure service. Most, if not all, examples used in the services marketing literature lie somewhere on the physical good/service continuum. Taxonomies built on the aforementioned dimensions can be quite useful to researchers interested in developing theoretical frameworks for the study of products positioned near the service end of the continuum. Therefore several taxonomies useful for the purposes of this paper are presented in Appendix A. Taxonomies can be useful in explaining Lovelock's (1983) proposition that "many commonly heard generalizations about service marketing do not hold true across a wide range of service industries or situations."

Consequences Of These Characteristics On Outcome Judgments

Intangibility

As products move along the continuum from tangible to intangible expectations become more "fuzzy" and it therefore becomes more difficult for the consumer to develop a clear precise norm or standard for evaluation.

Hypothesis 1a: The more intangible a service becomes, the wider the zone of indifference.

Hypothesis 1b: As information concerning a service moves from high to low, the zone of indifference becomes wider.

In the absence of a tangible product upon which to base one's evaluation of the exchange the social and physical contexts increase in importance (Berry 1980; Lovelock 1979; Shostack 1979). Green, Langeard and Favell (1974) found, in their study of attitudes toward new and existing retail services, that word-of-mouth was used to: (ascertain projected levels of confidence in an untried service; (2) alleviate the no prepurchase testability problem; and (3) form an image of the otherwise nontangibly representable service.

Price and physical facilities have also been shown to be important cues to the service consumer since expectations must be formed without employing such tangible factors as style, color, label, feel, package, brand name, etc. (Eiglier et al.; Beesom 1973).

Hypothesis 2: As intangibility increases there is greater reliance on functional quality as opposed to technical quality dimensions for evaluation of perceived quality.

It is expected, however, that technical service quality is always paramount. No amount of functional encounter satisfaction can compensate for a service never performed. Some researchers have suggested that the performance attributes that lead to dissatisfaction are different from those that lead to satisfaction (Swan and Combs 1976). Dissatisfaction

is caused by a failure of technical performance, while complete satisfaction also requires that the functional performance is above or at expected levels. It has been suggested by Czepiel, Solomon and Surprenant (1985) that functional satisfaction can overcome only small deficiencies in technical service quality.

Hypothesis 3: There exists a latitude of acceptance for the service customer within which small deficiencies in technical service will be overcome by encounter satisfaction.

This latitude of acceptance is wider for services than for physical goods due to the fact that services involve more encounters.

Recall from our foregoing discussion that if information obtained prior to product exposure is negative or positive, then weak disconfirmation will produce assimilation in the same direction.

Hypothesis 4: The following sources of information have a larger effect on evaluation of services' performance than on evaluation of the performance of tangible goods:

- a. word of mouth
- b. price
- c. image

Not all information is weighted equally. For instance word of mouth is generally held to be more credible than commercial messages and usage experience beliefs are held much more confidently than beliefs based on external sources. In addition, information which is similar to information already obtained is perceived as not adding much to overall knowledge but information which is different may receive more attention and weighting (Nisbett and Ross 1980).

Mizerski (1982) presents findings that suggest unfavorable word of mouth ratings, as compared to favorable word of mouth ratings on the same attributes, prompt significantly stronger attributions to product performance, belief strength and affect toward products. Furthermore, the less objective the criteria available for evaluation, the more this information is viewed as reflecting the source's personal feelings and thus should prompt more potential nonstimulus causal attributions. A larger potential causal array (which exists for services) would then provide more latitude for differences in attributions with each information type. The greater the attributional differences, the greater the impact on belief and effect formation. Oliver (1977) suggests that the impact of personal influence depends on the discrepancy of the influence attempt from the recipient's initial opinion.

Hypothesis 5: Negative word of mouth, when received has greater impact on outcome evaluation, than positive word of mouth.

Hypothesis 6: The more intangible the service the more likely the consumer is to view the information as reflecting the source's personal feelings, and this in turn will mediate it's effect. The mediation will be either negative or positive depending upon such factors as the source's expertise, credibility and the consumer's initial opinion.

