Research into consumer satisfaction has generally approached its conceptualization and measurement from two distinct theoretical perspectives: (1) in terms of the extent to which the individual feels his/her prior expectations of product performance have been confirmed or disconfirmed in the consumption process (Anderson 1973, Day 1977, Churchill and Suprenant 1982), and (2) in terms of the psychological distance between the product/service and the individual's ideal product/service in a multidimensional space representing salient product attributes (Day 1977). Most studies using the confirmation or disconfirmation of prior expectations approach have used one of three psychological theories as frameworks for studying the psychological processes associated with the assessment of the consequences of decisions: cognitive dissonance or assimilation theory, contrast theory, and assimilation-contrast theory. These theories provide alternative predictions of how the consumer behaves when expectations are not met by product/service performance (Anderson 1973).

The attributional approach visualizes the consumer as making rational decisions in order to maximize utility and satisfaction, and as implicitly or explicitly evaluating the cause of the performance (Valle and Wallendorf 1977). Although utility theory is highly abstract, it does provide an elegant model whereby the consumer experiences satisfaction or dissatisfaction and is also the method used in most previous research on patient satisfaction. Therefore, this approach will be emphasized in the remainder of this paper.

Conceptually, consumer satisfaction has been defined as the overall post-usage response to many different facets of a product/service (Aeillo, Czepiel and Rosenberg 1977), as the person's immediate reaction to a complex situation (Handy 1977), and as dependent on not only the product/service but on the experience surrounding its acquisition (Cardozo 1965). Evaluation may encompass a number of attributes of the product/service, and in the patient satisfaction literature a number of attributes have been reported. According to Churchill and Suprenant (1982), satisfaction can be operationally assessed as the sum of the satisfactions with the various attributes of the product or service.

Several studies have found provision of information to be an important aspect of physician conduct in determining satisfaction (Ware and Snyder 1975, Doyle and Ware 1977, Comstock and Slome 1973, Jenry 1976, Berhanovic and Marcus 1976, King and Goldman 1975), a result paralleled in consumer product research (Hunt 1977, Wall, Dickey and Talarzyk 1977). The lack of information provisions has been found to lead to poor compliance with treatment (Korsch and Negrete 1972) and can be therefore considered an important professional quality, or instrumental attribute, of patient satisfaction. Hulka and others (1970) found three domains: cost/convenience of the service, personal qualities of the physician, and professional qualities of the physician. Similarly, three other independent studies identified much the same domains: professional and personal qualities of the physician, and access mechanisms (cost, payment structure, location, waiting time, etc.) (Ware and Snyder 1975, Doyle and Ware 1977, Manglesdorf 1979). This suggests a limited set of basic attributes which determine satisfaction with a medical service and which describe domains not unlike the instrumental expres-

sion dimensions of consumer satisfaction postulated by Swan and Combs (1976).

The conceptualization for consumer satisfaction/dissatisfaction proposed here is very similar to the above mentioned domains, but it has been generalized for potential application to general CS/D. The three domains of this model include the (1) instrumental domain, which corresponds to professional qualities of the physician, (2) expressive domain, meaning personal qualities of the physician, and (3) access mechanisms, which include cost/convenience.

FIGURE 1
DIAGRAM OF CONCEPTUAL MODEL

Though the study discussed in this paper is about patient satisfaction, it is proposed that this model also applies to general CS/D. Suppose, for example, that a person is going to have dinner in a restaurant. He decides whether to have fast food or eat in a sit down place, what price he wants to pay, and what location he wants to go to. These are access mechanisms. If it is a very expensive restaurant, he wants the hostess and/or waitress to be pleasant and helpful and a nice atmosphere, falling into the expressive domain. Finally, he wants the food to be good and prepared correctly, this would fall into the instrumental domain.

It is expected that levels of satisfaction are expressed by patients according to the extent to which doctor and patient have the same summary evaluation (salience) of attributes or domains. This similarity or overlapping of perceptions has been called agreement or understanding in descriptions of interpersonal systems (e.g. Chaffee and McLeod 1968).

The Study

Typical of the previous research on patient satisfaction is a study recently conducted for the American College of Obstetricians and Gynecologists by a commercial marketing research firm. The study began by interviewing twelve OB/GYNS from across the country and asking them to choose the most important determinants of patient satisfaction. Participating physicians were predominantly male, in group practice, and from urban areas. In-depth interviews were conducted either in person or on the telephone with each of twelve physicians. They were asked (1) to comment on the importance of those issues emerging from the literature to their practice and (2) to discuss those aspects of the physician-patient relationship they wanted most to be addressed in a planned patient survey.

The issues included on the subsequent questionnaire were (1) medical costs, (2) billing and insurance procedures, (3) waiting time and appointment procedure, (4) information about procedures and treatment provided by the physician, (5) prenatal, postnatal, and primary care, (6) perceptions of breast and pelvic examination, (7) desire to learn breast self-examination, and (8) desire to discuss sexual topics with the physician. The three domains discussed most frequently in the literature, access mechanisms (1-3), instrumental qualities of the physician (4-7) and personal qualities of the physician (8) were all judged important issues by the physicians. Personal qualities of the physician appear to be perceived as the least important of the domains to physicians since only one issue (8) addresses this domain.

The questionnaire was pretested among 20 women between the ages of 21 and 35. After minor revisions, 200 questionnaires,

consisting of 45 closed-ended questions and three open-ended questions, were mailed to each of the twelve OB/GYN practices. Closed-ended questions were scaled from 3 to 6 points, depending on the nature of the question (i.e., for attitudes toward aspects of the exam categories were "very comfortable, somewhat comfortable, as comfortable as can be expected, somewhat/very uncomfortable). Questionnaires were personally distributed by a staff member to the first 200 patients who arrived for appointments. Of 2,400 distributed questionnaires, 1,349 were received which were usable--a response rate of 56.2 percent. Table 1 shows the composition of the sample.

TABLE 1
COMPOSITION OF THE SAMPLE

Age	Percent of the Sample (n=1349)
Under 25	20%
25 - 34	50
35 - 49	19
Over 49	12

Counseling	1
Other	8
Perception of OB-GYN as Principal Physician	
Yes	63
No	34
Don't know	3

Although the response rate was fairly high, certain biases were present, and the results must be interpreted with due caution. Response rates varied considerably among separate practices, from a high of 99 percent to a low of 19.5 percent. Non-respondents could be the most dissatisfied patients, particularly those in practices with the lower response rates. The distribution of questionnaires to the first 200 patients arriving for appointments may have biased the sample toward those patients with particular reasons for more frequent visits (e.g., obstetrical patients nearer term, gynecological patients with specific problems needing regular treatment). This method also excluded patients in the hospital and, most important, those who no longer used the particular practice. The latter group may well be the most dissatisfied since purchase and consumption are linked to repeat purchase and brand loyalty by satisfaction (Churchill and Suprenant 1982). In addition, the data were collected from private practices and excluded indigents who must rely on public medical care; however, since patients of private practice are freer to exercise choice, satisfaction is a more necessary outcome of continued consumption of the services of a particular practitioner.

Finally, the response categories for most of the questions were upwardly biased. Possible responses to "satisfaction with scheduling appointments" were "very satisfied," "satisfied," and "dissatisfied;" response categories for adequacy of information provided were similar: "very adequate," "adequate," and "inadequate." Such biased items lead the respondent to provide "right" (more positive) answers (Babbie 1973).

Results

For comparison, Tables 2 and 3 contain the responses to the close ended and open ended questions. While positive results were high for close ended questions, nearly 75% of the open ended questions had negative responses.

Access Mechanisms.

Patients seemed quite satisfied with scheduling of ap-

TABLE 3
SUMMARY OF OPEN ENDED QUESTIONS

Topic	Comment Summary
Miscellaneous	Need more privacy; soundproof rooms; more comfortable furniture.
Appointment Scheduling	Takes too long to get an appt; want varied hours or Saturday hours.
Time in Waiting Room and Exam Room	Wait too long (up to 2 hours); don't call patients when the doctor is running behind.
Support Staff	Staff not friendly or helpful; don't like nurse practitioners; in group practice, don't like seeing a different doctor each time.
Exam	Need new gowns, rooms too cold; don't like discussing things in the exam room.
Doctor as Information Provider	Take more time with patient; make small talk during exam; doctor in too much of a hurry; doesn't explain procedures; doesn't ask if there are questions.
Prenatal/postnatal Care	Spend more time explaining what is happening; give more information; want more printed material.
Fees	Unreasonable; lab fees too high; receptionist shouldn't discuss billing problems in waiting room; don't know.

pointments. About three-fourths of the respondents were very satisfied, about one-fourth were satisfied, and only 1% were dissatisfied. Open-ended responses indicated, however, that a number of patients have to wait too long to get an appointment, and requests were made for more varied hours as well as for receptionist to inform by telephone and in person if the doctor was running far behind schedule.

Helpfulness of the staff was rated as very good (by about 3/4 of the sample) or good (1/4). Again, only 1% reported the staff as not helpful. Open-ended responses indicated less satisfaction with the staff, requesting more respect, friendliness, and more satisfactory information. Most patients (88%) said they received sufficient information on billing and insurance procedures; most (91%) thought fees charged were reasonable, while 9% thought them unreasonable. Open-ended responses again indicated more dissatisfaction; fees were considered too high in relation to the short amount of time spent with the physician.

Instrumental Qualities of the Physician.

Just over half the respondents found examinations very comfortable, 20% found them somewhat comfortable, 25% found them "as comfortable as can be expected," and about 4% found them uncomfortable. Patients rated information received about problems, exams, and treatment as very adequate (73%) or adequate (25%); while opportunity to ask questions and physician willingness to respond were rated even higher (83% very adequate, 15% adequate, 2% inadequate). Again, open-ended responses indicated a desire for the physician to spend more time with them, a feeling of being rushed, and a desire for physicians to initiate more discussion. Many (41%) indicated a desire for more instruction on breast self-examinations; about half were very satisfied with prenatal/postnatal primary care (45% satisfied and 5% dissatisfied).

Personal Qualities of Physician

Most patients (84%) felt the physician was the appropriate person with whom to discuss sexual topics and 71% said they felt comfortable doing so. However, about two-thirds either did not want the physician to initiate the discussion (42%) or were not sure (26%). Verbatim responses ranged from indicating gratitude for special concern to disappointment at seeming lack of concern.

Implications

The implications from the study are that patients are generally satisfied with access mechanisms and the instrumental qualities of the physician. Verbatim responses indicated less satisfaction with these areas, perhaps due to the nature of the closed-ended questions and the halo effect in testing. Typically, high levels of satisfaction with different aspects of medical care have been reported (Freer, Burdette, and Crocker 1971, Day and Bodur 1977, Justice and McBee 1978), but Noyes (1974) argued that these high scores could be due to a tendency for patients to respond with stereotyped, socially acceptable answers.

The results of the study indicate three important findings. First, the conceptual domains of patient satisfaction appear to be adequately identified. Second, although agreement exists between doctors and patients on the importance of two domains, access mechanisms and instrumental qualities of the physician, a lack of agreement appears concerning the third domain of personal physician qualities. The personal qualities of the physician, deemed less important by the physicians themselves, appeared to be more important to patients and the area of least satisfaction. This indicates that physicians are not fulfilling an important need which exists in order to ensure complete patient satisfaction. Third, analysis of open-ended questions (the verbatim responses) indicates some divergence from closed-ended responses. The major shortcoming of closed-ended questions lies in the structuring of responses; that is, the response categories should be exhaustive, mutually exclusive and unbiased (Babbie 1973). This may explain the divergence of responses and may indicate to patient satisfaction researchers and practitioners that "true" responses may not emerge with only closed-ended questions. It seems, therefore, important to continue to encourage open-ended responses in order to get a more accurate impression of satisfaction and also to bring to attention unquestioned

issues which are important to the patient. Consumers of health care, although traditionally "satisfied" according to research instruments, may indeed not be quite as apt to indicate satisfaction when allowed to express themselves freely. Research (e.g., Blair *et al* 1977) indicates that particular methods should be used when eliciting responses on sensitive subjects such as drinking and sex.

Research Directions

This assessment of the ACOG survey reveals some issues which may be useful in directing future research. These directions can be addressed in terms of methodological and substantive issues.

Methodological Issues.

The shortcomings of the sampling approach may be overcome by more careful attempts to include non-respondents. Instead of distribution to the first appointment arrivals, efforts could be made to elicit responses from patients whose visits are less frequent, those who may deliberately schedule appointments on certain days (e.g., Friday or Saturday) or dates (e.g., end of month), those who frequently cancel appointments, those in the hospital after delivery or surgery, and those who have left the practice.

The instrument could also be improved. The three conceptual domains of patient satisfaction which emerged from the literature appeared to have been identified and agreed upon as important by both physicians and patients. However, personal qualities of the physician were deemed more important by patients than physicians, thus there should be a more even balance of attributes represented.

Other consumer satisfaction/dissatisfaction measurement approaches might be used. To avoid the tendency for patients to respond with stereotyped, socially acceptable answers, before and after treatment measures for fulfillment of expectations could be employed (Noyes 1974). Recent research on satisfaction has focused on the relationship among perceived expectations, disconfirmation, and satisfaction (e.g., Oliver 1979, 1980). Churchill and Suprenant (1982) found that the effects of perceived expectations, performance evaluations, disconfirmation and satisfaction differ for durable and non-durable products; disconfirmation positively affected satisfaction with a non-durable good while satisfaction with a durable good was determined solely by product performance. This type of research has not been applied to services and could provide further insights into the determinants of satisfaction in general and patient satisfaction in particular.

Another approach which has not been explored in patient satisfaction research is the analysis of the physician - patient dyad itself, although this is still the primary mode of health care consumption (Parsons 1960). The seller-buyer dyad has often been analyzed in terms of the personal selling role (e.g., Larsen and Rootman 1976), and studies have found a positive relationship between satisfaction with medical care and the degree to which the physician conformed to the role that the patient expected (e.g., Swan and Carroll 1979). One method of such analysis which might be useful would involve assessing perceived expectations and subsequent evaluations of the dyad performance of both patient and physician in order to more accurately determine the amount of agreement which exists between patient and physician. Lack of agreement on expectations and evaluations of certain attributes may result in dissatisfaction.

This method is based on the co-orientation and A-B-X model (Newcomb 1953), where the patient (A) is oriented to both the physician (B) and the object of health care (X) (Figure 2). The differences in orientation and perceptions of the other persons orientation may lead to satisfaction or dissatisfaction.

FIGURE 2

Source: T. Newcomb (1953), "An Approach to the Study of Communicative Acts," *Psychological Review*, 60, p. 396.

Finally, different questioning techniques could be used. The closed-ended response categories should be more carefully balanced in order to reduce yea-saying by respondents. More open-ended/unaided recall items might elicit better accuracy of responses, especially if placed before the closed-ended questions. The use of counterbiasing statements and projective techniques (Kinnear and Taylor 1983) might yield more honest readings of patient satisfaction (Blair *et al* 1977).

Substantive Issues.

From the open-ended responses, it appears that some issues which were not included in the questioning are important to patients. Systemization of appointment scheduling may increase satisfaction based on suggestions that patients be informed both in person (those already waiting) and by telephone (those with appointments later in the day), if the physician is far behind schedule. Other comments indicated lack of support staff courtesy and inadequacy of printed information.

A final issue concerns the restriction of ideas in the study of those specific to obstetricians/gynecologists. Insights might be gained not only from consumer satisfaction/dissatisfaction concepts in general but from even broader perspectives in marketing literature.

There are several areas for research that are suggested based on the results of this study. First, the same basic study could be repeated using unbiased response generators. This would validate the results of the first study. Then, to test the usefulness of the conceptualization to general patient satisfaction/dissatisfaction, a similar study could be performed for a tangible product type (such as an automobile), and a product that has both tangible and intangible aspects (such as a restaurant). Finally, there is the potential to study the applications of this model for general consumer satisfaction/dissatisfaction. For example, in this study the patients found the expressive domain the most important for tangible products or other services? A contingency model might be developed for the three domains and the kind of product or service being offered.

Another issue that can be raised is the affiliation of the party conducting the research. Having an organization conduct it's own research or interpret the results may not lead to the most objective of conclusions. For example, in the ACOG study, there was a lot of yea-saying among the close-ended questions, and even some of the open ended responses were "qualified." An example of this might be "Dr. X seems very rushed and doesn't answer my questions, but otherwise I'm perfectly satisfied and feel he's an excellent doctor." The doctors may interpret that response to mean that the complaint is minor when in fact, it may be a very important concern. This isn't to say this is done on purpose, but one might expect the doctor to subconsciously interpret a response to favor his best interest.

Conclusions

Negative public attitudes toward the U.S. health care system and toward the profession in general indicate a necessity for further research on satisfaction with these services. This study indicates future research directions which may contribute to a more general understand-

ing of consumer satisfaction/dissatisfaction in general and patient satisfaction in particular, and which could contribute to public policy and marketing decisions in the health care industry. If methods of increasing patient satisfaction can be found which do not compromise the patient's trust or the physician's standards of quality then there is less need for public policy which removes control of health care delivery from the health care professionals.

Research on patient CS/D can have impact upon medical practice marketing in several ways. By finding out what patients are unhappy about, the physician has a basis from which to initiate change to bring about an increase in patient satisfaction. While satisfaction is based on how close the patient and the doctor salient attributes are, change can only be made on one side of the dyad - by the doctor. This fact underscores the need for physicians to learn what their patients' expectations are. For example, if many patients feel that the staff is unfriendly and not helpful, the doctor (as a manager) should make sure that the staff does behave in a friendly and helpful manner. Also, research can uncover more broad goals toward which the physician can work. In this study, for instance, it can be inferred that many patients want a doctor who is kind and caring, but not overly friendly, and who is efficient without being mechanical. The study also pointed out the different expectations patients have. For example, some patients want the doctor to initiate conversations on sexual topics, while others feel they should be the ones to initiate the discussion. This gives responsibility to the physician to "feel out" the wishes of his patients, so he can act accordingly. Finally, research on patient satisfaction can bring out important issues that aren't directly related to immediate patient satisfaction. In this study, most of the women considered the OB/GYN to be her primary care physician. With this knowledge, physicians should not overlook problems that are not related to his or her specialty, thinking that it is being taken care of by another doctor. Research on patient CS/D is important because without the knowledge it gives the physician, s/he can't make the informed marketing decisions that are becoming more and more necessary in today's health care market.

THE CREATION OF PRODUCT SYMBOLISM

Elizabeth C. Hirschman, New York University

Abstract

A novel perspective of the process of product symbolism and symbolic communication is proposed. Based upon the sociological model of culture production systems, the flow of product meaning through institutional and consumer subsystems is described. Consumers are viewed as active contributors to product symbolism, instead of mere recipients of product meaning.

Introduction

During the 1950's there was substantial discussion concerning the symbolic aspects of products (Gardner and Levy 1955, Levy 1959). As Levy (1959, p. 118) noted, "People buy products not only for what they can do, but also for what they mean." This line of thought was extended forward during the 1960's to incorporate the notion of congruence between the lifestyle a consumer chose and the symbolic meaning of the products s/he purchased (Levy 1963). However, during the 1970's there was a hiatus of research and discussion regarding product symbolism and the ways in which meaning may be ascribed to products. This dearth of interest was possibly due to the excesses of the Motivation Research era, yet there is much to be gained -- both pragmatically and conceptually -- from inquiries into the processes underlying product meaning and consumption (Levy 1980).

The purpose of the present paper is to extend prior ideas on product symbolism in some novel directions. A central proposition is that marketing systems (Bucklin 1970, 1972) may also be appropriately conceptualized as culture production systems (Crane 1976). For our purposes, a culture production system may be defined as a system of specialists whose task it is to create, manage, and disseminate cultural symbols (Peterson 1979, Becker 1974, 1978, Hirsch 1972, Clignet 1979). Let us outline what is meant by each term [see Figure One].

Specialists are individuals whose occupation is the development of cultural symbols. For example, apparel and automobile designers, composers, architects, food chemists, and motion picture directors are members of the creative subsystem (Hirsch 1972). Such individuals originate product concepts, i.e., innovations, which are then selected for development by the managerial subsystem (Hirsch 1972). The managerial subsystem consists of specialists in the manufacture and distribution management of cultural products. Examples include Warner Brothers Records, Procter & Gamble, Paramount Pictures, General Motors, and Sears. In some of these examples, the creative subsystem is incorporated into the managerial subsystem (Procter & Gamble, General Motors); while in others it is separate (Warner Brothers Records, Paramount). Sears operates in both modes -- contracting with creative subsystems for some of its products and generating others internally. A third group of specialists is found in the communications subsystem, which functions to provide information about products to consumers. Examples include advertising agencies and public relations firms, professional critics, the industrial/trade press, and consumer-oriented, specialized media.

Through the integrated efforts of these three specialized subsystems, cultural products are produced and disseminated to consumers. A cultural product is defined within this context as a collection of tangible and intangible attributes, and is conceptually analogous to a marketing product in the sense implied by Kotler (1972) and Bagozzi (1975, 1979): For example, a bottle of aspirin, a motion picture, an automobile, and a concert performance are all products emanating from various cultural production

systems.

Culture Production Systems and Product Meaning

Culture production systems are responsible for providing products with meaning prior to their dissemination to consumers. A closer examination of how this meaning-formation process functions can provide some useful insights into new product development.

In Step 1, a product is conceived within the mind of a specialist in the creative subsystem. At this stage, the product is composed of intangible (i.e., idealized) attributes. These intangible units must then be translated into an external, tangible form to make possible the transference of the product to decision makers in the managerial subsystem. For example, a musician may record a demo-tape, a chemist may formulate a sample of a new food supplement, a playwright may write a new script, and so forth.

Of interest in Step 1 are the criteria used by creative subsystem specialists in formulating new product concepts. It has been proposed (Hirschman 1983; Polanyi and Prosch 1976) that some individuals responsible for originating novel product concepts may follow a set of personal aesthetic/ideological criteria which are not congruent with consumers' wants or managerial subsystem selection criteria; whereas other creators may be much more responsive to both consumers' and managers' values. Thus, new product originators may be ordered along a continuum based upon their willingness to comply with consumer and managerial demands regarding the types of products they create. The dual objectives of being true to one's own creative values, while at the same time achieving large-scale commercial success for one's creations, may be a difficult dilemma for some creative specialists (Michelson-Bagley 1981).

In Step 2, managerial decision makers examine the products emanating from the creative subsystem and select those to be commercially disseminated. As Hirsch (1972) notes, many cultural symbols are filtered out of the system at this point. Many more novels are written, dresses are designed, and foods developed within the creative subsystem than ever are made available to consumers. Further, products that are selected for dissemination usually undergo some modifications in their tangible form, while being prepared for mass distribution by the managerial subsystem. This process is commonly termed commercialization (Hirschman 1981). Such changes may alter the attributes of product so that it no longer resembles the concept originating in the mind of its creator.

Of importance here are the selection criteria used by managerial specialists for procuring novel material. Two tentative propositions may be suggested. The first is that in industries distributing primarily utilitarian¹ products (e.g., aspirin, detergent), feedback from the consumer may be sought more extensively during the commercialization process. For example, consumers' responses may be sought during the successive stages of concept testing, prototype development, new product test marketing, and regional expansion.

There are several reasons supporting this proposition. First, such products lend themselves to the inexpensive development of multiple options, each of which can be tested for consumer acceptance. For example, the color,

¹ By 'utilitarian' is meant products used to achieve functional, extrinsic objectives (e.g., relief of headache pain)

scent, and density of a new detergent can be manipulated relatively easily at the concept and prototype testing stages. Second, consumers can likely provide more reliable data regarding their reactions to alternative treatments of this type of product, because the results are more directly observable (e.g., relief of headache, cleaning of clothes).

Third, the creators of utilitarian products are likely to be more consumer-oriented than their creative counterparts in such areas as ballet or cinematography. In perhaps the majority of industries producing utilitarian products, the creative subsystem is integrated into (and dominated by) the managerial subsystem (e.g., Procter & Gamble, General Foods). Hence, creative specialists in such industries may experience less conflict between their own goals and those of the company for which they work.

Conversely, a second proposition is that for primarily aesthetic² products, such as motion pictures, artworks, and literature, consumer's reactions will be less frequently sought during the selection and development process, and those of creators and managers will be more extensively relied upon. There are several rationales for this: First, products such as musical compositions, sculptures, novels and plays lend themselves less readily to alternative treatments. Their constituent elements combine synergistically to form a unique gestalt (Hirschman 1983; Polanyi and Prosch 1976), and altering even one element of the composition may act to create another gestalt that differs in many, unpredictable ways from the original alternative.

Second, consumers are likely to be less able to predict their reaction to such products in advance of experiencing them in their final form. Hence, concept testing is likely to possess less predictive value (Hirschman 1983). For example, to be given story outline of a potential movie would likely provide consumers with insufficient information with which to gauge their reaction to the finished product. Additionally, developing realistic prototypes of alternative versions of aesthetic products is likely to be almost as expensive as producing each in final form. Finally, the creators of such products would likely be uncooperative in such testing efforts. Many architects, authors, directors, and designers, it is believed, are to be found at the self-oriented end of the creative continuum mentioned earlier. To the extent that they view a song, novel, or painting as arising from some inner vision, they are likely to resist attempts at altering it in order to increase its commercial marketability (Hirschman 1983).

Hence, it is posited that in selecting aesthetic products for commercial production, managerial specialists rely primarily on their own intuitive response to the creator and his/her ideas. Such intuitive decision-making is not uncommon in the motion picture, legitimate theater, and recording industries, where objective criteria are few and consumers' a priori reactions are believed unreliable or very difficult to obtain. In such situations, the most common approach to new product selection is likely to be the track record of the creator and the procuring manager in originating and selecting successful products.³

The final product forthcoming from the managerial subsystem may be viewed as a composition of formal, controlled, tangible attributes. By formal is meant

2

By 'aesthetic' is meant products which are consumed for their intrinsic qualities, e.g., their ability to communicate beauty, awe, or arouse emotion.

3

Based upon author's communications with Bob Krasnow, Vice President-Talent for Warner Brothers Records.

that the attribute is created by institutional specialists; that is, it is incorporated within the product by persons in the creative, managerial, or communication subsystems. This distinction is useful to segregate those attributes added to a product by institutional personnel from those added by consumers, which are termed informal. The term controlled refers to attributes incorporated within the product which are under the jurisdiction of managerial decision makers. This would constitute the portion of product meaning which they control either through the manufacturing process, or by control over advertising/promotional messages emanating from the communications subsystem.

Finally, the term tangible refers to objectively verifiable elements of the product -- its chemical composition, size, weight, color, density, height, length, etc. Hence, the product output by the managerial subsystem consists of a physical entity, whose form and content are the result of decisions made within the managerial subsystem. For example, a bar of soap, a motion picture film print, a record album, and an automobile are formal, controlled, tangible products at their point of departure from the managerial subsystem.

In Step 3, the communications subsystem issues messages which provide the product with additional meaning. There are several important points regarding this phase. First, the content of some communications subsystem messages is influenced by the managerial subsystem, while others are beyond its control. For example, the content of advertisements, publicity releases, package labels, and sales promotion displays are largely controllable by the managerial subsystem. However, the content of other messages is largely uncontrollable. For example, the published reactions of professional critics, reporters, rating services, and so forth are not generally controllable by the managerial subsystem.

Further, in keeping with the controllable/uncontrollable nature of messages output from the communications subsystem, some of the information may be desired by the managerial subsystem, while some is not. For example, Columbia Pictures in distributing a movie may instruct its advertising agency to describe the product as "erotic" and "exciting." We could rephrase this to say that the managerial subsystem wanted these two intangible attributes⁴ to be associated with the product and instructed members of the communication subsystem, which it controlled, to undertake this task. At the same time, professional critics view the movie and issue their reactions in the form of reviews. These may contain several additional intangible attributes (e.g., wonderful, boring), which also become associated with the product, but which are not controllable by the managerial subsystem. Because they are not controllable by managerial decision makers, such messages may contain negative evaluative information regarding the product.

Using our earlier nomenclature, two types of attributes emanating from the communications subsystem can be identified. First are the formal, controlled, intangible attributes, which are added to the product by communications specialists controlled by managerial decision makers. Second are the formal, uncontrolled, intangible attributes added to the product by communications specialists not under the control of managerial decision makers. These two types of attributes provide the consumer with the means to make a symbolic interpretation of the tangible product. In other words, they tell the consumer what the physical entity represents, i.e., what it symbolizes.

4

Intangible attributes are those which do not alter the physical form of the product, but do help to determine its symbolic meaning, e.g., banal, prestigious, masculine.

The Roles of Consumers in Contributing to Product Meaning

A fourth group of participants in the creation of product meaning is consumers. Despite the fact that consumers are often viewed merely as recipients of product meaning, they may also be active contributors to symbolic meaning, as well. A consumer's participation in creating product meaning begins when s/he associates intangible attributes with it, which were not derived from culture production system sources. For example, in reading an advertisement about a new home computer, the consumer may mentally generate a set of product associations, for instance, "complicated" and "expensive", which are not contained in the advertisement. These intangible associations constitute his/her personal contribution to the meaning of the product. These attributes may be unique to the consumer -- being derived from idiosyncratic life events -- and do not necessarily resemble those generated by other individuals (Hirschman 1981).

A second way consumers may influence a product's symbolic meaning is by communicating their idiosyncratic interpretations to other consumers. This type of interpersonal communication represents the spread of uncontrolled intangible attributes from one consumer to another, and has two related effects. First, it decreases the proportion of managerially-controlled symbolic meaning assigned to the product. Second, such interpersonal communication serves to increase shared, uncontrolled symbolic meaning among consumers. In other words, interpersonal communication causes more consumers to share symbolic product beliefs, which are beyond the control of product managers. This can have major implications, especially if interpersonal communication consists of the transmission of negative beliefs concerning the product, and if the sharing of those negative beliefs by consumers leads them to take collective action contrary to managerial objectives. Using the nomenclature previously proposed, attributes associated with products by consumers through personal interpretation and interpersonal communication would be labeled as informal, intangible, and uncontrolled.

Thus, there are two potential sources of informal product meaning (idiosyncratic consumer associations and shared consumer associations) versus three for formal product meaning (managerial subsystem, controlled communication subsystem, and uncontrolled communication subsystem). Also of interest is the fact that there are three potential sources of uncontrolled product meaning (idiosyncratic and shared consumer associations, uncontrolled communication subsystem associations), suggesting the pragmatic problems encountered by managers trying to manipulate product meaning through the formal channels they control. Finally, it should be noted that the proportionate shares for each source could conceivably have a range of $0\% \leq X \leq 100\%$ of product meaning. The actual proportion contributed by each is subject to a variety of factors (e.g., advertising budget, word-of-mouth activity, personal interest, etc.).

Culture Production Systems and Product Innovations

Application to Planned Social Change

The flow of product meaning outlined above depicts the social movement of the product through four subsystems, each of which increments and/or alters its meaning. The process described is somewhat like that of a pearl which begins as a grain of sand and is transferred through subsequent oysters, each of which coats it with attributes, perhaps disrupting underlying layers in the process. This conceptualization depicts the meaning acquisition path followed by a novel product from its inception through its mass dissemination among consumers. Within the diffusion paradigm such a product would be termed an innovation (Robertson 1971). There are two sources of change inherent in a product: (1) its tangible attributes, and (2) its intangible attributes.

It is proposed that by creating a product that is completely novel in both its tangible and intangible structure, the culture production system brings forth a radical innovation. By altering the tangible or intangible structure⁵ of an existing product, the culture production system can create a lesser (continuous) innovation. For example, annual model changes in the Mercedes Benz 450 may alter its tangible structure somewhat, but leave largely intact its intangible attributes (e.g., prestige, high quality). Conversely, the chemical structure of Arm & Hammer baking soda was left intact, but its intangible meaning was altered in the campaign to reposition it as a deodorizing compound. Both the new model Mercedes Benz and the newly-positioned Arm & Hammer baking soda are examples of continuous innovations (Robertson 1971). However, their innovativeness was brought about using distinctly different mechanisms.

We may also use this framework to isolate and identify the various cultural subsystems responsible for creating novel products. To create a radical innovation, for example, the integrated efforts of the creative, managerial, and communications subsystems are required. The creative subsystem originates the novel, tangible prototype of the product; the managerial and communication subsystems are responsible for disseminating additional controllable and uncontrollable product attributes to consumers who, of course, may supply attributes of their own.

To create a continuous innovation that is novel in its tangible form (e.g., the new model Mercedes), cooperative efforts between only the creative and managerial subsystems are required. Conversely, to create a continuous innovation that is novel in its intangible form (e.g., deodorizing Arm & Hammer baking soda), cooperative efforts between only the managerial and communications subsystems are required.

Application to Informal Social Change

The foregoing discussion of innovation creation refers to planned social change--that is, changes in product meaning that are undertaken by formal (institutional) channels in the culture production system. A less explored phenomenon is informal social change--that is, changes in product meaning resulting from non-institutional sources. Consumers, themselves, are among the foremost progenitors of this sort of social change (Hirschman 1982).

Consumers can control a substantial amount of the symbolic meaning attributed to a product. If through interpersonal communication, consumers define a novel social meaning for an existing product, they can in effect, originate innovations by themselves. This phenomenon has occurred several times in recent years and is especially common among sects or subcultures. For example, during the 1960's jeans and t-shirts were socially redefined as "hippie" apparel. More recently, adherents to the "punk rock" subculture have symbolically redefined razor blades and safety pins as jewelry (Hirschman 1982).

In the past, little research has been conducted on instances of consumer-generated symbolic innovation, likely because of a perceptual bias by researchers that products come into society only through formal, institutional channels. However, with the shifting emphasis in consumer research from marketer-dominated to consumer-dominated phenomena (Belk 1984) it is likely that more interest will be directed toward this type of symbolic innovation.

Such activity by consumers constitutes an example of use innovativeness, although not in the sense that this term has traditionally been applied (Hirschman 1980). Use innovativeness refers to consumers' modifications of or extensions to a product's managerially intended function, for example, use of a plastic credit card to jimmy open a door lock, use of mayonnaise as a hair conditioner, use

⁵Or by altering both to a relatively minor degree.

of coat hangers as television antennae, and so forth. However, in the present context of creating product meaning, use innovativeness by consumers could also be applied to the consumer-originated redefinition of a product's social meaning by assigning new symbolic attributes to it.

As noted earlier, such cases of symbolic redefinition are perhaps most common in sects and subcultures. Such sects are often centered around an ideological core (e.g., hippies ----> anti-materialism, personal freedom, communalism; punk rockers ----> nihilism, anarchism) that they may desire to communicate to others and also which may serve to set them apart from the values present in society at large.

The redefinition of existing products as symbols may help sects to attain both these goals. For example, hippies wore patched jeans, t-shirts, and sandals to identify themselves and communicate to others their subcultural value of antimaterialism; similarly, punk rockers wear razor blades, metal spikes and engage in self-mutilation to identify themselves and communicate their values of anarchism and self-destruction to the surrounding society. Ideological subcultures and sects may, in effect, operate as mini-culture production systems -- self-contained sources of symbol creation, management, and communication. Consumer researchers, especially those who desire to implement the humanistic research methodologies of ethnography and participant-observation, would likely find the subcultural generation of product symbolism a rewarding avenue for research.

Summary

A novel theoretical perspective has been presented concerning product symbolism and symbolic communication. This perspective argues that the flow of products from producers to consumers may be characterized as a culture production system. A culture production system is responsible for the creation, management, and dissemination of cultural products. Acting through three successive and interactive subsystems, the culture production system makes available to consumers various sets of tangible and intangible attributes, which are termed products. The meaning of these products is controlled by various sources -- the managerial subsystem, the communications subsystem and consumers. Product meaning may be decomposed into a series of dichotomies, depending upon its source and content: tangible/intangible, formal/informal, and controlled/uncontrolled. Each of these dichotomies carries implicit assumptions regarding the interpretation, evaluation, and diffusion of the product.

It was proposed that consumers are active contributors to product meaning, utilizing both idiosyncratic interpretation and interpersonal communication to supplement the meaning provided by the culture production system. Because of their contributions to product meaning, consumers should not be viewed merely as recipients of products, but as producers of product symbolism in conjunction with the marketing system.

It was also proposed that innovations be recast as novel assemblages of tangible and intangible attributes. While most radical innovations are brought forth via formal institutions in the culture production system, it was also noted that some continuous innovations of a symbolic nature may be generated by consumers. This phenomenon is a frequent occurrence among sects and other consumer subcultures who create symbols to differentiate themselves from society and may operate as self-contained culture production systems.

FIGURE ONE

CENTRAL COMPONENTS OF THE CULTURE PRODUCTION SYSTEM

CREATIVE SUBSYSTEM

Functions to originate product concepts.
Examples include song writers, playwrights, food chemists, automotive designers.

MANAGERIAL SUBSYSTEM

Functions to mass produce and distribute selected products.
Examples include automotive companies, record companies, motion picture companies.

COMMUNICATION SUBSYSTEM

Functions to provide information about products to consumers.
Examples include advertising agencies, product rating services.

HOW CONSUMER SUB-CULTURES CODE REALITY: A LOOK
AT SOME CODE TYPES

Jeffrey F. Durgee¹

Abstract

Writers in the area of symbolic consumption refer to how manufacturers and advertisers en-code--and consumers de-code--product designs, advertisements, pack designs, and even company logos. They implicitly suggest that some autonomous "code" exists yet few have tried to describe code systems and suggest implications of different codes for marketers. This article describes the code concept and provides examples of two types of codes, restricted codes and elaborated codes (based on the research of Bernstein 1973). Implications of these codes are provided for advertisers and product designers.

Background

Research on symbolic consumption has flourished over the last several years (ex. Hirschman and Holbrook 1982; Belk, et al. 1982; Levy 1981; Holbrook et al. 1984). Briefly, this research focuses less on consumer perceptions of the functional meanings of products and more on their perceptions of secondary (Eco 1980) or symbolic meanings. The focus is not on what the product does but rather what it means. All of the articles in this stream (note especially Solomon 1983; Csikszentmihalyi and Rochberg-Halton 1981) implicitly involve a symbolic interactionist perspective. This perspective is based on three premises: (1.) humans act toward things on the basis of the meanings that the things have for them (ex.: heavy breathing means two different things on a telephone verses in a gym), (2.) the meaning of things arises largely out of social interaction (we have to be taught what heavy breathing means on the phone), and (3.) meanings are not fixed; rather they are selected, transformed, suspended, and modified as part of an internal conversation that the individual has with himself (Is the heavy breathing a prank? For real? Who is it? etc.) (Blumer 1969). The focus of this article is on the second premise, viz., that meanings evolve from social interaction. Nearly all of the articles on symbolic consumption recognize this. Levy (1980) writes of socially shared "symbol systems". Hirschman (1980) refers to culturally and sub-culturally shared product attributes. Belk, Bahn and Mayer (1982) examine the process by which children are socialized into consumption symbolism patterns. And Wallendorf (1980) describes how aesthetic standards are created, diffused and moderated through social processes.

Similarly, Solomon (1983) and Kotler (1983) describe consumer action in terms of "de-coding" and "encoding" processes. The viewer of an advertisement de-codes the ad; he interprets the content of the ad based on some socially shared agreement of what the objects in it stand for (ex: big home = "wealth"). The content of this ad was originally encoded by a creative in an ad agency.

At the same time, products can act as stimuli to cause a particular self-image for a given individual (Solomon 1983). A young man climbs on a motorcycle, de-codes its meaning (tough, dangerous) and assigns that meaning to himself, i.e., he feels what the motorcycle represents.

¹School of Management, Rensselaer Polytechnic Institute, Troy, New York 12180-3590 (518) 266-6588

In short, the literature notes the existence of socially shared symbol systems or "codes" and describes the role they play in marketing and consumption processes. Usually, this role is one of an intervening variable between some stimulus (such as a new Mercedes model)--and a response (assignment of high status and desire to own it). Hillier (in Clark 1973, p. 409) reiterates this mediating role in the following quote: "an individual's relationship to the environment is mediated by an organization of representations into systems whose structure constitutes the means by which experience is made intelligible." In schematic form, the intervening role of a code system between consumers' needs and product selection--and between product usage and self-attribution--is shown in Figure 1. This figure shows the bi-directional relationship between products and consumers (from Solomon 1983) but adds to it (in heavy black lines) the mediating function of the code system.

FIGURE 1
BI-DIRECTIONAL RELATIONSHIP BETWEEN PRODUCTS AND CONSUMERS
INCLUDING MEDIATING ROLE OF CODE SYSTEM
(Adapted from Solomon 1983)

So far, there has been little examination of codes per se, in other words, the "what" of what is learned by new inductees into a given culture about consumption symbolism. Little has been done toward understanding types of rule systems or codes. The purpose of this article, therefore, is to describe the code concept and what it offers in terms of understanding consumers, and then provide examples of two code types. Implications of these types of codes for marketers are also included. We assume that if marketers know target market code systems, they will be able to develop advertising and product designs that facilitate de-coding efforts by these target markets. The first task, however, is to clarify the "code" concept.

Codes

Berger (1984) lists three types of codes: social codes, aesthetic codes, and logical codes. Social codes (ex. etiquette) specify correct vs. incorrect behavior; aesthetic codes (ex. Shaw's Major Barbara) specify good vs. bad art and literature; and logical codes (ex. Morse code, sign language, chemistry terms) specify meanings attached to certain sign objects which are used to characterize and understand the world. All of these satisfy Lachman et al.'s (1979, p. 68) definition of a "code": "a set of specific rules or transformations whereby messages, signals, or states of the world are converted from one representation to another, one medium of energy to another, one physical state to another." Codes, in short, specify how information is to be converted from one form to another.

As indicated earlier, codes represent socially shared

sources of product meaning. This is not to say, however, that product meaning does not spring from other sources. Hirschman (1980), for example, notes how meaning springs not only from the tangible attributes of the product (Jello Pudding means "creaminess" because it is, in fact creamy) but also idiosyncratic sources. Idiosyncratic sources, which Hirschman found to determine most of the product meaning for several product categories might include not only past experiences with the product but also the user's physiological make-up. Pabst beer might mean "sickness" to a person because he once got a bad can of Pabst--or because his individual neurological make-up doesn't jibe well with Pabst's chemical properties--or both.

The idiosyncratic or individual, cognitive analogue to the code concept is the schema. Schemas, according to Fiske and Linville (1980) are mental frameworks that individuals internalize and carry with them which help them organize new information, retrieve learned information, and guide situational behavior. Abelson's (1976) notion of the "script", for example, is a type of schema. As an example, an individual carries with him a cognitive script which programs for him a sequence of activities in a MacDonald's restaurant: look up at the menu, give the order, get it, sit down, etc. Any new learning about eating at MacDonalds will be organized and retained via that script or schema. In fact, MacDonald's restaurants everywhere are purposely laid out and organized in a way which satisfies consumers' expectations regarding "eating out" behaviors, that is, the sequence of ordering, paying, eating, etc. (Rapoport 1982).

The difference between the code concept and the schema concept concerns their levels of generality. A schema refers to a specific area of behavior. In the restaurant example above, it refers to a cognitive ordering of steps involved in eating in a restaurant. In contrast, codes refer to common tendencies of members of a given culture to cognitively organize every area of their lives. One term, for example, used by code theorists and symbolic anthropologists is "boundary" (Leach 1976). This refers to how strongly people demarcate separate spheres in life, i.e., work vs. leisure, sacred time (church service) vs. secular time, entree vs. desert, and living room vs. dining room. In some code systems, boundaries are very weak. The writer knows of student subcultures, for example, that maintain weak boundaries between library behavior, fraternity behavior, football game behavior, and classroom behavior. In other cultures, i.e., certain upper-class English cultures (Clark 1973), boundaries are firm and constant; life spheres such as living rooms vs. dining rooms and parties vs. football games are rigidly separate entities. Presumably, a highly enculturated member of the latter group might be somewhat befuddled in a fast food restaurant, where separate food courses -- salads, entrees, deserts, coffee -- are all purchased at once.

But first, what does the code concept buy us? The goal is to understand the set of rules that a group of people share and use to organize and make sense out of their environment. We contend that knowing a group's code provides a marketer with information that is not available from any other conceptual framework. To take an extreme example, suppose that an international marketer wanted to market a product to a nonindustrialized third world country. To do so, it planned to advertise that its product out-scored 3 competitors in product tests. A fact that Dorothy Lee (1977) has noted in certain third world cultures is their tendency to code everything in non-linear terms. For example, where our lineal culture includes such things as ordered career "paths", causal theories of history, and maps based on road lines, Trobriand Islanders perceive everything in non-linear terms. They see their careers and history as aggregates of unconnected, personal and social anecdotes, and structure their maps in terms of specific locations (i.e. not routes going in specific directions). Whereas our lineal culture has "lines" of

authority, many tribal cultures (Lomax 1970) consist of one, weakly designated leader and 100 to 200 semi-independent followers. In these same cultures, rather than have one singer sing to an audience (as in western culture), all singing is group singing. Since these people organize objects, time, and interpersonal relations in non-linear terms, marketing communications which rank order the performance of one's product versus competitor products would require special decoding efforts by these people. As Bernstein (1968) says, a two-step decoding effort would be required; step one: translate the message into one's own coding system, step two: decipher what the translated message means.

In short, the unique attribute of the code concept is its comprehensiveness. A code is a unitary concept which describes how members of a given culture subjectively structure interpersonal relations, geographic space, time, art forms, religion, language, architecture (Bunt, et al. 1980), and even home furniture arrangements (Douglas 1970). In contrast, the concept of "values" is the next most general concept. Values, however, refer to "desired states of affairs" for a given sphere of behavior--for example, "that all people have equal opportunity for economic advancement." The code concept is throughgoing; it represents a system of rules for the cognitive structuring of nearly all life areas. Also, as used in the writing of most sociologists, the terms "values," "norms," and "mores" imply that a group of people are familiar with nonconforming cases, e.g., not having equal opportunity, not serving in the army, not abstaining from cocaine. In a sense, they have a choice between different types of behavior. In contrast, the code concept indicates how people selectively perceive and organize reality. According to a given code, "equality" might be a nonexistent concept, in fact, there may be no word for it in the language!

One learns a culture's code mainly through its language. Language structures reality much the same as the underlying code does (Whorf 1956). A highly articulated language reflects a highly articulated structuring of reality. Also, words in the language specify which elements of the world will be attended to. Curiously, marketing researchers think they can learn the "languages" -- and underlying code systems -- of consumer subcultures in a few hours in focus groups. Cultural anthropologists claim it takes up to ten years to truly learn how a culture experiences and defines its external world!

Understanding Codes

Codes are like languages. They consist of primary elements (words, phonemes) and rules or an algorithm (or "grammar") for interrelating these elements (Eco 1980). Interestingly, several investigators (see Stiny and March 1981) have already written sets of rules (or codes) for conceptualizing product designs. Koning and Eizenberg (1981), for example, de-composed 11 house designs from Frank Lloyd Wright's "prairie design" period into essential elements (fireplace, rooms, porches, etc.), and devised a set of rules for designing Frank Lloyd Wright-style houses. One of the rules is that, "room additions to main living room should not exceed two-thirds size of main living room." They also built these rules into a computer program which generates house designs that many experts believe were designed by Frank Lloyd Wright. (See Appendix for example). Automobile designers who want to maintain a family similarity between all of the automobiles in their lineup might develop similar algorithms and programs for designing automobiles.

Research on a culture's code system begins by taking some functional area of the culture, for example, eating habits, language, or dress codes and then identifying components of this area as well as the underlying rules which determine how these components are interrelated. The researcher then studies other areas, looking for similar rules or algorithms. The goal is a single

algorithm which describes the total code system.

There are probably dozens of different ways to describe codes and code types. However, since this is only a first step at understanding codes and their implications for marketing actions, we focus on only two of the types of codes that researchers have studied so far, restricted codes and elaborated codes. These codes are described below along with implications for advertisers and product designers.

Restricted Codes

Bernstein's (1973) research on social relationships and linguistic patterns among middle and working-class London school children revealed two code types, restricted codes and elaborated codes. Restricted codes are dominant among working class cultures while elaborated codes are dominant among middle and upper-middle class cultures.

Restricted codes represent a high degree of sensitivity to the content of objects as opposed to the relationships objects share with each other, and a greater focus on description as opposed to analysis. A comment about Sears, for example, might be, "Sears treats you good; they're 'real' people"--as opposed to, "Sears has a more efficient home financial management center than Key Bank and City Bank although the interest on their insurance policies does not accumulate as fast as the industry average." Also, restricted codes call for less differentiation of objects, and meaning is largely dependent on context, that is, it tends to be implicit meaning. As Clarke (1973, p. 409), says, "Only those possessing a shared, unspoken, implicit understanding of certain features of the context can have access to its meanings." In a teenage gang, for example, an individual's identity, including his nickname, personality, etc. is largely dependent on the peer group. In the same gang, there are strong incentives to conform and few incentives to wear different clothes, have different interests or different behavior patterns from group norms.

In restricted codes, verbal communication relies heavily on non-verbal communication to communicate feelings. A woman in a fast food outlet asks "Where's the beef" and she looks mad. Since meaning is a function of shared, implicit experience, there are limited tendencies to create unique, individual or personal language forms.

Also, there are comparatively few adjectives or adverbs. Instead, words are strung together "like beads on a frame," (Clarke, p. 411) using simple conjunctions. Sentences are short, and rely on concrete, descriptive symbolism, e.g. "This product slices and dices and mashes and ..." As Clarke (1973, p. 409) describes the poetry of working class children, "it places an importance on the spatial ordering of lines, which allows symbols to reverberate against each other and points to the implicit and symbolic nature of space and the importance of condensed symbols."

The focus on individual objects (in place of a matrix of relationships) has implications for how these people code personal relationships, time, and personal feelings. More stress is placed on attributes of the individual ("he's a 'real person'") than formal role patterns ("he's supervisor to 30 middle managers"). Conceptions of time and one's own feelings are also relatively undifferentiated. The key time element, for example, is here and now, not different points in the past or future which might be causally linked (e.g. "if I start saving next year, I'll have a comfortable retirement"). Regarding feelings, one might say "I feel lousy" as opposed to "I feel anxious but mainly confident I can do the job." Since meanings are dependent on context, these people code spaces in terms of other spaces, e.g. "the front room", "the corner store".

Elaborated Codes

Elaborated codes, dominant among middle-class English people, represent a high sensitivity to differentiation between objects and how these objects are interrelated and hierarchically organized. The middle class child is born into a world that is carefully structured for him (or her), and soon learns to appreciate this structure. Their world, for example, contains a lot of qualifiers and causal connections: "If I buy bubble gum, my parents might be angry because the sugar is bad for my teeth." Meanings here are explicit. In contrast, the meaning of gum to a working class child is implicit: "Mom won't let me buy anything from the candy counter." This code is closely tied to these peoples' language patterns and determines how they cognitively organize social relationships, time, physical environment and personal feelings.

To the middle class person, language is seen as a set of theoretical possibilities for the transmission of unique experiences. The vocabulary is larger, and a premium is placed on verbalization of personal feelings which, in turn, are much more differentiated than in restricted code systems. Social interactions focus more on formal, relational components, and stress the instrumental qualities of these relationships, "if I do x for him, he is expected to do y." Time is also conceptualized in instrumental terms: "Save now for a better tomorrow." Physical spaces are organized based on formal, functional properties: "dining room", "financial district."

Elaborated codes and restricted codes are summarized in Figure 2.

FIGURE 2
THE IMPACT OF RESTRICTED CODES VS. ELABORATED CODES ON LANGUAGE,
SOCIAL RELATIONSHIPS, TIME, PHYSICAL ENVIRONMENT AND PERSONAL FEELINGS

	Restricted Codes	Elaborated Codes
General Characteristics	<ul style="list-style-type: none"> emphasize description and contents of objects low differentiation of objects meanings are implicit (context dependent) 	<ul style="list-style-type: none"> emphasize analysis and interrelationships between objects: hierarchical organization and instrumental connections high differentiation between objects meanings are explicit
Language	<ul style="list-style-type: none"> few qualifiers, few adjectives or adverbs verbal communications rely on non-verbal qualifiers to communicate personal feelings short sentences concrete, descriptive, tangible symbolism small vocabulary 	<ul style="list-style-type: none"> language rich in personal, individual qualifiers stress on verbalization of feelings language seen as a set of theoretical possibilities for communicating unique experiences large vocabulary, complex conceptual hierarchy

Time	<ul style="list-style-type: none"> focus on present; have only general notion of future 	<ul style="list-style-type: none"> focus on instrumental relationship between present activities and future rewards highly differentiated view of future
Physical Space	<ul style="list-style-type: none"> rooms, spaces located in context of other rooms and places: e.g. "front room", "corner store" 	<ul style="list-style-type: none"> rooms, spaces identified in terms of usage; formal ordering of spaces; e.g., "dining room", "financial district"
Personal Feelings	<ul style="list-style-type: none"> low differentiation of feelings 	<ul style="list-style-type: none"> high differentiation of feelings

Implications for Consumer Behavior and Advertisers

Bernstein's findings are based on English subjects. English middle and lower classes are different from

American ones (see Young and Willmott 1965) so the English codes do not describe American ones. Nevertheless, before designing a large scale American code study, it is interesting to note that American consumers in middle and working class sub-cultures share certain similarities with their English counterparts in terms of cognitively organizing their worlds and more importantly, their buying behavior.

Lower class codes in both countries are characterized by a higher focus on object content and a lower focus on differences from other objects. Thus, lower class American consumers have been found to be more oriented to the inherent qualities of a product than differences from other products. Appliances, furniture, and clothing are bought with an eye toward sturdiness and comfort, not style or fashion vs. other brands (Rich and Jain 1968; Levy 1966). In contrast, middle and upper class consumers are more attuned to differences of design and style, and are more willing to experiment with modern furniture and colored appliances (Roscoe et al. 1977). As Levy notes, middle and upper class people are skeptical of television and television advertising yet are "strongly appealed to by sheer difference, by approaches that seem somewhat individual in tone." (in Kassarjian and Robertson 1981, p. 455).

The stronger tendency of American middle and upper-class consumers to perceive products in terms of instrumental benefits is well documented. The VALS program at Stanford Research Institute (Hawkins, et al. 1983), for example, notes the upper-class emphasis on setting long term goals, and their higher spending on education, investment services and "investment clothing." Lower class consumers, in contrast, buy with an eye towards satisfying immediate needs.

Lower class consumers perceive products based on their implied meanings. They rely on context as a judge to evaluate products. Lower class consumers are poorly informed about relative merits of different products (Assael 1981) and rely instead on price as an implied indicator of product quality. Also, as Rainwater et al. (1959, p. 210) note, advertisers to lower class people should show how a product fits into a total life context, or should "convey an image of a gratifying world in which products fit functionally into the drive for a stable and secure life."

Also well documented is the fact that lower class consumers are more attracted to advertising which uses language that is more literal and concrete whereas middle and upper class consumers are attracted to language that is more symbolic, more abstract (Robertson et al. 1984).

However, additional issues in advertising to lower and middle/upper class consumers concern their perceptions of products in general. Take beer, for example. Since lower class consumers are less oriented to differences in general, this might make it that much more difficult to advertise to this group, that is, to single out one's product from competitors. Advertising here should stress the inherent contents or quality of one's product. Budweiser advertising, for example, stresses its "beechwood aging." Budweiser's success might also be due to the spokesperson, Ed McMahon. Levy (in Kassarjian and Robertson 1981), for example, notes how lower class consumers prefer stores with friendly, "real-type" sales people. Ed McMahon might satisfy this preference very effectively for Budweiser. Another tactic is to stress the implied benefits of beer drinking, that is, beer in a given context. (ex: "Natural Light: The Beer with a taste for food").

In contrast, advertising to middle and upper class consumers should stress differences, analysis, and instrumental ties to distant benefits. Beer advertising here, for example, emphasizes attributes such as foreignness, refinement ("the beer chosen by experts"), and weight loss (Lite Beer).

A summary of the implications of restricted codes vs. elaborated codes for advertisers is provided in Figure 3.

FIGURE 3
IMPLICATIONS OF RESTRICTED CODES AND ELABORATED CODES FOR ADVERTISERS

Restricted Codes	Elaborated Codes
• stress inherent product quality, contents (or trustworthiness, goodness of "real-type" spokesperson)	• stress diff., advantages vis-a-vis other products in terms of some autonomous evaluation criteria
• stress implicit fit of product with total lifestyle	• stress product's instrumental ties to distant benefits
• use simple adjectives, descriptors	• use complex adjectives, descriptors

Conclusion and Recommendations Regarding Next Steps

This article examines the code concept and how it explains consumer behavior. The code concept is described, and examples are provided from Bernstein's (1973) work on restricted vs. elaborated code systems among English lower and middle classes.

Briefly, a code is a socially shared set of rules for organizing and making sense out of one's environment. The idea of the existence of an autonomous set of rules for making life intelligible could be a springboard for many further studies. Rosenblum (1978) defines "style" as a set of "particular mannerisms or conventions that are frequently associated together." This suggests that a possible direction for research on consumers' "life styles" might focus on rules or code systems that cut across all life decisions: what clothes to wear, preferred architecture, car designs, career paths, etc. As Levy (1978) notes, each individual is an artist who creates his own lifestyle as a mosaic of separate elements. Just as researchers are now able to identify the codes that architects and artists use to design paintings and buildings, researchers should be able to identify the rule systems or codes that are implicit in all lifestyle choices. Are bright colors preferred in clothes, cars, furniture, and all items in a given culture? Are angular lines preferred in car designs, home designs, and appliance designs?

Research to date on code systems has mainly been descriptive. Not enough is known yet about code systems to develop a set of variables for classifying them, or, in other words, a system for coding codes. Researchers such as Bernstein (1968) look for ways that codes -- mainly, linguistic codes -- differ from each other. To do this, they study one or two languages in depth, and develop highly articulated descriptions of those languages, e.g.:

"Characteristics of a public (lower class) language are:
short, grammatically simple, often unfinished, sentences with a poor syntactical construction; simple and repetitive use of conjunctions (so, then, and), thus modifications, qualifications and logical stress will tend to be indicated by non-verbal means; frequent use of short commands and questions; rigid and limited use of adjectives and adverbs; infrequent use of the impersonal pronoun (it, one) as subject of a conditional sentence." (Bernstein 1968, p. 228).

This only refers to language. In Leach's (1976, p. 10) opinion, all non-verbal dimensions in a culture -- clothing styles, village layout, architecture, music, food, etc. -- "communicate," so a true code for a culture cannot be developed until many other aspects of the culture have been similarly described. In Levy's (1978, p. 143) words, what's needed is not empirical tests but more "spade work," that is, deeper knowledge of "how consumers process their physical, social and cultural circumstances through their psyches in deciding how to allocate resources of time, energy, attention, reasoning, emotion, desire -- and finally money -- to develop,

sustain, modify and elaborate the meanings that matter to them." Thus, further work might proceed on several fronts, all of which are essentially ethnographic and provide descriptive "building blocks" toward a conceptual framework for describing all code systems. Since much code research begins with language, psycholinguistics is a promising starting point. Research might focus on how a culture's language codifies or represents reality and then move on to other areas -- eating habits, non-verbal behavior, architecture -- to determine whether they "communicate" or represent reality in the same way. Another starting point might use structuralist methods from anthropology. Where Levy (1981) applied structuralist methods to understand dining habits, similar methods could be applied toward understanding all components of a culture (see Leach 1976). Finally, if current interest in cultural influences (e.g., ethnic influences) on consumer behavior continues to grow, findings from these studies could provide grist for new theories about codes and their effects.

A FRAMEWORK OF PSYCHOLOGICAL MEANING OF PRODUCTS

Roberto Friedmann, University of Georgia
V. Parker Lessig, University of Kansas

Abstract

The psychological meaning that products elicit in the consumer's mind is shown to be a function of the bundle of attributes found in the product, the consumer's perceptual mode, and the context in which the perceptual process takes place. As such, the psychological meaning of product stimuli is argued as being an area of consumer research that warrants attention. In developing this idea, a Framework of Psychological Meaning of Products is proposed, and directions for research into this framework are suggested.

Introduction

The major purpose of this paper is to highlight the importance and need of focusing on the development of the meaning that consumers derive from, and ascribe onto product stimulus. As argued below, the concept of psychological meaning (PM) of products is believed to be an important component in the analysis of consumer behavior. For the discussion which follows, (PM) will be defined as a person's subjective perception and affective reaction to stimuli.

Theoretical Foundation

Perception in Consumer Behavior Paradigms

In recent years, numerous articles have been written on the information processing perspective of consumer behavior (e.g. Bettman 1979). An important and complementary alternative to information processing is experiential consumption. Experiential consumption views consumption as being a subjective state of consciousness heavily dependent upon symbolic meanings, hedonic responses and esthetic criteria (Hirschman & Holbrook, 1982).

Two manifestations of experiential consumption are symbolic consumption (Hirschman 1981) and esthetic consumption (Holbrook 1981). The underlying notion of symbolic consumption is that products may be evaluated, purchased and consumed based upon their symbolic content (Zaltman & Wallendorf 1979). The central notion of esthetic consumption is that consumers may attend to, perceive and appreciate a product for itself, without regard to the utilitarian functions of benefits it may provide the consumer (Holbrook 1981).

One can regard consumer behavior as a continuum ranging from information processing to esthetic consumption. On the one extreme we can see a logical, methodical information-processor using choice heuristics. At the other extreme we see the consumer esthetically consuming based upon such feeling as fun, elation, and hedonic pleasure.

An important element commonly shared by all paradigms along this continuum is that of perception.

Role of Meaning in Perception Research

One of the earliest conceptualizations of perception can be found in Locke's (1690) proposed paradigm for the study of epistemology, the philosophy and science of knowledge. As discussed by McConville (1978), Locke's seminal idea was that knowledge enters the mind by first passing through the person's senses. Once inside the mind, these "sensations" are organized, compared and compounded into "complex ideas." Accordingly, Locke sees knowledge building as a two-stage process in-

volving primary sensory experiences and secondary cognitive elaborations.

Locke's influence can be seen in the work of Wilhelm Wundt (considered by some to be the main architect of the school of perceptual research and the theory known as Structuralism). Wundt postulated that a perceptual experience is comprised of unitary sensations. These sensations constitute raw material from which complex ideas and images develop. Wundt then postulated a second stage where "meaning building" from these raw sensations takes place. This is through the synthesizing of elementary sensations to form complex aggregates, or structures (thus the name of Structuralism).

Contemporary perceptual psychology can (for the most part) be labeled as Neo-Structuralism. While many researchers believe there are shortcomings in the two-stage theory, few have challenged its underlying assumptions (McConville 1978). An example is the work of Forgas (1966) who presents a model with four basic stages: input, sensory transduction, intervening brain activity and output.

There are, however, exceptions to the Neo-Structuralist approach. Gibson (1966), for example, holds that perceptual meaning is not deduced or inferred through non-perceptual secondary operations; rather perceptual meaning is directly caused by the combined effect of the totality of stimuli patterns an individual perceives.

Perhaps the most salient role of meaning within the perception process can be found in Existential-Phenomenological psychology (Valle and King 1978). This paradigm does not view individuals as objects in nature. Rather, there is a total, indissoluble unit or interrelationship between the individual and his environment in which the individual and his environment co-constitute one another. This notion of co-constitutedness is directly related to our interest in perceptual meaning. According to the Existential-Phenomenological psychological viewpoint, "it is via the world that the very meaning of the person's existence emerges both for himself and for others. The converse is equally true". (Valle & King 1978, p. 8, emphasis added).

The implications of Existential-Phenomenological psychology are that the meaning of a product can not be thought of without the existence and active participation of the individual (perceiver). Thus, phenomenology takes meaning as the starting point of the perceptual experience (McConville 1978), as opposed to traditional psychology which, for the most part, has treated meaning as a by-product of the perceptual process.

Meaning and its Categorizations

In this section, our focus is at the stage where perceptual stimuli have been perceived, organized, and interpreted and are now undergoing the process of being ascribed a particular meaning.

Researchers in different fields (for example, Szalay and Deese (1978) in sociology and Hirschman (1979) in consumer behavior) advocate classifying meaning into three types: lexical meaning, philosophical, and psychological. Lexical meaning addresses the relation between words and referents, in which the base for its

determination is a generally accepted code of labeling (Bloomfield 1933). Philosophical meaning focuses on the concept-referent relationship; here meaning becomes synonymous with rational knowledge (Katz 1972). Psychological meaning focuses upon "a person's subjective perception and affective reactions" to stimuli; "PM characterizes those things that are most salient in an individual's reaction while describing the degree and direction of its affectivity" (Szalay and Deese 1978).

Our interests lie with the psychological meaning of products. The reason is that the nature of buying behavior is not fully conventional or rational.

The major underlying problem in identifying and describing the composition or structure of PM is that the study of PM has been chiefly empirical. According to Szalay and Deese (1978), what little theory there is can be exemplified by the work of Osgood (1952).

Osgood's basic conceptualization of meaning was explained as being "that process or state in the behavior of a sign using organism which is assumed to be necessary consequence of reception of sign-stimuli and a necessary antecedent for the production of sign responses" (Osgood, Succi & Tannenbaum 1957). Osgood's work, then, presents the notion of a cognitive state with both representational and mediating roles.

A major contribution that Osgood's work provides in explaining meaning is his idea of meaning being a "bundle of components."

Components of Psychological Meaning

The conceptualization of PM as a "bundle of components" allows us to visualize these components as the basic structural elements of the construct. Building upon Osgood's work, the components of PM may be seen as representing a person's: understanding and evaluation of the concept/ stimulus; his direct and/or vicarious experiences, images, feelings and associated behavioral responses that have been accumulated over time.

Osgood's idea of meaning reflecting the individual's stimulus-associated feelings is also compatible with Szalay & Deese's notion of the "affective reaction" characteristic of PM. Within the perceptual process, it is a well accepted notion that individuals engage in a series of cognitive mechanisms such as selective exposure and affective distortion. If one looks at the affective distortion element of perceptual processes (Holbrook and Huber 1979), one can see that it indeed is a simple manifestation of the affective reactions contained in PM. Within consumer behavior research one can find evidence that affective distortion, both in its common and idiosyncratic forms, has been addressed with the goal of separating it from the perceptual processes and thus obtaining clearer measures (Holbrook & Huber, 1979). Nevertheless, Hirschman (1979) points out that while this may be a valuable goal in areas such as employee performance evaluations, this research purpose should not be pursued indiscriminately in consumer research. If we were to eliminate affective distortion from the consumer's perception of a product, how do we know that we are not eliminating a crucial component of the perceptual process, whose absence or presence, could drastically change the particular meaning of that product in the consumer's mind?

One can then see a structure of PM. This structure may be explained in terms of components of meaning derived from a subjective elaboration within the individual's perceptual process. This elaboration is conceptualized as being suffused with affectivity (or affective distortion).

Characteristics of the Components of PM

The components of PM described above exhibit certain

generalizable characteristics. These characteristics can be described as salience, commonality, tangibility and context, and are discussed below.

Salience is a measure of the relative importance of components in explaining individuals' reactions to stimuli. In an analysis of cross-cultural, sociological differences, Szalay and Deese (1978) agree that in the control of goal-oriented human behavior by subjective meaning, certain components, such as those involving anticipated behavioral consequences, will be of particular importance. Certain components of PM also play a heavier role than ignoring this idea of component salience, PM overcomes the primary weakness of lexical and philosophical meaning-type analyses (Hirschman 1979).

Commonality and tangibility are also important characteristics of meaning. It is a widely accepted notion in consumer behavior that culture is the primary determinant of consumer wants and needs. An extension of this notion is that our socialization, learning, attitudes and evaluative criteria will also be culturally bound. The individual is indeed operating in a society which can be described as homogeneous only in that it may represent a particular mix of heterogeneous subcultures which may be integrate/blend if one takes a molar perspective. Hirschman (1979) defines the relationship between culture and the individual as a "layer of meaning" paradigm. The underlying concept of the paradigm is that the meaning of a product stimulus consists of associated layers that vary in both their commonality and tangibility among members of society. The paradigm thus provides a framework for classifying the associations of product meaning within the minds of consumers. In the PM of products commonality and tangibility exist as continua that range from idiosyncratic meaning to commonly held cultural meaning and from intangible to tangible.

Context is a characteristic derived from the work of Peter and Olson (1983), who propose that the concept of meaning must always be considered as meaning in a given context. The assertion of meaning being always meaning in a given context is not incompatible with the representation of the components of PM as provided above. If the meaning associated with a particular stimulus is explained to consist in part of the person's evaluation the stimulus, it is then necessarily arrived at within the context and characteristics of the evaluation. Therefore, the evaluation is partially a determinant of the context, while at the same time the context (or the situation) can affect the evaluation, and thus PM. It is felt it would be unrealistic to think of a one way causal relation between context and PM.

A Framework of Psychological Meaning of Product Stimuli

The preceding sections highlight the interactive approach to perception as an issue that needs to be addressed in developing this framework. The two major units of perception are the perceived and the perceiver, or as McConville (1978) points out, what psychologists have traditionally referred to as distal and proximal stimuli. Briefly, distal stimuli refer to the objective, real physical world surroundings, reflecting energy (e.g. light) towards the perceiver. Proximal stimuli refer to the effects, processes, and outcomes resulting from the impingement of this energy upon the perceiver's sense organs.

Even though there has been some research on the perceived (Gibson 1966) and slightly more on the perceiver (Hochberg 1964), the bulk of the research on perception focuses on the interaction between the perceiver and the perceived. Clearly, (though perhaps at a somewhat abstract level of discourse) a product not being perceived has no "meaning." The notion of co-constitutionality (explained in the previous section within the contributions of experiential-phenomenolo-

gical psychology) specifically addresses this. Given a consumer behavior perspective, it is imperative to focus on the interaction between the perceiver and the product stimulus if the meaning of that stimulus to the consumer is to be understood.

Addressing this interaction between the perceiver and product stimulus, this section of the paper develops a framework intended to describe the process through which consumers tend to derive, and ascribe meaning to products. The development of this framework of psychological meaning of products (FPMP) builds upon prior perceptual research and has as its main elements the product stimulus attribute bundle characteristics, the consumer's perceptual modes, and a trichotomy of variables (i.e. individual, social and situational) representing the contexts within which consumers operate. These elements and their relationship are described below.

Tangibility and Product Attributes

The first element of the FPMP addresses the nature of the bundle of attributes that characterizes the product stimulus being perceived. Marketing literature has often defined a product as a bundle of need-satisfying components, a bundle of expectations, or a bundle of attributes. Using the 'bundle of attributes' notion in our proposed framework allows us to fully develop the idea of tangibility. To do this we must first digress to the concept of cognitive structures since developments in cognitive psychology support the relevance of the tangibility issue.

We agree with Olson's (1983) assertion that the most generally accepted conceptualization of a cognitive structure is that of an associative network where each mental representation or cognition represents a node in a network, with all the nodes being linked through associations or arcs. Recent work in this area has addressed such issues as: (1) the development of hierarchical models of cognitive structure (e.g. Olson & Reynolds, 1983) and (2) the use of cognitive structure as the basis for the consumer's heuristics in retrieving and processing information stimuli from cognitive "schemas" (Graesser & Nakamura 1982). It is suggested that PM is a necessary but not sufficient condition for the development of cognitive structures and schemas. We believe that without the individual's perceptual meaning responses, several (if not all) of the cognitive structural nodes would be "meaningless."

Observing many current consumer behavior models of cognitive structures, one can see labels for components of a product such as: product attributes physical and pseudophysical characteristics and concrete attributes and abstract attributes (Olson & Reynolds 1983). In spite of differences in semantics, we will look at attributes as the product's unit of analysis (as opposed to need-satisfying components or expectations). The categorization of product attributes in terms of tangibility has also been discussed by Hirschman (1979, 1981), Garner (1978), and Holbrook (1978).

Based on the previous arguments, we define tangible product attributes as objective, verifiable features of the product stimulus. Intangible product attributes are defined to be subjective impressions of the product under consideration, ascribed by the consumer onto the product stimulus.

Perceptual Modes

The second element of the FPMP addresses the perceptual modes--ways people tend to perceive--that consumers exhibit. Hirschman (1979, p. 10) states that: "After years of empirical investigation, there is substantial evidence which suggests that the recognition and identification of a stimulus by an individual are both 'data driven' and 'concept driven' to use the terminology of Norman (1976)." "Data driven" refers to features of the

perceptual stimulus that are acquired through the individuals' senses from the outside, physical environment (i.e., the product) and "concept driven" refers to the cognitive data that are the result of the individual's processing of the information received through the senses, and then ascribed onto the stimulus.

In developing the psychological meaning of a particular product stimulus, the consumer gathers the product's tangible attributes through his/her five senses. Here, data driven perception is at work, given the objective, verifiable elements of the product under consideration. In the same manner, the consumer's cognitive associations or abstractions bring about intangible attributes that are ascribed onto the product in question. At this stage, we have concept-driven perceptual modes bringing about the subjective impressions associated with the product stimulus.

Meaning in Context

The last element said to be influential on the process whereby individuals derive the psychological meaning of products, was said to be a trichotomy of context variables. The basis for this contention is the work of Peter and Olson (1983) who state that when considering meaning, one should always think of meaning in a given context. In order to formalize then, the idea of the meaning of a product having always to be considered as meaning in context, we can turn to models of consumer behavior.

Models of consumer behavior (e.g. Nicosia (1966), Howard Sheth (1969), Engel, Blackwell & Kollat (1978)) as well as the general developments in marketing and consumer behavior theory (e.g., Lutz 1981) of the last twenty years, allow us to identify three major categories of intervening or determining variables that are proposed to have an influence in the development of the consumer's PM. These categories of variable are: individual characteristics, social characteristics, and situational characteristics.

Individual characteristics manifest themselves primarily within the individual. Variables that reflect the social reality of the consumer's immediate environment may be labeled social characteristics. Situational characteristics refer to the general situations that the consumer is confronted by and interacts within.

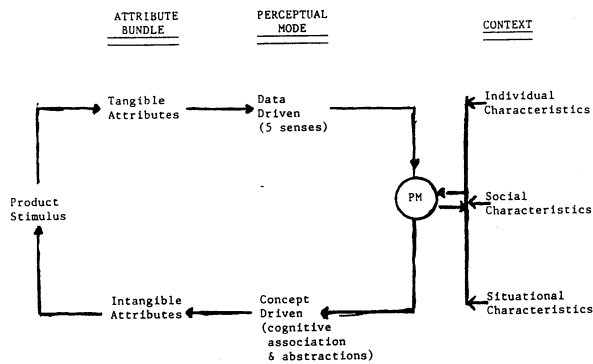

These purposefully widely labeled categories are each clearly representative of a vast array of issues/variables/constructs currently accepted as related to consumer behavior. The proposed FPMP does not attempt to list all the variables in the above categories. The framework, however, does highlight the typology of variables seen as formalizing the notion of meaning in a given context.

The proposed framework is graphically represented in Figure 1, and is intended to reflect how the psychological meaning of products comes about. The psychological meaning that consumers hold about product stimuli is dynamic in nature. This dynamism can be observed in Figure 1. The consumer gathers information about the product's tangible attributes through data-driven perception. At this stage, the consumer's senses are at work. The consumer can also operate in a concept driven mode. In such mode, cognitive associations and abstractions bring about intangible attributes which the consumer ascribes onto the product. At the same time, the context within which the perceptual process is taking place affects the consumer's derivation of psychological meaning. The consumer's individual, social and situational characteristics as the relevant elements at this stage.

The end result of the process depicted above, is that bundle of components derived earlier on this paper, which is said to represent a person's subjective perception and affective reaction to a product stimulus--the psychological meaning of products.

FIGURE 1

FRAMEWORK OF PSYCHOLOGICAL MEANING OF PRODUCTS

Research Questions

The FPMP is thought to highlight the typology of variables affecting the process of how the psychological meaning of a product stimulus is derived by the consumer.

Close examination of the major labels presented in the framework permit us to visualize a number of possible general research questions. Several of these research questions are now presented to illustrate the variety of issues the FPMP is believed to be applicable to, as well as serving as a foundation from which to develop specific, testable hypotheses.

R.Q.1. IS THE STRUCTURE OF P.M. SUCH THAT WE CAN OBSERVE GROUP DIFFERENCES IN THE COMPONENTS OF MEANING AND THEIR SALIENCE?

This first research question addresses the very core of PM. It does so by tapping into Osgood's (1952) conceptualization of meaning as a bundle of components as well as the salience of the components of meaning previously discussed.

The next three research questions are closely related:

R.Q.2. WILL MANIPULATIONS OF THE CONSUMER'S COGNITIVE ASSOCIATIONS/ABSTRACTIONS HAVE A SIGNIFICANT IMPACT IN THEIR PM OF PRODUCT STIMULI?

R.Q.3. WILL MANIPULATIONS OF THE LEVEL OF TANGIBILITY OF A PRODUCT STIMULUS HAVE A SIGNIFICANT IMPACT IN TERMS OF CONSUMERS' PM?

R.Q.4. HOW WILL THE INTERACTIVE EFFECT OF MANIPULATING COGNITIVE ASSOCIATIONS AND ABSTRACTIONS TOGETHER WITH THE LEVEL OF TANGIBILITY OF A PRODUCTS STIMULUS AFFECT PM?

Questions 2 through 4 address the interaction between the product's attribute bundles and the individual's perceptual modes. Given that intangible attributes are the result of cognitive associations and/or abstractions, one could assume that if we were to appropriately manipulate the latter, the relationship and thus impact on PM should be observable. That is what R.Q.2 asks. Addressing the other half of the interactive process between the individual and the product stimulus, R.Q.3 proposes the manipulation of the tangible attributes. These are the attributes captured through the consumer's data driven perceptual mode. R.Q.4 is a logical corollary, questioning the effect that joint manipulations could have on PM.

R.Q.5. WILL MANIPULATIONS OF CONTEXT VARIABLES HAVE A SIGNIFICANT IMPACT IN CONSUMER'S PM OF A GIVEN PRODUCT STIMULUS?

This question addresses the postulate and arguments that meaning is always derived in a given context. A natural inquiry, therefore, would be to observe the effects that manipulating the context variables would have on PM. This is a particularly rich area of research due to: a) the vast array of potentially relevant context variables within each of the categories presented in the FPMP and b) the possible interactions among the variables.

R.Q.6. WILL SIMILAR PRODUCTS AT DIFFERENT STAGES OF THEIR PRODUCT LIFE CYCLE SHOW SIGNIFICANT DIFFERENCES IN TERMS OF THE CONSUMER'S PM?

From a managerial perspective, this question addresses one example out of a variety of marketing concepts that may be researched in terms of their potential impact on the PM of product stimuli.

R.Q.7. CAN THE FRAMEWORK BE USED THROUGHOUT OLSON'S (1983) CONTINUUM OF CONSUMER MEANING VARIABLES?

If the above framework is theoretically sound, then the consumer's continuum of meaning described earlier (corporation, product, brand, product attribute) could be addressed without major adjustments in our conceptualization (for instance, focusing on a specific brand name as the stimulus cue versus the product stimulus currently being proposed).

Conclusion

Arguing that the psychological meaning of products demands more attention than consumer behavior researchers have given it up to now, a Framework of Psychological Meaning of Products was derived borrowing from several research fields. The theoretical foundations of the FPMP were also addressed by research questions provided to suggest the perceived opportunities for scholarly investigation in this topic.

METHODOLOGICAL LIMITATIONS OF THE HEDONIC CONSUMPTION
PARADIGM AND A POSSIBLE ALTERNATIVE: A SUBJECTIVIST APPROACH

Laurel A. Hudson, Virginia Polytechnic Institute and State University
Jeff B. Murray, Virginia Polytechnic Institute and State University

Abstract

The concept of hedonic consumption has not been as useful as could be or progressed as rapidly as possible. This paper seeks to examine the inconsistency of the hedonic consumption paradigm with the ontological and epistemological assumptions of the objectivist perspective. Because the paradigm is more consistent with the subjectivist perspective, suggestions are made regarding the type of research methods to utilize.

Introduction

There has been considerable frustration and dissatisfaction expressed with the research done in the area of hedonic consumption (Hirschman and Holbrook, 1982). The purpose of this paper is not to review the literature in the related fields of culture production systems (Becker 1973), motivation research (Dichter 1960), product symbolism (Levy 1959), and hedonic response in consumption (Hirschman and Holbrook 1981) but to suggest that the long-term contribution of these areas may be limited by researchers' choice of epistemological assumptions and research techniques. These perspectives all emphasize the subjective sensations that are evoked within the consumer by the product (Hirschman and Holbrook 1982, Hirschman 1983). Since these sensations vary a great deal across consumers, objective research methods designed to control extraneous variables across a population may not be appropriate. Certainly a novel, painting, or album remains constant in an objective sense, however, its interpretation by the consumer is probably unique. Each consumer will experience a different emotional and intellectual response to the art work (Hirschman 1983). The research questions that are being addressed must be a guide to the type of methodologies employed.

The purpose of this paper is first to compare for consistency the theoretical assumptions and questions of the hedonic response paradigm with the assumptions of the research methodologies used in this paradigm. A central theme of the paper is that there is an inconsistency. Based on the theoretical framework, the hedonic response in consumption can only be understood within the frame of reference of the participant, as opposed to the frame of reference of the observer of the action. Assuming that the variance of response is great, focusing on the central tendency will lose the richness, uniqueness and totality of the data. Therefore an objectivist approach is inappropriate and will limit the development of the research tradition. A subjectivist approach is more consistent in addressing the questions raised by the hedonic consumption paradigm. Lastly this paper will introduce subjective research approaches which are more consistent with the theoretical assumptions of this paradigm.

The Hedonic Consumption Paradigm

The hedonic consumption paradigm is concerned with those aspects of consumption that relate to the multisensory images, fantasy, and emotive aspects of product usage (Hirschman and Holbrook 1982). By multisensory, Hirschman and Holbrook (1982) mean the receipt of experience in "multisensory modalities including tastes, sounds, scents, tactile impressions and visual images." Multisensory images might involve subjectively recalling an actual event, or the imaginary construction of a unique sequence of events. Emotional arousal is proposed to be a significant motivation for the consumption of certain products. The perspective's content for analysis, therefore, is the subjective feelings and fantasies which arise from the consumption experience.

There is a growing body of empirical research suggesting that sensory-emotive stimulation seeking and cognitive information seeking are two independent dimensions (Hirschman and Holbrook 1982) and that emotional desires may override utilitarian motives at times (Ahtola 1984, Hirschman and Holbrook 1982). This means that traditional perspectives in consumer behavior do not take into account the full scope of buying behavior and product usage. If consumers imbue a product with subjective meaning and if emotional desires influence utilitarian motives, then traditional consumer research ignores important aspects of the consumption process. Hirschman and Holbrook (1982) argue that the hedonic viewpoint represents an important extension of traditional consumer research and offers a complementary perspective for conceptualizing many otherwise neglected consumption phenomena. The hedonic approach, providing it can deal with methodological problems, may take us further toward comprehending the complexities of consumption. Let us now examine the objective versus subjective positions while reviewing the concerns of the hedonic consumption research stream.

Subjective Versus Objective Approach

Different ontologies and epistemologies are likely to incline the social scientist toward different methodological techniques. The range of choice is so large that what is regarded as "science" by the traditional "natural scientist" covers but a small range of options (Burrell and Morgan 1979). Different philosophical assumptions cluster together to form different approaches to social science. The objectivist and subjectivist approaches will be examined in this section.

What will lead us to the decision of which methodology to use? This depends on the questions being asked and how the method fits with the assumptions the researcher is making. It also involves a question of what your social group accepts. The latter is a question that cannot be ignored as evidenced by the adherence to the positivist (objective) perspective often in spite of deficits and inconsistencies with theories. Many of the problems with the positivist perspective have been delineated elsewhere (Peter and Olson 1983, Anderson 1983) so will not be delved into here. Anderson (1985) and others (Olson 1981) also point out that there seems to be more acceptance of questioning the adherence to positivism. However, here we will focus on the former aspect in looking at the ontology and epistemology of the subjective and objective perspectives.

One of the problems of dealing in this philosophical area is the plethora of definitions. In this paper, at the extreme, we will characterize objectivity as "aiming to establish law-like associations between brute data" (Rubinstein 1981) and the expression of positivism which includes an emphasis on precise operationalization and quantification with the objective of scientific knowledge being prediction. Subjectivity, on the other hand, does not view the discovery of causal laws (nomothetic) as its goal, but rather examines the meaning of human action with the goal of attaining understanding. Thus, behavior then cannot be reduced to brute data, but must be interpreted (Rubenstein 1981). This research process is largely descriptive and tends to be holistic in its approach. Parenthetically, it is important to point out that the authors feel that there is no dualism, but objectivism and subjectivism lie on a continuum. However, our behavioral research traditions have tended to portray a dualism with objectivism being more emphasized than the subjectivism end of the continuum.

In actuality, there is no completely objective research. Researchers are constantly faced with the need to interpret and make judgments which range from deciding which questions to include on a survey, to how they are worded, to which variable to place first in a regression equation. A continuum would seem to better characterize research techniques and processes.

Fundamental Debates Over the Nature of Social Science

In order to understand the alternative points of view, it is important that a researcher be aware of the assumptions underlying the perspectives. As mentioned, different assumptions are likely to incline that social scientist toward different methodological techniques and provide philosophic guidelines for further development of the conceptual area (Anderson 1982). Two sets of assumptions will be further examined in this section which outline the extremes of the subjectivist-objectivist continuum. The assumptions are presented below as two philosophical debates: the ontological and epistemological.

The Ontological Debate

Ontological assumptions are concerned with the very essence of human nature and the "reality" to be investigated. These assumptions define the entities which are encompassed within this theoretical perspective. The social scientist's view of the external world and of an individual's relationship with this world will have definite implications regarding the kind of research program the scientist accepts as valid. Four assumptions will be defined in the context of the subjectivist-objectivist continuum. These assumptions are as follows: realism, nominalism, determinism, and voluntarism.

In the extreme, the objectivist approach assumes a realist and deterministic orientation to the external world and man's relationship with it. A realist believes that the social world is made up of hard, tangible, and relatively immutable structures which exist independent of the mind of the individual and operate whether or not the individual is aware of them (Pfuhl 1980). These elements have inherent meanings regardless of the individual. Concepts such as "mind," "self," and "social structure" may not exist in a concrete sense, but can be operationalized and measured empirically (Rubinstein 1981). Both cognitive (Fishbein and Ajzen 1975) and behavioral (Nord and Peter 1980) programs in consumer behavior accept the realist assumption. A "determinist" simply regards humans and their activities as being completely caused by the situation or elements in the environment in which they are located (Burrell and Morgan 1979). The behaviorist program for instance states that the individual experiences consequences which in turn determine future behavioral responses. If the external world is "real" in an empirical sense, and imposes itself on individual consciousness from without, then behavior, at least in part, is determined by the environment.

In the other extreme, the subjectivist approach assumes a "nominalist" and "voluntaristic" position to the external world and man's relationship with it. A "nominalist" orientation assumes that the individual uses names and labels to structure and make sense of the external world. Things do not have inherent meaning, but human concepts are imposed on objects (Pfuhl 1980) in order to structure reality. Words do not represent empirical entities, they are purely conceptual and exist only in the minds of the participant. It is therefore diametrically opposed to the realist position. From this perspective, the external world exists only in the subjective consciousness of the humans who have been socialized to that world. The external world, therefore, is names and words whose utility is based upon their convenience "as tools for describing, making sense of and negotiating the external world" (Burrell and Morgan 1979, p. 4). From this perspective, the words "mind," "self," and "social structure" are symbols which will have a

variety of meanings depending on the person who is thinking about them.

A "voluntarist" assumption views an individual as an active agent who interacts with his environment rather than is controlled by it. Humans from this perspective are symbol-producing, meaning-seeking creatures who have a certain amount of control over their lives (Pfuhl 1980, Schroyer 1970). The cognitive program, for instance, accepts a voluntaristic concept of human nature, stating that humans develop beliefs, attitudes and intentions which cause behavior.

Insofar as consumer behavior is concerned with human activities, at a basic level, consumer behavior theorists must implicitly or explicitly adopt a stance along these points of view and be aware of these assumptions. The definitions of the different assumptions outlined above represent extremes, there are, of course, intermediate standpoints which allow for the influence of both situational and voluntary factors.

The Epistemological Debate

Epistemological assumptions are concerned with how we obtain our knowledge of the world. These assumptions entail ideas about what is to be regarded as true and what is to be regarded as false (Burrell and Morgan 1979). As stated in the introduction, a central theme of this paper is that hedonic response in consumption might be better understood within the frame of reference of the participant, as opposed to the observer of action. This is an epistemological issue since it relates to how knowledge about the external world and human's relationship with it is acquired. This debate also includes four basic assumptions which need to be defined in the context of the subjectivist-objectivist continuum. These assumptions are as follows: positivism, anti-positivism, nomothetic and idiographic.

In the extreme, the objectivist approach assumes that credible knowledge can only be generated by making positivist and nomothetic assumptions. A "positivist" orientation assumes the existence in nature of an inherent order that can be discovered by the rational capacities of the researchers (Schroyer 1970). Once regularities and causal relationships of the "inherent order" are discovered, this knowledge can be used to explain and predict (Burrell and Morgan 1979). Positivism is based on the fundamental assumption that propositions are meaningful only if they can be empirically verified (Anderson 1983). Both the logical empiricists and the falsificationists would accept the notion that the growth of knowledge is essentially a cumulative process in which new insights are added to the existing stock of knowledge and false hypotheses eliminated (Anderson 1983, Burrell and Morgan 1979).

A "nomothetic" approach to social science emphasizes the importance of basing your research on systematic protocol and technique. A science which is "formal" in the sense of being a logical system would be nomothetic. The aim of this approach is to discover general laws (Rubinstein 1981). Examples of methodological techniques which would be consistent with both the positivistic and nomothetic assumptions are surveys, experimentation, standardized instruments and personality tests.

From the subjectivist perspective, credible knowledge can only be generated by making anti-positivist and idiographic assumptions. The "anti-positivist" would reject the notion that science can generate objective knowledge of any kind (Burrell and Morgan 1979). This assumption considers the social world to be essentially perceptual and can only be understood from the point of view of the individuals who are directly involved in the activities which are to be studied (Burrell and Morgan 1979). The world can only be understood by allowing the subject to unfold its nature and characteristics in order to obtain an understanding of his motives, meanings and other aspects of his subjective experience (Rubinstein 1981).

The "idiographic" assumption stresses the importance of particular decisive events rather than aiming to discover general laws (Rubinstein 1981). The idiographic mode of explanation will incorporate many different factors, including "accidental" or "exceptional" occurrences in order to increase the plausibility of the research (Smelser 1976). The nomothetic mode of explanation increases sample size until the central limit theorem makes it logical to exclude extraneous causes. This establishes the strength of the supposed causal relation. The ideographic mode of explanation will decrease sample size until the extraneous and unique become conspicuous and, therefore, significant. Examples of methodological techniques which would be consistent with both the anti-positivistic and idiographic assumptions are content analysis, participant observations, ethnographies, case studies, and certain types of comparative-historical analysis.

The Model

The model in Figure 1 diagrams the subjective/objective continuum. The extremes begin with ontological and epistemological assumptions and end with methodological techniques which are consistent with the assumptions made. Adjacent to this model is a continuum of products representing products which tend to be subjectively experienced on the left and products which tend to be objectively experienced on the right. The continuum is a qualitative figure meant to give some indication of the kinds of assumptions and, therefore, methods which would tend to be appropriate for different kinds of products. Its purpose here is primarily for conceptual clarity since the two diagrams together illustrate the theme of the paper regarding the choice of methodology.

Hedonic Consumption and the Objectivist Approach

According to Hirschman and Holbrook (1982), one objective of hedonic consumption research is to monitor and, if possible, to predict emotional reactions and fantasy imagery during product usage. They suggest a combination of two approaches to accomplish this research objective, traditional scaling techniques and physiological indices of arousal.

In terms of the first, there are two primary sources from which to draw Zuckerman's (1979) "sensation seeking scale" and Hilgard (1970) and Swanson's (1978) "absorbing experiences scale."

Both the sensation seeking and absorbing experiences scales are readily administered in survey research designs and are, therefore, potentially usable in the large sample studies favored by marketing researchers (Hirschman and Holbrook 1982, p. 98).

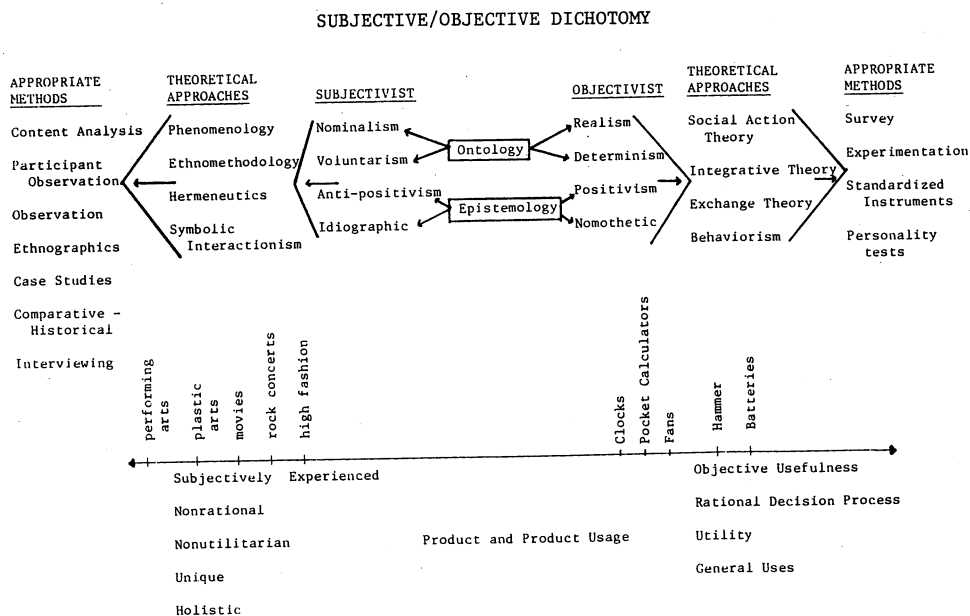

The second suggested approach involves measures of physiological changes which are stimulated by emotional arousal. This approach will measure chemical fluctuations in blood serum and cortical areas of the brain (Kroeber-Riel 1979); and alterations in vital signs which might indicate arousal and excitement (Schachter and Singer 1962).

The hedonic consumption perspective to date has assumed that an objectivist approach should be used simply because this approach is favored by marketing researchers. However, Hirschman and Holbrook (1982) openly acknowledge the inadequacies of this approach, stating that it is static in nature and, therefore, poorly suited to trace the "dynamic changes in the consumer's general degree of hedonic effort and capacity," that there is not the capacity to measure emotional arousal and multisensory imagery, that the product varies across time thereby decreasing the reliability of measures. Assuming that the defining element of science is that of "societal consensus" (Anderson 1983), the appropriateness of a subjectivist method becomes secondary to the more important issue of: "what methodologies will convince the marketing community of the validity of a particular theory" (Anderson 1983). Since interest in alternative approaches seems to be increasing, the place to begin is with an examination of how the questions asked in the hedonic consumption perspective might be better addressed by the subjectivist approach. Again, by stating that one cluster of assumptions may prove more fruitful for hedonic consumption than another, a relativist stance is being taken. This is not meant to advocate that one set of assumptions is legitimate and the other isn't; it depends on the research questions the researcher is asking.

Hedonic Consumption and the Subjectivist Approach

The subjectivist approach seems to be more consistent with the hedonic consumption perspective. The definitional aspects of hedonic consumption used by Hirschman and Holbrook (1982) are inconsistent with the objectivist approach: "esthetic, intangible and subjective aspects of

FIGURE 1

consumption," "multisensory, fantasy and emotive aspects of one's experience with the product," "products are viewed not as objective entities, but rather as subjective symbols," "the consumer's internal construction of reality may not be congruent with the external, objectively verifiable world," "then it is likely that such products may also be experienced at gestalts." (Emphasis added). Additionally, as Rubinstein (1981) points out, objectivists tend to either delete the concept of mind or operationalize the concept in the form of "brute data." But the concept of the mind is the very basis of the hedonic consumption conceptualization.

Two other concerns regarding the objectivist approach make the subjectivist approach more appealing. First is the riskiness of the choices the researcher has to make with regard to what variables are important and consequently what questions should be asked in the instrument or what specific behaviors observed. Although these are "objectivist" techniques, it is clear that these judgments (subjective) are risky in that they may be biased and also may miss important elements by not allowing the subject to unfold his or her experience. The second concern is the lack of a holistic approach. The tendency toward reductionism of variables in the objectivist approach deters the researcher from an understanding of the "whole picture," the gestalt, the context, which is fundamental to a subjective experience.

Hedonic Consumption Studies

As mentioned, the positivistic approach has tended to be the most accepted in marketing and consumer research. This is reflected in the research that has been done in the hedonic consumption area and even in the framing of the questions to be addressed. Questions regarding the amount of emotional arousal and degree of tendency toward absorbing experiences are quantifiable, but certainly miss the rich foundation of the conceptualization.

There has not been a lot of research done in the hedonic consumption area, probably due, in part, to its lack of consistency with the accepted objectivist perspective. As mentioned this objectivist perspective has however still been applied to research in this area. For example, Holbrook, Chestnut, Olivia and Greenleaf (1984) examined the relationship between a personality variable, type of product, observable behavioral performance and emotion (as measured by a multi-item scale). The consumptive experience dealt with was play. Andreasen and Belk (1980) looked at predictors of attendance at the performing arts. They utilized surveys to obtain information about lifestyles, attitudes and behavior toward specific performing arts and socioeconomic characteristics. The questions were derived from other research studies, from introspection and from focus-group interviews. The focus-group interviews would be consistent with the subjectivist perspective. Hirschman (1982) examined ethnic variation in hedonic consumption. The variables examined with regard to ethnic variation were projective behavior, imagery, favorite physical activities, enthusiasm, and motives. All were measured by either multi-item scales or lits.