Inseparability

For services which are more inseparable, the product is produced by both parties sometimes with equipment. Several researchers have suggested that in such situations role theory can be used to explain expectation formation (Solomon, Surprenant, Czepiel, and Gutman 1985; Smith and Houston 1983). It is assumed that each party to the transaction has learned a set of behaviors (a script) that is appropriate for the situation. Furthermore, in the case of a person's encounter with a novel situation, he or she will attempt to employ an existing script similarly structured (transferring a script for purchase

of bus fare to purchase of air fare) or an idealized script derived from TV, movies or books. Within this conceptualization satisfaction with a service is seen as a function of the congruence between perceived behavior and the behavior expected by role players. Such a view implies that role similarity across services is a viable basis for classifying services.

Hypothesis 7: As the degree of personal encounters with the customer increases the more opportunity exists for both positive and negative evaluations.

Degree of personal encounter can be measured in terms of complexity, length or degree of personal involvement from the service provider.

When high consumer involvement is required for delivery of the service failure to obtain satisfaction may not be blamed entirely on the producer, since the consumer must adequately perform his or her part in the production process as well. Consumers have three sources to which attribution of blame may be placed: the service provider, the consumer himself, and the equipment used in the service delivery. For instance a perm that turns out poorly could be the fault of the hairdresser, the consumer for not adequately describing the desired style, or the perm formula itself.

Hypothesis 8a: The more sources there are to which to attribute blame the wider will be the zone of indifference.

This in turn implies that the initiation of unusual satisfaction or dissatisfaction outcomes is (i.e., recommendations to friends, letter writing, legal action, etc.) is less likely to occur with services than with products where there are fewer personal encounters and interaction between service provider and customer.

Inseparability frequently implies a high degree of variability as services high in separability depend on who provides them and when and where they are provided. This, in turn, means that expectations as a norm become more difficult to develop.

Hypothesis 9: As service increases in variability the width of the indifference zone increases. This is accentuated as experience and expertise narrows.

Simultaneous Production and Consumption

As production and consumption move closer together there is a tendency to evaluate the service during, rather than after, consumption. This means that other people in the purchasing process have an opportunity to impact upon the evaluation. Other people here would include not only peripheral service providers such as clerks but other clients as well. Such encounters may take place in queue or reception areas or in a group setting (such as exercise classes or group therapy). Furthermore, other hypothesis already suggested would imply that there is a halo effect created by the early stages of any service encounter.

Other Characteristics

Many services are very complex, some services (e.g., medical diagnosis or pest control) are so technical or specialized that consumers possess neither the knowledge nor the experience to evaluate whether they are satisfied, even after they have consumed the product. These products are high in credence qualities. Experience and credence qualities imply high search costs. Gathering information for such products often involves trial usage or personal visits to examine only one brand at a time, and often the information is simply not available or extremely difficult to obtain.

Hypothesis 10: As services become more complex consumers will:

- a: form fewer expectations
- b. perceive others as more knowledgeable about alternatives

- c. reduce search activities
- d. depend upon other's recommendations as opposed to commercial sources

Hypothesis 11: As services become higher in credence qualities consumers will turn to others for evaluation.

Concluding Comments

There are two main directions in which customer satisfaction can be influenced: (1) what the customer expects and (2) what the customer perceives. The point is that these two factors need to be conceptualized as psychological phenomena and not necessarily as reality. The unique characteristics of intangibility, nonstandardization and simultaneous production and consumption lead to a much different process for evaluation of services than tangible goods. The psychological phenomena taking place is mediated by these special characteristics. In an early study, Day and Bodur (1977) reported that, compared to tangibles, dissatisfaction with services was related to the quality of the supplier's performance rather than to marketing practice and price related issues. This in turn, may be a reflection of the psychological phenomena taking place within the service sector.

Although some of these processes are implicitly understood and utilized by service providers, they have not been systematically integrated into the satisfaction/dissatisfaction paradigm. Such an integration would benefit not only the researcher but the service provider as well. By learning to research and understand the dimensions of their own services, managers can have a significant impact upon their customers' satisfaction with the service encounter. Researchers need to identify unique and relevant dimensions of physical and service products and then systematically relate these to the process of evaluation. As Zeithaml, Parasuraman and Berry (1985) suggest a research priority in services marketing is empirical study that transcends specific industries in order to test service marketing concepts across service industries as a whole.

Appendix A
TAXONOMIES OF PRODUCTS

Figure 1. Degree of Tangibility

Classification	Product Category
Products that are tangible dominant	Salt, necktie, computers, dishwasher, shampoos
Balanced tangible/intangible	Retailing, automatic vending, mail order
Intangible dominant	Repairs, personal care, insurance, advertising agencies, airlines
Pure intangible	Teaching, consulting, nursing, psychotherapy

Figure 2. Degree of Inseparability

Classification of service systems by extent of required customer contact in production of the service	
High contact	Health care Passenger transportation Beauty salons Exercise clinics Restaurants Haircutting
Intermediate	Banks Legal services Accounting Real estate/insurance
Low contact	Post office Laundry and dry cleaning Landscaping/lawn care Auto and appliance repair

Figure 3. Search, Experience, and Credence Qualities (as suggested by Zeithaml, 1981)

Continuum for different types of products

High in search qualities	clothing jewelry furniture houses automobiles
High in experience qualities	restaurant meals vacations haircuts child care
High in credence qualities	television repair legal services root canal auto repair medical diagnosis

THE DETERMINANTS OF SATISFACTION FOR A HIGH INVOLVEMENT PRODUCT:
THREE RIVAL HYPOTHESES AND THEIR IMPLICATIONS
IN THE HEALTH CARE CONTEXT

Mary Beth Barber, University of Pittsburgh
Meera Venkatraman, Boston University

Abstract

In contrast to our understanding of satisfaction with low involvement products, there is still very little understanding of the factors that influence satisfaction with high involvement products. This paper draws upon two distinct bodies of research, satisfaction theory and decision making theory, to develop three rival hypotheses on satisfaction with high involvement products. These three hypotheses have important, yet different implications, for satisfaction with a unique high involvement product - health care. According to these hypotheses, satisfaction is determined by (1) by the discrepancy between patient expectations and physician performance, or (2) primarily by physician performance, or (3) by providing the consumer with more information about health care alternatives.

Introduction

While researchers have focused on the determinants of satisfaction for a low involvement, frequently purchased, convenience product (Olshavsky & Miller 1972; Prakash & Lounsbury 1983; Swan & Combs 1976), less attention has been devoted to the factors that influence the satisfaction with a high involvement product (Day 1977; Oliver & Bearden 1983; Churchill & Suprenant 1982). The Disconfirmation Theory, which is the dominant paradigm in the satisfaction literature, has been successful in explaining satisfaction/dissatisfaction with a variety of low involvement products, but it is less successful in explaining the same phenomenon for high involvement products (Oliver & Bearden 1983; Churchill & Suprenant 1982). Other explanations of satisfaction with these types of products are suggested by the empirical research on consumer satisfaction but have not been systemically explored (Oliver & Bearden 1983; Churchill & Suprenant 1982).

It is important to understand the processes by which the satisfaction with a high involvement product is determined, since involvement affects the extent and nature of post-purchase processing, which in turn influences satisfaction. As defined by Petty and Capicippo (1981) and others, involvement refers to the activation of problem solving behavior when the act of purchase or consumption is seen by the decision maker as having high personal importance or relevance. The greater the involvement with a product, the greater the likelihood of post-purchase evaluation, and the more extreme the post-purchase evaluations (Gronhaug 1977; Richins 1982). The strength of post-purchase evaluations influences satisfaction, which determines the post-purchase behaviors such as repeat purchase and word-of-mouth. While the importance of repeat purchase is self-explanatory, word-of-mouth communication is important because it influences the purchase of others for high involvement products (Assael 1981; Engel & Blackwell 1982). Thus, satisfaction becomes an even more important issue for a high involvement product.