A study which was based on the subjectivist perspective was that of Levy (1981). He used depth interviews involving story telling to give him a holistic, symbolic understanding of food consumption.

The Subjectivist Alternative

Well aware of the risks of trying to reduce the concepts to a short introduction, the authors will nevertheless attempt to very briefly present three categories of subjective assumptions and several of the methodologies associated with them that could be utilized in the study of hedonic consumption.

Interpretive Methodological Techniques

We have emphasized that products such as art, novels, movies, or music seem to inherently inspire a high level of subjective response. These products need to be "interpreted," not merely consumed sensorially.

There is a great array of interpretive research methods that could be applied to the study of hedonic consumption. Basically these methods fall into three categories: interviews, observation, and examining residues. The first category might include in-depth interviewing, focus groups, or informant interviewing (c.f. Lofland and Lofland 1984). The second involves observing the phenomenon. This entails the participant-observer method which might range from complete participant to complete observer (c.f. McCall-Simmons 1969, Schatzman and Strauss 1973). The third category is that of examining residues. This includes document analysis, historical records, archives, photographs, official statistics, content analysis, erosion and accretion measures (c.f. Webb, Campbell, Schwartz, Sechrest, Grove 1981, and Van Maanen, Dobbs and Faulkner 1982). These methods are consistent with the interpretive approach and therefore can be applied very productively to the study of hedonic consumption.

The Interpretive Approach

The history of the interpretive approach has led to the construction of a great many theoretical perspectives. Three general categories are phenomenology, ethnomethodology and hermeneutics.

Edmund Husserl (1859-1938) is widely regarded as the founder and leading proponent of phenomenology. For this perspective, the study of society becomes the study of individual mental states and experiences the consciousness of individual social actors. It emphasizes an interpretive understanding of common-sense thought, the taken-for-granted (Rubinstein, 1981). According to Natanson (1966), the objective of phenomenology is for the researcher to transcend these "natural attitudes of daily life" in order to study them. Methodologically, phenomenology involves taking as little for granted as possible. Methods aim at suspending or "bracketing" investigators' presuppositions. There is a reliance on experience-oriented methodology. Thus, after they have tried to suspend all of their own common sense judgments, phenomenologists place themselves in everyday life situations and then examine their own experiences and meanings (Rogers, 1983). "A cardinal feature of interactionist research is the casting of the researcher's self into the position of those he is studying" (Douglas, 1970).

The participant-observer technique, positioned at the participant end is the most obvious method consistent with the approach. Research situations where the investigator actually becomes part of the situation ("experiences" the situation) and then records his/her stream of thought would exemplify the method. With regard to hedonic consumption, these situations might include the investigator experiencing the theatre, an art exhibit, a concert, the interior design of a room, or perhaps even law school as a student.

The research question in ethnomethodology is HOW some outcome is routinely achieved in practice. It is assumed that in each situation, individuals will find meaning in social interaction in light of their own presuppositions and interests (Campbell, 1981). The social reality is constructed by the participants themselves, not reconstructed by the researcher. Emphasis is placed upon the researcher's unmediated interaction with the subjects of inquiry, and description of the behavioral systems in the subjects own terms (i.e. classification system, nature typologies, accounts). Again, an attempt is made to eliminate any distortion the researcher may make due to his or her own ethnocentric categories. At a minimum, a researcher's account is submitted to the native community for verification and for explanation. Further attempts are made to avoid researcher bias by collecting

as much information as possible in the terminology used by the subjects. This is important because the words and their meaning serve as a native principle to organize and categorize behavior within a community and culture. It is often easiest to tape record all interview material. Additionally, translation and summarization are to be avoided. Often summarization is used to produce public records but eliminates a large portion of the actual situation (Knorr-Cetina, 1983). An example might be a surgeon's written summarization of a surgical procedure versus a verbatim account or a marketing textbook discussion of consumer decision making versus the verbatim account of two consumers during their decision making. Appropriate techniques might include participant-observation (more at the observer end), interviewing, document analysis, etc. Thus, during intermission, a researcher might locate themselves in a convenient place and record comments made regarding a theatre performance or make a continuous record via photography of facial expressions and physical positioning of a row of people during a wrestling match. Ethnomethodology is meant to describe the "native way" of performing tasks of living.

In hermeneutics, the researcher is viewed as an interpreter. Individuals externalize internal processes through the creation of external artefacts such as works of art, language, laws, rituals, institutions, literature, etc. Understanding of these productions of the human mind which characterize the social and cultural world can be obtained through interpretation of these artefact symbols (Bauman, 1978). There is a message or meaning being communicated from the producer of the symbol to the interpreter. In recent years Gadamer has emphasized language as it is viewed as the mediator of experience, social order and social life (Giddens 1976).

Methodological techniques might include document analysis, content analysis, use of photography, analysis of historical records, analysis of creative works, etc. An investigator of hedonic consumption might make the technology of film-making accessible to individuals attending a football game and ask them to produce a film exemplifying the experience of attending a football game.

Conclusion

This paper assumes the position that an interpretive approach should be taken as we investigate more deeply the subjective responses consumers have to the products they encounter. Since subjective response can only be understood within the frame of reference of the participant, an objectivist approach is inconsistent with the goals of the paradigm. Inconsistency between the assumptions of the conceptual paradigm and the research methods used will hinder the discovery and growth process.

THE MICAWBER CONNECTION: SUBJECTIVE DISCRETIONARY INCOME

William D. Wells, Needham Harper Worldwide

and
Martin I. Horn, Needham Harper Worldwide

Abstract

This paper presents a tentative operational definition of Subjective Discretionary Income. It demonstrates the construct's predictive power, and shows some ways this construct can contribute to our understanding of consumer behavior.

Subjective Discretionary Income

Some people with high incomes cannot pay for everything they think they need, and some people with low incomes seem to get along very well with what they have. In David Copperfield, Mr. Micawber said it best: "Annual income twenty pounds, annual expenditure nineteen six, result happiness. Annual income twenty pounds, annual expenditures twenty pounds ought and six, result misery." (Dickens 1849-1850).

Economists have captured the causal part of this relationship in the term "discretionary income" i.e., "personal income less what is spent on necessities." And, following Mr. Micawber, they have found that discretionary income is better than unmodified income when it comes to gauging "family well-being" (Morgan and Duncan 1980).

One problem with "discretionary income" is that its definition contains the term "necessities." Specification of "amount spent on necessities" requires arbitrary decisions as to what is necessary and what is not, and complex adjustments for household size, area of residence and other demographic characteristics (Katona 1975; Linden, Green and Coder 1982). These decisions and adjustments are inevitably difficult, and they may require information which has not been or cannot be collected.

Another way to define discretionary income is to take the subjective route, as in "true" or "false" responses to the following statements:

- 1) We have more to spend on extras than most of our neighbors do.
- 2) Our family income is high enough to satisfy nearly all our important desires.
- 3) No matter how fast our income goes up, we never seem to get ahead.

A person who answers "true" to statements 1) and 2), and "false" to 3) is arguably higher in subjective discretionary income than is a person who answers in the opposite direction. The result of 1)+, 2)+, 3)- may not always be happiness, but the result of 1)-, 2)-, 3)+ seems pretty likely to be misery.

In addition to predicting family well-being, this definition of Subjective Discretionary Income helps explain certain kinds of purchasing behavior. As economists have always known, people who have high incomes buy more of almost everything than do people who have low incomes. But there is more to the story.

The Literature

The related literature comes from economics, home economics and sociology. "Discretionary income" comes from traditional economics. While the concept is familiar and widely used, it is extremely difficult to operationalize, especially in research on buyer

behavior. Who is to say what should, and what should not, be counted as "necessities"? And who is to say how much of the money spent on food, for instance, is "necessary," and how much is luxurious?

"Life Satisfaction" is another related research area. Here, the intent is to determine what variables contribute most to an overall sense of well-being. One of the most consistent findings within this body of research is that assurance of a good income is a very important predictor (Bhardwaj and Wilkening 1977; Cantrill 1965; Dickens 1849-1850).

Most directly relevant is the literature on "perceived economic well being." Although this literature is not entirely consistent, a few generalizations can be made. First, although real income is correlated with perceived economic well-being, the two are far from synonymous (Williams 1983). Other major predictors are indebtedness, perceived expertise as a money manager, retirement concerns and a general sense of perceived security (Dunsing 1983).

So, from classical economics we have borrowed the concept of discretionary income: that which remains when one has purchased what is "necessary." From Sociology we have borrowed the concept of "life satisfaction." From home economics we have borrowed "perceived economic well being." And we owe a primary debt to Charles Dickens.

The Study

Data for this study came from the 1984 Needham Harper Lifestyle survey. Each year approximately 3500 U.S. adults fill out an extensive questionnaire. The instrument is administered via the mail to a national quota sample drawn from Market Facts' Consumer Mail Panel. A small gift is offered to encourage response. In 1984 response rates were 74.7% for men and 86.4% for women.

The instrument measures a wide array of attitudes, interests and opinions, personal and household purchases, product ownership, purchase intentions and media exposure patterns, as well as standard demographics. Both the instrument and the sampling procedure have undergone refinement every year since the study's inception in 1974 in an attempt to achieve reliable, valid and generalizable findings.

Three items consistent with the Subjective Discretionary Income concept are scattered among the 221 attitude and opinion measures in the Needham Lifestyle instrument. The three items are:

- 1) We have more to spend on extras than most of our neighbors do.
- 2) Our family income is high enough to satisfy nearly all our important desires
- 3) No matter how fast our income goes up we never seem to get ahead.

The statements are answered on a six point scale, with definitely disagree (1), and definitely agree (6) as anchor points. When the responses for the three items are summed, with the last item reverse coded, the result is a score with a range of three to eighteen. Respondents who score high on this scale are indicating that they have enough money to buy what they think they need, and then some. Respondents who score low are saying that they have a tough time simply making ends meet.

This study answered three questions: (1) Was Mr. Micawber right about misery and happiness? (2) Does Subjective Discretionary Income add predictive power to a basic demographic model? And, (3) How can we best characterize individuals with disparate levels of Total Family Income (TFI) and Subjective Discretionary Income (SDI)?

The Micawber question was answered with simple correlations reported in the Findings section of this paper. Questions (2) and (3) required methods which need some explanation.

SDI as a Predictor

To determine whether SDI adds predictive power to demographic variables, we constructed a simple demographic model. The model includes: total family income, household size, and lifecycle. The first two variables are self defining. The third includes chronological age, the presence or absence of children, and the children's stage of development. The lifecycle variable was defined as follows:

- 1= no children, respondent is less than 35 years old.
- 2= respondent has children; youngest child is less than six years old.
- 3= respondent has children; youngest child is 6-12 years
- 4= respondent has children; youngest child is 13-17 years
- 5= no children at home; respondent is at least 35 years old.

Total Family Income, Household Size and Lifecycle formed a demographic model against which we tested SDI's power as an additional predictor of buyer behavior. The first variable, TFI, indicates how much total money was brought into the home in calendar 1984. The second variable, Household Size, indicates how many individuals were in the respondent's household in that year. This variable is particularly important since it indicates among how many individuals Total Family Income must be divided. The third variable, Lifecycle, combines the effects of chronological age and the changing consumer needs and wants brought about by growing children.

Since this three-variable model should be very predictive in and of itself, it provides a tough test of SDI's ability to tell us something that we did not already know.

The three demographic measures were simultaneously entered into a regression equation. A test was then performed to see whether SDI would contribute significant additional explanation of the dependent measures. Since the dependent measures were either binary (owned; did not own) or ordinal (high, medium, low consumption) we used a logistic regression (Harell 1983; Press and Wilson 1978). The criterion for SDI's entry into the equation was a change in the adjusted chi square Q statistic (see Bartolucci and Fraser 1977) significant at the .05 level or beyond.

We explored a wide array of dependent variables, including consumer durables such as automobiles, personal care products such as toothpaste and deodorants, household goods and services such as food items, and use of media such as cable television.

Consumer Typologies

The third research question was: How can we best characterize individuals with disparate levels of Total Family Income (TFI) and Subjective Discretionary Income (SDI)? We addressed this question by dividing respondents into four groups. First, both TFI and SDI were split at their medians: \$25,000 per year for TFI; a score of 10 out of a possible 18 for SDI. These splits provided four groups: (Low TFI, Low SDI); (Low TFI, High SDI); (High TFI, Low SDI); and (High TFI; High SDI).

We developed "profiles" of each group by identifying the items which best typified the group. The "most typical" items were defined as items on which at least one group percentage was at least eight points higher or lower than all other group percentages. This arbitrary definition has the advantage of not being quite as cumbersome as a true multiple comparison test. Since the sample was large, the definition is statistically very conservative.

Findings

First, about Mr. Micawber

The Needham Lifestyle questionnaire contains another relevant statement: "I am very satisfied with the way things are going in my life." The correlation between Total Family Income and reported satisfaction was positive and significant ($r_s = .154$; $p \leq .0001$). But, as Dickens would have predicted, the correlation between Subjective Discretionary Income and reported satisfaction was much higher ($r = .363$; $p \leq .0001$). Mr. Micawber was right.

SDI and TFI

Subjective Discretionary Income (SDI) and Total Family Income (TFI) are related. The correlation was positive and statistically significant ($r_s = .292$; $p \leq .0001$), but far from perfect. Within every Total Family Income level, some respondents have high SDI, and some have low SDI (Table 1). We are comparing two related, but distinctly different constructs.

TABLE 1

SUBJECTIVE DISCRETIONARY INCOME BY TOTAL FAMILY INCOME

		TFI			
		<\$15,000	\$15,000- \$29,999	\$30,000- \$39,000	>\$40,000
LOW SDI		585 (18.2%)	768 (23.9%)	259 (8.0%)	156 (4.8%)
HIGH SDI		211 (6.6%)	526 (16.3%)	308 (9.6%)	407 (12.6%)

$$x^2 = 309.084$$

$$df = 3$$

$$p \leq .0001$$

SDI and the Demographic Model:

Income, family size and stage in life cycle are traditional, "hard" demographic variables; Subjective Discretionary Income is a "softer," psychological variable. Which is better at explaining consumer behavior? The answer turns out to be both interesting and complex.

The results of the logistic regressions, summarized in Table 2, will be discussed in five Outcome Categories.

Outcome Category 1 consists of goods and services for which Total Family Income (TFI) is essentially all that counts. Even though SDI meets the entry criterion, it plays at most a minor role relative to TFI. In six of the seven cases, TFI was a positive predictor of use: a microwave oven, a portable work table, an automatic electric drip coffee maker, a video cassette recorder, a plastic outdoor garbage can and plastic microwave cookware. In the seventh case, common household baking flour, TFI was negative -- i.e., low income predicted high consumption. The items for which TFI positively predicted ownership are for the most part expensive,

non-basic consumer durables. Flour, the item for which TFI predicted negatively, is basic and cheap.

TABLE 2

ADJUSTED BETA WEIGHTS FOR LOGISTIC REGRESSIONS*

Outcome Category	Good or Service	(b)	(b)
		TFI	SDI
1	Microwave Oven	7.72	3.80
	Portable Work Table	10.53	3.23
	Automatic Electric Drip Coffee Maker	9.24	2.54
	Video Cassette Recorder	8.61	2.47
	Plastic Microwave Cookware	12.36	6.06
	Plastic Outdoor Garbage Can	14.23	4.33
	Household Baking Flour	-6.96	1.94
2	Food Processor	n.s.	9.71
	Cream Cheese	n.s.	2.89
	Fresh Oranges	n.s.	2.49
	Non-Stick Cooking Spray	n.s.	2.40
	Candy Bars	n.s.	-2.47
3	Freezer	8.20	6.05
	Diet Bottled Salad Dressing	2.62	2.17
	Paper Towels	1.75	2.31
	Plastic Food Wrap	2.64	2.29
	Green Salad	3.47	4.89
	Hotel Visit (Pleasure)	8.73	6.50
	Cigarettes	-3.04	-2.58
4	Motorcycle	4.08	-2.81
	Multi-Symptom Cold Remedy	4.39	-5.14
	Potato Chips	4.05	-4.81
	Butter-Margarine Blend	1.49	-1.72
	Personal Loan Prom Commercial Bank	5.00	-5.95
	Burger King	6.66	-4.92
	Convenience Stores	3.64	-3.91
	Loan at Savings and Loan Company	2.93	-2.27
5	Cottage Cheese	-2.54	3.07
	Hi-Fiber Bran Cereal	-2.52	2.44
	Jams, Jellies and Preserves	-3.60	2.66

*Because the standard error estimates are asymptotic, the adjusted betas are not strictly comparable. They are, however, pretty close.

In Outcome Category 2, SDI carried most of the explanatory weight. It was a positive predictor of ownership or use in four cases, and a negative one in two. The positive items were food processors, cream cheese, fresh oranges, and non-stick cooking sprays. The negative items were candy bars and frozen TV dinners.

Oranges and cream cheese are natural, relatively unprocessed and simple foods. There is a wholesome quality about them. Non-stick cooking spray allows one to prepare food without adding saturated fats. In contrast, candy bars and TV dinners are highly processed convenience foods, and are generally perceived as less nutritious. The food processor's positive sign is consistent with these findings. Those who buy this generally expensive item are often concerned with nutrition, and are interested in preparing their own fresh foods rather than buying what someone else has processed, packaged and sold. Thus, the items in this outcome category reflect a health conscious group of consumers. When SDI is very important and TFI is insignificant, one observes consumption of food items which are wholesome, "natural" and nutritious.

In Outcome Category 3, TFI and SDI work together: both enter the equation in the same direction, and to a comparable and significant degree. In six of these cases both SDI and TFI were positive. In one case SDI and TFI were both negative. The positive items were: a freezer, diet bottled salad dressing, paper towels, plastic food wrap, green salad, and non-business related hotel visits. Heavy users of these items have high incomes and feel that they have extra money to spend. They are able and willing to buy what many would consider a luxury item (freezer), convenience products (paper towels, plastic food wrap), to travel for pleasure (hotel visits), and stay thin by eating green salads with diet bottled salad dressings. The single negative item was cigarettes. Users of this product have low incomes and feel pinched. It is not at all surprising that cigarettes are negatively related to the rest of the product cluster.

In Outcome Category 4, SDI was negative when TFI was positive: the higher the total family income, the more likely the purchase; but, at any level of TFI, people with low SDI are more apt to buy. The items in this category are: a motorcycle, a multi-symptom cold remedy, potato chips, a butter-margarine blend, a personal loan from a commercial bank, frequent patronage of Burger King, frequent patronage of convenience stores, and loans at both a savings and loan and a consumer finance company. The items in this group suggest a consumer who makes a good wage, but spends it on products and services with blue-collar associations.

Many of these items are purchased by consumers who live beyond their means in order to enjoy the lifestyle trappings of "the good life".

The fifth and last condition is one in which SDI and TFI are again at odds as predictors. This time, however, TFI is negative, and SDI is positive. Only three products comprise this category: cottage cheese, high fibre bran cereals, and jams, jellies and preserves. This product cluster suggests a preference for wholesome, relatively unprocessed and inexpensive foods.

So the answer to research question (2) is "yes". SDI does contribute to the prediction of consumer purchases, even when the effects of major demographic variables are partialled out. Furthermore, SDI's role in such predictions, both as to relative weight and as to sign, forms some interesting, non-obvious and intuitively appealing patterns.

Quadrant Analysis

The third research question addressed the task of profiling individuals with varying levels of TFI and SDI. By cutting TFI and SDI at their respective medians, respondents were divided into four groups: high on both Total Family Income and Subjective Discretionary Income, low on both, and two off-diagonal segments who are high on one but low on the other. When their activities, interests and opinions are contrasted, these groups present distinct lifestyle patterns. These lifestyle patterns are similar for both men and women. For the sake of brevity, we will look exclusively at the male typologies.

The descriptions below reflect each group's lifestyles relative to the other groups.

TABLE 3
CONSUMER TYPOLOGIES

MALES

A) (High TFI, High SDI): This man is the most "well off," economically and subjectively. He's more likely than other men to invest in money market funds, mutual funds, common stocks and certificates of deposit. He's less likely to adopt the philosophy

of spending for today and letting tomorrow take care of itself. He's an economic optimist. He is the least likely to believe that it's difficult to find a good job. He's more apt to believe that he will make more money next year, and less likely to believe that inflation will take a big bite out of his increasing income. He is, however, price conscious to the point of paying attention to food prices.

He lives the "good life." He eats out frequently and enjoys giving and attending dinner parties. He is a relatively heavy user of gin, cordials, liquors and after dinner drinks. He's also the most likely to visit an art gallery, and to want to live in or near a big city.

Since he has a well paying managerial occupation, he does a fair amount of traveling, occasionally outside the U.S. While much of his traveling is for business purposes, he also takes airplane trips and stays at hotels when vacationing.

He feels less pressure than most. He doesn't dread the future, wish for the "good old days", or feel that things are changing too fast today.

He's well educated (often post-graduate) and believes in making detailed plans. He is the most likely to read the Wall Street Journal, the Business section of his local newspaper, and the least likely to enjoy Country and Western music.

He's a little calorie conscious and is the most likely to consume diet sodas.

He is most likely to live in a two person household, make long distance calls, and own relatively expensive and non-essential items such as a high-priced 35mm. camera and microwave cookware.

B) (High TFI; Low SDI): This man's dilemma is that he makes a good salary, but he still has to struggle to get by. He's simply spending his money faster than he earns it. He admits that he has a difficult time saving money, and he is a heavy user of bank charge cards and credit unions. The fact that he is the father of teenagers may have something to do with this pattern. Although he invests, his investments most typically require smaller amounts of liquid capital: I.R.A.'s, retirement accounts and common stock. Still, he is interested in business matters. He is more likely to read the Wall Street Journal than are members of the two lower income groups.

He's not a very happy individual. He openly admits the desire to leave his present life behind. He feels more pressure than most, and does not believe that his neighbors perceive him as a leader. In the Walter Mitty tradition, he still believes that his greatest achievements are ahead of him.

If happiness were simply possession, this man would indeed be happy. He is likely to own relatively expensive and non-essential items such as power tools, home electronic video games, an expensive 35mm. camera, and plastic microwave cookware.

Two purely psychographic measures are worth mentioning. This individual is the least likely to describe himself as a "day person", and is the least likely to admire "a successful businessman."

C) (Low TFI; High SDI): More than a third of the individuals in this group are over the age of 65. This man, who is likely to be retired, is more inclined than other men to believe his greatest accomplishments in life are behind him.

But the picture is not entirely bleak. While his income from wages is relatively low, he has built up a comfortable nest egg which lets him enjoy life more fully (hence, his high SDI). His apparent fondness for saving his pennies is evident in his belief that one shouldn't spend for today and not worry about tomorrow, and in his greater use of savings stamps.

He is conservative, and some of his views seem old fashioned when compared to his younger counterparts. He thinks there is too much emphasis

on sex in general, and specifically on television. He is much less likely than others to care for science fiction movies; he believes the police should use as much force as necessary to preserve law and order; he believes that men should be clean shaven everyday, and that a women's place is in the home. Personal computers are new-fangled gizmos for which he has little use. And, not surprisingly, the chances of his frequenting a video arcade or playing video games at home are slim.

Being older, he tends to watch what he eats. He prefers natural foods to those that have additives. He tries to avoid caffeinated beverages and fried foods, to get fibre into his diet, and he is not inclined to eat at fast food restaurants.

He likes to read advertising supplements, Readers Digest, and watch the Today Show and Real People.

He is the least likely to describe himself as a "swinger", and the least likely to feel that he would do better than average in a fist fight.

D) (Low TFI; Low SDI): This man may well be the least fortunate of the four typologies we have met. He's not well off and doesn't feel well off either. He's an economic pessimist. He's no good at saving money, and shopping is simply no fun anymore.

His outlook on life is negative. He feels under pressure. He doesn't feel influential even in his own neighborhood. Of the four groups, he is the least satisfied with his current situation; he dreads the future and wishes for the good old days. He doesn't like to make detailed plans.

Compared to men in the other three groups, he appears to have few interests. He is less likely to have recently read a book, given or attended a dinner party, gone out to eat, gone to a club meeting, gone to the library, visited an art gallery, done volunteer work, or read the news section of his local news paper. However, he does have diversions, watching The A-Team and Knight Rider.

Money market funds, common stock, certificates of deposit or even IRA's are not part of his investment portfolio (if, indeed, he has one). He is not particularly concerned about stylish clothes, and he is the most likely of all the groups to purchase sportswear at K-Mart.

Conclusion

This paper has presented Subjective Discretionary Income, a psychological concept that adds a useful new dimension to our understanding of buyer behavior. It has also presented a three-item operational definition of the construct, and some interesting relationships among Subjective Discretionary Income, Total Family Income, and the way various purchases relate to other aspects of the purchaser's life.

We hope that the present scale will merit improvement. The three items that form the scale were all put into the survey for other purposes. A longer scale, deliberately constructed, would probably be more reliable and more valid.

We also hope that other researchers will find Subjective Discretionary Income interesting. The scale that measures it can be added to almost any questionnaire at little marginal cost, and may well be worth additional exploration. As Jack Bunsby said to Captain Cuttle et. al. in another work by Dickens (1848): "The bearings of this observation lays in the application of it."

INFORMATION UTILIZATION:
A VALIDATION STUDY

Peter C. Wilton
University of California, Berkeley

Abstract

Historically, most consumer information processing research has focussed upon the use of persuasive information in brand choice tasks. Of potentially increasing importance, however, is a second class of information which might be labelled objective, or non-persuasive, in nature. Much less is known about consumer use of this information.

In an earlier paper, we presented a reduced model of the process of utilization of objective information in consumer judgment tasks. The model has been developed and tested extensively in a series of controlled laboratory experiments. In the current paper, we present partial validation results from a field study of information use among a sample of potential adopters of a new technology. The results are strongly supportive of the proposed model and laboratory findings.

Introduction

In a series of recent articles, the process of utilization of objective (non-persuasive) information in judgment tasks has attracted the attention of consumer researchers (Deshpande and Zaltman 1982, 1984; John and Martin 1984; Wilton and Myers 1984, 1985, Sternthal and Craig 1982). As used in this paper, objective information refers to stimuli whose primary purpose is to inform, rather than persuade, consumers. Models of the utilization process have been offered for both managerial and (traditional) consumer contexts. While the unit of analysis (individuals in institutions vs individuals in households) may introduce certain context-specific model constructs, there also exist many theoretic commonalities across the two contexts. In this paper, we focus upon some of these commonalities, and report partial results of a field study designed to validate selected information utilization constructs developed and tested in a series of earlier laboratory experiments.

A Model of Information Utilization

Since this paper focusses largely on validation of a model of the utilization of objective information in judgment tasks developed in a laboratory setting (Wilton & Myers 1984, 1985), discussion of model development will here be kept relatively brief. In the section which follows, therefore, we provide only a summary description of the model, and its associated hypotheses. More elaborate discussion of utilization theory can be found in the articles referenced above, as well as Bettman (1979), Berg et alia (1978), Weiss (1979), Sabatier (1978), Gerstenfeld and Berger (1980) and, for persuasive information, Cacioppo and Petty (1983) and Mitchell (1983).

Previous studies of the utilization of objective information have generally suffered from one or more of the following limitations. First, there appears to be a paucity of empirical data amenable to controlled hypothesis testing, particularly among (but not limited to) studies reported outside the marketing discipline. Second, among causal studies supported empirically, there remains considerable ambiguity over both the definition and measu-

rement of key information utilization constructs. Many of these frustrations have been carefully reported by Deshpande and Zaltman (1982, 1984). In response to both these problems, a parsimonious model of the utilization of objective information has been proposed and tested in a laboratory setting by Wilton and Myers (1984, 1985).

This model, shown in Figure 1, attempts to refine the information utility construct, as well as enhance understanding of the process by which utility judgments are formed and modified. According to this model, when asked to choose from among a set of information items, consumers will first develop a set of expectations of the utility of each item. These utility expectations are hypothesized to be a function of the level of uncertainty associated with the judgment task, and the expected "performance" (part-worth) of the information along a set of attributes. In this paper, these attributes are parsimoniously described as the relevance, novelty, credibility and comprehensive ease of the information. The performance expectations are also based upon the individual's store of existing knowledge about the judgment task, and the set of cues (words, phrases, headings) available to summarize some block of more detailed information on an object. The individual is presumed to be a utility maximizer, and will if allowed, exhibit information choice and cognitive elaboration patterns consistent with his/her utility expectations.

The model also proposes a process of (dis)confirmation of utility expectations to describe the modification of utility judgments as a result of exposure to information. In the consumer satisfaction literature (Oliver 1977, 1979; Churchill and Suprenant 1982; Wilton and Tse 1983), expectancy disconfirmation has been offered as an important paradigm for explaining the consumer's response to a product following usage. According to this paradigm, a consumer's expectations of product performance may be confirmed (results consistent with expectations) or disconfirmed (results discrepant with expectations) during the consumption experience. If expectations are disconfirmed, the results may be either positive or negative. Negative disconfirmation (and hence dissatisfaction) will occur whenever the product is seen to perform worse than expected, while positive disconfirmation (and hence satisfaction) will occur whenever the product performs better than expected. In this paper, we extend the expectancy disconfirmation paradigm to the consumption of information products and services by explicitly modelling the formation of utility expectations and by manipulating the disconfirmation experience.

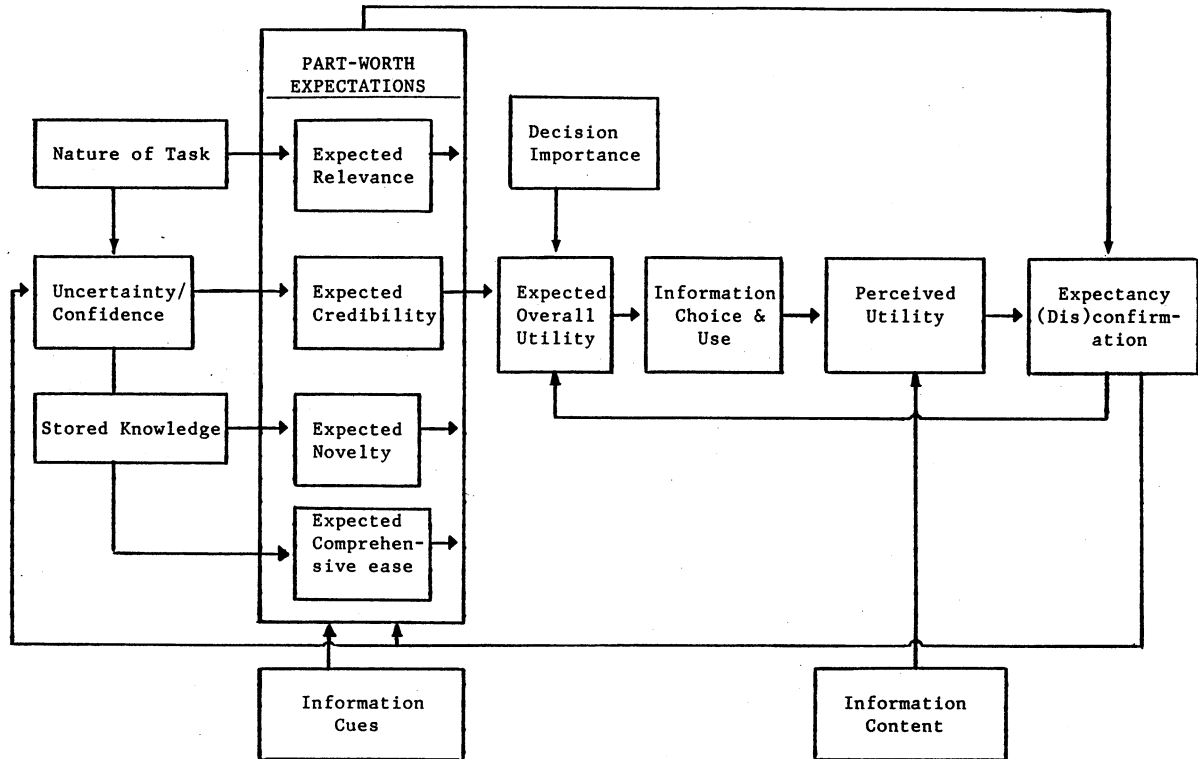

Although necessarily incomplete, the proposed utilization model does include factors found to be important in other contexts, some of which (e.g., information characteristics) are associated with significant measurement problems, and also introduces other factors (e.g., task situation and expectancy disconfirmation) which have not yet been examined empirically. The weakening of external validity implied by this simplified model, however, is considered a necessary trade-off against improved construct and process measurement, given the significant problems associated with prior utilization studies.

The testable hypotheses which can be derived from this model of information utilization can be summarized as follows:

H₁: Individuals facing higher task uncertainty will perceive greater utility for, and show greater use of, information than individuals facing relatively

1. Work on this project has been sponsored by a grant from the National Science Foundation, #PRA 81-10052, with the author and John G. Myers as principal investigators. The views expressed in this paper are those of the author and do not necessarily reflect the position of the Foundation.

FIGURE 1
SIMPLIFIED MODEL OF INFORMATION UTILIZATION

lower task uncertainty.

H₂: Utility for information can be represented as a multiattribute function of its characteristics. In particular, utility for information is positively and uniquely related to the:

- H₂₁: relevance
- H₂₂: credibility
- H₂₃: novelty
- H₂₄: comprehensive ease

of arguments expected/perceived to be contained in the item.

H₃: Modification of utility judgments can be represented as a process of expectancy disconfirmation during, or following, information exposure. In particular:

- H₃₁: the higher the expected utility for information, the more likely expectations will be negatively disconfirmed during utilization, and
- H₃₂: the lower the expected utility for information, the more likely expectations will be positively disconfirmed during utilization.

Extended discussion of the theoretical support for these hypotheses is contained in Wilton and Myers (1985). It should be recognized here, however, that hypotheses H₁, H₂₂ and H₂₃ are by no means obvious. Our hypotheses concerning the relationship between uncertainty and information utility, and the effects of novelty on utilization of information are in direct contrast to those proposed by Deshpande and Zaltman, who argue that (in organizational contexts) new information and/or high uncertainty will lead to lower, rather than higher, utilization. Similarly, evidence concerning the effects of credibility of arguments on utilization is also equivocal. Sternthal et alia (1978) and Kehret-Ward (1984), for example, in studies of source credibility, have found that moderately credible sources may actually induce higher cognitive elaboration among subjects than sources which are highly credible. Thus, both constructs warrant further study in information utilization research.

Model Operationalization

The model has been tested in a controlled laboratory experiment reported by Wilton and Myers (1985), and subsequently validated in a field setting, the results of which are the focus of the current paper. In these experiments, subjects were asked to study a data-base of objective information about a new technology (prepared by a non-partisan organization) with a view towards evaluating the technology. Manipulated variables in these experiments were task uncertainty (2 levels) and expectancy disconfirmation (3 levels).

(i) Task Uncertainty

Under the high uncertainty task condition, subjects were asked simply to examine as much or as little of the data-base as they felt they needed in order to identify all the important issues associated with the technology, to be used in preparing a background briefing to their superior. Since no explicit decision was required and the task parameters are essentially unbounded, this condition is referred to (after Berg et alia 1978) as a conceptual task orientation. Under the low uncertainty condition, subjects were asked to complete a hierarchical budget- or manpower-allocation problem, allocating a fixed set of resources across a pre-identified set of policy/investment options. Since this task is decision-related, it is referred to as an instrumental task orientation. For both conditions, arguments contained in the data-base bore a direct relation to the task assignment.

(ii) Expected Utility Disconfirmation

Expectancy disconfirmation can be manipulated by controlling the utility level of the information to which the subject is first exposed. In general, negative disconfirmation of expectations is more likely to occur among individuals who already hold high expectations for the information, while positive disconfirmation is more likely to occur among individuals holding low expectations for the information. If expectations are low, then either the information will in fact be seen (during processing) as low utility, in which case expectations will be

confirmed; or the information will be seen as higher in utility than anticipated, in which case expectations will be disconfirmed positively. Analogously, if expectations are high, then high utility information during use will be confirming, while low utility information will be negatively disconfirming.

In the current experiments, subjects first provided measures of the expected utility of information contained in various chapters/sections of the available data-base (both overall and by attribute). For any given subject, these scores were then used to identify which information was relatively higher, lower or indifferent in expected utility. Using a quota procedure, subjects were then assigned to one of three forced-exposure conditions. In the high utility condition, a subject was given information from the set of items which he had rated as having high expected utility. In the low utility condition, the subject was given information from the set of items scored low in expected utility. Subjects who rated the expected utility of all information items equally were assigned to the indifferent utility condition and given an information item chosen from this set at random. This manipulation thus served to operationalize the expectancy disconfirmation process described above.

Following this forced-exposure treatment, subjects were allowed free access to all remaining information contained in the data-base, subject to a time constraint of approximately one-and-a-half hours. Data-collection and information-exposure sequences of the research employed a computer-interactive system called STARSIS, or Strategic Technology Assessment Research and Information System. This environment also precluded any possibility for group interaction among subjects. Total time for completion of all experimental tasks averaged two-and-one-half hours, for which subjects (in the laboratory experiment) received twenty dollars.

Laboratory Results

Subjects for the laboratory experiment were 57 female and 94 male volunteer graduate students at a large Western University, evenly divided among Masters and Doctoral degree programs in a wide variety of disciplines, including seventy-two percent from outside the School of Business Administration. The data-base for the laboratory experiment comprised a 65-page National Science Foundation report discussing the nature and consequences of life-extending technologies in the U.S.. Results from this experiment, discussed in detail in our earlier paper, can be summarized as strongly supporting the overall model and each individual hypothesis.

Information was shown to have higher utility in tasks which were not tied to a choice dilemma; subjects in the instrumental task condition not only expected lower utility, but also reported lower utility after information was made available. Utility scores estimated as a linear combination of ratings of the information along its attributes provided high correlations with alternative, self-reported, overall measures of expected/perceived utility. Consistent with hypotheses H₂₁ to H₂₄, each individual attribute was shown to have a positive association with overall utility. A positive relationship for the novelty attribute is important since it suggests that not only can new arguments be tolerated during utilization, but that anticipation of new information is a strong inducement towards initial utilization.

Utility judgments were also significantly affected by the expectancy disconfirmation manipulation. For subjects in a high expected utility condition, expectations of both the relevance and novelty of arguments were strongly negatively disconfirmed during exposure, with resulting declines in overall utility ratings. Conversely, low initial expectations on these attributes tended to produce positive disconfirmation with corresponding increases in overall utility ratings.

Thus, in a controlled laboratory environment, our results

indicate that the influence of task uncertainty and information characteristics on the process of formation and modification of utility judgments can be validly measured. In the remainder of this paper, we focus our attention on validating the proposed model in more complex (externally valid) task environments.

Field Validation

Subjects for the field validation experiment were sixty landscape specialists and maintenance engineers in a large, Western, state-funded transportation organization. This sample represented the entire population of advisors and potential adopters for a new technology (integrated pest management) for controlling scale infestations along the state highway system. Information about this technology was contained in a 40-page document prepared by a team of researchers at a large, prestigious Western university. Data from the report were made available via the STARSIS computer-interactive data-collection system described earlier, in individual sessions lasting from one-and-a-half to three hours, administered in the subject's usual place of work activity.

Pre-Exposure Manipulation Validation

Table 1 gives the mean scores, and associated F-statistics on a variety of individual cognitive measures for each treatment condition, prior to exposure to objective information. The scores verify the effectiveness of the

- 1 Self-report, 6-point, bi-polar scales
- 2 PECS: Pre-exposure constant sum (100 points total) expected utility for information assigned during forced-exposure; given five information items, if all were expected to be equally useful, each would be assigned 20 points.
- 3 Future Use: percentage of all landscape problems on which new technology is likely to be used in next 18 months.

All items positively scaled, higher values denoting greater utility

* p < .0001

experimental manipulations. Subjects in the conceptual task condition, for example, show significantly higher expected utility for available information in completing the assigned task than do subjects in the low uncertainty, instrumental condition (means 4.4 and 2.9 respectively).

Similarly, consistent with the treatment design, expected utility scores for information assigned during the forced-exposure treatment are significantly lower for subjects in the low-expected-utility condition than for either subjects in an indifferent- or high-expected-utility condition (mean PECS scores, 7.2, 20.5 and 34.6 respectively). Thus, subjects appeared to enter the usage experience with variations in expectations consistent with the experimental manipulations or group assignments. On all other pre-exposure measures of the value of information or the innovation, the differences between experimental groups are not significant.

Information Attributes and Initial Utility Expectations

According to the utilization model proposed, the expected utility score for information can be expressed as a function of ratings of that information along its attributes. This hypothesis is tested in Table 2 which shows the mean expected performance rating of information assigned during forced-exposure, on each information attribute, for each of the three expected utility groups.

If overall utility scores are related to the individual attribute scores, then these three groups should differ in their ratings of information attributes, and group membership should be predictable by some linear combination of the attribute scores.

TABLE 2
 EXPECTED UTILITY FOR INFORMATION

Chi-Square		38.13 (p < .000)			

1. Attribute scores normalized within subject across all information items: higher scores denote more favorable expectations. Given five information items, scores above .20 denote above-average performance, while scores below .20 denote below-average performance.

* Standard deviation in parentheses.
 p < .01

The results are strongly supportive of the hypothesized relationship between overall utility expectations and individual attributes. On all but one attribute (expected comprehensive ease), subjects in the low-expected-utility condition expect assigned information to perform significantly worse than do subjects in either the indifferent- or high-expected-utility conditions. Consistent with hypotheses H₂₁ to H₂₃, the effect of each attribute on overall utility is positive; individual attribute ratings increase with overall expected utility. As can be seen from the expected novelty ratings, an absence of new arguments leads to low overall utility expectations.

The attribute ratings also provide a strong linear predictor of initial expectation condition. The Wilk's lambda obtained from a multiple discriminant analysis using expectations on all four attributes as predictors is .55, significant at p < .000; while overall percent correct group classification is 68.3. Thus, the results from our field study appear highly consistent with results obtained in our laboratory studies and provide further encouraging support for the proposed multiattribute information utility construct.

Expectancy Disconfirmation and Information Utility

Our utilization model also suggests that, in addition to information characteristics, initial expectations will influence the direction of the effect of exposure to information on subsequent perceived utility ratings. According to hypotheses H₃₁ and H₃₂, subjects in a low-expected-utility condition will experience positive disconfirmation of expectations and hence revise utility ratings upwards following information use, while subjects in a high-expected-utility condition will experience negative disconfirmation and hence revise utility ratings downwards.

Examination of the mean shifts in overall utility ratings for forced-exposure information, pre- and post-exposure, support the disconfirmation hypothesis. For subjects in the low-expected-utility condition, the difference between expected- and post-exposure, perceived utility ratings (using a 100-point constant-sum scale in which an "average" information item would be allocated 20 points) averaged 6.01, compared to -0.32 for subjects in an indifferent-expected-utility condition, and -5.2 for subjects in a high-expected-utility condition (F_{4,56} = 11.03,

p < .01).

An explanation of these shifts in overall utility is provided by the pattern of disconfirmation on individual attributes. On the relevance attribute, for example, the mean shift for subjects in the low-expected-utility condition was .89 (using a self-report, 6-point bi-polar scale), compared to -.36 for subjects in the high-expected-utility condition (F_{4,56} = 5.4, p < .01). Thus, on average, subjects holding low initial expectations of the relevance of the information find those expectations are positively disconfirmed during the usage experience. Since group shifts on the remaining information attributes are not statistically different, this would imply that, for the current stimulus, the relevance attribute plays the determinant role in expectancy disconfirmation.

Utilization and Technology Evaluation

An important issue in utilization research is the impact of information on evaluation of the target product or technology. While it is often easy to demonstrate shifts in evaluation of the technology following information exposure, it is usually more difficult to explain why such shifts are occurring. In this section, we attempt to relate individual cognitive processes to characteristics of the information to which the individual has been exposed. Table 3 gives the standardized beta coefficients for each information attribute obtained by regressing the average post-exposure (perceived) attribute ratings against each of three cognitive measures, attitude towards the technology, confidence in performing the assigned task, and overall evaluation of the report. The attribute ratings are the within-subject averages across all information items examined only (i.e., items not examined have been excluded).

The coefficients are intuitively meaningful and add insight to the cognitive processes associated with information utilization. First, evaluations of the technology are positively influenced by high perceived relevance and credibility, but low novelty, ratings. This result is interesting since it implies that new arguments are not a necessary condition to favorable evaluation of the technology, and may, if encountered, have a negative effect on those evaluations.

Second, post-utilization task confidence judgments are not affected by judgments of the information's relevance or credibility. Comprehensive ease and familiarity with the arguments encountered, however, both contribute significantly to higher confidence levels. Thus, information would appear to be being used as a confirmatory test against existing expertise.

Third, evaluations of the overall usefulness of the report in the judgment task can be attributed to the more "affectively-weighted" attributes of information relevance and credibility. These attributes are "affectively-weighted" in the sense that they denote higher-level processing of an argument once it has been read and understood. Technical ease and the number of new arguments, on the other hand, can be considered more "cognitively-weighted" (i.e., ask the respondent to report only whether the argument was known and could be understood, and not whether the premise should be accepted or rejected in the judgment task). While understanding of the argument would seem to be a pre-condition to higher level processing, it does not (at least for the current experiment), appear to significantly influence judgments of the utility of the overall data-base.

Of course, other factors will also affect these judgments. Among constructs included in our model, the nature of the task assignment will directly affect the confidence level associated with task completion. Our laboratory results suggest that conceptual tasks (i.e., those associated with broader judgment parameters), for example, will show greater improvement in confidence levels as a result of exposure to information, than will structured choice dilemmas such as that associated with the instru-

mental task in the current study. Our field results generally support this finding. Subjects in the conceptual task condition report a mean improvement in confidence level of 1.27 (on a 6-point, bi-polar scale), compared to .51 for subjects in an instrumental condition. This difference is significant at $p < .05$.

Discussion

In this paper, we have reported partial results from a field study of the utilization of objective information in judgment tasks. The purpose of the study has been to validate among a sample of potential adopters of a new technology, results obtained in a controlled laboratory experiment of information utilization.

The study lends strong support to the laboratory findings, and hence the proposed model. Both task and information characteristics significantly affect the formation of expected utility judgments. Consistent with our laboratory findings, objective information is expected to have lower utility in judgment tasks tied to a choice dilemma than in tasks requiring initial understanding of the choice parameters. In our earlier paper, we discuss the types of consumer judgments which might represent these two task conditions. Without repeating this discussion, our results suggest that the focus of consumer researchers on the role of information in the brand choice problem may overlook an important class of judgments in which consumers will be more receptive to information.

The field results also support the multi-attribute information utility construct proposed and tested in the laboratory environment. This result is important since it indicates that problems in measuring the effect of information characteristics on utility judgments, reported in earlier utilization studies in field settings (Deshpande and Zaltman 1982, 1984), can indeed be overcome.

A unique contribution of the current model is the testing of the expectancy disconfirmation paradigm as a model of the process of modification of utility judgments, following use of information. Again, our hypotheses concerning the effect of initial expectation on utility judgments are supported by the field results. This also is an important finding, since it implies that rejection of information following exposure is more likely to occur among audiences initially highly receptive to the stimulus. Since subjects holding low expectations are generally positively surprised by the stimulus, our data suggest that utilization of information may actually be enhanced by attempting to lower, rather than raise, initial expectations.

The study also demonstrates the separability of information characteristics to explain inherently different cognitive and affective judgments. For the current sample, "knowledge-related" attributes of technical ease and

familiarity with arguments are being used to assess the confidence which should be assigned to the task judgments, while "affectively-related" attributes of relevance and credibility provide input to evaluations of the overall utility of the arguments. For evaluations of the target technology, both sets of factors combine.

As objective (non-persuasive) information data-bases become increasingly available to consumers through innovations in communications technology, the importance of this class of information in consumer judgments is likely to increase. Such changes are likely to present marketing managers with new, and often particularly complex, communications challenges. In this paper, we take the position that increased understanding of the use of objective information products and services will provide marketing managers with insight not only into how to more effectively respond to these challenges, but also into the role of information generally in consumer judgments. We advocate increased efforts by consumer researchers in this area and present a reduced paradigm and set of findings to suggest how this effort might begin to be implemented.

PARENTAL DIFFUSION ROLES AND EFFECTS OF NUTRITION EDUCATION ON PARENTS AND CHILDREN

Sanford Grossbart, University of Nebraska-Lincoln
Lawrence Crosby, Arizona State University
Laurie Smith, University of Nebraska-Lincoln

Abstract

Effects of children's nutrition education depends on adoption of new consumption concepts and practices by parents and their children. This study employs a diffusion role typology and socialization perspective to examine the relations between parental influence and parents' and children's responses to nutrition education.

Most arguments about the causes of children's nutritional problems call attention to the importance of parental influence (e.g., those dealing with changing family lifestyles or children's exposure to television food advertising (Grossbart and Crosby 1984)). Research indicates mothers' knowledge has a significant impact on children's diets but many mothers have little understanding of a balanced meal, healthful eating habits or available nutrition information (Caliendo and Sanjur 1978; Richmond 1977; Jacoby, Chestnut and Silberman 1977; White 1976; Bauman 1973; Eppright et al. 1970). Consequently, considerable attention has been focused on developing and marketing nutrition education programs in schools (Fleming and Brown 1981; Fine 1980; Ward 1978; Baird and Shutz 1976; Kotler and Zaltman 1971).

Mothers may also play a pivotal role in this regard. In their various socialization roles (Wackman 1979) they can influence school curriculums, help create a home environment which emphasizes nutrition concepts and provide children with opportunities to eat a balanced diet, try new foods, aid in food buying decisions, etc. This suggests nutrition education results are apt to depend on family interactions and parental behavior (Fox and Kotler 1980). This study explores these matters from a diffusion of innovations and socialization perspective. Its purpose was to examine parental reinforcement of nutrition education and related psychological and behavioral effects on parents and children.

Nutrition, Innovation And Socialization

Nutritional concepts possess a considerable degree of perceived newness for parents unfamiliar with dietary principles for children's growth and development (Fox and Kotler 1980). Sheth (1979) suggests reception of a new idea or practice depends on the extent of risk associated with its use and the strength of consumers' prior habits. Innovations encountering ingrained habits and high risk perceptions face the greatest resistance. Sheth terms these "dual resistance innovations" and notes that social ideas (e.g., children's nutrition) and social programs (e.g., nutrition education) tend to fall in this category. Relatively strong habits are apt to govern frequently performed food buying and eating behaviors (Deutsch 1976; Eppright et al. 1970). These habits have often been passed down through generations or have roots in entrenched family lifestyles and values (e.g., those stressing a fast pace of life outside the family, immediate gratification, etc.).

The perceived risk which strengthens resistance stems from consumer confusion, uncertainty and suspicion of aversive consequences. Certainly, the apparent complexity of dietary requirements must seem great to parents who have been exposed to conflicting governmental suggestions on nutrition (Fox and Kotler 1980) or perplexing scientific terminology and quantification. Parents' documented lack of familiarity with nutrition ideas and practices may also increase their uncertainty about new eating regimens and lead to concerns about performance, social, and economic outcomes. Performance concerns stem from taste apprehension and a tendency to

associate nutritious foods with bad taste. Among mothers, this is accompanied by the social and economic risk of serving foods family members will not like. Children may also perceive social risk if nutritious foods lack peer approval. Finally, the tendency to equate nutritious foods with expensive health foods may increase the perceived economic risk. For many parents these concerns are not offset by the developmental and health benefits of a nutritious diet because they are not immediately observable. Moreover, chances to observe others preparing and consuming healthful foods are infrequent since these behaviors are most often performed within the home. In combination, these factors diminish the perceived relative advantage of nutrition education and nutrition-oriented behavior.

In this context, interpersonal family influences are important since adoption of nutrition education involves "collective" innovation decisions (Rogers 1983) in which both parents and children are the decision making unit. In these circumstances parents are in a position to play legitimizing roles as informal educators and motivators of consumption (Wackman 1979). By (not) sanctioning nutrition education concepts they can (decrease) increase the magnitude of program impact. Parents with the previously outlined concerns about nutrition concepts or education may not be inclined to communicate approval to children.

Insights into these dynamics are provided by Midgley's (1976) explanation of interpersonal diffusion roles in innovation-decision situations. His typology includes 1) active adoptors, who communicate favorable innovation experience, 2) passives, who do not provide indications of their evaluations to others and 3) active rejectors, who relate unfavorable experiences to others. His premise is that adoption is determined by communicated, i.e. verbalized, experiences which are disseminated through the social system. This study uses a previously employed adaptation of Midgley's typology (Grossbart, Crosby and Robb 1982). The relevant social system is defined as the family. A three-fold categorization of parental influence is used, i.e., actives who accept and reinforce the concepts in the nutrition education program, passives who accept but fail to reinforce the concepts and rejectors, who do not accept the concepts or provide reinforcement to their children.

Parents who play these different roles are apt to evidence additional differences in psychological and behavioral responses. First, they are likely to differ in the increased significance they place on nutrition related attributes of foods. Parents who accept and try to stress the aforementioned concepts to their children are more likely to devote increased attention to matters of food and nutrition. This should be reflected in more cognitive emphasis on the nutrition content of food products purchased and consumed by the family. Second, parents should vary in the extent of interaction with their child in grocery shopping and decisions about food purchases and eating choices. Variance in changed interaction levels is a likely consequence of both variable desires to more actively socialize the child in terms of food consumption and responses to child initiated requests and questions which are outcomes of more active parental influence attempts. Certainly, increased interaction is not probable in most cases, since active consumer socialization attempts by parent are not widespread (Wackman 1979; Ward 1974). However, it should occur in families with active parents. Finally, changes in parental buying behavior should occur. For the reasons stated above, active parents are most likely to alter their buying behavior, e.g., by

departing from past purchase patterns and buying a greater variety of products, employing nutrition content as a more determinant factor in item selection, etc.

- H1: Active parents will evidence more change in a) cognitive emphasis on nutrition, b) interaction levels with children and c) nutrition-oriented behavior than passives or rejectors.

Prior research (Grossbart, Crosby and Robb 1982) has examined parents' reports on children's responses to nutrition education. This study employs reports from children themselves. This permits a more direct test of the thesis that parental attitudes and behaviors should influence children's adoption of nutrition concepts. This is consistent with suggestions in the consumer socialization literature that verbal and nonverbal communications about consumption between parent and child are related to the child's development of consumption orientations (Moschis 1981). Without parental acceptance (i.e., among rejectors) nutrition education should have the least positive impact on children's nutrition attitudes or food preferences. In contrast, parental acceptance alone (i.e., by passives) should establish a sufficient basis for children developing somewhat more positive nutrition attitudes and a wider range of food preferences. Even if parents do not provide verbal reinforcements, lack of overt criticism and observation of their nonverbal behavior by children may convey positive nutrition cognitions and behaviors (Moschis, Moore and Smith 1983) and thereby foster positive orientations. Without verbal reinforcement, however, less legitimization may occur and only moderate effects on attitudes and preferences may result. Active parental reinforcement should lead to more pronounced changes in a child's nutrition orientation because it will signify the sanctioning of newly learned concepts and is likely to occur in the most relevant behavior contexts, e.g. when the parent responds to a child's food choices, requests, questions, etc. (Crosby and Grossbart 1984).

- H2: (a) Children of active parents will evidence enhanced nutrition attitudes and increased food preferences.
(b) Their responses will be greater than those of children of passives and rejectors.
- H3: (a) Children of passive parents will evidence enhanced nutrition attitudes and increased food preferences.
(b) Their responses will be greater than those of children of rejectors.
- H4: Children of rejector parents will not evidence enhanced nutrition attitudes or increased food preferences.

Relationships between the diffusion role a child's mother assumes and demographics are uncertain. If reaction depends on fears about cognitive defenselessness of younger children (Crosby and Grossbart 1984) and overt parent-child communication declines with age (Moschis and Churchill 1978), greater parental acceptance and reinforcement may occur when children are in lower grades. Since nutritional knowledge and attitudes and extent of purposive parental training of children have been found to vary directly with socioeconomic status (Eppright et. al. 1970; Ward and Wackman 1973), it might be anticipated that families with more educated parents and father's in white collar occupations would be more supportive. Families with agricultural ties could also be expected to place greater value on matters of food and nutrition. Conversely, prior pro-nutrition efforts might limit the perceived need for parental action. Finally, support from working mothers could stem from their openness to new experiences for their children and a desire for external help in socializing them as consumers. Similarly, those with larger families might respond positively to external help. However, these same parents may lack the time to engage in an active role.

Method

Analysis is based on data from surveys of mothers and elementary school children (grades 1-6) in thirteen schools participating in a federally funded experimental nutrition education project. Schools were randomly assigned to treatment and control groups and represented a cross section of communities from rural, suburban and urban areas. The program employed a set of psychometrically developed modules designed to impact children's nutrition orientations. During the school year children took part in classroom discussions and food tasting experiences and received information on possible food preparation and consumption activities for the family. The 5 control schools did not receive the program. With minor exception, all classrooms in the selected schools were involved in the study. Survey measures were taken on children (at school) both before and after program completion. Self-administered questionnaires were distributed to parents upon completion of the program. Returned parent questionnaires were evenly distributed across grade levels and represented a fifty percent response rate. A comparison of treatment (n = 379) and control (n = 223) parents showed the two groups had similar demographics and attitudes (on issues not directly related to the program, e.g. child rearing). A separate check confirmed that treatment group parents were aware of their children's participation in a new nutrition education program.

Parents in the treatment group were classified as rejectors, passives or actives based on the extent to which they agreed with concepts presented in the program and provided reinforcement by reminding their children about them. This was accomplished by dividing four-point (not at all - a lot) agreement and reinforcement scales at their mid-point and cross-classifying responses. Rejectors were those with low scores on both scales, passives were high on agreement but low on reinforcement and actives had high scores on both measures.

Hypothesized effects were measured by indices reported in Table 1. Using four-point (not at all - a lot) scales, parents estimated effects on themselves by reporting how ideas their child brought home from school increased their own 1) cognitive emphasis, i.e., concern about food and nutritional content of purchased and consumed food items, 2) interaction levels with the child, e.g., including him/her in purchase and food planning decisions and co-shopping and 3) nutrition-oriented behavior, e.g., likelihood of basing purchases on nutrition content and buying a greater variety of food products. Demographic information (grade in school, number of children and parents' education and occupation status) was gathered to profile parents who displayed different roles in the nutrition education program. Children's Nutrition Attitude employed three-point (disagree - agree) scales and included such items as "Food in nice packages always tastes good," "Too much sugar or candy can be bad for you," "It's o.k. to eat whatever you want as long as you eat enough" and "T.V. ads show the best foods to buy." Food Preference provided indications of children's fruit and vegetable preferences (which the program was designed to influence). Three-point (not like me - like me) scales were used. Higher scores on both scales indicate a more positive nutrition orientation.

Differences in parental response and demographics were tested by multiple and univariate analysis of variance, Scheffe contrasts and Chi-square. Differences in children's responses were analyzed by analysis of covariance with premeasures serving as covariates. Appropriate adjustments were made for group sizes and error terms were adjusted for variation in covariate scores. Following overall assessments of significance, adjusted means of treatment groups were compared. If no differences were present, a treatment versus control contrast was conducted. Otherwise, all planned comparisons were made. These procedures follow those suggested by Keppel (1982).

Results

Over ninety-eight percent of treatment group cases were categorized as either actives (n = 169), passives (n = 150) or rejectors (n = 60). These results indicate a high level of program acceptance among parents, but substantial reinforcement attempts in less than half of the cases. Information on reliabilities and mean index magnitudes is presented in Table 1. Alpha and beta coefficients reflect the internal consistency and unidimensionality of indices of response for parents and children (Revelle 1979).

TABLE 1
MEASURES ON CHILDREN AND PARENTS FOR CONTROL AND TREATMENT GROUPS

Measure	Number of Items	Coefficient		Means (Standard Deviations)			
		Alpha	Beta	Control	Rejector	Passive	Active
Measures on Parents							
Cognitive Emphasis	3	.84	.84	5.86 (2.57)	4.85 (2.00)	5.71 (2.17)	7.04 (2.46)
Interaction Level	4	.84	.82	8.52 (2.96)	7.52 (2.46)	7.90 (2.62)	9.97 (2.90)
Behavior	5	.95	.91	12.11 (5.10)	10.31 (4.91)	11.22 (4.48)	13.85 (4.39)
Measures on Children							
Nutrition Attitude premeasure	25	.63	.62	64.69 (6.18)	64.59 (5.30)	66.64 (4.88)	65.29 (5.15)
Nutrition Attitude postmeasure adjusted mean	25	.69	.69	65.34 (6.47) 65.66	65.15 (5.80) 65.62	(68.29) (4.68) 67.53	67.55 (5.18) 67.58
Food Preference premeasure	18	.69	.57	42.90 (5.88)	42.84 (6.17)	43.38 (5.33)	42.78 (5.29)
Food Preference postmeasure adjusted mean	18	.74	.62	43.58 (6.32) 43.64	43.94 (6.38) 44.05	45.05 (5.75) 44.75	44.52 (5.27) 44.66

Findings with respect to parent responses and demographics are included in Table 2. Examination of these results provides evidence of marked differences between actives and passives on all three measures of parental response but a lack of distinction between passives and the two other groups. As expected, actives exhibited significantly higher scores on cognitive emphasis on nutrition, consumption related interaction with their children, and altered food buying behavior patterns than any of the other groups. Responses for rejectors were significantly below control group responses on cognitive emphasis and behavior.

TABLE 2
ANOVA AND CONTRASTS ON PARENT MEASURES AND PROFILE CHARACTERISTICS

Measure	MS	MS error	F	Scheffe Test
Cognitive Emphasis	92.27	5.73	16.12 ^a	A > P ^c , A > R ^c , A > C ^b , C > R ^b
Interaction Level	153.60	7.91	19.43 ^a	A > P ^b , A > R ^b , A > C ^b
Behavior	270.98	22.43	12.08 ^a	A > P ^b , A > R ^b , A > C ^b , C > R ^c
Child's Grade	26.54	2.92	9.10 ^a	A < P ^c , A < R ^b , A < C ^b , P < R ^c
Number of Children	0.68	1.49	0.46	
Mother's Education	4.71	1.83	2.58 ^b	P > R ^c
Father's Education	9.15	2.39	3.84 ^a	A > C ^c

Note: ^adenotes p < .01, ^bdenotes p < .05 and ^cdenotes p < .10;

C = Control, R = Rejectors, P = Passives and A = Actives

Few demographic differences were revealed. Passive mothers tended to be more educated than rejectors while actives had more educated spouses than the control group. 'Actives' children were in lower grades than the other groups and passives' children were in lower grades than rejectors. While not inconsistent with the conceptual framework for this study, this finding

suggested the need for further analysis. Consequently, analysis of covariance was conducted on the two children's and three parental response measures. In each case child's grade was added as a potential covariate. The results did not differ from those reported above. Chi-square tests indicated no significant differences in mothers' occupational status or fathers being engaged in farm versus nonfarm jobs. However, rejectors had a higher than expected proportion of spouses in blue collar employment and passives had a higher than anticipated percentage in white collar positions. Among actives and the control group these proportions were nearly equal (Chi-square = 6.50, p < .10).

TABLE 3
ANCOVA RESULTS ON CHILDREN'S MEASURES

Measure/Hypothesized Comparison	MS	MS(MS') error	F
Nutrition Attitude	87.84	17.24	5.10 ^a
Active * Passive * Rejector	145.24	19.14	7.59 ^a
Active > Passive	0.15	18.02	<.01
Active > Rejector	241.89	17.41	13.89 ^a
Active > Control	175.37	18.79	9.33 ^a
Passive > Rejector	216.26	18.96	11.41 ^a
Passive > Control	135.33	18.79	8.80 ^a
Rejector * Control	3.42	17.24	0.20
Food Preference	50.28	17.22	2.92 ^b
Active * Passive * Rejector	17.39	17.39	1.02
Treatment > Control	63.24	17.22	3.67 ^c

Note: ^adenotes p < .01, ^bdenotes p < .05 and ^cdenotes p < .10

ANCOVA results on children's responses are presented in Table 3. For Nutrition Attitudes, findings of overall significance (F = 5.10, p < .01) and differences among treatment groups (p < .01) made it possible to examine between group comparisons. Results support the expectation that children of active and passive mothers have more positive nutrition attitudes than do children of rejectors or those in the control group (see adjusted means in Table 1). However, there was no significant difference on nutrition attitudes between actives and passives. In addition, attitudes of children of rejectors did not differ from those of the control group. Overall significance was also present for children's food preferences (F = 2.92, p < .05). While adjusted means for actives and passives were greater than the mean for the rejector group, these differences were not significant. Still, as a whole, children in the treatment group evidenced a significantly greater change in food preference than those in the control group (p < .10).

Discussion

It appears worthwhile to investigate children's nutrition education from a diffusion role/socialization perspective. Research is needed to validate findings in other states and measure effects over time. It would be useful to track actual trends in family consumption and check for possible sleeper or decay effects in cognitive, affective or behavioral responses. Attempts should also be made to employ more complex experimental designs which allow premeasures on parents and determination of possible test effects on children. This would allow further examination of effects of general familiarity with nutrition education and views on the program in question as an innovation. In addition, efforts should be made to investigate father's role in the adoption of nutrition concepts and practices.

Meanwhile, these findings provide support for focusing more attention on parents' responses to children's nutrition education. While the program in this study was primarily geared to directly influence children, important unintended effects were also observed among

active parents. They reported changes in concern about nutrition content, food socialization interaction with their child and buying tendencies which were significantly greater than those of passives, rejectors or the control group. These effects have important social and managerial marketing implications.

In social terms, they suggest the importance of targeting actives and perhaps developing strategies to increase the number of active parents. The present results provide useful, but limited, profile distinctions between parents with alternative diffusion roles. They suggest the possibility of considering different tactics for parents of younger versus older children and segmentation strategies reflecting the fact that, in comparison to passives, rejectors are likely to be less educated and have spouses in blue collar occupations. However, targeting efforts will be enhanced by a fuller understanding of the socio-psychological antecedents of parents nutrition orientations and response to nutrition education. In managerial terms, the results make it clear that nutrition education efforts should be monitored by food marketers. If these programs, in a direct or indirect manner, engender shifts in the importance of nutrition as an evaluative criterion for product selection, variety of products purchased and extent of child involvement in shopping and product choice, as was found among actives, their effects may be of great competitive significance. It appears that children's nutrition education may be capable, in the case of actives, of exercising a socializing influence on parents themselves. If so, there may be a need for evaluating current promotional positioning and product line development and management policies in light of subtle shifts in parental orientation and behavior.

Interesting issues are also raised by observed effects on children's nutrition orientations. The existence of differences in nutrition attitudes but not food preferences across diffusion roles may reflect the closer link between food preferences and actual consumption behavior. While positive attitudes may prove to be related to consumption of a wider variety of foods, such behavior is apt to be more immediately, i.e., directly, related to preferences. These results indicate that nutrition education impacts children's food preferences. In contrast, more positive attitudinal effects for children of actives and passives versus rejector and control groups support the argument that results of education hinge on parental socialization influence. However, these findings, in combination with the lack of differences between actives and passives, suggest that verbalization *per se* is not a requisite for impact on attitudes. The diffusion role perspective presented here emphasizes verbal influence, while the socialization perspective allows for the transmission of norms and consumption orientations by modeling (nonverbal) and overt behavior (verbal reinforcement). These findings are consistent with the thesis that there are multiple communication mechanisms involved in nutrition socialization and adoption of positive nutrition attitudes by children. These issues clearly merit further investigation.

FAMILY COMMUNICATION INFLUENCES ON THE DEVELOPMENT
OF CONSUMER BEHAVIOR: SOME ADDITIONAL FINDINGS

Abstract

The importance of family in consumer socialization has been shown in a large number of studies. This paper deals with the influences of family communications on the development of consumption-related behavior patterns. It presents additional data that suggest family communication patterns may be important in shaping the consumer behavior of young people.

Introduction

Understanding adolescent consumer behavior and its development may help us to understand adult consumer behavior. In fact, most patterns of adult purchasing behavior are acquired early in life (Olshavsky and Granbois 1979). Moreover, adolescence is believed to be a crucial time for socialization and a period during which much consumer learning seems to be taking place (Ward 1974; Moore and Stephens 1975; Moschis 1976). Consequently, recent consumer research has focused on consumer socialization, especially the effects of interpersonal and mass communication on the development of consumer behavior. Previous consumer socialization studies have examined, for example, the influence of family, television, and peers on the development of patterns of consumer decision-making such as information seeking, buying motives, and product evaluation (Moschis 1976; Moore and Stephens 1975; Churchill and Moschis 1979; Ward, Wackman, and Wartella 1977).

Although the family is considered an important agent in consumer socialization, and parents are preferred about twice as much as any other source of consumer information (Moschis and Moore 1979a), most of the research has treated family influence as a variable mediating media effects, especially with respect to television (Robertson 1979), with little attention being directed toward establishing the role of family communication processes in adolescent consumer behavior. In addition, research concerning family communication has focused primarily on the frequency of interaction rather than on the pattern or quality of the interaction.

Conceptualization

The typology of parent-child communication structures and patterns as developed by McLeod and Chaffee (1972) provides a useful vehicle for analyzing the quality of family interaction and its effects on consumer learning. The family communication patterns typology utilizes Newcomb's (1953) co-orientation model. Family communication structures refer to the two relatively uncorrelated dimensions which have been found repeatedly. The socio-oriented dimension is characterized by stressing A-B relationships and seems to produce deference and to foster harmonious and pleasant social relationships. On the other hand, the concept-oriented structure stresses A-X relationships and emphasizes helping the child to develop his/her own individual views of the world by imposing positive constraints.

Together, the two dimensions of family communication structure yield a four-fold typology of family communication patterns: *laissez-faire*, protective, pluralistic, and consensual (McLeod and Chaffee 1972) [Figure 1]. *Laissez-faire* families emphasize neither of the two dimensions and there is little communication between parents and children. *Protective* families emphasize the socio-orientation dimension, stressing obedience and

social harmony, and are not concerned with conceptual matters. Conversely, *pluralistic* families tend to stress the concept-orientation dimension, with an emphasis being placed on mutuality of respects and interest. Children are encouraged to explore new ideas and to express them openly without fear of reprisal. Finally, *consensual* families stress both the socio- and concept-orientation dimensions, and children are encouraged to explore the world about them but to do so without disrupting the family's established internal social harmony.

One of the most important factors in a child's development of consumer skills, knowledge, and attitudes is held to be intrafamily communication about consumption (Churchill and Moschis 1979; Moschis 1976; Ward, Wackman, and Wartella 1977). Effective consumer learning has also been found to be closely tied to the patterns of communication taking place within the home environment (Moschis and Moore 1978 and 1979b). Moschis, Moore, and Smith (1983) investigated the effects of both family communication patterns and family communication about consumption affairs, knowledge, consumer activities, and consumer role perceptions and found that the family communication pattern typology was significantly better than communication frequency measures in explaining consumer activity (defined as the ability to buy and use products and services in a rational and efficient manner).

Although various studies have examined consumer learning and particular stages of the decision-making process, none have looked specifically at the effects of family communication patterns on the development of adolescent purchasing behavior. The purpose of this paper is to extend existing consumer socialization research by investigating the effects of different family communication patterns on the pre-purchase, purchase, and post-purchase stages of the purchase process. The general hypothesis made in this study is that the adolescent's purchasing behavior is conditioned by the structure of parent-child communication roles in the home environment. Specifically, the family communication pattern (FCP), as a generalized socializing influence (see McLeod et al. 1982; McLeod and O'Keefe 1972; Chaffee et al. 1971; Sheinkopf 1973), would hypothetically lead to (a) different attitudes about brands and the marketplace in general, (b) different levels of adolescent shopping independence, (c) different perceptions of sex-roles, (d) different forms of conflict resolution, and (e) different levels of consumer discontent (post-purchase).

Hypotheses

A recent review of the role of family communication in consumer socialization suggests relationships between family communication patterns and various aspects of the youth's consumer behavior (Moschis 1985). One general proposition is that the pluralistic FCP pattern fosters the development of consumer competencies. Among these families, parental encouragement and the child's freedom to explore controversial issues and make up his/her own mind is likely to result in greater satisfaction with his/her choices in the marketplace and to foster skepticism about the marketplace at an earlier age than children from other types of backgrounds. In addition, political socialization research suggests that pluralistic children are more likely to develop party "loyalties" earlier than other children (McLeod and Chaffee 1972). Finally, the family's emphasis on

mutuality of respects and interests is likely to encourage not only more independence in purchasing decisions but also an egalitarian family decision-making pattern and a conflict resolution style that incorporates the children's input. The preceding discussion suggests the following hypotheses.

H1: Pluralistic children are more likely than their counterparts to (a) be satisfied with the products they buy/use--i.e. experience less discontent; (b) have more negative attitudes toward the market place; (c) have preferences for brands; (d) experience family independence in purchasing products; (e) have egalitarian sex-role perceptions; and (f) have a syncretic family-role structure.

Another general proposition is that the protective FCP pattern contributes to the person's susceptibility to outside-the-home influences, both commercial and non-commercial (Moschis 1985). In these families, the child has few opportunities to participate in family decisions due to the hierarchy of power structure accepted by, or imposed upon, its members, and he/she is constrained from developing his/her own views. Specifically, his/her consumer field of choices is rather limited, has fewer opportunities to explore controversial issues, which may result in less satisfaction with his/her choices on the marketplace, and has less family independence. Moreover s/he functions in a highly authoritative family with fewer opportunities for participation in family/decisions. Thus, one would expect the protective child to be the opposite of the pluralistic child.

H2: Protective children are less likely than their counterparts to (a) be satisfied with the products they buy/use; (b) have more positive attitudes toward the marketplace; (c) have preferences for brands; (d) experience family independence in purchasing products; (e) have egalitarian sex-role perceptions; and (f) have a husband dominant family-role structure.

Children from laissez-faire families spend little time communicating with their parents. While there is no evidence to suggest that a lack of communication is better or worse than the socio-oriented communication structure, one would expect little or no communication about family decisions among laissez-faire family members.

H3: Children from laissez-faire families are less likely than children from other family backgrounds to report a syncretic family-role structure.

Consensual families stressing both types of orientations often present conflicting views and alternatives to the child. They encourage the child to take an interest in the world of ideas and develop his/her own views/opinions, and also to respect the hierarchy of family power structure and parental views. Because the views the child develops on his/her own are not always in line with those of his/her parents, there is a tendency among consensual children to use outside-the-family referents as a means of determining "reality," and to seek escape from this conflicting situation by adopting the norms and values of outside sources of information, including commercials (McLeod and Chaffee 1972). This is likely to make them not only more susceptible to such influences but also less satisfied with the products they buy/use because of their greater reliance upon commercial stimuli in the marketplace.

H4: Consensual children are more likely than children from other family backgrounds to (a) have positive attitudes toward the marketplace; and (b) experience greater dissatisfaction with products they buy/use.

Method

Data for the study were gathered from 734 adolescents

who completed self-administered questionnaires during regular classroom hours in one middle and one high school in each of six counties of a Southern state. The selected schools were determined to be representative of the urban, suburban, rural, and semi-rural regions of the state on the basis of personal interviews conducted with school administrators. The resultant sample, though not randomly selected, proved to be demographically representative of the area with respect to sex (49% male; 51% female), age (53% middle school; 47% high school), race (11% black; 88% white), and socio-economic status as measured on Duncan's (1961) (scale mean = 45.3).

Criterion Variables

Employing the commonly-used consumer decision-making framework, six dependent variables were developed to coincide with the three primary stages of the purchasing process: pre-purchase disposition/attitude, purchase, and post-purchase evaluation. Measurement of these variables was achieved by summing the appropriate items and using the coefficient alpha to assess the resultant reliability of the scales. The range of the reliability coefficients was above the .50 minimum recommended by Nunnally (1967).

Brand preference is operationally defined to mean the extent to which an adolescent has a favorite brand for various products and was measured in line with previous research (e.g., Ward et al. 1977; Moschis and Moore 1979a). Respondents were asked to indicate their favorite brand for 12 randomly selected consumer products, evenly distributed between 1) those products used by a child vs. those not used by a child and 2) products heavily vs. lightly advertised. If respondents indicated a brand preference, a score of 1 was assigned, and if none was indicated, a score of 0 was assigned. A 0- to 12-point index was developed to indicate a measurement of the respondent's brand preference.

Attitude towards the marketplace means the cognitive and affective orientation of the respondent toward (1) various marketing stimuli such as advertising, stores, prices, and salespeople, and (2) general attitudes toward businesses. Respondents were asked to indicate their level of agreement or disagreement, using 5-point scales ranging from "strongly agree" to "strongly disagree," with statements such as, "The more famous the store, the better the product it sells," and "Today's consumers are being taken advantage of by companies."

Variables considered relevant at the purchase stage included shopping independence, egalitarian sex-role perceptions, and conflict resolution process.

Shopping independence indicates the degree of the adolescent's purchasing independence by determining his/her social environment during the actual purchase. Respondents were asked to indicate the circumstances under which they would purchase eight products: wrist watch, hair dryer, flash cubes, sunglasses, pocket calculator, wallet, pair of dress shoes, and household batteries. The purchasing situation choices given the respondent were alone, with friends, with family member(s), or ask someone in the family to purchase the item. By combining responses to the first two categories (alone or with friends), a 0- to 8-point index was developed which represented the adolescent's independence in purchase.

Egalitarian sex-role perceptions is operationally defined to mean the adolescent's perception of the relative influence of husband and wife in family decision making. Respondents were presented with 12 different decisions representing various degrees of husband-wife specialization with four response alternatives: "husband should have the most say," "wife should have the most say," "husband and wife should have equal say," and "I don't know." Respondents were asked who, "in a

** $p < .01$

E — indicates nature of relationship was in expected direction hypothesized.

O — indicates nature of relationship was in opposite direction hypothesized.

family with small children...should have the most say in..." six different categories, two decisions in each. The extent of egalitarian sex-roles in family decision making was measured by summing the "equal say" response to form a 0- to 12-point index.

Conflict resolution is a measure of the relative influence of various family members in purchasing situations where there is disagreement among family members. Respondents used a 5-point scale (1 = never, 2 = rarely, 3 = sometimes, 4 = most of the time, and 5 = almost always) to indicate which of the following was the primary decision-maker in conflict situations: father, mother, children, or all members (syncratic).

Consumer discontent was the one main variable considered relevant to the post-purchase stage of the purchase process. This variable concerns cognitive, affective, and behavioral tendencies toward products and product performance following purchase. Respondents were asked to indicate the level of agreement or disagreement, using a 5-point scale ranging from "strongly agree" (1) to "strongly disagree" (5), with statements such as "Some things I buy do not work as well as they are supposed to."

Independent Variables

Six items were used to measure each communication dimension. (All the scale items with instructions used are shown in the Appendix). Items designed to measure the socio-orientation dimension included:

[Your parents] say that they know what is best for you and you shouldn't question them.

[Your parents] want to know what you do with your money.

Examples of items used to measure the concept-orientation dimension were:

[Your parents] say you should decide yourself how to spend your money.

[Your parents] ask your advice about buying things.

Responses to these and similar items were measured on a 5-point scale ranging from "very often" to "never." Responses were then summed across the six items used to measure each dimension.

Internal consistency (coefficient alpha) for the items was established in previous consumer socialization research (Moschis and Moore 1978). Internal validity was confirmed through the application of factor analysis. Two factors representing each dimension of family communication structure were extracted using principal components analysis (varimax rotation). Further, for the present study, all items intended to measure each concept were loaded on their respective hypothesized family communication structure. Responses were not significantly affected by the respondent's demographic characteristics (Moschis et al. 1983).

Results

Table 1 shows the results of analysis of variance used to test the hypotheses. Generally, the results support Hypothesis 1. Specifically, pluralistic adolescents are more likely than adolescents from other family backgrounds to have more negative attitudes toward the marketplace ($p < .01$) (Hypothesis 1b), have preferences for brands ($p < .05$) (Hypothesis 1c), have greater purchasing independence ($p < .05$) (Hypothesis 1d), and they are more likely to hold egalitarian sex-role perceptions ($p < .01$) (Hypothesis 1e) and have syncratic family-role structures ($p < .05$) (Hypothesis 1f). The data did not support the hypothesis that pluralistics are less dissatisfied with the products they buy or use,

although the nature of the relationship was in the expected direction.

The data did not provide adequate support for Hypothesis 2, regarding relationships between protective FCP and consumer behavior. Although the nature of the relationships was in the expected direction, protectives were not more likely than their counterparts to score lower on measures of purchasing independence, brand preferences, attitudes toward the marketplace, and consumer discontent, nor were they more likely to hold traditional sex-role perceptions. The data, however, supported Hypothesis 2f, showing that protective families are characterized by a husband-dominant family role structure ($p < .05$). Perhaps the pluralistic child's susceptibility to outside-the-home influences may only apply to informal social rather than to commercial influences in the marketplace (Moore and Moschis 1978).

With respect to the hypothesis concerning laissez-faire families support was provided for the notion that there is little interaction about consumption among its members when conflict occurs (Hypothesis 3). Finally, the data provided adequate support for Hypotheses 4a and 4b concerning consensual children. Specifically, consensuals were more likely than adolescents in other groups to have positive attitudes toward the marketplace ($p < .01$) and to express greater dissatisfaction with products they buy or use ($p < .01$).

In addition, the data in Table 1 show other significant relationships that were not hypothesized. Specifically, laissez-faire adolescents are less likely to have preferences for brands than adolescents in any other group ($p < .01$). When it comes to resolving conflict in the family, the father is less likely to decide what the family should do among pluralistics, and the mother is less likely among consensuals ($p < .05$). Consensuals are less likely to adopt a syncratic family role structure ($p < .05$).

Discussion

While not all hypotheses were supported, the results of this study suggest that family communication patterns may have a significant influence on young people. The results appear to be in line with those reported in earlier studies using different sets of dependent measures of consumer behavior (Moore and Moschis 1978 and 1981; Moschis and Moore 1978 and 1979b; Moschis et al. 1983). Generally, the results across this limited number of studies suggest that pluralistics seem to be the most competent consumers at this particular age. This may be due to better training or earlier learning that can take place among these families. Protectives seem to develop patterns that are influenced by interpersonal relations (c.f. Moschis 1985), but such influences may only be confined to informal types. Consensuals appear to have patterns characterized by positive reaction toward marketing stimuli, while laissez-faires appear to be the least competent consumers.

Our study addressed general parent-child communication patterns, with little emphasis upon the specific parent (father, mother) and child (male, female) interaction. Future research should examine family communication patterns in such specific contexts). Further studies should also investigate different skills, attitudes, and behaviors, and they should replicate previous studies. Replication and accumulation of research findings in this area should help us better understand the important role of the family in the consumer socialization of young people.

Appendix

Family Communication Measures

The question designed to measure family communication patterns was the following:

Following is a list of things parents often say or do to their children. Read each statement carefully and check whether your own parents (or whomever you live with most of the time) say or do it very often, often, sometimes, rarely, or never.

Items used to measure socio-orientation were:

Your Parents ...

Tell you what things you should or shouldn't buy.
Want to know what you do with your money.
Complain when they don't like something you bought for yourself.
Say that they know what is best for you and you shouldn't question them.
Say you shouldn't ask questions about things that teenagers like you don't normally buy.
Say you may not buy certain things.

Items used to measure concept-orientation were:

Your Parents ...

Ask you to help them buy things for the family.
Ask you what you think about things they buy for themselves.
Ask you for advice about buying things.
Say you should decide what things you should or shouldn't buy.
Say that buying things you like is important even if others do not like them.
Say you should decide yourself how to spend your money.

Note: The sample was divided into "high" and "low" groups on each dimension by splitting each of the two summated scales at median, yielding the four-fold typology of FCP.

FAMILY DECISION MAKING IN LEISURE-TIME ACTIVITIES: AN EXPLORATORY INVESTIGATION
OF THE IMPACT OF LOCUS OF CONTROL, CHILD AGE INFLUENCE FACTOR AND PARENTAL TYPE
ON PERCEIVED CHILD INFLUENCE

William K. Darley, Indiana University
Jeen-Su Lim, University of Toledo

Abstract

This paper examines the impact of parental locus of control, child age influence factor and parental type (single or dual parents) on perceptions of child influence in three specific leisure-time activities. The results lend support to previous research in terms of child influence and its dependence on product or activity specificity. In addition, locus of control, child age influence factor and parental type are found to have differing impacts on the various stages of the decision-making process.

Introduction

Family decision-making studies have focused on the roles of the husband-wife dyad and have ignored the roles of children. Several reviewers (Burns & Granbois 1980; Dunsing & Hafstrom 1975; Ferber 1975; Granbois 1979) have expressed concern about the inherent dangers of the over emphasis on the dyad and the failure to take into account the total family composition, even when the products in question have been consumed by the total family.

Besides the limitations inherent in ignoring the influence of children in family decision-making, the trend toward more single parent families has not been adequately considered in family decision-making research. Not only may such neglect produce misleading results, but they may have far reaching effects on managerial decisions pertaining to consumption behavior.

The purpose of this study is to investigate parental perception of child influence concerning three leisure-time activities. These activities are movie-attendance (family-type movie), family outing (a picnic) and participant sports (e.g., the family going to bowl or skate together). The three leisure-time activities were selected because they represent three different types of discretionary activities (Holbrook & Lehmann 1980). The questions of interest are whether differences will be seen to exist in perceptions of child influence among external and internal locus of control parents, among single and dual-parent families, and whether this perceived influence varies at different stages in the decision-making process.

It is worth noting that most of the relevant research has focused on the decision-making process as it pertains to large, resource-binding and infrequent purchase experiences (Burns & Granbois 1980). Besides the limitations inherent in the types of products featured in the studies, the influence of children in family decision-making and the trend towards more single parent families have too often been ignored. Hence, the investigation of three leisure-time activities, and the impact of parental locus of control and parental type on perceived child influence may provide new insights in family decision-making.

Locus of Control

As a moderating personality characteristic, locus of control is concerned with the degree to which individuals perceive themselves as being in control of their lives and events that influence their lives, or the degree of control individuals perceive themselves to possess in regard to the consequences of their behavior (Rotter 1966). Individuals having an external locus of control tend to attribute the influences on their lives to such things as luck, fate, chance or strong forces they cannot overcome. People having an internal locus of control tend to attribute the influences on their lives to forces such as their own skills that are within their control. Externalists attribute causality to environmental forces while internalists

assign such attribution to personal forces.

Internal locus of control and external locus of control individuals differ not only as to their attentiveness to information immediately present in the environment, but also in terms of their actively seeking additional relevant information (Seeman 1963; Seeman & Evans 1962). Consequently, parental locus of control may have varied impacts on the search element within the decision-making process. In addition, persons with an external locus of control may be more likely generally to let others influence them, than may those with an internal locus of control.

Extrapolating from the foregoing ideas, we hypothesize that:

H₁: Different degrees of child influence will be perceived by internal versus external locus of control parents, with external locus of control parents assigning greater influence to their children.

It has been suggested that more consideration be given to the inclusion of personality variables in future studies as to family decision-making (Dunsing & Hafstrom 1975). Thus, the introduction of parental locus of control may provide additional insight into our understanding of child influence in family decision-making.

Type of Parenting (Single vs Dual Parents)

This paper also investigates single and dual parents' perceptions of the influence of children in various subdecision areas. Demographic data clearly indicates a trend toward more single parent families; the increase in one parent families is among the most dramatic social developments of the last decade. The number of one parent families in the U.S.A. increased 79% from 1970 to 1979. In 1970 about 11% of the families with children still living at home were maintained by one parent, but by 1980 this percentage had increased to 20%. That is one of every five families with children in the home (U.S. Bureau Press Release, CB 80-154; and interview with James Weed, Head, Marriage and Family, U.S. Census Bureau).

Such a recognized increase supports the argument of a changing family structure. Changes in family structure may lead to changes in decision-making patterns and coalitions within the family. The absence of a parent will lead to changes in decision-making patterns among the single parent and the children. This absence of a parent not only changes the family structure and composition, but it is expected that the decision-making patterns resulting from the influence of the child or children is likely to change as well.

Extrapolating from the aforementioned ideas, it is hypothesized that:

H₂: Different degrees of child influence will be perceived by single- versus dual-parent families, with single parents assigning more influence to the children than do dual-parent families.

It would be of interest to both practitioners and academicians, therefore, to understand the impact of the above changes on certain aspects of family decision-making and to identify differences between dual-parent and single-parent families.

Children

Previous studies suggest that the children's ages is one of the factors which affect the likelihood of influence upon a parental decision (McNeal 1969; Mehrotra & Torges

1976; Ward & Wackman 1972). Jenkins (1979), for example, found that older children, especially teenagers, were perceived to have more influence, and that both spouses perceived children to be highly influential in deciding on what activities the family will participate in jointly, especially regarding vacation decisions.

A purchase decision is composed of a sequence of decisions and different individuals within the family may play different roles at different stages (Davis 1970; Jenkins 1979). One should expect the perceived influence of children, therefore, to vary across the different stages of the decision-making process.

In keeping with the foregoing, for this study an age distribution index was computed by assigning the numbers 1, 2 and 3 to the different age groups 0 to 5, 6 to 12, and 13 to 17 respectively. This subdivision of the age groups of children is a modified version of the categorization proposed by Erik H. Erikson, a noted psychoanalyst (Thompson 1981, p. 51). The sum of the products of the assigned number and the number of children in the various categories was divided by the total number of children in each family. The age distribution index thus was used to determine high or low child age influence factor. The child age influence factor was classified as high for families whose indices were greater than 1.5 to 3. Low child influence factor reflected those indices from zero to 1.5.

Based on this discussion, we hypothesize that:

H3: Child age influence factor has significant impact on the degree of perceived influence assigned to children.

In addition, a major concern in this research is to enquire as to the extent to which locus of control, parental type and the child age influence factor affect perceptions of child influence. Hence, it is hypothesized that:

H4: The impact of locus of control, type of parenting (single or dual) and child age influence factor will vary, depending on the involved stage of the decision-making process.

Methodology

A convenience sample comprising 106 parents in the Washington, D.C. area was used in this exploratory study. The data were collected from small groups and residential family units in three geographic areas under the supervision of the first author. Three graduate students assisted in the endeavor. About two-thirds of the respondents were females. Of the total population sample, including both males and females, about a third were single parents. The average family income ranged between \$15000 and \$25000, while the typical respondent age ranged between 25 and 40 years.

Each parent was asked to respond to a series of questions about the perceived influence of his/her children pertaining to the subdecisions within each of three leisure-time activities. The three leisure-time activities were: (a) motion picture attendance (at a family type movie), (b) family outing (a picnic), and (c) participant sports (e.g. the family going together to bowl or skate). These activities were outside-the-home, leisure-time activities in which the entire family could participate. Following the tradition of Davis (1970, 1971), with slight modifications, respondents were asked to indicate child influence on a five-point Likert-type-scale, ranging from "never influential" to "almost always influential" for the seven subdecisions of when, how much, where, etc., pertinent to each leisure-time activity.

It should be noted that even where the household contained both parents, only one parent responded to the questionnaire. Much evidence (Davis 1970; Granbois & Willet 1970; Wilkening & Morrison 1963) is provided already that the responses of husbands and wives are very similar when compared on an aggregate basis. Indeed, Davis (1976) argues that if the purpose of a study is limited to describing the relative influence of husband versus wife in making

various decisions, it is sufficient to question only one spouse; on the other hand, if the researcher in subsequent analysis wants to use a measure of influence, data should be collected from both spouses.

After responding to the items relating to the degree of child/children influence on the three leisure-time activities, subjects were asked then to respond to Rotter's Internal-External locus of control scale (Robinson & Shaver, 1980). This scale consists of 23 question pairs using a forced-choice format. A point is given to each external statement selected. Thus, scores can range from zero (most internal) to 23 (most external). In this study, scores less than 11 were classified as "internals" while scores greater than 12 were classified as "externals."

The final section of the questionnaire asked the respondents to reply to a number of demographic questions. These included questions about ages of the children concerned, the sex of the responding parent, her/his marital status, annual household income, number of children in the home, age of the responding parent, and whether the parent questioned was currently a single parent or not.

Analysis

Multivariate Analysis of Variance (MANOVA) was performed to test the hypotheses. MANOVA unique sum of squares procedure (SPSSX) was used since the cell sizes were unequal. The dependent measures were the perceived child influences for the seven subdecisions/areas. The factors in the 2x2x2 full factorial design were: external versus internal locus of control parents, single versus dual-parent families and the high versus low child age influence factor. In addition to the overall significance, the contribution of the independent variables to the overall significance was investigated using Analysis of Variance (ANOVA).

Table 1A shows the group means of the responses made by the internal and external locus of control parents. As indicated by the results for the three activities, there were consistently greater perceived influence responses coming from the external locus of control parents than from the internal locus of control parents. This was true for each individual item statement from the 68 external locus of control parents and 38 internal locus of control parents.

Table 1B shows group means of the responses made by single and dual parents. For most subdecision items single parents made greater perceived influence responses. Excepting five instances (one for movie attendance, two for participant sports and two for family outing), the group means attained from the 40 single parents and the 66 dual-parent families indicated greater single-parent perceived influence assigned to children. Table 1C shows group means of the responses for the child age influence factor to be considerably greater for the high child age influence factor group than for the low child age influence factor group.

Table 2 shows MANOVA results of the three leisure-time activities this study investigated. Wilks' Lambda is the multivariate test of significance used. For movie attendance there was a global significant difference between the responses of the external and internal locus of control parents. No interactions were significant. For participant sports, significant difference was at the 0.05 level between the high and low child age influence factor groups. That significant result is qualified by a significant interaction between locus of control and child influence. For family outing, two significant main effects were obtained for single vs dual parent and low vs high child age influence factor. No interaction effects for family outing were significant.

Partial support thus is provided for H1, H2 and H3. The locus of control main effect was significant, at least for movie attendance. Main effects of single vs dual parent and child age influence factor for family outing were significant at the .05 and .10 levels respectively. However, because of the significant interaction between locus of control and child age influence factor, the main effect for participant sports is uninterpretable.

Hypothesis 4 can be examined in Table 3A, B and C. These tables show the ANOVA results for the three activities in terms of the seven subdecisions. In the case of participant sports (Table 3A), significant locus of control main effects were obtained for the following subdecision items: "what type," and "when to go." Significant parental type main effects were obtained for "how much to spend" and "where to go." All of the child age influence factor main effects were significant with exception of "where to go."

Pertinent to movie attendance (Table 3B), none of the locus of control main effects was significant and only "when to go" showed significant parental type main effect. Two

significant child age influence factor main effects were also obtained for "specific information" and "when to go." Considering Table 3C, significant main effects of locus of control and child age influence factor were found only for "specific information" and "how much to spend" respectively for the family outing subdecision items.

An examination of Tables 3A, B and C indicates that proportionately the child age influence factor shows a much greater variation than either parental type or locus of control. The hypothesis of no variation is rejected (H₄). The results show somewhat weak, but significant, variation.

Given the number of significant interaction effects between locus of control and parental type in the case of participant sports, this covariation was investigated by examining the marginal means. Table 4 presents the marginal means. In the case of external locus of control parents, there was no substantial difference in the perceived child influence between single and dual parents. However, for internal locus of control parents, the marginal means clearly show that the single parents perceive less child influence than do the dual parents in all stages of the decision making process, except "where to go."

Conclusion

Although this study does not offer conclusive results, it nevertheless lends support to the general idea that perceptions of child influence are product specific. Mehotra and Torges (1976) concluded that variables which increase the likelihood of parental yielding to influence attempts by children for such products as children's clothes,

potato chips and soft drinks, are product specific. In our findings, group differences in perceptions of child influence tended to be leisure-activity specific.

Partial support was provided for the Hypotheses 1, 2 and 3. The results showed that locus of control, parental type and child age influence factor had significant impact on perceived child influence. In addition, the results showed significant variation of the impact of the three factors on the perceived influence in the different stages of the family decision-making process as hypothesized in Hypothesis 4.

The child age influence factor showed a proportionately greater variation than either parental type or parental locus of control. This observation was particularly true for participant sports and for the stages of the decision-making process. Thus, for activities such as participant sports, involving a high degree of involvement, interaction and time commitment, the child age influence factor makes a big difference in the parental perception of child influence. In addition, the findings lend support to the fact that the age of the child has a significant impact on perceived child influence.

Where to go	3.74		3.59		3.89		3.66	

At the subdecision level, not counting the significant interactions, one locus of control main effect of the ANOVA results was significant for family outing. This was "specific information." Thus, at least for certain aspects of the search process, external locus of control parents perceive greater child influence. For movie attendance, there was only one significant parental type main effect, namely, "when to go." Hence, in the timing aspects of the decision making process, single parents perceive greater child influence. Finally, for the child influence factor the following significant main effects were obtained for participant sports, family outing and movie attendance: all subdecision items were significant except "where to go" in the case of participant sports; "how much to spend" for family outing; and "specific information" and "when to go" for movie attendance. The child age influence factor thus appears to make a major difference, not only to a great extent for participant sports, but also to some extent for movie attendance and family outing.

Future research should explore the locus of control and type of parent issues, using further similar and different kinds of settings with other product/activity types and in

other purchase situations. The locus of control and parental type (single versus dual) provide some insights into parental perceptions of child influence. The degree of influence which that parental type may have on the locus of control measure needs to be investigated. Given the trend toward more and more single parent families, future research should explore the effects of such changes on family decision making.