In this context, this paper examines the determinants of satisfaction for a high involvement product. Its contribution is that it studies the factors which influence satisfaction not only from the perspective of current research in consumer satisfaction theory but also from the consumer decision making theory perspective.

Consumer Satisfaction Theory: The Disconfirmation Paradigm

The disconfirmation theory is the dominant framework in the consumer satisfaction literature (Cardozo 1965; Olshavsky & Miller 1972; Swan & Combs 1976). According to this theory, satisfaction is related to the size and direction of the discrepancy between prior expectations and actual

performance. Specifically, when performance is equal to the prior expectations, confirmation results, which leads to satisfaction. Disconfirmation results when performance does not equal prior expectations. Positive disconfirmation is the result of performance exceeding prior expectation, which also leads to satisfaction. Negative disconfirmation, in contrast, is the result of performance being less than prior expectations, which leads to dissatisfaction. Thus, satisfaction results when prior expectations are confirmed or positively disconfirmed. Based on the disconfirmation theory of consumer satisfaction it is hypothesized that:

H1: Satisfaction with a high involvement product is determined by the discrepancy between expectations and performance.

Thus, according to the Disconfirmation Theory, EXPECTATIONS and PERFORMANCE determine satisfaction with a high involvement product. The theory and its building blocks, expectations and performance, have to be tailored to the study of satisfaction with high involvement products, since the dimensions of these building blocks that are relevant for high involvement products are different from those that are relevant for low involvement products. These dimensions will be briefly discussed next. EXPECTATIONS differ by type (Miller 1977), nature (Day 1977), and source (LaTour & Peat 1980). Four types of expectations have been identified: ideal, expected, minimum tolerable, and desirable (Miller 1977). "Ideal" expectations seem to be most relevant for high involvement products since highly involved consumers tend to have "higher" expectations (Oliver 1980). In contrast, "minimum tolerable" expectations seem to be a more relevant standard to compare performance with a low involvement product. The "minimum tolerable" standard implies a conjunctive decision making rule (Bettman 1979) that low involvement consumers are likely to use to reduce the cognitive and physical effort of searching and evaluating.

The nature of the expectations refers to the dimensions of the product about which the consumer has expectations (Day 1977). In the purchase of a high involvement product, the social, psychological and functional risks involved are high and consequently, consumers hold expectations about a greater number of attributes than they do for low involvement products. For example, in the purchase of an automobile, consumers have expectations regarding the appearance and style of the vehicle, quality of materials, the quality of the workmanship, warranty coverage, etc. (Day & Ash 1978). In contrast, for a low involvement product, the risks involved are fewer and lower and therefore, consumers have expectations about fewer attributes.

The source of the expectation refers to the information sources from which the consumer derives his/her expectations. Traditionally, research has concentrated on the expectations derived from test reports, manufacturers, and unspecified sources (La Tour & Peat 1980). However, this extant research ignores other important sources of expectations, such as personal past experience and others' past experience (La Tour & Peat 1980). These sources play a key role in the determination of expectations for a high involvement product. Since high involvement product decisions are risky and important, consumers tend to rely heavily on their own past experience and the past experience of others in the determination of expectations. The utilization of information from others tends to alleviate some of the uncertainty surrounding complex product evaluations (Cohen & Golden 1972) such as in the case of a high involvement product.

Two dimensions of PERFORMANCE become important in determining the satisfaction with high involvement products. The first is the functional or instrumental performance of the product. However, this dimension of performance is also important for low involvement products. The second dimension, expressive or psychological performance, becomes particularly relevant for high involvement products due to their high degree of social, financial, physical, and/or psychological risk (Swan & Combs 1976).

In summary, according to the disconfirmation theory, satisfaction for a high involvement product results from the discrepancy between expectations and performance. For a high involvement product, the standards used to compare performance are "ideal" expectations, which the consumer derives from a number of sources; the most important of which is personal sources. Further, the performance dimension that becomes particularly relevant in determining satisfaction with a high involvement product is the expressive/psychological performance dimension.