The locus of control construct may be applied to husband-wife purchase decisions in that different locus of control couples may practise a different influence strategy mix. Spiro (1983) identified several demographic and attitude variables as discriminators among influence strategy mixes used by husbands and wives in resolving disagreements concerning purchase decisions. The addition of the locus of control concept to such studies will introduce a new dimension in identifying the possible influence strategy mix of husbands and wives, since it is possible that different locus of control couples may practise different purchasing decisions. It is suggested, therefore, that the locus of control concept be investigated further in the context of husband-wife relationships in particular, and in family decision-making, in general.

Of all three factors investigated in this study, the child age influence factor appeared to have had the strongest impact on parental perception of child influence. This observation suggests that future research interested in perceived child influence would have to treat some child-age aspect as a covariate or would have to control this factor in the research design.

A CONJOINT MODEL FOR ANALYZING NEW PRODUCT POSITIONS IN
A DIFFERENTIATED MARKET WITH PRICE COMPETITION¹

Jordan J. Louviere, University of Alberta²

Abstract

This paper extends existing conjoint choice techniques to handle problems involving the positioning of new product concepts in existing, competitive product markets. It permits explicit competition for customer choices among a number of existing products and one or more new entrants. The approach therefore is useful for analyzing both positioning and repositioning strategy in competitive product markets. Use of split-plot or incomplete block designs together with the multinomial logit choice model permit considerable flexibility in both design and analysis. An illustrative application to an agrochemical marketing problem is provided.

Introduction

In 1975 D.F. Jones described a simple survey technique that could be used to anticipate changes in the demand for a product or service under different pricing policies. As Jones (1975, p. 75) expressed the problem:

"One of the more challenging tasks that confronts marketing researchers is that of determining the probable effect of different pricing policies on the sale of a new or existing product. Closely allied to this problem is that of determining how the modification of a product or its image will affect sales if price remains constant or if it, too, is modified in some manner."

Jones' approach permitted one to estimate the own-elasticity of the price of the product or service of interest, assuming constant prices of existing competitors and/or other brands for the same manufacturer.

Jones' (1975) approach was extended by Mahajan, Green and Goldberg (1982) to explicitly consider the simultaneous manipulation of the prices of all competitors, not just a single competitor. Furthermore, Mahajan, Green and Goldberg (1982) linked the estimation of these effects to a conjoint choice experiment, the results of which could be analyzed by means of the multinomial logit choice model (Theil 1971; McFadden 1974; Hensher and Johnson 1981; Amemiya 1981). Thus, Mahajan, Green and Goldberg (1982) succeeded in linking multiattribute conjoint concepts with an explicit competitive choice experiment, the analysis of which was consistent with a particular theoretical choice model.³ In their 1982 paper, Mahajan, Green

and Goldberg (p.341) suggested that the simple pricing model could be extended to include non-price competition:

"... it is straightforward to extend the technique to other classes of product-service attributes, such as physical characteristics, packaging, distribution and advertising. In principle, the same kind of procedure would be followed, but attributes other than (or in addition to) price would be systematically varied for both the firm's offering and various explicitly defined competitive offerings."

Louviere and Woodworth (1983) provided a systematic extension of the Mahajan, Green and Goldberg (1982) ideas to a wide variety of choice experiments, including those in which the set of competitive products-services varies. Louviere and Woodworth also prove that certain classes of choice experiments provide near optimally efficient estimates for multinomial logit choice models. Louviere and Hensher (1983, p. 352) note that choice experiments which do not explicitly include a "non-purchase" alternative produce market share and not true demand models.

None of these research papers have explicitly considered the problem of introducing a new product concept with differing levels of a set of product attributes into a product class of existing products competing on both price and non-price attributes. The solution to such a problem is of managerial interest because managers need to know how to best position the attribute levels of a new product concept given present product positions and potential competitive reactions, often price reactions. For example, as reported by Ingrassia (1980), Sony's market share was consistently eroded by the advent of slightly modified foreign and domestic TV products which engaged in intensive price discounting, to which Sony was eventually forced to respond. If an approach were available to managers of new or existing products that could provide information about the likely competitive consequences of various attribute/price configurations in competition with current positions and possible repositionings of existing products, this would constitute a useful extension of previous work.

Such an approach also has the potential to contribute to our empirical understanding of firms' strategic positioning policies as well as the market's response to such policies. The practical relevance of the approach is to provide information to management to anticipate the likely consequences of positioning policies of their own and of their competitors. Additionally, the information provided about positioning consequences for new and existing products in the face of competition provides an important extension to existing conjoint techniques.

The need for such techniques and for empirical research in this area is well-documented in the series of papers presented at the pricing conference at the University of Rochester (Gould and Sen, 1984): for example, reviews by Rao (pp. 39-60) and Nagle (pp. 3-26) clearly indicate the current limitations of applying theoretical economic models to real managerial problems; while Markham (pp. 257-263) indicates the value of empirical research on strategic pricing problems to enrich the axiomatic base of economic models. The approach proposed in this paper, therefore, has the potential to contribute to practical problem solution, theory testing and empirical understanding. The emphasis in this paper, however, is on practical problem solving, although suggestions for useful extensions of theoretical and empirical interest are discussed in The Discussion and Conclusions section.

The author also wishes to acknowledge the assistance in data collection and analysis provided by Mike Zenor, Tim Heath and Tim Eliason as part of an MBA Marketing Research Project. Dave Curry, Gary Gaeth and Mark Moriarty read the first draft and provided useful comments and suggestions which this version incorporates. Faults remaining, however, are my own.

²Jordan Louviere was Associate Professor of Marketing, University of Iowa when this paper was written.

³Although relying on an orthogonal design plan to vary absolute levels of prices, the design used by Mahajan, Green and Goldberg is not orthogonal in price differences, as required by the linear logit model they employed.

The purpose of this paper, therefore, is to describe and illustrate an extension to the strategic pricing model of Mahajan, Green and Goldberg (1982) which permits the evaluation of the market potential of new product concepts competing with a set of existing products. In addition we provide two methodological extensions for conjoint choice problems:

1. An extension of the Mahajan, Green and Goldberg (1982) method which permits existing products to vary on strategic dimensions other than price. This latter extension permits examination of the potential consequences of reformulations and repositionings.
2. An extension of the Louviere and Hensher (1983) approach for creating multiple levels of numerical variables that explicitly allows for tests of nonlinearities.

The proposed approach is particularly well suited to address strategic problems in product classes in which the properties (attributes) of the existing brands are relatively fixed in the short run, as for example, agricultural chemical formulations or ethical drugs. The original formulations may have been discovered accidentally, or may have benefitted from positioning research that suggested certain attribute configurations that would appeal to particular segments. Thus, major marketing strategies for these products involve (inter alia) communication of benefits, positionings and pricing policies. For the sake of example we assume that pricing policy is of major interest to management, an assumption shared by Mahajan, Green and Goldberg (1982) in their approach.

Such problems arise frequently in agricultural chemical marketing and ethical drug marketing because of the relatively permanent nature of the product attributes and the long lead times to introduction dictated by research, development and testing, and U.S.D.A. approval policies. Although agricultural chemicals can be reformulated, existing formulations often are fixed for the near term: hence, estimates of the likely market potential of new product concepts or repositionings of existing products can be of significant strategic value to management faced with a considerable time and monetary commitment to reformulating an existing product or introducing a new formulation.

Existing conjoint judgment techniques are ill-suited to this type of strategic problem because a) there is no explicit incorporation of competitive actions/reactions, b) judgments such as ratings or rankings are not choices, and assumptions must be made to transform such data into choice data, c) the number of judgments required of customers to duplicate choice information that can be easily obtained from a few, well-designed choice sets is often considerable (e.g., in the empirical study reported later, a minimum of 40 conjoint profiles would be needed to develop a choice simulation to duplicate the information obtained from 18 choice sets).

In contrast to this relatively complicated approach that requires a number of untested and untestable assumptions about choice in order to derive forecasts, the present approach is much simpler. In particular, choices are directly observed, not simulated and all relevant products and product concepts compete for customer choice simultaneously. Thus, the data needed to forecast the likely changes in customer choices in response to competitive actions are obtained directly from respondents and used to develop a statistical choice model. The choice model can then be tested for statistical adequacy using observed choices, unlike the conjoint judgment approach that can only be assessed in terms of ability to predict to some additional (hold out) choice data collected in the study.

This paper outlines an approach to competitive choice problems, and illustrates it with an application to an existing product class of agricultural insecticides. We

avoid mention of the type and brands of insecticide and the study region to protect the identity of the organization who sponsored the empirical research. It is important to note that the approach proposed in this paper has application to a wide range of high involvement products in addition to agricultural chemicals.

Proposed Research Approach

The effect on choice behavior of introducing various new product configurations into an existing, competitive market can be examined by developing a conjoint choice experiment. This paper develops the basis for a conjoint experiment that (1) accommodates a large number of different levels of price (or any other quantitative variable which is monotonically related to the response or can be prescaled to be monotonically ordered if nominal), and (2) permits simultaneous consideration of the effects of the prices of existing products in competition with a series of new product concepts or profiles. Although the application to a pricing problem is the primary focus, the approach generalizes to any non-price attributes of interest.

The proposed approach represents an extension of the Louviere and Woodworth (1983) choice experiments based on factorial designs to include "split-plot" and block designs (See, e.g., Federer 1975a, 1975b, Cochran and Cox 1957). The idea is to use two (or more) different (fractional) factorial designs to vary both the prices of existing products, and the attribute levels of new product concepts (profiles). These two (or more) designs are then combined into two (or more) "plots" or blocks using conventional procedures associated with these types of designs. The empirical example we use to illustrate the approach is based on the use of "split-plot" designs, although a balanced, incomplete block design could have been used. We concentrate on "split-plots" because they are so easy to construct, and because they satisfy the necessary conditions of alternative independence for estimating Multinomial Logit Choice (MNL) Models.

The "plots" are created by ordering the treatments in each of the two designs (e.g., 1. existing product prices, and 2. new product concepts) separately such that the rank order correlation between the order of treatments in one design with those of a second design is minimized.⁴ The MNL model assumes non-correlated, i.e., independent, marginal utilities, so minimizing the rank order correlation of two different sets of rank orders corresponds to minimizing the correlation between the attributes of the separate marginals. Because both designs have $m(=1,2,\dots,m)$ treatments, the ordered pairs determine the choice sets to be used (the merger of the two separate designs).

The specific procedure we propose is: (1) Create separate (fractional) factorial designs with the same number of treatments, e.g., a) to examine pricing policies for existing products, and b) to create new product concepts by varying the key decision attributes of the product class. (2) Develop two sets of rank orderings whose rank order correlation is as close as possible to zero for the m treatments. (3) Then, treat the ordered pairs as choice sets, consisting of a pair of treatments from each design. For example, if the first pair of orders is (6, 16), the first choice set should pair the 6th treatment from the pricing design with the 16th treatment of the attribute or concept testing design.

If the marginal relationship of each numerically valued attribute can be assumed to be monotonic with respect to the criterion variable (e.g., "utility") then a fairly large number of levels of this particular attribute can be investigated using a procedure suggested by Louviere and Hensher (1983). In particular, most monotone rela-

⁴If there were n such designs to be merged, the rank order correlation of the orderings of all $N(n-1)/2$ pairs would need to be minimized.

tionships can be inferred from (at least) a three level factor because most such curves have only one bend.⁵ Thus, an extension of the Louviere and Hensher (1983) approach which used factors with two levels to describe price effects can be accomplished by treating each existing product of competitive interest as a price factor with three levels. The main advantage of this approach is to generate a design which varies more than two or three distinct levels of numerical attributes, while retaining the statistical power to estimate nonlinear (but monotonic) marginal relationships relying upon regression rather than ANOVA procedures.

This approach requires that the analyst divide the range of prices that contains the possible variation for the study period of interest into three categories of equal width: e.g., "high", "medium" and "low". One then chooses a (fractional) factorial design to vary product prices which is some version of a 3ⁿ plan. Each "high" level of price in the 3ⁿ design plan is randomly assigned a particular numerical value of price from a range of prices categorized as "high"; similarly, each "medium" and "low" level of price in the design plan would be determined by randomly assigning price values from the range of prices assigned to the "medium" and "low" price categories. A variation of this would be to assign price values to each price category ("low", "medium", "high") according to a latin square ordering of these levels (e.g. (1,2,3), (1,3,2), (2,1,3), (2,3,1), (3,1,2), (3,2,1) in which each price factor would receive one of the six latin square orderings selected at random. The latin square would determine the order of the levels within each price category.

The use of both the procedure for creating additional levels and the "split plot" approach for merging compatible designs is illustrated in the empirical study reported in the next section.

Empirical Illustration: Farmer Choices Among Alternative Crop Insecticides

As part of a larger study of farmers' use of, knowledge about and perceptions of a variety of crop insecticide products, a choice experiment was designed and administered according to the ideas developed in the previous section. The project was underwritten by a grant to the University of Iowa from a major chemical company, so we will reveal only as much detail as necessary to understand the experiment, the data analysis and the interpretation of the results. The research project was concerned with investigating the effect of introducing new product concepts into an existing crop insecticide market of a particular type in which existing products compete on price because positions are relative fixed.

Details of the Study Design

Relevant product attributes were determined from interviews with chemical dealers, farmers, and chemical company officials. The following product attributes were selected for analysis: 1) Price per acre at recommended levels of application; 2) Efficacy against seed attacking, plant attacking or both kinds of insects; 3) The number of weeks of protection provided (duration of effectiveness); 4) Whether the odor is described as unpleasant, offensive or irritating to nostrils; 5) The degree of toxicity expressed as a "caution", "warning" or "danger" on the label; 6) Whether the product is formulated as a liquid or granular compound for Preemergent Banded application (applied in bands prior to plant emergence); 7) Whether the product is formulated as a granular compound for Preemergent In-furrow application (applied in the furrow at the time of planting); and 8) Whether the product is formulated as a liquid or granular compound for Postemergent Banded application (applied in bands after emergence).

⁵We recognize that S- and reverse S-shaped curves would not satisfy this condition.

These attributes were varied in an orthogonal main effects fraction of a 2x3 factorial that consisted of 18 treatments (conjoint profiles, or new product concepts). This plan was selected from a 6x3⁶ fractional factorial design cataloged in (Chacko 1980) and modified for this problem. Each of the 18 treatments, therefore, represents a new product concept or "position" in the marketplace.

Seven products competed in the product market of interest at the time of this study; we will refer to them as products A-G. Local farm chemical dealers provided mean price per acre estimates at manufacturers' recommended rates of application. These per acre prices were used to determine the pricing levels of the existing products, as well as the pricing levels of the new product profiles as follows:

Each of the seven existing products was treated as a three level factor, the levels of which were prices; three price categories ("high", "medium" and "low") were used to divide the mean per acre price +/-20% into equal thirds. Each price category was given three equally spaced levels ("high" was +10%, +15%, +20%; "medium" was -5%, the mean, +5%; and "low" was -10%, -15%, -20%). The design mentioned earlier (Chacko 1980) was used to develop a main effects fraction of a 3⁷ factorial to vary the price levels.

This design insures that the marginals of each existing product are statistically independent of one another. In order to insure that the marginals of the pricing design and the marginals of the new product concept design are independent, we use a "split-plot" (Fedderer 1975a,b; Cochran and Cox 1957) procedure to create choice sets that represent a treatment from the pricing design (one profile of the prices of all existing products) paired with a treatment from the new product concept design (a description of a new product and its price).

Because there are nine levels of price for each existing product and the new product concepts, each of the nine levels occurs twice in the main effects plans. The nine levels of price were randomly assigned within each of the three "high", "medium" and "low" price categories separately for each product (other assignment procedures could be used such as Latin Square orderings). The range of price levels for the new product concepts was determined by taking the lowest and highest price levels in the existing product pricing design; this range was divided into equal thirds, nine levels were created and these nine levels were then randomly assigned exactly as was done for the existing products.

The "split-plot" procedure used to create choice sets relies on the creation of two minimally correlated vectors of ranks (the numbers 1-18). The ranks index the treatments in each design; because the treatments in factorials are ordered systematically, minimizing the rank order correlation of the two sets of treatments should make the two sets of marginals approximately statistically independent. Numerical experiments and previous experience with this procedure suggest it achieves this objective. Nonetheless, it would be wise to check the statistical properties of such designs before proceeding to implementation because no mathematical proof yet exists regarding their properties.

Each pair of minimally correlated ranks is used to create a single choice set by associating one treatment from the existing product pricing design with a second treatment from the new product concept design. For example, if an ordered pair is (8,15), the corresponding choice set pairs the 8th treatment in the pricing design with the 15th treatment in the new product concept design. The 18 ordered pairs of ranks therefore generate 18 different choice sets that are shown to subjects in the empirical example described immediately below.

Data Collection and Subjects

The choice design was placed in a survey booklet together with other sections that surveyed demographics, perceptual

positioning and insecticide use and purchase. A list of farmers (owners/operators) was obtained from the A.S.C.S. offices in the target state of interest for each of 10 randomly selected counties. In each county 150 surveys were mailed to randomly selected names based on the A.S.C.S. lists. Surveying was conducted during the height of spring planting, which fact, together with a large (but unknown) proportion of non-farmers on the list, resulted in a return rate of 190 surveys. A raffle incentive was used, giving respondents a chance to win either a \$50, \$30 or \$20 cash prize in a drawing. 135 of these surveys had complete choice data, and form the basis for the illustrative analysis. While this appears to be a very low return rate, it is consistent with normal unsolicited mail survey return rates of 20%-30% because of the large proportion of non-farmers.⁶

The respondent was required to assume that the per acre prices for products A-G were as listed and that a "New" product was also available, with characteristics and price as described. The respondent was asked to examine each set of products and to decide whether they would have purchased any of those listed for their insecticide needs in 1984 had the products been available, and if so, to indicate which one, or to indicate that they would not have purchased any of the products. Instructions emphasized that the A-G products (listed by actual Brand Name) were the only products currently available in their area, so they would have to purchase one of these products or the "New" product, or do without. Each respondent therefore made a single choice in the manner described in each of the 18 choice sets created by the "Split-Plot" design.

Analysis and Results

The discrete choices made by the respondents were aggregated to absolute frequencies for analysis by Generalized Least Squares (G.L.S.) regression. As explained in Nakanishi and Cooper (1982) and Louviere and Woodworth (1983), weighted least squares regression will produce asymptotically efficient estimates of the parameters of the Multinomial Logit Choice Model. We assume that the MNL model is a reasonable model to approximate the choice data. The MNL model may be expressed as:

$$p(a/A) = \frac{\exp[U(a)]}{\sum_{j \in A} \exp[U(j)]}, \quad (1)$$

where $p(a/A)$ is the probability of choosing the a -th product given a set of competing products, A , of which a is a member,

$U(a), U(j)$ are the mean levels of utility associated with products a and j , respectively, and

\exp is the symbol for exponentiation (i.e., e to the 'x' power).

The mean utility levels correspond to the marginal probabilities of choosing each alternative. These marginals can be parameterized as follows:

$$U(x) = \sum_k b_k X_k, \quad (2)$$

where $U(x)$ is the utility of the x -th product,

X_k is a design matrix of levels of attributes, or non-linear transformations of attribute levels, or cross-products of attribute

levels, and b_k is a vector of regression-like parameters associated with each separate vector in the design matrix.

Equation (2) expresses the mean level of utility for each product as a linear-in-the-parameters and additive function of the vectors in the design matrix.

Interest centers on parameterizing the $U(x)$ s, which is accomplished by creating alternative specific attribute vectors and dummy variables for the denominators of equation (1) as explained in Louviere and Woodworth (1983). In the present case each of the seven products (A-G) has a brand-specific parameter (intercept), and a linear and a quadratic price term; the "New" product has a brand weight coefficient, linear and quadratic terms for price, and dummy variables for (n-1) of the levels of each of the product attributes. The "No Purchase" alternative has a utility value of exactly zero. These parameters were estimated from the choice data via a G.L.S. regression (see Table 1, which also lists the mean per acre price levels used for each product as well as the levels of the "New" product attributes).

Let us describe the results for the "New" product attributes: all numbers at the bottom of Table 1 are relative utilities. All had significant effects, although efficacy against insects, duration of effectiveness and price played very major roles in the choice of a "New" product, and odor and toxicity effects were minor, as can be seen by the differences in the utility values of the levels of each attribute. Thus, efficacy against insects and duration of effectiveness had the largest non-price effects. Although not obvious from the top of Table 1, price had the largest single effect with a utility at low of .67 and at high of -.67. All price effects were approximately linear for this product market for the range of prices examined.

The MNL model predicts that all cross-price effects are proportional to the shifts in utility values of the various products. This prediction can be tested by including the cross-price effects in a second G.L.S. regression analysis. These results are given in Table 2; they indicate that there are a number of significant cross-price effects (only the significant effects at the .10 alpha level are listed). Thus, the proportionality hypothesis must be rejected; there are cross-price effects that are less than or more than the effects predicted by the simple MNL model. Such violations of the MNL model can tell us about "who competes with whom", and which products the "New" product will most affect. For example, the "New" product most affects products A, D, F and G, all of which are either low share or cheap. So, it affects the market leaders less than these products. The model fits significantly better than the simple model; the F value for the 19 additional parameters is 4.2(19,96), which is significant well beyond conventional alpha levels. There is therefore no question that the simple MNL hypothesis must be rejected for these consumers.

Farmers were asked to estimate the per acre price of each product; these data were used with the estimates in Table 1 to forecast the 1984 market shares for each product. Shares observed in another section of the mail survey were compared to shares predicted by the derived choice model using the farmers' mean estimated selling prices per acre for each currently available product. Predicted and observed values are graphed in Figure 1; products are not labelled so as to preserve anonymity. As can be noted, the choice model predicts the observed shares well: all predictions lie within the error limits at the alpha-.05 level. This is especially encouraging in view of the fact that both the sample and model estimated shares have error. While this does not necessarily mean that the choice model is externally valid, it does bolster confidence in its use as a predictive model and as a vehicle for drawing strategic inferences for management.

⁶ Despite the low return rate, our estimates of the market shares for 1983 and 1984 are well within the statistical error limits of those independently supplied to us by the company sponsoring the research. Thus, there appears to be negligible bias due to nonresponse, at least as far as share estimates are concerned. Our demographic profiles for the farmers were also consistent with the sponsoring organization's expectations, lending additional support to the representativeness of the sample.

Discussion and Conclusions

This paper described an approach to studying competitive pricing strategy in an existing product market into which new product concepts with varying attribute levels are introduced. This approach extends the previous work of Mahajan, Green and Goldberg (1982) to include more levels of price and competition from a new product. The design approach proposed, when combined with the MNL choice model, permits an analyst to draw strategic inferences about the likely market share consequences of pricing strategies of existing products, as well as the potential shares which can be realized by various positionings of a new product. The proposed approach was illustrated with a strategic choice study of crop insecticides. Model results were meaningful, statistically significant and predictive of actual observed market shares.

Several extensions to the proposed approach are possible. As discussed in Green (1974), the fractional designs within each "plot" can be chosen so as to permit one to esti-

mate various interactions of interest. For example, it will normally be sufficient to estimate only the linear x linear component of each two-way interaction in order to test the null hypothesis of no interaction effects because the majority of the variance in the interaction terms usually will be in that component, even if other components are significant. This is especially true for models in which all marginal effects can be assumed to be monotonic with the criterion; and, of course, this should be the case with price.

An extension to the present study can be developed by imbedding the products that compete on price in a 2^n design as described in Louviere and Woodworth (1983). This 2^n design can be used to place combinations of products in subsets, each of which could have a (potentially) different pricing design. The use of these subsets of designs permits the analyst to simultaneously examine both the effect of entry and exit (presence/absence) and pricing strategy. In this way the analyst can make inferences about which products will gain share at a rate greater (or less) than in proportion to their average utility levels when competing with various other products. The analyst can also make inferences about the way in which pricing strategy might be expected to interact with the product effects, (See, e.g., Batsell 1980; Batsell and Polking 1984).

Another extension involves the new product concepts: the interactions of the attributes of interest could be examined by creating one or more designs which permit them to be estimated independently. The effects of multiple products being introduced could be examined by creating additional "plots" using minimally correlated n -tuples of orders, or by imbedding the products in a second 2^n design to create different choice surveys. In any case, the "split plot" approach allows one to examine a wide variety of realistic competitive choice problems from which strategic inferences can be drawn according to the nature of the design(s) employed. One could also use block design concepts to develop design strategies for studying these kinds of choice problems.

A major advantage to the strategic choice experiments described in this paper is that they are a step closer to simulating the competitive effects of real markets, while retaining many of the advantages of the traditional conjoint analysis approach. Their appeal is the ability to extend choice analyses to non-Luce type models which avoid the IIA (independence from irrelevant alternatives) and constant cross-elasticity assumptions (See, e.g. Batsell 1980; Batsell and Polking 1984). Allowing for the inclusion of certain types of interactions provides the statistical ability to test for violations of MNL assumptions and to estimate statistical models which describe the violations if appropriate. Yet another advantage is that the estimation can be accomplished using G.L.S. regression approaches with widely available statistical software. This should allow progress to be made in the development and testing of choice models which more closely approximate real behavior in response to competitive strategies and tactics.

CONSUMER REACTIONS TO STYLISTIC EXTENSION OF A PRODUCT LINE: THE THEORETICAL RELEVANCE OF TWO "ANCHORING" THEORIES

Kathy L. Pettit, Washington State University

Abstract

Previous fashion research has focused on innovation and/or the innovator. From the retailer's standpoint this emphasis may be disproportionate inasmuch as the majority of his/her sales comes from existing (non-innovative) items. Two psychological anchoring theories are proposed which are potentially relevant in predicting changes in product perceptions and purchasing propensities of previously-offered goods under conditions of product-line extension induced by stylistic innovation. A particular example is presented concerning the addition of the new ultra-wide women's belt. Limitations of the theories are discussed and a potential research methodology is proposed for testing the theoretical predictions.

Introduction

It can be acknowledged that when fashion for an item appears to be moving in a particular direction, at least some retailers respond by carrying innovative versions of the existing product (Wicks 1982). Such innovations, in which the "alteration of a product is involved, rather than the establishment of a new product," are often called continuous innovations (Robertson 1971, p. 15).

The offering by a retailer of these continuous innovations is often a necessity in terms of being competitive. According to Hirschman and Stempel:

The essence of intratype competition (retail) involves convincing consumers to buy a non-unique product from a supposedly unique seller that, in reality, shares many characteristics with other stores of the same type (1980, p. 21).

Thus, by offering the most "up-to-date" items a retailer may succeed in gaining patronage from other retailers by appearing to be unique and, therefore, preferable.

The study of the diffusion of innovation has received widespread attention within a variety of disciplines, and has grown rapidly within the marketing discipline since the 1960s. Research has been conducted by both commercially- and academically-employed marketers, and the S-shaped diffusion curve has become a well-known phenomenon within the discipline (Rogers 1962 and 1976).

However, inherent within such research is, from the standpoint of the clothing retailer, a (perhaps) disproportionate emphasis on innovation and/or innovators. Specifically, to the retailer revenues from the existing product-line are likely to be his mainstay; sales from continuous innovations, in the short-run, are usually a welcome bonus (Wicks 1982). Thus, an important and interesting side-issue concerning innovations is the effect they have on perceptions and purchasing propensities of various previously-offered items within a product-line. Some background considerations of two potentially relevant psychological "anchoring theories" will be discussed, which may prove useful in predicting such effects of product-line extension. Later, specific predictions of each theory concerning the effect of addition of the new ultra-wide women's belt to the product-line will be given. Finally, potential methodology for testing the various predictions will be presented.

Background

Anchoring theories were first developed to explain shifts in psychophysical judgements. Psychophysical

judgments are those in which an individual is asked to rate objects which vary along a physical dimension (e.g., weight) in terms of a subjective psychological dimension (e.g., light versus heavy). In psychophysical experiments certain stimuli which are external to the individual tend to serve as relatively strong judgmental anchors. That is, the range of the present objects along the physical continuum and/or the midpoint of the object series, as well as a "standard" (reference) object within the series, have been shown to affect psychophysical judgments (Helson 1947; Parducci and Marshall 1962; Postman and Miller 1945; M. Sherif, Taub and Hovland 1958; Volkman 1951).

Later, anchoring theories were applied to psychosocial judgments which underlie attitudes and attitude change. Psychosocial judgments can be distinguished from psychophysical judgments by both of the following:

- 1) The predetermined evaluative nature of categories is less inherent to the individual in psychosocial judgments than in psychophysical rating tasks, and
- 2) As a result, greater discrepancies among judgements of individuals are observed in psychosocial tasks than in purely psychophysical rating tasks.

Typically, in psychosocial judgments tasks individuals have been asked to judge the favorability of statements about an attitude object(s). Certain anchors external to the individual, usually stimulus range (Ostrom and Upshaw 1968; M. Sherif and C. Sherif 1969) and midpoint (Helson 1964) have again been shown to produce judgmental shifts. However, internal anchors such as the individual's own attitude or advocated position along a continuum of object-related statements (Helson 1964; Manis 1964; Ostrom and Upshaw 1968; M. Sherif and C. Sherif 1969; C. Sherif 1980; Upshaw 1977), his/her cultural membership (C. Sherif 1963), his/her prepurchase expectations (Olson and Dover 1979) or an instrumental value (Pettit 1983) have also been found to affect judgments.

When a consumer judges a product it can be argued that both psychophysical and psychosocial rating tasks are involved. For instance, when a woman judges the subjective width of a belt the task is predominantly psychophysical in nature. That is, a consumer is presented with a physical property of an object--its objectively measurable width--and asked to "translate" that cue into a psychological judgment such as wide, medium, or narrow. Such a judgment is characteristic of psychophysical rating tasks in that items of objectively wider dimensions are nearly uniformly rated as wider by all consumers.

However, when a shopper evaluates a product in terms of its appeal, or assesses her own propensity of purchasing the item, the judgment task becomes more psychosocial in nature. That is, consumers may have very idiosyncratic assessments of either the appeal of a particular item or their own likelihood of purchasing it. Thus, to a greater extent than with judged width, the appeal of the items lies in the minds of individual consumers.

It is rather easy to see in the belt judgment problem being proposed that the range of widths of belts available on the rack could serve as the relevant external judgmental anchors. However, what sort of internal anchor could reasonably be expected to affect width and/or purchasing propensity judgments? Early adoption propensity has been conceptualized as being functionally

related to the need-fulfillment potential of a product, product accessibility, the income sufficiency of the consumer, and the innovation disposition of the consumer (Kotler and Zaltman 1976). The question remains, however, whether the consumer is actually aware of her own innovation disposition.

Support for the notion of awareness of one's own innovation disposition comes from a variety of sources. First, self-image and self-concept is becoming increasingly recognized as a relevant predictor of human behavior (Archer 1980; Arkin 1980; Bem 1965; Enzle 1980). Markus (1977 and 1980) has identified several self-schemas which:

...Develop from the repeated similar categorization and evaluation of behavior by oneself and others, and result in a clear idea of the kind of person one is in a particular area of behavior. Such (cognitive) structures enable individuals to understand their own social experiences and to integrate a wide range of stimulus information about the self into meaningful patterns. They also direct attention to behavior that is informative of these aspects of the self (Markus 1980, p. 111).

A schematic, as opposed to an aschematic individual, views the particular dimension (e.g., fashion-conscious versus fashion-unaware) as important to herself. Furthermore, schematics for a particular dimension, for instance fashion-consciousness, may exhibit varying polarities, of which they are aware. Within marketing contexts self-image was shown to be successful in developing managerially-useful fashion lifestyle segments (Gutman and Mills 1982), and included such measures as "traditional-" versus "modern-", and "taking changes-" versus "playing it safe-" self-descriptors. Gutman and Mills have identified three distinct fashion lifestyles segments of "fashion-conscious" or "fashion-involved" shoppers which, collectively, comprised about one-third of their sample and included:

- 1) Leaders (14.0%): Individuals who scored high on such factors as fashion leadership, interest, and importance, and low on antifashion attitude, ...and who accepted the "establishment views" on fashion ...as demonstrated by their strong involvement with mainstream (e.g., designer) fashion looks,
- 2) Followers (8.3%): Individuals who exhibited a similar profile to leaders, but with an obviously lower score on the leadership dimension, and with a tendency to emulate the leaders, and
- 3) Independents (10.4%): Individuals who are also fashion-aware but differ from the first two groups in their strong antifashion attitudes, ...and who are interested in fashion, but resent designers and other fashion experts in the "fashion establishment" dictating tastes to them (Gutman and Mills 1982, p. 75).

Further support is found in the research of Crask and his colleagues who reported that "Modern males display a greater degree of fashion consciousness as well as a greater desire to differentiate themselves through their dress than do traditional males" (Crask et al. 1977, p. 244). Modernness of masculine lifestyle, as well as fashion-consciousness, was again determined through self-designation techniques.

Finally, upon reviewing the literature both within and outside of the domain of fashion, Darden and Reynolds conclude:

Studies which have employed two or three operations (self-designation, sociometric and key informants' ratings) with the same respondents have consistently found positive correlations between the operations (Abelson and Rugg 1958; Rogers and Burdge 1962; Rogers and Svenning 1969). These findings indicate that each of the methods is equally valid (Rogers and Shoemaker 1971). (Darden and Reynolds 1972, p. 324)

Thus, within the context of the present paper the position will be taken that: 1) innovation disposition is an important element of innovation propensity, 2) fashion-conscious individuals comprise a sizeable segment of the apparel retailer's market, particularly for upper-end specialty stores, 3) fashion-conscious consumers may be leaders (innovation-prone), followers (innovation-reluctant) or more moderate in their innovation disposition, and 4) that through the change agent role of retailers (Hirschman and Stampel 1980) consumers are aware in advance of the purchasing occasion of the "appropriate" physical attributes of a garment for consumers of their innovation disposition. Precise predictions of the two selected anchoring theories, based on the above assumptions, will be presented below.

Adaptation-Level Theory

Adaptation-Level Theory is centered around the assumption that every stimulus is perceived and judged in relation to some point of perceived neutrality (Helson 1947 and 1964). The "psychological zero" represents the organism's level of adaptation (AL) for the presented stimulus. The individual is characterized as maintaining some sort of running average of all the stimulus intensities to which she is exposed. She compares a new stimulus to this internal anchor to arrive at a judgment. Helson defines AL as the weighted logarithmic mean of three classes of stimuli. The first, "focal stimuli," are those which the individual is currently attending and judging. These focal stimuli are compared to "contextual stimuli." Helson further acknowledges "residual stimuli" which account for any unexplained variation.

In the present case of a woman judging the subjective widths of belts on a shopping spree, the actual items available on the rack would be presumed to be the focal stimuli. Contextual stimuli might include the purpose of purchase and the store environment. Individual differences in the backgrounds of various shoppers, such as education, occupation, and age might be regarded as the relevant residual stimuli.

The latter classification of stimuli becomes relatively more important when one considers the effects of promotional efforts made to convince a shopper of the "appropriate" width for her. Thus, a shopper usually knows prior to purchase what will be worn by the "up-to-date" woman, versus the more traditional sort. In the present belt-width rating task, AL Theory would predict that an extremely innovation-reluctant individual (traditional) would have an adaptation level (internal anchor) toward the narrow-width end of the continuum. Presumably, she would have had more product experiences with narrower belts, either directly (own purchases) or indirectly (seeing her reference group members wear narrow belts). The latter prediction is consistent with the Selective Exposure Hypothesis, as revised by Sears and Freedman (1965). Therefore, because she would judge items within the presented product-line relative to her own prevailing adaptation level, the theory predicts that the innovation-reluctant consumer will judge all items within the line as subjectively wider than will a shopper of more moderate innovation propensity. Conversely, an innovation-prone consumer will judge all belts within the line as subjectively narrower than will other shoppers, due to her prevailing AL toward the wide extreme of the continuum.

The direct effect of changing the range of widths of belts within the product-line (external anchors) should be an adjustment of AL. If wider belts are available on the racks or T-stands, along with other belts of previously-offered widths, the prevailing AL of all consumers should be shifted toward the wider end. This should indirectly result in all belts being judged as more narrow.

Thus, AL Theory would predict that both the innovation disposition of the consumer and the range of widths of belts offered in the product-line will affect her judgments of the width of various items. Indirectly, shifts in perceived width of the belts may induce adjustments in purchasing propensities for various items. No interactive effect, however, of innovation propensity and range of belt widths available in the product-line is predicted by Adaptation-Level Theory. Figure 1 presents a graphical representation of the AL Theory predictions concerning judgments of widths of an (objectively) intermediate-width belt.

FIGURE 1. JOINT EFFECT OF PRODUCT-LINE AND INNOVATION DISPOSITION: ADAPTATION-LEVEL THEORY

A second alternative, Assimilation-Contrast Theory, has been developed to explain apparent shifts in judgments of objects as predominantly a function of the proximity to one's "latitude of acceptance" (internal anchor) along some objectively measurable dimension of the judged object. Sherif and his co-workers (C. Sherif 1976 and 1980; M. Sherif and Hovland 1961; C. Sherif, M. Sherif and Nebergall 1965) postulate that judgments of items within a presented series will be displaced in different directions, depending upon the proximity of each item to previously encountered acceptable items. He believes that an objectively measurable continuum can be divided into various latitudes of relative subjective acceptability to a particular individual. The "latitude of acceptance" contains the most strongly advocated position along the continuum, as well as (possibly) other acceptable positions. Additionally, Sherif postulates that there exists a "latitude of rejection" which contains unacceptable items or positions. Other positions along the continuum, containing items neither acceptable nor unacceptable, are defined as belonging to the "latitude(s) of noncommitment."

In the present case concerning judgments of various belts within a product-line, latitudes of acceptance, rejection, and noncommitment may be defined by the widths within the product-line which the consumer finds acceptable, unacceptable, or neutral. Thus, as a result of both direct and indirect product experiences, as well as the promotional activities of women's apparel firms, the latitude of acceptance would be expected to be toward the wide end of the continuum for the innovation-prone consumer, and toward the narrow end for her innovation-reluctant counterpart.

When an individual is presented with items to judge, the model predicts that she will "assimilate" those items which lie within, or slightly beyond, her latitude of acceptance. By this it is meant that the judgment of the item should be displaced toward the judge's own preferred position. On the other hand, those items which lie relatively distant from one's latitude of acceptance are expected to be contrasted. That is, a displacement away from the judge's advocated position is predicted. Thus, for an innovation-prone consumer the perceived discrepancy between an objectively moderately-wide belt and her preferred width is predicted by A-C Theory to be underestimated relative to the judgments of the discrepancy between the same item-widths by a consumer of more moderate innovation disposition. In the case of an objectively narrow belt the innovation-prone shopper would be expected to "contrast" the item, or overestimate its discrepancy from her own preferred width, relative to the judgment of the same two widths by a consumer of moderate innovation disposition. Conversely, the innovation-reluctant consumer is predicted to assimilate those items toward the narrow end of the product line, and contrast the wider belts, relative to the judgments of the more moderate shopper.

The effects on judgments of intermediate-width belts by innovation-prone and innovation-reluctant consumers is further complicated by extension of the product-line through the addition of a new, wide (extreme) item. The reaction of the innovation-prone consumer to the addition of an extremely wide belt to the product-line is to assimilate its width with that of a belt of her preferred width prior to the purchase occasion. Thus, the effect on the previously preferred, moderately-wide belt under such conditions of product-line extension would be predicted to be an increase in the perceived width of the previously offered belt, due to its assimilation with the new product. For the innovation-reluctant shopper, the effect on the moderately-wide belt, induced by inclusion of the new, extremely-wide item, will be a reduction of perceived width of the intermediate belt. Such a shift in judgment would be predicted to come about as a result of a contrasting of the previously-offered item with the new one. Figure 2 depicts graphically the predictions of Assimilation-Contrast Theory concerning perceived width.

FIGURE 2. JOINT EFFECT OF PRODUCT-LINE AND INNOVATION DISPOSITION: ASSIMILATION-CONTRAST THEORY

Thus, the Assimilation Contrast Model would predict a significant shift in perceptions of widths of particular belts, induced by both the innovation disposition of the consumer and the extension of the product-line through the addition of a wide (extreme) item. Significant effects were also predicted for both variables by the Adaptation-Level Model. In the case of A-C Theory, shifts in both directions (wider and more narrow) are expected for intermediate-width goods depending on their proximity to the individual's previously-preferred belt width. However, the predictions of Adaptation-Level Theory involve only unidirectional shifts arising from the innovation disposition of the consumer. In the

terminology of Sherif's theory, the Adaptation-Level model can only account for "contrast" effects.

Furthermore, unlike Adaptation-Level Theory, the Assimilation-Contrast Model predicts an interactive effect of range of widths of the belts presented and the innovation disposition of the consumer. As originally postulated by Sherif, this prediction was not made concerning relatively purely psychosocial judgments. However, due to the inseparability of psychophysical and psychosocial judgments for certain objects, such a prediction was added to the theory (C. Sherif, C. Sherif and Nebergall 1965). Support for this notion was found in a study involving "valued stimuli" (products), which were judged by American Caucasian and American Indian children (C. Sherif 1963).

Effect on Retail Sales

When a new style or fashion of an item is introduced, it can be anticipated that at least some sales of the new item will normally be realized. If one could assume that total sales within a product category (women's belts) were fixed, then it would follow that sales of items of the originally-offered items would decrease. Thus, the retailer who decided to add an innovative product to the line (e.g., the new ultra-wide belts) would know to order fewer items of previous styles (narrow and intermediate-width belts).

However, demand for items that appear to be functional substitutes does not always conform to expectations rendered by such an assumption. Monroe states that "complementarity is likely to exist even if products are functionally substitutable" (1979, p. 12), a conclusion which was empirically supported by Urban (1969) concerning complementarity among brands within a product-line.

Why might this occur? One reason may be that product involvement may increase. As a result, women may wear belts more frequently or may wish to have more varieties of belts from which to choose to accompany particular garments. Furthermore, in his/her role as a change agent, the retailer may lead the consumer to decide that a previously-purchased item is obsolete in terms of fashion, and should therefore be removed from her wardrobe. However, another reason for altered purchasing propensities of certain items, based on perceptual shifts predicted by the anchoring theories, may also be responsible.

If one assumes that an innovation-prone shopper knows prior to the actual purchasing occasion that she wishes to purchase a wide belt, and the addition of a new ultra-wide belt alters her perceptions of the width of other belts, it should in some way alter her propensities of purchasing all items. Similarly, the innovation-reluctant consumer who wishes to purchase a narrower belt would be expected to adjust purchasing behavior of various items in response to width-perceptual shifts.

Thus, the differing predictions of the two anchoring theories concerning width perceptions become relevant in determining purchasing intentions toward the non-innovative items. Adaptation-Level Theory would predict that the addition of the ultra-wide belt would result in all customers--innovation-prone, moderate, and innovation-reluctant--to perceive the intermediate-width belts as more narrow than they previously did. The effect on sales would be predicted to be: 1) a slight decrease for the moderate consumer, 2) a more dramatic decrease for the innovation-prone consumer, and 3) an increase for the innovation-reluctant group. If approximately equivalent numbers of shoppers of each innovation disposition are among the retailer's customers, the net effect from the perceptual shifts would be a decrease in sales of the intermediate-width, previously-offered items. Figure 3 presents the effect on sales which would result from the perceptual shifts predicted by Adaptation-Level Theory.

FIGURE 3. JOINT EFFECT OF PRODUCT-LINE AND INNOVATION DISPOSITION: ADAPTATION-LEVEL THEORY

However, if the Assimilation-Contrast Model predictions obtain regarding width-perceptual shifts induced through the addition of the new item, the net effect may reverse (see Figure 4).

FIGURE 4. JOINT EFFECT OF PRODUCT-LINE AND INNOVATION DISPOSITION: ASSIMILATION-CONTRAST THEORY

Specifically, due to the prediction of an interactive effect of innovation disposition and range of widths of belts in the product-line, a different conclusion must result. As with AL Theory, the Assimilation-Contrast model predicts that addition of the ultra-wide belt will result in a narrowing of the perceived width of the (objectively) intermediately-wide belts among moderate shoppers. Again, this would be expected to result in a slight decrease in sales of that item among the moderate group. However, for both the innovation-prone consumer, who now judges the intermediate-width belt as wider (assimilation effect), and the innovation-reluctant shopper, who perceives the same item as narrower when compared to the ultra-wide item, an INCREASE in purchasing propensity of the intermediate-width item would be predicted to result. Thus, the new effect on sales predicted by the Assimilation-Contrast Model would be positive, assuming equivalent group sizes of the three consumer types.

Limitations

The previous discussion has been totally centered around the theoretical relevance of either of two psychological "anchoring" theories. Until the predictions of either theory can be empirically demonstrated in this type of fashion innovation problem, no conclusion concerning retailing strategy would be appropriate.

The cases in which either theory is potentially relevant are limited to particular types of fashion innovation. The above discussion is confined to the domain of extension of a series of items for which an objectively measurable continuum of values is present. Thus, these theories could be applicable for such types of innovations as skirt length, fullness of slacks, pointedness of the toes of shoes, or even "boxiness" of automobiles. However, they would not be useful in predicting such things as popularity shifts in particular styles of furniture (e.g., Early American versus Mediterranean).

Furthermore, the presented predictions of the two theories concerning effects on sales are centered around the assumption that consumers are fashion-conscious and know the "appropriate" style for individuals of their innovation disposition. Width-perceptual shifts might occur for consumers who were fashion-unaware, but the effect on purchasing propensities would be less predictable. Thus, if empirically validated, the theoretical predictions of the supported model would be most relevant for particular stores whose major clientele was fashion-conscious, regardless of relative percentages of innovation-prone or -reluctant customers.

Additionally, the effects of other factors, such as changes in product-category involvement, were not included in the above analysis. It is not believed that changes in perception of physical attributes of a product would be the only factor which might affect purchasing propensities of originally-offered items. Rather, the proposed effects should be treated as tentative contributory influences on sales responses.

Proposed Research

Previous researchers have identified a series of self-designation questions which have been shown to provide a reliable and valid measurement of fashion-consciousness or -involvement. As such, consumers can be classified as fashion leaders (innovation-prone), followers (innovation-reluctant) or independents (Gutman and Mills 1982, p. 72). Future research is suggested in which consumer subjects are measured on fashion-consciousness, as well as asked to rate various items within a presented product-line in terms of both psychophysical and psychosocial judgments (e.g., dependent measures of subjective belt width, preference, and likelihood of purchase estimates). In order to minimize bias and demand characteristics, half of the subjects should be asked the fashion-consciousness questions prior to judgments of the stimulus items; half should provide the dependent measures prior to their responses to the self-designation items. Finally a mixed effects model is proposed in which consumers of each type are asked to rate several individual items (within subjects factor) within a single product-line (between subjects factor)--which is either narrow or extended through the inclusion of an extreme item. Thus, subjects would rate the innovative fashion item (if present), as well as several other "original" items which differed objectively along the innovation continuum (e.g., belt width). Other attributes of the items within the line should either be counterbalanced or made as equivalent as possible (e.g., same color, similar closure types, etc.). If the predictions of either theory were empirically validated, it could lead to a greater understanding and prediction of consumer responses to innovative offerings of retailers.

PERCEIVED RISK AS A MEDIATOR IN REPETITION-AFFECT RELATIONSHIPS

Theo B.C. Poiesz, Tilburg University, the Netherlands

Abstract

This paper reports on two experiments that assess the relevance of the functional exposure hypothesis for the explanation of consumer repetition-affect relationships. The hypothesis suggests that these relationships are less positive under conditions of low and high perceived risk than under conditions of intermediate (medium) risk. In spite of operational problems concerning perceived risk levels, some supporting evidence is obtained.

Introduction

Repetition of marketing stimuli, such as brandnames, is a particular feature of the consumer's environment. For a variety of reasons, including differences between individual marketers' communication intensities, the level of repetition varies greatly over brandnames. Repetition has been shown to play a multiple role in consumer behavior. Repetition enhances learning and information processing (see Sawyer 1981, 1977, 1974). It also interacts with other factors relevant for the explanation of consumer behavior (see Belch 1982). Repetition, as an autonomous variable, has been linked with consumer affect in several attempts. The most widely known attempt was formulated and documented by Zajonc (1968). In his mere exposure hypothesis, mere repeated exposure to a stimulus is taken as a sufficient condition for the enhancement of positive affect toward that stimulus. However, research aimed at the assessment of the hypothesis' validity produced conflicting results. Vanbeselaere (1984), after discussing the available evidence, concluded that '(...) the exposure phenomenon remains a phenomenon in search for an explanation'. Poiesz (1983, 1981) introduced the 'functional exposure hypothesis' (FE-hypothesis) as a possible alternative to Zajonc's (1968) hypothesis. A series of both social psychological and consumer psychological experiments, reported in Poiesz (1983), produced supporting results. In the first part of this paper, the FE-hypothesis is described and a brief summary is presented of the social psychological experiments. The second part deals with two consumer psychological studies. Finally, in part three, possible implications for the status of the exposure hypotheses are discussed.

The FE-Hypothesis: Some Social Psychological Evidence

For a correct interpretation of exposure effects, it is necessary to first describe the experimental conditions under which they typically tend to be obtained. In a laboratory situation, subjects are requested to carefully watch the presented stimuli. Exposure may or may not be preceded by task instructions. In the case of instructions, they are usually very implicit. Stimuli tend to be unknown words, names or symbols that are exposed at different frequencies. Following exposure, subjects rate the stimuli on a Likert affect scale. Poiesz (1983) suggested that repeatedly exposed stimuli will be associated with more positive affect only and to the extent that these may be considered capable of reducing the subjects' subjective uncertainty, a state conceived as determined by incongruity or by the inability to predict the future, combined with apprehension concerning the consequences (Kagan 1972). At first sight, the FE-hypothesis seems very similar to the 'uncertainty reduction' hypothesis that Sawyer (1981) considers tenable for the explanation of exposure effects: the response competition hypothesis (Matlin 1970; Harrison 1968), the optimal arousal hypothesis (Berlyne 1971, 1960), and the two-factor theory (Stang 1973; Berlyne 1970). The FE-hypothesis is similar to these hypotheses in that it takes uncertainty reduction as effectuated by familiar stimuli to be the

responsible factor for the relatively positive affect towards these stimuli. Therefore, all these hypotheses could actually be labeled 'functional exposure' hypotheses. However, the uncertainty reduction hypotheses take functionality of repetition in a more narrow sense than the FE-hypothesis. They depart from uncertainty and repetition functionality as resulting from person and/or object characteristics. The FE-hypothesis, on the other hand, considers more explicitly the interaction of person, object and situational characteristics for the assessment of repetition functionality.

This difference between the two types of hypotheses has two implications. First, uncertainty (reduction) is taken in a broader sense by the FE-hypothesis than by the uncertainty reduction hypotheses. Second, while the other hypotheses view functionality as relating exclusively to uncertainty reduction, the FE-hypothesis allows for the possibility that uncertainty enhancement is preferred to uncertainty reduction. If so, to the extent that repetition produces uncertainty reduction, repetition is dysfunctional and will be associated with negative affect. That the two implications are not trivial ones will be clarified with the help of a few examples, in which the two types of hypotheses will be distinguished. According to the response competition explanation, the exposure of a novel stimulus elicits different, sometimes antagonistic response tendencies. By repeated exposure response competition and the associated tension is reduced, resulting in more positive affect towards the more frequent stimuli. However, this explanation focuses on novelty per se, thus ignoring the possibility that novelty may have a different psychological meaning in different circumstances. For example, for an experimental subject a novel task related stimulus is psychologically basically different from the same stimulus encountered outside of the laboratory as one of the many novel stimuli. It is clear that in the first case, the stimulus is much more likely to generate uncertainty and aversive tension (i.e. apprehension) than in the second case. Consequently, repetition in the first case is more likely to be functional and to lead to positive affect than in the second case. A second example may be offered in relation to arousal interpretations. In these, stimulus complexity is hypothesized to be related to exposure effects: the repeated exposure of a complex stimulus reduces its arousal potential to the preferred level, resulting in positive affect. In some studies, complexity was operationalized in mere physical terms: number of bits and redundancy (e.g. Vanbeselaere 1980). Again, the same physically very complex stimulus may or may not be associated with aversive tension (a surplus of arousal potential) depending upon the person and the situation: a complex visual pattern presented as task material in a laboratory is psychologically incomparable to the same pattern introduced as a painting in a museum. In the former as opposed to the latter case, uncertainty and apprehension are more likely to be generated. And, even though stimulus complexity is the same in both cases, only in the former case repetition may be expected to reduce uncertainty/to be functional and to result in affect enhancement. This latter example may also be turned around. If a person has been deprived of external stimulation for some time, the first exposure to a complex stimulus will be more functional than the repetition of that stimulus, which would result in a negative repetition affect relationship.

The FE-hypothesis does not view preference for familiarity and preference for novelty (Berlyne 1970, 1960) to be in theoretical conflict: these apparent opposites are seen as having a common denominator: repetition functionality.

It must be noted that also arousal and two factor explanations discuss negative repetition-affect relationships. However, these explanations view negative

relationships as resulting from repetition overdoses. At lower repetition levels, positive relationships are predicted. The examples above suggest that the interaction of person, object, and situational characteristics should be considered for the adequate assessment of repetition functionality as a basis for positive repetition-affect relationships. In summary, the FE-hypothesis does not provide a strict alternative for the uncertainty reduction hypotheses. It supplements them in that it takes the potential function or psychological significance of repetition to be broader than that of uncertainty reduction alone; mere object related uncertainty reduction is not taken as a necessary condition for positive repetition-affect relationships to occur. Extending this, it is expected that with the FE-hypothesis also nonpositive relationships can be predicted more accurately.

For unknown complex stimuli the uncertainty hypotheses would predict repetition to lead to more positive affect. The FE-hypothesis would make the same prediction but only for conditions under which repetition can be considered functional. For example, in a task situation in which subjects are apprehensive with regard to the quality of their performance.

In some initial social psychological experiments in which paralogues were repeatedly exposed (Polesz 1983) subjective uncertainty/apprehension and repetition functionality was expected to take place

- in task conditions in which the quality of S's performance is at stake (as opposed to non-task conditions or to conditions in which performance quality is irrelevant, stimulus type held constant);
- in task conditions in which subjects are informed of an intermediate probability (i.e. 75%) of success (as opposed to conditions with a very low or very high probability of success, stimulus type held constant).

Repetition-affect relationships were significantly more positive in the apprehension conditions than in the other conditions, supporting the functional exposure interpretation. Additionally, in these other conditions, repetition-affect relationships were usually nonpositive (not significantly different from 'slope zero', depicting the absence of any relationship). The obtained results were replicated in several laboratory studies.

Two Consumer Psychological Experiments

In essence, the step from a social psychological experiment to a consumer psychological experiment is not necessarily a large one. To adult subjects, the consumer's role is a familiar one; in prepurchase situations the concept of perceived risk can be taken as the equivalent of the concept of subjective uncertainty as both contain an unpredictability and an apprehension component; and unknown names can easily be presented as (unknown) brandnames. In the following, two experiments will be briefly described in which the validity of a functional exposure interpretation in a consumer laboratory situation was assessed.

In line with this interpretation, it is hypothesized that positive repetition-affect relationships will be observed only if subjects experience an intermediate level of perceived risk. At this level, to be interpreted as located between the levels of high and low perceived risk, repetition is expected to be functional by its uncertainty reducing effect. The functionality of higher exposure frequencies at the other two levels is limited for two different reasons respectively. If perceived risk is low, so is the need for information, that is, any information. So stimulus familiarity is bound to be irrelevant/nonfunctional as well. If perceived risk is high, the need for issue relevant (intrinsic product/brand quality or price) information is high. Here, the exposure frequency of stimuli is unlikely to serve as the single basis for the risky decision (unless no further information can be expected). Therefore, in general, if perceived risk is high, the functionality of higher exposure frequencies is low. In conclusion, we expect less positive repetition-affect relationships under conditions of low and high perceived risk than under conditions of intermediate (medium) perceived risk. Note that an uncertainty

reduction hypothesis would predict the relationships to become more positive with risk.

Experiment 1

Subjects (Ss). 48 persons, 20 men and 28 women of various ages participated in the experiment. Prior to the experiment, they were told that they would receive the standard compensation worth approximately \$ 3.00 for their cooperation. Ss were divided evenly over the three conditions. The data of 3 Ss were discarded because of incompleteness. These Ss were replaced. Stimuli. The stimuli ('brandnames') employed were the presumably unknown names of French hamlets that a group of 15 non-subjects rated affectively neutral (TRESSON, ENCAUSSE, LE DORAT, PREGONDE, VERGONS and MARCILLAT). Stimuli were presented 0, 1, 3, 6, 9 and 12 times, and were rotated over frequency levels. A particular stimulus did not follow itself in the exposure sequence. Stimuli were exposed for 2 seconds each. Interexposure intervals were 4 seconds.

Procedure. The experiment took place in the Laboratory of the Psychology Department, Tilburg University. Ss were situated vis-à-vis a Philips monitor. All Ss could clearly see the stimuli. Conditions were run simultaneously, with a maximum of 8 Ss participating at the same time.

Instructions. Ss will be confronted with one of three types of instructions, each aimed at producing a particular level of perceived risk. We may expect Ss to consider decisions to be more difficult with increasing risk. Also, with increasing risk Ss are assumed to reduce their perceived chance of being able to select the brand they would prefer most. Therefore, subjective ratings of 'difficulty of choice' and 'chance of preferred brand' will serve as manipulation checks on perceived risk.

Condition 1: Low Risk (LR). Instructions: This study is on the evaluation of roller pens. The Consumers' Guide wrote (in fact, it did not - note added in the present text) about these pens: "All brands of roller pens have passed our test excellently. There are quality differences but a bad buy is definitely impossible". The value of these pens is between 2 and 3 dollars a piece. You may select one of them later-on and keep it. It is not possible to try them out first because they are wrapped. However, if you, after selecting a pen, consider another pen somewhat more attractive, then we will simply change pens around. So, you will receive the pen that you prefer most. In a few moments we will acquaint you with the brandnames. These will appear on the monitor.

Condition 2: Medium Risk (MR). The instructions are equal to those of Condition 1, except for the so-called Consumers' Guide section: "You do not run the chance of a bad buy when purchasing a roller pen. Our test indicated that there are no bad pens. Yet, it can do no harm to be somewhat careful when choosing a pen because of the differences in quality. All pens are approximately equally priced". The sentence indicating that after the selection pens may be changed around is left out here.

Condition 3: High Risk (HR). Instructions are equal to those of Condition 1 and 2, except for the Consumers' Guide section: "When choosing a roller pen the consumer must be very careful. Some brands are fair or good, others are just bad. And the bad brands are not cheaper than the good ones. In all, a very risky product". Also here the sentence about the changing of pens afterwards is left out.

Immediately following the exposure phase, instructions relating to the affect ratings were handed out. For the rating each stimulus was presented once for 2 seconds. Between presentation times were 4 seconds. The order of stimuli in the rating phase was varied so as to approach counterbalancing. The time lapse between the exposure and rating phase was about 2 minutes. Affect ratings were of two types. The first type concerns the traditional affect rating on a 7-point scale ranging from 'this brandname makes a very unfavorable impression upon me' to '(...) a very favorable impression (...)'. The second type concerns the exposure frequency

of the chosen brand when subjects are requested to make a selection out of the various brands/brandnames that are available.

Results. Before being exposed to the various brandnames, SS had been requested to rate the manipulation checks 'difficulty of choice' and 'chance of preferred brand'. See Tables 1 and 2 for the respective results.

TABLE 1
"DIFFICULTY OF CHOICE" (LIKERT SCALE
1-5; 5=MOST DIFFICULT), PER CONDITION

Condition	mean	t-values (F2,45 = 9.85, p .001)
Low Risk	2.56	t(30) = .22 n.s.
Medium Risk	2.63	t(30) = 3.97, p < .001
High Risk	3.69	t(30) = 3.77, p < .001

TABLE 2
"CHANCE OF PREFERRED BRAND" (LIKERT SCALE
1-7; 7=VERY SMALL CHANCE), PER CONDITION

Condition	Mean	t-values (F2,44 = 7.77, p .01)
Low Risk	3.19	t(30) = .16 n.s.
Medium Risk	3.25	t(29) = 3.52, p < .001
High Risk	4.67	t(29) = 3.21, p < .01

Differences between conditions are in the right direction. However, the differences between the conditions Low and Medium Risk are not significant for neither one of the manipulation checks.

In spite of these outcomes, we will first consider the results as they relate to the hypothesis. Results will be presented for linear trends and frequency of the chosen brand. Only linear trends are considered here as these relate most directly to the hypothesis.

Linear trends. For the conditions LR, MR and HR the respective means are 4.06, 5.63 and 0.44, differences being in the expected direction. These are the mean sums of the transformed raw scores per individual (transformation by coefficients of orthogonal polynomials for a linear trend with 6 observations, coefficients being -5, -3, -1, 1, 3, and 5). The overall effect is not significant, however - $F_{2,45} = 0.60$ n.s. (analysis of linear trend (Winer 1971); a main effect in this analysis may be interpreted as equivalent to an interaction effect in an ordinary ANOVA).

Frequency of chosen brand. For analyses on this variable, absolute exposure frequencies were changed into the corresponding coefficients of orthogonal polynomials referred to earlier. Cell mean differences are in the expected direction, cell means being 1.27, 3.25 and 0.00 for the LR, MR and HR conditions, respectively. An ordinary analysis of variance indicates a significant effect for perceived risk ($F_{2,44} = 6.42$, $p < .01$). As hypothesized, there is no significant difference between the LR- and the HR-Condition ($t(29) = 1.21$, n.s.), a significant difference between the LR- and the MR-Condition ($t(29) = 2.11$, $p < .05$) and a significant difference between the MR- and the HR-Condition ($t(30) = 4.21$, $p < .001$).

Discussion. For the dependent variable 'frequency of chosen brand', but not for linear trends, the factor perceived risk did have the hypothesized effect. A possible reason for this difference may be that the consequence aspect, as one of the two aspects of uncertainty/perceived risk, is rendered more dominant in the case of choice than when Ss is required to give affect scores only.

An important question concerns the lack of a difference in both manipulation checks between the so-called Low Risk and Medium Risk Condition. The scores on the manipulation checks of the Ss in the former condition suggest that these Ss did experience an intermediate level of risk. Therefore, the outcomes of the manipulation checks leave us a second option for the analyses on the dependent variables. This option is to distinguish two instead of three levels of perceived risk, considering the insignificance of the LR and MR manipulation check

differences. When the LR condition is combined with the MR condition on the basis of the manipulation checks, the effect of risk on the linear trends is not significant at the customary levels. However, a trend is observed: LR + MR vs. HR : $t(46) = 1.44$, $0.05 < p < 0.10$. As could be expected on the basis of the results presented earlier, for the dependent variable frequency of the chosen brand, the combination of the LR and the MR condition differs significantly from the HR condition: $t(54) = 2.77$, $p < .01$.

Perceived risk may be assumed to be positively and linearly related to depth of processing and the various risk instructions may have resulted in depth of processing differences. These differences can not be associated with repetition-affect relationship differences, however, given the obtained results: the repetition-affect relationships do not increase positively and linearly with risk.

Experiment 2

In reference to the manipulation problems in Experiment 1, the main purpose of the present experiment is to attempt to generate low levels of perceived risk. In Experiment 2 the experimental situation and procedure will be equal to the ones in that Experiment 1. It is assumed that perceived risk may be lowered by attenuating its component 'consequence(s)'. For example, by eliminating S's possibility to make a choice, thus rendering choice outcome completely beyond his/her control. Alternatively, by giving S the expectation of an opportunity to actually try out the alternatives before making a selection, perceived risk may be assumed to be low relative to the situation in which there is no such expectation.

In combination with the Medium and Low Risk instructions of Experiment 1, these two alternative risk reducing possibilities may be worked out in the following experimental conditions:

1. Low Risk/Choice
2. Medium Risk/No choice
3. No Risk: Low Risk instruction; No choice.

Together with the Medium Risk Condition of Experiment 1 (Medium Risk instruction; Choice), these conditions form a complete 2x2 design.

It is hypothesized that in the no-choice conditions frequency-affect relationships and frequencies of the chosen brand¹ will be nonpositive/small, that is, approximating (slope) zero.

Because of the requirement to make a choice, the dependent variables will assume higher values in the Low Risk/Choice Condition. However, these are expected to be lower as compared to the corresponding values in the LR- and MR-Condition of Experiment 1.

Subjects. Subjects were 16 men and 32 women of various ages. Their names were drawn from the same participants-pool as used for obtaining the names of participants in Experiment 1. (Of course, no person participated in both experiments). For their cooperation the compensation worth about \$ 3.00 was announced. Ss were divided evenly over the three conditions: 16 Ss each. No data had to be discarded.

Stimuli and Procedure. See Experiment 1. For instructions see below.

Condition 1. Low Risk/Choice (LR/Choice). This study is on the evaluation of roller pens. The Consumers' Guide wrote about these roller pens - the same as we employ in this study: 'All brands of roller pens have passed our test excellently. A bad buy is definitely impossible'. The value of the pens is between 2 and 3 dollars a piece. Later-on we give you 6 pens of different brands. Then, you should try out these pens and make a selection out of them. You may keep the selected brand. You will have ample time for trying out the pens. In a few minutes we will acquaint you with the brandnames. These will appear

¹In each condition, Ss will be requested to make a selection anyway, but in such a way that the consequence component is not introduced.

on the monitor.

Condition 2. Medium Risk/No choice (MR/No choice). Up to the so-called Consumers' Guide section, instructions are equal to those of Condition 1. Then: 'You do not run the chance of a bad buy when purchasing a roller pen. Our test indicated that there are no bad roller pens. Yet, it can do no harm to be somewhat careful choosing a pen because of the differences in quality. By the way, all pens are approximately equally priced'. The value of the pens is between 2 and 3 dollars a piece. Later-on we give you one of these pens. After you have tried out this pen for a little while, we would like you to answer some very simple (written) questions about it. You may keep the concerning pen. It is not possible at this moment to indicate which brand that will be as the pens will be distributed completely arbitrarily. In a few minutes we will acquaint you with the brandnames. These will appear on the monitor. (As manipulation-checks on risk would be awkward here and possibly counteracting manipulations, they are left out).

Condition 3. No Risk: Low Risk instruction/No choice (LR/No choice). The instructions are the same as those in Condition 1 except for the part after the value information:

Later-on we give you one of these pens. After you have tried out this pen for a little while, we would like you to answer some very simple (written) questions about it. (Etcetera). (See instructions Condition 2).

For the no-choice conditions, the brand-selection question was adapted by formulating it as follows: 'If you would have to make a selection yourself now, which brand would you choose?'. The rest of the procedure is equal to the one in Experiment 1.

Results. With the three conditions LR/Choice, MR/No choice and LR/No choice, it was attempted to obtain perceived risk levels lower than those generated in Experiment 1, Conditions LR and MR. The only condition for which this can be checked is the LR/Choice Condition, of which the instructions announced the request to make a selection.

In Condition LR/Choice the mean of the variable 'difficulty of choice' is 13.9 on the 5-point scale and the mean of the variable 'chance of preferred brand' is 3.50 on the 7-point scale. It was expected that these means would be lower than the respective means of Conditions LR and MR of the previous experiment. However, this is not the case. The differences are even in the wrong direction. Assuming that manipulations in the remaining two conditions of the present experiment were successful, it seems justified to adapt the hypothesis: Considering the outcomes on the manipulation checks, we should expect a repetition-affect difference between the LR/Choice Condition on the one hand and the Conditions MR/No choice and LR/No choice on the other. At the same time, no repetition-affect differences are expected to be observed between the LR/Choice Condition and the MR/Choice Condition (Experiment 1).

Linear trends. Per condition, the mean sum of the raw scores transformed by coefficients of orthogonal polynomials (linear trend) are:

LR/Choice	5.88
MR/No choice	-0.06
LR/No choice	-1.31
(MR/Choice, Experiment 1)	5.63

An analysis of linear trend on the 2x2 design shows a significant effect for choice ($F_{1,60} = 4.70, p < .05$), but not for type of instruction ($F_{1,60} < 1, n.s.$). Also, there is no interaction-effect ($F_{1,60} < 1, n.s.$). The mean individual (linear) trend in the choice conditions is higher than in the no-choice conditions, as predicted. Means are, respectively, 5.76 and -0.69. The means of both type of instruction levels are in the predicted direction, MR instruction: 2.78 and LR instruction: 2.28. However, as the trend analysis indicates, we should not interpret the difference as supportive of the hypothesis.

Frequency of the chosen brand. For the dependent variable frequency of chosen brand, the factor choice is highly significant ($F_{1,58} = 13.08, p < .001$, ordinary ANOVA) and there is a significant choice x type of

instruction interaction ($F_{1,58} = 4.81, p < .05$). There is no significant effect for type of risk-instruction ($F_{1,58}, p < 1, n.s.$).

In the choice conditions, the mean frequency of the chosen brand is 2.31 (coefficients of orthogonal polynomials, linear trend); in the no-choice condition: -0.33. This difference is as hypothesized. When SS received an MR instruction, their mean frequency score is 1.27, while for the LR Condition, this score is 0.81. This difference is insignificant. The risk x choice interaction is significant, however. Condition means are: 1.38, -1.00 and 0.25 for the Conditions LR/Choice, MR/No choice and LR/No choice respectively. The mean of the MR Condition (Experiment 1) was 3.25.

Discussion. In the LR/Choice Condition, the intended low risk level was not obtained. Possibly, Ss in this condition still experienced the try-out of the pens and the subsequent selection as some type of performance task (see introduction). However, this post-hoc interpretation is exactly the reverse of the initial interpretation that led to the concerning operationalization. Because it was attempted, in three of the four conditions of Experiment 2, to obtain low risk levels, no significant effect for type of instruction was to be expected. Departing from the original hypothesis that supposed low risk in all three conditions, a difference should have been observed between the condition-combination MR (Experiment 1) and LR/Choice, with the former having a significantly more positive frequency-affect relationship as measured by the two dependent variables. Now that the manipulation in the LR/Choice Condition turned out to be unsuccessful, this hypothesis had to be adapted on the basis of the manipulation checks. In the adapted version, departing from medium risk levels in both Conditions MR (Experiment 1) and LR/Choice (Experiment 2), no difference was to be expected and observed.

Conclusion

Summing up, three general observations can be made. The first observation is that the FE-hypothesis differs from the mere exposure hypothesis and the uncertainty reduction hypotheses with regard to the prediction of repetition-affect relationships at various perceived risk levels, and that the FE-hypothesis is supported by some evidence.

The second observation is that risk manipulations are tricky. Even though, theoretically speaking, a low level of perceived risk is not problematic, operationally it is. It is likely that the very nature of the experimental setting is a disturbing factor here.

A final observation is that a number of questions is still open, one of them concerning the level of cognizing that is required for exposure to be functional. These questions will have to be dealt with before the implications of functional exposure for consumer behavior can be discussed.

MEASURE VALIDATION IN CONSUMER RESEARCH: A CONFIRMATORY
FACTOR ANALYSIS OF THE VOLUNTARY SIMPLICITY LIFESTYLE SCALE

Deborah Cowles, Arizona State University
Lawrence A. Crosby, Arizona State University

Abstract

The development of a measurement tradition in consumer research will necessitate a stronger emphasis on replication. The validity of standardized instruments must be established through repeated application of scales in different contexts and among different population groups. Leonard-Barton's Voluntary Simplicity Lifestyle Scale was administered to a sample of California and Colorado voters. Examination of the factorial validity of the scale supports a three dimensional structure which is based on theory. The values constructs of material simplicity, self-determination, and ecological awareness adequately account for the observed inter-item correlations.

Introduction

Consumer behaviorists have exhibited a renewed interest in the role that research plays in the theory development process. Increased attention to the relationship between research and theory has spawned "considerable interest in methodological issues related to theoretical constructs" (Brown and Gauden 1980, p. 241). Perhaps foremost among these concerns is the apparent lack of a tradition of measurement research and instrumentation in the marketing and consumer behavior disciplines. Bagozzi (1980) has observed that while marketers readily acknowledge in their journals the importance of measurement, they seldom examine in these same journals the conceptual underpinnings of measurement procedures and relate them to the purposes for which they were constructed. This indifference is remarkable, considering that measurement and theory "are inseparably bound in a logical sense" (Bagozzi 1980). Theory development requires theory testing. More than a decade ago, Heeler and Ray (1972) observed that tests of existing theories in marketing and consumer behavior have been marred because they were not preceded by adequate measure validation.

Some authors have pointed to replication as a way to solve at least some of the measurement problems plaguing marketing and consumer research, including the prevailing "disregard" (Ray 1979, p. 1) for measure validation. Consumer behaviorists, in particular, have been vocal in their call for replication (Jacoby 1978; Brown and Coney 1976; Engel, Blackwell and Kollat 1978), on the grounds that spurious conclusions hamper theory development. "There is a strong necessity for replicating our findings using different subject populations, test products, etc. The name of the game is confidence in our findings" (Jacoby 1978, p. 93). Replication lies at the heart of generalization of any body of knowledge (Kollat, Engel and Blackwell 1970). Generalizability, in turn, is fundamental to theory's capability to predict phenomena.

Measurement Validation in Psychology

Not all of the social sciences have been so neglect in building a foundation of replication and instrumentation. In contrast with marketing, psychology can boast a long tradition of measurement research. Indicative of this heritage is the science's regular publishing of compendiums of measurement tools. The Eighth Mental Measurements Yearbook (Buros 1978), for example, is a lengthy, two-volume collection of measurement instruments covering a wide range of topics (achievement batteries, multiple-aptitude batteries, personality, intelligence, education, etc.). Other similar repositories for published tests and measurement tools exist in the field of psychology (Straus and Brown 1978, Johnson 1976). Compendiums like these serve to facilitate measurement validation, as well as other aspects of measurement research, via exact replication and related studies.

Scholars like Frederic M. Lord of the Educational Testing Service have devoted most of their lives to the study of mental tests (Wainer and Messick, 1983). That is not to say, however, that these scholars have solved all the problems associated with psychological measurement, in particular the issue of measurement validation. "The determination of validity . . . is not so much a process as it is a program. The measurement of the psychological properties of individuals is a complicated affair, to be accomplished laboriously, and seldom, if ever, with the degree of precision desired" (Ghiselli 1964, p. 368).

Nevertheless, scholars in the field of psychology pursue this "broad problem area" (Ghiselli 1964, p. 368), evidently with a commitment to precision not known to the marketing discipline as a whole. Even a cursory review of the major psychology journals at any time would produce more than a handful of perfect and imperfect replications--tests of established measurement instruments, across time, various population groups and settings--designed to examine the validity of those tools (e.g., Gahar and Hale 1982; Ibrahim 1982; and LaFromboise 1983). Marketing and consumer behavior journals are all but void of such examinations. Calls for replications, lamentations over the sorry state of measure validation in marketing, and suggestions with respect to how one can improve measurement validation appear more frequently in the marketing literature.

Improving Measures of Consumer
Behavior Constructs

Psychometric procedures for developing better measures of marketing and consumer behavior constructs have been well described by Churchill (1979) and do not require restatement. Worthy of note, however, are two of the principles which underlie these procedures. One principle is that most measures of consumer behavior phenomena, and indeed the phenomena themselves, are seldom uni-dimensional. This means that in developing standardized instruments, correspondence rules linking theoretical dimensions to test components and subscales must be clearly established. This can be done only if the theory is sufficiently explicit about the definition and domain of the construct. Care must also be taken not to segregate the conceptual stage of the research from its test (Bagozzi 1980). The specification of theoretical constructs should include a measurement model, and it is this model which should be empirically tested. The initial concern is usually to verify the factorial validity of the proposed measure, with convergent and discriminant validity being established later.

Another principle is that measure validation cannot be accomplished in a single study. As in all research, apparent regularities involving measures and measurement items may be the result of chance or spurious relationships. There is also a need to establish that the measurement model holds across the full range of the underlying variables. If measures are found to behave differently when tested across time and across population groups, this suggests that either the measure is invalid or the concept, poorly understood. It is possible that a measurement instrument taps different constructs when applied at different times or to different population groups. Thus, repeated tests of the factorial, convergent, and discriminant validity of tests need to be made.

These two important principles are best illustrated with a specific example from the consumer behavior literature.

Voluntary Simplicity Lifestyle Scale

An examination of the Voluntary Simplicity Lifestyle (VSL) Scale (Leonard-Barton 1981) is especially appropriate for the purposes of this paper for a number of reasons. First, the scale has not been finalized; Leonard-Barton admits potential scale shortcomings and has suggested a number of areas that may need improving. Thus, the current research shows the value of measurement research to the theory development process. Second, Leonard-Barton's scale represents only one of a number of ways that have been suggested to model voluntary simplicity (VS) (Ensley 1983).

Despite the potential value of this scale and other similar instruments, some scholars have questioned the validity of lifestyle concepts and measures in general (Mehrotra and Wells 1977; Wells 1975; Wells and Cosmas 1982). Lastovicka observed that while there is an "overabundance of lifestyle traits" (1982, p. 138), there have been few attempts in the literature to examine the validity of the proposed traits. An examination of the scale (and the theoretical model it implies) enables one to consider more closely the relationship between theory and research, specifically, the relationship between theoretical constructs and the tools that are supposed to measure them.

The use of the VSL scale to explore the value of measurement validation to consumer research is appropriate also because the scale focuses on extremely dynamic characteristics of our society. Marketers more often than not face the challenges of a fast-changing marketplace while conducting research. Finally, the development of not only a theory (model) to explain voluntary simplicity, but also a measurement tool (scale) to predict (identify) the lifestyle are potentially matters of great concern to marketers. "Growth in the number of adherents to VS (voluntary simplicity) could dramatically affect current marketing practices" (Ensley 1983, p. 385).

Voluntary Simplicity: The Concept

An in-depth review of the VS literature is not required for the purposes of this paper. Recent reviews (Ensley 1983, Leonard-Barton 1981, Leonard-Barton and Rogers 1980) report agreement among scholars as to the building blocks of the lifestyle: material simplicity (nonconsumption-orientation patterns of use); human scale (a desire for small-scale institutions and simpler technologies); self-determination (desire for greater control over personal destiny); ecological awareness (recognition of the interdependency of people and resources); personal growth (a desire to explore and develop the "inner life").

Scholars do not agree, however, about what comprises the best method for identifying voluntary simplifiers. The measurement tool which is the focus of this article, developed by Leonard-Barton (1981), is essentially a behavioral scale. Leonard-Barton maintains that while certain "humanistic values" are an important part of the concept, "as any student of human behavior knows, there is often a large gap between an attitude and an act. . . Behaviors are, therefore, probably better indicators of public support for a voluntary simplicity lifestyle than verbal responses to survey questions" (p. 244).

The scale, which employs survey methodology, asks respondents to report the frequency with which they engage in behaviors that are "typical of self-proclaimed advocates of this scaled-down lifestyle and that were also suggested in literature on the topic. . ." (Leonard-Barton 1981, p. 244). Lastovicka (1982) has criticized the reliance of lifestyle research on self-report data as a "serious problem in lifestyle trait measurement" (p. 138). Another potential problem in the development of a behavioral scale that would be usable over time is the rate of diffusion of behaviors included in the scale. Table 1 shows that the so-called VSL behaviors have diffused considerably in just a few years. While the percentage of respondents giving a positive response in each

category increased as much as 47 percent, it is unlikely that the number of voluntary simplifiers has increased to the same extent. In short, the behaviors do not necessarily indicate VS. Leonard-Barton (1981) defends her approach, maintaining:

"an individual's high score on any one of these six factors by itself does not indicate an interest in voluntary simplicity. . . However, if an individual engages in many of the 18 behaviors. . . then we may assume that some sort of coherent (although often unrecognized) philosophy underlies these diverse acts" (p. 246).

But Ensley (1983) asserts that VS "is essentially an attitude, and adherents emphasize that no particular behavior is required" (p. 388).

TABLE 1
ITEMS IN THE VOLUNTARY SIMPLICITY INDEX
IN ORDER OF RATE OF ADOPTION

Scale Item	% of Respondents with Positive Response		Rank
	(Leonard-Barton 1981/Current Research)		
	n=812	n=424	
Make gifts instead of buying	71.9/81.8		1/3
Eat meatless main meals	70.8/82.0		2/2
Change oil in car	69.8/78.3		3/5
Get instruction to increase self-reliance	65.3/82.5		4/1
Recycle newspapers	62.3/71.3		5/7
Make clothes/furniture	59.5/73.3		6/6
Recycle cans	54.2/79.8		7/4
Recycle glass	52.9/67.2		8/8
Grow vegetables	50.7/57.9		9/12
Bike for exercise	49.9/62.0		10/9
Buy at garage sales	48.4/59.3		11/10
Exchange goods or services	44.3/58.3		12/11
Contribute to ecology organizations	33.1/40.1		13/14
Buy used clothing	32.1/44.1		14/13
Bike on errands	26.8/28.4		15/15
Have a compost pile	20.3/19.2		16/16
Bike to work	9.1/10.5		17/17
Belong to a cooperative	7.6/8.0		18/18

The Behavioral Scale

The scale developed by Leonard-Barton (1981, p. 244) "evolved through three stages, each revision being tested on a different California population. All three versions of the scale were factor analyzed; factors that emerged were reported by Leonard-Barton to be "quite robust" for all versions, across samples. Leonard-Barton characterized the six factors that emerged in the data collected from the most recent version (n=812 California homeowners) as: conservation through biking; self-sufficiency in services; recycling resources (metals, glass); self-sufficiency through making goods; recycling of durable goods (clothes, furniture); and closeness with nature.

"As Cattell (1961) and others demonstrate, factor analysis is the primary tool for systematically identifying and measuring (lifestyle) traits" (Lastovicka 1982, p. 126). Nevertheless, factors and traits are not the same. A factor is linked to a trait via a correspondence rule. In the case at hand, Leonard-Barton has employed exploratory factor analysis to identify six dimensions which are given a trait-like interpretation. While Leonard-Barton does not specifically use the word "trait", her discussion of the factors is consistent with the accepted defini-

dition of traits as "generalized action tendencies" (Allport 1966, p. 3). Figure 1 shows the implied relationship between scale items, resultant factors, and VSL. While the author acknowledges that at least two of the five "building blocks" of VSL are not represented (human scale and personal growth), no explanation is proffered concerning the conceptual meaning of the six empirically derived factors/traits.

Throughout the social sciences, there is growing recognition that the approach of exploratory factor analysis is seriously flawed. To quote Long (1983, p. 12), "The exploratory factor model's inability to incorporate substantively meaningful constraints, and its necessary imposition of substantively meaningless constraints, has

earned it the scornful label of garbage in/garbage out (GIGO) model." The use of exploratory factor analysis in the Leonard-Barton studies seems particularly unfortunate given there is fairly specific theory regarding the value underpinnings of VSL. Leonard-Barton can be criticized for failing to integrate her conceptualization with the empirical test. Figure 2 presents an alternative VSL model that is more theory-based. Behavioral constructs which comprise the alternative model are not the result of factor analysis, rather they are suggested by VSL theory as presented in the literature. According to this new conceptualization, individual items in the Leonard-Barton scale should be viewed as indicators of behavioral tendencies which are values driven. The undersampling of some behavioral constructs (i.e., two "building blocks" are not represented) and the oversampling of others can be directly traced to the decoupling of the theory and its test.

FIGURE 1
CONFIRMATORY FACTOR ANALYSIS (CFA) MODEL
IMPLIED BY VOLUNTARY SIMPLICITY INDEX
(Leonard-Barton 1981)

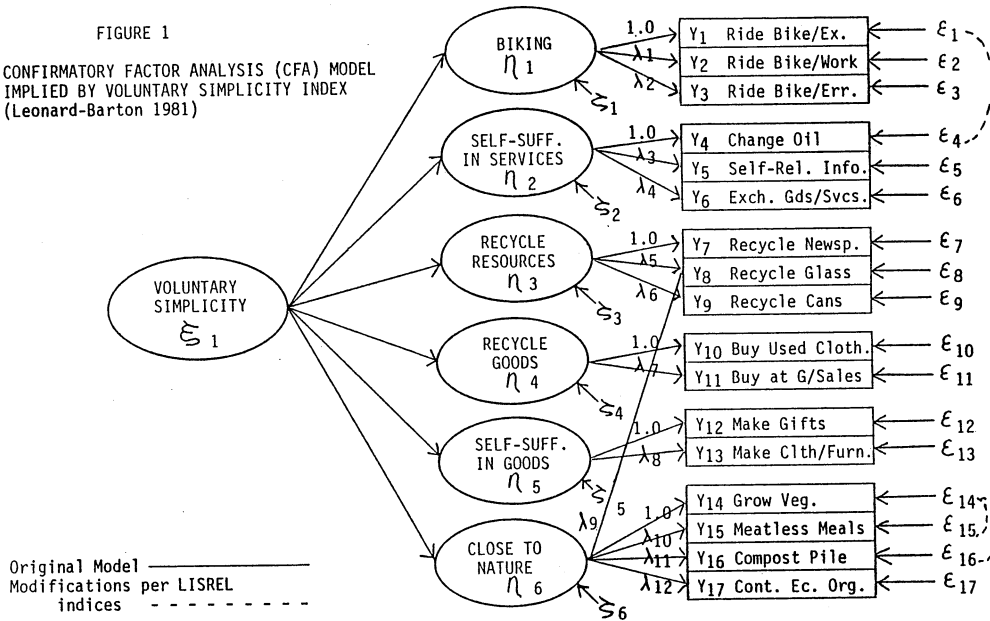

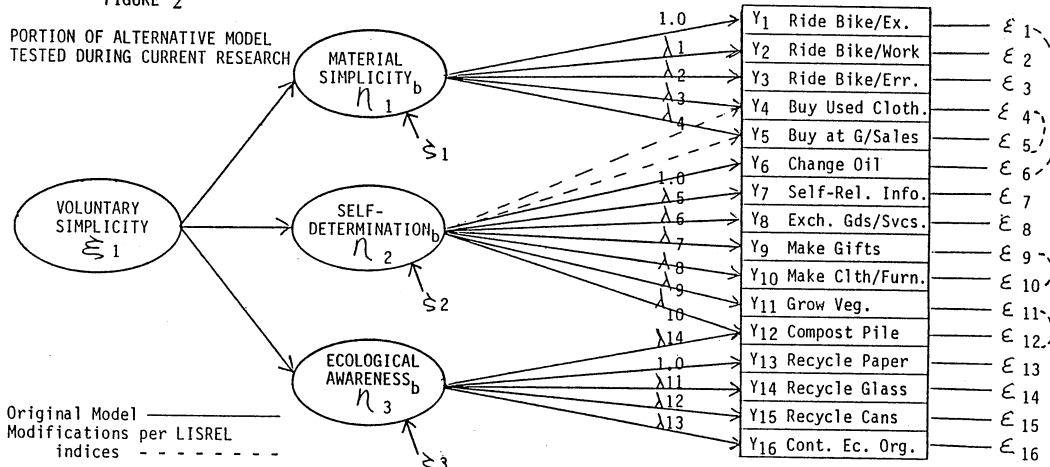

FIGURE 2
PORTION OF ALTERNATIVE MODEL
TESTED DURING CURRENT RESEARCH

Despite the above-mentioned problems, Figures 1 and 2 provide competing models or hypotheses concerning the structure of VSL. These models were compared, insofar as data would permit, in terms of their ability to account for the observed inter-item correlations in new data. The data were obtained as part of a voting behavior study which included Leonard-Barton's VSL scale as one of its measures.

Methodology

Data

Voter, legislator, and consumer behavior concerning "bottle bills" is an environmental issue of current public and research interest. The data for the analysis came from a study of voter behavior concerning bottle bills appearing on the November 2, 1982 ballots in California and Colorado. A quota sample of consumer panel households in these states was supplied by a large field research organization. Households were selected for inclusion by matching household characteristics with known census data for each state. A random selection procedure was then used to select an eligible adult voter within each household.

The questionnaire, which was preceded by a pre-alert postcard, was mailed to 1,000 panel members, 500 in each state. The Leonard-Barton VSL scale was one of several measurement instruments included in the questionnaire. A standard inducement was offered to panel respondents. A total of 662 surveys were returned (66.2 percent response rate); 424 of the returned questionnaires included complete responses to all VSL scale items.

Analysis

The VSL models portrayed in Figure 1 and 2, suggest that voluntary simplicity is a multidimensional unobserved, or latent, variable the presence of which to varying degrees can be measured by specific behaviors. Confirmatory factor analysis via the computer program LISREL (Joreskog and Sorbom 1977; Sorbom 1974) was used to assess the factorial validity of the models for a population other than those from which Leonard-Barton had developed the scale. Technically, these are both higher-order factor models which are estimated by Submodel #3 in LISREL. The endogenous latent variables ($\eta_1, \eta_2 \dots$) are assumed to be partial functions of a global tendency toward VSL. Errors in the equations for these latent variables ($\zeta_1, \zeta_2 \dots$) acknowledge there are other unspecified influences on the VSL responses. The fitting function for unweighted least squares (ULS) was used to obtain parameter estimates. The ULS estimator has been shown to be consistent without making assumptions about the distribution of the variables (Bentler and Weeks 1980). Estimation via ULS "involves minimizing the sum of squares, in much the same way that ordinary or unweighted least squares for regression analysis minimizes the sum of the squared residuals" (Long 1983, p. 57). Because ULS estimators are scale-dependent the scales of the observed variables were standardized by analyzing a correlation matrix.

Long (1983) notes that while it can be advantageous not having to make distributional assumptions about the observed variables, a major limitation is that "there are no statistical tests associated with ULS estimation of the confirmatory factor model" (p. 57). One must rely on an overall goodness-of-fit index, as well as an examination of parameter values, variances and covariances. Despite this limitation, a major advantage to using the confirmatory factor analysis approach over the exploratory factor analysis approach is that "a hypothesized factor structure can be specified as a pattern of zero and nonzero factor loadings. The adequacy of the model (and the theory for which it stands) as representation of the original data matrix can then be empirically assessed" (Aneshensel et al, p. 388). The technique also allows one to compare the hypothesized model with alternative specifications of the model in which parameter

constraints are modified, a most important feature for theory builders.

Results

The confirmatory factor model suggested by the Leonard-Barton research (1981) and shown in Figure 1, was tested to determine its tenability. Goodness-of-fit indices and ULS parameter estimates for a modified version of that model are found in Table 2. Modifications to the original model, which were indicated by LISREL program output, were made within the bounds of practicality and theory. These modifications took the form of an allowance for some correlated error among the indicators. The results show that the Leonard-Barton model is relatively robust for this population, with an adjusted goodness of fit of .956. Table 3 provides goodness-of-fit indexes and ULS parameter estimates for a modified version of the alternative model, which is at least as robust as the model suggested by Leonard-Barton. The adjusted goodness of fit index for the alternative model was .962. Table 4 compares the two models' estimates of indicator and construct reliability.

Discussion

Given the model in Figure 2 is incomplete, yet performs as well as the Leonard-Barton model, it would appear to be a better approach to the development of a VSL scale for a number of reasons. First, the constructs, as configured, more accurately reflect VSL theory as it is presented in the literature. Second, as Leonard-Barton points out, the meaning of a specific behavior can change over time and across boundary lines. The assignment of these or other behavioral indicators to theoretical (vs. behavioral) constructs would seem to offer more flexibility in theory/scale development. Finally, the model is more explicit in portraying the relationship between and among variables and constructs, a characteristic of great value to theory builders.

The current research has shown that Leonard-Barton has made a significant contribution to VSL research and theory development. Her scale, which was developed with a California-only population, yielded meaningful results when applied to a different California/Colorado population. However, as Leonard-Barton recommends in her 1981 article, future research should include a "further refinement of the index, including tests for the applicability of items to different geographic locations" (p. 250), and "expansion of the 18-item index to cover interest in holistic health, improved nutrition, and greater personal happiness" (p. 250) -- perhaps as a means of addressing the VSL components not included in the scale.

Curiously, however, Leonard-Barton at the same time calls for a streamlining of the scale, and suggests three different ways to achieve this: by factor analysis (selecting the highest loading variables); by multiple regression (dropping those behaviors that explain little variance in the regression line); and by using rate of adoption. Although a more streamline scale is not necessarily indicated, an analysis of the rate of adoption of VSL behaviors, seems appropriate for any VSL research. Indeed, it seems unlikely that researchers will be able to capture the underpinnings of VSL via simplistic models:

... recognition of nomological validity as a necessary tool for testing lifestyle trait concepts emphasizes the need for better lifestyle theory. The current elementary theoretical schemes provide settings for simple tests of trait validity, but as nomological validity is more seriously examined these schemes must become more elaborate. (Lastovicka 1982, p. 138)

Although the more complex model with all five VSL building blocks has not been put to a rigorous test, the preliminary analysis of a portion of the model holds promise for future VSL research. Opportunities exist to examine how VSL, and lifestyle traits, in general, relate to the individual's value structure. Also important is the manner in which lifestyles and

values combine to influence consumer and voter decision-making in specific choice situations. Finally, returning to the issue of measurement in marketing research, it is clear that research tools available to marketing will only be of value if they can be shown to be reliable and valid. The literature is consistent in its appraisal that the VSL concept is potentially of great importance to marketers (Ensley 1983). If for no other reason than this, the development of a valid and reliable VSL measurement tool based on theory should be an integral part of all future VSL research.

THE CONGRUENCE OF ALTERNATIVE OSL MEASURES
WITH CONSUMER EXPLORATORY BEHAVIOR TENDENCIES

Russell G. Wahlers, University of Notre Dame
Mark G. Dunn, University of Notre Dame
Michael J. Etzel, University of Notre Dame

Abstract

The present study examines the measurement congruence among several alternative operationalizations of the optimal stimulation level construct against a common set of exploratory tendency items. The results suggest that the alternative OSL scales examined in the study represent different dimensions of the OSL construct. The findings indicate that Arousal Seeking Tendency is the best measure of OSL in relation to exploration through shopping, risk taking, and innovativeness. Additionally, Raju's measure of exploratory behavior proneness appears to represent a useful, preliminary benchmark for identifying appropriate measures of OSL in a marketing context.

Background

As subsets of the general area of exploratory behavior, the concepts of variety seeking and novelty seeking offer significant implications for marketing managers concerned with promotion and product strategy development. While a copious volume of research has examined the consumer decision-making process and the concepts of brand and store loyalty, a great deal remains unknown about the processes and dynamics relating to variety seeking as a form of exploratory behavior in the consumer context.

In the traditional behavioral sciences, the arousal construct and the individual's quest for new experiences have interested psychologists since Freud and have been major themes in a number of behavioral theories (Hebb 1949; Duffy 1957; Malmo 1959; Berlyne 1960) involving the relationship between the state of an individual and his/her response to stimuli. However, Raju and Venkatesan (1980) have noted that in the consumer behavior literature the number of empirical findings that relate to variety or novelty seeking explanations are few, and no consumer studies have attempted to directly validate any particular framework. They assert that exploratory behavior processes have been neglected in consumer decision-making research due to the lack of a coherent theoretical framework appropriately modified for examining consumer behavior.

In identifying four alternative theoretical frameworks for the study of exploratory behavior in psychology, Raju and Venkatesan (1980) have critically compared and contrasted Berlyne's (1960, 1963) novelty seeking approach, Fiske and Maddi's (1961) activation theory, Hunt's (1963) concept of environmental incongruity, and the general incongruity adaptation level (GIAL) hypothesis espoused by Driver and Streufert (1965). A number of concepts are provided by these frameworks ... many of which are not in agreement with each other. However, all four frameworks are similar to the extent that they are based on the optimal stimulation level (OSL) construct and the notion that OSL varies from individual to individual.

In discussing some of the major conceptual and operational issues that need to be resolved in order to advance the discipline's understanding of the exploratory behavior process, Raju and Venkatesan (1980) note that while suggestions for operationalizing environmental stimulation have been implied by the various theoretical frameworks developed in psychology, actual OSL measures applicable to the study of exploratory behavior in the consumer context are unavailable. Thus, the measurement of OSL represents a fundamental issue to be resolved by consumer researchers interested in studying the

exploratory behavior process of consumers. The present study is an attempt to identify the most appropriate OSL measure for consumer research applications.

The Concept of Optimal Stimulation Level

Berlyne (1960, 1963) asserts that all stimulus situations have four attributes (novelty, uncertainty, conflict, and complexity) in varying degrees. These attributes, or "collative variables" join with affective characteristics (reward or punishment associated with the stimulus) and external physical features (such as size, brightness, color, or pitch) to create "arousal potential." When the environment's arousal potential is low, the individual is bored, and the desire for increased stimulation rises. Conversely, stimulus conditions exhibiting very high arousal potential will cause the individual to seek more moderate situations. In Berlyne's theory, exploratory behavior is manifested under both of these conditions. Between seeking and avoiding arousing stimuli is the individual's desired "arousal tonus" or the average, comfortable level of arousal required of an organism in a particular circumstance. The relationship between arousal potential and an individual's level of arousal has been described as an inverted-U in which low levels of arousal potential in the environment stimulate greater arousal in the individual (i.e., diversive exploration) up to some optimal level. Beyond that level, increases in arousal are disfunctional such that further increases in arousal potential produce lower levels of arousal as the individual seeks ways to return to a more familiar situation (i.e., specific exploration).

Whether the arousal potential of one's environment is perceived as too high or too low depends on the individual's optimal level of stimulation or ideal arousal. This optimal level, according to Berlyne (1960, p. 211) is determined by "personality factors, cultural factors, learning and psychological states."

In contrast to Berlyne's theory which holds that the minimization of arousal serves as the underlying motivational mechanism, Driver and Streufert (1965) suggest that over time individuals via past experiences develop expectations concerning the degree of environmental incongruity which characterizes certain situations. This level of expected incongruity is analogous to OSL and is termed the individual's general incongruity adaptation level (GIAL). According to Driver and Streufert's hypothesis, environmental deviations from one's GIAL causes cognitive action aimed at reestablishing a homeostatic GIAL. This cognitive action may take the form of exploratory behavior (if the associated incongruity is not too severe) and is specifically related to information search behavior (Streufert and Driver 1971).

Citing the refinement of a suitable framework for studying exploratory behavior as a critical problem facing consumer researcher, Raju (1979) has proposed a hybrid framework which combines Berlyne's ideas relating to the arousal potential of stimuli to Streufert and Driver's notion of environmental incongruity as the motivational mechanism underlying exploratory behavior. This approach likewise incorporates the optimal stimulation level notion as an integral component.

OSL and Consumer Research

Optimal stimulation has been the subject of a limited amount of empirical research in marketing but seems to

offer significant potential for application. The need for high levels of stimulation has been found to be positively related to the acceptance of new retail facilities (Grossbart, Mittelstaedt, and Devere 1976); new product trial (Mittelstaedt, et al. 1976); preferences for novel vacation experiences (Ettel and Wahlers 1984); exploratory tendencies relating to risk taking, variety seeking, and curiosity (Raju 1980); and selected personality traits and demographics (Raju 1980; Joachimsthaler and Lastovicka 1984). In general, the marketing literature supports the notion that OSL appears to be positively related to the degree of exploratory behavior manifested.

A fundamental issue in studies involving optimal stimulation level is the measurement of the OSL construct. Of the available scaling approaches found in the psychology literature, studies published in the consumer behavior literature have principally made use of either Mehrabian and Russell's (1974) Arousal Seeking Tendency Scale (Goodwin 1980; Raju 1980; Ettel and Wahlers 1984; Joachimsthaler and Lastovicka 1984) or the Zuckerman et al. (1964) Sensation Seeking Scale (Grossbart, Mittelstaedt, and Devere 1976; Mittelstaedt, et al. 1976). However, despite the variety of scales purporting to operationalize the OSL construct, to date little research has focused on the construct and content validity of OSL measurement in marketing context studies.

Research Objectives

Recognizing the paucity of marketing research addressing the OSL measurement issue, the present study was conducted to evaluate the efficacy of five alternative OSL-related scales found in the psychology literature in explaining exploratory tendencies in a consumer context.

More specifically, the research was conducted to:

- (1) Examine the measurement congruence among five alternative OSL-related scales.
- (2) Determine the appropriateness of the five alternative OSL-related scales as indicators of consumer exploratory behavior proneness.

The Study

Operationalization of Optimal Stimulation

A questionnaire was developed to measure both the subjects' exploratory behavior proneness and optimal stimulation levels. With respect to this latter issue, several alternative scales pertinent to OSL were included in the instrument to enable a comparison of measurement approaches.

In the psychology literature, OSL has been measured via a number of verbal instruments including the Sensation Seeking Scale (Zuckerman, Kolin, Price, and Zoob 1964), the Change Seeker Index (Garlington and Shimota 1964), the Stimulus Variation Seeking Scale (Penney and Reinehr 1966), the Similes Preference Inventory (Pearson and Maddi 1966), the Desire for Novelty Scale (Pearson 1970), and the Arousal Seeking Tendency Scale (Mehrabian and Russell 1974). Of these measurement approaches, previous studies in consumer behavior have made use primarily of the Sensation Seeking and Arousal Seeking Tendency instruments.

After a review of the available scales, five alternative measurement methods were selected for operationalizing OSL in the present study. Of these five measures, the Arousal Seeking Tendency and Sensation Seeking scales were included based on their popular use in the marketing studies dealing with OSL. Additionally, a more contemporary, abbreviated version of Arousal Seeking Tendency (Mehrabian 1978) was included. (Hereafter, Arousal Seeking Tendency I and Arousal Seeking Tendency II refer respectively to the 1974 and 1978 versions.) According to Mehrabian and Russell (1974, pp. 318-319), arousal seeking tendency reflects an individual's preference for arousal levels. Similarly, Zuckerman (1979, p. 10) describes sensation seeking as a "trait defined by the need for varied, novel, and complex

sensations and experiences..." Fourth, Pearson's (1970) Desire for Novelty instrument was selected because of its relative brevity and general applicability. Pearson (1970, p. 199) defines one's desire for novelty as a "tendency to approach versus a tendency to avoid novel experiences." Finally, Mehrabian's (1976) Stimulus Screening scale was included. The scale, according to Mehrabian (1976, p. 1), is an inverse measure of individual arousability.

Both Arousal Seeking Tendency I and Stimulus Screening instruments consist of 40 items scored on 9-point Likert scales ranging from "very strong disagreement" (-4) to "very strong agreement" (+4). Arousal Seeking Tendency II is similarly constructed but consists of 32 items. The Sensation Seeking Scale and the Desire for Novelty measure, consisting of 40 and 10 items respectively, require the subject to make a forced choice between two competing statements which comprise each item. For Arousal Seeking Tendency I and II, Sensation Seeking, and desire for Novelty -- the total score of the items after appropriate scale reversals indicates the respondent's OSL. In the case of Stimulus Screening, each respondent's total score reflects an inverse measure of OSL.

Exploratory Behavior and OSL

To measure general exploratory tendencies, Raju's (1980, pp. 277-79) 39-item lifestyle-type instrument was included in the questionnaire. Each item was scored on a 7-point Likert scale ranging from "strongly disagree" (-3) to "strongly agree" (+3). When the items are grouped according to Raju's directions and summed after the necessary scale reversals, the 39-item battery is purported to identify seven categories of exploratory behavior proneness. The seven categories include:

- (a) Repetitive behavior proneness: the tendency to stick with the same response over time.
- (b) Innovativeness: eagerness to buy or know about new products/services.
- (c) Risk taking: a preference for taking risks or being adventurous.
- (d) Exploration through shopping: a preference for shopping and investigating brands.
- (e) interpersonal communication: communicating with friends about purchases.
- (f) Brand switching: switching brands primarily for change or novelty.
- (g) Information seeking: interest in knowing about various products and brands mainly out of curiosity.

The 39 items which represent these seven response categories were developed such that they offer a general representation of exploratory tendencies, have demonstrated a lack of social desirability response bias, capture the essence of exploratory behavior as indicated by high item-total correlations, and are generalizable to a variety of populations of interest to marketers (Raju 1980, p. 277).

Data Collection

The questionnaire was administered to a sample of undergraduate business students at a major Midwestern university. A convenience sample of students was used to enable a comparison of results with those reported by Raju (1980) and Joachimsthaler and Lastovicka (1984) based on student data and was justified by the theoretical interest of the research (Calder, Phillips, and Tybout 1981). Subjects were given approximately thirty minutes to complete the instrument. Data reported in the study are based on 69 respondents.

Analysis and Findings

Each subject's responses to the five alternative OSL-related measures were scored in accordance with the procedures described in the literature. A reliability coefficient was calculated for each of the five scales. The results of this procedure are contained in Table 1. All five scales were found to exhibit KR-20 coefficients

greater than 0.7 thus demonstrating sufficient levels of internal reliability.

With respect to the question of the general degree of measurement congruence among the various OSL-related scales, correlations were calculated to assess the overall strength of association among the five instruments. The results of this analysis are included in Table 1. Both measures of Arousal Seeking Tendency exhibited a high intercorrelation as expected since the two instruments share many of the same items. The correlations between Sensation Seeking and both Arousal Seeking Tendency I and II were statistically significant but disappointing given the apparent presumption in prior consumer behavior research that the instruments are virtually interchangeable. However, given the reliability coefficients associated with Arousal Seeking Tendency I and II and Sensation Seeking, the between-scale correlations of .601 and .585 were considered too high to conclude that the scales are entirely different. Desire for Novelty was significantly related to only the Sensation Seeking measure - explaining only 5.9 percent of the variance between scales. As an inverse measure of OSL, Stimulus Screening correlated negatively with both measures of Arousal Seeking Tendency but was not significantly linked to either the Sensation Seeking or Desire for Novelty scales.

The directions and significance levels of the correlation coefficients in Table 1 thus suggest that the first four scales individually appear to reflect some common dimensions of OSL while the Stimulus Screening instrument represents a related inverse measure. However, four out of ten between-scale correlations were not statistically significant; and the levels of shared variance explained by those correlations, significant at $p < .05$, were at best marginal. The analysis, therefore, provides preliminary evidence that despite similarities among the five measurement scales in question, they may be tapping somewhat distinct and different aspects of OSL.

TABLE 1
CORRELATION AMONG ALTERNATIVE OSL-RELATED SCALES^a

Measure- ment Scale	Arousal Seeking Tend I	Arousal Seeking Tend II	Desire for Novelty	Stimulus Screening
Arousal Seeking Tend I	(.881)			
Arousal Seeking Tend II	.957 ^c	(.887)		
Sensation Seeking	.601 ^c	.585 ^c	(.802)	
Desire for Novelty	.168	.206	.242 ^b	(.772)
Stimulus Screening	-.516 ^c	-.519 ^c	-.126	-.226 (.889)

Note: ^aReliability estimates shown on the diagonal.
^b $p < .05$ ^c $p < .01$

An approach to investigate the similarity of two measures is to compare them to a common third measure. Raju's (1980) exploratory tendencies instrument served as such a common benchmark in this study. The 39 exploratory tendency items were scored and summed to yield measures of seven types of exploratory interest. The mean item-total correlation and internal reliability associated with each of the seven exploratory tendency categories were computed (Table 2) and were found to be in reasonable agreement with the figures reported by Raju (1980, p. 279).

Subsequently, the five OSL scores for each respondent were correlated with the scores associated with these seven exploratory tendency dimensions.

TABLE 2
MEAN ITEM-TOTAL CORRELATION AND RELIABILITY
FOR EXPLORATORY BEHAVIOR CATEGORIES

Exploratory Tendency Categories	Mean	
	Item-Total Correlation	Kuder-Richardson Reliability Coeff
Repetitive Behavior		
Proneness	.540	.591
Innovativeness	.550	.745
Risk Taking	.592	.761
Exploration via Shopping	.703	.803
Interpersonal Communication	.726	.561
Brand Switching	.573	.677
Information Seeking	.492	.669

The results of this procedure are shown in Table 3. The correlations between Arousal Seeking Tendency I and II and the exploratory categories were statistically significant with the exception of "interpersonal communication." Further, the respective degrees of association were found to be in reasonable accord with similar figures reported by Raju (1980, p. 279) in his study using Arousal Seeking Tendency I as an operationalization of OSL. However, the association between the exploratory tendency dimensions and the remaining OSL-related measures included in Table 3 was less than satisfactory.

Two general findings emerged from this correlation analysis. First, the level of variance associated with the exploratory tendency dimensions explained by either of the Arousal Seeking Tendency measures was substantially different (greater) than that explained by any of the remaining OSL-related instruments under study. Second, of the seven exploratory response dimensions, "repetitive behavior proneness" appears to be statistically related to the largest number of the various OSL measures. Thus, the analysis offers evidence that with respect to Raju's set of exploratory tendency categories the five alternative OSL scales appear to capture a common element of OSL related to repetitive behavior. However, despite this common thread, the remaining exploratory tendencies are not uniformly represented across alternative OSL measurement instruments.

To further refine the scale comparison, Raju's 39 items were subjected to principal component factor analysis using an oblique rotation. The results, shown in Table 4, produced seven factor with eigenvalues greater than 1.0, explaining 67.2 percent of the total variance. Thirteen items failed to load on any factor and are, therefore, excluded from further analysis.

Four of the factors are virtually identical to the categories of exploratory tendencies defined by Raju as: exploration via shopping (factor 1), risk taking (factor 2), innovativeness (factor 3), and information seeking (factor 7). Additional factors identified but not consistent with Raju's categorization are termed brand sensitivity (factor 4), new product interest (factor 5), and diversive exploration (factor 6).

The OSL scores for each respondent were correlated with the factor scores associated with these seven redefined exploratory tendency dimensions. The results are shown in Table 5. Statistically significant correlations were produced between Arousal Seeking Tendency I and II and exploration via shopping, risk taking, and innovativeness. Sensation seeking was significantly correlated with risk taking. Finally, Stimulus Screening was associated with exploration via shopping and brand sensitivity. The results, though less impressive than those found with Raju's categorization, support the Arousal Seeking Tendency scales as the most representative of consumer exploratory behavior.

Conclusions

Based upon the results of this study it would appear that OSL as measured by the Arousal Seeking Tendency scales (I and II) can be related to the consumer activities of exploration via shopping, risk taking, and innovativeness. That is, individuals with high Arousal Seeking Tendency scores are likely, as consumers, to engage in considerable shopping, assume greater risk levels, and behave as innovators. The relationships with other forms of consumer behavior would at best be speculative at this time.

Raju's scale to measure consumer exploratory tendencies proved to be useful as a benchmark for identifying the most appropriate measure of OSL. However, Raju's contention that the scale reflects seven dimensions or types of exploration appears open to question. To improve the description of the consumer behavior of arousal seekers, the scale should be refined. The objective would be a set of attributes in addition to the three substantiated in this study that would describe the consumer exploratory responses of arousal seekers and avoiders.

To the extent that the results reported here are generalizable given the nature of the sample, future buyer behavior studies that attempt to operationalize OSL should use one of the Mehrabian and Russell Arousal Seeking Tendency scales since they most clearly correlate with consumer behaviors associated with exploration. Since the more recent scale (Mehrabian 1978) incorporates more contemporary language and is briefer than the original version of the instrument (Mehrabian and Russell 1974), the newer version should be preferred.

Finally, based on the explained variance between the five scales tested, it would appear that despite some overlap -- each is measuring some unique dimension(s) of OSL. Future research addressing the construct should attempt to determine what these dimensions are and how they relate to consumer behavior.

TOWARD THE CONSTRUCT OF CONVENIENCE IN CONSUMER RESEARCH

Laura Yale, University of California, Irvine
Alladi Venkatesh, University of California, Irvine

Abstract

The authors evaluate the notion of convenience as it appears in the existing marketing/consumer behavior literature and explore the multidimensionality of the concept. With the emergence of consumer services in the past decade and the growing movement of the American society toward a service economy, the need arises to investigate consumer convenience in a systematic way. This paper addresses the issue by providing a background analysis of how the term "convenience" has appeared in marketing/consumer behavior literature and what further refinements are needed to define it in the total context of consumer behavior.

Introduction

The idea of convenience was assumably first introduced into marketing by Copeland in 1923 in his HBR article suggesting the now-classic product typology: convenience, shopping, and specialty goods. His original taxonomy has been criticized and modified over the years but the idea of a convenience good as one which requires little if any cognitive decision making has survived. Recently, convenience has been empirically operationalized by various researchers (Douglas 1976; Strober and Weinberg 1977; Strober and Weinberg 1980; Schaninger and Allen 1981; Reilly 1982), but the meaning attached to the term is not that of Copeland or his successors but of time-buying or time savings instead.

The underlying hypothesis of most of these studies has been that the more constraints on a consumer's time, the more likely he/she will be to use convenience products or services, i.e., those products and services that will save or buy time. In a recent paper, however, Venkatesh and Vitalari (1985) demonstrated that not all household technologies lead to net time savings. While the theory (of time savings) is intuitively appealing it has not proven to be strongly supported. Most studies yield insignificant results or only weak support for the hypothesis and the researchers express surprise, and some dismay, at these counterintuitive results.

In this paper, the authors propose some rationale for these enigmatic findings. It is proposed that the research suffers from three problems: 1) insignificant differences in the independent sets, 2) imprecise, "fuzzy" delineation of the dependent sets, and 3) most importantly, the lack of theoretical construction and consideration of convenience as a consumer construct.

The paper begins with a review of the original use of convenience in marketing and the theoretical underpinnings of its present use as equivalent to time savings. The recent empirical research is next summarized and critiqued. The authors then offer some preliminary theoretical development of convenience as a consumer behavior construct. Recent trends are suggested which will lead to an increase in convenience as a primary salient product attribute, and the paper concludes with proposed areas of research the authors believe are needed to develop convenience into a viable consumer construct.

Background

Convenience Goods Perspective

Copeland (1923) defined convenience goods as "those customarily purchased at easily accessible stores...." The consumer is familiar with these articles; and as soon as he recognizes the want, the demand usually becomes

clearly defined in his mind." In 1948, the AMA Definitions Committee defined convenience goods as those consumer goods which the consumer usually purchases frequently, immediately, and with a minimum of effort (Holton, 1958). Shopping and specialty goods entailed a more concerted and cognitive effort on the part of the consumer.

Holton (1958) recognized that goods vary from category to category depending on the perception and shopping propensities of the individual consumer. The consumer will consider a good a convenience (or shopping/specialty) good based upon his/her perception of the "probable gain (large vs. small) from making price and quality comparisons among alternative sellers." Interestingly, Holton suggested that nonworking wives would perceive more goods as shopping goods, while working wives would perceive more as convenience goods due to their greater opportunity cost of time. This deduction marks the link between Copeland's original usage of convenience and the recent time savings connotation.

Bucklin (1963) updated the definition of convenience goods by adding the modern concept of perceptual mapping to indicate the consumer's quick routine decision behavior: "those for which the consumer, before his need arises, possesses a preference map." Apparently, this simple definition has been accepted, by default, by marketing scholars and therefore they do not feel the need to define the term further. For example, Jolson and Proia (1976) assert "there is little disagreement as to the meaning of convenience goods." However, more recent research on the notion of convenience uses the term with a different connotation.

Convenience as a Time Dependent Construct

Through its operationalization in recent research, convenience is overwhelmingly implied to be equivalent to time saving or time buying. The theoretical framework for this new and restricted definition lies primarily in the economic concept of the household as production unit.

Becker (1965), and Michael and Becker (1973) expanded the classic economic consumer choice behavior model to include time. The classic model describes purchase behavior as a utility function in which the consuming unit attempts to maximize utility subject to constraints of income and relative prices of goods. In order to account for variations of demands (other than by the traditional economic catch-all of tastes), Michael and Becker suggest that the household produces basic commodities through the productive activity of combining purchased market goods and services with the household's own time. The household's "full income" then is composed of monetary income and total available time. Income and time constrain the production capabilities of the household.

Michael and Becker allude to the time saving connotation of recent researchers:

"it has long been recognized not only that consumers sell time in labor markets, but also that they buy time in the form of certain consumer goods and services: (these goods and services) are all in some measure time-savers. The demand for such items would be quite different if time were not a scarce resource" (1973).

Etgar, utilizing the notion of the household as a production unit, offers the marketing theory behind the recent empirical work conducted on convenience consumption

(Etgar 1978). He adds the consumption time component to previous Consumer Behavior models, transforming previous choice models into an overarching consumption model.

From the paradigm of the household as production unit, researchers, in general, hypothesize that consumers with greater time constraints will attempt to buy or save time through purchase of convenience goods (e.g., frozen dinners) and time saving durables. This intuitively appealing hypothesis, derived from the just mentioned theoretical background, has been empirically studied in the past ten years.

Findings from Previous Research

Studies, conducted within the last decade, have tested the time saving notion of convenience. However, most of these studies have focused on convenience consumption levels of working wife (WW) versus nonworking wife (NWW) households. Only one major study included single adult households in the study sample, and unfortunately for comparison's sake, it was merely an exploratory study (Hendrix 1984).

The empirical studies have found few significant differences in ownership of time saving durables or convenience good purchases between WW and NWW households. Strober and Weinberg (1977) considered the difference in purchase of time saving durables between WW and NWW households. Data from the 1968 Michigan Survey Research panel on Survey of Consumer Finances revealed no significant difference once income was taken into account. Mallan (1968), working with 1963-64 data, did find significant differences in WW families' likelihood to purchase durable goods. In 1980, Strober and Weinberg replicated and expanded their previous study using 1977 data and again found no significant differences between strategies used to cope with time pressures between NWW and WW households. "Convenience foods" were included as a variable in this latter study. Douglas (1976), too, found no significant difference in purchase of "convenience foods." Waldman and Jacobs (1978) also found no significant difference concerning expenditures for food away from home.

Schaninger and Allen (1981), noting the insignificant results of previous research, looked to wife's occupational status as an intervening variable to explain ownership of durables and purchase of many different products, including convenience foods. Results did indicate that, though WW and NWW households did not show a difference, wife's occupational status did explain some of the variation in consumption of convenience foods, but no significant difference in use of convenience stores and only weak support for ownership of appliances and durables.

Reilly (1982) conducted a study hypothesizing that role overload may be an intervening variable in the convenience consumption process. He found only weak support that those WW households reporting role overload consume more convenience foods and time saving durables. Interestingly, Reilly was the first empirical researcher to strongly suggest that the problem of the previous research may have been due to insufficient theoretical development of convenience as a construct:

"It may be that the measure of convenience consumption used in this and similar research is not particularly sensitive. Individuals may or may not use the measured convenience foods for a number of reasons other than a desire to save time. Similarly, the ownership of time-saving durables may be motivated by considerations other than work-load reduction. Some measurement research is needed to identify behavioral measures of convenience consumption which are not confounded with other factors.

"A second possibility is that the factors which influence the use of convenience foods and the ownership of time saving durables are not well explicated.

It may be that one or more important factors were omitted here. Further research is needed to identify these factors, so that our knowledge of convenience-consumption determinants might be more complete."

The foregoing empirical studies suffer from three problems. First, the independent variables in the studies were restricted to husband-wife households. Comparisons between the stratified groups (NWW, WW, and other slightly different variations) were then made. We suggest that the stratifications (clustering) of the groups were not dissimilar enough to allow for detection of significant differences in level of time saving durable ownership and convenience good consumption. In other words, the between treatment variation was not large enough to permit the emergence of significant differences on the dependent variables. It is possible, and we believe probable, that similar empirical studies utilizing strata representing all possible household types (i.e., singles, husband-wife, single parent, non-traditional households) would reveal significant differences in the dependent variables.

Compounding the problem of independent variable uniformity is the impreciseness in the operationalization of the dependent variables. The variables "time saving durables" and "convenience goods" were fuzzily delineated. Time saving durables included such commonly owned appliances as refrigerator, stove, freezer, waffle iron, drip coffee maker, and oven timer. Convenience goods included a wide variety of everyday products such as cream cheese spread, seasoning mixes, bottled juices, hot dogs, frozen vegetables, and teabags. Given the wide distribution and common usage of the just mentioned products, we believe these operationalizations measure the dependent variables in a very ambiguous, nonsensitive manner.

Lastly, but most importantly, the studies had a limitation because little specific theoretical development was undertaken to define the convenience construct. Few attempts have been made to reduce the ambiguities involved in the definition and operationalization of convenience. A construct can only be given clearer meaning when placed in a theoretical context which relates it to other variables. The simple unidimensionality of convenience as a time saving has proven too ambiguous for successful empirical study.

We believe it is time to pause in our empirical research and to reconsider the composition of convenience with some preliminary theoretical development. Hopefully, such theory development will lead to more fruitful operationalization of the construct.

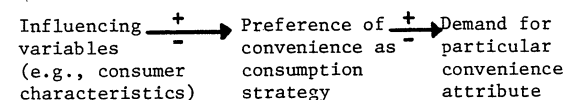

Convenience Issues in Marketing

There are two levels at which convenience becomes an important issue in marketing: 1) the determination of convenience seeking consumer segments, 2) the determination and inclusion of convenience attributes in products and services.

Figure 1 illustrates a modeling of these two related issues.

FIGURE 1

RELATION OF CONVENIENCE ISSUES

The influencing variables are characteristics of the individual consumer. These variables will increase or decrease the consumer's preference for convenience as a consumption strategy. A high preference for convenience

will lead to a heightened demand for products the consumer perceives as fulfilling his/her convenience consumption strategy. Hence, characteristics of the product and its marketing become important in motivating convenience-preferring consumer segments to purchase a product/service.

Convenience thus represents an important construct on two levels: a consumption behavior level and a product attribute level. Marketers must understand the complexity of convenience in order to determine convenience seeking consumer segments and to design products and marketing for these segments which highlight consumer perceived convenience attributes.

Proposed Variables Influencing Convenience Preference

Etgar (1978), Feldman and Hornik (1981), Hendrix (1984), and Nicosia and Mayer (1976), each called for researchers and marketers alike to consider the multidimensionality of the entire household production/consumption/time allocation function. In that context, convenience, as an integral factor in consumption, should be considered in psycho-behavioral as well as simple economic and temporal terms. What follows is only an admittedly first tentative step toward theoretical development of a multi-dimensional construct of convenience.

By and large, convenience has been implied to involve two variables, economic and temporal. The economic dimension simply articulates the monetary value of time; that the individual can sell his time for money, or refrain from selling his time, thus incurring an opportunity cost (Mincer 1963; Becker 1965).

The temporal variable, which has been mentioned throughout the first section of this paper, also refers to the consumer's ability to buy or save time, which is strictly constrained to the total available number of hours represented by the number of members in the household times 24 hours per day. Thus both the economic and temporal variables reduce to the same thing. We believe a single temporal/economic dimension inadequately delineates convenience. One could deduce that all consumption in any trade economy can be considered convenience consumption. For example, a woman buys a suit for work because she does not have time to sew; another woman buys wool cloth to sew a suit because she does not have time to weave. Still another woman buys sheared virgin wool because she does not have time to raise sheep! Additional variables need to be considered in order to gain clearer meaning of convenience in the consumption process.

For preliminary discussion and exploration, we suggest the consideration of the following variables: spatial, psychological, sociological, philosophical, and situational.

The spatial variable is inferred from the temporal/economic and variable. Proximity in location or in time offers utility to the consumer in a simple efficiency sense. This spatial sense is colloquially "being in the right place at the right time." It is this sense that Copeland implied in his original work. Once the consumer recognizes a need, the first opportunity to fulfill that need will be taken. The consumer will prefer to satisfy several needs in one location if given the option, as long as the economic cost incurred is not seen as significant.

There is also a psychological variable. The values, personality, opinions, attitudes, abilities, and preferences of an individual will influence his/her choice of consumption behavior. Different individuals will have different preferences for each style of consumption, each consumption strategy (Etgar 1978). A traditional mother-wife may place great value on her role as nurturer and therefore she will prefer consumption strategies which allow her to actively participate in production activities which she perceives as nurturing to her family. This same

woman, when placed in a more time constrained situation (e.g., she takes a job outside the home), will most likely continue with her values and traditional consumption strategy in order to maintain her feelings of fulfillment as nurturer. Many examples such as this can be suggested to demonstrate the importance of the psychological dimension of convenience. All that will be emphasized here is that, just as psychological variables influence all individual behavior, similar variables will influence the consumer's want for, and perception of, convenience.

The construct of convenience also includes a sociological dimension, again as all human behavior does. The various roles that an individual plays will influence the individual's perception of, and use for, convenience. Reference groups such as family, church, state, and peer groups all will contribute to the importance and meaning of convenience to the individual. In addition, social class, race and cultural norms and values may suggest or preclude certain behaviors which have an impact on convenience as manifested in society. The classic story of the rationale for the exclusion of powdered eggs from cake mixes serves as an example of cultural norms influencing socially acceptable convenience-seeking behavior.

Cultural and personal values, in their most macro sense, give rise to differing philosophies. There may indeed be a philosophical dimension to convenience. Above and beyond apparent cultural norms, the individual's philosophy of life may affect his/her perception of convenience and whether or not he/she chooses to value convenience as a product attribute or benefit of behavior. Those 1980's consumers with a conservationist philosophy of life decry many "convenience" products, e.g., disposables, aerosols.

Lastly, one would expect convenience to include a situational variable. As product choice has demonstrated situational variation (Belk 1975, 1979), convenience perception and need can also be expected to vary among differing usage situations. Hornik (1982) found that time allocation was situationally influenced. As convenience admittedly includes a temporal dimension, one can deduce that in severely constrained time situations, convenience may be of greatest importance. In less time constrained situations, convenience may not be considered salient at all. Similarly, other variables of convenience may be situationally affected.

Additionally, convenience may vary depending on purchase situation. For example, convenience (in its spatial sense) may lead to situationally suggested impulse purchasing where there had not been any previous purchase intent. The inclusion of florist departments in supermarkets assumably gives rise to many impulse purchases of flowers and floral arrangements for the evening meal that otherwise would not have been considered by the consumer.

The lack of empirical evidence supporting the simple singular time savings notion of convenience implies that the construct is more complex, with a number of variables interacting to determine the individual's need for and perception of convenience. Convenience apparently is many things to many people and it may vary among, and within, individuals along the variables just outlined.

Proposed Consumer Perceived Convenience Classes

In order to develop a more comprehensive concept of convenience, we explored a list of factors which the consumer may perceive as making a product "convenient." The many factors can be grouped into six categories, six "classes of convenience": time utilization, handiness, appropriateness, portability, accessibility, and avoidance of unpleasantness.

Table 1 lists these six classes of convenience with some product examples which we believe demonstrate each class. The six classes can be seen as marketing strategies which have been used by companies to meet consumer perceived convenience needs. Many of the products/services could

be included under more than one class but each product/service is listed only once under the class we believe is most applicable.

TABLE 1
CONVENTIONAL CLASSES
AND
SAMPLE PRODUCTS/SERVICES

Time Utilization	Fast food restaurants Child care Housekeeping chores Federal Express
Accessibility	Branch banking Vending machines Drive-up windows Frequent bus schedules 800 numbers (telephone)
Portability	Tapes vs. records Personal computers/ electronics
Appropriateness	Take-out food Frozen entrees Liquid margarine
Handiness	Frozen orange juice Movie rentals Under-cabinet appliances
Avoidance of Unpleasantness	Home and yard maintenance Disposable diapers Dishwasher

The time utilization class of convenience is the single type of convenience that has been operationalized in the research cited in this paper. It implies a time saving or time buying utility. But the consumer's preference for the time saving utility of a product depends on many considerations. Is there an assignable monetary opportunity cost to the consumer's use of the specific time of day, e.g., 7:00 p.m.? What amount of time does the consumer have available to allocate among consumption activities? Is the consumption time perceived as being enjoyable or creative? Can the time spent in consumption be combined with other rewarding activities, such as socializing with friends/family, watching the evening news, etc.? A most important element in choice of consumption activity may be the degree to which the activity is appreciated/rewarded by significant others, e.g., mother cooking evening meal for family.

The handiness class of convenience refers to effort saving capability. This classification represents "ease of production." A product may be viewed as convenient because it makes the consumption activity easier to perform. A food processor cuts, chops, etc. with more uniformity, speed, and with less mess than the equivalent manual activity. In addition, handiness can imply flexibility of use or production. A single appliance serves many functions, thus "easing" several different production processes.

Appropriateness refers to fittingness to specific needs. Single serving cans fulfill a specific need for single consumers. The new, under-the-cabinet appliances fill a specific need to have an appliance close at hand while still maintaining clear counter space. Gourmet frozen entrees provide singles with variety in their diet without the need to purchase and store the wide assortment of staples necessary to produce the dishes or to purchase larger than needed quantities of perishables. A further "convenience" the entrees provide is the lack of interminable leftovers that the single would otherwise accumulate.

Portability allows the consumer to consume the product in any location he/she desires. Individual packaging, dehydration, and several modern preserving methods make foods more "portable" in this convenience sense. The portable computer and the "Walkman"-type stereo allow the consumer to gain concomitant utilities, e.g., perform work while traveling and listen to music while exercising.

Accessibility is a primary class of convenience. This category includes proximity of location, availability when consumer desires product, and flexibility of delivery of product. The all-under-one-roof malls and superstores provide a variety of goods which are in the right place at the right time. Doctors and other professionals provide appointment times in the evening to be accessible when the consumer is free to partake of their services. Mail-order catalogs and videotex services allow the consumer to shop at his/her leisure at any time of day, any day of the week.

Avoidance of unpleasantness is a class of convenience in that it allows the consumer to forego an activity that he/she previously had to perform but did not enjoy. This concept includes a preference or relativity aspect. The consumer prefers other activities to activities that must be performed. The consumer would consider it "convenient" to have the necessary activities performed by someone other than him/her-self.

Figure 2 incorporates our proposed influencing variables and convenience classes into the previously illustrated convenience issues diagram (Figure 1). The proposed influencing variables increase or decrease the likelihood of a consumer choosing a convenience consumption strategy. If such a strategy is chosen the consumer will then compare products on one or more of the proposed convenience class attributes.

We are therefore suggesting that choice of convenience as a consumption strategy is a function of the previously mentioned influencing variables, and that consumer perception of a product as convenient is a function of the six just mentioned classes of attributes.

FIGURE 2

PROPOSED CONVENIENCE CONSUMPTION MODEL

Implications and Suggested Research Directions

We believe it is especially important to seriously and systematically study the idea of convenience at this time because a myriad of trends foreshadow that convenience, as theoretically discussed in this paper, will become a dominant salient attribute of virtually all products consumed in American society.

Existing research has already emphasized the hypothesized effect of the increasing proportion of women working on the demand for convenience. There are also many non-time-constraining trends which increase the likelihood of heightened demand for convenience.

Americans, with increased affluence gained via attainment of high levels of education and dual income/career households, are demonstrating a new frame of mind. Housework, chores, and traditional house and family maintenance activities are being seen as menial and

non-fulfilling. No longer is a woman a bad mother or unskilled woman if she can not bake a good pie or sew a practical dress. A man no longer need fear for his masculinity if he does not fix cars, mow the lawn or chop wood. The "upscale" American would simply prefer to pay others to fulfill such functions which are seen as boring or unpleasant. The affluent consumer is more and more likely to choose to devote non-working time to sports and hobbies.

The family structure of the country has changed markedly over the past 15 years, giving rise to a large minority of single person households and other non-traditional family patterns. These non-traditional households assuredly have different consumption needs and preferences than the traditional unit of husband, housewife, two kids, and a dog.

Marketers have responded to the increased level of affluence by offering products and services which could not have been afforded by a less affluent society. The mere availability of such new convenience services such as videotex and other electronic services increases the consumer's awareness of the "convenience attribute," and may increase his/her demand for "convenience" in virtually any goods.

All of these trends--increased time demands, greater affluence, increasing percentage of non-traditional households, and availability of new products--lead to the deduction that convenience as a construct and product attribute will become increasingly important to consumers, and marketers, in the future. Therefore, convenience needs much research effort in order to be utilized as a fruitful marketing construct. This concluding section represents a suggested path for future research.

First, an exploratory study is needed to gain preliminary knowledge on the perceptions consumers have concerning convenience. This exploratory effort would yield information concerning the variables influencing perceived need for convenience and information about product attributes perceived as making one product more convenient than another. Those mentioned in this paper may or may not be found to underlie convenience in the minds of consumers. Only ethnographic research can provide qualitative knowledge upon which to build the construct and lead to more valid and reliable operationalization of the construct in empirical testing.

After exploratory research has been conducted, theories and models must be generated in order to develop hypothetical links between convenience and other marketing and social science concepts and constructs. Once preliminary theories have been articulated, empirical studies need to be conducted, testing specific hypotheses. Samples representative of consumers at large need to be utilized in order to develop complete conceptualizations. Researchers need to begin to study the construct from the point of view of all household types. One can easily argue, for example, that single person households are under the severest time constraints in that there is no other household member to share in the consumption/production process.

Finally, after empirical tests have been conducted on a variety of theoretically derived hypotheses, it will be necessary to integrate the construct of convenience into the consumer behavior model and the broad area of marketing. The construct, once satisfactorily defined, operationalized, and understood, should then be applied by marketing practitioners to more effectively and efficiently deliver the products and services needed by the modern consumer. If the aforementioned trends do indeed give rise to greater consumer need for "convenience" as a product attribute and benefit, marketers must be aware of the complexity of the construct.

A RE-EXAMINATION OF COMMUNICATION CHANNEL USAGE
BY ADOPTER CATEGORIES

Linda L. Price, University of Pittsburgh
Lawrence F. Feick, University of Pittsburgh
Daniel C. Smith, University of Pittsburgh

Abstract

Because early adopters are pivotal in securing widespread acceptance of new products, they have been the subject of much research. Of particular interest in understanding the diffusion of innovations is the question of how early adopters find out about new products, and whether and how they communicate this information with others. Systematic research on the use of mass media channels compared to interpersonal channels by different adopter categories is notably absent in consumer research. This paper reports the results of research undertaken to examine communication channel usage by different adopter categories for consumer nondurable products. Results of a nation-wide study of 1531 households indicate that earlier adopters find mass media sources relatively more important than later adopters. However, earlier adopters rate both mass media and interpersonal sources as more important than later adopters. Earlier adopters also are more likely to transmit information than later adopters. These results are discussed in light of the media intensiveness of consumer goods markets.

Introduction

The diffusion of innovations is a communication process in which interpersonal transmission of information is of primary importance in facilitating awareness and trial of new products. Early purchasers have been the subject of much research partially because they are recognized as being pivotal in securing widespread acceptance of new products through their communicated experiences. The answers to two questions are of particular interest in understanding the diffusion of innovations: 1) how do earlier adopters find out about new products? 2) how do they communicate this information to later adopters? It is important to recognize that the questions address both the intake and transmission of information.

In answering the question pertaining to the intake of information by adopter categories, the literature suggests that earlier adopters rely on mass media more than interpersonal channels in making the adoption decision (Rogers 1983, Robertson and Gatignon 1985). A number of diffusion models are predicted on the assumption that the earliest adopters purchase products independently of the communicated experience of others (Bass 1969, Midgley 1977, Midgley and Dowling 1978, Horsky and Simon 1983). Rogers (1983) summarizes the relative reliance on mass media over interpersonal sources by adopter categories with the following generalization: "Mass media channels are relatively more important than interpersonal channels for earlier adopters than for later adopters," (p. 201). This same notion is proposed by Robertson and Gatignon (1985) (see proposition 26, page 851). Despite widespread acceptance of this generalization, there is little systematic research comparing adopter categories on use of mass media relative to interpersonal channels. While some research in marketing has shown that earlier adopters have greater exposure to mass media than later adopters (Summers 1971), the research has not explored the relative use of mass media and interpersonal sources in product purchase decisions.

In answering the question about the nature of information transmission by the various adopter groups, research indicates that earlier adopters communicate their experiences with products to others and are central to the acceptance of innovations by later adopters (Arndt 1967; Engel, Kegerreis, and Blackwell 1969; Midgley and Dowling 1978; Sheth 1971). In fact, a number of writers have noted that

interpersonal information transmission by earlier adopters is necessary for the cumulative diffusion curve to attain its familiar S shape (Midgley 1977, Mahajan and Mueller 1979).

In summary, accepted thinking regarding the information acquisition and transmission of adopter groups suggests that earlier adopters make their purchase decisions more-or-less independently of input from others. These individuals then serve as models for an imitation effect which occurs actively through word-of-mouth and/or passively in the case of highly visible innovations. This model suggests a one-way flow of communication from earlier adopters to later adopters. There is a substantial amount of intuitive appeal to this view. It seems reasonable to assume that at the earliest stages of introduction, the first adopters of a product must find out about its existence through mass media (or other seller-sponsored sources) since there is typically little opportunity for interpersonal information exchange until there is an awareness of the product's existence.

For a number of reasons, this model of the diffusion process deserves reexamination despite its intuitive logic. First, the model seems to be inconsistent with a number of studies which have found the diffusion of information to be more of an exchange process than a unidirectional flow (Arndt 1954, Whyte 1967). Second, research evidence in support of the model is limited. Of only ten studies that addressed the question, Rogers (1983) notes that eight studies supported the tendency of earlier adopters to rely more heavily on mass media sources than later adopters. All of the studies cited by Rogers, however, involved new agricultural technologies. Thus, the model is based primarily on research involving major, discontinuous innovations. These types of products and their associated information media are dissimilar to those found in consumer product markets. In consumer product markets, continuous innovations dominate discontinuous ones and appear to be a more relevant focus for inquiry by consumer researchers. Finally, the acquisition and transmission of information by earlier adopters has rarely been studied simultaneously in consumer settings. Past research, therefore, offers little insight into whether innovators who report a higher reliance on mass media information sources are also inclined to transmit information to other buyers.

The purpose of this research was to examine differences in earlier and later adopters both on the relative use of mass media sources of new product information, and also on the transmission of new product information. This study is unique in that it: (a) explores both the intake and transmission of information, (b) measures the relative reliance on mass media versus interpersonal sources, and (c) explores these phenomena in the context of the adoption of new products in frequently purchased product categories which are typified by continuous innovation rather than major discontinuous innovations.

Method

Data Collection Procedure

Data used to examine the sources and transmission of information by adopter categories were obtained from telephone interviews. The final data collection instrument was preceded by pilot testing designed to refine the measures. In total, 425 students were used in the pilot testing phase. The questionnaire on which the results presented

in this study are based, was administered by telephone interviews conducted during the middle two weeks of August 1984. Sample selection was done by random digit dialing of the 48 contiguous states. The researchers assigned sex, alternating male and female, to the telephone numbers. Interviewers then screened for either male or female head of household. In homes in which that person was not available, call backs were scheduled; in homes in which the person of the assigned sex did not exist, the interview spoke with the sole household head. Initial calls were made between the hours of 3:30 p.m. and 9:30 p.m. local time with call backs scheduled for any time convenient for the respondents. A minimum of three call backs per telephone number were made in an attempt to contact the pre-assigned household head.

A total of 1531 interviews were completed. The response rate (completed interviews as a percentage of eligible interviewees; where eligible interviewees are defined as the sum of completed interviews, refusals, and terminations) was 47 percent. The demographics of the respondents, with the exception of sex, closely approximated those of the 1980 census and recent updates. The sex distribution of the sample (64 percent female and 36 percent male) was significantly different from that of the population of household heads (57 percent female and 43 percent male).

Development of Measures

Definition of Adopter Category Membership. Traditionally, innovativeness has been viewed as a behavioral variable and defined as the actual adoption of a product. As a result of this definition, most studies have examined innovativeness by focusing on individuals who have adopted a new product at a single point in time (Assael 1983, Kotler and Zaltman 1976). This approach to studying innovativeness is plagued with at least three limitations. First, examining only the time of adoption does not consider differences in the time which elapses between exposure to the innovation and actual adoption (Kotler and Zaltman 1976). Second, such a measure is incapable of making the distinction between the product-specific and the general innovator (Midgley and Dowling 1978). Finally, as Midgley and Dowling (1978) suggest and Carlson and Grossbart (1984) empirically support, actual adoption is mediated by a host of situation specific variables.

As a consequence of these limitations and in an attempt to improve the generalizability of the findings, we used a single item self-designation method for identifying membership in the adopter groups. Half of the respondents were asked: "In general, when new food and common household products first appear on the market which of the following best describes when you are likely to buy the item? Would you say that you are among the first to buy it, you buy before most the majority of people, you buy at about the same time as most people, you buy after most people, or you buy much later than most people?" The other half of the sample was asked the same question except that the product class considered was "non-prescription drugs and health and beauty products". These product categories represent a substantial portion of consumer nondurables which were the focus of this study. The time-of-adoption measure used in this study aggregates across the two halves because initial analyses indicated that there were no differences between the two groups on the variables of interest in this research. Each of the five responses to the question was designed to correspond to one of the five adopter categories defined by Rogers (1962) -- innovators, early adopters, early majority, late majority, and laggards respectively. Our measure of time of adoption seemed to have reasonable convergent validity as it was correlated with a number of other measures that also appear to tap the construct of innovativeness. For example, the correlation between our measure of innovativeness described above and an item stated "I usually try a new product shortly after I learn that it is on the market" was to be .39, and .28 with an item stated "I am the kind of person who would try any new once."

Information Transmission. We defined information transmission to be an individual's tendency to share new product and other information with friends or acquaintances. Five items required respondents to indicate, on a seven-point scale, the extent to which they agreed or disagreed with statements pertaining to their information transmission tendencies. These items were:

1. I like helping people by providing them with information about many kinds of products.
2. My friends think of me as a good source of information when it comes to new products or sales.
3. I like introducing new brands and products to my friends.
4. People ask me for information about new products, and places to shop for sales.
5. If someone asked me where to get the best buy on several types of products, I could tell him or her where to shop.

The correlation between these five items was high, ranging from .43 to .55.

Reliance on Mass Media Relative to Interpersonal Information Sources. Reliance on mass media was measured by taking the average level of importance ascribed to four media (television, radio, magazines, and newspapers) in obtaining new product information.

Reliance on interpersonal sources was measured by a single item which required respondents to indicate the importance of friends and relatives in obtaining a new product information. Seven-point very important/not very important scales were used to measure both mass media and interpersonal source importance. For both sources of information, the items were framed in product-specific terms. For example, "When considering new food or common household products, how important to you are the following sources of information?"

Results

Definition of Adopter Categories

As illustrated in Table 1, the definition of adopter categories based on the self-report measure of innovativeness employed in this study closely mirrors the distribution proposed by Rogers (1962) and provides face validity for the measure.

TABLE 1

	This Study	As Proposed by Rogers
Innovators	5.5%	2.5%
Early Adopters	10.4	13.5
Early Majority	40.9	34.0
Late Majority	20.5	34.0
Laggards	22.7	16.0

Information Channel Usage Across Adopter Groups

The results on the importance of mass media and interpersonal sources of information are presented in Table 1. A one-way analysis of variance indicated that adopter groups differed in their the use of both mass ($F=29.1$, $p < .001$) and interpersonal information ($F=8.7$, $p < .001$) sources. The importance of both types of information declined with later adoption. The results, however, provided only partial support for previous research suggesting

greater importance of mass media sources among earlier adopters. Mass media sources had the greatest relative importance among earlier adopters. For example, the ratio of the mean on mass media to the mean on interpersonal sources for innovators was .97, while this ratio for the late majority was .85. However, mass media sources were consistently regarded as less important than interpersonal sources across adopter groups. While innovators and early adopters ascribed the greatest and second greatest importance, respectively, to mass media sources of information, they also were the adopter groups reporting the greatest importance of interpersonal sources. Among all of the adopter groups except for innovators and early adopters, the mean importance of interpersonal sources was significantly greater than mass media sources. In the innovator and early adopter groups the mean differences between mass and interpersonal sources were not significant.

The percentage changes in means by adopter categories included in Table 2 indicate that the decline in mass media sources importance is more precipitous than the decline of interpersonal source importance across the adopter categories. In addition, the table indicates a dramatic decline in the importance of both types of sources for the laggard group compared to the late majority.

Information Transmission

To examine the extent to which the adopter groups differed on disseminating product related information, the five items measuring information transmission were compared across groups. As reported in Table 3, one-way analysis of variance indicated significant differences among the groups on all four items. The tendency to actively disseminate information is highest for earlier adopters and declines sharply for later adopters.

TABLE 2

VARIATION IN INFORMATION SOURCE USAGE ACROSS ADOPTER CATEGORIES

A Closer Look at Acquisition and Transmission by Earlier Adopters

Because of the critical role played by earlier adopters in transmitting new product information, and because only partial support for previous research was obtained, we decided to do further analysis of the data. Of particular concern was the possibility that in aggregating we had obscured a group of earlier adopters who are mass media specialists. As a consequence, the sample was divided according to their relative usage of mass media sources. Individuals with a positive difference between mass and interpersonal source importance were classified as mass media intensive and those with a negative difference were classified as interpersonal source intensive. In addition, we divided the sample into earlier adopters (innovators and early adopters) and later adopters (early and late majority and laggards). We then examined the differences among the groups on information source importance and information transmission.

TABLE 3

MEANS AND STANDARD DEVIATION ON INFORMATION TRANSMISSION ITEMS BY ADOPTER GROUPS

ITEM	ADOPTER GROUP					F
	Innovators	Early Adopters	Early Majority	Late Majority	Laggards	
I like helping people by providing them with information about many kinds of products.	5.35 (1.62)	5.12 (1.72)	4.64 (1.87)	4.23 (1.99)	3.97 (2.18)	15.6*
My friends think of me as a good source of information when it comes to new products or sales.	4.82 (1.79)	4.70 (1.77)	4.38 (1.78)	3.93 (1.89)	3.77 (2.12)	11.5*
I like introducing new brands and products to my friends.	4.65 (1.98)	4.83 (1.81)	4.03 (1.93)	3.67 (2.12)	3.17 (2.12)	23.8*
People ask me for information about products, places to shop or sales.	4.83 (2.00)	4.68 (1.85)	4.13 (2.01)	3.77 (2.01)	3.59 (2.08)	13.1*

* p < .001

Figures in parentheses are standard deviations

Table 4 presents the results of these analyses. The F statistics indicated significant differences among the groups for the information source importance items. This result was expected since these questions formed the basis for defining the groups. The F statistics for the information transmission items also indicated significant differences among the groups. Post hoc comparisons (Scheffe procedure at $\alpha = .05$) of the information transmission items across the groups indicated that the mass media and interpersonal source specialists (i.e., the differences between groups 1 and 2 and between 3 and 4 in Table 4) are not significantly different among either the earlier or later adopters. However, mass media specialists in the earlier adopter group (group 1) differed significantly from their later adopter counterparts (group 3) on four of the five information transmission items. Similarly, interpersonal source specialists in the earlier adopter group (group 2) significantly differed from their later adopter counterparts (group 4) on all of the five information transmission items. Thus, the difference in information transmission among the groups appears to arise from the effect of the time of adoption, not relative use of mass media within the groups. However, there is a consistent, but nonsignificant, tendency for the interpersonal source intensive consumers to be slightly higher on transmission than the mass media intensive consumers. This tendency occurred in both earlier and later adopters.

In summary, the results indicated that the importance of both mass media and interpersonal sources of information was greatest among earlier adopters and declined steadily across later adopter categories. Mass media sources were relatively more important for earlier than later adopters. However, in all adopter groups, the importance of interpersonal sources was greater than mass media sources of information. While the tendency to transmit information was greatest for earlier adopters, there was no relationship between the tendency to transmit information and sources of information used to learn about new products.

Discussion

Our results provide only limited support for previous research on the importance of information sources by adopter categories. Consistent with Rogers' (1983) generalization, later adopters seem more attuned to interpersonal than mass media information sources, and mass media information sources are relatively more important for earlier than later adopters. However, the results on earlier adopters seem to differ from those that might be expected by previous research. Earlier adopters find mass media sources more important than do later adopters, but they also find interpersonal sources to be more important than later adopters. Earlier adopters seem to collect information from a variety of sources and appear to be generally information hungry.

The results indicating a more rapid decrease in importance of mass media than interpersonal sources from earlier to later adopters seem consistent with literature which suggests that the importance of an imitation effect increases as adoption of an innovation becomes more widespread (Bass 1969, Midgley 1978). In addition, the substantially lower importance of both mass media and interpersonal sources among laggards seems consistent with Rogers (1983) who indicates that laggards tend to be social isolates.

It is important to consider why our findings on the importance ascribed to interpersonal sources by earlier adopters seem to differ from those expected from Rogers' generalization. At least in part, our results may have occurred because the information environment for consumer goods seems to be substantially different from that of the agricultural industry on which Rogers' generalization was based. The consumer information environment is considerably more media intensive than that of agriculture and, as a result, large numbers of consumers can be aware of the existence of a new product even though they may have never tried it. Because of the relatively high

level of general awareness, earlier adopters are able to use interpersonal sources to learn about new products. This is consistent with the empirical work indicating that the product life cycle is shortening, partly because of increased availability of information (Olshavsky 1980). It is also consistent with the existence of information sensitive consumers who are either product class specialists or market generalists, but need not be users of a particular product about which they have information (Feick and Price 1985, Price and Feick 1984).

The results that indicated a relatively high reliance on interpersonal sources across all adopter categories suggest that the primary function of interpersonal sources may not be risk reduction. Since there is little risk associated with the purchase of the consumer nondurables considered in our study, we would expect to find (if risk reduction were of primary importance) less use of interpersonal sources. The consistent importance of interpersonal sources across adopter groups, but particularly the importance of these sources among earlier adopters, suggests risk reduction may not be the most important motivation for the use of these sources. They may, in fact, simply perform an information function.

While the findings presented in this study are based on consumer nondurables, they may generalize to durable goods as well since the information environment for consumer durables is very similar to that of nondurables. Because the fraction of individuals who are aware of the product but who have not purchased it would be expected to be greater for durables (given the higher cost, risk etc.), there should exist an interpersonal network of knowledgeable nonadopters available to earlier adopters.

Several caveats regarding the findings should also be recognized. First, due to the relatively large sample sizes for each of the adopter groups, certain differences between use of mass media and interpersonal sources were found to be statistically significant but may not be regarded as substantively important. Second, the reliance on mass media relative to interpersonal sources was not directly measured. A more direct measure (e.g., having the respondent allocate a certain number of points to each source of information) may have lead to somewhat different results. Finally, the measure used to assess reliance on each information source was framed in product-specific terms whereas the measure of information transmission was stated in more general language. It is conceivable that people may generally like to disseminate new product information to their friends for every product category except drugs and household items (i.e., the categories considered in this study).

We undertook this study to test some widely held beliefs about diffusion. As is the case with much of the received doctrine on the diffusion of innovations, the generalization tested here was derived from studies not undertaken in consumer product markets. Our results only partially supported the generalization we tested. It is interesting to speculate about how many of the commonly held propositions in the diffusion literature are not completely generalizable to the consumer setting. The exploration of these propositions in consumer settings may provide a very fruitful avenue for future research.

CORRELATES OF SEARCH PATTERNS
FOR AN INNOVATION

James W. Harvey, George Mason University

Abstract

This study addresses several of the shortcomings of diffusion research as summarized by Rogers (1976, 1983) and Robertson (1984). To better understand the role of marketer-dominated, sociometric, and non-commercial sources of information in the adoption process, factor analysis was used to infer subjects' information search typology from an information display board. Using indexes reflecting source structure, subjects were grouped by cluster analysis into patterns of typology use. Zero-order correlations provide insight into demographic, task environment, and behavioral associations with types of search for a discontinuous innovation.

Overview

Rogers (1976, 1983) and Robertson (1984) review several conceptual and research deficiencies in adoption theory which represent important challenges for the continued examination of this unique aspect of consumer behavior. These researchers argue that most innovation studies (1) neglect to use a process approach which tracks multiple dependent measures over time, and rely too heavily on retrospective measures; (2) focus on innovations of which adoption is assumed to be desirable; (3) fail to include thorough sociometric analysis, including multi-influence decision making; (4) avoid examination of innovations which are only tangentially important and are not highly recommended, for which low-involvement models of decision behavior may be most appropriate; (5) fail to consider that situations may exist where adopter categorization and innovator identification may not be relevant; (6) need a stronger emphasis on market segmentation; (7) avoid the study of innovations where performance of the offering is difficult to judge; and (8) neglect to account for the very real world influence of marketer-controlled communications such as advertising, personal selling, sales promotion, and packaging.

One aspect of the adoption process which draws together several of these seemingly disparate conceptual and research design issues is the magnitude and composition of external search. Search composition is determined by the information sought from various sources and has long been reported to have different effects on the prospective adopter. For example, commercial-source information detailing design, function and performance is thought to stimulate awareness and interest in the innovation, while support from professional and personal sources are needed to encourage trial (Katz 1961; Lionberger 1960; Ryan and Gross 1943).

However, most of the recent studies of search magnitude and composition (e.g., Newman and Staelin 1972), as well as those which examine effects of availability, format and number of alternatives (e.g., Jacoby 1984) and individual difference effects such as demographics, personality, cognitive structure and experience (e.g., Duncan and Olshavsky 1982; Schaninger and Sciglimpaglia 1980, 1981) base their findings on offerings other than innovations (for exceptions, see Arndt 1967; Berning and Jacoby 1974; Bettman 1970; Black 1983; Dickerson and Gentry 1983; Furse, Punj and Stewart 1984; Shoemaker and Shoaf 1975; Wilton and Pessemier 1981). Those studies which were conducted in an adoption of innovation context, however, possess many of the characteristics criticized by Rogers (1976, 1983) and Robertson (1984), outlined above. Consequently, more needs to be known about external search for innovations, using research designs which address these criticisms.

Research Goals

To address several of these shortcomings, six goals guided the development of this study: (1) to report the magnitude and composition of consumers' external search for an innovation in a real-time environment which would lessen the reliance on retrospective measures and strengthen the opportunity for both control and insight into process; (2) to make available to prospective adopters all possible combinations of commercial, non-commercial, personal and impersonal types of information; (3) to validate decision makers' perceptions of differences in these information sources; (4) to establish search patterns across information source and selected demographic and task environment measures, as well as behavior; and (6) to present these findings where the object of the study is a relatively inexpensive, comparatively unimportant product, true of most innovations to be found in the consumer marketplace.

Method

One hundred twenty-four women responsible for food preparation were recruited through a variety of civic, special interest, and church groups. Their average age was just over 35 ($s = 14$), with 1.8 children ($s = 1.3$), middle income and house value, with 55% college educated.

Upon arrival at their meeting room, subjects were seated away from the information display boards and handed a written product introduction which was described as a "press release to familiarize the public with a new texturized vegetable protein food product which was soon to become available in local supermarkets." Having read the press release, each subject was seated in front of an information display board (IDB) and told that the next thing requested of them was to select as much or little information beyond the press release as they would need to decide whether or not to try the product.

Each IDB contained sixteen cards which were visible to the subject: Package Front, Comment of a Family Member Who has Tasted Product, Sales Representative, Manufacturer's Reputation, Government Report: Flavoring, Product Ingredients, Consumer Reports Study, Print-Ad, Nutritional Information, Good Housekeeping Test, Cooking Instructions, Government Report: Coloring, Government Report: TVP, Comment of a Friend Who has Tasted, No Trial, and Trial. The women were told that the information labeled on the front of each card was contained on the back and that to obtain the desired information they were to remove the card from the hook, turn it over, read it, stack it in a pile, and then choose whatever information was next desired. Subjects were told to repeat this process until "you have enough information to decide whether you want to try the product or not, and then select the card which reflects your choice: Trial or No Trial."

Fourteen of these pieces of information (Trial/No Trial Deleted) represent combinations of commercial, non-commercial, personal and impersonal sources, as outlined by Robertson, Zielinski and Ward (1984, p. 89) and serve as the primary dependent variables of the study. Figure 1 presents the categorization of these cues.

After completion of the search task, subjects completed a questionnaire which gave them an opportunity to "order" units of the product at \$1.00 each, and contained the demographic and task environment variables which serve as the measures for this study. The homemakers were paid \$8.00 for their time and cooperation.

FIGURE 1
SOURCE TYPOLOGY OF AVAILABLE CUES

	Impersonal	Personal

Non-Marketer Controlled	Government Report (flavor) Government Report (color) Government Report (TVP) <u>Consumer Reports</u> <u>Good Housekeeping</u>	Family Comment Friend's Comment

Results

Data Reduction

To infer the underlying structural character of information usage, counts were made on whether each of the fourteen cues was selected by the subjects. As advocated by Schaninger and Sciglimpaglia (1980), Rao's canonical factoring was applied to these fourteen types of information to infer subjects' taxonomy of information source. Rao's factoring with varimax rotation is appropriate in instances characterized by scale-free variables and where the elimination of multicollinearity is desired. Four factors with eigenvalues greater than 1 were found, explaining 59% of the original variance. Table 1 presents the factor pattern matrix, with decimals and loadings less than .3 omitted.

TABLE 1

Govt. report (TVP)	64844			
Friend's comment				64800

^aDecimal points omitted, factor loadings <.3 omitted.

With some exceptions which will be discussed later, the results of factor analysis appear to have considerable correspondence with the expected typology. Factor 1 (31% of the variance) can be labeled Nonmarketer Controlled/Impersonal, with information from government, independent, and non-manufacturer testing sources being sought. Notice that Nutritional Panel has mixed loadings with Factor 2 and that it as well as Consumer Reports and Good Housekeeping have comparatively low loadings on Factor 1. The level of these three loadings suggests that these cues do not fit well into this typology. The format and contents of Nutritional Panel may have been seen as somewhat objective and "scientific" despite being from a commercial source (albeit non-manufacturer), while Good Housekeeping and Consumer Reports may have been viewed as "nonmarketer," but not as much as the government reports.

Factor 2 (12%) is a Marketer Controlled/Impersonal factor, as seen by search from Package Front, Product Ingredients and Cooking Instructions. Note again the Nutritional Panel mixed loadings with Factor 1 and those of Print-Ad with Factor 3. The mixed loadings of Nutritional Panel across Factors 1 and 2 reaffirms the argument that this cue is less clearly seen as either marketer controlled or nonmarketer controlled, while the mixed loadings of Print-Ad make interpretation of Factor 3 problematic.

Factor 3 (8% of the variance) is a Marketer Controlled factor with both Personal (Sales Representative) and Impersonal (Print-Ad) information cues having high loadings. The low loadings of Manufacturer's Reputation reflects

further lack of subject clarity as to how to classify this cue. Factor 3 may be best labeled, therefore, as a Marketer controlled-Advocate factor. Last, Factor 4 (8%) offers clearer interpretation. The high loadings of Family Comment and Friend's Comment support the conclusion that Factor 4 is a Nonmarketer controlled/Personal source of information.

The results of this analysis reasonably well confirm the proposition that consumers view information across two dimensions: marketer and nonmarketer controlled and personal and impersonal. What remains to be examined are the ways in which these factors are combined into patterns of use while subjects learned about the food innovation in the study.

Search Patterns

To examine search patterns, the factor analysis described above was used to guide a follow-up cluster analysis in a fashion similar to that taken by Kiel and Layton (1981). Counts of the information cues comprising each of the four factors determined by the analysis presented in Table 1 were calculated for each subject and divided by the number of cues identified in each factor to lessen the effect of different numbers of cues comprising each factor (Nutritional Panel was assigned to Factor 1 and Print-Ad was assigned to Factor 3). Therefore, four new variables (indexes) were created for each subject which represented the percentage of information selected, represented by each of the four factors, ranging from 0 to 100. These search indexes were used as the input to K-Means clustering of cases, BMDPKM (Dixon 1983). Euclidean distances of the unstandardized data was used as the grouping criterion. A five cluster solution was chosen based on spreads of centroids, cluster size and parsimony. The F-ratios for the four search indexes within each cluster, ranged from 13 to 133 (df=4,119;p=.000). Pooled within cluster correlations ranged from |.03| to |.17|. A summary of this analysis is reported in Table 2.

TABLE 2
CLUSTER ANALYSIS RESULTS

	Low Search		Selective Searchers			High Search	Mean
	Cluster:	Search	(a) 23%	(b) 27%	(c) 20%	11%

Cluster analysis reveals that searchers can be classified into three groups according to their magnitude of search: low (19% of the sample), high (11%) and "selective" (70% of the sample). Further, the composition of search, especially between the selective searchers appears to be quite different. Low searchers undertook little search from any source. These subjects were, however, most interested in cues from the Nonmarketer/Impersonal factor; the

Nutritional Panel was the most frequently selected piece of information. High searchers made extensive use of most of the available sources, with six of the fourteen cues being selected by all subjects in this cluster. Cues from the Advocate factor were least selected by this group, while a government report on the product's artificial color received the least attention.

Examination of "selective searchers" reveals three distinct patterns of search, despite increasing magnitude across these groups. The low magnitude, selective searchers (23% of the sample) took most of the information sought from the Nonmarketer/Personal factor and secondly from the Nonmarketer/Impersonal group of cues. These people chose the least information from the Advocate group of cues, while the cue most frequently chosen was Family Comment, and the least was Sales Representative and Print-Ad. Using the language of adoption theory, this segment of searchers can be best labeled "Legitimizers" (Lionberger 1960), because of their reliance on nonmarketer information from impersonal and personal sources.

Sensitivity to Marketer/Impersonal and Nonmarketer/Impersonal information characterizes the search patterns of the intermediate selective searchers (27% of the sample). This group selected very little information from either the Advocate or Nonmarketer/Personal categories. Product Ingredients was most frequently selected while none of these searchers picked the Sales Representative cue. This group of people can best be labeled "Problem Solvers" because of their propensity to search for information mostly from Marketer/Impersonal sources, secondly from objective, testing sources of data and their avoidance of advocate and normative influence.

The final group of selective searchers (20% of the sample) is one which sought information mostly from Nonmarketer/Personal sources, secondly from the Marketer/Impersonal group and a substantial amount from the Nonmarketer/Impersonal cues. This segment of searchers chose very little information from the Advocate group of cues, while every member of this group selected both the Family Comment and Friend's Comment information. Conversely, none of these decision makers selected the Sales Representative card. This segment of searchers can be best labeled "Normative/Problem-Solvers," due to their "balanced" sensitivity to nonmarketer/personal, marketer/impersonal and nonmarketer/impersonal types of information, coupled with their avoidance of advocate sources.

Correlates of Search

To contribute to improved understanding of these patterns of search, correlates of source use with three categories of variables were examined: demographics, task environment measures, and a behavioral measure (see Table 3). While the demographic variables are self-explanatory, the task environment and behavioral measures require brief discussion. The task environment group contains twelve items which measure selected aspects of the decision process to adopt. These include subjects' self-reported measures regarding their care and ease of food preparation, general nutritional information use, bacon use and liking, brand switching, direct and indirect experience with TVP products and two measures of innovation proneness. The behavioral measure was based on the number of units purchased by the subjects.

The criteria for selecting these variables were (1) to include those commonly reported in other diffusion and information search studies which are reported to mediate magnitude and composition of search and (2) to also select those which were suited to the specifics of the product class (i.e., bacon) and the innovation (i.e., TVP). This exploratory, correlational analysis is useful in identifying for future research, those variables which have the greatest apparent mediating effect, as well as determining whether these effects may differ between the four information sources.

TABLE 3
CORRELATIONS OF SEARCH WITH INDEPENDENT VARIABLES

Correlates	Nonmarketer/ Impersonal Search	Marketer/ Impersonal Search	Advocate Search	Nonmarketer/ Personal Search	Total Search
Demographics

Brand switching	NS	-.1470*	NS	NS	NS
Not familiar with TVP	NS	NS	NS	NS	NS
Not tasted TVP	1456*	NS	2515	1620	1195
Not talked to others about TVP	1921	NS	3055	NS	2157
Others liked TVP	NS	1277*	NS	-.1680	NS
Awareness of innovations	1463*	1169*	1401*	NS	1602
Purchase new food products before my friends	NS	NS	NS	NS	NS
Behavioral measure					
Number products purchased	1307*	NS	NS	NS	NS

* p-value <.10; all others <.05; decimals omitted; NS = not significant.

To document overall effects for this analysis, a one-way MANOVA was performed, using the five clusters as levels of an independent variable (search magnitude) with the 22 correlates as multiple dependent variables. Because of the exploratory nature of this analysis, p<.10 will be considered trends, while p<.05 will be considered significant. A multivariate main effect of cluster was obtained (F=1.372, df=88,404; p=.0228) using the more conservative Pillai test. Follow-up univariate F-tests revealed that age and speaking to others who liked TVP had p<.01, while five other measures yielded p<.10. Following this overall test, zero-order correlations between the four indexes of search, total search, and the 22 variables were determined.

Demographic Correlates

Younger subjects selected more total information, as well as more from nonmarketer/impersonal sources, marketer/impersonal information, and nonmarketer/personal sources, while higher income was associated with greater levels of nonmarketer/personal search. Higher educational achievement lead to higher marketer/impersonal search, but a negative relationship with this type of information was found with higher spousal education. Higher home values correlated negatively with total search, as well as advocate and nonmarketer/impersonal source search. The subject's social class had a positive relationship with marketer/impersonal search while spousal social class had a positive association with nonmarketer/impersonal source search. Finally, while married women searched for more information in total and from nonmarketer/impersonal sources but single women selected more marketer/impersonal information.

Task Environment and Behavior Correlates

Subjects who reported greater concern for cooking used more advocate sources, while those who claimed generally to use nutritional information sought more total information, more from nonmarketer/impersonal and advocate sources, but less from nonmarketer/personal sources. Women who stated a greater liking for bacon sought more information, comprised of more nonmarketer/impersonal source and marketer/impersonal information. The more different brands of bacon used (an indication of brand loyalty), subjects sought less marketer/impersonal information. Direct and conversational experience with TVP products had a negative relationship with total search, nonmarketer/impersonal, advocate, and nonmarketer/personal sources. Having talked with others who liked TVP products lead to more marketer/impersonal search, but less nonmarketer/personal search. Those who claimed to be more generally aware of innovations sought more total information, more from nonmarketer/impersonal sources, more from the marketer/impersonal category, more advocate source information, but none with nonmarketer/personal sources. Women who purchased more of the TVP bacon used slightly more nonmarketer/impersonal source information. Surprisingly, bacon use, TVP familiarity and proneness to purchase food innovations before ones' friends had no

effect on either pattern or magnitude of search.

Summary

These correlational results reveal the importance of both demographic and task environment variables in understanding search magnitude and composition. This can be seen in that the percentage of significant findings (39% demographics - 58% task environment) closely parallels the percentage of variables tested (41% demographics - 55% task environment). This conclusion argues for the necessity of diffusion theory researchers to carefully specify a broad range of relevant effects in their inquiries.

Another way to present the demographic and task environment findings presented above, is to examine the largest magnitude of effect for each of the four sources of information and total search. The Nonmarketer/Impersonal factor is best predicted with the extent to which individuals had talked to others about this class of innovations; this sociometric effect also had the largest relationship with two other issues: selecting advocate sources and total search. These findings underscore the importance of the role of sociometric effects in adoption of innovations. Finally, marketer/impersonal search is best explained by the extent of liking for the product category, while nonmarketer/personal search has the highest correlations with age.

Discussion

To achieve the research goals of this study, especially insight into process, control of decision setting, and freedom from reliance on retrospection, sacrifices were made. Lack of mundane realism and possible threats to external validity are two which warrant discussion. Despite these sacrifices, the results generally mirror those found in studies using instrumentation other than the IDB technology. For example, despite a "cost free" information search environment, considerable variance in search magnitude occurred. Second, definitive search patterns emerged which generally parallel those reported in the adoption theory literature. Last, subjects' perceptions of information source developed into a typology closely approximating that which was expected. Consequently, these findings support the continued efficacy of IDB findings as argued by Lehmann and Moore (1980) and provide additional convergent validity to what is known of external search for innovations.

The findings of this study also underscore issues of continuing interest to adoption theory researchers, marketers, consumer educators and those concerned with public policy. For example, Robertson (1984) points to the need for increased use of market segmentation in improving understanding of the adoption process. The results of this analysis reveal clear distinctions across segments of searchers. Further study to more fully describe and determine the underlying reasons for these search segments would advance understanding of this aspect of adoption theory and confirm the value of examining the process using segmentation analysis.

These findings also confirm the wisdom of the marketer to use segmentation analysis. Marketers concerned with information sources under their control take great care to create formats, quantity and types of information to attract and persuade customers. The findings of this study affirm that different segments of decision makers display variable interest in the types of information controlled by marketers. Further, these results reveal that sociometric experience and product category liking are comparatively important mediators of search for marketer controlled types of information. This underscores the significance of task environment considerations to the marketer when developing communications strategies.

Consumer educators and those concerned with public policy need to continue their efforts to understand external search dynamics. Despite the low cost of search in this study, considerable magnitude variability was found.

Those who view search from a cost/benefit perspective, should be encouraged to shift their efforts toward the "benefit" side of this equation. The value of strategies developed to increase consumers willingness to search for more information becomes clear since this study confirms that many decision makers are not willing to search even in very low cost situations.

COMMUNICATING INNOVATIONS: CONVINCING COMPUTER PHOBICS
TO ADOPT INNOVATIVE TECHNOLOGIES

Thomas Hill¹, University of Tulsa
Nancy D. Smith, University of Tulsa
Millard F. Mann, University of Kansas

Abstract

In a recent paper, Lepper (1985) has pointed out that the rapid development of microcomputer technology has provided a unique opportunity to investigate, *in vivo*, the process of technology adoption. This paper summarizes the results of two experiments that were concerned with the responses of "high-tech phobics" to innovative technologies. Previous research has demonstrated that personal efficacy with respect to computers is a strong predictor of subsequent adoption of computer technology. The results of the present research show (a) that the more technologically advanced a product, the more important a factor is personal efficacy in the decision to adopt the technology, and (b) that people low in personal efficacy (as compared to people high in personal efficacy) with regard to computers tend to be more easily persuaded by expert communicators to try an advanced software product.

Introduction

A new business was recently described in a local newspaper of a midsized midwestern town (The Tulsa World, February 8, 1985). For a reasonable fee, a technician will come to your home, connect your VCR (video cassette recorder), stereo, or other "sophisticated" appliance, set all switches and options, and show you how to operate your electronic gadget. As the manager of the business put it, "technology has just gotten away from people." Business is booming.

"Computer phobic" has become the common term for describing a person who avoids computers, regardless of how useful they might be. Considering the success of the business offering the service described above, it appears that many people are afraid not only of computers but of "high-tech" electronic consumer goods in general. "High-tech" phobia is probably a better, more general term for describing the anxiety and uncertainty that many of us experience when dealing with a technologically advanced product for the first time.

Most consumer research concerned with the adoption of new technology has focused almost exclusively on the identification of the life style and personality of early adopters (Danko and MacLachlan 1983, Dickerson and Gentry 1983). The results of these studies have shown that, as one would expect, the early adopter of, for example, computers is not at all afraid of new technology; on the contrary, the early adopter perceives these innovations as a challenge (Danko and MacLachlan 1983).

Other recent research (Hill, Smith, Mann, and Roberson in press; Hill and Smith 1985; Smith and Hill 1985) has applied Bandura and his associates' theoretical framework (Bandura 1977, Bandura and Schunk 1981, Bandura, Adams and Beyer 1977). According to this view, phobias can be explained in terms of lack of personal efficacy, i.e., the belief that a particular behavior cannot successfully be performed. If an individual thinks that he or she is unable ever to successfully interact with a computer, then it is likely that he or she will avoid such interactions, regardless of how useful it might be to learn about or use computers.

In their research, Hill and his associates (Hill et al. in press, Hill and Smith 1985) used pathanalytic methods to show that, in three independent samples of college students, computer efficacy (a) uniquely contributes to the prediction of behavioral intentions to purchase a microcomputer, (b) is independent of (not correlated with) people's beliefs about the instrumental value of learning about computers, and (c) is positively related to people's previous experience with computers. Further, Hill et al. (in press) showed that personal efficacy in general, but not interpersonal efficacy (i.e., efficacy with respect to interpersonal relationships), as measured with Paulhus' sphere specific measures of control (Paulhus 1983), is related to the use of various technologically advanced products (e.g., programmable pocket calculators, automated bank teller machines, automatic garage door openers).

Phenomenologically, personal efficacy with respect to technological innovations can be construed both as a characteristic of the person perceiving an innovation (e.g., "I can make this machine work") and as a characteristic of the innovation ("I can make this machine work"). In the research described above, personal efficacy with respect to computers was treated as a characteristic of people, i.e., as a personality variable: Some people report less efficacy with respect to computers and they are less likely to learn about or use them; others report more efficacy and are more likely to learn about or use them. However, the person who lacks efficacy with respect to an innovation will not perceive him or herself as "low in efficacy," but will perceive the innovation as complicated or complex. The more complex the innovation actually is the more likely it is that people will lack efficacy with respect to the innovation. As Rogers and Shoemaker (1971) have pointed out, complexity of an innovation - a characteristic of the innovation itself - is an important factor determining the rate of its adoption.

Study 1

Study 1 was designed to explore the importance of efficacy in the decision to adopt new products of varying complexity. It was expected (H1) that the more complex a product is, the more likely it is that people will feel little personal efficacy with respect to the product, and, hence, the less likely it is that they will purchase it, and (H2) that the more complex a product is, the more important a role will personal efficacy play in the decision to purchase it.

Method

Eighty-three male and female college students participated for extra credit in their courses. Data were collected in ten experimental sessions with between six and ten participants each. The study was introduced as an advertising evaluation study. Subjects were asked to evaluate three new products based on "rough drafts" of advertisements. These products were an electric typewriter (presumably low in complexity), an electronic typewriter (presumably of moderate complexity), and a personal computer with wordprocessing capabilities (presumably of high complexity). Subjects were asked to complete a set of questionnaires containing a scale designed to measure efficacy with respect to each product, a scale designed to measure perceived instrumentality of each product, and a scale designed to measure liking of each product. All scales pertaining to

¹ Address all correspondence to Thomas Hill, Department of Psychology, University of Tulsa, 600 South College Avenue, Tulsa, OK 74104; (918) 592-6000, X2248.

a particular product were preceded by the description of the product; the order in which the products were presented was carefully counterbalanced.

Product descriptions. All product descriptions began with the following sentence: "Consider the following advertising copy describing the features of a new [personal computer with wordprocessing/electronic typewriter/electric typewriter] about to be put on the market. This product is designed to assist in the preparation of professional-looking manuscripts and term papers." This introduction was followed by a list of six features appropriate for the respective product (e.g., personal computer: 64k of memory, screen editing, etc.; electronic typewriter: one-step error correction, format memory, etc.; electric typewriter: adjustable tabs, power carrier return, etc.).

Questionnaire. The questionnaire contained seven items designed to measure personal efficacy with respect to each product. These items were worded similarly to those of the computer efficacy scale developed by Hill et al. (in press) (e.g., I will never understand how to use this product [reversely coded], I could reliably control the functioning of this product, This product would be easy to use). Eight items were designed to measure perceived instrumentality of the respective product (e.g., I could do a better job with this product, I could accomplish more by using this product, Time savings from using this product would be minimal [reversed]). Each item was accompanied by a 6-point Likert type scale, labeled "strongly disagree" or "strongly agree" at its extremes.

The items for both scales were chosen from a larger pool of items based on the criterion that the items from each subscale correlate fairly highly among themselves for each of the three products. It should be stressed that the scales were constructed before the analyses to test the hypotheses of this research were performed. This procedure resulted in reliability coefficients (Cronbach's α) for each scale within each product in excess of $\alpha = .88$. Although this procedure ensured the reliability of scales, it, of course, does not ensure validity. The items comprising the efficacy scale, however, are, as mentioned above, very similar to those comprising the computer efficacy scale used in a previous study by Hill et al. (in press). In that study scores on the computer efficacy scale were shown to validly predict students' subsequent enrollment in university computing courses, a finding which supports the validity of the efficacy scale in the current context. Nevertheless, it should be pointed out that the primary reliance on the face validity of items in the present study poses limitations to the confidence with which conclusion may be drawn.

The questionnaire also contained four items designed to measure liking of the product. The items were formulated so that they asked for the likelihood that the respondent would behave in a way indicative of product adoption (Would you recommend this product to a friend? If money were not a consideration, would you purchase this product? Would you like to learn more about this product? Would you like to own this product?). The reliability of this scale for each product was always greater than $\alpha = .90$.

Results

In order to test whether the three product descriptions elicited differential perceptions of efficacy, a repeated measures analysis of variance was performed on the personal efficacy scores across the three products. As expected, subjects' ratings of personal efficacy with respect to the three products were significantly different, $F(2,164) = 42.24$, $p < .0001$. Subjects reported greater efficacy with respect to the electric typewriter than with respect to the electronic typewriter (means were $M = 31.02$ and $M = 33.29$, respectively, $t[82] = 8.46$, $p < .001$), and greater efficacy for the

electronic typewriter than for the personal computer with wordprocessing ($M = 36.34$, $t[82] = 5.99$, $p < .001$). It can be concluded from this analysis that the different products, designed to vary in complexity, led to differences in subjects' ratings of personal efficacy.

In order to test whether differential personal efficacy with respect to the three products is related to differential liking of these products, a repeated measures analysis of variance was performed, treating expressed liking of the three products as three levels of the dependent variable, and treating personal efficacy and instrumentality with respect to the three products as two covariates that were repeated for each level of the repeated measure (this analysis was performed with the MANOVA routine in SPSSX). This analysis revealed that, overall, only perceived instrumentality was related to the average liking of all three products, $F(1, 80) = 51.16$, $p < .001$. This effect probably reflects the extent to which students perceive any machine that facilitates the writing of manuscripts as instrumental for facilitating their everyday life. Overall, personal efficacy with regard to the three products was not related to average liking of the products, $F(1, 80) = 1.46$, $p > .20$. However, differential personal efficacy (i.e., the difference in personal efficacy across the three products) was related to differential liking of the products, $F(2, 154) = 6.02$, $p < .01$.

Finally, in order to assess the importance of efficacy in the prediction of liking, separate zero order correlation coefficients between scales within each product were calculated. As expected, the zero order correlation between efficacy and liking increased as the product became more complex. The correlations were $r(81) = .05$, n.s., for the electric typewriter; $r(81) = .43$, $p < .001$, for the electronic typewriter; and $r(81) = .64$, for the personal computer with wordprocessing. It should be noted that the standard deviations for each of the scales for each product were virtually identical (efficacy: 5.3, 5.6, and 6.2, for the electric typewriter, the electronic typewriter, and the personal computer with wordprocessing, respectively; liking: 5.3, 4.3, 3.8, respectively), and that all correlations between instrumentality beliefs and liking were in the range from $r(81) = .67$ to $r(81) = .72$. Because the reliabilities for the efficacy scale across products were virtually identical as well, it appears unlikely that the change in correlations for efficacy with liking across products was an artifact due to differences in variances or reliability of measurement.

The results of Study 1 support the hypothesis that greater complexity of a product implies less efficacy with respect to the product, and, further, that differential efficacy with respect to different products is a predictor of differential liking (or, as measured in this study, of expressed likelihood to perform behaviors indicative of product adoption). Finally, it appears that the more complex a product, the more important a factor is efficacy with respect to product adoption.

Study 2

Study 1 provided further support for the notion that personal efficacy plays an important role in the adoption of innovative technology, particularly when it is complex. The question arises as to how to change personal efficacy with respect to a specific technological innovation. For example, how can one convince a "computer phobic" that he or she is capable of learning how to successfully interact with a computer? One straightforward approach to solving this issue would be simply to tell the person that it is indeed quite easy to make computers work. Of course, the trick is to get the person to believe the communicator.

The classic Yale communication studies on persuasion (Hovland, Janis and Kelley 1953) have pointed to the importance of source credibility in determining the effectiveness of a persuasive communication. With

respect to innovative technologies in general, and computers in particular, the question is whether computer phobics are more likely to trust the opinion of an expert or the opinion of a relative novice, who perhaps used to be a phobic him or herself.

Actually, both predictions could be derived from different theoretical positions: On the one hand, the findings of the Yale communication group suggest that the opinion of a computer expert should carry more weight than that of a computer novice. Furthermore, previous research on locus of control and persuadability has demonstrated that people with an external locus of control (i.e., people who believe that they are being controlled rather than in control themselves) are more easily persuaded by high prestige, expert sources (Ritchie and Phares 1969, Ryckman, Rodda and Sherman 1972). Following this logic it may be argued that people who think that they are incapable of successfully interacting with computers are more likely persuaded to purchase a computer (or computer related product) by "experts who know what they are doing" than are people who feel that they are in control and quite capable of learning to use computers.

On the other hand, social comparison theory (Festinger 1954) predicts that computer phobics are more likely to trust and be influenced by the judgement of people who are similar to themselves, while people who feel confident about interacting with computers are less likely to trust the judgment of such individuals, because they are different from themselves. In practice, the issue for advertising is whether to present a computer novice attesting to the ease of use of a new computer or new computer software, or whether to introduce an expert who assures potential customers of the "userfriendliness" of the new system or software. Study 2 addresses this issue.

Method

A questionnaire designed to measure computer-specific efficacy (the same scale used by Hill et al. in press) was administered to a sample of 87 female college students. Subjects for the present study were recruited from among those who had completed this questionnaire. Because the questionnaire was administered along with various other questionnaires (in a mass testing session), subjects were not aware that the current research was concerned with computer related efficacy.

A total of 54 subjects volunteered to participate. However, of these subjects, ten (five in each experimental condition) had actually not completed the computer efficacy scale during mass testing. The data for these subjects were excluded from all analyses involving this measure.

Procedure. The entire study was conducted in 12 sessions with four to six participants per session. The experiment was conducted in the preview room of the media services department in the library of a midsized private midwestern university.

Upon arrival, the experimenter explained that the study was concerned with the evaluation of an innovative software package specifically designed for college students, called the "College Advisor." All subjects were then handed the same brief description of this program. To foster the credibility of the cover story, the description was printed on the stationary of a midwestern research firm.

The program was described as an integrated wordprocessing and database management program with special subprograms for college students to assist in the planning of classes, writing of papers, and monitoring of grade-point averages. After all subjects had read the description of the program, the experimenter explained that the sponsoring research firm was interested in college students' evaluation of the program. The experimenter

then started a slide show which was presented as a "rough draft" of a potential advertisement for the program.

Manipulation of source expertness. There were two different versions of the slide show. The actual slides, which depicted four different females working at a personal computer, were the same in each condition. The slide show was synchronized with one of two different tape recording (recorded by the same individuals) of testimonials of the four women. The four women described themselves as either a computer science major, an MBA student specializing in Management Information Systems, a mathematics major, and an engineering major (expert sources), or as a fine arts major, a language major, a music major, and an English literature major (non-expert sources). In both conditions, the individuals presented in the slide show commented on the ease with which the program could be learned. Subjects (groups of subjects) were randomly assigned to one of the two conditions (slide shows).

Dependent measure. At the conclusion of the slide show, subjects were asked to complete a set of questionnaires evaluating the computer expertise of the individuals presented in the slide show (manipulation check). Also, subjects were given the opportunity to sign up (and put down their address) for a six-month trial period of the College Advisor. It was explained that the program would be provided with a special microcomputer, the rental of which would cost approximately \$10.00 per month. This amount was determined in pretesting to be sufficient to prevent approximately 50% of all college students from signing up for the trial period. This measure constituted the dependent measure of adoption of this new product.

In order to reduce potential experimental demand (i.e., the experimenter's being perceived as interested in subjects' signing up), subjects were handed, along with the questionnaire, an envelope addressed directly to the sponsoring research organization. Subjects were told that they should put the completed questionnaire in the envelope, seal it, and drop it in a mail box when leaving.

At the end of the experimental session, subjects were asked to complete the computer efficacy questionnaire which most had previously completed during the mass-testing session. They were then thoroughly debriefed and thanked for their participation.

Results

Overall, the manipulation of source expertness was successful. One item on the advertising evaluation questionnaire asked for subjects' rating of the computer expertise of the individuals depicted in the slide show (1 = none at all, 9 = very much). Subjects who had watched the slide show depicting the expert sources rated the expertise of these individuals significantly higher than subjects who were exposed to the non-expert sources, $t(51) = 7.59$, $p < .0001$. The means in the expert and non-expert condition were 2.70 and 6.08, respectively. However, subjects' ratings of the individuals presented in the slide show did not differ with regard to overall appeal (all F 's < 2.00).

The major dependent variable of interest was whether or not subjects signed up for the trial period of the College Advisor. Overall, of the 27 subjects who watched the non-expert sources, 19 signed up for the trial period; of the 27 subjects who watched the expert sources, only 11 signed up. This difference is significant, $\chi^2(1) = 4.90$, $p < .05$. In order to assess the potentially differential effect of the slide shows on subjects high or low on computer efficacy, the biserial correlation coefficient between computer efficacy (both the initial measure and the measure that subjects completed after the experiment) and subjects' choices regarding the trial period was calculated within each experimental condition. In the non-expert condition,

computer efficacy was not related to subjects' choices, $r(25) = .05$ for the premeasure of computer efficacy, and $r(25) = -.03$ for the postmeasure. However, in the expert source condition, both measures appeared to be related to subjects' choices, $r(22) = -.38$, $p < .10$, and $r(25) = -.52$, $p < .01$, respectively. Performing a median split on the computer efficacy scale shows that subjects who were low on computer efficacy were more likely persuaded by the expert sources than subjects high in computer efficacy; 67% of the subjects in the former group signed up for the trial period with the College Advisor as compared to 20% of the subjects who scored high in computer efficacy. The non-expert sources did not differentially influence low and high computer efficacy subjects (67% and 75%, respectively, signed up for the trial period).

The results of Study 2 support the prediction derived from the research on locus of control and persuasion. Although, given the particular scripts used in this study, the non-expert sources were more successful in persuading subjects to sign up for the trial period, it appears that the less computer efficacy subjects reported, the more likely were they to trust an expert's opinion.

Conclusion

The results of the current research support the notion that personal efficacy, i.e., the extent to which a potential consumer thinks that he or she will be able to successfully "master" a "high-tech" product, is an important variable contributing to or inhibiting technology adoption. Personal efficacy with respect to a particular product is a joint function of the "objective" complexity of the product and of the psychological characteristics of the potential consumer. Study 1 was concerned with products of varying complexity. The results suggest that the more complex a product is in actuality, the more important personal efficacy is in the decision whether or not to adopt the product. Study 2 was concerned with the effectiveness of expert and non-expert sources in influencing individuals who possessed varying degrees of personal efficacy with respect to a particular product. The results of Study 2 suggest that experts attesting to the "userfriendliness" of a new product are more likely to convince individuals low in efficacy with respect to the product than individuals high in efficacy with respect to the product.

WHAT SHOULD ACR WANT TO BE WHEN IT GROWS UP?

Russell W. Belk, University of Utah

Abstract

It is argued that ACR is facing an adolescent identity crisis and that its search for a meaningful identity would be aided by a rich vision of a future in which it emerges as an independent social science. It is further argued that to do so requires first broadening ACR's aspirations and perspectives rather than narrowing them.

Birth to the Present

Once upon a time a fledgling discipline was born and given the name Consumer Research--the bastard child of Marketing and an unknown father variously alleged to be Economics, Psychology, Sociology, Anthropology, Home Economics, or occasionally others as well. Despite these humble and ignoble beginnings, the infant developed precociously and was admired, housed, and nurtured by Mother Marketing. It found it had occasionally kind uncles named Business and Government, but the former did not always appreciate the child's talents and the latter tended to favor more legitimate nephews and nieces with names like Art, Science, and Medicine. Society tried to withhold judgment about the child, but made no secret of its prejudices toward the mother and was critical of the uncles as well (the supposed fathers seemed above reproach).

The child grew and learned. It tried to be a good child and did many things to please its mother. But in moments of pensive reflection it felt there was something more to life. It knew that society expected more from it, but knew too that Mother Marketing was likely to disapprove of activities that withdrew the interests of Consumer Research from her. Thinking that it might have more to learn from its alleged and distant fathers than from its mother, Consumer Research turned to them often and assimilated much of their world views, and Psychology's world view in particular. Still there was a part of the child that yearned to be free to think and do as it pleased and to make its own mark on and contribution to the world. This part felt that it was too much its mother's child and increasingly found even the venerable Psychology's world view to be unfilling.

The child was suffering what one of Psychology's legitimate children, Erik Erikson, called an identity crisis. In addition to not having a sense of identity, the child was searching for life and career goals that might lead it to a more promising future. It appreciated that Mother Marketing had thus far provided nurturance and paid the bills and it felt pulled to be loyal to that up-bringing and be a true Marketing person. But, it had also learned from its real or surrogate fathers that there was a whole big exciting world out there if it could stop doing everything just to please its mother. Each of these surrogates provided a different career model, although it sensed that mother liked Psychology best since it had a more practical bent than the others who often seemed to be either impractical altruists or philosophers. A third type of option was to strike out on its own and forge a career without the benefit of a role model or mentor. This seemed to be a difficult and risky course, and it was possible that mother would not foot the bill for such venture indefinitely.

Present Into Future

At this point the child is confused, torn, and frightened. Its more conservative friends urge filial loyalty and remind that it has a good thing going and that Uncle Business will likely help to make a marketing career path a lucrative one. Its more rebellious friends urge revolution and suggest that anything that would be admired by Mother Marketing or Uncles Business and Government is to be deplored as hopelessly wrong-minded. A third peer group recently

encountered consists of some of the acknowledged children of Anthropology and Sociology as well as some other bastard children of Mother Marketing. This group urges a path of individual freedom and creativity; follow your own muses and don't be too concerned about pleasing or displeasing anyone but yourself. If there is a reference group for this latter perspective it is society at large and the societal benefits of the career path are an important criterion for evaluation of its worth. Uncle Business might not be as pleased with such a career, but Uncle Government might ultimately be convinced of its merit. And the child Consumer Research might with such a career even hope to gain the status of its more mature father figures some day.

Appealing as the latter alternative seems, it is not the obvious solution to all concerned. Consumer Research feels both internal and external conflict in evaluating the choice. None of these solutions will jointly please it, its friends, its mother, its uncles, and its surrogate fathers. As the advocacy groups become more polarized they tend to blame any real or imagined weakness of Consumer Research on what they see as its inclination toward any position other than its own. Clearly the time is ripe for a choice. What should Consumer Research want to be when it grows up?

Myth Into Reality

Inasmuch as ACR is the preeminent organization concerned with consumer behavior, it is essentially true that as ACR goes, so goes consumer behavior. While I believe that ACR should continue to represent a broad and diverse membership, and should in fact seek to further broaden, diversify, and balance its membership. I also believe that the status of the field of consumer behavior depends upon the richness of its visions of that which it aspires to be.

My own vision is one of consumer behavior as a discipline unto itself, with a variety of constituent groups, but with no overriding loyalty to any existing discipline or interest group. That is, consumer behavior should not be a subdiscipline of marketing, advertising, psychology, sociology, or anthropology, nor the handmaiden of business, government, or consumers. It should instead be a viable field of study, just as these other disciplines are, with some potential relevance to each of these constituent groups.

In order to achieve this mature and independent status, in the short-run consumer behavior should seek to divorce itself from the parochial interests of any single constituent group. Given the dominant allegiance to marketing in the past, a counter effort of clearly non-marketing-inspired theory and research efforts seems needed. This should also encourage a needed macro orientation within the field and lend credibility to the sincerity of the field's aspirations to be more than an engineering discipline serving a narrow scope of interests. It also seems necessary that meaningful and neglected macro issues be addressed such as the effects of various types of consumption on consumer and societal well-being, the political economy of consumption, tradeoffs between experiential and material consumption, historical, biological, and motivational bases for acquisition, possession, and collection, and consumption's interaction with self-definition. These foci should help to establish consumer behavior as a behavioral and social science of relevance to understanding an important domain of human behavior.

It is significant that occasionally, and especially recently, some prominent scholars from other behavioral and social sciences have begun to turn their attention to consumer behavior phenomena. They include for instance anthropologists Mary Douglas and Marshall Sahlins, sociologists Michael Schudson and Eugene Rochberg-Halton, historians

Neil McKendrick and T. J. Jackson Lears, literary critics Lewis Hyde and Marc Shell, psychologists Lita Furby and Mihaly Csikszentmihalyi, communication theorists William Leiss and Stephen Kline, and economists Richard Easterlin and Albert Hirschman. It is also significant that none of these except Lita Furby has ever participated in ACR. The forces that tend to keep these consumer behavior scholars within their original disciplines may well be the same forces that cause Rich Lutz to urge that we keep our focus within marketing as a parent discipline. This is unfortunate since it fractionates and dissipates the efforts of what could otherwise be a cohesive and meaningful discipline of consumer behavior. There is much that we might say to one another, and ACR is the most logical organization to bring about such a dialogue.

It is for this reason that the 1985 ACR Conference Call for Papers' plea for a back-to-the-basics-of-marketing focus was so upsetting. Although it seems to have had little impact on the excellent program at this year's conference, such a call for narrowing the scope of ACR is the opposite of what I feel is needed. We should be seeking ways to broaden our membership rather than send cues to those trained in disciplines other than marketing, or interested in consumer behavior phenomena of interest to someone other than marketers, that they are unwelcome.

I do not mean to send the counter message that I do not welcome those trained in and interested in marketing-related consumer behavior phenomena in ACR--I do welcome them. As Rich Lutz correctly points out, they are largely responsible for making ACR the strong and viable organization that it is today. I come from such a background. But I think we need to welcome other types of consumer researchers even more warmly, both because we need the non-marketing perspectives they can bring to the discipline and because it is they who are currently most likely to feel that they are entering an alien world in coming to an ACR conference. We need to seek them out, cultivate their involvement in ACR, and talk and listen to them when they arrive. We all have much to learn and share.

In the long-run I believe that the academic discipline of consumer behavior should seek a status outside of current departmental boundaries as a social science department on a par with other social sciences. In order for this to happen we first need to establish a critical mass of serious scholarship. ACR can play a pivotal role in developing such scholarship by seeking to redress imbalances in membership across existing disciplines and constituencies, encouraging a broader agenda of research and research methods, and fostering a common member identity of mutual, if diverse, interest in pursuing consumer behavior for the sake of learning more about an important, neglected, and fascinating aspect of our existence.

If we instead turn inward, set up boundaries, and follow what De Tocqueville called "the tyranny of the majority," we will be condemning the child of Marketing to never know of or contribute to the world outside its backyard--the ground that it has walked over for all of its infancy and childhood with few if any original pathways to show for it. This may win mother's praise, but it is unlikely to make much of a contribution to the human condition. And while it may be temporarily difficult and frightening to first cross the street, as Consumer Research matures I believe it will be much the better and more satisfied for having done so.

RESEARCH AS A VOYAGE OF DISCOVERY

Alden G. Clayton, Marketing Science Institute, Cambridge

Abstract

The proper leadership role for ACR in the field of consumer behavior research is being re-examined. A position is taken, and supported, that ACR should encourage a broad rather than narrow vista for research, that innovation and creativity should be encouraged, and that the practice of marketing needs continual nourishment from multi-disciplinary research of the type distinctively associated with ACR. It is also proposed that encouragement of multiple streams of inquiry is in the best interest of researchers (to follow their natural interests) and marketing practitioners (who can selectively utilize the new knowledge that emerges from these varied streams).

ACR has invited reflection on its current state and its future direction. It has been suggested that "the pendulum has perhaps swung too far in the direction of broadening consumer research" and that because the domain of consumer behavior rests both empirically and definitionally on the effects of marketing activities on consumers, "special sessions and workshops devoted to the study of the effects of marketing variables on consumer behavior" should be encouraged. This point of view implies that the proper field of inquiry for ACR research should be narrowed and focused on issues of direct application to practitioners.