Rival Hypothesis to the Disconfirmation Theory

While much of consumer satisfaction research is based on the disconfirmation paradigm, alternatives to this classical model are suggested by both the conceptual and the empirical research on consumer satisfaction. Oliver and Bearden (1983) found that the importance of expectations as a determinant of satisfaction decreases for high involvement products and the importance of performance increases. Thus, according to Oliver and Bearden (1983, p. 253), "high involvement decreases his/her sensitivity to pre-usage phenomena and increases his/her sensitivity to outcome phenomena." This means that, performance becomes an independent determinant of satisfaction.

Churchill and Suprenant (1982) report this independent role of performance in the determination of satisfaction for a video disk player. In an empirical research study of 126 respondents, they found that satisfaction with a video disc player is primarily determined by the performance of the product. "Neither the disconfirmation experience nor subjects' initial expectations affected subjects' satisfaction with the product" (Churchill & Suprenant 1982, p. 502). Thus, the authors report the existence of a direct performance-satisfaction link for some products.

Even though these empirical findings could be the result of an artifact of gross differences in the performance manipulation, nonetheless further attention is warranted before a decision can be made to support or disregard the findings. As a result of this conceptual and empirical research an alternative to Hypothesis One is proposed -

H2: Satisfaction with a high involvement product is determined primarily by the performance of the product.

Consumer Choice Literature

The consumer choice literature should help us understand the processes through which satisfaction or dissatisfaction is achieved. However, the research that links consumer decision making processes with satisfaction is very limited (Bettman 1979; Day & Hunt 1979). In applying consumer decision making theory to satisfaction, this paper adopts the interactionist model proposed by Punj & Stewart (1983). This framework is relevant for high involvement products since involvement is the result of the interaction between person and situation (Mitchell 1979; Kassarian 1981).

The research on consumer decision making indicates that involvement has a tremendous impact on consumer choice processes. This research is summarized into five categories: (1) Pre-purchase Expectations; (2) Search; (3) Processing; (4) Post-purchase Evaluation; and (5) Consequences.

Pre-purchase Expectations: Little research has been con-

ducted which relates pre-purchase expectations to choice processes (Bettman 1979).

Search: The risk and uncertainty of high involvement decisions stimulates a high degree of search (Jacoby, Chestnut & Fisher 1978; Swan 1972; Wright 1975) and encourages consumers to rely on referent groups and other alternative sources of information (Assael 1981; Engel & Blackwell 1982; Leibenstein 1976, 1978).

High involvement decisions are associated with high search costs and high experience costs. The high experience costs of high involvement products are a result of the psychological, social, financial, and physical risk associated with purchasing an unsatisfactory product (Price 1981). The high search costs result from a possible delay in the purchase decision (Engle, Blackwell, & Kollat 1978), from the frustrations incurred in search (Downs 1961), and from the amount and appropriateness of existing information (Engel & Blackwell 1982).

Processing: The literature indicates that consumers conduct extensive information processing and attempt to maximize their expected satisfaction with the purchase of a high involvement product (Assael 1981; Engel & Blackwell 1982). Likewise, high involvement decisions tend to produce faster evaluation and more alternative (brand) evaluations (Gardner, Mitchell, & Russo 1972; Wright 1972).

Post-purchase Evaluations: The level of product involvement will affect the strength of the post-purchase evaluation (Oliver & Bearden 1983) and whether or not post-purchase evaluations are triggered (Day 1977). The higher the level of involvement, the more active and more extreme the post-purchase evaluations.

Consequences of Satisfaction/Dissatisfaction: Consumer satisfaction is generally a significant determinant of repeat sales, positive word-of-mouth, and consumer loyalty (Bearden & Teel 1983; LaBarbara & Mazursky 1983). Day and Landon (1977) suggest that dissatisfaction encourages three different consumer behavior patterns: (1) No Action; (2) Private Action, e.g., warning friends, family, etc. and personal decision to stop buying the product and/or boycott the store; and (3) Public Action, e.g., seek redress from the firm or manufacturer; complain to business, private or government agency; take legal action.