This position paper will argue that the proper domain of consumer behavior research is broad rather than narrow, that marketing has been historically an eclectic discipline that benefits from a flow of ideas, concepts, and theories from outside of its traditional boundaries, and that multi-disciplinary research on all aspects of consumer behavior should be encouraged for its own sake and as a source of applied research for marketing management, thus satisfying both innovators who do not wish to be constrained and practitioners who need fresh insights and new understanding of consumer behavior. Finally, it will be stated that the Association for Consumer Research is the appropriate, in fact the desired agent for encouraging broad inquiry on consumers.

This perspective with respect to research is consistent with a broad view of marketing itself, as expressed by Corey (1983) "Marketing is the function that relates the organization creatively and profitably to its customer environment." If marketing is to fulfill this function in a dynamic and continually changing environment it must also be dynamic and flexible in response. Thus, "marketing variables" identified as of 1985 may not be permanent, and if research attention is paid only to these, important new variables may not be identified and studied.

What are the reasons for taking this position? We will examine some key factors.

1. Marketing is an eclectic discipline

The dates and contributions shown in Table 1 have been selected from "The History of Modern Marketing: A Time Line," Evans and Berman (1981). Only those individuals who were clearly from disciplines outside of the traditional academic fields of marketing are listed.

TABLE 1

1857	Ernst Engel: Engle's Law of Consumption
1929	L.L. Thurstone: Thurstone Attitude Measurement Scale
1932	Rensis Likert: Likert Attitude Measurement Scale
1941	W. Lloyd Warner and Paul Lunt: Social Class Structure
1943	Abraham Maslow: Theory of Human Motivation
1948	Paul F. Lazarsfeld, Bernard B. Berelson, Hazel Gaudet: Two-step Flow of Communication
1951	George Katsona: <u>Psychological Analysis of Economic Behavior</u>
1955	Wilbur Schramm: Communications Process Model
1957	Charles Osgood, George J. Suci, Percy Tannenbaum: Semantic Differential
1957	Leon Festinger: Cognitive Dissonance
1958	Fritz Heider: Attribution Theory
1962	Everett Rogers: Diffusion of Innovative Concept Sources

Other contributions to the field of marketing would include the work on multi-attribute scaling by Fishbein and Rosenberg; "brain-wave" research, originally associated with the study of psychophysiological phenomena (e.g., 'phantom limbs') but recently applied to measurement of advertising response; and the concept of 'corporate culture' from cultural anthropology, originally developed in conjunction with the study of 'primitive' societies now applied to the study of corporate (and individual) behavior. In addition, the many contributions from mathematics have been enormously important and should be recognized.

2. There is a continuing need to enrich and expand marketing knowledge

Top managers have high expectations for marketing. In his study of how top management executives view the marketing function in their firms, Webster (1980) quotes some of the CEO's he interviewed.

"Marketing is the greatest leverage factor in the management mix. It is the mainstream of our business and always has been."

"Marketing is becoming more important due to the rapidly changing environment facing this industry."

"I expect marketing to be the cutting edge of our business. Without it, nothing happens."

"We have taken a very aggressive growth position in our industry. Marketing is the key in the planning system. The undergirding of our resolve to move aggressively was a marketing judgment. Marketing is the key input."

"Marketing is change. Good marketing strategy brings out good technology, good manufacturing facilities, and so on. Good marketing is the glue that holds things together. Marketing is the key to the whole business."

"When I talk about marketing planning, I am talking about the very fundamentals of business and strategic planning, the basic selection of markets and products which is the fundamental strategic choice the firm makes."

"To me 80 percent of corporate strategy is marketing strategy and that is the guts of any business plan — how you win or lose in the marketplace based on your marketing decisions."

High expectations, of course, carry a large down-side risk if expectations are not achieved. Thus, some CEOs expressed concerns to Webster about the actual performance of marketing.

"The marketing function has had an inability to readily change direction and to accept new developments."

"Marketing has not provided the proper stimulus for R&D. I'm looking for guys who can find ideas."

"The marketing people have lacked foresight and have not been able to read what the market is going to be. So they run a product right into the ground. Marketing has not been supplying R&D with new product ideas."

"They haven't been as creative or innovative as they should be. For example, R&D and engineering have given them new products but they have not been terribly creative in developing marketing approaches for those new products."

"They haven't shown leadership in changing product orientation and product positioning. There is a real need to break out of the box and come up with fundamentally more challenging approaches. In general terms, marketing people are not risk-takers, not entrepreneurial enough in their approach."

"There is a real tendency for marketing to become ingrained. They are not open-minded, not able to anticipate change in the marketplace and to adjust accordingly, to develop and refine new approaches. They try to solve new problems with traditional marketing approaches."

Clearly, marketing managers need help. They need new ideas, new concepts, new insights about their markets, their consumers, and the changing world around them. These do not normally come from more exhaustive study of existing ideas nor from repeated iteration of conventional analyses. Practitioners need a continuous stream of innovative and creative research in all aspects of consumer behavior from which they can select those which have applications to marketing management. Thus researchers can do "their thing" without feeling pressure that it be "practitioner oriented." The trade-off that such researchers must accept, of course, is the risk that their work may be ignored by practitioners.

3. ACR is the appropriate agent for a broad research agenda on consumer behavior

ACR is one of the few multidisciplinary groups that does serious, high quality research. As science in all fields grows more complex, there is a corresponding need to pool resources and learn together. As stated by Lewis Branscomb (1985), vice-president and chief scientist of the IBM Corporation, "successful science is becoming much more heavily multi- and cross-disciplinary, with the role of separate disciplines becoming that of 'gatekeepers' for quality-standards," ACR should continue and, in fact, nourish this tradition. If attention were focused on "marketing variables" much of the interaction and synergy of its multidisciplinary nature could be lost, thus reducing the distinctive value of the Association.

One final observation. The position expressed in this paper with respect to the domains of academic research and practitioner interest — and their areas of overlap — are consistent with the mission of MSI. This has been restated by the Executive and Research Policy Committee of the Board of Trustees (1983) as follows:

"The MSI position at the intersection of the business and academic research worlds embodies several important ideas about the MSI research philosophy.

- o We very clearly intend to exclude from the MSI research domain many kinds of business research projects that may well have great value to individual companies as well as great intellectual or technical merit — on the grounds that they do not contribute to the development of theory, basic knowledge, or techniques that have a reasonable prospect of being applied (over some

reasonable time horizon) to understanding and/or solving marketing problems affecting more than one company or improving marketing education.

- o We equally clearly intend to exclude from the MSI research domain many kinds of academic projects that may well have great intellectual or technical merit — on the grounds that there is not a clear connection between the subject of the research and its eventual marketing application.
- o Since there is no precise definition of the boundary of the MSI research domain on either side, periodic questioning is necessary to test our sense of where the boundaries ought to be. Hence the need and value of priority setting, steering committees, mini-conferences, advisory councils, etc., to provide vehicles for collaborative decision making about where the boundaries ought to be for a particular zone of research.

MSI occupies a very special niche in the world of business and academic research. We will always need to reaffirm and to refine our understanding of that niche."

Abstract

Representing users to producers is the subject of this paper -- the essential yet, outside of marketing practice, most overlooked aspect of marketing. It requires basic science that breaks new ground. As appropriate conceptualizations become available, chances improve that the producer's question: What shall we produce? will be answered more efficiently than heretofore. Consumer researchers are invited to create the behavioral science that marketing needs.

Introduction

A conference session devoted to our topic, "Whither ACR?," has to be an occasion for speakers to state their personal beliefs, wishes, dreams, perhaps, for the domain of scholarship that we share. Certainly, no panelist's answer to the question the topic poses can dictate the answer that actually unfolds over time. Collectively, the varied interests of individual members will see to that. Nor can the answer of any member predict the answer that unfolds over time. If it could, that would imply that we know now the full scope of our subject matter and much of the fun of our pursuit would have been taken from us. We might as well seek other lands to conquer. Our session is surely intended as background briefing, to promote communication that goes beyond the usual scope of scholarly papers. The call for papers for this conference noted that roughly 20% of the membership of the Association for Consumer Research is not affiliated with marketing. It gave me the idea that it might be in line with the our topic's spirit of communication if, as one who shares affiliation with the majority, I were to try to clarify for nonmarketers what it means to do consumer research for marketing practice.

Let me start by stating where I stand. There is no assignment anywhere in world of scholarship or science that I would choose over that of behavioral scientist in the service of the practice of marketing. My reasons reflect the janus-like feature of that assignment -- one face is turned to the world of everyday action in real time and the other to the world of representation, reflection, scientific understanding, and action-in-the-laboratory. Whichever face one considers, the work is important and not easy. There are urgent problems begging to be addressed and, everywhere, new ground to explore. My plan for this paper is to describe some of the tasks on each side of the gate but first I must review, for nonpractitioners, the nature of marketing as a business and societal function.

The Marketing Function

What it means to do consumer research for the practice of marketing flows from two features of producing goods/services: the need for an intermediary between users and producers, and for a survival strategy in a free market.

User-Producer Intermediary

When society opted for division of labor, it created the need for a function that would represent user-perspectives to producers. Adam Smith (1776/1961) brilliantly analyzed the reasons why division of labor enhances productive efficiency but he neglected to discuss an attendant problem. If I make coats for you and me, and you make bread for both of us, we may each become efficient at our tasks. But if I do not make for you the coat you would want to make for yourself, and you do not make for me the bread I would want to make for myself, then each of us is less well served than we would wish to be. As long as users and producers live in close proximity to each other, face-to-face communication may mitigate the disadvantages that flow from assigning the roles of user and producer to separate individuals. But in an era of mass manufacturing and mass communications

with its impersonal exchange-at-a-distance between producer and user, society needs an institution that is charged with regaining for users access to control over what is made in their name, which they forfeit to division of labor.

In assigning the task to marketing, society requires that marketers stand in the shoes of users, understand the influences that users experience, and act for the user. It follows directly from the notion of division of labor that goods/services have no claim on existence except as a response to the circumstances, psychological and nonpsychological, of prospective users. It is the marketer's role to ensure that the productive enterprise is brought in touch with the influences that users experience and is made to be, in effect, an extension of the user's mind and body.

Surviving Free Competition

The logic of viewing marketing as a societal function that division of labor makes necessary is independent of the nature of the economic system. Whether one has in mind a centrally planned economy or one that espouses free enterprise, division of labor means that individuals other than prospective users make the decisions about what is produced. In either case, the conditions that allocate people's energies to doing the things they do are the same conditions to which producers must be responsive if they are to assist people in achieving their ends. A centrally planned economy seems to lack a built-in mechanism for giving effect to user-perspectives. People may choose not to use some or all of the output that central planners provide but, in a closed economy, they have only two means of recourse -- become their own producers or go without. Neither option is likely to bring pressure to bear that would make planners more responsive to users' wishes. In a closed system, to ensure a productive output that is responsive to users' wants, it would be necessary deliberately to design a mechanism that leads to unpleasant consequences for planners when users remain unsatisfied. In a free enterprise economy, the marketplace performs precisely such a function by penalizing producers whose offerings users find to be less than desirable or useful, relative to the competition. Who is more likely to succeed -- producers who try to make people buy what the producer "happens" to make or their competitors who first find out what is wanted and then make that available? Accordingly, what reflection finds to be implicit in division of labor namely, that output ought to mirror users' wants becomes, under conditions of competition, a means of survival for producers. The argument from division of labor suggests that logic requires society to find a way to reestablish user-producer communication, which division of labor severs. The argument from competition sees reestablishing that communicative link as the producer's strategy for survival. Both arguments give similar direction to the behavioral scientist: Marketers need a model of the naturally-occurring process of want-satisfaction i.e., of an interrole exchange that occurs within an individual who is both user and producer (Fennell 1985c).

What Do Marketers Do?

From the preceding view of its nature, it follows that marketing is the function that is primarily responsible for what is produced. Marketing works collaboratively with other specialties on aspects of how the firm's offerings are produced, in the sense of which technology, raw materials, and costs, but it is for marketing to answer producers' substantive question: Within the general domain of our expertise, to which real-world circumstances, psychological and nonpsychological, shall we respond with a productive output? Indeed, to be responsible for that decision is marketing's unique contribution to the firm. No other department may legitimately claim to compete for that turf. No other department is charged with, or equipped for, the

responsibility of representing the perspectives of users. Or, more accurately stated, the characteristics of contexts of use. It follows that much of the content of the humanly designed environment is marketing's responsibility. It is there because marketing reported that contexts of use existed in the lives of some people that required the production of a certain kind of good/service. Or, if marketing did not so report, it allowed others so to claim, without offering effective challenge, thus yielding the marketing function to individuals outside the marketing profession. In either event, what exists is marketing's responsibility.

Accordingly, on the one hand marketing claims credit for: relief from fatigue, pain, drudgery, monotony, discomfort, anxiety, dirt, hunger, thirst, body odors, cold, heat, decay, mold, mildew, and ravages of the elements; provision of fun, intellectual stimulation, fascination, and play; provision of pleasures for every sense; in other words, for all the easements and enjoyments that flow from the availability of goods/services; and, on the other hand, accepts blame for the potential for irritation, hurt, and harm that inheres in any capability that is provided for human use.

Producers must also have an eye to the background conditions of today's productive arrangements. Mass manufacturing and mass media of communication lead to a user-producer transaction that is conducted largely in public and, willy nilly, people become exposed to wants beyond those that had arisen in the circumstances of their own lives. Not only physical contact with goods/services may help or hurt people but also the information contained in the public display, or announcements of availability for sale, of goods/services. Producers need the marketing function to guide their response to the wants of prospective users. They also need it to assess likely side effects of exposure to goods/services and to information about their availability. Included here are effects on people other than those whom the producer intends to serve, e.g., effects on nontargets and nonprospects who, without seeking it, may be exposed to the firm's offerings, directly or symbolically, as well as effects of using the goods/services in nontargeted ways.

Let me be specific about the nature of the marketing function. When the government uses society's resources to introduce a new coin that it must later withdraw from circulation because of popular rejection, that is an example of a failure to employ the marketing function. When goods/services are transplanted from one culture where they have been safely used to another where the frequency of misuse and harmful consequences rises dramatically, that is an example of a failure to employ the marketing function. When a new generation of computer software is promoted as "user friendly," that is an example of failure to employ the marketing function initially. When medicines are sold in non-tamperproof packaging so that a capsule for treating minor pain may be used as a lethal weapon, that is an example of a failure to employ the marketing function. In all these cases, the problem traces to a failure to ensure that top management understands the nature of marketing's task and uses its contribution. In the previous examples, where were the representations of and empirical data on: (1) The relevant behavioral domains for which the various offerings were intended, and (2) The wider context in which the offerings' availability would be announced and their use would occur? These questions touch on what is both the least visible side of marketing and its essence. Marketing's essential function involves three stages of communicative flow between users and producers (Fennell 1985b), starting with information flowing (1) from prospects to producers, then (2) from producers to targets, in the possible presence of nontargets and nonprospects, and (3) from targets and triers to producers. The first stage comprises the core assignment of representing users' circumstances to producers. It is largely concerned with describing users' worlds i.e., the psychological and nonpsychological contexts in which goods/services will be used. As regards conceptual development, it is the most neglected of the three, understandably, since it implicates hitherto intractable issues that touch the very essence of human nature. The rest of this paper deals with some aspects of the task of representing users to producers: A. Describing lived worlds;

B. Models for marketing's descriptive task; and C. Interdisciplinary collaboration. In each case, I first describe marketing's needs; then the opportunities that await researchers who would break new ground, in the real world no less than in the world of scholarship and science.

A. Describing Lived Worlds

As intermediary between user and producer, marketers make decisions about what to produce for whom in which contexts, and what to communicate, when and where. The task involves describing aspects of peoples' lives in certain regions of space (e.g., United States), and time (e.g., twelve month period). To grasp marketing's difficulty, one need only recall that marketers are attempting to answer the monumental question: What do people want? and to do so with specificity sufficient to permit a producer to choose the physical and psychological attributes of a good/service.

Over the years, marketers have relied heavily on common sense, intuition, and professional experience in approaching the task of describing the world of prospective users. They usually gain entry to that world by first defining a focal behavioral domain (e.g., doing household chores), and then interviewing people who perform one or more activities in that domain. Many years ago, marketing practitioners discovered that asking people to describe the kind of goods/services that they would like to see available rarely produces good information. It is more productive to ask people to describe the internal and external context for an activity in which the marketer is interested. With regard to a focal activity, the marketer tries to obtain information such as: what people believe, know from experience, and feel (i.e., like and dislike), the sensations they experience, the information they possess, the behavioral routines they follow in which contexts of space and time. Depending on the exigencies of a particular project, researchers may obtain qualitative information only or, sometimes in surveys of considerable scope, may quantify the information that they had obtained through qualitative research. At the present time, the resulting descriptions of everyday activities are primarily in the proprietary domain. The time is long past due for the significance of this aspect of the practitioner's task to be appreciated outside of marketing, to the benefit of practice and science both.

Description is one of the classic components of scientific method along with explanation, prediction, and control. Yet, in the mainstream of philosophic reflection on scientific method, it has been largely overlooked, in comparison with the attention philosophers of science have accorded to the other three. Similarly, or perhaps as a consequence, in the disciplines of psychology and marketing, some of us seem to equate "doing science" with explaining, predicting, and controlling. In the case of the various natural sciences, scientists in well-established fields see to it that needed description gets done, with or without critical reflection. Not so, in mainstream psychology and marketing where absence of reflective commentary on description goes hand in hand with neglecting to describe the discipline's subject matter. Marketing practice has suffered in a number of ways, which I have described elsewhere (Fennell 1985a). My focus here is on opportunities, of which I mention three: (1) With the interest and support of consumer researchers, we may look to the accumulation of systematic information, in the public arena, about the major behavioral domains of everyday lives, and we shall thus begin to remedy behavioral science's longstanding failure to undertake the systematic description of its subject matter. Imagine how much more we should know about behavior if, for a universe of individuals in some region of space and time, we were to describe and publish the internal and external contexts for all occasions of one activity. And then, of one more, and then another. Consumer researchers who may be interested in embarking on such a descriptive task, would be well-advised to first become acquainted with the major scholarly tradition that has offered critical reflection on the subject of description, namely phenomenology, which brings me to the second opportunity: (2) Let us develop a well-rounded portrayal of the nature of science that includes description as a full member deserving of phi-

losophic reflection, textbook space, and respectability, along with explanation, prediction, and control. The third opportunity (3) is for marketing practice to benefit from the infusion of insights, which are to be found in phenomenological psychology, on many specific aspects of the task of describing lived worlds.

Is Help Available in Phenomenological Psychology?

Have we considered what phenomenological insights may mean in facilitating communication from users to producers? As just one example, phenomenological psychologists alert us to the presence in self-report of self-deceptive justification. What makes self-reports "inauthentic" is that they result in and, in fact, are found to be motivated by, a "disclaiming of agency" (Schafer 1982). Self-deception is judged to be present whenever a description lapses into pseudo-scientific explanation: "my unconscious made me do something against my will." The assessment of self-reports as deceptive is grounded in the phenomenologist's appreciation of what constitutes valid description namely, a description that reveals, whether implicitly or explicitly, the subject's own participation (agency) in the situation being described. Such description is referred to as naive or prescientific, insofar as it faithfully captures the phenomenal realm i.e., the realm of experience as it is lived spontaneously, or "prereflectively," in everyday situations (Churchill & Wertz 1985). As marketers communicate user-perspectives to producers it may be important to strive to have prospective users report "naively," that is, without imposing their own, often deceptive, efforts to explain and justify. There is an opportunity here for consumer researchers to take the initiative in integrating the phenomenological with our other traditions so that we may assess its implications for helping marketers do the job that society assigns.

B. Models for Marketing's Descriptive Task

Models have a special contribution to make to the task of describing the user's world. They help marketers to decide what to look at in the natural world, and how to look at it, in other words, to be systematic both in defining the domain to investigate and in surveying that domain. If the models are appropriately detailed, marketers may be reasonably confident of not neglecting any major aspect of the relevant universe. Marketers need at least three kinds of models: Class I models to represent the antecedents of individual action; Class II to represent the universe of interest in a naturally-occurring population; Class III, roughly the obverse of Class II, to represent the nonfocal universe i.e., the world of nontargets, and nonprospects, and nontargeted use-contexts in which marketers, perforce, place their offerings and messages about their offerings. Classes II and III differ from models of Class I in that they are intended to classify elements in the natural world in order to help marketers to distinguish figure (Class II) and ground (Class III). Class I models are intended to suggest order -- what goes with what -- in the figural domain. They represent the antecedents of marketing's major dependent variables (e.g., actions of interest within the focal behavioral domain, brand information/choice/use). In sum, models of the focal universe (II) help marketers to define the universe they select for study, models of individual action (I) organize their search for strategic options within that universe, and models of the nonfocal universe (III) help them to review the possible side effects of their planned offerings.

Later in this paper I discuss the extent to which work that has been done in mainstream psychology lends itself to use in connection with marketing's tasks. In order to prepare the ground for that discussion, I must describe some key features of the three kinds of models that marketing needs.

Modeling Individual Action

An individual wants to achieve some result. A producer wants to participate in bringing about that result. Marketing's task is to help them both. If marketers are to compensate for the fact that division of labor separates users

and producers, they need to understand the naturally-occurring process of want-satisfaction, which is the domain of instrumental action. Most obviously, an action effects some change in the relationship between individual and environment. Why is the individual making that particular kind of change and, more difficult to answer with any degree of certainty, what exactly is the nature of the change the individual is trying to make? Why is the individual trying to make any change at all? The last question may be the most helpful because it opens the door to the notion that change had first occurred in the relationship between the individual and the environment, and that what we see as action is not change, but counterchange. Action is a compensating adjustment that tries to bring about some reference condition

Figure 1 BEHAVIORAL EPISODE

CHANGE COUNTERCHANGE-----? LEARNING

One way of thinking about action is the three-part behavioral episode that is depicted in Figure 1. The episode begins with a change in the relationship between the individual and the environment i.e., change in Figure 1, the result of which is unpleasant to the extent that the individual allocates resources to effecting counterchange. In Figure 1, counterchange is followed by a question mark to indicate that what is at issue here is attempted counterchange, which may or may not be successful. In either event, learning is envisaged i.e., some record of the episode remains in the individual. For example, I find myself feeling uncomfortably cold. Thought and action are two kinds of resources I can draw upon to deal with this state of affairs. I may, initially, reexamine my feeling of discomfort and conclude that I am not seriously uncomfortable after all. The episode may end right there. More likely than not, in about ten minutes I shall again feel uncomfortably cold and this time I may take some action to restore a comfortable state. My attempted counterchange may or may not be successful. In either case, I shall add the outcome to whatever else I may previously have experienced in association with the particular means of counterchange I used.

To understand action, then, we need to make the following distinctions, at least: a. An initial ("prechange") state; b. The occurrence of "activating change" i.e., change in Figure 1, which instates a reference condition -- a desirable state of affairs present only in imagination; c. Allocation of resources to effecting counterchange i.e., to bringing about the desired state; d. Action; e. Evaluation of outcomes; f. Learning. It is important to note that these are analytic distinctions that may not correspond to an individual's experience. For example, while individuals are experiencing a "prechange state," they may not be focusing on the qualities that become salient following "activating change." If asked, they would probably have described the prechange state along many dimensions, only a few -- or even none -- of which may now have become salient due to the occurrence of activating change. The question of practical import then becomes: What kind of change occurred to interrupt experience, differentiating a present state from what went before, and putting in place a reference condition? Understanding what changed is going to help effect an appropriate counterchange, which is marketing's task. It is for marketing to understand action and the process of which action is a part in order to help producers provide the means for taking action. The mechanism underlying the process of change-counterchange may not be particularly complex. Complexity arises because of the sheer number of environmental and personal variables that may be involved, and the difficulty of identifying the operative variables in any instance.

Fortunately, the complexity of the task that marketers face is limited in two respects: (1) Because of specialization in production, at any one time marketers do not have to confront the full range of possible environmental influences but may restrict their focus to fairly narrowly-defined domains of human activity that correspond to different products -- feeding a family, treating minor ailments, taking care of pets, and (2) Marketers do not need to be right for any particular individual at any particular moment but may

strive for probabilistic accuracy at the level of incidence within a universe of interest.

Modeling the Focal Universe

In basic research, when scientists study a general process i.e., one assumed to exist in a wide variety of contexts, the act of selecting the particular substantive domain in which the process is studied may receive scant attention, possibly on the assumption that substantive domains are interchangeable. In the real world of marketing practice, the choice of substantive domain is a major facet of any planning assignment.

There are a number of distinct aspects to the definition of a domain of substantive interest. The first is the domain of environmental impact -- the particular kind of change one intends to effect e.g., remove soil from clothes, or beard from face, or administer a fast-acting, lethal injury (e.g., to pests or sport animals). Typically, there are multiple ways for achieving such effects and producers tend to specialize in a small number of the relevant technologies (e.g., laundry detergents or dry cleaning; electric or wet shave; fire arms, or archery equipment, or chemicals). Second, there is what I have called elsewhere the focal behavioral domain -- a domain of experience and action that corresponds to the producer's domain of expertise. Since actions are performed by individuals and take place in space and time, it becomes necessary to specify a universe of person-activity occasions -- which actions performed by which individuals in which space/time environments are of interest to the producer (Fennell 1982). Space, time, and human beings are multidimensional, and the task of specification is complex.

Modeling the Nonfocal Universe

At any one time the producer's response to the circumstances of prospective users is highly selective and narrowly-focused. It is directed not only to a limited number of people in a naturally-occurring population but to a narrow band of the activities of those individuals. Producers do not, however, make available their productive output and information about that output in a vacuum but place their output, actually and symbolically, in public view in a world that consists of nontargets, and nonprospects, as well as targets. To help assess likelihood of unintended harm, producers need models of the nonfocal universe.

The task is relatively straightforward, to the extent that the nonfocal universe is specified by exclusion in the course of defining the focal universe. In principle, marketing planners can review the nature of proposed goods/services and accompanying messages in the context of the various kinds of activity, individuals, occasions of use, and periods of time that planners excluded when they defined the focal universe (Fennell, in press). The sheer enormity of such an undertaking is intimidating, but we must not allow the task's dimensions to get in the way of acknowledging that the kind of background conditions in which marketing operates today implicates such a task. Remote transactions between users and producers that are conducted largely in public involve, of necessity, people other than the immediate parties to the user-producer transaction.

Is Help Available for Marketing's Modeling Needs?

When we turn to behavioral science for help, we do not find models of the kind just described -- of the antecedents of individual action and of the focal and nonfocal universes. For example, mainstream psychology has not produced a major body of work, conceptual or empirical, that addresses the modeling of action. Indeed, it is philosophers rather than psychologists who are responsible for the bulk of scholarly work in the domain of conceptualizing action.

Considering a behavioral episode of change-counterchange as in Figure 1, much of psychology's work has been concerned with events in the realm of counterchange. One example is the large body of work that addresses the act of choosing -- among objects or alternative courses of action. Existing

models of choice belong in the realm of counterchange. In the typical research paradigm, individuals are presented with a set of options among which they are asked to choose. Usually, the researcher attempts to explain choice as a function of what are referred to as cognitive and affective variables e.g., expectations and utilities, or beliefs and importances. Because researchers do not establish a systematic connection between the presented options and conditions that affect the subjects, the paradigm is not relevant to the essential marketing assignment. By excluding consideration of the domain upstream from utility i.e., the conditions that imbue objects/courses of action with value in specific instances ("change" in Figure 1), researchers are unable to examine the extent to which their options reflect conditions that are operative for the subjects.

In much of mainstream psychology, researchers study the reactions of humans to stimuli, with little attention given to establishing the systematic status of the attributes of the stimulus. Consider the classic stimulus-response (S-R) paradigm. In the literatures of marketing and consumer behavior, authors sometimes speak of a brand, or an advertisement, as S, and purchase or use of a brand as R, which is a construction of S-R events as elements of counterchange. By excluding the context that gives meaning to S and R i.e., activating change, the practice is doomed to vacuity from the start. Events that are relevant to counterchange are understandable only in the context of activating change, which is also the context in light of which marketers would want to choose the attributes of their brands and the corresponding claims that they make in their ads.

The interests of many psychologists appear to lie in research domains where the attributes of stimuli are determined by variables that are outside the system of interest. The attitude-change literature is a prime example in this vein. Its thrust is to study possibilities for changing some aspect of human response to given "stimulus objects." The task of marketing is exactly the opposite. It is to create "stimulus objects" with attributes that are adapted to conditions that humans experience. For marketers, the attributes of such conditions are given, and the attributes of the stimulus -- the brand or "attitude object" -- are variable. Such is the behavioral meaning of the marketing concept: "Don't sell what you happen to make; make what the customer wants to buy." Or, to put it in terms of a behavioral episode: Marketers accept the attributes of activating change as given. They must identify such attributes to help producers to devise means for effecting counterchange.

A similar comment applies to the domain of information processing, much heralded for its supposed rejection of the mantle of stimulus-response psychology. In cognitive psychology, the dependent variable may have changed from overt response to various kinds of cognitive response but, from the present perspective, the essential stimulus-response paradigm remains in place. The conceptual sway of the stimulus-response paradigm will be broken only when researchers dislodge the influence of reflex arc thinking by substituting a behavioral episode of change-counterchange, and attempt to show a systematic link between attributes of activating change and subsequent S-R events.

It is of interest to ask why it should be that the needs of marketing practice focus attention on a view of human behavior that appears to have been neglected in mainstream psychology. Or, why is it that psychologists appear to have focused on events having to do with counterchange while neglecting to conceptualize activating change, perhaps failing to realize that what they have been focusing on is counterchange? "Personality" and "motivational" considerations are two among possibly numerous reasons.

Personality. In western culture, the tradition is well-entrenched of focusing on the person as an entity of intellectual and moral interest. Psychologists do not escape sharing in that tradition. Interest in persons as objects of study seems to have been antithetical to focusing on action. Describing persons implies summarizing across all of the different activities an individual engages in, with accompanying variation in the individual's role, environ-

mental context, and task or hobby orientation. Given an interest in action, theorists sample the behavioral universe in a different way. They focus on one or a few activities and, in a given region of space, summarize across individuals, with accompanying variation in the external and internal context for action. Focusing on persons: (1) Leads to using concepts whose scope is too wide for the reach of individual products, and (2) Gets in the way of seeing behavioral determinants that are specific to individual acts -- the focus marketers need in order to try to participate in the ongoing actions of prospective users. If one's primary interest is studying persons -- certainly a significant pursuit on many grounds -- one is likely to seek and find behavioral explanations in attributes of persons e.g., traits, values, needs. In scope, such concepts are poorly adapted to the marketer's task and they distract one from looking where marketers need to look.

Motivation. In the case of personality, marketing's problem traces to the presence of a long-standing fascination with a particular concept. In the case of motivation, absence is the problem. In western culture the concept of motivation, as marketers need to construe motivation, has been singularly underdeveloped. Since Aristotle distinguished final from other kinds of cause, neither science nor philosophy has made much progress in understanding motivation. In this respect, psychology has been no more successful than has philosophy, where motivation arises for discussion in the context of philosophers' work on action, and where its scant treatment is, at least, lamented (e.g., Von Cranach & Harre 1982 p. 393).

The reasons for motivation's neglect are likely profound. They may implicate the boundary conditions of self-awareness that affect scholars and scientists, no less than other humans and most acutely, perhaps, in regard to the process that directs the allocation of one's resources. Consider the previous discussion of activating change -- a change in the relationship between the person and the environment that may bring to the fore some feature of the pre-change state that had not been salient. Individuals may, of course, deliberately reflect on the conditions that have just redirected their attention but the more usual pattern may be to proceed immediately to taking corrective action or, when the individual is in fairly unfamiliar circumstances, to constructing and reflecting on possible courses of action. From the standpoint of survival, it seems to make sense that the human capacity for reflection and analysis should come into play after, rather than during, the time when individuals are experiencing conditions that allocate their resources to effecting counterchange. A resource-allocating mechanism that errs on the side of taking countermeasures more often than is necessary is preferable to one that errs by subjecting every hint of possible danger to self-monitoring reflection.

The reason for motivation's neglect may be yet more subtle. It may lie in the notion that the "standpoint from which commentary is made must always be one remove from experience, and cannot have attention focussed upon it" (Harre & Secord 1972 p. 91). We cannot scrutinize that with which scrutiny is performed. In the case of motivation, the operative "scrutinizer" is the standard by which we judge whether what we are experiencing can be allowed to continue without our taking countermeasures, or whether things have reached a point where we must allocate resources to making adjustment.* But what is the nature of this scrutinizer? To be able to interrupt whatever is receiving our focal attention, the scrutinizer must be set to operate automatically. Since the most we can hope for is to learn about our scrutinizers inferentially, it may be no wonder that motivation is the aspect of our being that is most mysterious. There may, then, be very good reasons, intimately bound up

*In using the word "scrutinizer" to refer to affective reactions, as I am doing here, I depart from the cognitive context in which the authors used it (Harre & Secord 1972, p. 91). Thinking of affective reactions as a form of commentary adds a significant dimension to discussion of the limits to self-awareness.

with the limits of our capacities as conscious self-monitors, why insight into the conditions of our activation is hard to come by, whether at the level of everyday experience or of formal study. Monitoring others of our species is one way we may try to compensate for these limits, an interesting extension of which is the special case of monitoring what psychologists do when they want to allocate the resources of their animal subjects. For example, students of instrumental learning may arrange things so that the resources of some rats are allocated to escaping from a source of aversive stimulation, or to avoiding its likely occurrence. They may then proceed to study change, over time, in the rats' escaping or avoiding actions. If we assemble the major kinds of conditions that students of instrumental learning use to allocate the resources of their experimental animals, we may have at least the rudiments of a model of basic kinds of motivating conditions (Fennell 1980; Michael 1982, in preparation). Collectively, these conditions help us to appreciate how environmental and personal variables combine to allocate resources and to specify the domain of action. They may begin to give us a new perspective on the mystery of our scrutinizers.

C. Collaborating for Marketing's Descriptive Task

When individuals are both producer and user, they may adjust what they produce until it yields results approaching those that their personal scrutinizers demand. People may do this without being able to communicate much about their personal scrutinizers. When the user and producer roles no longer reside in the same individual, producers are being asked to create goods/services that are responsive to those most intimate scrutinizers of prospective users. Accordingly, while we should push to its limits whatever help marketing may find in prospective users' descriptions of the context for their actions, there is good reason for not relying solely on that source of information. Minimally, researchers should use comprehensive models to guide prospective users' through the full range of possibly relevant terrain. But, for marketers to do their job, the obvious limits to what the layperson knows about the environmental conditions of one's activation must be overcome. In trying to understand the nature of activating conditions i.e., of events that both raise the question of taking action and shed light on what needs to be done, marketers seek information that experts in the human environment can provide.

Consider a well-established product such as dentifrice, and the behavioral domain of oral hygiene routines. Over time, the range of brands that has come on the market represents a growing understanding, on the part of producers collectively, of the personal and environmental conditions that may allocate people's resources to oral hygiene in the form of teeth brushing. The range of brands points to the variety of considerations that may be found in a universe of adult men and women, comprising beliefs about: the process of dental decay (e.g., food particles remaining in the mouth, bacteria, plaque, tartar), and staining (e.g., tobacco); the consideration we owe to each other in avoiding mouth odor; what is, or what is regarded as, beautiful (e.g., white teeth, or pearl-like teeth); and many others.

Eventually, marketing planners will use models of action to generate a comprehensive set of such personal and environmental elements. For interested consumer researchers, the field is wide open to develop the models marketing needs. The models have to be stated at a level of abstraction that permits marketing planners to use them in any domain of substantive interest. Considering activating change, for example, personal and environmental variables combine to allocate an individual's resources to effecting counterchange. A general model of action must allow for any aspect of the person e.g., sensation, feeling, belief, rules, information, imagination, to combine with environmental events in producing behavioral activation. (Which class of environmental events a researcher should consider is a difficult question to answer in principle. Fortunately, it need not detain us in the context of marketing practice, where it is answered on a pragmatic basis. Marketers select a substantive domain that roughly corresponds to one or more existing products within the range of the producer's

expertise e.g., products for cleansing teeth and gums). It is marketing's responsibility to obtain the collaboration of experts in appropriate realms of nonpsychological knowledge so that together they may spell out, for subsequent investigation, the real-world conditions that prospective users may be experiencing.

Collaboration between marketing and production management, including R&D, is fostered by enlightened producers of goods/services but, in the absence of models of the kind to which I refer, it does not, and cannot, proceed systematically nor can marketing readily assume leadership in such collaboration. For example, (1) Excessive attention may accrue to a candidate brand concept due to the political status of its source, to the total disregard of the idea's objective worth as measured by relevance to any existing aspect of prospects' worlds. Comprehensive models are, perhaps, the only effective means of ensuring that such privileged ideas are placed in the context of numerous competing alternatives. (2) Models would make it easier than it now is for marketing to communicate the nature of its function to production management, and within the firm generally. Nominally, top management understands that marketing represents user-wants, but what does a user-want look like? What do marketers have to bring to the conference table that gives flesh and substance to their role? If marketers were able to be articulate about the conditions that allocate prospects' resources, to which it is production management's job to be responsive, they would have something to say that top management is waiting to hear. They would be seen to give effect to their mission as users' emissaries to producers. (3) More specifically, at meetings with production management, marketers would assume their proper leadership role. They would be equipped to: a. Outline a comprehensive range of conditions that may be operative within the focal universe; b. Ask production management to specify in detail the possibly operative kinds of nonpsychological conditions corresponding to categories that marketing's general models specify; c. Initiate collaboration with production management in specifying the kinds of conditions that may result from the combined operation of psychological and nonpsychological elements; d. Proceed to study each of these theoretically specified options, identifying whether gaps exist in the firm's information about the physical or the behavioral realm, and directing investigations accordingly. Comprehensive models permit planning such as I describe which, in turn, permits the role of each of marketing's diverse kinds of research project to be clearly visible. As members of the planning team grasp the big picture, and the potential contribution of each piece of empirical work in the context of the big picture, the actual yield of relevant information improves.

Consumer Research at the Frontier

Given today's technological sophistication, there is nothing easier than producing vast quantities of goods/services. The first milestone on the way to a new frontier is recognizing that mere production warrants no accolades. The contribution that society demands from its productive enterprise is not simply to produce but to produce the right goods/services. Therein lie problems and opportunities aplenty. First, the fact that producers may not know what the "right" productive decisions are does not prevent goods from being produced. Second, all of us have an interest in the kinds of things that get produced, announced in our communications media, displayed in our stores, used by our neighbors and ourselves, and disposed of in our dumps. As individual consumers, many of us feel, perhaps wrongly, that there is little we can do to influence the kinds of things that get produced. As marketing practitioners, the kinds of things that get produced are our responsibility. Within law and ethics, it is our assignment to see to it that what gets produced is what users of goods/services would make for themselves. Third, as consumer researchers, we could have much more to say than we do now, if we would take the action that is ours to take namely, develop the conceptual tools that help marketers effectively represent user-circumstances to producers. Fourth, as marketers and as consumer researchers, if we do not do our job, others will do it, and are doing it. Decisions are made and goods

services are produced, with or without our input.

So, there is a job that needs to be done, that is being done, that many people would like to have a say in doing, that is marketing's responsibility, that consumer researchers may take as their interest and responsibility. It is located at the frontier of the realm that science and scholarship have made their own. What more could anyone ask for, measured by yardsticks of intellectual challenge and importance to society? In the decade of the 1920s, "rationalization of production" was much in vogue. The phrase referred to introducing more efficient, streamlined, methods of production and to the replacement of human labor by machines. The process of deciding what shall be produced has not yet benefited from rationalization. Instead, it is characterized by bumbling, chaos, and colossal waste that make the era of prerationalized methods of production seem serenely ordered. It does not have to be this way. But the best hope for order are consumer researchers ready to study the essential marketing task. Those who do will not only serve marketing, and the public at large. They will extend the boundaries of what is thinkable, both for the nature of our productive enterprise and for behavioral science. If ever a task needed the help of basic science, it is society's charge to marketing to represent users to producers. If ever a task was at the frontier of knowledge, close to human hearts, and at the center of human mystery, it is that of consumer researcher for marketing practice.

MARKETING, INTELLECTUAL CREATIVITY, AND CONSUMER RESEARCH

Elizabeth C. Hirschman, New York University

Introduction

Marketing has suffered from a schizophrenia of purpose since its inception. As a field of intellectual inquiry, its purpose should be to generate knowledge about its central phenomena -- i.e., the elements and processes of exchange. However, as an applied discipline its primary purpose has frequently been to generate knowledge of value to marketing practice--and more specifically, to benefit marketing management. These two goals were recognized early on by MacInnes (1965) who stated (p. 57) that "marketing in its widest sense, therefore, is any activity which actualizes the potential market [i.e., exchange] relationship between the makers and users of goods and services. A science of marketing would attempt to analyze and form testable hypotheses about this actualization; the practice of marketing would exploit the actualization process to generate sales."

However, despite MacInnes' explicit recognition of the distinction between marketing science and marketing practice, many leading scholars of the era felt that marketing science should be subservient to marketing practice. That is, that any intellectual inquiry into marketing phenomena must be ultimately judged according to its contribution to marketing practice. For example, Alderson (1957, p. 24) stated, "More generally, this question as to where science should start raises the fundamental issue of the relation of science to action. On the one side is the pragmatic view that a science should begin as quickly as possible to handle its data in such a way as to produce practical results. On the other side is what might be called the 'existential' view, that science is concerned first of all with the nature of reality and that questions of human purpose are secondary. [My] present view is that marketing would not exist as a separate field of study except to promote practical objectives, and that any theory that will provide a useful perspective for this field is necessarily pragmatic..." Despite Alderson's misapplication of the term 'existential', his statement quite clearly advocates the position that marketing science exists to serve marketing practice.

This normative positioning of marketing science to further the goals of marketing practice was recently reiterated in an editorial in the Journal of Marketing. Writing on reviewing criteria for articles submitted on marketing programs, Cunningham and Enis (1983, p. 6) state, "It is particularly important in the Marketing Programs section to discuss the managerial implications of research. In short (sic) contrast to the analytical rigor characterizing the research design of many papers, the discussion of managerial implications is often nothing more than speculation. Too few researchers discuss their research with practitioners and even fewer involve them in the project, for example, as 'feasibility advisers'..."

Even more recently (August 1984) the AMA Education Council was asked by the American Marketing Association to formulate an official definition of marketing. Initially a Council subcommittee proposed a definition that would have effectively equated marketing with marketing management; their original definition was: "Marketing involves the integrated analysis, planning, and execution of a set of activities concerning pricing, promoting, and distributing ideas, goods, and services intended to bring about exchanges to satisfy human or organizational objectives." When this definition was presented to the full Council, a minority segment (including the present author) argued strongly against the equating of marketing--as a field of intellectual inquiry--with the practice of marketing management.

Eventually, this notion prevailed and two definitions were forwarded by the Council to the AMA Board of Directors. Marketing was to be defined as the process intended to bring about exchanges to satisfy human or organizational objectives. In contrast, marketing management was defined as the integrated analysis, planning, and execution of a set of activities concerning the pricing, promoting, and distributing of ideas, goods, and services.

Unfortunately, when these two definitions were reviewed by the AMA Board of Directors for approval, the Board, which is representing a constituency that is 15% academicians and 85% practitioners, reverted back to the earlier "marketing management" version as the official definition for marketing. To wit: "Marketing is the process of planning and executing the conception, pricing, promotion, and distribution of ideas, goods, and services to create exchanges that satisfy individual and organizational objectives" (Marketing News, March 1, 1985, AMA Board).

This definition of marketing is derived in large part from what practitioners (and some academicians) think marketing is and it leads to the expectation, on their part, that academic research should serve the interests of or at least be useful to marketing management. Research which has no practical application or, worse yet, is conducted just because the academician thought it might be interesting is viewed by them as a wasteful use of academic resources that should be directed toward solving their problems. This view is expressed so eloquently by marketing practitioner, Robert MacLaren Lawrence, in the July 19, 1985 issue of Marketing News that I will simply excerpt portions of his article (p. 2):

The Gap Widens Between Educators, Practitioners

"I recently attended a regional marketing conference to present a paper on direct marketing in current curricula. While waiting for my time to come, I went to several presentations on sales management research and marketing strategy. Once again, I sat and shook my head and wondered: Where is the field going? We're not talking [about] better marketing or even [better] research. We're talking about a bunch of people writing papers for publication and no one is addressing the issues of the people on the firing line -- the managers.

When I asked one of the speakers how his research information translated to the managers for dissemination, the question drew blank stares. It didn't seem to be important...Perhaps part of the problem lies with the efforts of marketing academics to practice scholarship and behavioral science research and not attend to the distribution of the information to the marketing community at large. I do not know why.

Pure research in the field may be chasing windmills. Applied research seems to be limited to persons with consulting practices, and the two seldom appear in the same journals. My only conclusion is that the two segments are addressing mutually exclusive audiences.

In general, the current challenges facing managers in terms of operating the marketing organization are being ignored by the academicians...Indeed, the authors have shrouded themselves in a private language and call it marketing. Some of the professors have no experience at all. They have never run a budget, introduced a new product, managed a product, or done any advertising. They have no idea that doctoral tools represent a small portion of the marketing situation. In the mad scramble for schools to hire professors with the proper credentials--the PhD, which certifies the holder's ability to do research--issues such as experience and the ability to

communicate marketing to students and managers are ignored, and sometimes given negative points. This entire situation angers me.

Perhaps the problem lies in the doctoral programs where the emphasis is thrown too much on one area. Perhaps the availability of teaching jobs in marketing has attracted people who ordinarily would have gone into some branch of the social sciences. I would like to see some direct impact on management policy. Modify the current format of marketing conferences to include managers, and invite papers and special sessions. So often I've even seen the most elementary of presentations by managers draw the audience of professors into an almost awestruck state.

My purpose is not to say that all current research is without merit. [However], I do believe that much of the research is geared towards getting published rather than disseminating information throughout the marketing community. After all, we should be, practitioner and professor alike, members of the same body politic. In fact, we are not...The scholars seem content to study and develop models of behavior, many of which are seldom used in the private sector. They argue about the incessant measurement of meaningless minutiae and ignore the plights of management in operating the process."

After reading Mr. Lawrence's indictment of scholarship and the absurdity of marketing academicians pursuing 'social science' research for its own sake, I was in a state of depression until I came upon the following article by Herbert Rotfeld, an Assistant Professor of Advertising at Penn State, in the same issue of Marketing News, albeit 'buried' at the bottom of the next-to-last page:

Marketing Educators Must Become More 'Scholarly'

" Marketing teachers often lament their lack of academic respectability. There are grounds for it, and educators have only themselves to blame.

Marketing is not respected as an academic discipline for the very good reason that it isn't. Merely being taught at a university does not make something an academic discipline. No one would dare assert that typing, swimming, and videotape editing should be so considered. Simply being called "professor" does not make one a scholar.

How many [marketing academicians] can say they objectively view marketing activities with the same disinterested, scholarly curiosity with which the anthropologist studies a primitive tribe, or with which the biologist watches the microbes squirming under a microscope? More directly, if marketing educators were scholars, they would not discuss the value of their education programs solely in reference to their ability (or inability) to train students for entry-level jobs.

Although the liberal arts form the basis for the vast bulk of our college and high school programs, it is rarely claimed that their importance to education is based on the course materials being necessary for future employment...Education for its own sake is an important ingredient for the working of our popular democracy; the people best able to adapt to the world around them are those with the greatest (and broadest) exposure to variation of that world.

If all that marketing education is capable of accomplishing is training students to be practitioners, there should be serious doubt about its value to the university campus.

The point is that the study of business practices could become an important body of scholarship, and the assistance such programs might provide to people in entry-level [positions] should serve a secondary role. However, if all that were offered were job skills and training, such programs would belong in vocational train-

ing schools and not in universities.

It should be intuitively obvious that when a group gathers to discuss how to train people for jobs, they clearly abandon any pretense of scholarship. They confess to being propagandists. Now, there is nothing intrinsically evil about propagandists, but their place is in the public relations office, not in the classroom. And that is the key to what is fundamentally wrong with marketing education; why it lacks an academic discipline and why many of its teachers are not scholars. This problem limits marketing education's social worth as well as its academic respectability.

How many marketing or advertising teachers worry not about improving the reputation of business, but rather try to provide the detached, penetrating criticism that is needed? How many of our programs require courses on the history of business organizations, ethical issues, or law, not in an effort to turn out "better" managers, but rather to criticize common business practices? How many courses on marketing and society are simply case studies of management problems instead of analysis of marketing's dysfunctions as a social force?

A scholar cannot share goals, viewpoints, and values with practitioners. An educator should not be the businesses' representative on campus, nor their recruiting officer or defense counsel. Educators should work for society, not industry, based upon the belief that they serve society by serving truth."

Professor Rotfeld's letter expresses with great clarity why it is that the interests of marketing managers should not drive academic marketing research and why, by extension, marketing management variables are not the 'core' of consumer research. Such a focus acts to stifle intellectual creativity, to limit our horizons, and to compromise our integrity as scholars and social scientists.

This misguided norm, which I term the Doctrine of Managerial Utility, threatens inquiry in two ways. First, and probably most importantly, it narrows and distorts the field of potential research issues considered by marketing and consumer researchers. When an academician begins any inquiry with the notion that its results must be beneficial to marketing practitioners, s/he starts out with a pair of intellectual blinders on. The researcher's field of vision becomes necessarily restricted to those areas where practical results are believed to be forthcoming.

Further, the scientist's view of even these practical areas will be distorted because s/he will tend to see them from the perspective of the marketing manager and not from the viewpoint of other participants in the exchange (Anderson 1983). Marketing and consumer behavior can make little progress as sciences unless and until these restrictions and distortions are removed and the researcher feels free to investigate any aspect of relevant phenomena, regardless of the potential pragmatic payoff.

A second--and probably quite frequent--threat to marketing and consumer behavior as sciences resulting from the Doctrine of Managerial Utility is that it forces researchers to engage in hypocritical attempts to dream-up managerial implications for their research before submission to a journal or academic conference. I suspect that there is probably a certain segment of researchers who do investigate 'non-practical' topics of interest to them, but who then must exert great effort to think of some managerial implications when writing up the investigation as an article. In fact, the most creative thinking done in some articles is probably concocting a discussion of managerial utility, when the research contains none.

What is quite unfortunate about this scenario, however, is that the researcher may have made a major conceptual or empirical breakthrough in the study, one that could contribute greatly to our understanding of consumption phenomena, but is forced to submerge the intellectual value of this finding beneath a weak and worthless discussion of

its 'managerial utility'. What is even more unfortunate is that a reviewer of the article may respond by noting that the finding is quite interesting theoretically, but since it is of little or no use managerially, the article should be rejected. Doubtless this scenario has been enacted in reality on too many occasions.

If marketing and consumer behavior are to achieve their best as fields of intellectual inquiry, then marketing and consumer researchers must be permitted to act as artists and not as craftsmen, to use Becker's (1978) terminology. An artist is one who creates out of an inner desire for personal expression; whereas a craftsman is one who creates to serve the will of the client. Marketing and consumer researchers should be free, as artists, to follow their intellectual curiosity wherever it takes them--even if those areas are impractical, nonutilitarian, or even anti-business. Research which places managerial utility ahead of intellectual curiosity subverts marketing and consumer behavior as sciences; it makes a craftsman of the researcher and degrades the intrinsic value of the knowledge produced.

Marketing Inquiry and Consumer Research

One reason why I, as a professor of marketing, (and I suspect many other marketing professors) chose to specialize in consumer behavior research is because it was relatively less restricted by the Doctrine of Managerial Utility. There is a widely-shared perception among consumer researchers that they are less hemmed-in intellectually by the necessity of producing practical results, than are marketing academicians as a whole. There has been an excitement and comradeship at the ACR Conferences throughout the 1970's and early 1980's that derives from the fact that the participants believe they are 'getting away' with something. That they are in some sense a secret society, thinking about and talking about things 'forbidden' in a traditional marketing academic setting. In short, they are having fun; they are enjoying themselves, because they are investigating what they are intellectually curious about, and not what they are 'supposed' to be studying -- i.e., phenomena of interest to marketing management.

Because of its intellectual freedom, consumer research is considered by many to be as the most rapidly progressing aspect of marketing inquiry. It is generally perceived as the most intellectually rigorous and theoretically advanced area of our discipline. And revealingly, the majority of AMA Consortium PhD students in the past several years have chosen dissertation topics focused upon consumer behavior and not marketing management.

Perhaps the greatest intellectual discovery we have made in consumer research is that scientists do their very best work when they are investigating topics they are naturally curious about; when they are acting as artists and not as craftsmen. Far from 'reining ourselves in' and getting 'back to basics', I believe every encouragement should be given to intellectual diversity and topical heterogeneity in consumer research.

This course of action cannot be pursued without a cost, however. I must report to you that in the general marketing management community and among some marketing academicians, ACR-affiliated consumer researchers are now widely viewed as eggheads, impractical oddballs, and even -- in the case of the experiential-hedonic fringe elements such as Holbrook and Hirschman -- as certifiably insane. If we continue to pursue our errant ways, this perception will no doubt increase. So be it.

Beneath this overt derision lies a sneaking suspicion that maybe ACR researchers are onto something that the others are missing. That something secret, exotic, and probably sinful must be going on at those ACR Conferences, because (unlike AMA) people are actually attending sessions; they are actually arguing over research ideas; they actually care about what they are doing.

So, my position is this:

--if a consumer researcher wants to apply neo-Marxist thought to consumption practices in industrialized countries and comes to the conclusion that capitalism is a failure, that effort should not only be tolerated but encouraged.

If a consumer researcher wants to spend a year investigating the home production of handicrafts in the Appalachian mountains, that effort should not only be tolerated but encouraged.

If a consumer researcher wants to systematically examine the meanings of aesthetic objects using humanistic methodologies, that effort should not only be tolerated but encouraged.

And if a consumer researcher wants to examine the material culture of Neanderthal man using archaeological inference, that effort should not only be tolerated but encouraged.

All of these phenomena constitute consumer behavior; all are intellectually challenging; and although none of them has any direct utility to marketing management, they are nonetheless appropriate and important topics for consumer research.

As scientists it is critical that we have the freedom to investigate the phenomena of our field with a minimum of normative restrictions. Our research should be bounded only by our curiosity and our innate abilities to discover and to comprehend. We owe no allegiance to managerial pragmatics, nor should we be bound to further them.

WHITHER ACR?
SOME PASTORAL REFLECTIONS ON BEARS, BALTIMORE, BASEBALL, AND RESURRECTING CONSUMER RESEARCH

Morris B. Holbrook, Columbia University¹

Yet once more, O ye laurels, and once more,
Ye myrtles brown, with ivy never sere,
I come to pluck your berries harsh and crude,
And with forced fingers rude
Shatter your leaves before the mellowing year.
Bitter constraint, and sad occasion dear,
Compels me to disturb your season due
("Lycidas," John Milton 1637, ll. 1-7).

I'd be pretty dumb if all of a sudden
I started being something I'm not
(Yogi Berra, quoted by Clark 1984, p. 6).

Against the rules, yes, Boo Boo. But I am a
nonconformist bear (Yogi Bear, quoted by Clark
1984, p. 6).

We have the obligation of pressing the unpleasant
questions...the embarrassing questions, the taboo
questions. Being so privileged as we are, it is
almost our damn job not to ask the nice questions,
not to ask the comfortable questions (George
Steiner, quoted by the New York Times 1985, p. 22E).

Abstract

The Bad News Bears return. Hattie pays for the Baltimore Sun. The buyer goes downtown. The consumer researcher plays left field. Sweet Lou comes home. The shepherds weep no more.

The Bad News Bears Return

The Bad News Bears are back! Only this time, they are wearing baseball uniforms, reading poetry, and playing on our team.

Last year, in an ACR session entitled "The Vices and Virtues of Being Relevant: Perspectives on Consulting," I prompted some debate by examining the forces that push consumer research toward managerial relevance, comparing these pressures to the Three Bears, likening our discipline to Goldilocks, and retelling the ancient tale in a new version that bore deadly consequences for our fair-haired heroine:

When the bears returned to the cottage from their day in the woods, they found Goldilocks peacefully asleep.... They immediately did what any self-respecting bears would do. They killed her on the spot (Holbrook 1985b, p. 154).

In his presentation, Jack Jacoby took exception to my distortion of this beloved fable and generously supplied me with a children's book that contains what he regards as the appropriate ending:

Goldilocks woke up with a start. She ran to the window and jumped out. And the three bears never ever saw her again (Lothrop, Lee and Shepard Books 1982, p. 23).

Though I doubt that whether Goldilocks is "killed on the spot" (my account) or simply "never seen again" (the authentic version) makes much difference to those who

loved her dearly, I have learned one thing--namely that, as a metaphor for the fate of consumer research, my Three Bears story fails to do the trick. Besides, I've always liked bears and mean them no harm.

Lycidas Is Dead

So what we now need is a story that really is sad--by anyone's standards--but, to preserve our optimism, one that has a hopeful resolution. I can think of no sadder but ultimately more hopeful tale than John Milton's elegy on the death of Lycidas in which the poet "bemoans a learned Friend, unfortunately drowned...on the Irish Seas":

Bitter constraint, and sad occasion dear,
Compels me to disturb your season due,
For Lycidas is dead, dead ere his prime,
Young Lycidas, and hath not left his peer.
Who would not sing for Lycidas? He knew
himself to sing, and build the lofty rhyme.
He must not float upon his watery bier
Unwept, and welter to the parching wind,
Without the meed of some melodious tear
("Lycidas," Milton 1637, ll. 6-14).

I shall therefore take "Lycidas" as my symbol for the potential premature demise of consumer research--Lycidas, the fair-haired and beautiful shepherd boy who has drowned beneath the sea and "sunk... beneath the watery floor" (l. 167). This oceanic image recalls last year's comparison of commercialization and overzealous managerial relevance to sinking like a stone in water:

We can pursue knowledge like beauty for its own sake...or we can wrap our feet in utilitarian slippers of lead and perform soggy pirouettes beneath a sea of managerial practicalities. As Charlie the Tuna found out to his dismay, the pursuit of Truth and Beauty gets nowhere on the ocean floor. Sorry, Charlie. Practitioners don't want tunas with good taste. They want tunas that taste good (Holbrook 1985a, p. 30).

As soon as business intrudes into science, one hears complaints from scientists about loss of academic freedom and interference with scholarly integrity. Yet, in my experience, one seldom hears such complaints voiced in the context of business schools or among consumer researchers. Apparently, we are like fish in water. We have so long been submerged under the influence of business sponsorship that we don't even notice it any more Usually, we swim in the tide of corporate sponsorship without really noticing the ebb and flow of the invisible currents that steer us (Holbrook 1985b, p. 153).

Milton's poem contains numerous cases of water-and-light, sea-and-sun imagery. In this spirit, then, let me begin with a story about the sun--in this case, the Baltimore Sun, that town's daily newspaper.

Hattie Pays for the Baltimore Sun

Once upon a time, in a story told and retold by my mother-in-law, one of her friends named Miss Lee moved from her home on a plantation near Charlottesville to the city of Baltimore. Miss Lee had grown up in the patrician luxury of the Virginian countryside, surrounded by crops, servants, and the good things in life. In her later years, Miss Lee took her loyal and devoted housekeeper called Hattie and went to a small apartment to be near her doctor

¹The author thanks Russ Belk, Geraldine Fennell, Beth Hirschman, Rich Lutz, and Rich Yalch for their helpful comments on an earlier draft of this paper. He also gratefully acknowledges the financial support provided by the Columbia Business School's Faculty Research Fund.

in the big city. Miss Lee enjoyed the cultural stimulation of the urban environment; but Hattie, who was less well-educated, found it difficult to adapt. Finally, one day, the arrival of the newspaper boy asking to be paid for delivery of the paper pushed Hattie over the edge. She came bursting into Miss Lee's bedroom in tears and cried:

"O, Miss Lee, I can't stand it no more. Back home, when I needed eggs, I just went to the hen house and grabbed up a few; now I need to place an order with the delivery man and wait two days. Back home, when I wanted milk, I could just go out to the barn and get me some from the cow; now I have to call the dairy company and pay them to come and bring it. Back home, when I had to fix vegetables for supper, I could just go out to the garden and pull some up right out of the ground; now I have to carry a shopping basket and a pocketbook full of money all the way down to the grocery store. And now--Lord, Lord --there's a boy down there at the front door who says he's here to collect for the sun."

At one level, Hattie had missed the point. She had failed to recognize that the "Sun" in question was a newspaper and not the big star that sits at the center of our solar system. But, at a much more profound level, Hattie had grasped one key issue better than do many of us who call ourselves consumer researchers, attend ACR conferences, and ponder the future direction of the Association.

Hattie understood, metaphorically, that consumers want to enjoy the sunshine and that marketers want to collect for the sun--that marketers want to charge them money for their consumption experiences. In other words, Hattie recognized that there is a fundamental difference in perspective between consumers and marketing managers and by extension, therefore, between marketing and consumer research. The consumer's perspective, Hattie knew, centers in consuming and in phenomena related to the consumption experience; presumably, consumer research should reflect those interests. By contrast, marketing research does and definitely should reflect the marketing manager's concern for buying behavior and for phenomena related to purchase decisions and their impact on profitability. Hence, as Hattie instinctively recognized, consumer research and marketing research differ fundamentally in orientation.

I like marketing. I spend many of my waking hours worrying about marketing and trying to teach MBA's what I know about the formulation of marketing strategy and the solution of marketing problems. But still, even though I deeply believe that marketing is a worthwhile (probably the most worthwhile) business activity, many of us in marketing are in the position of trying to collect for the sun. Therefore, our concerns as marketers may differ from the concerns that inform the activities of consumers. It follows that marketing research and consumer research are and should be different sorts of things.

To repeat, I regard marketing as a noble profession. If I did not, I could not stand up and teach it for a living. I want the companies whose stocks I own to practice good marketing management and make lots of money. I want my students to go out and become good marketers and succeed on the job. I would even let my son marry a marketing woman. Further, as Levitt (1960, 1962) has taught us so well, I recognize that marketing often involves a large component of customer orientation and, therefore, that any decent piece of consumer research may eventually be relevant to some marketer somewhere, some way, some time. But, as Levitt's critics have insistently pointed out, customer orientation must be tempered by some concern for the firm's skills, strengths, capabilities, resources, costs, and other internal constraints so that, ultimately, we arrive at what is sometimes called the profit orientation, the survival orientation, or the "marketing orientation" (in the truer sense of that abused term).

This marketing orientation, by focusing on internal considerations of the firm's profitability, differs fundamentally from the perspective of the consumer. Accordingly, the research intended to serve it does and should differ fundamentally from consumer research. Thus, in my view, consumer research emerges from the perspective of the (value-seeking) consumer and marketing research adopts the orientation of the (profit-seeking) marketing manager.

But, already, I have used such terms as "consumer," "consumption," "buying," "business," and "marketing"--words that have served as endless sources of confusion in our discipline and that occasionally have even led to the abandonment of consumers by some of their erstwhile most devoted friends and to the redefinition of consumer research by some of its most illustrious spokesmen.

Where were ye, Nymphs, when the remorseless deep
Closed o'er the head of your loved Lycidas?
("Lycidas," ll. 50-51).

The Buyer Goes Downtown

A spectacular case in point appeared in a recent statement by Ralph Nader, surely one of the consumer's most passionate advocates:

"I don't want to use 'consumer' anymore," Mr. Nader said. "I want to use 'buyer.' You don't go downtown to consume--you go downtown to buy" (Molotsky 1985, p. 44).

Nader's claim was "that people ought to use their buying power to bring them to parity in dealing with large corporations and government" (p. 44). But, however well-intentioned, his treatment of "consumers" as people who "go downtown to buy" endangers the recognition that consumers are not just buyers and that our research should reflect this fact. Besides purchasing, consumers also engage in other forms of consumption involved in the acquisition, usage, and disposition of the products they consume:

consumer behavior is the acquisition, consumption, and disposition of goods, services, time, and ideas by living units.... It encompasses much more than just the purchase of products and/or services by humans (Jacoby 1975, p. 979).

Most definitions of consumer behavior shackle us by confining attention to purchase.... purchase is only one form of acquisition.... Consumption must be given greater salience.... disposition...appears to have been completely neglected. This neglect should be rectified (Jacoby 1978, p. 94).

in addition to choice behavior, we must encourage research on procurement behavior..., on consumption behavior...and on disposal behavior (Sheth 1985, p. 1).

Hence, as these warnings suggest, the use of "buyers" to signify "consumers" encourages dangerous misunderstandings, some of which have afflicted our own literature.

But the confusion between "buying" and "consuming" is not the only terminological problem that threatens us. Another concerns the meaning of the word "marketing" itself. On the wall outside my office, I have an old *New Yorker* cartoon. It shows a door labelled "Vice-President of Marketing" with a man coming out of the door, carrying a shopping basket, and clearly heading toward some nearby grocery store. This cartoon serves to remind us that our language carries at least three meanings of the word "marketing." The first, "marketing" in the sense of "going to market" or "shopping," belongs to the discourse of housewives or househusbands and focuses entirely on the activities of the customer. The second, "marketing" as a set of managerial responsibilities concerned with exchange

processes (Kotler 1972) or with the removal of gaps between producers and end-users (McInnes 1964), adopts the perspective of practitioners and corresponds most closely to the usage that prevails in both academic and management circles (Marketing News 1985). The third, "marketing" as a very broad set of phenomena involving interactions between customers and managers (with an equal emphasis on the viewpoints of each), would better be called "business" or "commerce" and constitutes a vaguely delimited area in which we all participate to some degree.

A similar confusion surrounds the natures of "marketing research" and "consumer research." Some of the smartest people I know insist that the two are essentially the same thing. For example, John Farley (current Executive Director of the Marketing Science Institute) walked into my office the other day and assured me that there is no difference between consumer research and marketing research. Their union minus their intersection is the null set. As we shall see, the 1985 ACR Call For Papers by Rich Lutz (this year's Conference Chairman) conflates the two. Again, one might interpret Jack Jacoby's (1985a, b) position as blurring the distinction somewhat. Geraldine Fennell (1982), another friend from the world of consulting, also seems to suggest that marketing research and consumer research are (or at least should be) indistinguishable insofar as "marketing's central assignment" involves "responding to consumer wants in a competitive environment" (p. 1). Thus, in their comprehensive review of marketing R & D, Myers, Massy, and Greyser (1980) suggest that

in the early 1960's...marketing research became, in effect, "consumer research," and the emphasis was placed on developing theories of consumer motivation and behavior or consumer decision processes (p. 4).

These examples reflect a prevalent conception based on considerable common sense. Indeed, compared to the difference between marketing research and, say, biophysics, marketing and consumer research do seem almost identical. Further, the tendency to equate the two may exhibit nothing more than one side of the age-old debate between those inclined to see the One and those drawn instead to a view of the Many.

Almost 2500 years ago, two Greek philosophers named Heraclitus and Parmenides represented opposite sides of a controversy that most of us still grapple with millennia later. This controversy concerns what Hare (1982) calls the problem of the One and the Many and stems from the fact that people adopt contrasting world views. Some see everything as different and changing. Others see everything as constant and the same:

Two great philosophers...took up opposite points of view on the problem of 'The One and the Many.' The first was Heraclitus...emphasizing the diversity and changeability of the Many at the expense of the One; Parmenides, by contrast... went to the opposite extreme, denying the reality of appearances altogether...and...concluded that, in spite of appearances, the universe is really solid throughout and immobile (pp. 12-13).

Clearly, those who insist that "buyers" and "consumers," "marketing management" and "business," or "marketing research" and "consumer research" are the same things adopt a Parmenidean view of our discipline. They receive support from a 2500-year-old philosophical tradition. Yet I believe that they blur some important distinctions, fudge some key contrasts, and thereby encourage confusion. Accordingly, I wish to revive the spirit of Heraclitus and to argue for a more Heraclitean temperament at ACR.

In an effort to remain as consistent as possible with common usage (and with myself), I shall adopt the following terminology. I shall define "business research" as investigations pertaining to customer-manager interactions broadly considered. For example, business research would

include work on public policy or on social welfare. In accord with the official AMA viewpoint (Marketing News 1985, p. 1) and the book by Myers, Massy, and Greyser (1980), I shall define "marketing research" as investigations intended to address managerial problems and to provide practical solutions or applications for marketing managers:

A basic assumption adopted by the ERDMM Commission... was that the broad purpose of knowledge development in marketing should be to improve, or make more effective, marketing management. Marketing's R & D system, it can be argued, has this as its fundamental goal (pp. 143-144).

Finally, I shall define "consumer research" as investigations that address issues dictated by their relevance to consumption phenomena (e.g., acquiring, using, disposing, etc.) and that contribute managerial applications, if at all, only incidentally or even by accident. Notice that, as just defined, business research encompasses all or most marketing research and some consumer research, while consumer and marketing research may overlap in content but differ fundamentally in purpose.

I cannot insist strongly enough on two points: (1) that I agree with the generally prevailing articulation of the purpose for marketing research and (2) that I view consumer research as having a different objective--namely, to understand consumption behavior in the acquisition, usage, and disposition of products (goods, services, and other consumable events). Here, I freely admit that there is some tendency for much consumer research to be or to become relevant to the decisions of marketing managers. I only wish to claim that, whatever its relevance to practitioners, managerial applicability does not serve as its primary motivation nor its main intention. The fundamental purpose for consumer research (in my definition) is to understand the nature of consumption behavior broadly conceived. From my perspective, this view should serve as our window on the world. It is like the contact lens through which we observe reality. But, like a contact lens, it easily gets misplaced. We must guard it carefully. And if, perchance, we drop it, we must bend and search for it before we lose it or someone else tramples it under foot.

Anyone who has agreed, even partially, with my comments to this point must surely have reacted with alarm to ACR's 1985 Call For Papers (Lutz 1985).

But, oh! the heavy change, now thou art gone,
Now thou art gone and never must return!....
As killing as the canker to the rose,
Or taint-worm to the weanling herds that graze,
Or frost to flowers, that their gay wardrobe wear,
When first the white-thorn blows;
Such, Lycidas, thy loss to shepherd's ear
("Lycidas," 11. 38-49).

In the 1985 ACR Call For Papers, Rich Lutz (1985) offered "some thoughts on the 'state of the association,'" echoed Sheth's (1985) concern that "ACR has lost some of the 'excitement' which was characteristic of the organization during the 1970's," suggested that "the pendulum has perhaps swung too far in the direction of broadening consumer research," argued that "what the field needs is more systematic attention to the 'core' of the domain rather than its fringes," specified that "the core of the domain of consumer behavior rests both empirically and definitionally on the effects of marketing activities on consumers," and concluded:

Accordingly, I would like to offer another potential remedy to those which have been discussed in the past and hereby actively solicit papers, special sessions and workshops devoted to the study of the effects of marketing variables on consumer behavior (p. 5).

This hard-core theme (including an apparently pejorative use of the term "fringe") was soon picked up and echoed by Rich Yalch (1985) in his departing editorial for the ACR Newsletter:

It seems to me that ACR has gone through phases that basically correspond to the interests of the members who have formed the heart of the Association since its beginning. At present, these individuals (and hence the association) seem lost.... The need for variety characteristic of cognitively complex individuals seems to be motivating radical proposals for how the discipline should approach consumer research and what constitutes important areas of interest.... In addition to being skeptical of the contribution of this endeavor, my concern is that younger, impressionable members of the discipline might mistake the leaders' temporary disinterest with the discipline's core areas of research and fascination with the fringe areas as evidence of a major paradigm shift.... However,...the focus will remain on the purchase behavior of the "shopper" in the household for common consumer goods and services (p. 2).

Surely, these polemics by Lutz and Yalch constitute an "Embarrassment of Riches." It seems clear (from my own biased position) that these two scholars have been listening to the same muse--one that issues bad advice. How can this have happened?

But now my oat proceeds,
And listens to the Herald of the Sea,
That came in Neptune's plea.
He asked the waves, and asked the felon winds,
What hard mishap hath doomed this gentle swain?
("Lycidas," 11. 88-92).

In my admittedly idiosyncratic view, three sirens of the deep have been calling to the two ACR leaders. Lutz (1985) describes these three siren songs quite specifically as his three major assumptions:

- (1) ACR was conceived of, founded by, and continues to be dominated by marketing academics (approximately 80% of the current membership);
- (2) Consumers would have little to "consume" were it not for the activities of marketers....
- (3) It is entirely possible to conduct scholarly, scientific research on the effects of marketing variables on consumers (p. 5).

All three assumptions strike me as either untenable or irrelevant to the issue at hand. First, while the perspective of marketing management may once have dominated ACR, I doubt that it continues to do so. One's title as a marketing professor does not necessarily determine the content of one's thought processes. Further, many of us think that the participation of ACR members from other disciplines deserves expansion, not contraction. Seeking a hard-core marketing focus for the organization hardly seems likely to foster that end.

Second, as vividly articulated by Hattie, we should avoid the assumption that consumption depends exclusively or even largely on the activities of marketers. I doubt that Lutz really believes consumers would have little to consume without marketing. Only someone trying, like Polaroid, to sell us "a piece of the sun" would make that claim seriously.

Third, though scholarly work on marketing variables is indubitably "possible," it does not necessarily follow that it is "fundamental" to consumer research nor that such a focus should be proclaimed as our guiding light at ACR. Indeed, good reasons exist for thinking that scientific progress often moves fastest when it remains relatively independent from the pressures of various interest groups (Holbrook 1985b). Perhaps I may clarify this last

point by turning to an analogy drawn from another pastoral source--namely, baseball.

For we were nursed upon the self-same hill,
Fed the same flock, by fountain, shade, and rill;
Together both, ere the high lawns appeared
Under the opening eyelids of the Morn,
We drove a-field....
("Lycidas," 11. 23-27).

The Consumer Researcher Plays Left Field

In a classic comedy sketch, George Carlin contrasts the sports of football and baseball. The first emerges as pragmatic, tough-minded, and rapacious, the second as fun, tender-hearted, and gentle:

Baseball and football. Baseball is pastoral. Football is technological. Baseball is played in a park. Football is played in a stadium. Baseball... (pause)...has no time limit; we don't know when it's gonna end. Football is rigidly timed; and it will end, even if we have to go to sudden death. Baseball has the bunt. Football has the punt. Baseball's object is to go home.... In football, we are down in enemy territory, reaching for the end zone. In football, we have the block, the clip, the kick, the blitz, the bomb, the offense, the defense. In baseball, we have the sacrifice. And, in baseball, you make an error. In football, you pay a penalty. Woody Hayes wears a baseball hat during the football game. Can you imagine if Walter Alston wore a football helmet during the baseball game? They would truck him away, man (Carlin 1975).

Carlin's contrast vividly undercuts the analogy frequently drawn between business and football. Business does not resemble a football game, where the purpose is to bash, battle, and bruise the opponent into oblivion:

What is football...except eleven people who line up, beat the shit out of the other guys, and take their land? It's a ground-acquisition game (Carlin 1975).

Clearly, football--with its intent on destruction--resembles war, not business. Hence, the business strategists who dwell excessively on football and military analogies pursue the wrong metaphor. Rather, business is like a baseball game in which the sphere of action at any moment includes a batter, a pitcher, a catcher, some other fielders, and maybe some base-runners. In football, there is no meaningful analogy to the customer. In baseball, the batter corresponds to the business customer. The pitcher parallels the salesman. The catcher resembles the marketing manager. And the consumer researcher plays left field.

Consider, first, the batter. The batter stands at home plate and waits for his pitch. He is a discriminating customer. He does not want to expend his resources on a bad product. But, when he sees an offering he likes, he swings with it--or at least at it.

Meanwhile, the pitcher is a salesman--in the worst sense of that term, as embodied by Levitt's (1960, 1962) merciless critique of the selling orientation. The pitcher wants to persuade the batter to swing at a bad pitch. His art is deception, misrepresentation, and chicanery. As the consumer of pitches, the batter's best interests are directly antithetical to those of the pitcher. This tension was beautifully captured in a poem by Robert Francis (1976) called "Pitcher":

His art is eccentricity, his aim
How not to hit the mark he seems to aim at,

His passion how to avoid the obvious,
His technique how to vary the avoidance.

The others throw to be comprehended.
He throws to be a moment misunderstood.

Yet not too much. Not errant, arrant, wild,
But every seeming aberration willed.

Not to, yet still, still to communicate
Making the batter understand too late
(Gillman 1985, p. 32).

I do not wish to suggest that all or even most salesmen behave in the product-oriented manner of Levitt's selling orientation nor with the deception of Francis' baseball pitcher. But some do. And we should not blind ourselves to that fact either. Nor should we blithely assume that, as marketing manager, the catcher always strives to keep the pitcher honest. Often the catcher does ask the pitcher to throw strikes. But even the most artful spitballer needs a little help from his backstop. However, that is not the important point.

The important point is that the consumer researcher resembles an outfielder. As a scientist interested in explanation (why or how might the batter swing at the next pitch) and prediction (when and where will a fly ball come floating into the outfield), he focuses primarily on the customer. Watching the batter--his stance, his swing, how the ball leaves his bat, where the ball travels--becomes his chief preoccupation.

The outfielder is also an artist. He plays the key role in one of the most beautiful and awe-inspiring moments in all sports. I refer to the towering fly ball--the high arching trajectory--majestic in its soaring freedom, seemingly unfettered in its flight, apparently capable of a path that might take it anywhere but that just happens to take it, as if by magic, into the tiny crevice of the fielder's outstretched glove. Thus, the outfielder participates in a visual phenomenon that seems at once entirely surprising, yet somehow completely inevitable. Just as an artist creates unity-in-variety or resolution of departure from structure or order out of chaos (Holbrook and Zirlin 1985), the outfielder turns deviation into reconciliation and tension into resolution. In this capacity, he again resembles the consumer researcher engaged in theory development, who in turn resembles the artist engaged in creation (Holbrook 1984). And his motivation is essentially similar: joyful exploration of a phenomenon found fascinating, namely the batter's manner of consuming the product delivered by the pitcher or even the fungo hitter's manner of swatting fly balls when there is no pitcher at all. As Robert Redford said from his hospital bed in *The Natural*, "God, I love baseball." As Ernie Banks used to say nearly every time he came to the ball park, "It looks like a good day for a game; let's play two." In the unforgettable words of Roy Campanella, "To play baseball, you gotta have a lot of little boy in you."

So, when we say colloquially that an idea or a suggestion "comes out of left field," we may subconsciously mean something very closely linked to this image of the outfielder. We refer to something unexpected, divergent, or even wildly improbable that somehow magically fits. We refer to the liberating sense of fun suggested by the old Von Tilzer and Norworth song:

Take me out to the ball game;
Take me out to the crowd.
Buy me some peanuts and Crackerjacks;
I don't care if I never come back.

We refer to the vantage point of playfulness that informs all truly creative activity.

One example of these playful roots to creativity was brilliantly encapsulated in the following brief dialogue between Leopold, Adrian, and Andrew in Woody Allen's *Midsummer's Sex Comedy*:

Leopold: So, you're an inventor, eh?

Andrew: Hmm, a crackpot inventor. I help people with their investments until there's nothing left....

Adrian: You know, Andrew's invented a wedding present for you and Ariel.... Tell them about that.

Andrew: It's nothing.... It's a silly apparatus that takes the bones out of fish, you know. That's all. Or, if you prefer, you know, although there's no point to it, it puts bones into fish.

What a perfect nonconformist working of the mind on display! What a clear example of a thought from left field! Let's turn the handle backwards and see what happens. Ah, yes, it puts bones into fish, though this serves no useful purpose. What a marvelous evocation of the artist's ability to take intellectual risks, almost as if by faith or duty:

The responsibility...of the intellectual...(is) to try as best we can to live our convictions. I think the person who lives the risks of his conviction, of his passion...won't sizzle at the last judgment.... you leave any city rather than sacrifice to it what bit of truth possesses you or what you believe to be the truth (George Steiner, quoted by the *New York Times* 1985, p. 22E).

Many people have found--and sometimes lost--the same feeling in baseball:

I lost interest in spectator sports the day the Dodgers left Brooklyn, which was also the day I became a cynic. As a kid, I spent nearly every weekend--and almost all of my allowance--in the second tier at Ebbets Field cheering Gil Hodges, Roy Campanella, Jackie Robinson, Pee Wee Reese, Duke Snider and the rest of the great team. The Dodgers were the good guys in the terrible fight against hate and racism, and they seemed to say, somehow, that Brooklyn was a more humane, liberal and moral place than, say, St. Louis. They deserved our loyalty. Then one day they moved to Los Angeles for something as trivial as money. I have never again been to a professional sports event (Reinhold 1984, p. 38).

Reinhold's description of the disillusionment he felt when the Dodgers left New York for California reminds me of the way the Yankee fans responded to Reggie Jackson twenty years later. Jackson was a power slugger from Babe Ruth's hit-a-home-run-or-strike-out school of batsmanship. But Reggie would shy away from running into the fence when chasing a fly ball, would complain if asked to play the role of designated hitter so as to let a more talented fielder occupy right field, and would still demand ever higher salaries. Reggie finished by getting traded to the California Angels and by leaving the Yankee fans in a state of disenchantment.

Ay me! whilst thee the shores and sounding seas
Wash far away, where'er thy bones are hurled;
Whether beyond the stormy Hebrides,
Where thou perhaps under the whelming tide
Visit'st the bottom of the monstrous world....
Look homeward, Angel, now, and melt with ruth
And, O ye dolphins, waft the hapless youth
("Lycidas," ll. 154-164).

Sweet Lou Comes Home

Perhaps instructively, my own greatest baseball hero has been--not Willie Mays, Mickey Mantle, Hank Aaron, or Dave Winfield--but rather Sweet Lou Piniella, left-fielder for the New York Yankees during the last ten years

of his career. Other players have been fleet of foot (Mays), stronger in muscle power (Mantle), higher in batting average (Aaron), and much better paid (Winfield). But Sweet Lou was the quintessential ballplayer. Whereas his teammates resembled college professors (Reggie Jackson), TV comedians (Mickey Rivers), movie stars (Bucky Dent), gangsters (Goose Gosage), truck drivers (Don Mattingly), politicians (Tommy John), or dentists (Ron Davis), Lou Piniella looked like a baseball player and nothing else. With his square jaw, steady gaze, and incredibly smooth swing, he resembled the prototype; but, in spirit and love for the game, he approached the Platonic Ideal.

Lou would play in pain. Lou would cheerfully crash into the fence in pursuit of a fly ball. Lou would line a clutch single over the shortstop's head, time after time. Lou never hassled anybody about his salary. He simply took all the risks and tried with all his heart because he loved to play the game. As he approached the plate, the fans would begin a chorus of "Looo-oooo-oooo-oooo!" The fans loved Lou because Lou loved baseball. In a radio interview just after his final game, he declared:

It's been a lot of fun. It really has.... It's been a thrill.... I enjoyed it. I had goosebumps out there the whole day.... I play the game with emotion.... The fun I've had playing baseball will be with me the rest of my life.

This moment did not mean the end of Sweet Lou Piniella's career with the Yankees. A short time later, on "Lou Piniella Day" at Yankee Stadium, he told his fans, "This is not a farewell, this is only a hello," and added, "The good thing is that I'm not going anywhere." Indeed, he has remained and has returned for another year as batting instructor and coach. During games, he has sat on the bench at the right hand, first, of Yogi Berra and, more recently, of Billy Martin. When Martin was injured in Texas, Piniella filled in as manager. He is widely regarded as Martin's likely and logical successor in that role. It appears that, far from fading into oblivion, Sweet Lou has come home.

Weep no more, woeful shepherds, weep no more,
For Lycidas, your sorrow, is not dead,
Sunk though he be beneath the watery floor.
So sinks the day-star in the ocean bed,
And yet anon repairs his drooping head,
And tricks his beams, and with new-spangled ore
Flames in the forehead of the morning sky
("Lycidas," ll. 165-171).

The Shepherds Weep No More

As I began by saying, my story needs a hopeful ending. We have talked about Hattie and the Baltimore Sun, about Sweet Lou Piniella in left field, and about the consumer researcher as Lycidas sunk beneath the watery floor of managerial relevance. All three metaphors permit optimistic resolutions. The sun sinks, but rises again tomorrow morning. Sweet Lou retires but comes home as the Yankees' batting coach. Similarly, Lycidas dies but can himself be brought back to life:

Now, Lycidas, the shepherds weep no more;
Henceforth thou art the Genius of the shore,
In thy large recompense, and shalt be good
To all that wander in that perilous flood
("Lycidas," ll. 182-185).

In response to the question "Whither ACR?," the members of this association have a choice. We can resurrect Lycidas, or we can bury him under the sea. We can celebrate the homecoming of Sweet Lou Piniella, or we can root for Reggie to hit another long one and milk the Angels for a few more points on his salary. We can strive to bring daylight back into the field, or we can simply announce that we are here to collect for the sun. Conversely, we can strive for managerial relevance in order to earn

some big consulting fees or to win some big research grants, or we can try hard merely because we love to play consumer research.

My own personal preferences lean heavily toward the latter possibility. I believe that consumer research must put the consumer at its center and that for us marketing is, at best, peripheral and parasitic on the role of consumer behavior. I believe that consumers are as central to business as are managers. I believe that both deserve study, but that some have chosen to put the former first, that those people call themselves consumer researchers, and that they live here--here at ACR, where we must always remember that our focus on the consumer takes precedence, that marketing variables attain importance only on that basis, and that, far from damaging or misleading our field of inquiry, this focus continues to serve as its main source of interest and inspiration, its spring of wonderment and delight.

Finally, I want to close by thanking the participants in this session entitled "Whither ACR?" Together, their efforts have shown: (1) that real differences still exist in the views of ACR members on the purpose(s) of the Association; (2) that answers to the question "Whither ACR?" will depend on how we approach and perhaps eventually reconcile these differences; (3) that our cooperative effort to make these differences clear may have moved us as far as we can presently go toward reaching a consensus; and (4) that it may therefore be time to put the issue back in mothballs for another ten years or so until we can more closely approach some kind of resolution.

Thus sang the uncouth swain to th' oaks and rills,
While the still morn went out with sandals grey:
He touched the tender stops of various quills,
With eager thought warbling his Doric lay;
And now the sun had stretched out all the hills,
And now was dropped into the western bay;
At last he rose, and twitched his mantle blue:
To-morrow to fresh woods, and pastures new
("Lycidas," ll. 186-193).

THE EFFECTS OF ALCOHOLIC BEVERAGE ADVERTISING AND MARKETING PRACTICES:
THE CURRENT STATE OF AFFAIRS

Edward T. Popper, Northeastern University

Abstract

This paper addresses the current controversy over the effects of alcoholic beverage advertising focusing on the need for valid research in the area. Based on a literature review that highlights the current lack of relevant research the paper discusses the methodological problems confronting researchers in this area and presents a series of research opportunities.

Introduction

On April 16, 1985 the Federal Trade Commission (FTC) rejected a petition from Center for Science in the Public Interest (CSPI) which had requested increased regulation of alcoholic beverage advertising. In rejecting the petition the FTC stated that they found "no reliable basis on which to conclude that advertising significantly affects alcohol abuse. Absent such evidence, there is no basis for concluding that rules banning or otherwise limiting alcohol advertising would offer significant protection to the public (Rock 1985)."

Obviously the FTC rejection of the CSPI petition is not the end of the alcoholic beverage advertising controversy. However, the basis for the rejection highlights a central issue facing all regulators (and legislators) in this area ---the near total lack of valid and reliable research on the effects of alcoholic beverage advertising. Until this research vacuum is filled the controversy is likely to be characterized by adversarial posturing rather than reasoned analysis.

The purpose of this paper is to stimulate research in an area that provides researchers with an opportunity to contribute to an issue of pressing public concern as well as to confront significant methodological challenges. In order to provide the context for the research issues, the paper will, first, briefly describe the current public policy debate (highlighting the role of research in the various proceedings). Next, the paper will review the current state of research in the area (including both consumer and economic research). Following the literature review will be a discussion of the methodological issues confronting researchers in this area. Finally, the paper will address some of the research needs and opportunities in the area of the effects of alcoholic beverage advertising.

The Current Controversy

The sales and advertising of alcoholic beverages have been controversial since the repeal of prohibition. However, the controversy had traditionally focused on the sale of the product rather than advertising and other marketing practices with the principal advertising control being the voluntary NAB ban on advertising for distilled spirits. In recent years this has changed as some states have limited or banned broadcast advertising of any alcohol beverages (i.e., Mississippi and Oklahoma) and other states limited certain promotional practices (for example, in 1984 Massachusetts banned happy hours).

On November 21, 1983 this controversy was brought to the FTC in the form of a petition from CSPI (and cosigned by approximately thirty other organizations and individuals) requesting that the FTC act against alcoholic beverage advertising. Among the requested actions were a ban of all alcoholic beverage advertising, promotional, and marketing practices that: were aimed at or reach large numbers of youth or heavy drinkers; use athletic, show business or music celebrities; depict alcohol use in connection with risky activities; use subliminal techniques; link consumption of alcoholic beverage consumption with social, sexual,

or business success or athletic prowess; encourage excessive consumption; and/or discourage the treatment of alcohol abuse. The petition also requested that any remaining print advertising for alcoholic beverages be required to include one of a series of rotational warnings (Jacobson *et al* 1983, pp. 21-24).

While the CSPI petition provided a limited amount of empirical support for its request it contended: "While the available literature does not demonstrate a causal connection between (alcoholic beverage) advertising and harm, the evidence is sufficient to justify a Commission action in light of the disastrous health and social consequences of alcoholic beverage consumption (Jacobson *et al* 1983, p. 20)." The petition went on to describe the allegedly unfair and deceptive techniques in great detail without providing empirical data on the effects (or even interpretation) of those techniques. The petitioners supplemented their argument by presenting a monograph, *The Booze Merchants*, prepared by CSPI which purported to analyze the advertising and marketing practices of the alcoholic beverage industry (Jacobson, Atkins and Hacker 1983). While the monograph provided a number of examples of alcoholic beverage advertising the interpretation of its effects appeared to be based solely on the authors' subjective judgments rather than any empirical research.

The FTC's initial response to the CSPI petition was to instruct its staff to undertake a careful review of the petition and its charges and to make a recommendation to the Commission. The report resulting from this investigation recommended that the petition be denied (Levine *et al* 1985). The Commission Staff took the position that given that alcoholic beverage consumption was legal and might even have some beneficial effects when consumed in moderation (c.f. Gordon and Gordon 1984) simply demonstrating a linkage between alcoholic advertising and consumption of alcoholic beverages would be insufficient. Rather, it would be necessary to demonstrate that the advertising resulted in alcohol abuse.

The FTC staff report (Levine *et al* 1985) included a detailed review of the literature (including that research cited in the CSPI petition) which concluded that there was insufficient reliable evidence linking alcoholic beverage advertising causally with consumption, much less abuse. Indeed the report cites a number of aggregate studies that actually fail to show any relationship between advertising and consumption (Levine *et al*, Appendix, A, p. 10).

While denying the industry wide bans and rules requested by CSPI, the Commission indicated that it would "continue its ongoing review of alcohol advertisement and marketing practices to identify any that warrant challenge as deceptive or unfair under Section 5 of the FTC Act (Rock 1985). It is clear that the Commission's need for research evidence linking the advertising practice to alcoholic beverage consumption and abuse will be as critical in the case of an individual advertiser as it was in considering industry-wide intervention. Thus it might be inferred that without such research future FTC action is unlikely.

At the same time as the FTC was considering CSPI petition, the anti-alcoholic beverage advertising forces were opening a second front. An organization called SMART (an acronym for Stop Marketing Alcohol on Radio and Television) was organizing a petition drive on Congress. Organized by many of the same groups who were co-signers of the CSPI petition to the FTC, SMART was attempting a major grass roots lobbying effort aimed at convincing Congress that their constituents wanted an end to broadcast alcoholic beverage advertising. As of this writing congressional hearings on the anti-alcohol advertising issues had not been scheduled but were clearly in the works.

Another Federal agency that is currently addressing issues of alcoholic beverage advertising is the Bureau of Alcohol Tobacco and Firearms (BATF). An arm of the US Department of the Treasury, the principal alcohol related task of BATF is the collection of alcohol taxes. The BATF also is the Federal agency with statutory authority to regulate alcoholic beverage advertising. In this role they issue Trade Rules and Regulations (for example, the long standing ban on active athletes in alcoholic beverage advertising is a BATF rule) and preclear all voluntarily submitted alcoholic beverage advertising (by way of contrast, the FTC will not preclear any advertising both as a matter of policy and in an effort to avoid prior restraint of speech).

The BATF has had an ongoing rulemaking proceeding, since 1978, examining essentially the same issues as those raised in the CSPI petition to the FTC. Indeed the BATF was the recipient of a nearly identical CSPI petition. In the seven years that the BATF has been engaged in their current rulemaking there has been little indication of progress towards arriving at a rule (with the exception of a 1984 ruling reaffirming the BATF's support of nonmisleading advertising and a proposed rule banning subliminal advertising). However, the agency has indicated that it intends to actively pursue a rulemaking incorporating industry self-regulatory codes into their rules (George 1984).

Although neither the US Congress nor the BATF faces the same evidentiary burdens as a law enforcement agency like the FTC it is unlikely that either legislative or regulatory action will be based on pure emotion. While both the Congress and the BATF will undoubtedly receive impassioned appeals from parties to all sides of the issue their conclusions will certainly be influenced by the quality of support furnished. Unfortunately, as the next section of this paper will summarize, neither side will have good support to offer.

The Present State of Research

Mirroring the policy questions this brief review will address the following issues: first, does alcoholic beverage advertising result in increased alcoholic beverage consumption (or attract new users)? Next, what is the relationship between alcoholic beverage consumption and abuse and what is the role of advertising in this process? Finally, the review will examine the relevance of other research into advertising effects.

In 1976 a Rand Corporation study concluded that there was a total lack of empirical evidence on the relationship between media advertising and alcoholic beverage consumption much less abuse (Comstock 1976). Unfortunately, as of 1985, there has been little change in this situation.

Since the methodological problems confronting researchers looking at the alcoholic beverage advertising - consumption link are less severe than those relating to the advertising - abuse link (see discussion in the next section) most of the existing research has addressed this question. In one of the few internal industry studies of the effects of alcoholic beverage advertising on consumption to be made public, Ackoff and Emshoff found that while a 50% increase in advertising for Anheuser-Busch resulted in a 7% sales increase a 25% decrease in advertising resulted in a 14% sales increase (1975).

Given the applicability of statistical analysis of aggregate industry data to the advertising-consumption question a number of researchers have pursued this approach. Most of these researchers have failed to find a positive relationship (Grabowski 1976; Bourgeois and Barnes 1979; Ashley et al 1980; McGuinness 1980; Duffy 1982; Hagen and Waterson 1983) between alcoholic beverage advertising and consumption. Unfortunately, many of these studies have limitations that, while in no way undermining their validity, reduce their applicability to the issues facing US policymakers. Many of the studies (e.g. Bourgeois and Barnes; Duffy; Hagen and McGuinness) draw their data from countries other than the US. Given the cultural variations in both the consumption of alcoholic beverages and the exposure to

advertising/media it is not possible to reject the hypothesis that the advertising/consumption relationships in another country are different than in the US without supporting data. These studies provide no such data. Further, all of the statistical studies examine the effects of incremental advertising expenditures. Given that policy makers are examining a total ban, incremental data have only marginal relevance. Finally, Ashley, et al, not only fail to find a causal relationship between advertising and consumption, they find evidence of a causal relationship between consumption and advertising (a not too surprising given the tendency of some advertisers to set advertising budgets as a percentage of sales).

Another research approach has been the small scale experiment in which a small number of subjects is exposed, under controlled conditions, to advertising for an alcoholic beverage and then their subsequent consumption is monitored (McCarty and Eging 1983; Kohn and Smart, 1984; Kohn et al 1984). Only Kohn and Smart found even a temporary effect on consumption and none found an enduring effect. Once again these findings can have only limited relevance to the policy issues (in spite of their internal validity) in that the brief exposure to advertising and the unnatural research environment cannot be readily generalized to the environment in which most advertising exposure and alcoholic beverage consumption occurs. Indeed, the McCarty and Ewing study uses a method so contrived that serious questions can be raised as to the validity of the study. Finally, as will be discussed in greater detail below, one must question the ethicality of experiments in which subjects are induced to consume alcoholic beverages.

A final stream of research into the effects of alcoholic beverage advertising on consumption, content analysis, will be discussed only in passing as it isn't directly relevant to any of the public policy issues. Some of the researchers in this stream appropriately use content analysis to objectively report what themes, illustrations, or situations appear in alcoholic beverage advertising (e.g. Strickland et al 1982). Others use this methodology far more cavalierly, inferring advertiser intent and advertising effect in the complete absence of data supporting such inferences (e.g. Defoe and Breed 1979; Marsteller and Karnchnapee 1980). An unfortunate consequence of this latter type of research is that it appears both superficial and adversarial, thus subjecting all research considered in public policy settings to higher levels of scrutiny (a result which, in the final analysis, might benefit both researchers and policymakers).

It is obvious that there is a relationship between alcoholic beverage consumption and alcohol abuse. Without consumption there can be no abuse. This is not to say, however, that there is a causal relationship between consumption and abuse. A majority of the people who drink alcoholic beverages in the United States could be termed moderate (or social) drinkers---not alcohol abusers (US Dept. of the Treasury and US Dept. of Health and Human Services 1980). Thus consumption leading to abuse is the exception---not the rule.

If alcoholic beverage consumption does not inexorably lead to alcohol abuse, than it is clearly insufficient (given the current public policy debate) for researchers to look only at the advertising-consumption question. Rather, researchers interested in supplying public policy makers with relevant data must examine the relationship between alcoholic beverage advertising and alcohol abuse. Unfortunately only a very few researchers have attempted to confront the methodological obstacles and complexities to work in this area.

One of the largest studies of the effects of alcoholic beverage advertising attempts to address some of the issues surrounding effects on alcohol abuse (Atkin and Block 1980) also is one of the most controversial. While the study indicates relationships between alcoholic beverage advertising and both consumption and abuse it has been criticized by the FTC staff report (Levine et al 1985), the researcher who was the government's technical officer

on the study (Mizerski 1980), and other researchers (Strickland *et al* 1982, pp. 659-660; Strickland 1984; Kohn *et al* 1984, p. 36). The criticisms of this report focus on sampling problems, the weaknesses of self-report data (particularly in the area of alcoholic beverage consumption), inadequate measures, inappropriate causal inferences, and statistical weaknesses. The FTC staff concluded: "it is impossible to make any meaningful statements about the effects of alcohol advertising on alcohol consumption based on Atkin and Block's results" (Levine *et al* 1985, Appendix A, p. 39). Strickland *et al* (1982) and Strickland (1984) are troubled by atkin and Block's use of content analysis, particularly when that use goes beyond content and attempts to infer advertiser intent.

It is particularly troublesome that in spite of Atkin and Block's clear statements of the limitations of their study (i.e. Vol. 1, p. 1) they frequently contradict these stated limitations and speak of effects in causal terms (i.e. Vol. 4, p. 2). Obviously, no study can be perfect. However, when authors go beyond the stated limitations of their research the objectivity of the work has to be questioned. Unfortunately, these questions undermine the otherwise valuable contributions of an important exploratory study.

A final study to be discussed (Strickland, 1981) found "advertising...to have meager effects on the level of consumption and these effects rarely translated into effects on alcohol problems" (p. 32). Unfortunately this study's total reliance on self report data undermines its results (particularly since its author not only neglects to mention any of the problems associated with self-report data but, instead, says that the strength of his findings are supported by the study's "methodological adequacy").

This brief review has demonstrated that researchers in the area of the effects of alcoholic beverage advertising are plagued by the methodological complexity of the area. The next section will focus on those methodological issues.

Methodological Issues

To provide data that is useful in a public policy forum presents methodological challenges more severe than those typically facing an academic researcher. Key among these is the need for maximizing external validity without destroying internal validity. Obviously there is a tradeoff between these two forms of validity. However, the policy maker require external validity to a greater extent than the theorist. At the same time the resulting reductions in internal validity can provide meaningless data. Clearly, researchers in this area need to make hard choices (as do all researchers). However, unlike other research settings, the policy arena requires that the researcher explicitly state the limitations of the study (both internal and external). Otherwise the less sophisticated policymaker may misapply the findings and the research may be labeled adversarial.

While there are a wide range of additional methodological issues that researchers in this area must address this paper will briefly touch on three of them: causal designs, ethical issues, and self report measures. The need for causal designs is a direct result of the policy issues. Obviously, it is inappropriate to apply correlational data to these issues since reverse causality is often a valid and viable explanation. Unfortunately, this eliminated many useful research methods including much of econometric analysis.

This area also raises serious ethical questions for the researcher. To what extent can researchers causally examine the advertising abuse (or even consumption) link without actually attempting to induce consumption? This problem becomes particularly acute for researchers attempting to investigate advertising effects on alcohol abusers. Clearly, in this area researchers must be particularly attuned to the effects of their research on their subjects.

A final methodological issue to be addressed is the use of self report measures. Many of the studies described above

have been widely criticized for their use of self-report measures of advertising exposure, alcoholic beverage consumption, and abuse. Given the well documented tendency for that method to systematically over and/or understate responses (e.g. Clancy *et.al.* 1979) it is clearly inappropriate when studying such sensitive issues as alcoholic beverage consumption and abuse. Unfortunately, few alternatives exist. Thus, an early issue for researchers to address is the development of more reliable measures.

Research Opportunities

As the review of the literature in the area of effects of alcoholic beverage advertising has demonstrated, there exists little credible research evidence regarding these effects. This is not to say that there are no effects. Rather, the current state of research in this area is so poor, it is not possible to ascertain what effect this advertising has.

As various government agencies consider a range of rules that would govern alcoholic beverage advertising it is possible that consumer research could provide valuable inputs to the proceedings. This potential research falls into two categories: general and specific.

Underlying all regulatory considerations in the area of alcoholic beverage advertising is the fact that alcoholic beverages can be (and frequently are) abused. Thus, requests for the banning of certain advertising and/or promotional practices are often based on the allegation that the practice leads to alcohol abuse. As the literature review demonstrated, there currently exists no research support for this allegation. Therefore, the general research question of whether alcoholic beverage advertising has an effect on alcohol abuse is an appropriate question for consumer researchers to address.

The question of what effects alcoholic beverage advertising has on alcohol abuse is remarkable complex and will require considerable research effort. It is not even clear that existing research methodologies are appropriate for addressing this question. Thus, an early stage in the research process would be to have researchers address the methodological question itself. One avenue for this might be an interdisciplinary research conference bringing researchers together (including researchers who had never worked in this area), updating them on the state of current research, and exposing them to the methodological problems and concerns in the area. The output of such a conference could be twofold: first, new methodological options and approaches could be considered; second, the conference could be expected to stimulate researchers to begin working in the area.

Before the question of the potential abuse related effects of alcoholic beverage advertising can be considered, a preliminary question must be addressed: whether alcoholic beverage advertising leads to alcoholic beverage consumption. Obviously, if alcoholic beverage advertising does not lead to consumption (or increase existing levels of consumption) it cannot lead to abuse. This could be an important distinction, since research on the question of consumption effects may be less formidable, methodologically, than research on abuse effects. While a finding that alcoholic beverage advertising resulted in (or could result in) increased alcoholic beverage consumption would be insufficient to conclude that such advertising led to abuse, a finding that no consumption effect existed would imply the lack of an abuse effect. Thus, the general research question that might be addressed first is what effect alcoholic beverage advertising has on consumption of alcoholic beverages. Only if that research indicated the existence of a consumption effect would research into the abuse related effects of alcoholic beverage advertising be necessary.

The general research projects described above can be expected to be long term efforts, spanning a number of years, and, because of the complexity of the research, it is likely that any results will be controversial and require

replication by a number of researchers. Because of the currency of regulatory interest on issues relating to alcoholic beverage advertising, it would be useful if research were conducted that might shed light on specific issues even if some of the general questions were left unanswered. Carefully conducted copy research might provide a useful source of more readily accessible information on those narrower issues.

Copy research cannot address the broad issues of the effects of advertising on alcoholic beverage abuse and/or consumption. These issues are behavioral and copy research (with the exception of quite complex research systems) is not an appropriate source of behavioral data. However, copy research is appropriate for examining the the communications effects of an advertisement (or an advertising campaign). Further, copy research can provide a surrogate measure of behavior by measuring whether one of the communications effects of an advertisement is to change behavioral intent. Finally, copy research can provide causal data. That is, it can demonstrate that the communication effect that was observed was actually caused by the ad.

The copy research that is suggested here can also aid in the pursuit of the general research questions described above. Without a measure of what is communicated by an advertisement it is impossible to measure the behavioral effects (i.e., consumption and/or abuse of alcoholic beverages) that might result from that advertising. Finally, the copy research may provide researchers with the opportunity to test the methodological approaches they are developing.

FREQUENCY INFORMATION AS A DIMENSION OF
CONSUMER KNOWLEDGE

Joseph W. Alba, University of Florida
Howard Marmorstein, University of Florida

Abstract

An often ignored aspect of knowledge -- knowledge about event frequency -- is discussed in terms of consumer decision making. A brief description of frequency theory is provided and some speculations about how frequency knowledge might affect judgment and choice are offered. Finally, a preliminary experiment is presented which demonstrates that frequency knowledge can dominate more important information when consumers form price images of retail stores.

Introduction

Until recently, researchers had been more concerned with the effects of consumer knowledge on consumer behavior than on the nature of consumer knowledge itself. Though such an orientation directly addresses the questions that are most relevant to real-world behavior, it carries with it the inherent danger of fostering simplistic conceptualizations and measures of consumer knowledge (e.g., product familiarity, product ownership). Not surprisingly, attempts to explore the nature of consumer knowledge have revealed it to be complex and multidimensional (Alba and Hutchinson 1985; Kanwar, Olson and Sims 1981). Moreover, recent research that has incorporated a multidimensional perspective has shown that the effects of consumer knowledge on consumer behavior are a function of how that knowledge is operationalized (Brucks 1985; Brucks, Mitchell and Staelin 1984; Punj and Staelin 1983).

An analogous situation exists with regard to the learning of new information. That is, traditional measures of consumer learning constitute a fairly narrow set. Though numerous variations exist, most measures consist of some form of aided or unaided recall. The focus of these recall tests often is on memory for the substantive facts presented in a promotional message or information display board. In many cases, these measures are the most appropriate and informative ones available. Judgment and choice often are based on the specific facts one can recall about alternative brands, and recall and recognition of brand-attribute facts represent reasonable measures of what a consumer has learned about them. However, problems lie in the exhaustiveness and sensitivity of these measures.

In this paper we wish to make the point that there are aspects of knowledge that contain little semantic detail about the characteristics of a brand or the content of a message, but nonetheless contain information relevant to consumers' decisions. We will discuss one such aspect, namely, the knowledge consumers have about brand and attribute frequency.

Frequency Knowledge

The notion that people are attentive to the frequency with which events occur in the world is not new. There now exists a considerable amount of research demonstrating that people are highly sensitive to the frequency with which even very mundane and innocuous events occur, both in real-world and laboratory settings. Moreover, this research has identified some peculiar characteristics of frequency knowledge which suggest that the learning of frequency information is an automatic process. Within the context of the Hasher and Zacks (1979, 1984) theory of automaticity, this implies that the process of encoding frequency information (a) operates continually, (b) cannot be improved by practice, (c) cannot be willfully inhibited, (d) does not require

conscious awareness, and (e) drains minimal amounts of cognitive resources. As Hasher and Zacks report, empirical support for each of these assertions has been found. It has also been shown that, due to its unique mental representation, once frequency information is encoded it may be less susceptible to interference than other types of knowledge (Hintzman, Nozawa and Irmscher 1982). These traits suggest that frequency knowledge may represent a particularly important aspect of memory when information is presented under conditions characterized by low involvement or high information load.

Frequency knowledge is important also from a measurement perspective. As noted, people may learn and remember information concerning the frequency of events without being able to recall the exact nature of those events (cf. Pitz 1976). Inasmuch as one major goal of marketing research is to assess what consumers know about products, a significant underestimation of consumer knowledge may obtain if a researcher measures only recall for specific brand and attribute information. Sounding a similar theme, Singh and Rothschild (1983) have argued that simple recall measures understate memory for an advertisement; they call instead for greater use of recognition measures. It is our contention that tests of frequency memory may tap an additional and unique aspect of knowledge.

What Might Consumers Count?

Assuming that people are sensitive to event frequency, the next issue concerns the nature of an event. That is, what can and what do people count? Below, we speculate about events that are pertinent to consumer behavior.

Individual Objects. The majority of research demonstrating frequency knowledge has dealt with the frequency of single sterile events such as individual words in a longer list of words. Typically, subjects are shown a word list, in which some words are repeated various numbers of times, and are asked to estimate the number of times each critical word appeared. However, extensions of this paradigm to less sterile situations have proven successful. For example, people's sensitivity to the true relative frequencies of real-world occupations and lethal events has been shown to be surprisingly accurate (Lichtenstein, Slovic, Fischhoff, Layman, and Combs 1978).

In a marketing context, there are numerous events that, if counted, could influence perceptions of a product, even if the details of the product cannot be retained. For example, consumers may be sensitive to the relative frequencies of different brands they observe. Such knowledge might lead to beliefs about the relative popularity of different market offerings. These beliefs about market share, in turn, might lead to further beliefs concerning quality (cf. Duncan and Olshavsky 1982). And, for consumers who have a high need for conformity, frequency knowledge might lead directly to purchase.

Similarly, consumers may have an implicit understanding of the frequency with which advertisements for different brands appear. Such knowledge could lead to inferences about market share, company size, and company stability. Moreover, if research can establish the accuracy of such knowledge, frequency estimation could be used as a direct measure of advertising exposure and impact.

Frequency counting, however, may not be limited to mere objects or events such as brands and advertisements. It

may also apply to attributes associated with those objects or events. For example, a consumer's price image of a store might be influenced by the consumer's perception of the number of sale items and/or sale periods promoted by that store. The consumer's rankings of competing stores along a price dimension might then be determined by inter-store comparisons of the aforementioned frequencies. Such impressions may be formed without effort or conscious counting and may exist independently of the details of each store's prices.

This is not to say that details cannot be counted. Attributes are objects and, as such, may be subject to counting. Consider a recent study by Malmi and Samson (1983). They presented to subjects a range of numbers and asked for an estimate of the mean value. Results showed remarkable accuracy regardless of the skewness and mode of the distribution of the numbers. Further investigation suggested that subjects had constructed in memory a frequency distribution and had derived the mean by estimating the balance point. Generalizing this finding to knowledge of prices, it may be the case that, without conscious intention to do so, consumers learn the price distribution of a brand across stores or over time; the price distribution of different products within a store; or the price distribution of all brands within a product category. Distribution information could then lead to beliefs about the central tendency of a category and the deviation of particular brands.

Semantic Categories. In addition to a sensitivity to the frequency and distribution of individual items within a category, a small amount of evidence suggests that people directly tally the number of times a category has been encountered when they have been exposed only to exemplars of that category (Alba, Chromiak, Hasher, and Attig 1980; Barsalou and Ross, forthcoming). For example, after being presented with particular names of animals, trees, etc., people can state with accuracy the number of times each category was encountered without appealing to memory for the individual instances. Though we would expect this result to generalize fairly well to product categories, a more interesting but unexplored question concerns the case of attribute categories. For example, the abstract category of "comfort" in the context of an automobile can be instantiated by such attributes as bucket seats, plush carpeting, leg room, and so on. When presented with such features, do consumers automatically encode and tally them as comfort features? The answer may depend on the degree of association between the features and their category. To the extent that consumers do tally such information, they may automatically form impressions of how a product rates on its major dimensions. And, such knowledge may endure while specific information decays.

Evaluative Categories. With respect to decision making, one of the most important types of frequency counts a consumer can make involves evaluative categories. Here the issue is whether consumers tally the number of desirable and undesirable attributes associated with a product, irrespective of the exact meaning of those attributes. Research on this question is sparse, but at least one set of studies suggests that consumers may be sensitive to such information (Alba 1985). More importantly, there is a recent but growing body of evidence demonstrating that, once encoded, such information can drive judgment and choice even in the presence of more relevant and important information.

Consider, for example, research on message persuasiveness. Chaiken (1980) has demonstrated that when subjects are highly involved and the message arguments are relevant, persuasion is positively related to the number of arguments favoring a particular position (cf. Assam and Bucklin 1973). This finding by itself is not unexpected, inasmuch as message recipients should be more persuaded by many good arguments than by a few good arguments. However, Petty and Cacioppo (1984) demonstrated that argument number can dominate argument importance if subject involvement is sufficiently low. That is, many irrele-

vant arguments may be more persuasive than a few relevant ones if people do not process the information deeply. Thus, argument frequency may be considered a peripheral route to persuasion.

The importance of frequency has also been shown in choice contexts, as first suggested by Bettman and Park (1980). In their protocol analyses they noted that some subjects were prone to use a "counting" strategy, by which decisions were based in part on the number of good and bad attributes associated with each brand. Similarly, Russo and Doshier (1983) showed that binary choice decisions are sometimes based on a "majority-of-confirming-dimensions" heuristic. People who employ this heuristic choose the alternative that dominates the other one on the greater number of dimensions, sometimes at the expense of dimensional importance and the size of the interbrand differences on those dimensions. Further, the likelihood of adopting this heuristic seems to increase as the number of dimensions increases, and may also be related directly to the involvement and fatigue levels of the subjects.

Finally, consider the role of evaluative frequency in predictive judgment. The judgments consumers make about a product often involve predictions of its efficacy. Evidence suggests that when previous judgments have not been made and the outcome is uncertain, predictions about the likely occurrence of an event may be based partially on a comparison of the sheer number of reasons that can be generated for and against its occurrence (Hoch 1984).

Moreover, when a prior history of success and failure exists, it appears that prior event frequency greatly influences perceptions of future event probability (Estes 1976). That is, when making judgments of probability, people rely on the frequency rather than the proportion of times an event has occurred in the past. Though investigated in other domains, Estes notes the applicability of this finding to consumer situations. For example, when evaluating the preferability of two medicinal remedies, consumers may choose the one that has worked most often in the past, even though the two brands may have had an unequal trial rate. Estes suggests that the brand with the most successes will be chosen, even if its proportion of successes is lower than that of the competing brand.

Experiment

Though we believe that the encoding and use of frequency information is prevalent, much of what we have said heretofore with respect to consumer behavior has been speculative. Below, we present a preliminary study of the effect of frequency information on decision making. In particular, we examine evaluative category frequency in the context of memory-based consumer decisions. Further, we examine judgments that might be highly influenced by frequency information, i.e., judgments consumers make about the relative expensiveness of competing retail stores.

Briefly, subjects were presented with a list of grocery items along with the price of each item at several hypothetical stores. The critical comparison involved two of the stores, one of which was more expensive overall but cheaper on a greater number of items than the other one. To the extent that consumers use a frequency heuristic, they should describe the more expensive store as being the less expensive of the two.

Method

Stimulus. The stimulus was a two-page price advertisement which compared three supermarkets (A, B, and C) on 60 items. The price of each item at Store A was always nine cents lower than the price at the cheaper of the remaining two stores.

Of focal interest were the differences between Stores B and C. In 36 of the 60 cases (i.e., 60% of the items), Store C was cheaper than Store B. The mean advantage of

Store C on these items was eight cents. These price differences were distributed approximately symmetrically and varied from two cents to 16 cents. Store B was less expensive than Store C on the remaining 24 items. However, the mean difference in these instances was 33 cents. Moreover, when Store B was the cheaper of the two, the price difference ranged from 28 to 38 cents. Thus, the two distributions of price differences were nonoverlapping, making the differences maximally observable.

Overall, the 60 items cost approximately \$5 (or about 5%) more at Store C than at Store B, but it was more frequently the case that Store C was cheaper than Store B. The items were arranged in the list such that within each group of fifteen, Store C was cheaper on a random subset of nine of them. The specific price difference attached to each item was also randomly determined.

Procedure. Subjects were asked to imagine that they had recently moved to a new city and that price was important when choosing a supermarket. They were provided with the comparative ad and were told that they would have 90 seconds to examine each page of it. The experimenter emphasized that they should examine the information about all three stores carefully in preparation for some questions about the stores' prices.

At the end of the 3-minute study phase, subjects were asked to rank the stores in order of their relative expensiveness. They also were asked to estimate the total cost of the 60 items at each store. Finally, they were asked to explain how they had decided whether Store B or Store C was the more expensive of the two. At no time during this test phase were subjects able to re-examine the stimulus.

Subjects. A group of 30 undergraduate marketing students volunteered to participate in the study. Two of them failed to follow instructions and were eliminated from the analysis.

Results

Normatively, all subjects should identify Store B as being less expensive than Store C. Note that a correct response could result from either an accurate tally of the total price of each store or from reliance on the nearly four-fold difference in the average price difference between Stores B and C.

To the contrary, a significant proportion of subjects behaved in a counter-normative fashion. That is, 57% of the subjects identified Store C as the less expensive store. This figure is significantly different from zero ($p < .001$). Because subjects were almost equally split, the mean estimates of the total cost of items at each store did not differ, though both differed from the estimate for Store A.

It could be argued that subjects randomly chose between Stores B and C, resulting in a significant amount of counter-normative behavior. However, an examination of the reasons subjects gave for their choices does not support such a claim. Subjects were classified according to whether or not they employed a frequency heuristic. Of the 16 subjects who made the counter-normative choice, 10 clearly relied on frequency information; the remaining subjects did not articulate their rationale in a clear enough way to allow classification. Of the 12 subjects who correctly chose Store B, only 4 made reference to frequency. These 4 subjects either confused Stores B and C, leading us to underestimate significantly the effect frequency had in this study, or they used frequency as a rationalization for their choices. It is not possible to identify the true explanation at this time. Regardless, the results indicate that frequency information was a significant factor in the decisions made by a number of our subjects.

Discussion

The purpose of this paper has been to emphasize an aspect of knowledge that has been virtually ignored in consumer research. It is our contention that under many circumstances, particularly those that adversely affect information processing such as low involvement and high information load, knowledge of event frequency will play a significant role in consumer decision making. In cases in which other information is lacking, frequency knowledge will enable consumers to make decisions that are not completely arbitrary. In other cases, as in the present experiment or when advertisers intentionally manipulate frequency to overstate the advantages of their brand, frequency information may lead to suboptimal decisions.

PRODUCT FAMILIARITY AND THE STRENGTHS OF BRAND-ATTRIBUTE ASSOCIATIONS:
A SIGNAL DETECTION THEORY APPROACH

J. Wesley Hutchinson, University of Florida
Mike Zenor, University of Florida

Abstract

The theory of signal detectability (TSD) is applied to pick-any data for brand/attribute associations. It is argued that the pick-any methodology introduces a desirable form of item selection bias and the TSD method of analysis removes undesirable response biases. The assumptions of the methodology are presented and tested with exploratory data from the domain of non-prescription cold remedies.

Introduction

It is commonly assumed that there is a strong relationship between product familiarity and consumer knowledge (e.g., Bettman and Park 1980; Brucks 1985; Johnson and Russo 1984; Kanwar, Olson and Sims 1981; Punj and Staelin 1983). That is, one result of numerous encounters with product information (including purchase, usage and advertising) should be that consumers will learn more facts about the various competing brands. These facts are presumably represented in memory by corresponding associations between brands and attributes (Anderson 1983; McClelland and Rumelhart 1985). Under perfect conditions valid facts would be represented by strong associations and invalid facts would be represented by weak (or non-existent) associations.

In actuality, however, there is good reason to suspect that validity and strength of association will sometimes be at odds with each other. That is, through lack of involvement, lack of education, and/or misleading advertising, consumers may become confused about which brands have which attributes. Since associative strength is likely to be a major determinant of which facts will be accessed during decision making, it is important to know the extent to which validity and strength are correlated.

Measurement Issues

In cases which are designed to test general properties about consumer information processing, the specific brands and attributes investigated are typically either hypothetical or some small convenience sample of all possible brand/attribute associations in an existing market. The problem of whether such a sample will generalize to the total population of brands and attributes is often not given serious attention. One reason for this is that this population is extraordinarily large. For instance, consider non-prescription drug products (which will be discussed in greater detail later). The FDA has estimated that there are approximately 500 active ingredients distributed among approximately 300,000 brands. Thus, there are 150 million possible brand/attribute associations that may exist in consumer memory. Of course, only a small fraction of these are valid associations and an even smaller fraction are likely to be represented in memory for most consumers. In this sense, measuring consumer knowledge is rather like searching for the proverbial needle in a haystack. Therefore, it is of considerable theoretical and pragmatic value to be able to estimate, at an aggregate level, the amount and validity of consumer knowledge about various product domains. The remainder of this paper presents one methodological approach to this problem and illustrates its use in an exploratory study of the relationship between product familiarity and the strengths of brand/attribute associations for cold remedy products.

Using Pick-Any Data

The most straightforward approach to estimating consumer knowledge might be a test instrument such as a simple true/false test covering brand/attribute associations. This approach would require preselecting a subset of items that was somehow representative of the product domain. Great care would be needed in order to ensure that experimenter bias was not introduced by the selection procedure. An alternative approach that has been suggested for situations such as this is the use of pick-any data (Holbrook, Moore and Winer 1982). In particular, respondents might be allowed to choose the brands that they are most familiar with and then indicate the attributes they believe are possessed by those brands. This approach is especially appropriate for descriptive studies, such as the one reported later, because the respondents choices focus the data on the brands that are most likely to be in the realm of consideration during purchase. Thus, the use of pick-any data converts item selection bias from a liability to an asset.

Signal Detection Theory Analysis

In addition to the problem of item selection bias, there is great potential for response biases of various sorts to affect the measurement of brand/attribute associations. It seems likely that some attributes may be more frequently chosen or avoided in general, regardless of the strength of the association between that attribute and any particular brand. One methodology that has proven extremely useful in eliminating such biases is the theory of signal detectability (TSD; Baird and Noma 1978; Combs, Dawes and Tversky 1970; Green and Swets 1966; McNicol 1972). This approach assumes that respondents are trying to discriminate two types of events. The most developed domain for this method is psychophysics where the events are typically trials in which a stimulus was presented and trials in which no stimulus was presented. The goal of the methodology is to measure the sensitivity of the respondent to the presence of the stimulus unbiased by the respondents beliefs about the likelihood of such events or their predispositions to respond one way or another. This methodology is not limited to psychophysics, however, and has been recommended as a preferred method for measuring recognition memory as well (Murdock 1982; Srull 1984).

In the present context, the goal of the analysis is to measure consumer sensitivity to true vs. false brand/attribute associations. This application of TSD is illustrated in Figure 1.

FIGURE 1
An Illustration of the Theory of Signal Detectability as Applied to Brand/Attribute Associations

The associative strength of a given brand, a, and a given attribute, b, is assumed to be normally distributed random variable, Sab. Figure 1 depicts the probability distribution functions for a true association (SabT) and a false one (SabF). The TSD model assumes that people use associative strength to judge the validity of a brand/attribute association. There is considerable psychological evidence for the plausibility of this assumption in memory-based decision making (Atkinson and Juola 1974; Murdock 1982; Smith, Shoben and Rips 1974).

For pick-any data, it is natural to assume that an attribute is chosen for a given brand whenever its strength exceeds some criterion, or threshold (c in Figure 1). The probability that a given valid attribute will be chosen (referred to as a "hit") is given by the area to the right of the criterion under the p.d.f. for SabT. The area under the curve to the left of the criterion corresponds to the probability that a valid attribute will not be chosen (referred to as a "miss"). Similarly, the probability that a given invalid attribute will be chosen (referred to as a "false alarm") is given by the area to the right of the criterion under the p.d.f. for SabF, and the area under that curve to the left of the criterion corresponds to the probability that an invalid attribute will not be chosen (referred to as a "correct rejection").

The TSD model assumes that response bias results in raising or lowering the criterion, but does not alter the strength distributions for the two types of associations. Therefore, the difference between the means of the two distributions (referred to as d') is an unbiased estimate of sensitivity. If the two distributions are assumed to have equal variances, then d' can be estimated as follows:

$$d' = ZH - ZF = \bar{S}abT - \bar{S}abF \quad (1)$$

where ZH and ZF are the z-score transforms of percent hits and percent false alarms, respectively. Moreover, correct choices will be maximized when the likelihood ratio, $\beta = HT/HF$, of the two distributions at the criterion is such that

$$\beta = p(F)/p(T) \quad (2)$$

where p(F) and p(T) are the base rate probabilities associated with false and true associations, respectively. The subjective value of hits (VH) and correct rejections (VCR) and the subjective costs of false alarms (CFA) and misses (CM) may vary depending on the situation, however. Under such circumstances, optimal β is given by

$$\beta = \frac{p(F) \times (VCR + CFA)}{p(T) \times (VH + CM)} \quad (3)$$

In summary, TSD makes three basic assumptions.

- A1 Associative strength is normally distributed.
- A2 The distributions of strength for different brand/attribute pairs may have different means but variances are equal.
- A3 Respondents set their criteria at optimal levels.

Given assumptions A1 and A2, response rates for hits and false alarms are sufficient for estimating an unbiased sensitivity measure, d', and a measure of response bias, β . If A3 is also holds, then the base rates may be divided out of β to yield the ratio of subject "importances" which we will denote by v.

$$v = \frac{VCR + CFA}{VH + CM} = \beta \times \frac{p(T)}{p(F)} \quad (4)$$

Level of Aggregation

TSD seems most appropriate as an individual level model of association strength for particular brands and attributes. As such the estimation of d' and β would require numerous within subject observations for each brand attribute pair. This is clearly not feasible given our earlier discussion. Therefore, a major issue becomes whether or not there is a reasonable way to aggregate data such that the assumptions of TSD are at least approximately preserved. That is, various groups of individuals, brands and/or ingredients must be identified that are plausibly homogeneous with respect to associative strength. Since the present goal is to develop a viable, descriptive measure of consumer knowledge, a relatively liberal criterion for the satisfaction of TSD assumptions may be adopted. If the goal were to develop a theoretical model of information processing based on TSD, the criterion would need to be much more strict. That is, we are more concerned with removing response bias and estimating sensitivity than with modeling the decision process in a pick-any task, per se.

A TSD Analysis of Knowledge About Cold Remedies

In order to illustrate the application of TSD to pick-any data, we have analyzed a subset of a larger data base comprised of several measures of consumer knowledge about non-prescription cold remedies. We will not describe the full study since its details are not relevant for the present analysis.

Method

Subjects. One hundred and fifty-four undergraduate Marketing majors at the University of Florida participated in the study for course credit during the Fall semester of 1982.

Stimuli. All brands listed in the Handbook of Non-Prescription Drugs (1979) as either Internal Analgesic Products or Cold and Allergy Products as well as a few new brands not listed (total = 154) were displayed in alphabetical order down the left hand side of three consecutive response sheets. A list of several types of descriptors (ingredients, symptoms relieved, side effects, dosage forms, etc.) was given on a cover page. In this analysis we focus on the four major types of ingredients found in cold remedies: analgesics, antihistamines, decongestants, and cough suppressants. The exact response alternatives are given in Table 1. On the cover sheet, they were listed along with 16 other ingredients in alphabetical order.

TABLE 1
General (G) and Specific (S) Ingredient
Response Items

Antihistamine (G)	Cough Suppressant (G)
Chlorpheniramine Maleate (S)	Codeine (S)
Methapyrilene Fumarate (S)	Dextromethorphan (S)
Decongestant (G)	Pain Reliever (Analgesic) (G)
Ephedrine (S)	Acetaminophen (S)
Phenylephrine (S)	Aspirin (S)
Phenylpropanolamine (S)	
Pseudoephedrine (S)	

Procedure. Respondents were given a four-page booklet. The first page contained instructions, a reference list

of brand descriptors, and a response form for indicating for each of five cold symptom categories (1) the number of times in the past year that they experienced each symptom type, (2) the brands they used last in treating those symptoms, and (3) the brands they would consider purchasing for those symptoms if they needed them today. The five cold symptom categories were Allergy, Cough/Sore Throat, Flu, Headache, and Head Cold. The subsequent three pages listed the 154 brand names and provided spaces for reporting brand descriptors. Respondents were given three tasks. First, they were to examine the brand names and identify approximately twenty brands with which they felt "very familiar." Second, they reported their frequencies of illness, brands used last and brands they would currently consider. Finally, next to each brand they had previously identified as "very familiar," they recorded the number associated with each descriptor they felt applied to the brand (up to a maximum of 14 descriptors). Sex and age information was also recorded.

Results

The average number of brands chosen as familiar was 19.1. The Handbook of Non-Prescription Drugs (1979) was used to identify the correct ingredients for each brand. Then, for each brand chosen as familiar, each ingredient was classified as either a hit, a miss, a false alarm, or a correct rejection depending on its validity and whether it was chosen, or not. Thus, there were over 41,000 observations in the initial data base (i.e., 154 respondents x 19.1 brands per respondent x 14 ingredients per brand).

Respondents were classified on the basis of whether, or not, their self-reported symptom frequency was above the group average. (Flu was excluded because of its generally low frequency and because computer capacity constraints required a reduced analysis; therefore, there were four Symptom Frequency variables: Allergy, Cough/Sore Throat, Headache, and Head Cold.) Brands were classified on the basis of whether, or not, they were recorded as used last (referred to as Brand Usage) and/or currently considered (referred to as Brand Consideration). These two variables are jointly referred to as Brand Familiarity. Finally, Ingredients was also used as a classification variable. Hits, misses, false alarms, and correct rejections were aggregated within each class formed by crossing these variables (i.e., 896 possible classes). Any class with less than four valid brand/ingredient associations (i.e., hits plus misses), less than four invalid brand/ingredient associations (i.e., false alarms plus correct rejections), or less than four positive responses (i.e., hits plus false alarms) was dropped from the data base in order to ensure a minimal level of stability. (Only 8 of the 14 ingredients given in Table 1 met this criterion.) An estimate of d' , β , and the importance ratio, v , was computed for each of the 220 remaining classes.

Specific Assumptions. In order for the TSD measures to be meaningful the three assumptions discussed earlier must be modified as follows.

- SA1 The associative strengths of all valid respondent/brand/ingredient triples within each aggregation class are independent, identically distributed normal random variables.
- SA2 The associative strengths of all invalid respondent/brand/ingredient triples within each aggregation class are independent, identically distributed normal random variables.
- SA3 All associative strengths within each aggregation class have equal variance (although their means may differ).
- SA4 All respondents have knowledge of the base rates, have the same importance ratio and set their criteria so as to maximize subjective utility.

Strictly speaking, it is highly unlikely that these assumptions will hold. However, as an approximation they are fairly reasonable. Since the classification scheme uses those variables that seem a priori most related to associative strength (i.e., Symptom Frequencies, Brand Familiarity and Ingredients), SA1 and SA2 are plausible. SA3 is also plausible since the sources of error variance in memory are probably fairly general and large relative to error variance due to specific aspects or valid versus invalid information. Moreover, there are several ways that SA3 can be tested (McNicol 1972). The standard tests require manipulations that are designed to affect β and v but not d' . These include changing the base rates for the stimuli and changing an explicit payoff scheme for the four types of responses. In the present analysis, certain factors are hypothesized to affect d' , but not β or v , or d' and β , but not v . Specifically,

H1 Frequency of illness and the brand usage/consideration variables should affect d' , but not β or v ,

H2 Different ingredients are likely to be associated with different base rates and therefore both d' and β , but not v , may be affected by which ingredient is involved,

and

H3 None of the factors should affect v and, therefore, β should be linearly related to the objective base rates across aggregation classes (see Equation 3).

SA4 is stated in rather strong terms so that v can be computed empirically. Even if people have imperfect knowledge of the base rates and are unable to be completely optimal in setting their criteria, v should be related only to Ingredients and the relationship should be weaker than for d' or β . If SA3 does not hold, however, and true and false associations have substantially different variances, then differences in their means will affect the computed values of β and v as well as d' .

Data Analysis. As a check on the validity of assumptions SA3 and SA4, hypotheses H1 and H2 were tested by simple dummy variable regressions of d' , β and v on Ingredients, Symptom Frequencies, and Brand Familiarity. The results of these regressions (given in Table 2) were generally consistent with the hypotheses. The three classes of knowledge related variables had significant effects on d' , but not on β or v . Thus, H1 was supported and H2 was partially supported. The absence of an effect of Ingredients on β most likely resulted from consumers having a poor knowledge of base rates. Interestingly, the effects of Ingredients and Brand Familiarity were larger than the effects of need related factors (i.e., Symptom Frequencies). If consumers who needed the drugs were learning about product alternatives prior to purchase (in order to make an informed choice) rather than after purchase, a stronger effect of Symptom Frequency would have been expected. Alternatively, perhaps people who have frequent symptoms use prescription drugs and, therefore, do not know much more than others about nonprescription drugs.

TABLE 2
Mean Values and Regression Results For
d', β , and v

VARIABLES	N	MEANS		
		d'	β	v
Ingredients:				
<u>General</u>				
Antihistamine	32	1.21	44.4	20.4

* p < .0001
+ n.s.

H3 was tested by regressing β on the ratio of the objectively determined) base rates, p(F)/p(T). Overall, this regression was not statistically significant. However, inspection of the scatter plot of these data revealed a linear trend for high values of β . Separate analyses revealed that there was a significant positive relationship for $\beta > 10$ ($r=.57$, $p<.001$, $df=30$), but not for $\beta < 10$.

Discussion

The application of TSD to pick-any data appears to provide a potentially fruitful method of measuring associative strength at an aggregate level. A preliminary test of the assumptions required for such analyses was positive and the estimated values of d', in general, conformed to a priori expectations. However, these results must be qualified by the facts that (1) the pick-any methodology lead to many specific ingredients be largely ignored, and (2) the assumption that respondents use knowledge about base rates to make subjectively optimal choices in the pick-any task (i.e., A4) received only weak support. This suggests that this approach will be most useful for revealing relatively large differences in consumer knowledge or for establishing a reasonable unit of measurement (d') for comparisons between different product classes. Fine grained analyses of consumer knowledge are likely to require other methods.

THE MEASUREMENT OF DECLARATIVE KNOWLEDGE

Peter A. Dacin, University of Toronto
Andrew A. Mitchell, University of Toronto

Abstract

Models of declarative memory and procedures for measuring their content and structure are discussed. Then, the results of a study which applies these procedures are presented and their implications discussed.

Introduction

A considerable amount of research in cognitive psychology has recently been directed at understanding the problem solving of experts within a domain (see for example; Chi, Glaser and Rees 1982; Voss, Greene, Post and Penner 1983). Initial work in the area focussed on the strategies used by experts in problem solving, however, few quantitative differences in the strategies of experts and novices were found. For instance, both chess experts and novices were found to have similar breadth and depth of search in planning chess moves (de Groot 1965). These findings indicate that it is the quality instead of the quantity of search that define expertise in decision making. This suggests that more effort should be directed at understanding what knowledge experts have within a domain.

As a result of these findings, knowledge is now recognized as one of the most important variables which affects behaviour. Where previously researchers directly compared the effects of various treatments on behaviour, a more common approach now is to first examine the treatment's effect on memory and then to see whether the effects on memory are related to subsequent differences in behaviour. This approach has resulted in a growing body of literature which indicates that knowledge has a strong effect on how individuals process new information (e.g., Graesser and Nakamura 1982) and solve problems (e.g., Chi, Glaser and Rees 1982)

In consumer behaviour, a similar shift in interest has occurred. For instance, recent research examining individual level advertising effects has used different measures of memory to explain these effects (e.g., Beattie and Mitchell 1985). In addition, a number of recent studies have examined the effect of decision strategies on memory (e.g., Biehal and Chakravarti 1983) and the effects of consumer knowledge about a product category on information search (e.g. Bettman and Park 1981; Brucks 1984). However, in marketing as in cognitive psychology, most of the research examining the effect of knowledge on various information processing activities has generally viewed knowledge within a domain as unidimensional.

Knowledge within a domain, however, is most likely multidimensional. Consequently, in order to obtain a better understanding of how knowledge affects various information processing activities, we must first obtain finer grained measures of knowledge and its organization in memory. However, as we point out in this paper, these measures should be based on a theory of memory.

Given this problem, it is not surprising to find little systematic effort directed at actually measuring differences in the content and organization of information within a domain between individuals (for exceptions, see Chi and Koeske 1983; Chi, Glaser and Rees 1982; Scott, Osgood and Peterson 1979). Although the outlines of a theory of memory are available, it is

still not developed well enough to provide strict guidelines for measuring knowledge. Consequently, developing systematic procedures for measuring knowledge is an arduous and time consuming task. It literally involves feeling your way in a largely unknown area.

The following paper represents an attempt to build on the existing literature in cognitive and educational psychology, social cognition, and consumer research by discussing models of memory and various procedures, based on these models, for measuring knowledge. Furthermore, we will also present and discuss the results of a study in consumer research which demonstrates the application of some of these procedures. First, however, we will discuss models of memory.

Models of Memory

The usual distinction between long term memory (LTM) and short term memory (STM) will be used in this paper (e.g. see Horton and Mills 1984), however, we will only be concerned with measuring information in LTM. Here, LTM is defined as that subcomponent of memory which is permanent, virtually unlimited in storage capacity, and well organized. Although LTM is often represented as a complex system (Anderson and Bower 1973), a simplified representation is often sufficient for a task such as we are undertaking (e.g., Shavelson and Stanton 1975).

Also, it should be noted that knowledge within a domain can be represented in both procedural and declarative form (Anderson 1983), however, we will only be concerned with declarative knowledge here. Declarative knowledge consists primarily of the facts that are known about a particular domain while procedural knowledge represents the algorithms and heuristics that operate on these facts. A current issue in psychology is whether all our knowledge is represented in either declarative or procedural form. Here we will take the more general position that knowledge is represented in both forms.

Declarative Knowledge

The most generally accepted model for representing declarative knowledge in LTM is a semantic network (Wickelgren 1981). A semantic network is a node-link structure in which concepts are represented as nodes that are linked together according to a defined set of relationships (for a discussion of nodes see Rumelhart et al. 1972; for the various relationships between nodes see Anderson 1976; Norman and Rumelhart 1975). Although, this view of LTM results in a static, though manipulable form of memory, it must be acknowledged, that for many purposes, a dynamic model may be more appropriate.

The retrieval of information from a semantic network involves a process of spreading activation (Anderson 1983). Recall of the contents of a node will occur when the amount of activation at that particular node exceeds some threshold level. Which nodes then become activated depends on the strength of the association between the activated node and linked nodes. Those nodes that are most strongly associated are the most likely to be activated.

Declarative memory is, also, frequently divided into

episodic (knowledge of events we have experienced) and semantic (generalized knowledge) memories (Tulving 1983). Although initially hypothesized as two separate memory systems, there exists evidence to the contrary (e.g. Anderson and Ross 1980; McCloskey and Santee 1981). In this paper, we will assume that episodic information may be linked to semantic knowledge in some cases (e.g., Reiser, Black and Abelson 1985), while in other cases it may be located in a separate memory system.

Finally it should be noted that it is also currently believed that much of our generalized knowledge is organized into packets of information. A number of different terms have been used to refer to these information packets. These include schema (Alba and Hasher 1983), scripts (Abelson 1981; Schank and Abelson 1977), frames (Minsky 1975), prototypes and exemplars (Cantor and Mischel 1979; Rosch 1978), and MOP's and TOPS's (Schank 1980, 1981).

Briefly, schema and frames are generic terms for information packets. Scripts contain our generalized knowledge about the temporal sequence of events which occur within an event (such as visiting a restaurant). A prototype is an abstraction of a particular class of objects, while an exemplar is a specific instance that is considered representative of a set of objects. MOP's (memory organizational packets), which are similar to scripts, contain generalized knowledge about general events, however, they also contain linkages to specific events when the events do not meet expectations. TOP's (thematic organizational packets) represent higher order organization of events which are used to identify instances of a general theme.

It is also important, to recognize the major competitor to the network model of memory, the feature model (Smith, Shoben and Rips 1974). Here, members of a particular category are located in a multidimensional space whose dimensions are the defining features of the objects. In this model, category members have both defining features, which are common to all the objects within the category, and characteristic features which are unique to a subset of members. Scott (1969) used a similar model to develop procedures for measuring the relationship between objects within a domain. We will refer to the latter model in this paper, however, it should be noted that although the network and feature models are conceptually different, Hollan (1975) demonstrated their mathematical equivalence.

Measurement of Declarative Knowledge

In measuring declarative knowledge, it is important to make the distinction between structure and content (e.g., Scott, Osgood and Peterson 1979). Although a number of other dimensions of both structure and content of knowledge have been suggested (see for example, White and Gunstone 1980), the general distinction remains the most widely accepted and will be used for the purposes of our paper. Structure refers to how information within a domain is organized in memory. In a network model of memory, examples of different measures of structure might be the number of independent knowledge structures (e.g., structures with no links between them), the number of associations linked to a particular concept or the number and pattern of linkages between concepts within a structure (e.g., Chi and Koeske 1983). In addition, it may also be important to consider the pattern of linkages with other structures in memory (White and Gunstone 1980). In a feature model, examples of different measures of structure might be the number of dimensions or attributes associated with each object and the extent to which the same attributes are associated with each object.

The content of knowledge refers to the type of information stored at the nodes in memory. For instance, some individuals may have specific events associated with different brands in a product class while other individuals may have specific characteristics associated with the brands.

There are a number of different procedures that may be used for measuring either the content or the structure of knowledge within a domain. For a review, the reader is referred to Mitchell (1982) and Mitchell and Chi (1985). These procedures include paper and pencil tests, elicitation and word association, questionnaires which require the subject to evaluate objects and their attributes, tasks requiring the retrieval of information, response times, and scaling procedures. Most of these procedures, however, are capable only of measuring content or structure, but not both. One notable exception is the elicitation/word association procedure (e.g., Olson and Muderrisoglu 1979; Shavelson 1974). Under this procedure, subjects are given key terms from the domain to be tested and are asked to tell the experimenter everything that comes to mind or everything that is related to that term.

Deese (1965) was among the first to use the word association test as a means for examining knowledge within a domain. He defined the associations to a given stimulus probe (i.e. node in memory) as the responses obtained from that probe. He argued that although this was only a subset of all the associated concepts, it was the largest possible subset obtainable by any single technique. In addition, Deese has argued that the word association procedure comes closer than any other technique to being context free, and consequently is the most appropriate procedure for studying organization in memory. Finally, comparisons of the word association procedure with other procedures for measuring the structure and content of knowledge (e.g., paper and pencil tests) indicate substantial convergent validity between procedures (Shavelson and Stanton 1975; Preece 1976).

As mentioned previously, the major advantage of the elicitation and word association approaches is that they provide the data necessary for obtaining measures of both content and structure. Measures of the content of knowledge can be obtained by coding the elicitations into different categories, while measures of the structure of knowledge can be obtained if we assume that whenever one concept elicits or is associated with a second concept, a link between these two concepts exists in memory. Once these links are determined, we can then examine the structure in terms of pattern of links (Chi and Koeske 1983).

In addition, this procedure allows responses to be analyzed in several ways. For example, the degree of association between concepts within a domain can be calculated by the degree of overlap of the responses between concept probes (Preece 1976; Shavelson 1972).

The major problem with this approach is that we do not know exactly what probes or words to use to measure a subject's knowledge in a particular domain. Theoretically, we should probe each schema that is used to store information within that domain, however, currently our theories of memory are not precise enough to tell us which schemata individuals may have in a domain. It is also not clear how many concepts will be linked within a particular schema. If a schema contains many concepts, more probes should be used to elicit these concepts. This may be accomplished by increasing the depth of probing. For instance, after a subject has initially provided all the associations with the key word, second level probes could be used. These probes use both the key word and one of the

associations given by the respondent. When subjects have complex schemas for particular concepts, these second level probes or even third level probes may be necessary to get at all this knowledge.

Second, previous research has indicated that the reliability of these procedures, while acceptable, is somewhat modest. For example, Olson and Muddirisoglu (1979) found that the same probe given at two different points in time resulted in the elicitation of 50 to 60% of the same concepts. High reliabilities for this procedure cannot be expected because according to spreading activation models, the recall of a particular node in memory is the result of a probabilistic process. However, it still needs to be determined if these reliabilities are high enough for this procedure to be useful.

Third, if the researcher is interested only in what information is stored in memory, he or she must be careful that the subject provides only the information that is activated from the memory probe and does not attempt to construct new information. In order to increase the likelihood that the construction of new information does not occur, the subject should be kept in a passive state during this procedure.

A final and related problem is that context frequently seems to have a strong effect on information retrieval. This has been demonstrated in a number of experiments (e.g., Bower 1981). In word association techniques, however, it has been argued that as long as the major contextual variables are held constant (i.e., setting, interviewer, probes, etc.) the technique can be considered to be almost context free (Deese 1965).

Example

In this section we will discuss the use of both elicitation procedures (based on the semantic network model) and questionnaires (based on the feature model) to examine differences in the content and structure of declarative knowledge within a domain between high and low knowledge individuals. The purpose of this example is to provide an illustration of the use of these procedures and an indication of the type of results that can be obtained.

Method

Domain: The domain of motorcycles was selected for a number of reasons. First, there appears to be a wide variance in the amount of knowledge that individuals have about motorcycles. Individuals seem to be either very knowledgeable about motorcycles or have very little knowledge. Second, motorcycles have distinct product types allowing for examination of these types as a basis for organizing information in memory. Third, motorcycles have a fairly large number of attributes, different manufacturers and models so that the difference in the content and structure of knowledge between high and low knowledge individuals would be evident.

Subjects: The subjects were 24 individuals associated with an eastern university in the United States. They were recruited from classrooms and from signs placed on campus. To insure that the subjects differed in their knowledge with respect to motorcycles, the subjects were first prescreened based on their self-reported knowledge about motorcycles. Only subjects that reported that they were either very knowledgeable about motorcycles or had little knowledge about motorcycles were selected. Of the 24 subjects used in this study, twenty were men and four were women. Their ages ranged from 18 to 28.

Memory probes: As mentioned earlier, in order to design the memory probes, we must first determine the different schemata that individuals have containing information about that domain. Since there has been virtually no research on how consumers organize their knowledge about a particular category, the following assumptions had to be made. First, it was assumed that there would be a schema for the product class, so our first memory probe was the word "motorcycle". Since it was believed that individuals may have very complex knowledge structures for motorcycles, second and third level memory probes were also used.

It was also hypothesized that individuals would probably have separate knowledge structures for the different brands, models and types of motorcycles of which they were aware. Therefore, we asked each subject to name all the different motorcycle brands, models and types that he or she could think of and then conducted separate probes for each brand, model and type that was mentioned.

Finally, we hypothesized that individuals may have separate knowledge structures for different components (e.g. motorcycle engine) and performance characteristics (e.g. handling) of motorcycles. Consequently, separate probes were conducted for different component and performance characteristics of motorcycles.

Procedure: Three different sessions were used for collecting data from each subject, however, only the first two sessions are of concern in this example. These sessions took place approximately two weeks apart. In the first session, a questionnaire containing a number of different self-report measures of knowledge that have appeared in the literature (e.g., questions concerning ownership of motorcycles), measures indicating the amount of exposure to information about motorcycles (e.g., frequency of reading motorcycle magazines) and demographic information was given to the subjects.

After completing this questionnaire, the subjects were then given a series of memory probes. Answers were recorded on a tape recorder for later transcription and analysis.

In the second session, approximately two weeks later, the subjects were given additional memory probes and a series of questionnaires to obtain the measures of memory structure proposed by Scott (1979). Except for minor modifications due to the difference in topics, these questionnaires were virtually identical to the ones in Scott, Osgood and Peterson (1979). Next, the subjects were given a series of categorization tasks and a vocabulary quiz on a number of different motorcycle terms. Finally, a list of the five most important performance measures of motorcycles (e.g. acceleration) were given to the subject and they were asked to state which characteristics of motorcycles affected these performance attributes.

Dependent variables: One set of dependent variables that was developed included the self report measures of knowledge, number of brands, models and types mentioned, number of elicitations from each memory probe and scores on the vocabulary and the characteristic attribute tests. This set of variables was used to define level of expertise.

In order to measure the content of knowledge, a coding scheme with twenty six different categories was developed for the elicited concepts. These categories contain a number of broad groupings. Two of these groupings were whether the knowledge was specific to the product or related to the product. Examples of product specific knowledge include: performance (acceleration etc.),

general characteristics (size, weight etc.), specific characteristics (seat, tires etc.), brands, models, types, maintenance, and quality.

The second category consists of those variables which, although not specific to a motorcycle are objects or phenomena related to motorcycles. These include events (involving strangers, read about), personal experiences, other's experiences (of known people, friends, relatives etc.), people associated with motorcycles (actors, Hell's Angels etc.), places and objects encountered while riding (bridges, potholes etc.), type of riding (racing, highway etc.), procedures involved in riding (shifting weight etc.), safety, advertisements, company or country, and motorcycle clothing.

In addition to these two categories, a third category was created which consists of personal statements. This includes feelings/emotions, evaluative statements (I like that etc.), general statements (some people enjoy it), personal thoughts/philosophy (I think it is important to, I wonder what etc.), and images in mind (I picture ..., I can see, etc.).

Finally, a category for comparisons was developed which classified a comparison either as direct (comparing one motorcycle to another) or indirect (comparing a motorcycle to something else ... car, bicycle etc.). A preliminary measure of the reliability between coders for the coding scheme was .81.

Scott's (1969) questionnaires provide a number of different measures of the structure of knowledge. These include complexity (the number of associations an individual has about an object), evaluative centrality (the degree to which evaluative attributes are more central than attributes of neutral valence), image comparability (degree to which the attributes associated with the objects are the same) dimensionality (the number of independent dimensions or attributes required to represent the group of objects), and affective - evaluative consistency (associations between the evaluation of an object and the evaluation of the associations with that object) (Scott, Osgoode and Peterson 1979). The questionnaire also provides a measure of the number of motorcycles listed.

Results

An examination of the correlations between the first set of dependent variables indicates that most of these correlations were quite low (around .30), however, a number of the measures were quite highly correlated (around .75). These highly correlated measures included Rating of Knowledge, No. of Motorcycles listed, and the scores on the Vocabulary Quiz. The scores for these variables were standardized over subjects and the sum of the standardized scores was used as a measure of the subject's expertise. An examination of the subjects' scores on this variable indicated that they fell into four groups of approximately equal size. These groups were labeled novices, semi-novices, semi-experts and experts.

Differences in the Content of Knowledge: In order to examine the differences between these groups on the different content categories, a one way analysis of variance was used. Both the number and percentage of statements elicited for each category were analyzed.

An analysis of the number of statements elicited indicates that, overall, significantly more statements were elicited from the experts than from the novices. Although this was expected, it provides an indication of the complexity of the knowledge structure of the experts. Significant differences were also found in the number of statements elicited for eighteen of the

twenty six categories. Fourteen of these categories also displayed a significant linear trend. For all but one of these categories, the number of statements elicited increased with expertise. Six of the categories that increased with expertise were from the motorcycle specific grouping. These were: general characteristics, specific characteristic, brands, models, types, and quality. The other five categories where similar significant differences were found were company/country, procedure, feeling/emotion, specific evaluation, and generalized statement. The only category where the number of elicitations decreased with expertise was specific evaluations. Interpretation of the category specific evaluation would indicate that novices tend to respond to a probe with an evaluation (i.e., "It's good," "I don't like it," etc.) more frequently than experts.

In a second analysis, the percentage of each category was analyzed using oneway analysis of variance. First, however, an arcsin transformation was applied to equalize the within cell variances. Significant differences in the means between groups or a significant linear trend was found for 12 of the twenty six variables developed from the elicitations. These results also indicate considerable differences in the content of knowledge between experts and novices.

Of particular interest are the differences across the groups in terms of the three categories of content variables. Again, with the exceptions of performance and maintenance, the differences between groups in the motorcycle specific category were all significant and demonstrated a linear trend increasing with expertise. These results indicate that as expertise increases, an increasing percentage of an individual's motorcycle knowledge is specific knowledge. Other variables demonstrating the same significant linear trend were company/country of origin, procedures, and direct comparisons.

Significant linear trends decreasing with expertise occurred for the following variables in the other two categories: events, riders/people associated with motorcycles, advertisements, indirect comparisons and personal thought/philosophy. This suggests that novices tend to have more knowledge based on advertisements, newspaper stories, and people they associate with motorcycles (especially Hell's Angels). Also, as a result of less motorcycle specific knowledge, novices tend, when making comparisons, to make them with things with which they are more familiar (cars, bicycles) than to other motorcycles.

Differences on measure of structure: A similar pattern emerges with the Scott measures. Experts, for instance, could name a significantly greater number of motorcycles than novices. The measure of complexity was also significantly different between groups and demonstrated a significant linear trend increasing with expertise. This indicates that experts have many more associations with the different motorcycle brands, types and models than do novices. The dimensionality index was also found to increase between novices and experts indicating that experts used more dimensions in thinking about motorcycles. Perhaps the most interesting finding is an increase in affective evaluative consistency between novices and experts. This measure is based on the correlation between a subject's evaluation of each motorcycle and the sum of the evaluations of each characteristic associated with the motorcycle. For novices, this measure was actually negative, while for experts, this measure is positive and reasonably high. This suggests that experts based their evaluations of the motorcycles on careful consideration of the characteristics of the motorcycles, while novices may have based their evaluations on ex-

ternal sources, such as friends or advertisements, a result which was also apparent in the analysis of elicitations.

Finally, significant differences and a significant linear trend was also found on the image comparability measure. The linear trend decreased with expertise which indicated that experts were the most likely to have unique characteristics associated with different brands and models of motorcycles.

Differences in knowledge structures: In order to examine the differences in the structure of knowledge between experts and novices, we constructed a network representation of each subject's knowledge based on the memory probes. In constructing a network, a linkage was made between the node representing the memory probe and the nodes representing the various elicitations to the probe.

For novices we generally find that all of the elicited information is interconnected. That is, responses to one probe were often found in responses to other probes. This seemed to occur because there were only a few basic ideas about motorcycles in the structures, and almost all of the probes would tap into one or more of these ideas. For example, one novice's knowledge about motorcycles consisted of the experience of riding around on the back of her boy friend's Harley Davidson, television advertisements about motorcycles, knowledge about how powerful and dangerous motorcycles are, and a memory of a high school acquaintance who was badly injured in a motorcycle accident.

In contrast, experts generally had very complex knowledge structures and had developed separate knowledge structures for different types of knowledge about motorcycles. For instance, the knowledge structure of experts, for the most part, revealed few if any direct linkages between the elicitations from a particular probe and all the other probes. However, there may exist superlinks between structures which were not uncovered with the particular probes which were used.

What is particularly interesting about some of the expert structures is their hierarchical organization. For example, the motorcycle engine probe given to one of the experts elicited different characteristics of motorcycle engines (e.g. 4 cylinder, fuel injected). Connected to these characteristics was information about how these characteristics affect performance.

Experts also demonstrated a tightly knit structure relating brands, models and types of motorcycles. For instance, connected to each brand were generally found the specific models for that brand and these models, in turn, were linked to the different types of motorcycles. Consequently, the expert can access specific models of motorcycles either through the brand or through types of motorcycles.

Discussion

Overall, the patterns found across the two different procedures seems to indicate important differences in the content and structure of motorcycle knowledge between high and low knowledge individuals. Especially noteworthy was the finding that the proportion of motorcycle specific elicitations increased with expertise while the proportion of motorcycle related elicitations decreased. In addition, experts were found to have more associations with each brand, model or type of motorcycle, use more dimensions in thinking about motorcycles and had greater affective evaluative consistency.

Although still at preliminary stages, the procedure

developed for identifying the content and structure of knowledge appears to be a useful tool for the consumer researcher. The ability to identify the concepts associated with a product and the relationships between these associations provide researchers with a clearer picture of knowledge within a particular product class across subjects. They may also be useful as dependent measures, for example, the ability to map knowledge prior to and after the acquisition of product knowledge will give the researcher a better understanding of how the subjects integrated the newly acquired knowledge into their prior knowledge structures.

We have, however, also discussed a number of problems with the approach. These include the reliability of the measures and whether or not these procedures tap all the knowledge within a product domain. It also remains to be seen whether our coding schema for the elicitations will be useful for other product classes. Future research should address these issues so that reliable and valid procedures will be available for accessing the content and structure of product class knowledge.

A NEW NONMETRIC CONJOINT METHOD: SOME PRELIMINARY RESULTS

Philippe Cattin, University of Connecticut
 Alan Gelfand, University of Connecticut

Abstract

A new nonmetric conjoint method is presented. This method is simple and it precludes the inconsistent predictions which can be obtained with the traditional methods, when using fractional designs. Preliminary simulation results are encouraging.

Introduction

The purpose of this paper is to present a new nonmetric method for estimating conjoint models. The method makes the two following assumptions:

Assumption A - the preference order of the levels of each attribute is known for each respondent;

Assumption B - each respondent is "rational" (i.e., each respondent prefers stimulus A over stimulus B if A dominates B, which means that all the levels of A are the same as or preferred to the levels of B).

Work is being done to adapt the method to cases where either assumption does not hold. Moreover, it can be used only with full profile data. But then "full profile" is the method the most used by practitioners (Cattin and Wittink 1982, Table 4).

Potential Inconsistencies With Traditional Estimation Methods

Let R be a (N x 1) vector of observed rankings where the most preferred stimulus receives the highest rank (N) and the least preferred the lowest (1). The design matrix X which defines the stimuli is expressed through indicator variables. An attribute with k_i levels can be described by $(k_i - 1)$ vectors. For instance, for an attribute with 4 levels we have 3 column vectors:

	level	1	2	3
least preferred level	1	0	0	0
	2	1	0	0
	3	0	1	0
most preferred level	4	0	0	1

Such an attribute will have $(k_i - 1)$ parameters associated with it if a model is fitted. In the above notation, if we include an intercept, then X is $N \times (\sum k_i - r + 1)$. Let b be the $(\sum k_i - r + 1) \times 1$ vector of parameters, wherein b_{ij} is the parameter associated with level j of attribute i (with the parameter associated with the lowest level, b_{i1} , taken to be 0). Under the assumption of ordered levels for each attribute, we have $0 \leq b_{i2} \leq \dots \leq b_{ik_i}$, $i = 1, 2, \dots, r$.

Suppose we have 3 attributes, 3 levels each, and that we are using a fractional design of 9 stimuli (Figure 1). For each attribute, level 1 is the least preferred and level 3 the most preferred. One can verify that the rankings (A) shown in Figure 1 are rational. They can be derived from an additive model or from a model with non-crossover interactions (with or without errors.)

If we use regression on rankings (A), we get $\hat{b}_{12} = -1/3$, $\hat{b}_{13} = -2/3$, $\hat{b}_{22} = 1$, $\hat{b}_{23} = 5$, $\hat{b}_{32} = 5/3$ and $\hat{b}_{33} = 10/3$

FIGURE 1: A 3 x 3 x 3 FRACTIONAL DESIGN WITH N = 9

Stimulus	Attribute			Rankings (A)
	1	2	3	
1	1	1	2	3
2	1	2	3	6
3	1	3	1	7
4	2	1	3	5
5	2	2	1	2
6	2	3	2	8
7	3	1	1	1
8	3	2	2	4
9	3	3	3	9

($\hat{b}_{i1} = 0$ for $i = 1, 2, 3$). The utility estimates obtained for attribute 1 are contrary to expectations (monotone decreasing instead of increasing). Suppose we use these utility estimates to predict the rankings of stimuli (1, 2, 2) and (2, 2, 2), where (a_1, a_2, a_3) represents a stimulus with levels $a_1, a_2,$ and a_3 of attributes 1, 2 and 3, respectively. We get $\hat{R}(1, 2, 2) = 4.33$

and $\hat{R}(2, 2, 2) = 4$, which is inconsistent (contrary to expectations).

It can be shown analytically that under assumptions (A) and (B) inconsistent utility estimates and predictions can be obtained with fractional designs, but not with full designs (Gelfand and Cattin 1984). There are no analytical results in the context of nonmetric methods, but inconsistent estimates and predictions can also be obtained with such methods. One solution is to constrain parameter estimates to be monotone (increasing or decreasing), which can be done with LINMAP. One can also use the method presented below.

Nonmetric Estimation of the Ranking of a Stimulus

The ranking of an unobserved stimulus $a = (a_1, a_2, \dots, a_r)$ is estimated using the following formula:

$$R(a_1, a_2, \dots, a_r) = \frac{\underline{R}(a) + \overline{R}(a)}{2} \quad (1)$$

where

$$\underline{R}(a) = \begin{cases} \max R(a_1^*, \dots, a_r^*), L(a) = \{a^* : a_1^* \leq a_1, i=1, \dots, r\} \\ a^* \in L(a) \\ 0, \text{ if } L(a) \text{ is empty.} \end{cases}$$

$$\overline{R}(a) = \begin{cases} \min R(a_1^*, \dots, a_r^*), U(a) = \{a^* : a_1^* \geq a_1, i=1, \dots, r\} \\ a^* \in U(a) \\ N + 1, \text{ if } U(a) \text{ is empty.} \end{cases}$$

Under rational rankings, (1) precludes the creation of inconsistent rankings. For instance, in the example in Figure (1), $R(1, 2, 2) = 3.5$ because $\hat{R}(1, 2, 2) = 4$ and $\hat{R}(1, 2, 2) = 3$, and $R(2, 2, 2) = 3.5$, as well.

Note that this method does not estimate any attribute utility. It predicts the ranking of an unobserved stimulus from the rankings provided by a respondent on N stimuli. These predicted rankings can (in turn) be used to

estimate preference shares, which is often done by practitioners (Cattin and Wittink, 1982, p. 50).

A Brief Simulation Study

Simulation Design

The purpose of the simulation is to gain insight into the behavior of the nonmetric approach compared to regression. All simulations were carried out with three attributes, each with 4 levels. Two orthogonal arrays of 16 stimuli each were used: one to create estimation samples, the other validation samples. Two main types of data were produced: additive and (non-crossover) interactive, to which varying levels of noise were added. Interactive data were also produced without noise. The rationale is that respondent's unreliability (i.e., noise) and interaction are two major reasons for imperfect fit when estimating additive models.

The additive data were produced using the following model. The r th response, or rating Y_r , is such that

$$Y_r = \sum_{i=1}^3 \sum_{j=1}^{k_i} b_{ij} X_{rij} + e_r \quad (2)$$

where

$$X_{rij} = \begin{cases} 1, & \text{if level } j \text{ of attribute } i \text{ is present in stimulus } r \\ 0, & \text{otherwise.} \end{cases}$$

$$b_{ij} = b_{i,j-1} + \text{Abs}(u) \text{ for } j \geq 2, i = 1, 2, 3.$$

$$b_{i1} = 0, i = 1, 2, 3.$$

Abs(u) = Absolute value of a variable drawn from a normal distribution with mean zero and variance one.

$$e_r = \text{noise.}$$

$$Y_r = \text{"rating" of stimulus } r.$$

The noise (e_r) was drawn from a normal distribution with mean zero and variance σ^2 , where σ^2 was set such that the expected percentage of noise in the data took on the values 11.5, 26 and 65 percent. These percentages correspond to high, medium and low predictive validity found in real data (e.g., Scott and Wright, 1976).¹ The noise was added to the stimuli in the estimation sample, but not in the validation sample. In this manner, it takes fewer replications to obtain significant differences between methods. There were five hundred replications for each level of noise.

The ratings of the stimuli in the estimation sample, obtained using (2), were transformed into rankings. These rankings were used to predict the rankings of the 16 stimuli in the validation sample using the nonmetric approach, i.e., (1). Both the ratings, obtained from (2) and the rankings of the stimuli in the estimation sample were used to estimate a least squares regression model. The estimated models were used to predict the ratings and rankings of the stimuli in the validation sample.

The order of the levels of each attribute is known. Thus, following Srinivasan, et al. (1983) and Cattin and Punj (1984), constrained least squares regressions were also performed to constrain the parameter estimates to be monotone increasing for each attribute. This was done as follows. For each attribute, b_{ik} and $b_{i,k-1}$ were averaged if \hat{b}_{ik} was found to be less than $\hat{b}_{i,k-1}$.

¹See footnote 3 in Cattin and Punj (1984).

Next, $\hat{b}_{i,k-1}$ and $\hat{b}_{i,k-2}$ were averaged if $\hat{b}_{i,k-1}$ was found to be less than $\hat{b}_{i,k-2}$ (and \hat{b}_{ik} , $\hat{b}_{i,k-1}$, $\hat{b}_{i,k-2}$ were averaged if \hat{b}_{ik} was found to be less than $\hat{b}_{i,k-2}$), and so on. The estimated models thus obtained were used to predict the ratings or rankings of the stimuli in the validation sample.

The predicted ratings or rankings obtained with each method, as well as the true ratings (in the validation sample) were transformed into rankings 1 through 16 (allowing for ties). Spearman rank and Kendall tau correlations were computed between true and predicted rankings and averaged across the 500 replications for each cell of the simulation design.

The interactive data were produced with the following model. Again, the r th rating, Y_r , is such that

$$Y_r = C_{jkl} + e_r \quad (3)$$

where j, k, l indicate, respectively, the levels of each of the three attributes. With $C_{111} = 0$, we create

$$C_{jkl} = \text{Max}(C_{j-1,k,l}, C_{j,k-1,l}, C_{j,k,l-1}) + \text{Abs}(u).$$

Abs(u) = Absolute value of a variable drawn from a normal distribution with mean zero and variance one.

$$e_r = \text{Noise.}$$

This is one way to produce interactive data of the non-crossover type. The noise was again drawn from a normal distribution with mean zero and variance σ^2 , where σ^2 was such that the expected percentage of noise in the data was 0% (i.e., no noise), 11.5%, 26% and 65%. Again, the noise (if any) was added to the estimation data only and there were 500 replications for each level of noise. The estimation and prediction procedures used with these interactive data were identical to those used with the additive data.

The b_{ij} and C_{jkl} values in (2) and (3), used to produce the additive and interactive data, were all drawn from the same distribution, thus implying relatively "compensatory" models. To gain further insight into the behavior of the nonmetric approach, another set of additive data was produced in which the b_{3j} values, drawn from the same distribution as before, were multiplied by 10, thus producing data in which the third attribute tends to be more important and implying a model with a "dominant attribute" (similar to a lexicographic model). Data were thus produced, followed by estimation and prediction, as described above.

Simulation Results

The mean Spearman rank and Kendall tau correlations obtained for each cell of the simulation design are shown in Tables 1 and 2. Not surprisingly, the best regression results are obtained when using constrained least squares on ratings. The improvement (compared to unconstrained least squares) is greater when the data are additive than when they are interactive.

Comparing the results obtained with the nonmetric method to those obtained with constrained least squares on ratings shows that the constrained least squares method outperforms the nonmetric method only with additive data when the noise level is 11.5% (i.e., high predictive validity). (Note that most of the standard errors of the mean correlations shown in Tables 1 and 2 are between .002 and .005.) The predictive validities of the constrained least square and nonmetric methods are about the same when looking at the results obtained with 11.5% noise under additive data with a dominant attribute. The predictive validity of the nonmetric method is higher everywhere else: i.e., with interactive data (whatever

the noise level), and with additive data with medium to high noise levels.

Conclusion

The intent of this paper was to present a new nonmetric method which precludes the inconsistent predictions which can be obtained with traditional methods when using fractional designs. The method is quite simple and preliminary simulation results are encouraging. Additional simulations and empirical work are needed to gain more insight on the behavior of this method, compared to the traditional methods.

The method can be used only with full profile data and makes two important assumptions (given at the beginning of the paper). This limits its use. However, work is being done to infer the preference order of the levels of an attribute (when unknown) from full profile data, and to adapt the method to inconsistent (full profile) rankings. This will broaden the potential use of the method.

SIMULTANEOUS VERSUS SEQUENTIAL ESTIMATION OF MULTI-STAGE MODELS OF PERCEPTION, PREFERENCE, AND CHOICE

Ruth N. Bolton, University of Alberta
 Randall G. Chapman, University of Alberta

Abstract

Simultaneous and sequential estimation procedures for multi-stage models of perception, preference, and choice are reviewed and discussed. The relative performance of these estimation procedures is assessed with Monte Carlo experimentation for a simple multi-stage choice model with quantitative endogenous variables. The results indicate that 2SLS estimates have about 35% less error than OLS estimates in the presence of substantial cross-equation error correlation. This result appears to hold regardless of the level of correlation in the model's exogenous variables.

Introduction

In modeling choice behavior in high-involvement settings marketing scientists have used both physical attributes and buyers' perceptions of the characteristics of the choice alternatives as explanatory determinants of choice. Either physical attributes or perceptions -- but not both -- are typically used in a single-stage choice model.

In contrast to single-stage choice models, multi-stage choice models seek to integrate physical attributes, perceptions, preferences, and choices into a comprehensive model of judgment and decision making. A popular multi-stage choice model has the following form:

$$\begin{aligned} \text{Perception} &= f(\text{Physical Attributes, Information,} \\ &\quad \text{Other Factors}) \\ \text{Preference} &= g(\text{Perceptions, Other Factors}) \\ \text{Choice} &= h(\text{Preference, Situational Constraints,} \\ &\quad \text{Other Factors}). \end{aligned}$$

This multi-stage choice model incorporates both physical attributes and perceptions. The model also makes a distinction between preference and choice. Preference is often defined as "unconstrained preference", where the decision maker is specifically assumed (and directed in survey research questionnaires) to ignore certain constraining factors in providing the preference judgment. However, choice is affected by these situational constraints. This multi-stage model is consistent with models of consumer behavior proposed and applied by many marketing researchers (c.f. Tybout and Hauser 1981). This multi-stage choice model may be viewed as falling within the Lens' model paradigm (Brunswick 1952) or as being derived from the information integration view of judgment and decision making (Anderson 1981).

Marketing scientists typically estimate the various parts of this multi-stage choice model using the following approach. The assumption (usually implicit) is made that the errors of the three equations are uncorrelated across equations. Under this assumption, each equation in the multi-stage model may be estimated separately, in a sequential fashion, and this procedure will yield parameter estimates with the usual desirable statistical properties, such as unbiasedness and efficiency. However, the appropriateness of this sequential estimation approach depends critically on the assumption about the uncorrelated error terms.

Cross-equation error correlations in the multi-stage model may exist for several reasons. Correlations may arise because common measuring scales are used to measure perception, preference, and choice. Omitted variables would be another factor which induces cross-equation error correlation.

If the equation errors are correlated, sequential estimation of the multi-stage choice model will yield inconsistent parameter estimates. With cross-equation error correlation, the model should be estimated with

simultaneous equation techniques, using either single equation (such as two stage least squares) or system methods (such as three stage least squares). Single equation methods (also termed limited information methods) for simultaneous models will yield consistent parameter estimates. However, system methods (also termed full information methods) estimate the equations jointly, typically yielding more efficient parameter estimates.

The purpose of this paper is to compare simultaneous and sequential estimation procedures for multi-stage models of perception, preference, and choice. We explore the conditions under which it is necessary to use a more complicated simultaneous estimation procedure, rather than using the simpler single-equation-at-a-time sequential approach. This investigation focuses on the extent to which sequential estimation procedures may be deficient in the presence of cross-equation error correlations.

In the next section, a multi-stage model of the choice process is formulated. It is shown that some aspects of the model specification depend on the choice modeling context. In subsequent sections, appropriate estimation procedures are described for alternative model specifications. Simultaneous equation estimation techniques are discussed in detail. Monte Carlo experiments are conducted to compare the statistical properties of parameter estimates generated by sequential versus simultaneous estimation procedures. Some concluding remarks complete the paper.

Model Specification of the Multi-Stage Choice Model

The multi-stage choice model has two components: a structural sub-model and a measurement sub-model. The structural sub-model describes the links among the theoretical constructs; the measurement sub-model describes the relationships between constructs and their measures. The structural sub-model focuses on three aspects of decision making: perceptions, preference, and choice. Hence, perceptions, preference, and choice are considered to be endogenous (dependent) variables. The remaining variables are exogenous (independent).

A decision maker's perceptions, P_j , of an alternative in his/her unconstrained choice set are modeled as a function of the objectively-verifiable physical attributes of the alternative, informational cues in the environment, and other factors. The decision maker's preference, PR , for an alternative in his/her unconstrained choice set is viewed as a function of his/her perceptions of the alternative as well as other factors. Choice, C , is considered to be a function of preference and other factors, subject to situational constraints. (The "other factors" may include both individual- and situation-specific aspects of the choice process.)

The general form of this multi-stage model may be written in the following fashion:

$$P_j = f(W, X) + \epsilon_{1j}, \quad \text{for } j=1,2,\dots,J \quad (1)$$

$$PR = g(P, X) + \epsilon_2 \quad (2)$$

$$C = h(PR, X, Z) + \epsilon_3 \quad (3)$$

where:

j = a perceptual dimension ($j=1,2,\dots,J$) which characterizes the alternatives

\underline{W} = a vector of objectively-verifiable physical attributes of the unconstrained set of alternatives and the information cues available in the environment

\underline{X} = a vector of other factors (e.g., socio-demographic and other individual-specific variables)

\underline{Z} = a vector of situational constraints which mediate the choice process

ϵ_m = a stochastic disturbance term which reflects model specification and measurement errors for the dependent variable in equation m.

In equations (1)-(3), all variables have an implicit subscript denoting the alternative in the consideration set. This subscript has been suppressed for notational convenience. In equation (1), the subscript j denotes a perceptual dimension of an alternative. For example, "quality" of a college may be a relevant perceptual dimension in college choice modeling.

Throughout this paper, we make a number of assumptions about this model. First, it will be assumed that the functional forms of the equations -- the f(.), g(.), and h(.) functions -- are linear in the parameters. However, this assumption is relaxed when the principles discussed in this paper are extended to (non-linear) discrete choice model forms. Second, the disturbance terms have been defined to include both model specification and measurement error in the endogenous variables. Our parameterization of this multi-stage choice model in equations (1)-(3) does not distinguish between these two types of errors. Third, it is assumed that:

$$E[\epsilon_m | \underline{W}, \underline{X}, \underline{Z}] = 0, \quad \text{for } m = 1, 2, \text{ and } 3. \quad (4)$$

That is, equation (4) specifies that the equation error terms are uncorrelated with the exogenous variables. This is a standard econometric modeling assumption.

The structural sub-model also specifies the nature of the variance-covariance matrix of the equation disturbances. These disturbance terms may be correlated or uncorrelated across equations. Cross-equation correlations among the disturbances may arise from either model specification error, or due to the nature of the measurement error in the dependent variables.

Model specification error will be reflected in correlation among the equation errors when a common exogenous variable is omitted from all three equations. Alternative-specific indicator variables are often used to attempt to account for such omitted variables. Measurement error in perceptions, preference, and choice will also be reflected in the equation disturbances. Hence, the methodology used to measure the endogenous variables may induce correlation into the equation errors. Correlated errors may arise when the three endogenous variables are measured with similar scales, or when all the endogenous variables are measured at the same point in time rather than in stages. In the first instance, the use of a common scaling procedure may lead to a common source of error in the measures of perception, preference, and choice. In the second instance, halo effects are more likely to occur when all measures are collected simultaneously. Furthermore, the causal links among measures of perception, preference, and choice become complex when all the measures are taken at one point in time.

The measurement sub-models for the endogenous and exogenous variables will depend on the model context. To focus on specific model estimation issues, this paper considers alternative measurement sub-models for the endogenous variables. However, it is assumed that the exogenous variables are measured without error. The exogenous variables will typically include both objectively-verifiable physical attributes and individual-specific socio-demographic variables. Both types of variables are likely to have little measurement error, at least compared to the measurement error inherent in perceptions, preference, and choice.

Two features of the measurement sub-model for the endogenous variables are important in determining the appropriate estimation procedure for the multi-stage model. One of these features, the correlations among the measurement errors of the endogenous variables, has been discussed above. Another important feature of the measurement model is whether perceptions, preference, and choice are represented by quantitative or qualitative (discrete choice) measures. Our preliminary exploration of the estimation issues in multi-stage choice models focuses primarily on the quantitative dependent variable case.

Model Estimation Procedures For Quantitative Dependent Variables

This section describes estimation procedures for the multi-stage choice model when the measures of the endogenous variables are quantitative. The appropriate procedure depends on whether the equation disturbances are uncorrelated or correlated.

Uncorrelated Errors Across Equations

Consider the multi-stage model in which disturbances are uncorrelated across equations. That is, assume that:

$$E[\epsilon_{1j}\epsilon_{2j}] = 0, \quad \text{for } j = 1, 2, \dots, J$$

$$E[\epsilon_{1j}\epsilon_{3j}] = 0, \quad \text{for } j = 1, 2, \dots, J$$

$$E[\epsilon_{2j}\epsilon_{3j}] = 0.$$

This scenario is likely to occur when the endogenous variables are measured with different scales and at different points in time. It is also likely to occur when perceptions, preference, and choice are based on somewhat different sets of alternatives due to the presence of mediating constraints.

If the covariances of the error terms are restricted to be equal to zero, the multi-stage model has a recursive structure (Johnston 1972, pp. 377-9). A recursive structure implies that the disturbances of equations (2) and (3) are uncorrelated (in the probability limit) with the endogenous variables on the right-hand side of those respective equations. In this situation, all three equations are appropriately estimated with a straight-forward application of OLS to each equation. The OLS parameter estimates will be consistent and asymptotically efficient, if the model has a recursive structure.

Correlated Errors Across Equations

Consider the multi-stage model in which the disturbances may be correlated across equations. Hence, the variance-covariance matrix of the disturbances is unrestricted. This scenario is likely to occur in "one-shot" studies (i.e., when all measures are collected simultaneously), studies which use the same measurement methodology for all endogenous variables, and studies where perceptions, preference, and choice are based on the same set of alternatives.

If the disturbances are correlated across equations, the multi-stage model has a simultaneous structure. The disturbances of equations (2) and (3) are correlated (in the probability limit) with the endogenous variables on the right-hand side of the respective equations. Hence, the direct application of OLS will yield parameter estimates which are biased and inconsistent. The asymptotic bias will be greatest when there are a few exogenous variables with high intercorrelations (Johnston 1972, p. 411).

To present an alternative estimation procedure, it is useful to express the structure model in its reduced form:

$$P_j = f(\underline{W}, \underline{X}) + \epsilon_{1j}, \quad \text{for } j = 1, 2, \dots, J \quad (5)$$

$$PR = g'(W, X) + \epsilon'_2 \quad (6)$$

$$C = h'(W, X, Z) + \epsilon'_3 \quad (7)$$

where ϵ'_2 and ϵ'_3 are stochastic disturbance terms. Note that ϵ'_2 is a function of ϵ_{1j} and that ϵ'_3 is a function of ϵ_{1j} , ϵ_2 , and ϵ_3 . Hence, the stochastic disturbances in equations (5)-(7) are correlated across equations.

Identification conditions may be used to verify whether it is possible to recover the structural parameters from the reduced form model. These conditions will depend on the functional form of the model (Maddala 1977, pp. 220-31). Assuming a linear functional form, the structural parameters of this multi-stage choice model may be shown to be identified.

The structural parameters of the simultaneous multi-stage model can be estimated with a single equation method, such as two stage least squares, or system methods, such as three stage least squares or full information maximum likelihood methods. These estimation procedures yield parameter estimates with different statistical properties.

To apply the two stage least squares (2SLS) procedure to this multi-stage choice model, the following two steps would be required (Johnston 1972, pp. 380-4):

Step 1: Equations (5) and (6) of the reduced form model are estimated with OLS. Instrumental variables for perceptions (P^*) and preference (PR^*) are formed from the predicted values.

Step 2: The instrumental variables replace the endogenous variables on the right-hand side of the structural model as follows:

$$PR = g(P^*, X) + \epsilon_2 \quad (8)$$

$$C = h(PR^*, X, Z) + \epsilon_3 \quad (9)$$

Equations (8) and (9) are estimated with OLS. Note that the estimated standard errors from the second stage must be adjusted to obtain the correct values at the second stage (Maddala 1977, p. 239).

Since equation (5) of the reduced form model is identical to equation (1) of the structural model, stage one yields consistent estimates for the structural coefficients of equation (1). The disturbances in equations (8) and (9) are uncorrelated (in the probability limit) with the variables on the right-hand side of the equations because the instrumental variables do not have a stochastic component. Hence, stage two will yield consistent estimates of the structural coefficients of equations (2) and (3). If the instrumental variables are "poor" surrogates for perceptions and preferences, the sampling variance for the parameter estimates may be very large. In these circumstances, Johnston (1972, p. 211) points out that this may be a high price to pay for consistency.

2SLS estimates will be less biased than OLS estimates in finite samples. Monte Carlo studies indicate that multicollinearity may produce a greater increase in bias in 2SLS estimates than in OLS estimates, but the results are mixed on this point. When bias and standard deviation are combined in a measure of mean square error, the results are also mixed. However, 2SLS is more likely to lead to correct inferences about the true values of structural coefficients because the estimated standard errors are centered around an unbiased expectation. It is important to note that the differences between the estimation procedures are not very large, and vary considerably across data sets (c.f., Johnston 1972, pp. 410-7). In addition, OLS estimates tend to predict well and be more robust than many simultaneous methods in the presence of model specification error (Maddala 1977, p. 231).

As an aside, the reduced form version of the multi-stage choice model consists of "seemingly unrelated" equations. Such equations are characterized by error terms which are

correlated across equations and by sets of exogenous variables which differ across equations. Under these conditions, Zellner's system method (1962) will provide asymptotically more efficient estimates than OLS. Hence, Zellner's method of seemingly unrelated regressions could be used in stage one to estimate the reduced form model and form the instrumental variables.

If the structural model is characterized by error terms which are correlated across equations, and by at least one equation which is over-identified, system estimation methods will provide asymptotically more efficient estimates of simultaneous equation coefficients (Zellner and Theil 1962). System estimation procedures include full information maximum likelihood techniques and three stage least squares.

In full information maximum likelihood (FIML), it is assumed that the disturbances of equations (1)-(3) are normally distributed and serially uncorrelated, with an unrestricted covariance matrix. Then, the joint likelihood function is maximized with respect to the structural parameters (i.e., structural coefficients and error covariances). FIML is complex (involving the solution of non-linear equations) and computationally expensive. As a result, FIML is less frequently used than other simultaneous equation methods.

In three stage least squares (3SLS), the first two stages are those of 2SLS. In the third stage, generalized least squares is applied to equations (1), (8), and (9) using the covariance matrix of the estimated equation errors (Johnston 1972, p. 398).

Although system methods are asymptotically more efficient than 2SLS, they have a number of disadvantages (Theil 1971, pp. 528-9). System methods require a much more detailed specification of the equation system than 2SLS does. With 2SLS, if a coefficient in a given equation is postulated to be equal to zero when in fact it is not, the coefficient estimates for that equation will be biased. In system methods, the same model specification error will bias the coefficient estimates for all equations. Thus, model specification error -- a particularly common problem in marketing modeling efforts -- will have its influence felt throughout all equations when using a system estimation method, even if the specification error is only in a single equation!

Whether system methods really outperform the much simpler OLS estimates in real marketing data remains an unresolved issue. Chapman and Palda (1984) compared 3SLS and OLS estimates for a 10-equation model of "sales response" in an electoral marketplace. They found that the theoretically preferable system estimation technique (3SLS) yielded approximately the same pattern of parameter estimates as the simpler OLS (equation-by equation) approach.

Model Estimation Procedures For Qualitative Dependent Variables

This section describes estimation procedures for the multi-stage choice model when at least one dependent variable is qualitative (discrete choice). For the purposes of the present discussion, it will be assumed that choice is a qualitative variable, while perceptions and preference are quantitative variables.

Choice may typically be a polychotomous variable because it represents a selection from a finite set of alternatives. When choice is polychotomous, a popular model form is the multinomial logit model (McFadden 1974):

$$C = MNL(PR, X, Z) \quad (10)$$

where MNL is the now familiar multinomial logit model functional form. Thus, equation (10) replaces equation (3) in the specification of the multi-stage choice model.

As before, the estimation of the model consisting of equations (1), (2), and (10) depends on whether the

three equations' disturbances are uncorrelated or correlated.

Uncorrelated Errors Across Equations

Consider the multi-stage model of the choice process described by equations (1), (2), and (10) in which the disturbances are uncorrelated across equations. (The conditions under which uncorrelated errors are likely to occur were described earlier for quantitative endogenous variables.) As before, the multi-stage model has a recursive structure. Hence, all three equations can appropriately be estimated with limited information estimation procedures. OLS techniques may be applied to equations (1) and (2), and maximum likelihood estimation of the parameters of equation (10) may be performed. Sequential estimation of each equation yields coefficient estimates which will be unbiased and asymptotically efficient.

In the above discussion, it has been assumed that choice is the only qualitative (discrete) endogenous variable. Preference might, of course, also be a qualitative endogenous variable. Under the assumption that the equation errors are uncorrelated, this version of the multi-stage choice model would also be estimated by limited information estimation procedures. Elliot and Hollenhorst (1981) formulate a sequential response model with four stages, each measured by a qualitative endogenous variable. The outcome at each stage is conditional on "success" at the previous stage. For this type of model, the joint likelihood function can be maximized by maximizing the likelihood functions of each equation separately (Maddala 1983, pp. 49-51).

Limited information estimation procedures are typically utilized for multi-stage models of the choice process (e.g., Hauser, Tybout, and Koppleman 1981; Hauser and Wisniewski 1982). However, the underlying assumptions about the disturbance terms are generally not discussed, despite their impact on the statistical properties of the estimates.

Correlated Errors Across Equations

Consider the multi-stage model of the choice process described by equations (1), (2), and (10) in which the variance-covariance matrix of the disturbances is unrestricted. (The conditions under which correlated errors are likely to occur were described earlier for quantitative endogenous variables.) If the disturbances are correlated across equations, the multi-stage model has a simultaneous structure and limited information estimation procedures will yield biased and inconsistent parameter estimates.

The reduced form of the multi-stage model with quantitative endogenous variables was described by equations (5)-(7). Since choice is now defined to be a qualitative variable, equation (7) should be re-written in the form of equation (10), where choice (C) depends on all the exogenous variables (W, X, and Z).

Identification conditions for models with both quantitative and qualitative endogenous variables are somewhat different than those in the usual simultaneous equations model (Maddala 1983, pp. 117-25; Lee 1981). However, the identification problems in the multi-stage choice model are much the same as those in the usual simultaneous equations model, except that some parameters are estimable only up to a scale factor due to the presence of the qualitative endogenous variable (Maddala 1983, p. 120).

The structural parameters of the simultaneous multi-stage model can be estimated with a single equation or a system method. These estimation procedures yield parameter estimates with different statistical properties.

A two stage estimation method for the multi-stage choice model is the following (Maddala 1983, pp. 242-7):

Step 1: Equations (5) and (6) of the reduced form model are estimated with OLS. Instrumental variables for perceptions (P*) and preference (PR*) are formed from the predicted values.

Step 2: The instrumental variables replace the endogenous variables on the right-hand side of the structural model. As before, equation (2) is re-written with instrumental variables P* as shown in equation (8). Equation (10) is re-written with instrumental variable PR*, as follows:

$$C = MNL(PR^*, X, Z) \quad (11)$$

Equation (8) can be estimated with OLS. Equation (11) can be estimated with maximum likelihood estimation techniques.

This two stage procedure yields consistent estimates of the structural coefficients. As with 2SLS, it yields poorer estimates in the presence of multicollinearity (Maddala 1983, p. 252). Note that the estimated standard errors from the second stage must be adjusted to obtain their correct values. Lyon (1984) uses a variation of this two stage method in her study of the dynamic attitude behavior relationship.

With regard to system estimation methods, maximum likelihood methods can be applied to the multi-stage choice model with mixed quantitative and qualitative endogenous variables. (These methods were described in the previous section.) Two stage estimation methods are likely to be more popular than maximum likelihood, due to their computational simplicity.

Amemiya (1979) has suggested some alternative estimators to two stage estimators, such as the one described above. Such estimators are more efficient than two stage estimators, but there exists a generalized instrumental variable estimator that is more efficient than the GLS estimator derived from Amemiya's method (Lee 1981; Maddala 1983).

Relative Performance of Simultaneous and Sequential Estimation Procedures

To compare the relative performance of simultaneous (2SLS) and sequential estimation procedures, Monte Carlo experimentation on simulated data may be used. In this preliminary analysis, we focus only on quantitative endogenous variables. The corresponding analysis for a mixed system of quantitative and qualitative endogenous variables is deferred to future research efforts in this area. Our goal is to examine how cross-equation error correlations and multicollinearity among the exogenous variables influence the relative performance of OLS and 2SLS estimation procedures.

Design of the Monte Carlo Experiments

The following multi-stage choice model was used in these Monte Carlo experiments:

$$P = \alpha_0 + \alpha_1 X + \alpha_2 W + \epsilon_1 \quad (12)$$

$$PR = \beta_0 + \beta_1 P + \beta_2 X + \epsilon_2 \quad (13)$$

$$C = \gamma_0 + \gamma_1 PR + \gamma_2 X + \gamma_3 Z + \epsilon_3 \quad (14)$$

These equations are the simplest possible representation of the multi-stage choice model which was originally described in equations (1)-(3): there is one perception variable and the minimum number of X, W, and Z variables. This model might be used by decision makers in the evaluation and assessment of a single alternative or action.

In simulating choice model data, the distributional characteristics of the exogenous variables and the error terms must be specified, the true parameter values must be chosen, and correlation patterns (among the exogenous variables and between the error terms in the three equations) must be specified. Random draws made from the

specified distributions substituted into equations (12)-(14) yield measures for the endogenous variables in this model. The model's parameters may then be estimated by OLS and 2SLS procedures, and the resulting parameter estimates may be compared to the true (known) parameter values to assess the relative performance of the estimation procedures.

In these Monte Carlo experiments, all exogenous variables and error terms were drawn from normal distributions with mean zero and variance equal to one for exogenous variables and variance equal to four for the error terms. With regard to the true parameter values, all constant terms were set equal to zero and all slope parameters were set equal to one. These choices resulted in the explained variance averaging about 30%, 75%, and 85% in the P, PR, and C equations, respectively. Note that these levels of explained variance indicate that the instrumental variables generated by the reduced form equations will be "adequate" surrogates for the endogenous variables on the right-hand side of the structural equations. Hence, it should be expected that simultaneous estimation methods (such as 2SLS) achieve consistency at the expense of sampling variation.

Correlations among the exogenous variables were generated by making the W and Z variables equal to a linear combination of X and a white noise term. With an appropriate choice of weights, correlations of 0.00, 0.24, and 0.45 were obtained for the low, medium, and high correlation conditions in the experiment.

For the error terms, correlations were induced into ϵ_2 and ϵ_3 terms by making them linear combinations of the preceding error term in the model plus a white noise term. Appropriate choice of the weights and the error variances of the white noise terms yielded correlations of 0.00, 0.40-0.44, and 0.50-0.71 for the low, medium, and high cross-equation error correlation conditions in the experiment.

A factorial design was employed in the experiment. Each of the three levels of exogenous variable correlation was tested with each of the three levels of cross-equation error correlation, for a total of nine separate experiments. In each cell of this experimental design, a total of 25 replications were conducted. Each replication involved generating 250 observations, according to the model in equations (12)-(14) and the specified correlational structure of the exogenous variables and the error terms. After generating the data in each of the replications, the model was estimated using both OLS and 2SLS techniques.

Performance Measures

Two measures of precision were chosen for gauging the performance of the estimation procedures, related to bias and squared error deviation:

$$\text{BIAS}(c) = \frac{1}{R} \sum_{r=1}^R (c_r - c^*) \quad (15)$$

$$\text{RMSE}(c) = \left(\frac{1}{R} \sum_{r=1}^R (c_r - c^*)^2 \right)^{0.5} \quad (16)$$

where c_r is the estimate of parameter c obtained on replication r ($r=1,2,\dots,R$) of the Monte Carlo experiment and c^* is the true (known) parameter value. $\text{BIAS}(\cdot)$ measures the tendency of coefficient estimates to be, on average, above or below their true value. $\text{RMSE}(\cdot)$ is a measure of the precision of the parameter estimates (i.e., how "close", in an absolute sense, the estimates are to truth). $\text{RMSE}(\cdot)$ is equivalent to adopting a squared error loss function to account for deviations between a coefficient estimate and its true value.

The performance measures defined in equations (15) and (16) are for a single parameter. If these measures are summed over all parameters in the model in equations (12)-(14), 10 in total, we obtain BIAS and RMSE, the aggregate bias and root mean squared error, respectively. These measures of aggregate performance were used to compare OLS and 2SLS estimation procedures in these Monte Carlo experiments.

Results

The results of these Monte Carlo experiments are reported in Table 1. The aggregate BIAS and aggregate RMSE are reported in each cell of the experimental design. The key findings are as follows:

- (1) 2SLS outperforms OLS in terms of both BIAS and RMSE in the presence of any degree (medium or high) of cross-equation error correlation. This is, of course, expected based on standard results in econometric theory.
- (2) When there is medium cross-equation error correlation, the RMSE for 2SLS is about 10% less than the RMSE for the OLS estimates. In the high cross-equation error correlation case, the 2SLS estimates are about 35% more precise than the OLS estimates.
- (3) The bias in the OLS estimates increases as the degree of cross-equation error correlation increases.
- (4) OLS consistently underestimates the true values of the parameters.
- (5) If there is no cross-equation error correlation, the application of 2SLS yields less precise estimates than OLS (by about 35%), as measured by RMSE. There is no apparent pattern of bias in the 2SLS estimates (in the situation where there is no cross-equation error correlation).
- (6) As the collinearity of the exogenous variables increases, the precision of the estimates decreases (i.e., RMSE increases), for both OLS and 2SLS regardless of the degree of cross-equation error correlation.

As expected, the Monte Carlo experiments yield results which are consistent with the theoretical econometric results. These numerical results are particularly interesting, however, because they provide some sense of the magnitude of the potential gains in precision available by applying the theoretically correct, but more complicated, 2SLS estimation procedure.

The main finding is that the degree of cross-equation error correlation is crucial to the relative performance of 2SLS versus OLS. If the cross-equation error correlation is small (less than 0.50 in our Monte Carlo experiments), then the potential gains in precision are fairly small, about 10%. However, even small "errors" in parameter estimation may lead to incorrect inferences about the statistical significance of model parameters. In more extreme cross-equation error correlation situations, it will be necessary for the marketing scientist to use 2SLS since (a) precision will be improved by about 35% and (b) the parameter estimates will be noticeably less biased. These results hold regardless of the degree of correlation among the exogenous variables.

Concluding Remarks

Theoretical considerations suggest that simultaneous estimation procedures, rather than sequential procedures, may be more appropriate to estimate the parameters of multi-stage models of perception, preference, and choice. The rationale for this claim, plus issues associated with simultaneous estimation methods, were reviewed in this paper. Monte Carlo experiments indicate that limited information methods of estimating simultaneous multi-stage choice models dominate sequential estimation methods, if there is cross-equation error correlation.