To summarize this discussion, the greater the involvement with the product the greater the search for information about the product, the larger the number of information sources used, and the more extensive the information processing undertaken by the consumer. More importantly, the consumer undertakes extensive post-purchase evaluation and attempts to maximize their satisfaction with the product. The implication of this paradigm is that by providing the consumer with more information about a product with which the consumer is highly involved, the satisfaction with the product can be increased, since the consumer will process this information and develop well defined and realistic expectations.

The empirical research on consumer choice behavior for a high involvement product suggests an alternative to Hypothesis One and Two.

H3: The greater the amount of information available the greater the satisfaction of the consumer.¹

This hypothesis suggests that given more information, consumers will conduct extensive choice processing, develop well defined expectations, and consequently make better decisions and be more satisfied. However, this premise has generated some dialogue and controversy in the area of consumer decision making. Those in support of the proposition favored the development of consumer information programs to bring about significant changes in the cognitive processes, behaviors, and satisfaction levels of consumers (Bloom 1976; Richardson 1975). They contended that the possession of more information is a sufficient condition for improved decision making (Stern 1967).

¹This hypothesis assumes that the product's performance would be adequate and/or satisfactory and therefore, the consumer would deserve to be satisfied.

Those in opposition argued that more information is not necessarily better, and in fact, may lead to substantially worse decisions (Jacoby 1974). These less optimal decisions may be due to information overload (Jacoby, Speller, & Kohn 1974). Moreover, not only is the amount of information related to decision making, but the content of the information is also relevant. Consumers are often unable to use the information because they do not understand its significance (Capon & Lutz 1979).

In the case of high involvement products, however, it is hypothesized that more information will lead to better decisions. This is due to the fact that since the consumer is highly involved, he/she is motivated to search for this information, evaluate and integrate it, and base decisions on this information. Thus, the critical difference between research that found that more information does not improve decision making and this research, is the nature of the product.

A Unique High Involvement Situation: The Choice of a Physician

Based on a review of the research on satisfaction and consumer decision making, three alternative hypotheses on the determinants of satisfaction for a high involvement product are proposed. The three explanations are:

H1: Satisfaction with a high involvement product is determined by the discrepancy between expectations and performance.

H2: Satisfaction with a high involvement product is determined solely by performance of the good.

H3: The greater the amount of information available about a high involvement product the greater the satisfaction of the consumer.

The requirements of a decision making context in which to test these hypotheses are (1) It should be a high involvement decision making situation (2) There should be a paucity of relevant information based on which the consumer can make the decision, and (3) Satisfaction or dissatisfaction should have important implications.

The health care context is an appropriate setting in which to test these hypotheses because: (1) the choice of a physician is a high involvement decision with a great deal of risk and uncertainty (Berkanovic & Reeder 1974), (2) there is a lack of objective information on which to base this decision (Feldman 1966), and (3) satisfaction and dissatisfaction have significant implications for consumers (patients), practitioners, and society at large.

High Involvement Situation: According to the definition of involvement previously stated - 'the activation of extended problem solving behavior when the act of purchase or consumption is seen by the decision maker as having high personal importance or relevance' - the choice of a physician and the subsequent utilization of medical services may be considered a high involvement situation. While the level of involvement may vary across different types of health care services, the purchase and utilization of health care services has traditionally tended to have a high degree of personal importance or relevance to the patient. Therefore, in choosing a doctor, patients often experience high levels of perceived risk and uncertainty (Swan & Carroll 1979). Of course the level of risk and uncertainty may vary according to the type of care sought (immunization shot versus pre-natal care), seriousness of the illness (common cold versus lung cancer), costs involved in care (\$25 office fee versus \$1000 surgical fee), and the personality of the person seeking care (healthy woman in her 20's versus a sickly elderly man in his 70's). Moreover, the research indicates that in general, patients, as consumers in the health care market, tend to be highly involved in the purchase of medical services, often fearing blame, punishment, and victimization in medical encounters (Berkanovic & Reeder 1974).