Simultaneous estimation methods yield substantial gains in the precision of parameter estimates compared to sequential estimation methods. Also, bias is reduced. The Monte Carlo results reported in this paper provide

TABLE 1

SUMMARY RESULTS OF THE MONTE CARLO EXPERIMENTS

		Degree of Correlation Among the Exogenous Variables			
		Low	Medium	High	
<u>Degree of</u> <u>Cross-Equation</u> <u>Error</u> <u>Correlation</u>	<u>Low</u>	BIAS: OLS	-0.113	-0.041	-0.074
		2SLS	-0.069	0.064	-0.007
		RMSE: OLS	1.109	1.180	1.234
		2SLS	1.547	1.744	1.963
	<u>Medium</u>	BIAS: OLS	-0.174	-0.451	-0.821
		2SLS	-0.059	-0.097	-0.224
	RMSE: OLS	2.060	2.230	2.703	
	2SLS	1.813	1.946	2.065	
<u>High</u>	BIAS: OLS	-0.311	-0.670	-1.110	
	2SLS	-0.247	-0.015	0.285	
	RMSE: OLS	3.118	3.636	4.160	
	2SLS	2.060	2.368	2.629	

- Notes: (1) BIAS is the aggregate mean bias across the ten parameters in the simulated multi-stage choice model. The "bias" for each parameter in a replication is based on comparing the estimated coefficient (under the given estimation procedure) to the true, known parameter value. The "mean bias" for a given parameter is the arithmetic mean of the calculated "bias" values over the 25 replications.
- (2) RMSE is the aggregate root mean squared error for the ten parameters in the simulated multi-stage choice model. The "squared error" for each parameter in a replication is based on calculating the squared difference between the estimated coefficient (under the given estimation procedure) to the true, known parameter value. The "mean squared error" for a given parameter is the arithmetic mean of the calculated "squared error" values over the 25 replications. The "root mean squared error" is the square root of the "mean squared error."
- (3) The low, medium, and high correlation conditions among the exogenous variables refer to correlations of 0.00, 0.24, and 0.45, respectively.
- (4) The low, medium, and high cross-equation error correlation conditions refer to correlations of 0.00, 0.40-0.44, and 0.50-0.71, respectively.

numerical estimates of the potential gains in precision for a simple multi-stage choice model with quantitative endogenous variables.

Extensions of this work would involve a detailed study of the qualitative endogenous variable case, as well as considering how sample size, relative size of the error variances, and the ratio of exogenous to endogenous variables influence the relative performance of sequential and simultaneous estimation procedures.

EXPERIENCE AND EXPERTISE IN COMPLEX DECISION MAKING

Jacob Jacoby, New York University
Tracy Troutman, Lever Brothers
Alfred Kuss, Free University, West Berlin
David Mazursky, Hebrew University, Jerusalem

Abstract

This paper has two objectives. First, we posit some conceptual distinctions between experience and expertise and indicate their implications for measuring the latter. Specifically, expertise needs to be operationalized in term of either knowledge and/or performance based indices that can be compared to some external criterion. Second, a top line summary is provided of the findings from a recent investigation that utilized a performance based operationalization to study the differences in the pre-decision information accessing behavior of practicing security analysts.

Introduction

The great number of factors that influence decision making may be organized into three broad categories: those relating to the nature of the decision task itself, the decision environment, and the decision maker. Theory (e.g., Bettman, 1979) suggests that one characteristic of the decision maker that should be particularly relevant is experience. Yet, at least with respect to the information search aspect of consumer decision making, the empirical literature has produced conflicting findings. Some studies suggest that people with higher levels of experience do less information search; others (e.g., Jacoby, Chestnut, Weigl and Fisher, 1976) suggest just the reverse.

Consumer research studies almost routinely include questions relating to past experience (e.g., purchase and/or consumption frequency and/or quantity). Few consider the related construct of expertise. This is not surprising since, as noted elsewhere (Jacoby, 1977a), consumer behavior offers few areas in which objective criteria exist for evaluating the quality of consumer decision making:

As Ross (1974) notes, the central problem in defining decision quality concerns use of appropriate criteria. One approach is to have "experts" identify what constitutes the "best" decision and then to assess the extent to which the subject is able to achieve this objective standard. Accordingly, we requested assistance from Procter & Gamble in identifying the single best laundry detergent available on the market for the purpose of using it as an external standard in our investigation. Their reply was illuminating. Though P&G believed that, overall, its products were superior to those of its competitors, there was no way to determine objectively which brand was best for all consumers because the specific needs, problems, and desires of individual consumers, and the types of stains, fabrics, etc., all varied considerably. What was best for one consumer or one type of laundry situation was not necessarily best for another consumer or another type of situation. It was obvious that, no matter which product category we approached, we had an identical problem (Jacoby, 1977, p. 571).

Without an objective basis for identifying decision quality, there is great difficulty in identifying just what constitutes expertise.

Selected insights on measuring expertise derived from the perceived quality and abilities literatures.

Notwithstanding the very substantial difficulties, there have been several attempts in the consumer behavior literature to incorporate the notion of expertise. Perhaps the first mention appears in Scitovsky's (1944) classic paper on perceived quality wherein he hypothesizes that experts would be less likely than non-experts to rely on price when arriving at a purchase decision. Though others speculated about the issue (e.g., Jacoby, Olson and Haddock, 1971, p. 578; Shapiro, 1968), it wasn't until 1972-1973 that attempts to assess the relationship began to materialize.

One investigation, Valenzi and Eldridge (1973), operationalized expertise via two self report questions probing the frequency and quantity of beer consumption. The subjects' answers to these two questions were combined and the distribution was split at the median in order to identify experts vs. non-experts. Aside from the methodological problems with self report data (e.g., no independent effort was made to verify that the stated frequency and quantity estimates indeed corresponded to any objective fact), and median splits (particularly based on the integration of two disparate distributions), it can be seen that a major conceptual problem was that the concept of expertise was operationalized in terms of experience. Yet these two constructs are actually conceptually orthogonal. One can have considerable experience, yet not be an expert. People at the same level of expertise may have different levels of experience, and vice versa.

The tendency to define expertise in terms of experience may stem, in part, from dictionary definitions of these terms. According to Webster's New Collegiate Dictionary: experience includes "something personally encountered; knowledge, skill or practice derived from direct observation or participation in event." The word experienced is defined as "made skillful or wise through observation of or participation in a particular activity." In contrast, the word expertise is defined as "skillful in a particular field." Reflecting upon these definitions suggests that both experience and expertise involve acquiring knowledge and/or skill. The essential distinction appears to be that expertise reflects qualitatively higher levels of either knowledge or skill. One implication is that if one wishes to study expertise, then that construct needs to be operationalized as more than "something personally encountered," as would be the case if one simply assessed purchase and/or consumption frequency and/or quantity. While drinking twenty-six packs a day may make one experienced, heavy and drunk, it would not necessarily make one an expert on beer. "Personally encountering" does not equate to "expertise." Any measure that purports to assess expertise needs to utilize indicants that reflect either knowledge and/or skill.

A second study, conducted over the 1972-3 academic year, relied on such a rationale to derive a knowledge based test of expertise (Jacoby and Williams, unpublished). A full description of how this test was developed is provided in a replication (Williams-Jones, 1974) which incorporated additional levels of the independent variable and followed immediately.

Briefly, a pool of items designed to assess stereo and high fidelity knowledge was developed, revised, pared down, and administered to a set of 50 pre-test subjects whose scores spanned virtually the entire range. The test was then administered to 12 stereo repair technicians whose scores ranged from 22 - 30. Based upon these re-

sults and a consideration of the two distributions, cut offs were assigned as follows: people scoring 22 or above were defined as experts and those scoring 12 or below were defined as non-experts. As applied to the 487 subjects employed in the replication study, 25% of the subjects were classified as experts and 23% as inexpert. This same test of expertise was later used to investigate whether people classified as opinion leaders in the realm of stereo equipment actually knew more about stereo concepts -- they did ($r = .69$) -- and a complete copy of the test is reprinted in that source (Jacoby and Hoyer, 1981).

Of present interest, the Williams-Jones and Jacoby replication also included four experience measures: stereo ownership, frequency of usage, number of magazines read each month which were directly relevant to stereos and stereo equipment, and number of electronic related courses that the individual had completed. Due to the large sample size ($n = 487$), the correlations between scores on these experience indicants and scores on the test of expertise (.24, .20, .25, and .26, respectively) were all significant at $p = .001$ or better. However, the low correlations means that none of these experience indicants explained more than 7% of the variance in the expertise scores. (N.B. The .24 correlation with ownership compares favorably to the .25 correlation obtained several years later by Jacoby and Hoyer, 1981.)

Moreover, knowledge does not always equate to skill. Demonstrating that one is an expert based on one's performance on a knowledge test is not necessarily equivalent to being able to exhibit that skill in actual task performance. Coaches may be exceedingly knowledgeable while, at the same time, exceedingly incapable of executing that knowledge. Of course, one might argue that these coaches are expert coaches, not expert players, and their players may be expert players, but not they are not expert coaches. It remains true, however, that many of the elements that constitute either coaching or playing expertise are incapable of being assessed via knowledge tests. Being able to do something doesn't necessarily mean one is able to identify or articulate what it is that one does. As Polyani's (1966) notion of tacit knowledge suggests, many aspects of performance are encoded (if at all) in hazy, non-verbal form.

The results of a study by Denisi and Shaw (1977) are instructive here. These authors had subjects first rate their abilities in ten areas and then administered a battery of standard, commercially available tests to measure these abilities. These authors report: "Correlations between self-rated and tested abilities, although generally significant, were too small to have any practical significance. The self-ratings were also unable to differentiate between those who would score high and low on the ability tests, even for extreme self-rated groups. No moderator effects were found. It was concluded that self reports of ability could not substitute for ability tests" (p. 641). The median correlation between self reports of abilities and actual abilities across all ten areas hovered near .3 and no single self report measure explained more than 16% of the variance in the corresponding test score.

Studying Decision Maker Expertise

Though far from a thorough discussion of the relevant experience/expertise literature, the work noted above was paramount among those things that influenced the senior author's thinking in developing the study reported below. Briefly, both prior theory and research (as well as common sense) suggests that pre-decision information accessing behavior of experts might differ appreciably from those who were inexpert. To effectively study whether this was indeed so required a satisfactory means of operationalizing expertise. This eliminates both experience based indices (e.g., those which probe the quantity and/or frequency and/or variety of purchase and/or usage experiences) and self reports of expertise. Though expertise might also be approached sociometrically (e.g., via peer ratings), we know of no such approach

that has been used and validated (against an appropriate criterion) in the consumer behavior realm. Finally, though a knowledge based measure might be appropriate for assessing the knowledge component of expertise, it would be inadequate for assessing the other principal facet of expertise, namely skill.

This eventually led to outlining a performance based study in 1977. Implementation of this research had to wait until the appropriate hardware (computers for containing and presenting the information environment) could be obtained. The study itself, which had a variety of other research objectives as well, was implemented over the 1981-82 academic year. Reports based on this database have either been published (Jacoby, Mazursky, Troutman and Kuss, 1984), are in press (Jacoby, Kuss, Mazursky and Troutman, 1985), or are under review (Jacoby, Jaccard, Kuss, Troutman and Mazursky, submitted; Jacoby, Kuss, Troutman and Mazursky, submitted). Beyond raising the conceptual issues noted above, a second objective of the present paper is to highlight some of the major findings from this investigation and to direct the interested reader to these other, more complete reports.

Overview of Methods/Procedures.

The nature of the subjects, decision task, task instructions, setting and procedure have already been described in considerable detail elsewhere (Jacoby, et al, 1984, 1985). Suffice it to say that seventeen professional security analysts participated in a behavioral process simulation (see Jacoby, 1977b, for a definition of terms) of security analyst decision making.

The analysts were motivated to participate by virtue of two incentives. First, the analyst who performed the best on the task was awarded \$500. Second and probably more important in an industry where recognition of one's performance counts highly, all the analysts knew that press releases would be issued to the relevant media publicizing the name of the winner.

Since it reflects upon their experience, note that the median age of these analysts was in the upper 30's, and their careers as professional security analysts ranged from 1.5 to 17 years (mean = 6.9 years; s.d. = 5.7 years). Fifteen of the analysts had Masters degrees, two held B.S. degrees. Two analysts declined to respond to an item regarding the income they derive from their activities as professional security analysts. Another eight indicated that their income was below \$75,000 a year; seven indicated that their income was above this amount.

The task objective was to select the "best buy" (defined as that stock most likely to show the greatest percentage of growth in price per share over the next ninety day period) from among eight securities for each of four successive ninety day periods. Except for the names of these securities, all information provided to the analysts was authentic and taken from the 1969-1970 period when these securities were listed on the New York Stock Exchange. (Post test manipulations revealed that only one of the 17 analysts correctly ascertained the identity of one of the eight stocks. Since there were $17 \times 8 = 134$ opportunities for someone to make such a correct identification, the one correct identification suggests that the camouflage manipulation worked as intended.) Subjects could access any of 26 types of fundamental factor information regarding each of the eight securities. Both pre- and post-investigation efforts suggest that, with few exceptions, these 26 factors are those of greatest interest and use to professional security analysts.

Operationalizing Expertise: The performance criterion used to distinguish between the better and poorer analysts was based directly on the increases in price per share of each security, calculated separately for each of the four test periods. The analysts were arranged in descending order, based upon the aggregate net yield they produced across the four periods.

Summary of Findings

Expertise and Experience: Across the entire sample of 17 analysts, task performance (i.e., expertise) correlated nonsignificantly with age ($r = -.22$) and length of time with present employer ($r = -.37$). Most noteworthy, performance correlated negligibly with either experience (defined in terms of number of years working as a professional security analyst ($r = .03$) or income ($r = .04$).

The depth, content and sequence of information accessing behavior were examined both for the entire sample and separately for the five (or seven) best versus the five (or seven) poorest performing analysts. These data and analyses were quite extensive and proved to be too much for any single article. Indeed, despite the five papers that have thus far been prepared, a number of the analyses have not yet been reported. Hence, what follows is necessarily a highly restricted "top line" summary of some of the findings.

Depth of Search: Expertise appeared to be related to the overall depth of search. When each analyst's performance score was correlated with the number of items acquired across all four periods, a significant relationship was revealed ($r = .41$; $p = .05$). However, much of this result is due to the extensive accessing of the top performing analyst. When his data are removed, the correlation for the remaining 16 analysts hovers near .2.

Second, there was no significant difference on the molar dimensions of information. That is, experts and in-experts did not differ on the number of stocks (median = 8) or number of fundamental factors (median = 9) considered across the four test periods. A period-by-period analysis revealed that, while the better analysts accessed a relatively constant $8.6 \pm .4$ properties across the four periods, the poorer analysts displayed a very high initial accessing rate (13.6 properties during the first period) followed by a dramatic and significant ($p = .02$) drop for the second, third and fourth periods (where the median was 7.2 properties).

Third, the more expert analysts were significantly more thorough in examining the stocks and factors that they had looked at. This is determined by examining the "percent of submatrix" accessed. While the 26 factors in eight stocks made available to each subject represented the experimenter-determined information matrix, not every piece of information in this matrix may have necessarily been useful, worthwhile or meaningful to any given subject. Hence, it is insightful to adopt a respondent oriented perspective and ask: If attention were limited to only those stocks and factors considered by the analyst at least once, then what percent of the information from that submatrix was accessed? The results indicate that better performing analysts were consistently more thorough in examining the contents of their submatrices (77% overall) than were poorer performing analysts in examining the contents of their submatrices (55.5% overall).

Much greater information on depth of search is provided in the Computer in Human Behavior article, with supplemental material appearing in the Journal of Applied Psychology piece.

Content of Search: The differences between expert and in-experts in terms of the type of information accessed was substantial. First, both expert and in-expert analysts devoted approximately 45% of their total information accessing to only 4 of the 26 available factors and only one of these four factors (12 month price/earnings ratio) was common across both groups (see Jacoby, Kuss, Mazursky and Troutman, 1985).

Second, when tests were applied on a factor-by-factor basis, significant differences (at the .01 level or better) were found for 16 of the 26 factors. As one example, though the better analysts devoted only 1% of all their information accessing behavior to acquiring

"interim earnings for the previous year expressed in terms of price per common share" information, this factor counted for 9% of the information accessing of the poorer analysts (see Jacoby, et al, 1985).

Two types of information are of particular interest. The first is feedback information. Since it was one of the 26 factors (namely, "Perceived price change over the past three months"), feedback was made available as part of the external information environment. Most discussions suggest a positive relationship between feedback and performance. However, as explained in Jacoby, Mazursky, Troutman and Kuss (1984), there are more compelling reasons for postulating an inverse relationship when feedback provides only descriptive information regarding the prior outcome without providing any diagnostic information (i.e., information which has either predictive and/or explanatory value). Our data are consistent with this expectation. Across all 17 analysts, the correlation between expertise and the accessing of outcome-only feedback was $-.48$ ($p = .02$).

Subsequent to publication of the above reports, one of our colleagues (Prof. Martin Gruber, Editor of the Journal of Finance) suggested that the data be reanalyzed to see what insights might be provided on a long-standing controversy in the domains of finance and accounting. Specifically, the question was whether better and poorer analysts could be differentiated in terms of their use of accounting based information. Accordingly, the 26 factors were apportioned into three categories: fully accounting based, partially accounting based, and non accounting based. A paper detailing these analyses is currently under review (Jacoby, Kuss, Troutman, and Mazursky, submitted); hence these data are not described here.

Sequence of Search: Probably the most dramatic differences of all were obtained with respect to the information accessing sequences employed by the better vs. poorer performing analysts. Those who were more expert were overwhelmingly Type 3 (within property; see Jacoby, Chestnut, Weigl and Fisher, 1976, for a discussion of the operationalization of this index) information accessors. In contrast, the in-expert analysts devoted nearly equal proportions of their search to within property and within option search. These data are detailed in a paper now under review (Jacoby, Jaccard, Kuss, Troutman and Mazursky, submitted).

Discussion

This report had two principal objectives. The first was to raise some perspectives regarding the distinction between experience and expertise -- perspectives that have both conceptual and operational implications. The second was to highlight several of the major findings emanating from a recent investigation which, using a performance based procedure to assess expertise, revealed strong differences between expert and in-expert behavior in regard to pre-decision information accessing.

Several concluding comments are in order. First, virtually every operationalization is flawed in some respect. A significant flaw inherent in using performance as an indicator of expertise is the danger that the subject may make an objectively good decision, but for the wrong reason, or vice versa. This is especially true in the realm of security analysis, since the stock market doesn't necessarily function in a rational fashion.

Second, even if this measure were entirely accurate, it still represents an assessment of only the skill/performance aspect of expertise, not the knowledge aspect. Though the data reveal no relationship between expertise and experience (the correlation between performance and number of years as an analyst was only $r = .03$), a study is still called for that would assess both knowledge and skill components in the same investigation.

(N.B. A number of other criticisms may be found in the other reports. Also note that the present paper was prepared at "the last minute" by the senior author without any opportunity for review by the junior authors. Hence, he assumes all responsibility for any flaws.)

ENERGY CONSERVATION ACTIONS: ANALYSIS OF PREDICTORS¹

Patricia A. Tripple, University of Nevada, Reno
Carole J. Makela, Colorado State University

The continued demand on finite resources to provide energy for an ever increasing population requires a more comprehensive understanding of consumers' intentions and actions. This understanding is vital to provide rational responses to short term crises and long term solutions to the demand-supply imbalance whether public policy or personal practices. With lessened public policy related to energy, personal practice is expected to respond to supply and price fluctuations and to national well-being. The hoped for outcome is sound energy use practices, the reality is yet to be assessed.

Conservation has been advocated as an important factor in easing the energy problem. Response to the crises of the 1970s has proven that conservation practices can result in lessened energy use and decreased acceleration of the growth in demand. Yet predictions of the energy situation in the United States label conservation trends as 'highly uncertain' (Energy Information Administration 1985).

If conservation and its dependence on the individual consumer are viewed on a continuum, on one extreme conservation is dependent on the design and production of energy efficient structures and systems, automobiles and appliances. On the other extreme are the actions and behaviors of individuals or groups who occupy the buildings and use these goods. Though efficiency has been built into new structures and goods, gains in efficiency are dependent on the replacement of current inventories and on the maintenance of optimal use through consumer practices and actions. Meanwhile, existing units may need to be retrofitted and operated and/or used differently from in the past to effect sustained conservation. Changes in the actions of people are essential to achieve optimal levels of conservation whether it be setting thermostats higher in summer and lower in winter, lessening heat loss or gain from one's living unit or using less hot water.

This paper looks at the plans and implementation of conservation measures by consumers in a longitudinal study done in the Western United States. The dynamics of factors in the residential energy picture and conservation efforts are explored to develop understanding between intent and action. Directions to take in further research related to the consumer and the conservation of energy are put forth.

Do people plan their actions to implement energy conservation retrofits? How much time elapses between stated plans and implementation of conservation actions? Do planners implement conservation actions more often than nonplanners? Is planning an ever present mode for a portion of people since actions can be done in increments (some weatherstripping this year, some next; add storm doors this year, windows at some later time)? What do people identify as barriers to taking planned actions?

Methodology of Sampling and Data Collection

Mail questionnaires were used to obtain a western states' perspective of attitudes and energy behavior in 1981 and again in 1983. Eight states--Arizona, Colorado, Idaho,

Nevada, Oregon, Utah, Washington, and Wyoming--participated in the study. In 1981 and 1983 all eight states administered their questionnaires simultaneously using the same mail survey procedures. This common use helped assure collection of comparable data in each of the states and legitimized the combining of states' data for regional analyses. The technique used was Dillman's (1978) Total Design Method (TDM). The method includes the following steps: 1) an initial mailing of a cover letter (individually addressed and signed), a questionnaire and return envelope; 2) a follow-up postcard designed as both a thank you to respondents and a reminder to nonrespondents one week later; 3) a replacement questionnaire with cover letter and return envelope to nonrespondents three weeks after the first mailing; and 4) either a telephone follow-up or a second replacement questionnaire sent by certified or special delivery mail. Copies of relevant survey and correspondence implementation materials for 1981 are included in Makela, *et al.* (1982); those for 1983 were similar.

The 1981 sample was a stratified (rural/urban) random sample of approximately 1500 households in each state drawn from telephone directories. Households responding to the 1981 survey were included in the 1983 survey. This was considered important for the purpose of measuring change over time. In addition to the follow-up of 1981 respondents, each participating state was required to draw an independent random cross-sectional sample from each of its rural and urban strata in 1983. Minimum sample size requirements proportional to state population were specified. The overall sampling plan is summarized as follows:

*In 1981, a cross-sectional stratified random sample of approximately 400 from the rural and from the urban populations of each of the eight states (useable returns 6,893, 58 percent);

*In 1983, a resurvey of the 6,893 respondents using a similar questionnaire (useable returns in panel resurvey 4,548, 67 percent);

*In 1983, a new cross-sectional stratified random sample in each of the states (rural and urban), (useable returns 2,768, 57 percent).

Conservation Plans and Actions

In their analytic framework, Cooper *et al.* (1983) indicated that three elements interact to determine the impact of rising energy prices on consumers. These elements are changes in income, expenditures and 'avenues of retreat.' The regional project explored the latter two elements to the greatest extent. Changes in expenditures include those for energy, other goods and services and 'instantaneous' responses--behavioral conservation and reductions in savings. The regional project explored changes in expenditures for selected goods and services, savings and the practice of behavioral conservation.

Respondents indicated a greater adjustment in their expenditures for other goods and services in 1981 than in 1983. By 1983 cutbacks had moderated especially for the basics of food, housing, education and health care. Less than one-fifth of the respondents assessed their cutbacks as 'alot' or 'some' in the aforementioned expenses in 1983. Discretionary items (vacations, recreation, eating out) were being cutback by two-fifths to one-half of the respondents. This may reflect that adjustments were made during the periods of rapidly rising energy costs and highest inflation. The result may well be that consumers have settled in on a new spending pattern that will be

¹"Research completed in Western Regional states (AZ, CO, ID, NV, OR, UT, WA, and WY), part of Regional Project W159, Consequences of Energy Conservation Policies for Western Region Households. Financial resources for the collection of the data were provided, in part, by USDA Regional Research Project W-159."

readjusted when internal or external events cause disequilibrium due to a strain on one or more of the expenditure categories.

'Avenues of retreat' relate to plans to cope with the impact of energy costs. Behavioral conservation, investment, indebtedness and reductions in living standard are the avenues used by Cooper, *et al.* All of these were studied in the regional project. Behavioral conservation and investment were explored to the greatest depth. Fourteen structural features were studied. Those most commonly added by the panel between 1981 and 1983 were weatherstripping and caulking (16 percent), storm or double pane windows (10 percent), and insulated window treatments (10 percent) (Table 1). Four other features had each been added in the two year period by 7 to 9 percent of the panel.

These longitudinal findings indicate that people do carry through with plans implementing the less technical and more proven features while being less likely to implement the high technology features. Yet, plans to add 'newer' features continue. Planners were more likely than non-planners to add features.

The portion of persons who plan and take action may appear small, but various factors influence the 'intent and action' relationship. The factors include:

- *the presence of the feature at the time of the initial survey;
- *climatic conditions that make the feature inappropriate;
- *structure characteristics that make the feature inappropriate;
- *nature of the feature that makes incremental additions appropriate;
- *general reluctance to replace features in working order or good condition with 'improved' models (more energy efficient in this case);
- *renters limited motivation or incentive to 'improve' their unit;
- *perceived short term tenure in current housing unit.

What are the standards for annual rates of adding of these individual features? What internal or external factors will decelerate or accelerate these rates? Answers to these two questions would help us better understand diffusion and adoption of energy conservation features.

As its state research focus Colorado explored the reasons that respondents identified as preventing their planned implementation of the projects (Makela 1984). Economic reasons were frequently given as the barrier preventing two or more of the projects from completion. Forty-five different reasons were indicated by 675 Colorado respondents. Their statements ranged from the costs of the projects to the age of the respondents to the constraints of their housing situation. The reasons most often cited and their respective percentages were lack of money, 66 percent; renting, 13 percent; lack of time, 9 percent; plans to move, 5 percent; and lengthy payback period, 5 percent.

When categorized by the type of limitation that they presented the pattern for the 675 reasons were primarily economic. Current economic limitations (57 percent of the reasons), housing limitations (18 percent of the reasons), and time limitations (7 percent of the reasons) were most frequently cited for preventing implementation of the projects. These three groups of reasons accounted for more than four-fifths of the deterrents to implementation of the projects.

The identification of economic barriers and the small portion (no more than 13 percent in any one state) of people who borrowed to implement features in 1981 need further exploration now that energy prices are increasing at slower rates than earlier, interest rates have declined and energy conservation has taken on (or been relegated to) a low profile. Will the addition of energy features decline as price pressures moderate or will this situation be viewed as an opportunity to use dollars that might otherwise be earmarked for rising expenses?

Conclusions

The following conclusions are drawn from these preliminary analysis.

- *Over the two year time span, the portion of planners remain fairly constant for most energy features.
- *During the 1981-83 period the portion making energy feature additions was similar to the portion planning to in 1981 except for the technical and 'newer' features--setback thermostats, solar water heating and home heating.
- *While nearly 80 percent of the respondents indicated projects they would like to do on their homes, only a small portion planned to add any one feature.
- *Of the projects that respondents would like to do, most were to improve structural efficiency or to allow for use of an alternative energy source.
- *The reasons most frequently cited as deterring the implementation of the projects were current economic and housing limitations.

With the continued demand for finite resources to provide energy for an ever increasing population, a more comprehensive understanding of consumers' intentions and actions is vital to provide rational responses to short term crises and long term solutions to the demand-supply imbalance. The relationships of consumer intentions to actual consumption behavior have been modeled by many renowned consumer researchers. The conclusions are not definitive. New choice situations call for continuing study of the relationship of what consumers 'say they plan or will do' to what they actually do. The 'intent to action' relationship is of prime importance in our individual and national efforts to decrease dependency on foreign supplies of energy and to maintain reasonable costs for delivery of energy to the residential sector. Our next step is the exploration of the predictive power of consumer attitudes, demographic and housing variables as they relate to consumers' intent and actions.

The study of diffusion of energy conservation features and consumers' intentions and actions may not mirror even the 'hazy' picture found for other consumer goods and services. Conservation features are not the relatively permanent goods and services described by Frankel (1977) "Prediction is apparently more successful for those goods and services that are relatively more permanent, such as financial services (bank accounts and credit card usage) and products for which the consumer is brand loyal" (p. 8).

Energy conservation practices and priorities are characterized by mixed messages at best. The major ones include the following:

- *Media reports of contradictory scenarios as to the supply and price of energy now as well as in the future. What can we believe?
- *Decreased attention to the need and practice of conservation as energy tax credits are allowed to expire and informational and educational efforts wane. Are we really convinced?

TABLE 1
STATUS OF ENERGY FEATURES IN HOMES OF 1983
PANEL MATCHED BY STRUCTURE

Feature	Present in 1981	Planned in 1981	Added 1981-1983
	(percent of respondents)		
Insulation - ceiling	64	10	9
Weatherstripping/caulking	59	14	16
Insulation - wall	58	4	4
Double pane/storm windows	49	11	10
Storm doors	38	13	7
Insulation - floor	30	8	4
Wood stove	26	8	9
Insulated window coverings (interior)	24	11	10
Glass doors/fireplace	22	6	7
Evaporative cooler	15	4	3
Window shades (exterior)	13	6	4
Setback thermostat	12	8	4
Solar water heating	2	10	2
Solar heating	1	7	1

Anderson, et al., adopted from Table A9.

*Limited advertising of conservation features of housing units, heating and cooling systems and appliances. Seemingly even less advertising of conservation products --weatherstripping, storm doors, solar systems. Insulation isn't sexy!

*Time cost for do-it-yourselfer to obtain the materials and tools. Some of us speculate it takes longer to shop than to install the features. This is a highly researchable area exploring time as well as money limitors.

*The confusion/misunderstanding that the 'payback' period message has given compared to a message that return on expenditure/investment might give. Would you make an expenditure if you thought you would sell the house before the payback period expired?

Research on residential energy use is now ready to go beyond the study of energy usage patterns and the explanation of these to the explanation of conservation actions and practices. This research will provide answers that enable the consumer to gain some control in their energy environment where they often feel at the mercy of a utility company, builder or auto manufacturer.

DETERMINANTS OF HOME INSULATION INTENTION¹

W. Fred van Raaij, Erasmus University Rotterdam
Theo M.M. Verhallen, Tilburg University, The Netherlands

Abstract

Home insulation intention of home owners and renters is explained by a set of determinants: home characteristics, energy-related household behavior, attitudes, expectations, and sociodemographics. In a survey among 845 owners and 1101 renters, differences between owners and renters with and without insulation, are shown. Some home characteristics, attitude components, and expectations are significant determinants, although the level of explained variance is low. Home insulation intention of renters is mainly a matter of expected savings and expected high energy prices. For owners, comfort and an expected favorable household financial situation are the main determinants.

Introduction

One of the objectives of the energy policy of the Dutch government is to reduce the amount of energy, mainly natural gas, for home heating. This objective can be realized through a number of policies, one of them being a better thermic insulation of homes. The typical approach of a policy of better home insulation is to start with a survey of the technical state of homes and their possibilities for insulation, e.g. filling cavity walls and installing double glazing. Secondly, the economic aspects of home insulation are studied, and economic tradeoffs are made of the costs of installing home insulation of different types of homes and the energy conservation that can be attained. Thirdly, the behavioral aspects of home insulation come into focus. Why do some homeowners not insulate their homes, if this is technically and economically feasible? Why do other homeowners insulate their home, while they do not get enough return on this investment? Why do homeowners start their home insulation with double glazing, which is economically less effective than wall cavity filling? How do renters relate to the owners of their homes, and how does this influence home insulation decisions?

Determinants of Home Insulation

A number of factors influence the home insulation intention. Verhallen and Van Raaij (1981), in their study of factors determining household energy use, distinguish situational characteristics (climate, weather, technical home characteristics), behavioral factors (energy-related household behavior), and special circumstances, e.g. the presence of babies or elderly persons with a need for a higher temperature. Attitudinal and life-style factors may affect household energy behavior and thus energy use.

In a similar manner, the home insulation intention may be influenced by home characteristics, energy-related household behavior, home insulation attitudes, expectations with regard to the future energy price and prices in general, and sociodemographic characteristics of the homeowners and renters. A number of these determinants are discussed below.

Home Characteristics

Verhallen and Van Raaij (1981) use the following home characteristics in their study on household energy use: degree of home insulation, type of home (free standing,

semi-detached, row house, apartment), energy use of neighbors in attached homes, and wind orientation of the home. These home characteristics have both a direct and an indirect effect on energy use. The direct effect is the energy required to bring the home to an acceptable temperature. The amounts of energy required differ between home with different technical characteristics. The indirect effect is the effect of home characteristics on energy-related household behavior, and thus on energy use.

While the degree of home insulation is a significant determinant of energy use, we expect the reverse for this study. Energy use may be an important determinant of the home insulation intention. High energy bills might elicit an intention to install better home insulation, improving the "shell" (Van Raaij and Verhallen 1983b) of the home.

Related to the home's energy use is the type of heating system. We expect that people living in a home with an individual central-heating system (and their individual energy bill) will be more likely to consider home insulation than people living in a home without individual heating and billing.

Houses with a cavity wall are easier and less expensive to insulate than houses with a single wall. Most houses built after 1945 possess a cavity wall. Only a part of the houses built between 1925 and 1945 have a cavity wall, and almost no houses built before 1925 are built with a cavity wall.

Other relevant home characteristics are the maintenance level of the home. Owners of well-maintained homes are more likely to install home insulation than owners of poorly maintained homes. Homes with a low level of maintenance might be insulation in a process of home improvement and renovation.

Type of home, free-standing bungalow, row house, apartment, is a fifth relevant home characteristic. Larger, free-standing homes with a higher energy use have a higher potential for energy saving than, for instance, apartments. These homes are thus more likely to be insulated. Related to type of home is home ownership. Owners, living in their own home, make their own home insulation decisions. Renters, often renting apartments, have to make an arrangement with the home owner (private person, private organisation or municipality in the case of public housing). In the study of home insulation intention, the distinction between owners (living in their own home) and renters will prove to be essential.

Household Behavior

Energy-related household behavior may be described by the components "temperature" and "ventilation" (Van Raaij and Verhallen 1983b). After a principal components analysis, Van Raaij and Verhallen (1983b) obtained two central temperature variables (home temperature while at home and during absence from home) and two ventilation variables (airing rooms and the use of the hall door). Temperature variables apply to the "kernel" (heating of the home), whereas ventilation variables pertain to the "shell". Based on these variables, respondents are grouped in five behavioral clusters: "Conservers" are characterized by low temperature and low levels of ventilation. The "spenders" have the opposite pattern: high temperature and high ventilation. The "cool" are low on temperature, but high on ventilation. The "warm" are high on temperature, but low on ventilation. The other respondents are "average" on both temperature and

¹This study is financed by the (Dutch) National (Home) Insulation Program, Rotterdam. We thank Ineke Brouwer and Anthonie van Onzenoort for their computational assistance.

ventilation.

It is expected that respondents of these five behavioral clusters also differ with regard to their home insulation intention. We expect that the "conservers" and "warm" have higher home insulation than the "cool" and the "spenders", unless they have already insulated their homes.

Attitudes

Verhallen en Van Raaij (1981) obtained three principal components in their attitude statements: (1) Energy consciousness, beliefs that one should reduce energy consumption, (2) Home comfort and susceptibility to draughts; and (3) Price consciousness, energy saving for financial reasons.

One may distinguish costs and benefits of home insulation (Verhallen and Pieters 1984; Verhallen and Van Raaij 1985). Costs are short-term, related to the trouble and disorder, when the home insulation is installed. Long-term costs are also perceived as negative effects of home insulation, e.g., a damp and humid atmosphere in the home, and lack of fresh air. Benefits are the energy saving and increase of comfort of the home. Note that these costs and benefits are not only financial, but also behavioral.

Expectations

Consumer expectations with regard to economic developments, especially energy prices, prices in general, and the financial situation of the household. Consumers expecting higher prices in the future, may be more intended to insulate their homes than consumers not expecting higher prices. The expectation about unemployment is taken as an indicator of optimism/pessimism about future economic condition in the Netherlands. The expectation questions are similar to questions used to measure the "index of consumer sentiment" (Katona 1975; Van Raaij and Gianotten 1982).

Study Design

In order to investigate the relative importance of the home insulation determinants, a survey has been done among home owners and renters, commissioned by the (Dutch) National Insulation Program (NIP). The NIP is a government organization to stimulate and promote home insulation, and to perform research on the factors determining home insulation.

The survey was done by NIPO/Gallup Amsterdam on a national sample of addresses in The Netherlands. During a five-week period in February-March 1985, each week a sample of persons living at 400 addresses was interviewed. The random sampling procedure was to select 80 addresses from a universe of all available private addresses in The Netherlands. Starting with these 80 addresses, five interviews are held. This result is a clustered sample of five interviews per cluster. During the five-week period, 2000 interviews have been held, of which 1946 questionnaires are complete and available for analysis.

The sample consisted of 1101 renters and 845 owners of homes. No systematic differences are found between male and female heads of households.

Home Insulation Intention

In this paper, we will analyse the determinants of home insulation intention. Home insulation intention is measured with two questions on how likely/unlikely it is that the home will be insulated. The results are shown in Table 1. For most respondents, home insulation intentions are low or very low. For 54.3 percent of the renters it is very unlikely that they will insulate their homes; for owners this is 44.6 percent. For 18.1 percent of the renters and 32.4 percent of the owners home insulation is likely or very likely.

TABLE 1
HOME INSULATION INTENTIONS OF RENTERS AND OWNERS

	renters		owners	
very likely	73	8.6%	118	17.0%
likely	81	9.5%	107	15.4%
unlikely	234	27.6%	160	23.0%
very unlikely	461	54.3%	310	44.6%
	849		695	

The category "very likely" pertains to home insulation intentions within the next 12 months. The other categories pertain to home insulation after 12 months.

The home insulation intentions of owners are significantly higher than of renters. Owners have more freedom to insulate their homes. Renters have to negotiate with the home owner or have to accept the home owner's proposals. Renters face a rent increase after home insulation that may be higher than their energy savings.

Home insulation intentions may be lower for people who have already insulated their home. Prior partial insulation, however, may lead to higher intentions to continue on the way to a better home insulation. In the remainder of the analysis, we distinguish between renters and owners of insulated and non-insulated homes.

Home Characteristics

Four groups are formed of renters and owners with insulated and non-insulated homes: (I) Renters with home insulation; (II) renters without insulation; (III) owners with insulation; and (IV) owners without insulation. Group sizes are 313, 348, 408, and 155, respectively, due to missing data on intentions or on home characteristics. Multiple regressions are run for each of these four groups.

Year of building is a relevant home characteristic. Renters and owners of a more recently built home with insulation have lower insulation intentions, because their homes are already insulated (groups I and III). Renters of a non-insulated home also have lower intentions, probably due to institutional problems with the home owner. Another explanation is that group II constitutes a group of renters without intentions, left over after all renters with the positive intention did have their homes insulated. Insulation intentions of group II are positively related to the presence of cavity walls and an individual heating system.

For home owners with insulation (group III), the presence of cavity walls is related to a lower intention. Homes with a cavity wall are generally already insulated. For home owners without insulation (group IV), an individual central-heating system is correlated with more insulation.

Household Behavior

Based on reported behavior with regard to temperature and ventilation, five behavioral groups are formed: "conservers", "spenders", "cool", "warm", and "average" (Van Raaij and Verhallen 1983b). Respondents with a room temperature lower than or equal to 19° Celsius, and with lower thermostat settings during absence, are classified as "conservers" or "cool". They are classified as "conservers" if they do not air their rooms very often and rarely leave the hall door open. Otherwise, they are classified as "cool".

Respondents with a room temperature higher than 19° Celsius, who do not always have lower thermostat settings during absence, are classified as "warm" and "spenders". They are classified as "warm", if they do not air their rooms very often and rarely leave the hall door open. Otherwise, they are classified as "spenders". Respondents remaining unclassified by the above procedure, are named "average".

TABLE 2

A. Multiple Regressions of Home Characteristics Explaining Home Insulation Intention

Home Characteristics	Renter with insulation	Renter without insulation	Owner with insulation	Owner without insulation
	I	II	III	IV
cavity walls	.00	-.12 *	.16 *	.00
(semi) detached	.03	.03	-.03	.23
row house	.00	-.06	-.08	.15
maintenance level	.00	.02	-.07	-.11
own heating system	.02	-.15 *	-.05	-.19 *
collective heating	.08	-.10	-.07	.08
energy costs	-.02	-.02	.02	.02
year of building	.23 *	.14 *	.21 *	.11
R ² (explained variance)	.06	.04	.10	.07
	n=313	n=348	n=408	n=155

B. Multiple Regressions of Consumer Typology Explaining Home Insulation Intention

Consumer Typology	I	II	III	IV
conserver	-.05	.03	.00	.00
spender	-.04	.00	.04	.05
cool	-.04	-.06	-.03	-.14

<u>Attitude components:</u>				
I. saving	-.20 *	-.10 *	.03	.09
II. benefits	.05	.06	.14 *	.33 *
<u>Expectations:</u>				
energy price	-.08	-.16 *	-.03	.05
household finances	-.10	.00	-.09	-.19 *
R ²	.13	.10	.14	.28
	n=313	n=348	n=408	n=155

* p < .05

The size of the five groups are as follows: 298 "conservers", 368 "cool", 410 "warm", 456 "spenders", and 406 "average".

Group membership, as dummy variables, is used in multiple regressions to explain home insulation intention (Table 2B). Explained variances are extremely low and regression weights are insignificant. One may conclude that energy-related house hold behavior, as measured with these five groups, is not related to home insulation intention. Daily energy conservation or spending behavior is apparently not generalized to home insulation intentions. There might be no generalizable "energy conservation ethic" (Painter, Semenik, and Belk 1983). Or, insulation intention and behavior belong to a behavioral category (Verhallen and Pieters 1984) different from daily energy-related behavior. It might be clear that these behavioral groups, although successful in explaining differences in energy use (Van Raaij and Verhallen 1983b), are no useful basis for segmentation on home insulation intention.

Insulation Attitudes

The questionnaire contained 15 questions on the attitudes toward home insulation (agree-disagree scale). A principal components analysis of these questions provided a four-component solution, explaining nearly 50 percent of the total variance. Only component loadings over .40 are reproduced in Table 3.

The four questions loading on the first component relate to savings and costs. Saving money and energy have positive weights; while statements that home insulation is after all more expensive or that home insulation has no benefits have negative loadings. The second component unites a number of insulation benefits (comfort, cosiness), insulation interest, and the statement that insulation is a necessity for all homes. The third component brings together a number of non-financial costs, e.g., damp home, humidity, mould, lack of fresh air, and ventilation problems. The fourth component is related to the behavioral costs of insulation installment.

We interpret this principal components solution as follows. Home insulation has two types of benefits: Financial/energy savings (I) and improved comfort (II). Respondents perceive two types of costs: Long-term costs of humidity (III) and short-term installment costs (IV).

Component scores of each of these four components are computed for all respondents and used in a multiple regression analysis to explain home insulation intentions.

Explained variance is generally low, between 3 and 16 percent. For renters, home insulation is related to financial/energy saving, in the sense that they believe that the costs are higher than the savings. For home owners, the benefits (comfort, cosiness, necessity, interest) are related to home insulation intention. For owners with insulation, long-term costs (damp home, humidity) are related to insulation. Other regression weights are insignificant, notably the short-term (behavioral) costs. We may conclude that a major obstacle for renters to have their homes insulated, is the belief that the costs exceed the benefits. Owners perceive more benefits related to home insulation, but tend to become aware of long-term disadvantages after home insulation (Table 2C).

Total Set of Determinants

In order to integrate the findings of the multiple regressions shown above, the total set of determinant variables is used in multiple regressions to explain home insulation intentions. Even when using 22 variables, the proportions of explained variance remain low, between 10 and 28 percent. These proportions are much lower than in studies explaining energy use. Verhallen and Van Raaij

(1981) explain almost 60 percent of the variance of energy use employing home characteristics household behavior, special circumstances, and attitudes. Home insulation intentions are obviously difficult to predict with the variables employed in this study. Discriminant analyses to distinguish between intenders and non-intenders were unsuccessful.

The home characteristics in Table 2D show a similar pattern as in Table 2A. Building year, cavity walls, maintenance, and own heating system, show significant relationships with insulation intentions. Household behavior, again, is insignificant in explaining insulation intention (Compare Tables 2B and 2D). The attitude components show a similar pattern (Compare Tables 2C and 2D). Renters relate home insulation to financial/energy saving; owners benefits, such as comfort, are related to insulation intention.

Sociodemographic variables, such as respondent's sex or social class, have no effect on home insulation intentions.

Consumer expectations, in combination with other variables, have only a minor effect on insulation intentions. For renters without insulation, pessimistic expectations about the energy price are related to higher insulation intentions. For owners without insulation, more optimistic expectations about the financial situation of the household are related to higher insulation intentions.

Note that for renters and owners with home insulation expectations are not relevant for their insulation intention. A rising energy price might increase the insulation intentions of renters. For owners, however, a better financial situation might be a stimulus for home insulation. If economic conditions improve, one may expect an increase of insulation intention for home owners.

Conclusions

Home insulation intentions, and probably behavior, do not belong to the same behavioral category as energy related household behavior. Explaining home insulation with the same set of variables as explaining energy use (Verhallen and Van Raaij 1981) is not successful, explaining a maximum of 28 percent of the variance (of owners without insulation). Energy use and behavior are daily activities, to be characterized by the dimensions "temperature" and "ventilation". Home insulation intentions are probably seen as investments in conservation done only once or a limited number of times. For renters, home insulation is probably the owner's business and they may feel that their intentions do not matter.

The behavioral model, proposed by Van Raaij and Verhallen (1983), for the explanation of energy use, is less applicable to the explanation of home insulation intention. The behavioral cost-benefit approach, however, may be useful. Owners and renters perceive different benefits (financial, comfort) and costs (short-term disorder and long-term humidity) related to home insulation. The task of advertising and promotion is to provide a realistic picture of benefits and costs, and to overcome the perceived short-term costs.

Home characteristics provide the opportunities and feasibility of home insulation, but they do not offer a sufficient explanation, why people decide to insulate their homes. For home owners, the building year of the home, the maintenance level, and the presence of cavity walls are the important home characteristics. For renters, the building year of the home and the presence of an individual heating system, are important.

Home owners, intending to insulate their homes, are inspired by the perceived benefits of insulation (comfort, cosiness) and optimistic expectations about their household financial situation. Energy or money saving are apparently not the first objectives. Home

insulation, as an expenditure category, is probably competing with other outlays on home improvement.

Furthermore, it was found that the intention of home owners with a non-insulated house (group IV) could be better predicted than the intentions of the other groups. This is probably so because they think more often about home insulation, and it is their own decision. Moreover, an economic upturn, resulting in better household financial situations, may result in an increase of home insulation intentions and consequent behavior.

Renters, on the other hand, considering home insulation, keep a sharp eye on savings. They face higher rents. Savings should thus be higher than the rent increase. Renters with pessimistic expectations about the future energy price, are more likely to consider home insulation. A major obstacle, however, is their lack of discretion or freedom. The owner of the house should cooperate or take the initiative. Renters' intentions may be less predictive of home insulation, because of institutional factors of home ownership and renting contracts.

MARKETING TO VULNERABLE GROUPS:
TESTING THE EFFECTS OF PEERS AND INCENTIVES
ON ELDERLY RESPONSE TO HOME ENERGY AUDITS

R. Bruce Hutton, University of Denver
Olli T. Ahtola, University of Denver and University of Tampere
Dennis L. McNeill, University of Denver

Abstract

This article presents the results of a field experiment designed to test the effects of the use of peer group members and incentives on elderly homeowners' response to home energy audits. Results provide insights into the decision processes of this important segment of society and the impact of two motivational tactics on subsequent behavior.

Background

In the United States, energy conservation programs have historically focused on information provision and motivation. Since 1980, market price has been the cornerstone public policy for encouraging conservation. Prior to this the Residential Conservation Service Program (1978) represented a landmark attempt at making available to all consumers, through a home energy audit, information on how to conserve energy. RCS was designed to encourage and facilitate the installation of energy conservation measures and renewable energy measures by making available low cost home energy audits. Utility companies were designated the primary distributor of the audits and audit programs. Since 1981, about one million such audits have been conducted each year (Morris et al. 1983, Centaur 1983). To date, neither pricing nor the RCS program have produced optimal consumer response in terms of conservation behavior. It is hypothesized that one of the reasons for this is the lack of attention to the differing demand schedules and situations of various market segments within the energy user marketplace.

This research deals with one component of society--the elderly--that has historically had special problems adjusting to the changing energy environment, presents unique challenges to utility companies trying to meet their needs, and in which there is very little known or understood about their responses to conservation efforts. Two reports by Hutton and McNeill (1981, 1983) summarize both the plight and opportunities facing the elderly.

In their literature review on vulnerable groups, it is documented repeatedly that the elderly and poor react differently to external stimuli compared to other segments of the population. Besides the traditional physical and monetary-related reasons why the elderly do not participate in conservation actions, particularly important is the concept of alienation stemming from financial, health, and/or educational disparities. Both endogenous and exogenous factors appear to affect elderly response.

Endogenous factors consist of the alienated individual's own personal psychological make-up and the adaptive ways in which he/she confronts the outside world. While program planners and activators can have little control over these factors, they can and should take them into consideration in the institutionalization of the programs.

The individual increases his/her alienation from society by withdrawing from or disengaging in participation in that society. Social disengagement involves decreasing emotional dependency, commitment, or involvement. The former results in what is termed an external orientation, the latter in what is termed an internal orientation. It has been shown that "externals," though withdrawn socially, are nonetheless emotionally dependent on others and have a locus of control outside of themselves. They therefore

respond well to psychographic presentations enhancing self-image and abilities. "Internals," however, are not emotionally independent, and their locus of control is internal. For this reason, they are harder to reach and influence than externals. However, if convinced of the seriousness of a situation, by the means of well-organized data, they may take action based on their own assessments rather than reliance on another's advice or persuasions. In either case, the alienated individual's response may be slow in coming due to the inertia of partially or completely reversing the process of alienation which he/she has entered into.

The other category of variables impacting an elderly or poor individual's degree of alienation are exogenous factors (i.e., societal factors). Exogenous factors may also either increase or decrease the sense of alienation. Programs which have tended to be unsuccessful have usually exhibited such qualities as a particularistic orientation which segregates servicers from utilizers, poor quality control, and/or insufficient knowledge of the target group's needs, wants, and tastes.

On the other hand, the literature review also describes a number of characteristics that have led to successful programs including:

- The servicers should go more than "half-way"--the participation of the alienated individuals should be encouraged and facilitated as much as is feasible possible at each step. At no point should their automatic participation be assumed.
- In light of limited resources that must usually be taken into consideration when planning how much effort to expend on attaining the goods leading to culmination of a successful program, involvement of associated community organizations and volunteers is the key.
- Market studies should be conducted to pinpoint the perceived problems, value systems, priorities, desires, and tastes of the vulnerable group of interest so that properly targeted communications can be addressed to the group.
- There should be a sense of shared responsibilities and shared accomplishments between the servicers and the utilizers and a minimization of manipulation of one group by the other.
- Management of these programs should also be as efficient as possible, with a high degree of flexibility, to enable rapid response to developing problems in the program, as well as to maintain a fairly rigorous quality control system. This efficiency and flexibility help ensure a good reputation for the program, which in turn gradually filters into the households which need to be reached and facilitates a greater receptivity to the program.
- Each separate individual involved in the program, from the home energy auditor to the telephone receptionist, must display an inspired attitude toward the program. The attitude is as important as the information conveyed.

- Follow-up procedures are necessary at all stages of the program. Constant reminders--or even periodic ones--maximize the likelihood of the occurrence of the desired conservation behavior.
- Personal selling seems to work better than mass appeals to low-income and elderly groups, although its cost should be weighed in making a decision as to how to reach the desired market.
- Patience is a key factor. In general, many of these groups are more withdrawn from contact with service-providing organizations because of past experiences with exploitation, causing a high degree of suspicion, mistrust, and lack of cooperation. Time is required to reverse these suspicions and that is why even many successful grass-roots organizations demonstrate such slow-moving programs and hard-won achievements. However, with a program which has "passed the test" the rate of participation will increase.
- At all times, the positive should be stressed, benefits should be emphasized over sacrifices.
- Peer/Incentive. In receiving the RCS audit through a utility company auditor, a peer was present during the audit to answer questions, install the incentive, and demonstrate other conservation actions.
- Peer. A peer member was present during the audit; however, an incentive was not provided.
- Incentive. The utility company auditor was responsible for providing the incentive, answering questions, and any demonstrating. A peer was not present.
- Control. The standard utility audit was conducted. Neither peer nor incentive was present.

Peer group personnel were recruited by the local utility from area organizations. Each peer went through several training sessions, including having an RCS audit conducted for their own home. Peers were compensated at \$20 per audit completed.

The primary incentive used was a hot water heater blanket. For each home designated to receive an incentive, a hot water heater blanket was installed. In the Peer/Incentive condition, the blanket was installed by a peer. In the Incentive only condition, the auditor installed the blanket. In cases where a hot water heater blanket was already installed, other appropriate low-cost incentives were substituted.

Sample

The sample for the study was a judgement sample selected to generally represent elderly homeowners in a large western metropolitan area. Qualifications included screening for homeowners 60 years of age and older who lived in single family detached homes and had never had an audit. Subjects were recruited at random by telephone. The total sample of 120 (30 per group) was then randomly divided into four experimental groups. Thirteen subjects refused to cooperate (i.e., changed their minds before the audit could be done) resulting in a final sample size of 107 (Peer/Incentive [28], Peer [28], Incentive [26], Control [25]).

Data Collection

Two types of data were collected for the study. Consumption data was collected via utility company billing information. Data was collected approximately 10 months prior to the audit in order to have baseline consumption information. Billing data was then collected for the 10 months following the audit. Analysis centered on changes in average daily consumption between the pretest and posttest periods.

The second type of data collection was a posttest-only survey of households conducted by means of a 15-minute telephone interview. Questions focused on measurement of a range of consumer response levels including knowledge, attitudes, intentions, and reported behavior. Respondents represented a family member present during the audit.

Results

Results will be presented by consumer response level beginning with the earlier response levels in the hierarchy. Responses are the result of the posttest telephone survey, except for the consumption analysis. Change in consumption is represented by prior minus posttest period billing data.

Recall

A series of questions were asked dealing with homeowners' recall of the audit experience. In both conditions where a peer was present, over 90.0 percent of the sample remembered the peer. However, no one was able to recall

While many of these conclusions apply to other segments of the population as well, they have been shown to be particularly important in reaching the poor and elderly. The combination of understanding the target group's needs and being able to integrate those needs with program goals and available resources will increase the probability of implementing a successful conservation effort.

In response to the environment for the elderly regarding energy conservation behavior and the social responsibility of policymakers to particular groups such as this, the previously described factors were taken into consideration in the development of this study. Two strategies were tested to improve elderly response to an RCS audit.

- Peer. Accompanying each utility company auditor would be a trained elderly person. The role of the peer would be to provide support, information, and demonstration of some conservation actions.
- Incentives. The utility company auditor would provide one or more incentives to the elderly household (e.g., installation of a hot water heater blanket) to encourage them to engage in more such actions recommended by the audit.

Both strategies, peer involvement and the use of incentives, are well-tested and proven marketing strategies for other goods and services. The use of incentives, for example, was particularly effective in encouraging homeowners to take low-cost or free conservation actions in the Low Cost/No Cost Energy Conservation Program (Hutton and McNeill, 1982).

Method

Two primary objectives were the focus of the study:

- Gain insight into elderly household response to the RCS audit experience, including changes in knowledge, attitudes, intentions, and behavior.
- Assess the impact of two marketing strategies--peer involvement and incentives--on different levels of consumer response.

Design

In order to attribute causality to the independent variables (i.e., peer, incentives) and to assess response in a "real world" setting, a field experiment was utilized. The design chosen was a 2 x 2 factorial. Each treatment had two levels. Either the peer or incentive was present or absent. The four groups were:

the name of the peer representative.

In both the Peer/Incentive and Incentive Only conditions, over 70.0 percent remembered that something was done to their home during the audit to help them save energy (Peer/Incentive = 71.4%, Incentive = 76.9%). Only one person in each of the other groups reported something being done. It is interesting that 25.0 percent or more of those who actually received an incentive did not recall it.

Perceptions

Table 1 reports household impressions of the audit and provides insight into the word-of-mouth potential for diffusing positive perceptions and knowledge among other members of the elderly household segment.

Prior consideration of an audit ranged from 48.0 percent in the Audit Only condition to 38.5 percent in the Incentive Only condition. Households were asked why they had not requested the utility audit. The most mentioned responses were:

- . Cost,
- . Felt they had already done everything they could,
- . Never got around to it, or
- . Already knew what they needed to do.

When asked what they learned from the audit, households gave a wide range of responses. However, the most mentioned were:

- . Need for some type of insulation,
- . Caulking and weatherstripping,
- . General knowledge, and
- . Nothing/don't know.

Large majorities in all conditions reported discussing the audit with friends or relatives. Additionally, of those that said they had discussed it, about 50.0 percent indicated their friends or relatives would request an audit in the future.

An additional question asked was whether households felt that they would be able to save energy as a result of this audit. Majorities in each condition felt that they would. However, while the three test conditions involving some combination of incentives and peers all reported over 70.0 percent feeling this way, only 56.0 percent in the Audit Only (control) condition felt they would save. However, those that did feel that they could save energy, most had no idea how much they could save. For those that did estimate their savings, the most mentioned responses ranged from 5.0 percent to 15.0 percent.

TABLE 1
AUDIT IMPRESSIONS/KNOWLEDGE

Question	Group			
	Peer/ Incentive	Incentive	Peer	Audit Only
Before being contacted by a utility company, had you ever considered having an audit? (percent yes)	46.4%	38.5%	39.3%	48.0%
As a result of this audit, do you think you will save energy? (percent yes)	71.4	73.1	71.4	56.0
Have you discussed your audit with friends or relatives? (percent yes)	71.4	69.2	71.4	64.0
Do you think they will request an audit?				
Yes	50.0	50.0	47.6	56.3
No	10.0	--	9.5	6.3
Don't Know	40.0	50.0	38.1	37.5

Perceptions of the Audit Process

A series of questions concerning the audit process showed that all of the conditions were generally satisfied with the audit process. Few households would change anything about the audit, including the way the information was explained and presented. Additionally, there was virtual consensus that the audit should be offered to all elderly households. Primary reasons for this feeling included:

- . Increased awareness/knowledge of the little things that can save,
- . Improve utility company image, and
- . Good service to the elderly because it is free and they need it.

Audit Evaluations

There were two types of evaluation efforts. The two conditions (Peer/Incentive, Peer Only) that received a peer member treatment were asked to evaluate the peer. All conditions were asked to evaluate the utility company auditor and the audit process (Table 2).

In both conditions, the peer was evaluated favorably. However, the Peer/Incentive condition produced relatively higher scores across all positive categories. The presence of the incentive along with a peer produces more favorable responses, probably because the peer has a better chance of getting involved by installing the blanket or other incentives.

The utility company auditor was rated on the same characteristics by all four conditions. As one would hope, the auditor was viewed very favorable across all conditions. No consistent pattern of differences was found.

TABLE 2
AUDIT EVALUATION

Question ¹	Evaluation ²			
	Very		Not	
	P/I	P	P/I	P
Do you feel this person (peer) was . . .				
Helpful	60.7%	50.0%	10.7%	7.1%
Knowledgeable	53.6	32.1	7.1	7.1
Useful	57.1	35.7	10.7	--
Friendly	85.7	71.4	--	--
Encouraging	53.6	35.7	7.1	10.7
Credible	42.9	21.4	10.7	7.1
Intimidating	--	--	96.4	85.7
Bothersome	--	3.6	100.0	85.7
	Very Favorable		Unfavorable	
	P/I	I	P	A
Attitudes toward ³ . . .				
Home energy audit	67.9%	57.7%	46.4%	64.0%
Utility company	46.4	34.6	28.6	32.0
Auditor	78.6	76.9	53.6	64.0
Audit printout	50.0	57.7	50.0	64.0
Audit educational material	57.1	61.5	53.6	60.0
Peer	55.6	N/A	23.1	N/A
Do you think it is a good idea to have someone (peer) accompany the utility company auditor?			P/I	P
Yes			67.9%	53.6%
No			10.7	7.1
Don't Know			21.4	39.2

¹ Only two groups received this question: P/I = Peer plus Incentive, P = Peer only.
² A 3 point scale was used for this series. The "Somewhat" and "Don't Know" categories are not presented here.
³ Groups are: P/I = Peer plus Incentive; I = Incentive; P = Peer; A = Audit only.
 "Very Unfavorable" and "Unfavorable" scale points were collapsed to "Unfavorable." Also, the "Favorable" category is not reported.

Other attitude questions also reflected favorably on the audit experience. Only in the evaluation of the utility company were there any significant unfavorable responses. About 20.0 percent of the sample in each condition had an unfavorable attitude toward the utility.

In a final evaluation of the peer, the Peer/Incentive condition continued to view the peer more positively than the Peer Only condition. While 55.6 percent of the Peer/Incentive condition reported "very favorable" attitudes toward the peer, only 23.1 percent in the Peer Only condition did so. Also, 67.9 percent of the Peer/Incentive condition felt it was a good idea to have a peer accompany the auditor; only 53.6 percent of the Peer Only condition felt this way. For those that did feel it was a good idea, the most mentioned reasons were cuts down on time, helps the auditor, and helps in understanding what to do.

Actions Resulting from the Audit

Tables 3 and 4 present the results of both self-reported behavior and an analysis of consumption data. Subjects were first asked what one change could be made in their home that would save them the most energy. The most mentioned responses were:

- . Attic insulation,
- . Caulking/weatherstripping,
- . Storm windows/doors, and
- . Turn thermostat down.

When asked whether they had actually done the one recommended change to save the most energy, there were significant differences between conditions. The Peer/Incentive condition was the only one to have a majority reporting taking the recommended action (59.3%). The Incentive and Peer conditions were next with 38.1 percent and 37.0 percent, respectively. Only 28.6 percent of the Audit Only condition responded positively. However, the Incentive and Audit Only conditions tied with the largest percentage planning to take the action in the future (83.3%). The Peer condition reported the largest percentage making other recommended changes (35.7%), and, again, the Incentive condition reported the highest percentage of intentions to take other actions (34.6%).

TABLE 3

ACTIONS RESULTING FROM THE AUDIT

Question	Group			Audit Only
	Peer/Incentive	Incentive	Peer	
Based on the audit, have you made the one change recommended that would save you the most money? (percent yes)	59.3%	38.1%	37.0%	28.6%
Do you plan to do so in the future? (percent yes) ¹	75.0	83.3	58.8	83.3
Have you made any other recommended changes? (percent yes)	17.9	15.4	35.7	16.0
Do you plan to make any? (percent yes)	25.0	34.6	21.4	12.0
Have you done anything since the audit to save energy that wasn't recommended? (percent yes)	10.7	7.7	14.3	4.0

¹ Base sample is composed of those households who had not made the change yet.

Table 4 measures behavior based on actual consumption. The analysis of variance table indicates that there are significant differences in mean consumption patterns between the conditions ($p < .05$). Analysis was accomplished by subtracting average daily consumption during the test period (following the audit) from average daily consumption during a pretreatment period (prior to the audit). Consequently, positive mean values (average daily change in consumption) reflect a reduction in consumption from

the pretreatment period. In order of effectiveness in reducing consumption, the conditions rank:

Incentive	.0864
Peer	-.1041
Audit Only	-.1852
Peer/Incentive	-.4145

The Incentive condition was the only one that achieved a reduction over the pretest consumption figures. The only statistically significant difference is between the Incentive condition and the Peer/Incentive condition.

TABLE 4

ANALYSIS OF VARIANCE RESULTS

Source	D.F.	Sum of Squares	Mean Square	F Ratio	F Prob.
Between Groups	3	3.24	1.08	3.05	.03
Within Groups	97	34.45	.36

Group	Mean Values ¹	Standard Deviation
Peer/Incentive	-.4145	.6071
Incentive	.0864	.4930
Peer	-.1041	.8113
Audit Only (standard)	-.1852	.3232

Rank Order Effectiveness²

1. Incentive*
2. Peer
3. Audit Only (standard)
4. Peer/Incentive*

¹ Mean values are in terms of gas.

² Difference scores determined by subtracting average daily consumption after the audit from average daily consumption before the audit over a 10-month period.

* Significant at $p < .05$.

Conclusions

The results of this study provide several insights for both policymakers and utility companies. Perhaps most important was the positive evaluation given the audit process. At least for the utility company involved in this study, the problem of elderly response to their audit program is not with the product. It is more with strategies to encourage accessing the audit and then motivating the household to take action. For example, one area that shows strong potential is the development of strategies that enhance diffusion of the audit concept by word-of-mouth.

Behavior measures presented both interesting and unexpected results. The condition that was most likely to believe they would save energy was the Incentive condition, followed closely by Peer/Incentive and Peer. Subjects in the Audit Only condition were significantly less likely to believe they would save. In reported actions to save the most energy, the Peer/Incentive condition led. However, the Incentive condition reported highest intentions

in both cases and was second in reported actions.

In terms of actual savings from the pretest period, only the Incentive condition showed a decrease in consumption from the pretest period. These figures most likely reflect an extremely severe winter. The Incentive condition showed an average daily saving of just over .08 therms per day. Any average percentage reduction, however, is somewhat misleading. There was extremely high variance across both seasons and households. For example, winter gas usage varies from several thousand therms per month for a household to 150 therms per month for other households. In summer, gas usage dropped to a low of 10 therms per month. Further analysis is needed to refine these figures. However, it does appear that the .08 therms-per-day saving is a significant amount.

The unanticipated result in this study was the poor showing of the Peer/Incentive condition. While it is impossible to say for sure why this condition performed so poorly, at least two possible explanations are worth considering. The first is differences between groups going into the study. For example, an analysis of classification data show the Peer/Incentive condition to be slightly less educated, older, and lower income than the Incentive condition. Another factor could have been the lack of coordination between the auditor, peer, and incentive. For the elderly homeowner this may have produced a type of environment that was not conducive to the most positive response.

In summary, several marketing and consumer behavior implications arise from the results of this study. The first is the importance of understanding the target market, particularly a segment such as elderly homeowners. Second, and most important, the product (i.e., audit process) does not appear to be the problem in explaining peer response to energy audits. Increasing response to audits and conservation among the elderly is more a function of appropriate front-end marketing efforts (i.e., pricing and targeted promotional strategies) and the utilization of positive incentives to gain follow-up action. However, more information is needed about how to supplement audits with incentive packages and other motivational tactics. This study is just one step in that direction.

Abstract

Theoretical perspectives based upon goal-setting and comparative processes are elucidated and proposed as mediators of the feedback effect found in energy consumption studies. A field experiment designed to test these perspectives revealed that, for natural gas consumption, both goal-setting and activation of comparison processes are necessary conditions in obtaining the feedback effect.

Social Comparison Processes in Energy
Conservation Feedback Effects

Since the onset of the 1973-1974 oil crisis people have been awakened to their reliance upon energy for maintaining or altering their life-styles. Researchers in both the natural and social sciences quickly responded to the crisis via technological and behavioral solutions. Businesses also responded to the challenge through the development of more energy efficient appliances and modes of transportation. Consequently, the vast majority of the early research investigating energy utilization was descriptive in nature and followed by a vast wave of application-oriented research primarily designed to promote energy conservation.

Currently, over a decade later, with consumers having adapted to the relatively higher energy prices and with some energy sources dropping in costs (e.g., oil) the magnitude of published research examining energy consumption has dwindled. However, the current situation offers an opportunity to begin systematic efforts to examine the mediators as well as moderators of various strategies that have been shown to influence energy consumption. Only with a thorough understanding of the parameters and causes of consumption can policies be developed and strategies implemented for dealing with any future shortages.

A variety of intervention strategies, variable manipulations, and research classification schemes have been utilized in examining energy consumption (for reviews see: Becker, Seligman, & Darley 1979; Cone & Hayes 1980; Cook & Berrenberg 1981; Gottlieb & Matre 1976; McClelland & Canter 1981; McDougall, Claxton, Ritchie, & Anderson 1981; Olsen & Goodnight 1977; Shippee 1980 & 1981; Stern & Gardner 1981; Winett & Nietzel 1975; Winett & Kagel 1984; Winkler & Winett 1982). One strategy acknowledged by virtually all of the reviews as being effective in reducing energy consumption is termed the feedback effect.

Comparison Processes in Feedback Effects

Basically, the feedback effect entails providing consumers with frequent information (e.g., daily or weekly) concerning their energy consumption. Consumers provided with this consumption feedback have subsequently reduced consumption 10% to 20% when compared to consumers not receiving the feedback (Becker 1978; Becker, Seligman, & Darley 1979; Bittle, Valesano, & Thaler 1979 & 1979-1980; Hayes & Cone 1977 & 1981; Palmer, Lloyd, & Lloyd 1977; Seaver & Patterson 1976; Seligman, Becker, & Darley 1981; Winett, Kagel, Battalio, & Winkler 1978; Winett, Neale, & Grier 1979) and the effect tends to be maintained even when the frequent feedback is no longer provided and regular monthly utility billing represents the only consumption information. The generalizability of the feedback effect is acknowledged when one notes that it has "been shown to be effective in studies conducted in at least 10 states, with diverse samples of people, during all four seasons, and over a period of a decade" (Winett & Kagel 1984, p. 664).

A variety of parameters have been identified which moderate the feedback effect and are useful in providing insights into the possible mediators that are active. First, studies have shown that cost feedback as opposed to or in conjunction with usage feedback (e.g., kilowatts of electricity) is more effective in reducing consumption (e.g., Palmer et al. 1977). Furthermore, the superiority of cost feedback tends to be more pronounced with cumulative as opposed to discreet feedback for a limited time period (Bittle et al. 1979-80). This superiority of cost feedback is consistent with the long-term effect of pricing on demand from an economic perspective (i.e., Winkler & Winett 1982). Second, externally-generated feedback (e.g., supplied by the researcher or utility company) tends to result in less usage than self-generated feedback (e.g., generated by the consumer) although some reduction is found when consumers self-monitor their consumption (e.g., Winett et al. 1979; Pallak & Cummings 1976). Third, individual feedback is more effective at reducing consumption than group feedback such as for a neighborhood or region (e.g., Winett et al. 1978-79). Fourth, as suggested by some authors (e.g., Winett & Kagel 1984), increasing the frequency of providing the feedback may result in increased energy savings. For example, daily feedback may be more effective than weekly feedback which in turn may be more effective than monthly feedback as currently supplied by most utility companies. Unfortunately, no studies have been conducted which have systematically examined the effects of the frequency of feedback on consumption; most studies have utilized daily feedback and the suggestion for increasing the frequency of the feedback as been via extrapolations from other studies using weekly feedback. Also, as noted by Shippee (1980) and Stern and Gardner (1981) the costs of providing daily feedback may make it impractical. Furthermore, other studies have shown that even weekly feedback can result in a 24% reduction in consumption (i.e., Bittle et al. 1978) or, in the case of another study, simplifying the format and content of monthly utility bills resulted in a 10% reduction in consumption relative to normal billing format and content (i.e., Hayes & Cone 1981); reduction figures similar to those found for daily feedback. These studies suggest some caution in attempting to generalize about the effects of the frequency of feedback. Fifth, some studies have shown that a public commitment to saving energy as opposed to a private commitment results in a greater reduction in consumption levels (i.e., Pallak & Cummings 1976; Pallak, Cook, & Sullivan 1980; Seaver & Patterson 1976). Finally, other studies have demonstrated that providing consumers with a difficult goal for reducing their energy consumption results in lowered consumption rates when compared to rates for consumers provided with a relatively easy goal (e.g., Becker 1978).

An examination of the above parameters suggests that for feedback to be effective at lowering energy consumption consumers must have some standard against which to evaluate their performance (Becker 1978; Becker et al. 1979; Seligman et al. 1981; Cone & Hayes 1980). Consumers must be able to "evaluate how well or poorly they are doing with respect to their desired level of conservation" (Becker et al. 1979, p. 52). This interpretation entails three necessary conditions. First, consumers must have some standard or goal in evaluating their consumption. This standard or goal may entail previous usage levels, experimenter suggested reduction goals, or budget maintenance goals. Second, consumers must engage in the comparison process in comparing present consumption levels or behaviors with the standards or goals. Third, the information utilized in setting goals or standards and comparing with present consumption levels

or behaviors must be understandable and germane. This interpretation suggests that an understanding of the feedback effect and, hence, identification of the mediators, is based upon when comparisons will be invoked, what is being compared, and the prediction of behaviors following the comparison process. Festinger's (1954) social comparison theory provides an "established core of confirmed theory" (Singer 1981, p. 171) for testing the veracity of the comparison process in explaining the feedback effect.

Social comparison theory postulates that individuals have a drive to evaluate their opinions and abilities. In the absence of objective physical standards upon which to make these evaluations, individuals will utilize the opinions and abilities of others in assessing their opinions and abilities. Festinger (1954) also predicted that individuals would prefer to make these evaluations, along relevant dimensions, with similar as opposed to dissimilar others. Given that an individual's opinions and/or abilities are different from others', the individuals can either (a) attempt to persuade others to adopt his or her opinion or ability, (b) modify his or her opinion or ability to match the others', or (c) reject the others' abilities or opinions for use in making comparisons due to the dissimilarity along some dimensions.

The ability to wisely use or conserve energy and/or an individual's opinion of himself as being a prudent consumer or energy conscious consumer justifies the examination of energy utilization from a social comparison theory perspective. In the absence of any objective standards (e.g., experimenter provided, RCS audit) against which to judge their energy consumption, consumers may use information concerning similar others' consumption levels in assessing their own performance. For example, an individual may engage in the comparative process by asking a neighbor "how much was your electric bill?" A study by Pallak et al. (1976; 1980) also supports this notion in finding that consumers receiving both usage feedback and the average usage figures for all individuals in the study conserved more energy than did consumers receiving only the usage feedback.

Given the previous energy related research, the discussion of social comparison theory up to this point, and the Pallak et al. (1976; 1980) study, a number of predictions can be made. First, consumers provided with usage and cost feedback which does not facilitate the setting of standards nor the activation of a comparison process should conserve less energy than consumers provided with the same feedback plus facilitators. More specifically, consumers provided with current usage feedback plus previous usage figures should be more likely to engage in a self-comparison process using the previous figures as a standard and, hence, reduce their consumption more than consumers provided with only current usage feedback. Second, if consumers actually desire to evaluate their performance in conserving energy or their opinion about themselves as related to consumption, those consumers provided with feedback allowing them to make social comparisons should alter their consumption in the direction of the comparison point more than if they received self-comparison feedback. Consumers provided with their current usage figures and the current usage figures of their neighbors should adjust their consumption levels using their neighbors' consumption levels as a standard. These hypotheses suggest that consumers would be utilizing either their past consumption levels or others' consumption levels as an implied goal or standard in judging their own consumption and making adjustments in consumption according to the standards. The change in consumption should be greater under social-comparison as opposed to self-comparison feedback since consumers could justify changes in their own consumption as being due to temperature fluctuations.

The information that one receives for comparative purposes obviously plays an important role. From Becker's

(1978) study, one would predict that when an individual uses past consumption levels as a standard or goal in comparing current consumption levels, the higher the discrepancy the more the individual would attempt to conserve energy, assuming previous levels were lower than current levels of consumption. In other words, if previous consumption levels are utilized as a standard in a self-comparison situation, the greater the discrepancy with current levels of consumption the greater the change in future consumption levels. However, although this replication of Becker's findings should be found for self-comparison feedback, social comparison theory postulates the opposite effect for social-comparison feedback. Specifically, hypotheses III of social comparison theory suggests that as the discrepancy between one's ability/opinions and those of others increases, the probability of the comparison being made decreases and, hence, the tendency to alter behavior decrease. Therefore, as the discrepancy between an individual's consumption level and others' consumption level increase, less attempts should be made by that individual to alter their consumption level. Hence, an interaction should be found such that for self-comparison feedback a more difficult goal should result in more change in consumption while for social-comparison feedback a more difficult goal should result in less change in consumption when compared to a relatively easy goal.

Method

Sample

A local natural gas utility company submitted the names and addresses of 173 natural gas consumers to the author. These consumers were selected from the company's records on the basis of being within the same billing cycle, residing within similarly constructed homes located in one of three subdivisions, and with the restrictions that all homes were equipped with natural gas heating furnaces and water heaters. The majority of the homes selected were either single-level brick or wood-frame homes and occupied by two adults and either one or two children.

Initially, the consumers received a letter from the Vice-President of the local utility company explaining the consumers' potential involvement in the study and emphasizing the fact that participation was voluntary. Subsequently, the consumers were contacted in person and were asked to participate in a natural resource utilization study to be conducted over an extended period of time, allow access to their usage records of natural gas, and to give their permission for their utility meters to be read on a weekly basis. Of the 145 consumers that were contacted, 122 agreed to participate (84.1%) and signed consent and release forms. After examining previous usage records and subsequent records prior to the onset of experimental treatments, 14 consumers were dropped from the study due to floor effects in consumption; these consumers did, however, receive weekly usage feedback. Hence, 108 consumers were eligible for assignment to treatment conditions.

Feedback

A 3 X 2 X 4 two-between, one-within design was used manipulating the type of comparison feedback (self, social, or both), the implied goal as indicated by the feedback (13% or 23% reduction in usage), and feedback trials (first, second, third, and fourth week). A trailer control condition was also included in the design in which participants received only usage feedback.

All of the participants received usage feedback consisting of the amount of natural gas used during the previous week in thousands of cubic feet (MCF) and the estimated cost. The cost figure was computed by estimating the monthly consumption, applying the appropriate billing rate structure, and deriving the weekly cost figure. Participants in the trailer control condition received only this usage feedback (cost & MCF consumed).

Participants in the comparison feedback conditions were provided with information indicating an implied goal with which to compare their usage of natural gas. The implied goal was manipulated by showing the participant that the comparison information indicated either a 13% or 23% discrepancy between their own present usage and past usage or between their present usage and the use of a group of comparison others. The participant was always indicated as having consumed more natural gas than shown in the comparison feedback. The participant received only the usage and cost figures for use in making comparisons; the percentage difference was not indicated. Participants receiving this false feedback were provided with comparison information for natural gas consumed either by the participant during the same week of the immediately preceding year (self-comparison feedback), similar households during the same week (social-comparison feedback), or both (self-comparison plus social-comparison feedback). For example, the self-comparison feedback indicated to the participants that they consumed either 13% or 23% less natural gas during the same week of the previous year.

For the participants receiving both self-comparison and social-comparison feedback, the self-comparison feedback was presented first for half of the participants and last for the other half of the participants within the 13% and 23% implied-goal conditions. Because of the possibility of arousing the suspicion of the participants receiving both types of comparison feedback if the figures were exactly equivalent, 12% and 14% reduction figures were used for the 13% implied-goal conditions for the first and second type of feedback presented on a single feedback trial while for the 23% implied-goal conditions, 22% and 24% reduction figures were used. Feedback was provided to the participants by mailing a single post card containing the appropriate feedback on the same day their utility meters were read.

Procedure

After obtaining permission from the participants for their involvement in the study and for their usage records to be released from the utility company, the participants were not contacted in person at any time in the future. The participants' natural gas usage records were obtained from the utility company for December, 1981, and the average weekly consumption rate for each participant was determined. Ten participants were randomly withdrawn prior to any subsequent assignment to the experimental conditions. These participants were withheld for the purposes of replacing any of the other participants assigned to the treatment conditions who might withdraw from the study or move from the area prior to the presentation of the feedback. However, none of the participants assigned to the treatment conditions withdrew from the study. Hence, the withheld participants were included in the usage feedback condition. Using the average weekly consumption rate during December as a baseline, a ranking of the 98 remaining participants was made according to consumption rate and they were assigned to each of the seven conditions using a block-randomized procedure. With the inclusion of the ten participants withheld earlier for replacement purposes, 24 participants were included in the usage feedback condition while 14 participants were assigned to each of the other conditions.

Beginning in the third week of January, 1982, participants' natural gas utility meters were read and recorded once a week for six weeks. Meters were read on the same weekday and at approximately the same time each day. Five research assistants unaware of the purposes of the study were trained by the natural gas company to read the meters. Periodically, a sixth separately trained research assistant read a subset of the meters in order to obtain reliability estimates. An overall reliability estimate of $r = .96$ was obtained.

The last week in January was used as the baseline level to be used for the designation of half of the partici-

pants in each condition as high-level users and the other half of the participants as low-level users. Also, this week was used as the baseline level for subsequent analyses. During this week no feedback was presented; the MCF usage was used for subsequent feedback. Beginning in the first week of February, 1982, the participants received via a mailed post card the appropriate feedback for the particular condition to which they were assigned. Feedback was provided for four weeks.

Results

As a manipulation check, an analysis of variance was conducted on the amount of natural gas consumed during the last week of January for the type of comparison feedback (self, social, or both) X implied goal (13% or 23%) X usage level (high or low) matrix. The only significant effect was the main effect of usage level, $F(1,72) = 79.17$, $p < .0001$, with means of 3.45 MCF and 4.91 MCF for low-level and high-level users, respectively. No other effects approached statistical significance, $p > .10$.

The dependent measure employed for all subsequent analyses investigating the change in consumption due to feedback was the percent consumed relative to baseline levels. Because of the lower limits involved in using the percent consumed relative to baseline as the dependent measure, a square root transformation was employed. Means reported in the text, however, have been retransformed into the percentage figures.

General Findings

A four-factor analysis of variance with one repeated measure was conducted on the type of comparison feedback X implied goal X usage level X feedback trials matrix. A marginally significant comparison feedback X implied goal interaction was obtained, $F(2,72) = 2.74$, $p = .07$. The means contributing to this interaction are presented in Table 1.

TABLE 1
MEAN PERCENT NATURAL GAS CONSUMED RELATIVE
TO BASELINE CONSUMPTION LEVELS

Comparison	Implied Goal		Total
	23%	13%	
Self	101 _{ab}	101 _{ab}	101
Social	93 _a	108 _b	101
Self + Social	102 _{ab}	100 _{ab}	101
Total	96	103	

Usage Feedback Only: 103_b Expected: 102_b

Means not sharing common subscripts differ at $p < .05$.

Tests of simple main effects revealed a significant difference in percent consumed between participants receiving social-comparison feedback indicating a 23% implied goal and participants receiving social-comparison feedback indicating a 13% implied goal, $F(1,24) = 7.96$, $p < .01$. For the social-comparison feedback, whereas participants receiving the 23% implied goal decreased their consumption by 7% relative to baseline levels, participants receiving the 13% implied goal increased their consumption relative to baseline by 8% during the same time period. None of the other simple main effects approached acceptable levels of statistical significance, $p < .10$.

Significant main effects for the usage level factor, $F(1,72) = 2.81$, $p < .10$, and trials, $F(3,216) = 441.21$, $p < .001$, were qualified by a significant usage level X trials interaction, $F(3,216) = 2.85$, $p < .05$. Simple main effects revealed that, during Trials 1, 2, and 3, low-level consumers altered their usage relative to baseline (\bar{X} s = 1.31, 1.41, .88, .79, respectively) more than did high-level consumers (\bar{X} s = 1.19, 1.31, .79, respectively). No significant differences between usage

levels were present during Trial 4 (low-level users $X = .60$, high-level users $X = .59$).

Comparison Versus Usage Feedback

Using a pooled mean square error term, Dunnett's t -tests were calculated testing the differences between the means for the usage feedback condition and the comparison feedback X implied goal conditions using computations outlined by Winer (1971, p. 470). These analyses revealed that participants receiving social-comparison feedback indicating a 23% implied goal reduced their consumption relative to baseline ($\bar{X} = .93$), while participants receiving only the usage feedback increased their consumption relative to baseline levels ($\bar{X} = 1.03$), $t(94) = 1.82$, $p < .05$. Hence, the addition of the social-comparison feedback indicating a difficult goal resulted in a 10% decrease in energy consumption when compared to the usage feedback. No differences were found between the other feedback conditions and usage feedback condition.

Because of the significant usage level X trials interaction found for the participants receiving comparison feedback, it was deemed appropriate to compare the means involved in this interaction with the corresponding means of the same interaction for participants receiving usage feedback using pairwise Dunnett's t -tests. Again, a pooled mean square error term was employed. None of these comparisons revealed any significant differences, $p > .10$.

Comparisons Involving Expected Usage

In order to assess any differences between the percent consumed relative to baseline consumption due to the various types of feedback in the present study and the percent of natural gas consumption that would be expected due to temperature fluctuations, it was necessary to derive the percent change in heating degree days relative to baseline for each of the respective feedback trials. Basically, heating degree days are the number of degrees that the average temperature per day is less than 65 degrees F. (18.33 C.). To obtain the number of heating degree days over a set period of time (i.e., seven days in the present study), the number of heating degree days are summed. Degree days, whether heating or cooling, are the units of measurement commonly used by utility companies to predict energy consumption during specific periods of time and have been used in previous studies (e.g., Becker & Seligman, 1978).

Heating degree days were obtained from the National Weather Service for the area in which the study was conducted and the percent of heating degree days was calculated for the treatment time periods relative to the baseline time period. These estimates of expected usage due to changes in heating degree days were felt to reflect the changes in energy consumption due to temperature fluctuations. Using the square root transformation, the expected change in energy usage due to heating degree days was compared to the changes in energy usage found in the present study using Dunnett's t -tests for comparisons involving a single control group (i.e., expected change in usage due to temperature changes) and multiple experimental groups (i.e., means involved in the comparison feedback X implied goal conditions and usage feedback condition). However, caution should be exercised in interpreting the results of these analyses. First, these analyses assume that if a control group had actually been included in the study the mean percent consumed would have been equal to that predicted by changes in the number of heating degree days. This assumption may be erroneous in that changes in degree days may not be related to actual changes in natural gas consumption in a one-to-one relationship. Also, the slopes and intercepts may be different. Similarly, the analyses assume that energy usage can be perfectly predicted by changes in temperature, an assumption that is unlikely. Second, using the percent of heating degree days during the experimental periods as compared to

baseline levels of degree days in creating a control group for comparison purposes, an assumption must be made that if a control group had actually been included in the study, the obtained variance would have been homogeneous with the variances obtained for the participants receiving the experimental manipulations.

In order to minimize some of the possible violations of the assumptions mentioned above in testing the changes in consumption by participants in the study with the expected percent change in energy usage predicted from heating degree days, the corresponding mean square error terms and number of subjects considered in the immediately preceding analyses were employed as the denominator in calculating the Dunnett's t -statistic. Using this procedure actually results in a more conservative estimate of t than assuming that a control group was actually included in the study (i.e., specifying a number of subjects for the expected change scores).

The results of the Dunnett's tests indicated that participants receiving the social-comparison feedback indicating a 23% goal reduced their consumption relative to baseline ($\bar{X} = .93$) differentially than would be expected from changes in heating degree days ($\bar{X} = 1.02$), $t(94) = 1.67$, $p < .05$, one-tailed test. This result can be interpreted, with the cautions mentioned above, as demonstrating that participants receiving social-comparison feedback indicating a difficult goal used 9% less natural gas than would be expected by changes in the number of heating degree days. None of the other comparisons approached statistical significance.

Discussion

The effects of feedback found in the present study can not be adequately explained by either the goal-setting perspective (Becker 1978; Seligman et al. 1981) nor by a social comparison perspective (Festinger 1954) when these perspectives are considered independently. However, when these perspectives are integrated, the present data suggest multiple necessary causes. From the goal-setting perspective, it seems clear that individuals will attempt more effective energy conservation efforts when a difficult, as opposed to a relatively easy goal, is imposed. This goal-setting effect is qualified, however, by the comparison processes that are activated via the feedback. Feedback about others' energy usage patterns appear to be more effective in promoting energy conservation than feedback about past personal consumption levels or than feedback simply stating current consumption levels. However, contrary to hypothesis III of social comparison theory and consistent with the goal setting perspective, the social-comparison feedback in the present study was only effective when consumers received information indicating that others were using considerably less energy than the consumers. Consumers were able to utilize information about others' energy consumption levels in evaluating their own consumption levels and in adopting personal energy usage goals. Hence, the present study tends to support an integrated goal setting and comparative process interpretation of the feedback effect.

A number of issues can, however, be raised concerning the two perspectives for explaining the feedback effect and, specifically, the lack of any main effects. From the goal-setting perspective, the absence of a goal main effect may have been due to the source of the goal, the commitment to the goal, or to the credibility of the information provided. In previous studies examining consumption goals (e.g., Becker 1978), the goal has been set by the experimenter. In the present study, the goal was merely implied to the consumers via the feedback. Hence, the goal effect found in previous studies may have been due to demand characteristics or, simply, to the overall saliency of the goal itself. Consumers may not have been as committed to the goal in the present study as when they made a "public" statement to try to achieve a goal in previous studies. The lack of the

goal main effect could also be due to consumers justifying their consumption levels since outside temperature was not controlled for in the feedback; a factor impacting upon the credibility of the feedback (Winett & Kagel 1984). Similarly, previous studies have provided feedback concerning performance relative to the goal. However, in the present study no attempts were made to provide information to the consumers indicating performance relative to the goal. In fact, in the present study the discrepancy between current and previous usage levels remained constant throughout the study. However, the plausibility of this factor in contributing to the lack of a main effect is weakened when one notes the absence of any goal X trials interaction. Finally, the absence of a goal effect may be due in part to the generalizability of the finding from electricity consumed for home cooling (Becker 1978) to natural gas usage for home heating. Some ancillary evidence for this proposition exist from a study by Winett and Nietzel (1975) which found rebates to be effective in lowering electricity consumption but not for natural gas usage when both energy sources were used for home heating. Also, the ability to detect significant differences due to measurement sensitivity for kilowatts of electricity as compared to thousands of cubic feet of natural gas may have contributed to the null finding.

As with the absence of a goal main effect, measurement sensitivity may have hampered the ability to detect a comparison feedback main effect. In other words, the insensitivity of MCF (thousand of cubic feet) as opposed to KWH (kilowatts) may have caused any differences between social-comparison and self-comparison feedback to be undetected. An additional problem for social comparison theory involves hypothesis III. From hypothesis III of social comparison theory it was predicted that when a relatively large discrepancy between others' consumption levels and the individuals consumption level were portrayed via the feedback, the individual would be less likely to engage in the comparison process and, hence, alter their subsequent consumption. However, it was found that under the larger discrepancy (i.e., goal) individuals did alter their consumption. This effect may be due to the 23% goal not being perceived as a difficult goal or as not indicating "different" others. Alternatively, individuals receiving the social-comparison feedback implying a 13% goal may not have perceived the difference to be discrepant from their own consumption levels. In other words, either the 23% goal may not have been discrepant enough, the 13% goal may have not been perceived to be discrepant, or both factors may have contributed to the lack of an effect. Future research examining the difference thresholds for comparative feedback is warranted.

It was predicted that the combined self- and social-comparison feedback would increase consumers perceptions of the similarity between themselves and others, leading to more conservation attempts. However, at least for the 23% implied goal, when provided with both types of comparison feedback the self-comparison feedback negated any beneficial effects of social-comparison feedback. It is feasible that when both types of feedback were presented to consumers the similarity between their previous usage levels and others' current usage levels may have been used as indicating or emphasizing a dissimilarity between the other individuals and themselves. Alternatively, the amount of information presented for the combined comparison condition may have acted as a buffer in not initiating or facilitating the comparative process.

On a more general level, the results of the present study underscore the importance of examining the parameters and mediators involved in energy utilization from a process perspective. The underlying processes involved must be examined empirically and used in making policy decisions. For example, the results of the Pallak et al. (1976; 1980) study and the present study seem to suggest that providing consumers with comparative information and, specifically, social comparison

information on utility bills may effect subsequent consumption. However, if one acknowledges that if an average consumption figure was provided to consumers, the information would indicate a higher rate of consumption for half of the recipients and a lower rate of consumption for half of the recipients and, hence, any beneficial effects could be negated; lower level users may cease any efforts to conserve. Additional systematic research is warranted examining the feedback effect and testing alternative theoretical perspectives in field settings in order to further identify and understand the energy consumption process.

A LONGITUDINAL STUDY OF FACTORS AFFECTING HOUSEHOLD
ENERGY EXPENDITURES IN CANADA 1969-1982

Louise A. Heslop, Carleton University and Statistics Canada¹

Abstract

Data from the Family Expenditure surveys between 1969 and 1982 provide one of the best sources of historical information on the behaviour of Canadians throughout the 'energy decade'. Through the application of special regression analysis procedures, the relationship of energy use to demographic and capital stock characteristics is assessed.

Introduction

Much research has been directed to determining the factors related to and affecting energy use. These efforts have had two main goals. One is to determine who has been most burdened by the rapid increases in energy prices. Policymakers need this information in devising programmes of protection for those disadvantaged groups. The second goal of the research is more directly related to conservation programmes. By sorting out those factors related to high energy use, the targets for conservation programmes can be identified. By determining the characteristics of those who have constrained energy use, the effectiveness of such conservation programmes can be more clearly assessed.

This study makes use of the wealth of some existing Statistics Canada data and multivariate analysis procedures to simultaneously examine several factors known or postulated to be related to energy use. The data set has particular historical value as it covers the period 1969-1982, spanning the 'energy decade'.

Difficulty of Conducting Research on Energy Use

Studying energy use by household consumers is a very difficult process. Actual energy consumption data is hard to get and is highly suspect in many cases. The problems arise from the fact that most households do not keep long-term information on their ongoing energy purchases. Moreover, since the 1972 'energy crisis' and subsequent pressures on Canadians to conserve, most respondents are cautious to say that they do try to conserve energy and that they have been cutting back on its use. So answers to questions on use are highly reactive. Even worse, it is quite possible that the bias due to self-reporting may be unevenly distributed across the population. Those with higher incomes and educations have repeatedly been found to be more sensitive to energy conservation issues and to report more conservation-oriented attitudes. However, energy use has also been consistently related to incomes. Therefore, there might be more under-reporting of energy use among those who on attitude measures are the most conservation-minded but yet are using more energy than those with lesser incomes. Non-reactive and reasonably accurate measures are needed.

Another problem which makes energy research difficult is that it is generally not possible to get comparative data over long periods of time. To assess the impact of the 'energy crisis' at the individual level, data must be available from before and after key events in the history of that crisis period. However, it was only after the beginning of the energy situation that researchers generally became interested in energy consumption and began collecting information on usage rates. Retrieving comparable information from pre-crisis years is very difficult. Certainly respondent recall is not adequate.

In some studies consumption data has been obtained from utility company records (Heslop et al. 1978, McDougall et al. 1979). Such records are excellent sources of detailed data that are not reactive and are historical. However, it has proven very difficult to obtain such data on large samples of respondents. Utility companies require signed releases before they will allow consultation of records on households. Also in many cases records are not kept by suppliers longer than two years. Finally, the number of suppliers of home heating fuel is quite large especially if a large geographical area is being studied. In a recent study (McDougall et al. 1979) electricity utility records could only be obtained on about half and gas and heating oil records on about one-third of respondents who were members of a research panel and, therefore, more likely to co-operate.

The Value of FAMEX Data

The Family Expenditure Survey data base offers many advantages for studies of energy use under these circumstances. Detailed expenditures on a national sample of households were collected in 1969, 1972, 1974, 1976, 1978 and 1982. So the time period covered precedes the 1973 "crisis" and includes an early post-1973 measure, then one preceding the large price increases in 1978-79 and one following them, during a time of moderating and stabilizing prices. Sample sizes are typically several thousand and the sample is nationally representative. There is no problem arising out of selection into the sample because of personal interest in the subject matter. The information on energy use can be considered as non-reactive. The study is not focussed on energy use itself. Respondents are asked about energy expenditures just as they are asked about all other expenditures. So the respondent is likely to be less sensitive to give the "right" answers.

The data set also includes a wealth of other information which can be linked to energy use, including expenditures on other categories of goods and services, demographic information on family composition, age, income and education of the head, and also capital goods information such as dwelling type, size and location, and appliance ownership. The use of this information along with energy expenditures allows for the profiling of the lifestyle of the energy user and the factors associated with energy use.

The data includes energy expenditure information in dollar terms, but not in quantity terms. Where accurate price information is available, conversions are possible. However, in order to make these conversions, within-year price changes make it necessary to do some rather rough interpolations of proportions of the total year's energy which may be consumed at different times of the year. This would be a highly judgmental process and so was not undertaken in this project. So this study is of energy expenditures as one measure of energy use.

The data set is not without its problems, however. There have been many changes over the years in how some categories of expenditures have been handled in reporting. For this study, these categories were manipulated where necessary to provide for a consistency in categorization across the 13-year period. As far as possible the 1982 categorization format was used.²

²For detailed information on the construction of the data sets used in this study, contact the Social and Economic Studies Division of Statistics Canada.

¹The views expressed in this paper are the responsibility of the author alone, not of Statistics Canada.

The study is a recall study, but considerable care is taken to aid recall, and householders can check personal records for assistance. The data is collected in the first 3 months of the year following the year under study to minimize recall difficulties. Therefore, errors are likely to be relatively small and random.