Type of Available Information: In the choice of a physician, an "individual decision maker must rely upon a variety of informal, highly subjective, sometimes inconsequential,

and perhaps conflicting sources of information" (emphasis added) (Feldman 1966, p. 580). One important source of information is the recommendations of friends, family, neighbors, etc. (Wolinsky & Steiber 1982). Although individuals usually consider the information acquired from interpersonal sources the "next best" thing to personal experience (Feldman 1966), this information is sometimes irrelevant, informal, and conflicting which results in confusion. In summary, in the health care context, there is a lack of objective, verifiable, and relevant information on which to base decisions.

Implications of Satisfaction/Dissatisfaction: Patient satisfaction and dissatisfaction has significant implications in the health care context. The former has been shown to enhance patients' psychological trust, physical well-being, compliance, and utilization of medical care. Dissatisfaction has been found to encourage doctor shopping and the incidence of malpractice (Betz & O'Connell 1983; Hulka, Kupper, Cassel, and Babineau 1975; Jasnoski 1985).

Implications of Alternative Hypotheses in the Health Care Context

These three alternative hypotheses have important, yet different implications, for actions that need to be taken to increase satisfaction with health care.

Implications of Hypothesis One

Hypothesis One proposes that satisfaction with high involvement products is determined by the disconfirmation paradigm or the relationship between expectations and performance. This implies that practitioners should attempt to influence both EXPECTATIONS and PERFORMANCE. The former can be impacted through consumer education programs, advertising campaigns, community workshops, brochures about office procedures, cost of services, medications prescribed, etc. The goal of such endeavors is to adequately inform patients about what to expect in the medical encounter. In terms of PERFORMANCE, practitioners should concentrate on the "caring" aspects of performance. Performance will be addressed in more detail in the next section.

Implications of Hypothesis Two

Hypothesis two states that satisfaction with a high involvement product is determined primarily by the performance of the product. Support for this hypothesis would suggest that practitioners should focus their attention on the PERFORMANCE aspect of medical care. Two types of behaviors are important in a patient's evaluation of a physician's performance: (1) Caring behavior, and (2) Curing behavior. The latter refers to the technical competency of the physician and the former refers to his/her affective behaviors or interpersonal skills. Lacking the ability to judge or evaluate the technical competency of a physician, patients confine their judgements to the mode of interaction, the caring behaviors of a physician (Ben-Sira 1976). Thus, to enhance patients' evaluation of performance, efforts should concentrate on the affective or caring behaviors of physicians. Some suggestions would include (1) developing coursework on interpersonal skill training and requiring it in the medical school curriculum, (2) offering continuing education seminars for physicians which allow them to sharpen skills and acquire new skills in verbal and non-verbal communication, and (3) strengthening the physician-patient rapport.

Implications of Hypothesis Three

Hypothesis Three proposes that if consumers are given more information, they will conduct extensive choice processing, develop well defined expectations, and consequently achieve high levels of satisfaction. Support for this hypothesis would indicate that consumers should be provided with more information to assist them in their choice of a health care delivery system such as solo practice, group practice, emergency care centers, health maintenance organizations, preferred provider organizations, etc.

In today's rapidly changing environment, the consumer is faced with a confusing multitude of alternatives that have only recently emerged. The Hypothesis Three suggests that to increase satisfaction with health care services, the consumer needs to be educated about how to choose a health care delivery system. As opposed to Hypothesis One, which implies that consumers must be educated about what to expect from their encounter with the physician, Hypothesis Three suggests the need to educate the consumer about health care alternatives. The focus of such an education program must be two-fold. One objective is to make the consumer aware of the alternatives, and the second is to educate the consumer about the advantages and the disadvantages of the alternatives and the criteria that can be used to evaluate them.

In summary, Hypothesis One implies that to increase satisfaction with health care, consumer education programs need to focus on influencing the consumer expectations about the encounter with the doctor. The performance of the doctor is also important according to this theory, since the discrepancy between the doctor's performance and expectations influences satisfaction. According to Hypothesis Two in contrast, the performance is the sole influencing factor of satisfaction. This suggests that the performance of the doctor needs to be improved especially in terms of the "caring" aspects of the encounter. The third Hypothesis implies that consumer education programs need to be instituted to make consumers aware of the health care delivery alternatives which are available and provide them with criteria to evaluate these alternatives.

Summary

This paper examines the determinants of satisfaction for a high involvement product from the perspective of consumer satisfaction theory and consumer choice theory. This investigation of the determinants of satisfaction leads to the development of three alternative hypotheses on the factors that influence satisfaction for high involvement products. The first hypothesis, based on the dominant paradigm in consumer satisfaction literature, the disconfirmation theory, suggests that the discrepancy between expectations and performance influences satisfaction with a product. The second hypothesis which is derived from recent research on consumer satisfaction proposes that satisfaction is influenced primarily by performance. The third hypothesis, based on consumer decision making theory, is that "reliable" and "valid" information can help increase consumer satisfaction with high involvement products.

The health care context is proposed as a relevant context in which to test these hypotheses because: (1) the choice of a physician is a high involvement decision; (2) there is a lack of objective information; and (3) satisfaction and dissatisfaction have significant implications for consumers (patients), practitioners, and society at large.

RESEARCH ON PATIENT SATISFACTION:
POTENTIAL DIRECTIONS

Ruth Belk Smith, University of Maryland
Paul N. Bloom, University of North Carolina
Kelley Sonon Davis, University of Maryland

Abstract

This research is concerned with several issues. There is the need for general understanding in the area to help the focus of the public health care system and to help provide guidance to health care marketers in understanding their consumers. Finally, the domain of satisfaction both as patient and generic satisfaction is discussed and the implications for marketing to consumers in general and in the health area are discussed.

Introduction

Most of the studies in what has come to be called consumer satisfaction/dissatisfaction (CS/D) have approached its conceptualization and measurement in terms of consumer products or shopping outlets. Only a few have dealt with services (Day and Bodur 1977, Darden and Rao 1977, Braden 1979). Since a high proportion of consumers report dissatisfaction with some services (Day and Bodur 1977), it would seem appropriate to investigate this area for additional insight into the nature of CS/D. One research area in particular which appears to have been ignored is patient satisfaction with medical services. It is quite likely that research on consumer product/service satisfaction can be enriched by research that adds to the limited existing literature on patient satisfaction (Swan and Carroll 1979).

Besides contributing to a more general understanding of consumer satisfaction/dissatisfaction, additional research on patient satisfaction could prove valuable for resolving certain public policy questions about the U.S. health care system. Public attitudes toward this system, and toward the professions in general, have become more negative, manifesting themselves in the form of a variety of policy proposals that suggest removing some control over health-care delivery from the health-care professions themselves. Evidence concerning patient satisfaction may offer some leverage for the health care sector against social aggregation (e.g., community medicine or the formation of adverse public policy). On the other hand, evidence concerning patient dissatisfaction could suggest a need for greater social control.

Additional research on patient satisfaction could also be useful in guiding the marketing activities of health-care practitioners in the turbulent environment they are facing. There is no longer any question that health care must be marketed; the question now is how to market it. Research on patient satisfaction could contribute to the development of improved marketing approaches.

Thus, research on patient satisfaction can contribute to our understanding of consumer satisfaction/dissatisfaction in general, while at the same time providing practical help for formulating public policy and designing health-care marketing programs. The purpose of this paper is to suggest several directions for future research on patient satisfaction. The discussion begins by reviewing previous research that is relevant to the study of patient satisfaction. Next, the results of a study on patient satisfaction that was recently conducted by the American College of Obstetricians and Gynecologists are reported. Though this study was not actually conducted by the authors, it is discussed here because it is illustrative of the kind of research that has been done in the past on patient satisfaction. The study's research design and findings provide a good basis from which to suggest new research directions. The last section of the paper reviews several research directions where methodological and

substantive contributions can be made to our understanding of patient satisfaction.

Conceptualization of Patient Satisfaction