Data on direct energy use is only available from those households who pay directly for their energy. Apartment dwellers by and large and especially during the earlier periods under study were on bulk meters. Therefore, how much they actually pay for their in-home energy cannot be determined as their rent payments include some unknown proportion for energy. Some studies have arbitrarily assigned a certain proportion of the rent to be the measure of energy use. However, this has not been done here. Where the procedure has been used, the judgments as to the rental proportion going to energy have been vaguely and arbitrarily set as a fixed proportion of rents. There appears to be no justification for this technique, except to increase sample size. Furthermore, renters usually can do very little to control energy use in their dwelling and have no incentive to do so. They are, therefore, likely to be far less sensitive to energy price increases and efforts to encourage conservation. It should also be kept in mind that such renters are atypical of the entire population. They are likely to have lower incomes and be younger than average or older with small families. So, because accurate in-home energy consumption on such apartment renters is not available and because they are a less important set of energy consumers in terms of the amount they consume and as targets for conservation activities, they have been removed from the sample. Their energy levels especially within the home are likely to be lower than average.

Also rejected from the sample were part-year families, who lost or gained members or who were formed in the year to ensure that such major within-year changes did not affect the ability of models used in the study to explain variances in expenditures. Therefore, only full-year households who were owners and renters of houses - detached, semi-detached, row, town - throughout the year and who made payments directly for their energy were included in the sample.

Finally the data set used in this study contains data only from the eight major urban areas used in all six surveys for consistency. Although it does restrict the conclusions to city-dwelling Canadians, this is the vast majority of Canadians. It also allows for the inclusion of climate factors in energy use analysis as discussed later.

Two main measures of direct energy use are used in this study -- in-home energy and transportation energy for the personal use of the car or truck. The in-home energy expenditures measure was created by combining heating and electricity information. This was done because there was no feasible way to determine what proportion of an electrically-heated home's electricity was used for home heating and how much was used for lighting and cooking. Similar problems arise in the case of other fuels which have multiple uses.

In this study then in-home energy and car and truck fuel expenditures are examined. Factors known or postulated to be related to energy use are combined and used in regression models to determine if they are useful in explaining these expenditures in any or all of the years for which data is available. The results can be usefully applied to meeting the two goals of such research, identifying who has been most affected by and who has responded to the rapid energy price increases of the 1970's.

Regression Techniques for Use with the Survey of Consumer Expenditures

The Family Expenditure Surveys use samples drawn from the Labour Force Area Sampling Frame. The sampling procedure is of the stratified cluster sampling type. It also

involves disproportionate sampling of smaller cities in order to ensure the reliability of city estimates. In developing total estimates, individual records are weighted to restore to each city its appropriate importance in the total and compensating for any variability in response rates between cities as well as variable sampling ratios.

Because of the cluster sampling procedures used, the assumptions of independence of observations made for ordinary regression analyses are violated. Kish and Frankel (1970) suggest that with large samples the regression coefficients themselves that arise from the use of normal regression procedures of data from complex (correlated) samples tend to approach a normal distribution about the corresponding parameters. It is, however, the variance estimates which are more problematic. With the usual regression procedures they are likely to be underestimated, thus affecting the validity of tests of statistical significance.

Several modified regression techniques have been suggested and used to deal with these problems including balanced repeated replications, jackknife, Taylor linearization and, more recently, bootstrap procedures. The first two tend to be very time consuming and expensive operations because of the high number of iterations required. The Taylor linearization procedure has been chosen as an equally effective and less costly alternative.

The problem of variance estimation for the regression coefficients is solved "by finding a linear approximation to the estimator of the coefficients. This approximation is then used to derive an approximation of the variance" (Holt 1977, p. 5). The linearization technique used is the Taylor series expansion of the estimator.³ The regression results discussed in the following sections have used this procedure with sample weights included as derived from the original data set.

The Models

The regression models used in this study have the following variables:

Dependent variables

1. Dollar expenditures on in-home energy and gasoline for private car and truck operation as explained in an earlier section.
2. In-home energy and personal transportation energy per person or per capita in the household.
3. In-home energy per room in the dwelling per 1000 degree days.⁴

These last two measures are extremely useful measures over time of efficiencies in energy use. Schipper and Ketoff (1981) note the importance of focusing on intensity of energy use in order to understand what is actually occurring in energy use over time and to tease out the effects of conservation efforts that may be hidden in simple consumption data.

Independent variables

1. Total expenditures- This variable is being used as a substitute for the income effect frequently found to be an important explanatory variable. At the aggregate level Schipper and Ketoff (1981) note that higher

³For more detail on the Taylor linearization procedure, see Frankel (1971) and Holt (1977).

⁴Degree-days are determined as the number of days of temperatures below 18° celsius. The information on degree-days for each year for the cities used in the study was obtained from Environment Canada and added to the expenditures data set.

average incomes of a population are associated with higher energy usage. At the individual level family income has been positively associated with in-home energy use (see, for example, McDougall, Ritchie, Claxton 1981) and also with energy conservation efforts involving capital investments (see, for example, Decision Research 1982; Pitts, Willenborg and Sherrill 1981; Tienda and Aborampah 1981).

Total expenditures has several advantages over income as an independent variable here. The expenditure data collected for the Family Expenditure Survey is collected in a careful and detailed way, but less emphasis is placed on the income data. From a theoretical perspective, using total expenditures allows expenditures on categories of goods and services to be viewed within the perspective of total allocations of monies to this function. Moreover, there is no concern then as to whether monies for these expenditures were derived from current income or from dissavings. The current flow of resources for expenditures is the basis of analysis. Of course, in using this variable in the regressions, expenditures on the energy source under study were subtracted from total expenditures to eliminate the situation of using the energy expenditures on both sides of the equation.

2. Stage of family life cycle - Energy is used to carry out activities in the household, rather than as a direct end in itself. Therefore, it is to be expected that families of different composition in terms of age of head and number and ages of children would have different energy needs for the different range of activities in which they must be involved. For example, the use of the family car has been repeatedly linked to the presence and ages of children (McDougall, Ritchie, Claxton 1981; Pitts, Willenborg and Sherrill 1981; and Zimmerman 1981).
3. House characteristics - These have been found to be the most useful in explaining energy use in the home as well as energy conservation activities (Decision Research 1982; McDougall, Ritchie, Claxton 1981; Tienda and Aborampah 1981; Verhallen and Raaij 1978). Number of rooms in the dwelling and whether the house was a single-detached, semi-detached, rowhouse or duplex could be identified from the FAMEX data.
4. City - In Canada there is a dramatic difference among the regions in the need for energy to maintain comfortable house temperatures. The heating degree day information for each of the cities for each of the years under study was obtained and added to the data set as a way of accounting for these differing needs. Also the eight different cities are in seven different provinces representing all the different regions of Canada. Each province differs in the price charged for the major forms of energy because of differences in distances from sources of energy, differences in provincial taxes, and, in the case of provincially-owned or controlled utility companies, differences in legislated rates and rate structures. So city variables hold useful information relating to the supply of energy, the demand for energy and its price. Since provincial factors are so important the two cities within the province of Ontario, Toronto and Ottawa have been combined for analysis.
5. Education - This variable has been found to be related to energy conservation activities (Decision Research 1982; Pitts, Willenborg and Sherrill 1981). It also can serve as a proxy measure of socio-economic status which has also been linked to the holding of socially conscious attitudes.

The regression models then take the form

$$E_1 = a + b_1 (TE-E_1) + b_2 (S') + b_3 (Rooms) + b_4 (H') + b_5 (C') + b_6 (E') \quad (1)$$

where

a, b_1 = parameter estimates.

E_1 = expenditures on the energy in the home or in the car

$TE-E_1$ = total expenditures for the household minus the expenditure for the energy under study

S' = dummy variable set for stage of the family life cycle where

Stage 1 = married couple with head under 45 years of age and no children

Stage 2 = married couple with head under 45 years of age and at least one child under 5 years of age

Stage 3 = THE OMITTED REFERENCE CONDITION, married couple with head under 45 years of age and at least one child 5-16 years of age

Stage 4 = married couple with head 45-64 years of age or over with at least one child 5-16 years of age

Stage 5 = married couple with head 45-64 years of age with no children under 16 years of age

Stage 6 = married couple with head 65 years of age or over

Stage 7 = unattached individual under 45 years of age

Stage 8 = unattached individual 45-64 years of age

Stage 9 = unattached individual 65 years of age or older

Rooms = number of rooms in the household dwelling unit

H' = dummy variable set for the type of dwelling unit with single-detached dwelling being the OMITTED REFERENCE CONDITION

S = a semi-detached dwelling

R = a rowhouse

D = a duplex unit

(NOTE: Information on this variable set was not collected in 1969.)

C' = a dummy variable set for cities where Toronto and Ottawa (Ontario cities) combined are the OMITTED REFERENCE CONDITION

SJ = St. John's, Newfoundland

H = Halifax, Nova Scotia

M = Montreal, Quebec

W = Winnipeg, Manitoba

E = Edmonton, Alberta

V = Vancouver, British Columbia

E' = a dummy variable set for education where

Grade 8 or less completed is the OMITTED REFERENCE CONDITION

PLS = partial secondary level completed

CS = completed secondary level

PS = non-university post-secondary education, partial or complete

PU = partial university

CU = university degree completed

The entire list of independent variables was used in the models involving the dependent variables of in-home energy expenditures and in-home energy expenditures per capita. For the in-home energy expenditures per room per

1000 degree days, the number of rooms and the city variables were dropped from the list of independent variables.

For the car and truck fuel expenditures the house characteristics were, of course, not included as independent variables.

Results

Tables 1 and 2 summarize the results of the testing of the regression models. Presented in these tables are all the significant variables in the models with the numerical values given for the estimates of the intercept terms and the total expenditures variable parameters. Also given are the adjusted R-squared values for the models.

has been increasingly dramatically over the thirteen-year period. For in-home energy dollar expenditures it jumped sharply between 1969 and 1972, then more slowly but consistently until 1976, then took a large leap to the 1978 value and finally levelled off. The total increase over the period was 404%. For dollars per capita the general pattern was the same with an overall increase of 1123%. For dollars per room per degree day this increase was more gradual throughout the early period until after 1978 with it took a very large jump with the final percentage increase being 256% for the period. The much larger increase for the per capita expenditures likely reflects the basic changes in family structure that occurred during this period due to such demographic changes as the decline in the number of children per family, the

Note: See text information on the meanings of numbers for stages and letters for type of dwelling, city and education.

All factors reported in this table are significant at the <math>\alpha < .05</math> level or beyond unless indicated ^{NS} (not significant).

N.A. - data not available in that year.

In-Home Energy

In-home energy expenditure variances were well explained by the model elements. All the adjusted R-squares are significant and most are reasonably high. The adjusted R-squared values were higher for the dollar expenditures and the dollar per capita measures than for the dollar per room per degree day indicating the fundamental importance of climate, prices of energy and house size in understanding energy consumption. Also for the first two measures there is a definite decline in the model's ability to explain the variance over time suggesting that individual factors not included in the model may be accounting for more and more of the differences among households over time. For the dollars per room per degree day measure the R-square increases somewhat in the later period as more of the variables in the model (stage of family life cycle and education) become significant.

The intercept term can be thought of as a minimum amount of expenditure for the household as defined by the set of reference or baseline conditions for all the dummy variables. In this case it would be a family in Stage 3 of the family life cycle (male head under 45, one or more children 5-16 years of age) living in Ontario in a single-detached house and the male of the household head has less than a high school education. The amount of this minimum

maturing of the baby-boom generation, and rising divorce rates. All these lead to drops in average family size. Further the population of elderly families continuing to maintain their own homes is increasing. The smaller increase in the expenditures per room per degree day may indicate that the Canadian population is making some real efforts to curtail energy use which may not be as obvious when only total expenditures are examined.

The household's total budget has a consistent significant positive effect only on the total energy expenditure measure. The trend in the size of the parameter estimates for total expenditures seem to follow the trends in the real prices (adjusted for income increases) of energy in Canada which declined in the early 1970's, rose in the mid-70's and then levelled off or moved down slightly towards the last part of the period under study. Total expenditures are not significant for the other two energy expenditure measures until prices started upward. Those with more money to spend then were the ones who could continue despite these price increases to spend more intensively, i.e., more per person and more per room per degree day. They clearly were more able to absorb the price increases, whereas those with more limited resources had to find ways to hold the line. So it would appear that as prices of energy increased those with larger budgets spent more and made significantly greater gains in their use of energy.

The stage of the family life cycle variable set is very interesting in what it reveals across the different measures of energy use and the different years. For in-home energy expenditures it appears that most families spend alike and do not differ substantially from the reference condition (Stage 3). In the early periods, the smaller younger families spent less. During the later periods with energy prices much higher, the elderly couples spent more in 1978 and the young singles spent less in 1978 and 1982. However, in terms of expenditures per capita the economies of scale of the full nest families (Stage 3 and 4) become obvious. All other households spent more in every year. Finally, again for dollars per room per degree day there is little difference. The full-nest families may spend less per person but they usually occupy larger homes and do not use the energy any more or less intensively in these rooms. The only trend seen in this last measure of in-home consumption of note is the evidence that the elderly are spending more in later periods. These households are more likely to be in older homes, less well-insulated with older, less efficient oil-fired heating systems (see Heslop 1985a). For a variety of social and economic reasons they seem to be less able to make the necessary moves to improve their efficiency of energy use and must bear the costs resulting.

House characteristics are very important as would be expected from the previous research. Number of rooms is significant for four of the six periods when relative energy prices are highest for dollar expenditures and all years for per capita expenditures. Rowhousing seems to be the only consistent winner over detached single houses for all measures for all years. The other multiple unit dwellings are in some periods but are not in others, especially the later ones. This would suggest that perhaps those in single detached dwellings have been improving the energy efficiency of their dwellings.

The set of city variables indicate the hardship experienced by those who are more isolated from energy supplies and are burdened with high prices. The cities in the Eastern Maritime provinces spent significantly greater amounts on total in-home energy and on a per person in the household basis. Those in the West near the Alberta oil supplies or in Quebec with its abundance of hydro-electric power spent less. Also those blessed with more temperate weather on the West coast usually, but not always spent less.

the other two measures in later years. Post-secondary education is associated with higher per capita consumption between 1972 and 1978 but then is not, suggesting that those with higher education made disproportionately heavy use of energy on a per capita basis until its price rose dramatically in 1978-79. Moreover, with regards to expenditures per room per degree day those with the highest education used significantly less after the first 'crisis' period. This may suggest that those with higher education levels could and did respond more effectively to information about energy conservation and incentives to conserve energy or switch to less expensive sources.

Car and Truck Fuel Expenditures

For expenditures on fuel for personal private transportation (see Table 2), again the models used are significant in explaining variance in both expenditure measures across all the years. However, the adjusted R-squares are much lower than they were for in-home energy expenditures. This is undoubtedly due to the absence from the models of vehicle characteristic measures (gross vehicle weight and total engine displacement) which usually explain most of the variances in usage.

The intercept terms take a slight drop between 1969 and 1972 and these gradually increase until there is a large jump between 1978 and 1982. Again the trend reflects the trends in real energy price increases. The dollar expenditures intercept term increases by 430% and the dollar per capita term by 469% over the thirteen-year period. Again, as for in-home energy, there appears to be a greater increase in per capita expenditures suggesting that car use is increasing despite gasoline price increases. Demographic shifts may explain much of the change. The period was marked by a rapid increase in the number of young drivers who are traditionally heavy users of cars and by an increase use of cars by older married couples (see Heslop 1985b).

Total expenditures again are very significant in accounting for individual differences in both expenditure measures. Those with larger budgets spent more in all years. The value of the parameter estimate increases generally over time and suggests that the 'income' sensitivity of expenditures for personal transportation is increasing.

TABLE 2
FACTORS EXPLAINING VARIANCE IN CAR AND TRUCK GASOLINE EXPENDITURES OR URBAN CANADIAN HOUSEHOLDS, 1969-1982

Independent Variable (Reference Condition In Dummy Variable Set)	Intercept	Total Expenditures	Stages of Family			adj R ²	D.F.
			Life Cycle (Stage 3)	City (Ontario Cities)	Education (<Gr. 9)

1982	179.3	3.3x10 ⁻³	1,2,5,7,8(+)	SJ(+),M(+)	PS,CU(-)	.16	20/2108

Note: See text information on the meanings of numbers for stages and letters for type of dwelling, city and education.

All factors reported in this table are significant at the <.05 level or beyond.

Education effects are very interesting. They do not contribute much to the understanding of total expenditures. However, several education variables do enter for

the stages of the family life cycle that are important differ greatly between the two measures. In gross expenditures it is clear that older households spent less.

Also those households with middle-aged heads and older children still at home spent more during the middle 1970's but not thereafter. This would suggest that these heavy users responded to the need to cut back. In terms of per capita consumption the results look more like those for in-home per capita expenditures. Almost all family types consumed more per capita than the full nest families. Only the unattached individual elderly consistently did not. Even elderly married couples frequently consumed like younger households indicating recent growth of interest in driving among this group.

City location is not as consistent a predictor of personal transportation fuel expenditures as it is for in-home energy. Essentially it seems to capture here the effects of provincial variations in fuel prices. The Maritimers do not appear to be so burdened in this case. Since driving is somewhat more discretionary than home heating, they may prefer to drive less in the face of their higher gasoline prices. Montrealers appear to have lost any advantages they had in earlier periods which allowed them to have lower expenditures before 1982. Indeed, in 1982 the average price of gasoline was higher in Montreal than in all of the other seven cities (Statistics Canada 1983).

Finally again the education variable set is interesting. During the early periods those with some or all of secondary school or a non-university post-secondary education spent more than those with less than Grade 9. However, those with a university education did not. By 1982 those with post-secondary education of any kind spent significantly less than the reference group. Again there appears to be an educational achievement effect in conservation efforts resulting in lower energy expenditures.

Summary and Conclusions

The Family Expenditures Survey data on energy expenditures can be a very informative source of historical information on the experiences of households and their responses to the events of the 'energy decade'.

Those households in the Eastern Maritime provinces have been particularly burdened with high costs of in-home energy. Those households with higher incomes spent more and used energy more intensively. Smaller households used less total energy in the home, but families in the full nest stages used less per capita. Some multiple unit dwellings, especially rowhousing, used less in-home energy than did single-detached houses and larger houses used more.

Further there is evidence to suggest that the more highly educated have been more responsive. Also those living in single family dwellings appear to have made more efforts to improve efficiencies of in-home energy use. Finally there are indications that the elderly may be falling behind in efficiency of energy use in the home and so are incurring larger than average expenditure burdens.

The expenditure increases of households has been rapid and dramatic. The overall pattern of dollar expenditures for energy indicates little effort to control increases as they generally parallel price increases. However, a closer look at the data through the use of intensity of use measures (per capita and per room per degree day) give more evidence that efforts to counteract the price increases with restraints on the growth of energy use have occurred. Demographic and economic trends have masked some of these efforts so that they are not obvious in the gross measures.

FOUR SCRIPT STUDIES: WHAT HAVE WE LEARNED

Paul H. Schurr, SUNY Albany¹

Abstract

This paper describes four studies designed to examine the influence of scripts on attitudes and judgment. There are two objectives for this discussion. The first objective is to tie together the findings of four script studies. The second objective is to identify conceptual issues that have arisen from this program of study.

Introduction

One advantage of a programmatic series of studies is that they offer a chance to evaluate multiple facets of a theory or conceptual model. Before discussing what we have learned from four script studies, the theory that prompted these studies will be discussed. Then, an overview of the conceptual findings of four studies will be presented.

A Conceptual Model

The conceptual model encompasses four main components. The first two components may be viewed as input components: information stored in an individual's memory and information from an organizational (purchasing) task environment. The third component in the model controls the informational input. It is a collection of sense-making psychological mechanisms - knowledge structures or schemata - that combine an individual's stored knowledge with information from an organized task environment (Weick 1979; Calder and Schurr 1981). The fourth component is the output. In this case we are interested in attitudes and judgment as the output of the sense-making schemata.

Of information input, information control, and output components of the conceptual model, the information control mechanism is perhaps the least understood. First, we will discuss schemata and, particularly, scripts as control mechanisms. Then, information input will be discussed, with special attention to the task environment as a trigger for schematic processing.

Schemata as Control Mechanisms

A schema is defined as "an abridged, generalized, corrigible organization of experience that serves as an initial frame of reference for action and perception" (Weick 1979, p. 50). A schema assumes the operation of four central processes: selection of all incoming stimuli for mindful representation, abstraction of the meaning of perceived information, interpretation using prior knowledge to aid comprehension, and integration for storage in memory (Alba and Hasher 1983).

A schema controls information selection by directing attention to a limited portion of stored knowledge and by causing selective perception of information in the environment. By organizing information, a schema gives meaning to stimuli and enables interpretation and comprehension. Sense-making itself seems related to a network of thought connections, which makes the notion of episodic scripts a good starting point for research into information control mechanisms.

Scripts

A script is an event-centered schema in which knowledge is organized like a causal model around expectations

concerning a sequence of events or actions (Abelson 1976). Scripts are of particular interest because scripts link the individual with an organizational context and role (Calder and Schurr 1981).

Further, according to Abelson (1981), scripts capture most of the conceptual elements of other types of schemata, yet permit more focused analysis and experimentation because scripts are simple and well-structured. A script is a mental picture - "picture plus caption" in Abelson's terms (1976, p. 34) - representing the action sequences, participants, and physical objects found in a situation. Information is organized around one or more scripts.

The activation of scripts by an individual depends on three general conditions that must be satisfied for scripted processing to occur (Abelson 1981): the individual must have a cognitive representation of a script, an evoking context must be present, and the script must be physically or mentally entered.

Scripts are evoked by a context. Therefore, because a task environment acts as a trigger for scripts, a task environment at least in part determines what information stored in memory will be activated and what environmental information will be selectively perceived. Thus, a script is a significant way for past experience and organizational task environments to influence individuals (Weick 1979; Calder and Schurr 1981; Axelrod 1976).

Input: Information from the Task Environment and Memory

Essential to the process leading to attitudes and judgment are the informational inputs: information from the task environment and from memory.

The task environment. The organizational task environment is defined as the context, structure, and content of a decision problem and decision-making situation (Newell and Simon 1972). It serves two key functions. First, prominent cues in a context activate the scripts that will in turn guide further information processing. Second, as a context for a role occupant's thought processing, the task environment provides information relevant to role behavior and problem solving through the process of perception.

The role of memory. Like the task environment, an individual's memory contributes to information processing in two different ways. First, scripts are stored in memory and must be activated. Second, memory provides basic units of information - thoughts and beliefs - as input to active processing. That is, individuals have in their memory information obtained from actual and vicarious experience, more information than could ever be processed efficiently for a given problem (Newell and Simon 1972). Part of this reservoir of information is tapped by a script.

In summary, attitudes and judgment are a function of three elements: information provided by a task environment, information activated in memory, and information processing guided by sense-making knowledge structures. Knowledge structures, such as scripts, are stored in memory, but activated by the organizational purchase context. Our simple conceptual model suggests knowledge structures provide the basic ingredients for attitudes and judgment (cf., Cialdini, Petty, and Cacioppo 1981; Greenwald 1968; also see Calder and Schurr 1981). Thus, the following research focuses on demonstrating that an understanding of purchasing buyer scripts can result in accurate predictions concerning buyer attitudes and judgment.

¹Associate Professor, School of Business,

A Summary of Four Studies

Our research program called for sequential studies that allowed the researcher to learn at each step in the research program. Four studies in our research program are discussed here. The goal was to test the causal relationship between scripts and purchase evaluations in an organizational purchasing context. The approach was to manipulate aspects of the purchasing task environment and examine hypothesized effects on attitudes and judgment. To evaluate script-information interactions, information was also manipulated in two of the four studies.

A brief summary of the four studies is provided, along with a reference to where more detailed information can be obtained about the study. Then the studies are critiqued from the standpoint of substantive findings and conceptual issues.

Study 1

Background and Hypotheses (see Schurr 1980 for details). The purpose of the first study was to challenge the assumption that the relationship between a purchase decision problem and attitudes is relatively fixed. Our rival hypothesis was that an attitude changes with the perspective (schema) in mind at the time.

In particular, consider boundary role theory (Katz and Kahn 1966; Goffman 1969; Adams 1976; Vidmar 1971). A boundary role person, such as an organizational buyer, performs two representational roles. On one hand, an organizational buyer represents a seller's viewpoint to individuals within the organization, such as users. On the other hand, an organizational buyer also represents the viewpoint of internal constituencies, such as users, to sellers' representatives. Thus, organizational buyers potentially bring two different perspectives to the analysis of every purchase decision problem.

Consider, for example, a situation where there is a disagreement between a user and a supplier of a product. (All four studies focus on purchase problem evaluations stemming from user-supplier disagreements.) Say, for instance, the user claims the competition is promising a better delivery schedule, but the current supplier claims a better delivery schedule is not realistic. As a boundary role person, an organizational buyer must convey the views of the user to the supplier's representative. In seeking a resolution of a purchase-related disagreement, the reverse also holds. That is, the purchasing agent must represent the supplier's view to insiders (i.e., the user) so they will be able to develop realistic expectations about how to resolve the disagreement.

Notice how this example based on boundary role theory lends itself to Abelson's (1976) idea of a script. The basic script concerns the event sequence leading up to and including a meeting between the purchasing agent and one of the disagreeing parties. In the meet-supplier track of the script the participants are a purchasing agent and an outsider (supplier's representative). In the meet-user track of the script the participants are a purchasing agent and an insider (user). We found meetings of this kind to be quite familiar to purchasing agents. The evoking context is provided by the problem (user-supplier disagreement) itself and an anticipated meeting with the user or supplier to discuss the disagreement.

We hypothesized that the meet-supplier induction would cause a purchasing agent to adopt an insider's perspective when expressing attitudes or judgments; the subject would be less favorable toward the supplier's position and more favorable toward the user's position. Essentially, the purchasing agent will organize thoughts to represent the user's viewpoint. By comparison, the meet-user induction would have the reverse effect and cause subjects to be more favorable toward the supplier's position and less favorable toward the user's position in a disagreement.

Method. Twenty-eight organizational buyers rated four items in an attitude scale (Cronbach's alpha = .96) for each of nine different user-supplier disagreements. The between-subject manipulation was simply to interchange the terms "user" and "supplier" when giving instructions to subjects regarding problem evaluations: "You are preparing to meet with the user (supplier) of a product to discuss a disagreement between the user and the supplier..."

Results. The main effect was significant at the .001 level ($F(1,26) = 12.7$). As hypothesized, the meet-supplier script caused a more favorable attitude toward the user's position in the disagreements, as compared to the meet-user script.

Critique. As a first step in the pursuit of attitude-script linkages - indeed, a baby step - the study yielded interesting results. In particular, subjects did not have a patternless reaction to the nine stimulus problems (the null hypothesis). Rather, the meet-user and meet-supplier inductions differentiated the responses. This result suggests something in the "black box" of the human information processors was "switched on" (evoked) in one condition, and something different was evoked in the other condition. Unfortunately, Study 1 offers little supporting evidence that a script was evoked or activated by the inductions. A remaining task is to demonstrate that scripts were actually involved in the effects.

Study 2

Motivation (see Schurr 1980 for details). Study 2 attempted to enhance the evidence that scripts caused attitude differences in Study 1. Thus, one tactic was to carefully design a study in which all the ingredients to script activation would be present. In particular, action sequences, entry conditions, specific roles, and props (physical objects) were included in pictorial stimuli. A second tactic was to manipulate informational inputs so that the interaction of scripts and information processing could be examined. An interaction would suggest that the black box mechanism was handling information differently in different contexts - a theoretical effect of a script or schema. A third tactic was to utilize dependent measures to assess whether action sequences were mindfully represented.

Background and Hypotheses. Study 2 again pursued a substantive issue prompted by boundary role theory. The aim was to utilize role partner relationships to activate script processing. According to Adams (1976, p. 1176), boundary role persons, such as organizational buyers, operate at a distance from the organization and in closer proximity to the outside world. This physical and psychological distance generates suspicion among a buyer's role partners inside the organization and makes a boundary role person sensitive to the reactions of insider role partners, such as a product user. The more exposed a boundary role person is to monitoring by an insider role partner, the more a boundary role person tries to avoid the appearance of compromising the insider's best interests.

Following work by Organ (1970), it was hypothesized that a monitored-buyer script (a user is present in a purchasing agent/sales rep meeting) would cause a less favorable evaluation of a supplier's position in a user/supplier disagreement. In an unmonitored script (the user is not present) it was hypothesized that the subjects would evaluate a supplier's position more favorably in relative terms.

A script by information interaction was conceptually motivated as follows. First, Calder, Insko, and Yandell (1974) demonstrated that adding arguments favoring a particular viewpoint increases the persuasiveness of that viewpoint, at least up to the point where the number of arguments swamps short term memory. Second, scripts can increase or decrease the perceived persuasiveness of a communication by influencing meaning, stimulating counter

arguments, and affecting attention (Taylor and Crocker 1980). It was hypothesized that the monitored-buyer script would neutralize the persuasiveness of a salesperson's arguments as compared to the unmonitored-buyer script, because the former script would stimulate counter arguments.

Method. Data from forty purchasing personnel in a large company in Chicago were utilized. Monitored/unmonitored buyer scripts were crossed with two levels of supplier's arguments (3 and 6) in a between-subject, two by two factorial design.

Scripts were induced using three small pictures depicting arrival (an entry condition) and meeting actions. Pictures were accompanied by captions identifying participants in the meetings. The user was depicted only in the monitored-buyer version. The objective was to convey realistic but minimal cues consistent with these scripts.

A user-supplier disagreement problem from Study 1 was adapted for use in Study 2. Either three or six supplier arguments (and three user arguments) accompanied the inductions as presented to the purchasing personnel.

Twenty rating scales items were employed, including five measures designed to assess mentally represented actions prompted by the inductions.

Results. One scale (three items, $\alpha = .77$) indicated the monitored-buyer script caused less favorable ratings of the sales representative's position in the user-supplier disagreement than did the unmonitored-buyer script as predicted ($F(1, 36) = 12.1, p < .001$).

There was a script by number of arguments interaction, but only for one item that measured how good or poor the user's arguments were perceived by the purchasing agents. The scripts actually reversed the intuitive effect of the number of arguments. That is, monitored buyers rated the user's position more favorably when there were six, not three, supplier arguments ($F(1, 36) = 16.9, p < .001$); there was no difference between three and six arguments for unmonitored buyers.

Other aspects of the results are less conclusive. The buyer's overall attitude toward the supplier was not influenced by the manipulations. Further, there was no script by number of arguments interaction for the primary scales, although a main effect for the number of arguments was significant in the predicted direction ($F(1, 36) = 5.6, p < .02$).

Finally, the five measures of script-prompted actions yielded little evidence that generic action sequences were brought to mind by the inductions.

Critique. The results indicate the relationship between a boundary role person and his or her role partners is a determining factor when attempting to predict the attitudes and judgment of a boundary role person, such as a purchasing agent.

With respect to scripts, the results are only slightly encouraging. The presence of a script by number of arguments interaction for one item suggests additional research is warranted, but the single-item effect must be recognized as a possible result of chance, since the pattern of results was inconsistent. The main script effect on the three item scale provides more cause for optimism.

Our major conclusion is that the script inductions caused different purchase problem evaluations. Without a convincing interaction effect and without confirming evidence that action sequences were brought to mind by the script inductions, support for script theory is less than hoped for in Study 2.

Study 3

Motivation. The results of the first two studies could be explained by role theory. In fact, since the manipulations simply involved roles, role theory is perhaps the best explanation for the effects. (Nevertheless, script theory explains why simple role manipulations in the context of stereotypical organizational events prompted significant differences in purchase problem evaluations.)

The next two studies focus less on the role aspect of scripts and more on subtle manipulations of the props - physical features - present in a stereotypical action sequence. This strategy further examined the notion that the effects in the first two studies were the result of script, rather than role, manipulations.

Background and Hypotheses (see Schurr and Calder 1986 for details). Study 3 provides an interesting connection between the restaurant script, which has received much attention thanks to Abelson's writings, and the every day business lunch. The published report of this study (cited above), in fact, focuses on substantive issues related to buyer-seller interactions at business lunches. Script theory motivates the method used (not the hypotheses) in the published report. In contrast, the discussion here will center on how this study relates to script theory.

Because script research has devoted considerable attention to the notion of stereotypical restaurant scripts (e.g., Abelson 1981), the restaurant script is a firmly anchored starting point. Briefly, script theorists regard the restaurant script as a commonly experienced event sequence around which we organize information. Most people have in their memories a script for traveling to a restaurant, being seated, having a drink, ordering from a menu, being served the first course, and so on.

In organizational buying, an equally common script is the business lunch script (see Schurr and Calder 1986). The business lunch script in Study 3 had a purchasing agent and a supplier's sales representative arriving at a restaurant to discuss, as in the previous studies, a user-supplier disagreement. We are interested in two versions. One is a regular business lunch meeting at an ordinary restaurant. The other version is a meeting at a fancy restaurant. Notice we are primarily interested in the setting, defined by the ordinary or elaborate "props" - the restaurant decor.

Based on previous studies of business lunch meetings (Dempsey, Bushman, and Plank 1980; Halvorson and Rudelius 1977) and Webster and Wind's conceptualization of the buying process (1972), we reasoned that as task environments, the restaurant settings would influence a buyer's interpretation of events by evoking knowledge of specific norms, shared ideals, and positive or negative thoughts that contribute to attitudes and judgment.

The norm for regular meetings at ordinary restaurants is business-as-usual: attention is given to problem-solving and relationship development. Regular business lunch meetings include an element of mutual persuasion, but the motives of the participants are not questioned for the most part.

Fancy restaurants in the context of addressing a disagreement are less normal. While nearly everyone prefers a fancy restaurant to an ordinary restaurant for celebrations and social occasions, when business must be conducted, a fancy restaurant to some extent creates the impression that a buyer's objectivity is impaired.

In our hypotheses we compared the effect of a regular meeting with that of a fancy restaurant meeting. We hypothesized that a regular restaurant meeting would influence an industrial buyer to: (H1) evaluate a sales representative's arguments more positively and a user's arguments more negatively, (H2) judge that the user must yield relative to the sales representative in the buyer-

seller disagreement, and (H3) give a more positive overall supplier evaluation.

Method. Data was collected from 211 purchasing personnel in the Purchasing Management Association of Chicago by means of a mail survey.

Two scripts and three buyer-seller disagreement problems were evaluated in a six cell between-subjects design. The restaurant meeting script inductions utilized the picture-plus-caption approach of Study 2. Three scenes were depicted: (1) buyer and seller arrive at the door of a restaurant, (2) buyer and seller are shown at a table, and (3) buyer and seller engage in discussion at the table. All three scenes appeared in both restaurant meeting inductions, but the physical appearance of the surroundings - the props in Abelson's terms - were manipulated. The regular restaurant scenes showed unpretentious surroundings and decor, while the fancy restaurant scenes displayed more elegance.

The three disagreement problems were developed from the earlier studies, and four categories of dependent measures were collected.

Results. All three hypotheses were supported at the .025 level or better. Further, four measures designed to capture perceptions of the meeting scripts gave some indication that the respondents were thinking along lines consistent with a script interpretation of the effects (see Schurr and Calder 1986).

Critique. There are several ways to assess the results. First, the substantive finding that norms related to the task environment - in this case the ordinary or fancy restaurant - in part determine attitudes and judgment agrees with theories of organizational buying (e.g., Webster and Wind 1972).

Second, Study 3 demonstrates that the use of script-related inductions allows researchers to explore questions that might otherwise be intractable. In this case, examination of meeting place effects on attitudes was made possible by the script inductions.

Third, Study 3 addresses at least one of the limitations of the first two studies. Compared to the role manipulations in the first two studies, the Study 3 manipulations concerned only the physical aspects of the restaurant settings (nevertheless, role theory was needed to develop the hypotheses). Cognitive reactions to these inductions could not easily be explained without considering that the meeting setting prompted some sort of knowledge retrieval and information organization. Because restaurant scripts have been shown to organize event-related knowledge (Abelson 1981), it is reasonable to suggest that restaurant meeting scripts would, indeed, organize information related to a business lunch meeting task environment.

Fourth, in Study 3 there is more assurance that the subjects were likely to have business meeting scripts stored in memory. Subjects were required to meet two criteria: the respondent must have had experience meeting with supplier's representatives at business lunches, and their primary area of responsibility had to be purchasing.

Study 4

Motivation (see Schurr 1985). Two aspects of Study 3 warranted additional attention. First, it was argued in Study 3 that the meeting script effect was directly related to norms of the task environment associated with the purchasing agent's role and relationship to role partners. This reasoning suggests different roles have different scripts; a seller and buyer should react differently to different stimuli. Second, Study 3 did not examine script effects on information.

Background and Hypotheses. A role by script interaction was predicted. Buyers in Study 4 were expected to react

to the meeting scripts as before, with the fancy restaurant meeting resulting in a less favorable attitude and judgment with respect to the seller. By comparison, no script effect was expected for sales representatives.

Study 4 also tested information effects by manipulating subjective or objective information content in the sales representative's response to the user's concerns in the user-supplier disagreement. Compared to subjective information, objective information has been found to cause a more positive response (Edell and Staelin 1983; Holbrook 1978).

An interaction of interest would be a script-induced neutralization of information effects caused by the organization and meaning given to information. We tested the notion that a fancy restaurant meeting would give increased (negative) importance to subjective information.

Method. Data was collected from 248 subscribers to a leading Chicago business letter publication. All of the subjects had direct experience in restaurant meetings with their counterparts. Purchasing and sales people were differentiated based on their responses to a series of questions, such as job title and job responsibilities.

Three independent variables (role, script, information) with two levels each were crossed in an eight cell design. The script and role variables have been described. The information inductions are reported in Schurr (1985). Dependent measures were drawn from the previous studies in this program.

Results. The hypothesized role by script interaction was supported by a two item scale capturing an evaluation of the sale representative. Subjects who were identified as being in a purchasing role in their organizations reacted as did subjects in Study 3: they rated the seller's position in a disagreement less favorably in the fancy restaurant meeting context. Subjects identified as being in a selling role, on the other hand, expressed a positive evaluation of the sales representative, regardless of the script condition. This interaction is significant at the .05 level.

The only script by information interaction was indicated by a single item that concerned a judgment of whether the buyer or seller in the disagreement should make concessions in the disagreement. The concession item indicated that subjectively embellished information neutralized the script effects, while objectively embellished information did not affect the script effects.

Critique. Study 4 did not close the door on script research by any means. On one hand, the role by script interaction supports our conceptualization of scripts, but this interaction was indicated by but one scale; the effect was not pervasive. On the other hand, the information by script interaction was inconsistent with our conceptualization of scripts, but this contradictory evidence was indicated by only a single item.

Summary and Conclusions

What We Learned

The results of any single study in this program does not provide sufficient evidence in support of script theory. Yet the accumulated evidence is consistent with script theory. We propose that the following propositions warrant additional consideration, based on the encouraging pattern of results in our research program.

Proposition 1: Scripts affect attitudes and judgment by evoking an organized body of knowledge.

Two kinds of evidence are available. First, previous research has established that people store in memory information related to action sequences (Abelson 1981;

Bower, Black, and Turner 1979; Leigh and Rethans 1984). Second, our research program has found effects suggesting a direct relationship between scripts and attitudes and judgment.

Proposition 2. Scripts are role dependent.

Again there appears to be two forms of evidence. First, boundary role theory has served as the conceptual foundation for all four studies. Support for the boundary role hypotheses has been quite consistent. Second, Study 4 demonstrated that individuals in different roles react to scripts differently.

Proposition 3. Scripts capture important aspects of a task environment which in turn frames a buyer's reactions to problems in buyer-seller exchange relations.

All four studies demonstrated that purchasing agents evidence different assessments of user-supplier disagreements, depending on the task environment script in mind at the time.

Unsolved Conceptual Issues

Based on these four studies (and the reactions of many who have read reports of these studies), the following issues need attention.

Issue 1: How does script processing relate to information processing explained in terms of cognitive response theory?

A reasonable critique of script research is that many of the effects can be explained in a cognitive response framework. Does script theory represent a more complicated way to explain simple cognitive response? Does script theory explain mental information control processes better than cognitive response theory?

Issue 2: How do we know that scripts, not informational cues in the inductions, prompted the effects on attitudes and judgment?

Script theory claims that scripts organize a body of knowledge related to attitudes and judgment. A rival hypothesis is that script inductions of the kind used in the above studies simply provide pieces of information that cause the results. If so, an organized body of knowledge - information connected to other information - is irrelevant to effects on attitudes and judgment. This explanation resembles a stimulus-response interpretation.

Conclusion

We believe the conceptual framework offered in this paper provides a reasonable starting point for research. Effort must be directed toward pitting competing theories, such as script theory and cognitive response theory, against one another. Although we cannot disprove these theories, we can demonstrate which theories explain causal relationships more simply and completely.

Finally, based on formal and informal debriefings and discussions with subjects in our studies, we think script-based inductions offer a powerful tool for studying substantive issues that otherwise might not receive attention (e.g., Schurr and Calder 1986). Script-based inductions, with a focus on entry conditions, event sequences, and roles in a task environment, apparently evoke a frame of mind that reflects actual situations.

MEASURING SCRIPT DEVELOPMENT:
AN EVALUATION OF ALTERNATIVE APPROACHES

Ruth Ann Smith, Virginia Polytechnic Institute and State University
Michael J. Houston, University of Wisconsin - Madison

Abstract

A common limitation in script research, both in the consumer context and in other settings, is the failure to quantify subjects' level of script development. The majority of studies simply assume a homogeneous script across all subjects for an event selected at the researcher's discretion. This assumption clearly hampers developmental studies of scripts, and also restricts the ability to make unambiguous statements about the effects of scripts on consumer information processing. This paper discusses various approaches to the measurement of script development that will reveal the degree to which the structural features of such representations are present in consumer memory.

Introduction

The impact of knowledge on product evaluations and purchase decisions is a growing concern in the consumer behavior literature (Brucks 1985; Johnson and Russo 1984; Sujan 1985). The need to measure consumer knowledge structures, and assess their influence on information processing, is acknowledged by Mitchell (1982), who suggests that "in order to develop valid measures, you must first have a theory of memory" (p. 45). The objective of this paper is to describe and evaluate several techniques for the measurement of consumers' knowledge structures which are derived from schema theories of memory.

The first part of the paper will briefly review the basic propositions of such theories, and describe the structural characteristics of schematic memory, with particular emphasis on scripts, or event schemas. Given this theoretical framework, attention will then focus on alternative stimuli and dependent measures that may be employed to quantify an individual's level of script development, as indicated by the presence or absence of these structural features.

Schema Theory

Although the organization of human memory may assume various forms, memory schemas appear to perform an important role in the structure of consumer knowledge (John and Whitney 1982; Leigh and Rethans 1983; Roedder John and Whitney 1985; Whitney and John 1983). Event schemas, or scripts, consist of abstract knowledge about the sequence of actions typical of a commonplace event (Abelson 1976, 1980; Schank and Abelson 1977). Scripts, like all schemas, are propositional, verbally or semantically encoded knowledge structures (Lord 1980). However, they possess several structural characteristics that differentiate them from other memory representations, including concept abstraction, a set quality, causal or temporal sequence, and hierarchical structure (Abbott and Black 1980; Thorndyke and Yekovich 1980).

Concept abstraction refers to the nature of the knowledge represented in a script. An event schema does not contain the specific details of any particular occurrence of an event. Rather, it consists of a prototypical event composed of the common actions abstracted from repeated experiences. Thus, the structure of a script is a network of generic actions and rules for combining them. In addition, this network possesses a set quality in that activation of any component action provides access to the entire group of actions constituting an event. The temporal or causal sequence typical of a script's organization refers to the characteristic that certain actions in this set must precede other actions in time in order to provide the

enabling conditions necessary for the latter action to occur.

Finally, scripts possess a hierarchical structure which defines the relationships among actions of varying levels of specificity or centrality to an event. As described by Abbott and Black (1980), this hierarchy is composed of three levels including a script header, scene headers, and scene actions. A script header represents the most general, or macro level of the hierarchy, and summarizes an entire event (e.g. dining in a restaurant). This event is composed of several scenes which are identified by scene headers such as entering the restaurant, ordering the meal, and eating. The scene headers exist at an intermediate level of the hierarchy, and contain more detailed information about the event. At the lowest level of the hierarchy are scene actions, which are the individual actions relevant to each scene. Thus the ordering scene may consist of reading the menu, discussing the choices, and placing the order.

Given these structural features of event schemas, the task of quantifying the level of script development may be clarified. As an individual's script for an event becomes better articulated, it would be expected that their response to some stimulus would exhibit a higher degree of concept abstraction, the set quality, temporal/causal sequence, and hierarchical structure. Thus the measurement task involves devising stimuli that will elicit responses that can be quantified using various dependent measures to assess the presence or absence of these structural features. It should be emphasized that measuring script development should focus on assessing the structure of knowledge, rather than its processing effects. The influence of scripts on consumer information processing can only be demonstrated once it has been determined that consumers have actually organized their knowledge of an event in a schematic structure.

Measuring Script Development

The script literature is replete with a variety of measures that are used to elicit event schemas or to evaluate their impact on information processing. Only rarely, however, have these measures been employed to assess respondents' level of script development, although many are adaptable for this purpose. In the following discussion, verbal and visual stimuli appropriate to this task will first be considered, and various dependent measures useful in assessing responses to these stimuli will then be discussed.

Stimulus Materials

Verbal Stimuli. Inasmuch as scripts are composed of semantically or verbally encoded propositions (Lord 1980), verbal stimuli are naturally suited to measuring script development. A wide variety of measures employing this approach are found in the script literature, although by far the most common verbal stimulus utilizes a probe to elicit a written or spoken description of an event. Typically referred to as protocols or retrospective self-reports, stimuli employing such free-recall tasks have served several purposes in script investigations, including identifying the component actions of an event (Bower, Black, and Turner 1979; Bozinoff 1982; Fivush 1981, Graesser, Gordon, and Sawyer 1979; John and Whitney 1982; Rethans and Hastak 1982; Whitney and John 1983), evaluating the influence of a script on information processing (Black and Bern 1981; Bower, Black, and Turner 1979; Brewer and Dupree 1983; Graesser, Woll, Kowalski, and Smith 1980; Lichtenstein and Brewer 1980; Martin, Harrod, and Siehl 1980; Salmasso,

Baroni, Job, and Peron 1983; Whitney and John 1983), and assessing level of script development (Roedder John and Whitney 1985; Smith and Houston 1985).

Although only rarely used in this final context, it seems reasonable to expect that the responses of subjects with various levels of schematic memory for an event would vary systematically with respect to all four of the structural properties noted previously. That is, an individual with a highly developed script would be more likely to generate an abstract description of a complete set of actions, ordered in their typical temporal sequence and reflecting the hierarchical structure of component scenes than a respondent lacking a script. A potential limitation on this approach, however, is that generating a response to the stimulus imposes a substantial cognitive burden, and one which would seem to be inconsistent with the automatic, mindless nature of script-based processing. Some preliminary evidence that responses may not adequately reflect script development is offered by Smith and Houston (1985) who observed substantial instability over time in the responses of individuals with well-developed scripts. The lack of test-retest reliability suggests that this type of verbal stimulus should be used cautiously when assessing script development.

Verbal stimuli requiring cued recall may be designed, however, that minimize this problem of cognitive load. For example, subjects might be presented with a single action in an event, and be asked to recall the action that precedes or follows it. Such responses would obviously be informative with respect to the temporal sequence quality of scripts, but might indicate the set quality as well. That is, as the set of actions stored in memory was less complete, one would expect larger "gaps" between the stimulus action and the action given in response. Moreover, a respondent's use of abstract versus episodic language would offer a clue to the degree of concept abstraction. Finally, findings by Abbott and Black (1980) imply that the degree of hierarchical structure would also be evident in responses to such stimuli. These authors found that subjects with scripts exhibited an asymmetrical recall pattern, such that the probability of recalling a scene action given a scene header was less than the probability of recalling a scene header given a scene action. This systematic pattern would not be expected, however, among individuals whose knowledge of an event was not hierarchically structured.

A third type of verbal stimulus that also minimizes the problem of excessive cognitive load consists of a list of randomly ordered actions, only some of which are relevant to the event. The response to such a stimulus involves a recognition task in which subjects select the actions they feel are relevant to the event, and number those chosen to indicate the normal order of occurrence. While a number of studies have employed verbal stimuli which require discrimination, rather than reconstruction of an event, to assess the processing effects of scripts (Abbott and Black 1980; Bower, Black, and Turner 1979; Brewer and Dupree 1983; Graesser, Woll, Kowalski, and Smith 1980; Lichtenstein and Brewer 1980; Salmaso, Baroni, Job, and Peron 1983), their use in evaluating script development is less common. However, Smith and Houston (1985) found that this approach was effective in determining the presence of the set quality and temporal sequence characteristics of scripts. Moreover, the measure employed in their study exhibited reliability superior to that of a retrospective self-report measure. This type of verbal stimulus offers a promising approach to measuring script development, and one whose potential should be further explored.

A fourth type of verbal stimulus that has been employed to assess script development consists of a multi-item scale of experience/knowledge about an event. A variant of this procedure is a single-item scale consisting of a self-rating of familiarity. A higher score (as indicated by the scale value of a subject's responses) is presumed to indicate a more highly developed script. Although such measures have been used in a number of studies (Alba 1983; Conover 1982; Schurr and Calder in press; Smith and Houston 1985; Smith, Houston, and Childers 1984, in press),

they suffer from a major conceptual flaw in that responses indicate only the level of knowledge, but not the structure of that knowledge. Therefore, a response to this type of stimulus may be only indirectly related to the level of script development. Close correspondence has been observed, however, between questionnaire scores and those obtained on the dependent measures used to quantify responses to other verbal stimuli (Smith and Houston 1985; Smith, Houston, and Childers 1984, in press). Therefore, self-ratings and questionnaires may be useful in validating other measures of script development.

Visual Stimuli. In spite of the strongly propositional and semantic character of scripts, prior research has demonstrated a strong link between script development and the ability to generate visual images of an event (Smith, Houston, and Childers 1984; in press). Therefore, visual stimulus materials are also appropriate in assessing script development, and offer certain advantages over verbal stimuli. In particular, they avoid the vagaries of verbal stimuli, a feature that is particularly desirable in research settings where certain age groups (i.e. children or the elderly) may experience difficulties encoding verbal presentations.

While verbal stimuli dominate script research, a few investigations have utilized visual approaches to ascertain the component actions of a script and assess its effects on information processing (Brewer and Dupree 1983; Goodman 1980; Lichtenstein and Brewer 1980) as well as to evaluate script development (Fivush 1981). In the latter context, Fivush (1981) used a visual stimulus consisting of a set of pictures depicting the component actions of an event in a study of the development of children's scripts. The stimuli contained pictures of actions that were both relevant and irrelevant to the event. The children responded by selecting the relevant pictures, arranging them in the proper sequential order, and then telling a story based on the selected pictures.

Although such responses would reasonably be expected to reflect the presence of all the structural characteristics of scripts, Fivush concluded that they may be misleading with respect to script development. Compared to the responses of children who were simply asked to describe an event, the children performing the picture sorting task were more prone to include irrelevant actions and to improperly order the chosen action pictures. It appears that children relied on existing scripts to guide their spontaneous construction of a verbal description of an event, but not their selection of pictures. While tentatively suggesting the inappropriateness of picture sorting for measuring script development, the generalizability of these results to adult subjects remains an empirical issue.

Studies of the processing effects of scripts in which visual stimuli have been used suggest that videotaped presentations offer a more promising approach to assessing the level of development of consumers' scripts. Lichtenstein and Brewer (1980) reported that videotapes of goal-directed events elicited patterns of memory effects similar to those observed when verbal descriptions served as the stimuli. Specifically, recall for goal-directed actions was generally superior to that for non-goal-directed actions, a pattern that was also observed in subsequent studies by Brewer and Dupree (1983).

Although videotapes have never been used specifically to evaluate script development, these findings suggest that they may offer an attractive alternative to consumer researchers. The utility-seeking nature of consumer events implies that they are goal-directed. Videotaped presentations afford an opportunity to represent such action sequences in a more comprehensive and externally valid manner than verbal descriptions. Moreover, if subjects are asked to respond to such presentations by describing what they observed, their responses may reflect the structural properties of scripts in much the same way that responses to verbal probes would, but without the attendant task-related effects.

Dependent Measures

Regardless of whether verbal or visual stimuli are employed to evaluate script development, a variety of dependent measures may be used to analyze responses and to determine the degree to which the structural characteristics of scripts are present. Since any single measure is unlikely to reflect all the structural properties of a script, multiple indicators will often be desirable.

For those stimuli that elicit responses indicative of concept abstraction, two types of dependent measures are available. The first is a content analysis system developed by Martin, Harrod, and Siehl (1980), in which various language characteristics are analyzed. The system permits a subject's description of an event to be categorized as representing an episodic (most concrete), categorical, or hypothetical (most abstract) script (Abelson 1976). A simpler adaptation of this measure was developed by Roedder John and Whitney (1985), in which coders were given examples of the language typical of these three developmental stages, and assigned an overall rating of script development based on their reading of the response as a whole.

A second indicator of concept abstraction is the relative number of central and incidental actions in a response. As the event representation becomes more highly developed, responses will reflect less frequent mention of actions incidental to the main theme, relative to the occurrence of those actions central to the continuation of the event. Moreover, the central actions will be described abstractly, rather than episodically, as script development increases. Roedder John and Whitney (1985) used both these measures in a study of the development of children's scripts, and as expected found that older and more experienced children described a consumer event more abstractly and reported fewer incidental actions.

To assess the degree to which responses reflect the set quality of scripts, a different approach is necessary. Since activation of any part of a script permits access to the entire action set that comprises the event, it would be expected that the responses of subjects with well-developed scripts would be more complete than those of individuals without schematic representations. Therefore, the number of central actions (independent of the occurrence of incidental actions) will be indicative of this aspect of a script's structure. Moreover, the order in which these central actions appear in a response offers a clue about the temporal sequence characteristic. That is, if a script were used in retrieving these actions from memory, the order of retrieval should correspond to the generic sequence typical of the event.

Evidence concerning both these points is provided in an investigation by Smith and Houston (1985). A measure was constructed that evaluated both the completeness and sequence of actions in responses to two types of verbal stimuli (a free recall protocol and a recognition task). Variations of this measure, which incorporated corrections for omitted actions and for false alarms (in the recognition task), were also constructed. All versions of the measure successfully differentiated between individuals with varying levels of script development.

Clustering indices represent another type of dependent measure adaptable to assessing script development, and may be used to indicate the degree of hierarchical structure in a memory representation. Such measures are only useful for responses that involve free recall, however. A clustering index is designed to "measure the degree to which a series of responses provided by a subject conforms to a hypothesized structure within the set consisting of all possible responses" (Hubert and Levin 1976).

Clustering indices have usually been employed to assess categorical, rather than schematic memory. However, if the action set comprising a script is viewed as the total set of responses, the actions comprising each scene in the event constitute its hypothesized structure (Abbott and

Black 1980). Therefore, the degree to which actions related to each scene cluster together during recall will be indicative of the presence of this structural quality.

A variety of clustering indices are available, and their strengths and weaknesses have been reviewed elsewhere (Frankel and Cole 1971, Roenker, Thompson, and Brown (1971). Further consideration of the individual indices is beyond the scope of this paper, but it should be noted that one measure, the adjusted ratio of clustering index (ARC) was used by Srull (1983) to evaluate the structure of consumers' brand knowledge. While there is no empirical evidence of its ability to differentiate levels of schematic knowledge about consumer events, it appears to overcome the shortcomings of certain other indices, and bears further consideration in this context.

A final dependent measure suitable for use with either verbal or visual stimuli is response time. In a few investigations, chronometric devices have been used to assess the processing effects of scripts (Bower, Black, and Turner 1979; Galambos and Rips 1982; Nottenburg and Shoben 1980). These findings indicate that response latencies may also be informative with respect to the temporal sequence and hierarchical structure of event schemas.

Bower, Black, and Turner (1979) found that subjects with scripts more quickly recognized the proper order of action pairs that were closer together in the script than those further apart. They also found quicker comprehension of actions later rather than earlier in the event, perhaps because of their temporal nearness to the goal-outcome of the script. Among individuals lacking a schematic representation of an event, no such systematic relationship between response latencies and temporal position of actions would be expected.

Other investigations have reported that reaction times may be related to the hierarchical structure of a script. Nottenburg and Shoben (1980) observed lower response times to recognize typical or important actions among subjects with scripts. Such actions would occupy higher positions within a script's hierarchy, while less central actions, for which response time is greater, would be located at lower levels. Responses latencies for individuals lacking a script should be independent of the hierarchical position of component actions.

It should be noted, however, that teasing out the separate effects of hierarchical structure and temporal sequence on response time may be problematic since these characteristics may not always be independent. Galambos and Rips (1982) reported that the centrality of actions more strongly influenced response latencies than did temporal position. Thus, in using chronometric measures to assess the presence of these script qualities, it is important to ensure their independence, in so far as possible. In the consumer context, however, centrality may be the more important consideration in evaluating script development since central actions are likely to be associated with greater utility.

Summary

This paper has described various stimulus materials and dependent measures available to assess the level of script development for consumer events. All of the techniques evaluated have the potential to provide insight as to the presence or absence of various structural characteristics of event schemas. Since it is not possible to demonstrate the effects of scripts on consumer information processing without first ascertaining the degree to which knowledge has assumed these structural features, the use of these measures, either individually or in combination, is a vital component of research on consumers' scripts.

THE POST-AFFLUENCE CONSUMER: CONSUMER DECISION PROCESSES REVISITED

Franco M. Nicosia, University of California, Berkeley

Abstract

Consumers behave in a social and economic environment. During the long period of industrialization, a number of paradigms emerged as useful devices to describe, predict, and even explain consumer decision processes. The domain --i.e., variables and their interactions--posited by such paradigms were similar; for some of us, they were "equivalent" (e.g., the domain of the neo-classical household is equivalent to that postulated in S-R or Watsonian work, and, making appropriate changes in time-ordering, both are equivalent to a Skinnerian domain).

The fruits produced by industrialization efforts began to be harvested, and, by the 'fifties, consumers were learning how to behave in an affluent environment. The change from a pre-affluent to an affluent consumer revealed some limitations of the previous domain and called for new conceptualizations. New paradigms began to be proposed from the 'fifties on.

For several years, some of us have become tangibly aware of, and in fact often frustrated with, an increasing number of limitations in the prevailing conceptualizations of decision processes by affluent consumers--e.g., paradigms ranging from the known comprehensive "models" of behavior (including my own), through the "Fishbeinization" era and the information processing period, and the period of structural "estimation" equations.

The prevailing domains today reflect the ways increasing numbers of consumers in Western societies began to experience affluence, and the ways the private and public sectors reacted to the emerging affluent consumer. Yet, especially for problems facing corporate managers and public policy makers since the early 'seventies, these prevailing domains (e.g., the roles of attitude toward a class of brands, etc.) do not capture the new mechanisms that guide the behavior of post-affluence consumers.

By trial and error, I have put together a number of quasi-propositions describing consumer decision processes in a new domain. This domain drastically differs from those that have been reasonable and often useful for the study of affluent consumers.

Although the traditional conceptualizations may be still relevant for the study of brand choices, such choices are themselves guided by consumer decision processes that concern choice of activities, allocation of time to activities, and changes in the institutions (e.g., family, place of work, place of worship, and "schools") where pre-purchase and, above all, post-purchase activities occur. For the purposes of modeling the birth and behavior of the post-affluent consumer, long-term changes in the technologies affecting the structure and function of the work, and then family, institutions are considered to be the exogenous variable driving this new, or revisited, consumer decision process.

THE PROSUMER MOVEMENT : A NEW CHALLENGE FOR MARKETERS

Philip Kotler, Northwestern University

Alvin Toffler (1980), in his book The Third Wave, argues that consumers are a phenomenon of the Industrial Age. As society moves toward the Post-Industrial Age, so will the number of pure consumers decline. They will be replaced by "prosumers," people who produce many of their own goods and services. Although his prosumer theorizing has not attracted much critical comment, his concept is sufficiently provocative to merit the attention of consumer behavior scholars and marketing practitioners. If Toffler is right, we might have to retitile the field "prosumer behavior" and revise our notions of effective marketing.

My purpose is three-fold: first, to describe Toffler's prosumer thesis; second, to extend the prosumer concept further; and third, to examine its validity and implications.

The Prosumer According to Toffler

Toffler defines prosumers as people who produce some of the goods and services entering their own consumption. They can be found making their own clothes, cooking their own food, repairing their own cars, and hanging their own wallpaper. All of these services could be purchased in the marketplace. And in fact, most people today purchase these goods and services from others. This is the essence of being a consumer. The essence of being a prosumer, on the other hand, is to prefer producing one's own goods and services.

Underlying this is the distinction between production for use and production for exchange. When people produce for use, production and consumption are united in the same person. When they produce for exchange, then production and consumption are separated. In this case, people put their time into producing one thing and they use their earnings to buy all the other things they need.

Toffler argues that production and consumption activity became separated during the Industrial Age. In fact, he distinguishes between three stages or waves in human history.

In the First Wave, agriculture is the dominant institution (see Figure 1). According to Toffler, the vast majority of people are prosumers. They hunt or grow their own food, make their own clothing, and create their own amusements. They are Sector A, the largest sector of society. A few members of the community specialize in some mode of production, such as candlemaking, blacksmithing, and fishing. They trade their surplus output for things that others produce. They are consumers and make up a much smaller Sector B. The dominant process of First Wave societies is self production, the norm is survival, and the social nexus is kinship, friendship, tribe.

The Second Wave occurred with the Industrial Revolution in England. The factory became the dominant institution. An increasing number of people now spend their productive hours there. They work in factories (or offices) for eight hours a day and use their income to buy what they need in the marketplace. Most people produce for exchange, not for use. Sector A (prosumers) has grown small, while sector B (consumers) has grown large. The only prosumers are housewives who cook, clean, sew, knit and shop, while not getting paid for this. Prosumer activity is so undervalued in Second Wave Societies that these societies don't include homemaker activities in estimating the gross national product.

Toffler says that the dominant processes in Second Wave Societies are industrialization and marketization. Second Wave societies are marked by the establishment and elongation of exchange networks through which people obtain needed goods and services. Goods are produced under the norm of efficiency, and are consumed under the norm of indulgence. The social nexus holding people together are contracts and transactions in addition to kinship and social relationships. With industrialization and marketization, people increasingly become specialized producers and are increasingly unable to produce almost anything else, even cooking well.

Toffler sees the post-industrial age as moving toward a synthesis of First and Second Wave societies, which he calls the Third Wave. The dominant institution in Third Wave societies is the home, or electronic cottage, in which most people carry on their own production and consumption. For reasons which we will examine below, more people shift more of their time into prosumption. Sector A starts increasing in size relative to sector B. Because people now produce more of their own goods and services, markets become less important, since they exist to meet exchange needs in those societies where most production is for exchange.

Toffler sees the dominant process in Third Wave societies to be demarketization, including demassification as well. The norm of Third Wave societies is individuation rather than mass consumption. The social nexus is the family, and secondarily, the neighborhood.

Why will people move toward more prosumption activity? Toffler presents several arguments. First, the workweek will continue its long run decline, from 80-90 hours during the early days of the Industrial Revolution to 40 hours today to even fewer hours in the future. The scarcity of jobs will lead some companies to adopt share-the-work schemes. Furthermore, some people will volunteer to work less than 40 hours, preferring more leisure time.

Second, people will be more highly educated. They will not accept boring work as readily. Advancing technology, especially in computers and telecommunications, will tempt them to use their time in other ways.

Third, the rising cost of skilled labor — plumbers, carpenters, etc. — will drive more people to do their own work. And if they are unemployed or underemployed, they will have time to take care of these tasks. Thus, rising service cost will lead to more prosumption.

Fourth, people want more physical activity as their work becomes increasingly mental in a technologically advancing society. Those sitting at desks all day will seek physical activities, including some involving self-production.

Fifth, some people will feel that they can produce better goods and services than are available in the market, especially if manufactured goods and services decline in quality. Some groups — such as the Dutch and the Germans — have developed a high sensitivity to quality and a strong "instinct for workmanship." They will undertake projects at home that normally would be contracted for in the marketplace.

Sixth, more people will turn away from mass produced goods and seek individuation by producing their own goods and services. They will attend more courses on cooking, gardening, knitting, weaving, and painting. This pre-

diction follows Maslow's (1954) "hierarchy of needs" which argues that as people satisfy lower order needs, they will focus increasingly on self-actualization, much of which will take the form of prosumption activity.

In advancing these points, Toffler presents sporadic rather than systematic evidence. He likes to cite miscellaneous statistical anecdotes drawn from a variety of sources. He notes, for example, that whereas ten years ago, 70% of all electric power tools were purchased by professional craftsmen, today 70% are bought by "do-it-yourselfers." He notes that self-care items -- do-it-yourself pregnancy kits; throat cultures etc. -- have grown into a \$2.5 billion industry in 1981. He cites the rapid growth of self-help societies for overcoming problems of alcoholism, drug abuse, and the consumers' turning away from "professionals." He notes that more people are attending more colleges to learn more crafts and skills than ever before.

The Marketing Challenge

If Toffler is right about a swelling wave of prosumption activity, then marketers face a challenging, if not frustrating, future. They will find fewer customers for mass-produced goods and services and less consumer interest in brands. On the other hand, alert marketers will discover new opportunities in the areas of marketing research, product, price, place, and promotion. I would like to outline some of these new opportunities.

Marketing Research

Marketers will find it increasingly hard to sell those goods and services which people can produce themselves. Therefore, marketers need to research which goods and services people are most likely to start producing themselves. If more people learn how to repair their own automobiles, garages will have less work to do. If more people hang their own wallpaper, professional wallpaper hangers will face less work.

Prosumption activities that are likely to attract consumers will have four characteristics. They would promise high cost saving, require minimal skill, consume little time and effort, and yield high personal satisfaction. One activity, for example, that satisfies many of these criteria is house painting. The person saves the high cost of a painter; finds it easy to paint well with modern paint rollers; finds that it does not involve much effort or time; and feels some satisfaction while painting and when finished painting. We would therefore predict that house painting would move more into the prosumption camp.

On the other hand, auto repair is less likely to become a widespread prosumer activity. Although the potential cost savings are high, the person would have to spend considerable time learning about auto repair, expend substantial effort in making repairs, and generally not enjoy the activity very much in view of all the frustration that can occur, the dirtiness of the work, etc. Therefore, we would predict that consumers will be less drawn to auto repair.

Products and Product Designs

We would predict that people will want to play a larger role in designing or producing certain goods and services they consume. One is reminded of the homemakers who rejected a brand of cake mix that required only adding water because they wanted to add milk or fresh eggs themselves. They wanted to participate more fully in "giving birth" to the cake. We should also note that more people are buying and grinding coffee beans and brewing their own coffee instead of just adding boiling water to instant powdered coffee. Instead of moving toward task simplification, some consumers are moving toward task elaboration in the interest of achieving better quality.

In Japan, some of the "famous" scroll painters made their own brushes, mixed their own paints, and even made their own paper. These painters were thoroughgoing prosumers. Most painters, on the other hand, buy their paints, brushes, and canvases. Manufacturers will need to study which stages in the production value-adding process people might want to perform themselves.

Modern computers will permit people to participate more in the designing the products they want. General Motors' Saturn project visualizes car buyers entering a showroom, sitting down at a computer terminal and responding to questions about what they want in the way of the car's color, engine, seat material, radio, and so on (Newsweek, June 17, 1985). Their order is transmitted to the auto plant which proceeds to produce the desired car. Similarly, future home buyers will enter an architect's office, sit down at a computer terminal, specify room sizes and layout, examine the results, and modify them until satisfaction is achieved.

We can imagine further examples of consumer participation in designing manufactured goods and services. A person will enter a clothing store, stand before an electronic mirror and press appropriate buttons that will project various suits on him in different colors, style, and materials. After finding the most pleasing look, he will press another button and laser beams will cut and prepare the clothing (Newsweek, April 22, 1985). Still, in another case, people will call their travel agency, describe the kind of experience they want -- climb the Himalayas, conduct the Vienna Symphony Orchestra, etc. -- and the agency will arrange or design it for them (Kotler, 1984).

The fact that people enjoy participating in production is evidenced in a number of situations. Salad bars are increasingly popular in restaurants because many people prefer to "compose" their own salads. Certain ice cream parlors allow people to make their own sundaes. The success of the "Bradley GT kit" -- where a person can turn his or her Volkswagen into a sleek sports car -- shows the interest of some people in producing complicated goods. The author heard about a direct mail order company that sells step-by-step blueprints for making one's own helicopter.

Instead of marketers fighting prosumers, they should look for opportunities to facilitate prosumption activities. One way to facilitate prosumption is to create better tools for prosumers to use, including better electric power tools for carpentry work, better tools for farming small plots of land, and so on. Another way is to simplify the production process. Thus, "painting by number" kits allow "Sunday painters" to produce better looking paintings. "Adhesive wallpaper" allows more people to hang their own wallpaper.

One of the major growth markets spurred by prosumption will be the instruction market. More people will want to acquire skills for producing their own goods and services. They will attend day and evening classes in cooking, gardening, auto repairing and dozens of other subjects. "How-to-do-it" books, magazines, audio and video tapes, and computer-aided instruction will flourish. Some marketers will develop "cool lines" in which they will sell information over the phone on how to make or fix things.

Thus, prosumer-oriented marketers can seize on a number of opportunities. They need to identify the most popular prosumer activities and think through appropriate product and service responses.

Price

As prosumption activity increases, manufacturer value-adding activity will decrease. Whereas producers in Second Wave Societies continued to add new consumer benefits to an elementary offer (called "product augmen-

tation"), the tenor of Third Wave Societies will be to pare down the number of "built-ins" (called "unbundling"). The price of goods and services will therefore fall because their content has been reduced. The only marketers who will command premiums are those who add strong benefits that are valued by consumers which consumers cannot add themselves.

Place

Sellers will have to revise their place strategies. They will carry lower inventories of finished goods because people will want to individuate their goods. And with people spending more time in their electronic homes, more goods and services will have to be located reasonably nearby. We would predict a dispersion and deconcentration of retailing and a renewal of neighborhood life.

Prosumers will show preferences for certain forms of retailing. They will rent more goods to clean their rugs, repair their cars, and maintain their gardens. Car washing establishments in which people drive into bays and wash their own cars will boom. People will also drive their cars into do-it-yourself garages and rent the tools to fix their cars. They will enter picture framing workshops and rent the tools and materials to make their own frames.

Promotion

Marketers will have to direct their promotion appeals to themes stressing individuation, skill-building, and productiveness. They will find it hard to sell mass consumption goods and hedonistic values.

Specialized, as opposed to mass media, will continue to grow in popularity. People will want to follow their own interests, not mass interests. They will search for others with kindred interests, finding them and communicating with them through electronic media, such as computer networks and CB radios. Marketers will have to develop more specialized messages to reach these highly segmented target markets.

How Far Will Prosumption Go and How Fast?

Any movement or change is always the resultant of opposing forces. We have described several forces that would lead to more prosumption activity. Among them is the growth of structural unemployment, the rising cost of labor, the desire for higher quality goods and services, the development of new technologies that enable people to participate in the design of customized goods, and a general increase in education and therefore desire for self-actualization.

At the same time, we should not underestimate the forces that will inhibit prosumption. First, threatened interest groups will use the law to prevent people from producing certain goods and services themselves. Thus, construction trade unions will support the enforcement of building codes to prevent people from building their own garages and doing their own electrical work and plumbing. Physicians will want to discourage people from buying self-care and self-medication products. The teachers' union will oppose families who want to take over their own children's education. The goal of professionals is to sell people on buying their services rather than performing these services for themselves (McKnight, 1977).

Second, corporate America will continue to promote the hedonistic life style. They will appeal to people's interest in status goods and easy living.

The effect of rising incomes on prosumption activity is ambiguous. Consumers with higher incomes can buy more services they need. On the other hand, they could have more leisure time and spend it more productively.

We should recognize that few people will opt for 100% prosumption. The 100% prosumer would be a hermit living in the woods like Thoreau, producing his own drinking water, food, and clothing. Or they would model themselves on Robinson Crusoe or the Swiss Family Robinson.

We can, in fact, identify two major prosumer profiles that are found in society.

1. **The Avid Hobbyist.** These are people who spend most of their time producing for exchange but who fill their leisure time with one or a few dominant hobbies. The avid gardener, the versatile home repairer, and the skilled cook, describe people who are producers in two domains, their main occupation and their major hobby or hobbies.

2. **The Archprosumer.** These are people who practice a lifestyle of "voluntary simplicity" that is closer to nature and produce many things themselves. They grow and can their own fruits and vegetables, knit and sew their own clothing, and avoid the mass production, mass consumption society. Their themes are "small is beautiful" and "less is more."

Interpreting Changing Time Budgets

If Toffler is right, prosumerism will not suddenly burst on the scene. It is already foreshadowed in the activities of some people and in some places. We would see it reflected in people's time budgets. People would spend more time producing goods and services for their own use rather than buying them in the marketplace. People would favor "make" decisions over "buy" decisions. They would walk to work rather than "taxi" to work. They would cook at home rather than eat in restaurants. They would fix their own plumbing rather than call in a plumber.

At the same time, apparent increases in prosumer activity can easily be misleading. In the first place, the person who suddenly starts cooking a lot may have found the time to do it by giving up some other prosumer activity, such as no longer doing his own gardening and hiring a gardener instead. This means on net that he has not increased his prosumer activity; he has simply become a prosumer in one activity, and a consumer in another.

Second, many people who take up cooking (prosumers) at the same time like to eat at fine restaurants (as consumers). One activity does not exclude the other. Also, prosumers may bake their own bread but they don't want to do this all the time. They will still buy most of their bread at stores.

Third, many people take up cooking or other activities not out of individuation motives but simply to change their routine. Next week they might sew their own clothes or wash their own cars.

Fourth, people who take up prosumer activities such as cooking often buy a lot of equipment — blenders, culinets, woks. They also buy cookbooks and sign up for cooking courses. Thus more prosumption activity is often accompanied by more market purchase activity.

Fifth, an increase in the purchase of "do-it-yourself equipment," such as electric power tools, computers, etc., does not necessarily mean an increase in prosumer activity. Many of these tools are bought and not used.

Implications for Marketers

In order to learn more about prosumerism, we should study certain groups more closely. Do young archprosumers continue their lifestyle when they grow older? Do older retired people with time on their hands move toward more self-production or do they spend most of their time consuming television? Do poor people perform more prosumer activities?

In many ways, prosumers should be looked at as another market segment(s). We would want to identify those who have a strong need to produce their own goods and figure out ways in which marketers can help them meet this need.

The aim of marketers should not be to protect the exchange system. The purpose of exchange networks is to facilitate the pursuit of human satisfaction. If the market system is overextended, and if people want to meet more of their own needs, on what grounds should marketers object? The market, after all, is a human invention and it will last as long as it serves human needs. Before markets, there were other ways for goods and services to be created and distributed, including reciprocity and redistribution arrangements. Societies that move in new directions to meet human needs should not surprise us. Whether Toffler is saying that prosumerism spells the end of marketing or only a contraction in its scope, he has raised some worth while issues for marketers to consider.

YUPPIES AS ARBITERS OF THE EMERGING CONSUMPTION STYLE

Russell W. Belk, University of Utah

Abstract

Yuppies are treated as both real and a media event in the recent history of U.S. consumption. This eighties consumption style is contrasted to those of the two preceding decades and a paradox is noted in yuppies' simultaneous dedication to career and leisure pursuits. This apparent paradox is argued to result from the demographic phenomenon of the baby boom and concludes that yuppies may be engaging in compensatory consumption, a practice previously associated with blue collar workers. Implications of yuppie consumption patterns are discussed in the context of world patterns of materialism.

A Brief Popular History of U.S. Consumption Since 1960

The Sixties

In examining recent patterns of consumption in the United States, the decade of the 1960s presents some interesting contrasts to adjacent decades. More accurately, starting in the mid-sixties and extending into the early seventies the U.S. saw the ascendancy of counter cultural consumer values that increasingly challenged the middle class materialism that had flourished since the end of World War II. Due in part to ill will generated by U.S. involvement in Vietnam, the world was increasingly critical of what was seen as the selfishly acquisitive lifestyle of U.S. consumers. Both conservationists and concerned economists began to argue that we must view world resources as finite and scale down our desires in order to save something for the rest of the world and future generations. The OPEC oil embargo of 1973 made this argument manifest for nearly all Americans. And hippies rebelled against middle class values and consumption patterns in a variety of ways. These included the rejection of achievement motivation and the work ethic, and the adoption of blue collar clothing (e.g., jeans, work shirts), Spartan furnishings, and unpretentious automobiles (Yablonsky 1968, Levin and Spates 1970, Lind and Roach-Higgins 1985; Hirschman 1985). Communal living rose in popularity and the Peace Corps and social service occupations were greatly esteemed. Perhaps we should have been curious that this new austerity was accompanied by more self-indulgent use of recreational drugs and sex but we weren't. In the late sixties, with growing domestic protest against U.S. involvement in Vietnam and much popular press coverage of hippies as the trendiest youth movement, predictions that altruistic and ascetic hippie values were harbingers of future mainstream values seemed highly plausible.

The replacement of materialistic acquisitiveness by non-materialistic love also seemed a distinct possibility to sociologists and other scholars during this period. Davis (1967) sought to explain "Why All of Us May Be Hippies Someday". Schumacher (1973) suggested that in consumption as well as production technology, "small is beautiful". Others warned that unless we scaled back our consumption ecological catastrophe was inevitable (e.g., Chamberlin 1970, Meadows, et al., 1972). Forecasts of a growing trend toward voluntary simplicity are partially based on this sort of reasoning (Elgin and Mitchell 1976, Center for Science in the Public Interest 1977, The Simple Living Collective 1977). In the VS lifestyle consumption is frugal, non-energy-intensive, and largely rejects symbolic product attributes in favor of utilitarian consideration. If not quite a return to Henry David Thoreau's Walden Pond or Thomas Jefferson's agrarianism, voluntary simplicity at least questioned the necessity of economic growth, high technology, and mass consumption.

Blumberg (1974) and Felson (1976) concluded that with consumer abundance and affluence the status symbols that motivated our materialism were dead or dying. A more basic argument was that abundance in material goods would soon sate us and eventually make consumption an odious

task (Weisskopf 1966, Piel 1974). This argument is illustrated in the short story "The Midas Plague" by Frederick Pohl (1954/1982). It involves a future society in which there is such an abundance of goods, produced by robots, that it is a burden to consume them. To solve this problem the privileged "rich" are allowed to consume in moderation and live in modest homes with simple food. The underprivileged "poor" however are made to acquire large amounts of clothing, jewelry, and furniture, eat heavily, own numerous cars, live in large homes, and use ration books to show that they have acquired their mandatory quotas of consumer goods.

The underlying hypothesis here may well be Maslow's (1954) proposed need hierarchy suggesting that material needs are "lower order" and that when they are satisfied "higher order" needs such as those for self-esteem and self-actualization become the most compelling. This was the explicit assumption of Inglehart (1971) who hypothesized that a generation brought up in affluence and without a world war would feel secure enough to begin to satisfy higher order, less materialistic, needs. Presumably as lower order needs are met material goods provide decreasing amounts of satisfaction and are decreasingly important to us (Scitovsky 1976).

Logical as these consumption hypotheses may seem, their formulation based on observations of the decade of the sixties appears to have been premature. For instance, contrary to Elgin and Mitchell's (1977) projection that by 1987 over one-third of the U.S. population would be full or partial voluntary simplifiers Mitchell now (1984) classifies VS as a minor lifestyle that may or may not have some potential for the future. Similarly, after some initial support, tests of Inglehart's hypothesis of decreasing material emphasis have failed (Ike 1973, Marsh 1975, Flanagan 1979). The communes of the sixties have largely disbanded and the free stores have long since closed. Counter-culture poet and former voluntary simplicity advocate Gary Snyder explained or rationalized, "I ask you, which is the real simplicity: a person who owns almost nothing but is obsessed with it, or one who owns a great deal but is unattached to it?" (Dardick 1985). Whether or not the underlying cause for these failures is the untenability or lack of universality of Maslow's need hierarchy as some have suggested (Nevis 1983), the proximate cause seems to have been a change in consumption patterns beginning in the decade of the seventies.

The Seventies

The seventies have been called (Weber 1974, Wolfe 1976) "the 'me' decade". While this suggests a reemergence of self interest or selfishness, the 1970's appear to be something of a searching transitional decade in the way that this self interest affected consumption. Rather than an immediate reemergence of fifties-style materialism, it appears to have been a time of inward turning self-fulfillment seeking. As Yankelovich (1981) concludes from his firm's tracking of value trends, the use of exercise, health foods, self-help books, and self-awareness programs (e.g., Esalen, Est, primal scream therapy) all represent a searching for a meaningful self definition. The emphasis was largely experiential (Holbrook and Hirschman 1982), emphasizing the acquisition of services and non-durables over significant increases in durable expenditures. This is still potentially consistent with a self-actualization drive rather than a return to a material need focus.

To the extent that the seventies saw an increase in material expenditures, it seems to have been subtle rather than blatant. For instance, jeans became less blue collarish when they were replaced with expensive designer jeans in what Brooks (1979) calls parody display. Parody display involves the use of reverse status symbols or status symbols

based on ostensibly low profile consumption. There was status competition, but the association of bigger and more with better was removed or reversed. A small car under these circumstances might be more desirable than a large car. Perhaps such practices reflected a desire to return to materialistic ostentation that was inhibited by guilt from the residual mores of the sixties and the energy crisis of the seventies. Thus in 1979, U.S. News and World Report headlined "Status Symbols: U.S. Swings Back to Basics" (U.S. News and World Report 1979). The following year the headline was an even more austere "Goodbye to Our Good Life?" (Maloney 1980).

The Eighties

Interestingly, one year later U.S. News and World Report ran the nearly opposite headline, "Flaunting Wealth: Its Back in Style" (U.S. News and World Report 1981). It may well be significant that between these two headlines Ronald Reagan was elected to his first term as President of the United States. Not only was he perceived as a staunch ally of the rich, but some of first lady Nancy Reagan's first acts were to spend extravagant amounts on new china and decorations for the White House. If such symbolic acts did not by themselves mark the death of sixties altruism and idealism, the "defection" of former counter-cultural heroes such as Jerry Rubin, Tom Hayden, and Eldridge Cleaver into the ranks of the establishment did.

The result, at least according to the popular press, was the emergence first of the preppie (with clothing emulating elite prep school garb and mass adoption of "signature goods"), followed by the yuppie (or young urban professional) with a whole pattern of elitist consumption. As Mason (1981) argued, conspicuous consumption had come within reach of the masses. To the searching egoism of the seventies was added hedonism, ostentation, and status-seeking materialism. By the end of 1984 the year had been designated "the year of the yuppie" in a Newsweek cover story (Andler 1984). Yuppies have also become the subjects of comics (Alter 1984), songs (Royko 1985), poems (Freundlich 1985), and advertising and marketing strategies (Advertising Age 1985, Morgan 1985). Reactions against threats of the "yuppification" of society have also emerged (e.g., Fotheringham 1985, Heard 1985, O'Reilly 1985, Samuelson 1985, Thornton 1985, L. W. 1985, U.S. News and World Report 1985), just as reactions against the "hippification" of society emerged in the sixties.

The fact that these trends in the recent history of U.S. consumption have primarily been dealt with in the popular press should not cause us to dismiss or discount them as either fictitious or beneath scholarly inquiry. Real behavioral insights are hardly the sole province of the academic scholar or scientist (Belk forthcoming). In addition, as will be argued more fully, it is possible that popular press coverage of a lifestyle legitimizes it, makes it a concrete symbolic pattern to emulate, and hastens its adoption. And one need only look to the reawakened consumption ethic emerging in the People's Republic of China to appreciate the potential impact of such a change in consumption attitudes (e.g., Schell 1984).

The Yuppie

What is a Yuppie?

The yuppie is much more than a media fiction, even though precise criteria defining who is and is not a yuppie are somewhat arbitrary. The Newsweek cover story defined yuppies as age 25 to 39, earning \$40,000 or more in professional or managerial positions (Andler 1984), which would mean there are 1.2 million yuppies in America. By more liberal definition, estimates go as high as 12.2 million (Fisher 1985). Even the largest estimates make it clear that yuppies are a minority, even among the baby boom generation of which they are a part. A study by Market Facts estimates that less than one-fifth of the baby boom generation meets the financial criteria to be considered yuppies (Marketing News 1985b) and a zip code based classification estimates that young urban professionals comprise just over three

percent of U.S. households (Marketing News 1985a). But both because of their large incomes and the media lionization that makes them a socially distant reference group (Cocanougher and Bruce 1971) to be emulated by others, the impact of yuppies on U.S. consumption greatly exceeds their numbers. The Market Facts study finds that half of the baby boom generation (born 1945-1960) think and act like yuppies, not to mention the impact on those younger and older. For instance, one recent study (Sporkin 1985) found that the most desired possessions among college students included VCRs, compact disc players, Filofax organizers, and skis--all stereotypical yuppie items.

Thinking and acting in unique ways are the key to defining a yuppie more than mere demographic qualifications. Only partly satire, The Yuppie Handbook defines a yuppie as "A person of either sex who meets the following criteria: (1) resides in or near one of the major cities; (2) claims to be between the ages of 25 and 45; (3) lives on aspirations of glory, prestige, recognition, fame, social status, power, money or any and all combinations of the above" (Piesman and Hartley 1984, p. 12). This attitude is summarized in the updated view of Maloney titled "Success! The Chase is Back in Style Again" (Maloney 1983). More than anything else, the yuppie is distinguished by pursuing both quality and status symbolism in selecting products and services. For instance, the male on the cover of The Yuppie Handbook is shown with a Cross pen, pin stripe suit, Rolex Watch, squash racquet, Burberry trench coat, Gucci briefcase, co-op offering prospectus, and L. L. Bean duck hunting boots, while the female yuppie is shown with a Sony walkman, Ralph Lauren Suit, Cartier Tank Watch, coach bag, fresh pasta, gourmet shopping bag, and running shoes (Piesman and Hartley 1984).

Nor are yuppie consumption patterns limited to the United States. In Great Britain there are the very similar Sloane rangers and similar satirical consumption handbooks are available (York 1980, Barr and York 1983). And in France the yuppie's counterpart is the bon chic bon genre who can find Thierry Mantoux's Bon Chic Bon Genre Handbook (Patterson 1985). Although Sloane rangers and the bon chic bon genre differ in some respects (e.g., concern with titles) from yuppies, they share the same purpose in using consumption to make a statement about their success and status. Significantly, these phenomena seem to be confined to the wealthy post-industrial countries of the world; the very countries where declining materialism was predicted a decade ago (e.g., Inglehart 1971, Bell 1973). Not confined to a single race, marital status or religion, the ability and willingness to spend in a particular fashion that shouts success seems to be their hallmark. Subgroups and imitators are to be expected. Piesman and Hartley (1984) identify buppies (black urban professionals), guppies (gay...), hippies (Hispanic...), Juppies (Japanese...), and puppies (pregnant...). Others have suggested additional variations. These cultural and subcultural variations merely highlight the significance and impact of yuppie consumption patterns.

In order to clarify the distinguishing conceptual characteristics of yuppies, it is useful to compare their traits to those of the hippies of the sixties. The following list is distilled from the few empirical studies of these groups and the abundant journalistic accounts of each:

	Hippies	Yuppies
Value of clean, neat appearance	Low	High
Value of success/achievement	Low	High
View of conspicuous consumption	Negative	Positive
Relationship to others	Altruism	Egoism
Primary activity emphasis	Leisure	Work and Leisure
Focus of gratifications	Immediate	Mixed -- Delayed and Immediate

	<u>Hippies</u>	<u>Yuppies</u>
Stereotypical consumption preferences:		
Residence	Rural Commune	Urban Co-operatively Managed Apartment
Vehicle	Old Psychedelic Van	New BMW, Saab, Small Mercedes, Volvo
Beverage	Annie Green Springs	Perrier, wine spritzer
Drugs	Marijuana, LSD	None, cocaine
Exercise	None	Running, Squash, home gym, health club
Music	Grateful Dead, Jefferson Airplane, Doors	Anything on Windham Hill label, James Galway
Travel	India, Nepal by backpack	Alps (Ski), Mazatlan (beach)
Retail Outlets	Free stores, head shops	Brooks Bros. Sharper Image

Other distinctions such as clothes and food have already been noted.

Why this Consumption Emphasis?

For the most part, the consumption distinctions just noted can be explained in terms of a shift toward greater materialism and more conspicuous consumption. However, two of the distinctions above require further explanation: the suggestions that yuppies seek both immediate and delayed gratifications and that they value both work and leisure activities. To understand these seeming anomalies and to understand the reversion to materialistic patterns of consumption in what was forecast to be an age of voluntary simplicity typifying the postindustrial era (Bell 1973), it is necessary to further consider the origin of yuppies in the baby boom generation.

Being a part of the U.S. baby boom generation has created unique problems for yuppies and their poorer or less urban cohorts. While those born during the low birthrate years of the thirties through World War II had a relatively easy time competing for jobs and promotions opened by the retirement of the larger generations that preceded theirs, the situation has been just the opposite for the baby boom generation (Ahlburg and Kimmel 1985, Easterlin 1980, Fisher 1985, Jones 1980, Levy and Michel 1985, Population Bulletin 1980). Not only are they unable to advance as rapidly because of the number of baby boomers they are competing against, the economy has stopped growing at the rates of the 1950's and 1960's, and real income has actually declined in the past ten years for the first time since World War II. Furthermore, while their parents who grew up during the Depression had modest expectations of financial success, the baby boomers who grew up during the strong economic growth of the fifties and sixties had high expectations for their futures; expectations that made their inconsistent actual futures all the more disappointing.

And this may paradoxically be the key to understanding the hedonistic consumption patterns and simultaneous career success orientation of yuppies. In order to enjoy the

income they expected to earn and might have earned a generation earlier, yuppies have postponed marriage, relied more on two incomes when they do marry, and had fewer children at a later age (Levy and Michel 1985). They have also been willing to take on more debt than earlier generations (Fisher 1985). Debt and an upward, if slower than hoped for, job mobility have kept yuppies dedicated to careers, at least until recently. It is delays in job gratifications that yuppies have tolerated rather than consumption gratifications. If it were merely a case of sacrifice for the sake of career, yuppies would simply be a reincarnation of the organization man of the 1950's (Whyte 1956). But the yuppie appears far less dedicated to the organization than to their consumption (Maloney 1983). Lately career sacrifices such as long hours of work are being examined more critically, with yuppies increasingly asking themselves whether it is worth it (e.g., Prince 1985, Schwartz 1985). If career sacrifices are increasingly scrutinized, the question remains as to why yuppies make the sacrifices they do for the sake of consumption.

The reason for their greater materialism may lie in the same baby boom job pressures that require them to sacrifice family life for the sake of purchasing power. The phenomenon is called compensatory consumption and has previously been observed only in lower class occupations for which job advancement is blocked by lack of skills, lack of education, and prejudice (Chinoy 1952, 1955; Gorz 1967; Best and Connolly 1976; Gronmo 1984). With the traditional blue collar situation, given no opportunity for further advancement on the job, aspirations are deflected to consumption (Nicosia and Mayer 1976). The analogous situation among yuppies may not arise because of lack of job mobility as much as slow job mobility relative to aspirations and preceding generations, coupled with lesser prospects for gains in real income due to the same job market competition slowing their advancement. Looking for some reward to justify their work effort and lives, and not finding it often enough in their careers, yuppies have increasingly turned to consumption to seek their gratifications. From this perspective, while yuppies may indeed be materialistic, they are not necessarily more greedy and selfish than others. They just have fewer opportunities to derive the same ego-enhancement from careers than were available to their parents.

Thus the explanation advanced for the simultaneous commitment to careers and consumption by yuppies is that job competition from the large number of other baby boomers forces sacrifices to (often dual) careers in order to accrue earnings anything like those expected; at the same time slower than expected career advancement has deflected their search for ego fulfillment into the realm of consumption. What remains is to consider what yuppie consumption patterns mean for more general consumption trends.

The New Materialism

It is important to recognize that the yuppie phenomenon is to some degree a media phenomenon, just as were the hippie phenomenon of the sixties and the me generation of the seventies. While yuppies and meism, and to a lesser degree hippies, are relatively upper class phenomena engaged in by a minority of the population, there exists a strong possibility of trickle-down effects when the media pay such great attention to the consumption patterns involved. Besides specific consumption fads, it may be more significant that the general sanctioning of materialism may spread throughout the population of the U.S. and quite possibly to other countries as well.

Besides attention to yuppies qua "yuppies", U.S. mass media have generally portrayed a very upscale portrait of consumption. Analyses of magazine portrayals of occupations and consumption styles have found a consistent upscale bias (Berelson and Salter 1946, Johns-Heine and Gerth 1957), and magazine biographies which featured the heroes of production in the first part of this century were featuring instead the heroes of consumption by the 1940's (Lowenthal 1961). Television programs have been found to show a similar bias (DeFleur 1964, Fox and Philliber 1978, Gerbner

and Signorelli 1982, O'Guinn, Faber, and Rice 1985, Smythe 1954, Stein 1982). Prime time television programming has largely abandoned featuring the minorities and lower class characters of the sixties for instead featuring the higher class characters of the eighties. Both here and abroad the potential heroes presented nightly are now mostly millionaires living and loving in a very selfish fashion (Gunderson 1984). The foreign influence is due mostly to the wide distribution of U.S. television series like "Dallas" on other continents, but France now has their equivalent of "Dallas" or "Dynasty" called "Chateaufallon" (Tuttle 1985). Research reviewed by O'Guinn, et al. (1985) suggests that those exposed more heavily to such programs tend to overestimate the wealth and consumption patterns of the society represented. Shows like "Dallas" and "Dynasty" (both highly popular) are indicative here, but the epitome of such shows may well be "Lifestyles of the Rich and Famous" (MacKenzie 1984, Greenfield 1985, VerMeulen 1985). Belk and Pollay (1985) also find a generally escalating pattern of materialism themes in twentieth century U.S. magazine ads. A similar trend was found in Japanese magazine and television advertising since World War II (Belk, Bryce, and Pollay 1985). Friedman (1985a, 1985b) has found evidence of increasing materialism in popular U.S. and British plays, songs, and novels. In this context yuppies may be seen as merely the latest catalyst for a continuous parade of materialistic lifestyles before the American consumer, with hippies the sole recent exception to this trend. And yuppies themselves may be seen less as arbiters of consumption styles than as interpreters helping such styles to trickle down to the masses and simultaneously reinforcing and legitimizing such consumption. Their greatest importance may lie in the fact that they have a name and thus form a label that people may try to affix to themselves via consumption.

Taking a longer view still, materialistic consumption patterns seem to follow cyclical ups and downs (McCracken 1985). High points and places of consumption since the industrial revolution that made mass consumption of luxuries a possibility include 15th and 16th century Europe (Braudel 1967/1973, Mukerji 1983), 17th and 18th century England (McKendrick, Brewer, and Plumb 1982, McCracken 1985), 19th century France (Williams 1981), and late 19th and early 20th century America (Boorstin 1973, Harris 1981, Lears 1983). While there have been fluctuations during some periods (e.g., depressions, the sixties), the overall trend is toward greater materialism. This rather than a less materialistic post-industrial consumer, seems to be the main lesson of historical studies to date. Yuppies are an interesting recent manifestation of this long run trend, but what has burst upon the scene in the eighties is perhaps more the label than the phenomenon.

MODELING DISTANCE STRUCTURES:
PRODUCING USEFUL KNOWLEDGE FOR THEORY AND APPLICATION

Daniel R. Denison, University of Michigan

Abstract

This paper presents distance structure analysis as an alternative to more sophisticated techniques such as covariance structure analysis, with particular reference to two techniques, confirmatory multidimensional scaling (CMDS) (Lingoes and Borg 1980), and LISREL (Joreskog and Sorbom 1983). The paper highlights the differences between the two types of techniques, and discusses the applications and advantages of each.

Introduction

Over the past few years, developments in structural modeling techniques based upon multidimensional scaling algorithms have made the conceptual similarity between MDS techniques and more sophisticated techniques based upon covariance structure analysis much more apparent (Bloxom 1978; Lingoes and Borg 1978; Lee and Bentler 1980; Carroll, Pruzansky, and Kruskal 1980; Borg and Lingoes 1980; Lingoes and Borg 1983). This paper discusses the conceptual similarities between these two types of techniques, as well as the differences, and makes suggestions about the conditions under which the two types of techniques are most appropriate, and most useful.

Earlier work on this topic (Fornell and Denison 1981; 1982; Denison 1982; Denison and Fornell 1985) has argued that the basic principles of structural modeling logically derive from the multitrait-multimethod logic first introduced by Campbell and Fiske (1959) and that convergent, discriminant, and nomological or theory-based validity can all be expressed within the context of confirmatory multidimensional scaling, with generally similar results to covariance structure analysis.

Within the general context of a theoretical model like the one in Figure 1, a procedure has been developed for expressing the structural characteristics usually associated with a "causal model" in terms of distance structures. Figure 2 shows a set of points in a two dimensional space which we will then use as an example of the representation of a theory in terms of distance relations.

FIGURE 1.
HIERARCHY OF EFFECTS MODEL OF CONSUMER BEHAVIOR

This simple example allows us to briefly illustrate our basic approach to operationalizing convergent-discriminant and nomological validity (Denison and Fornell 1985). Presentation of the specific formulae for the estimators, the procedures by which to express a set of theoretical constraints in MDS terms, and criteria for the fit between the model and the data, are beyond the scope of this discussion, but are clearly spelled out in the original paper.

FIGURE 2.
EUCLIDIAN DISTANCE ESTIMATES

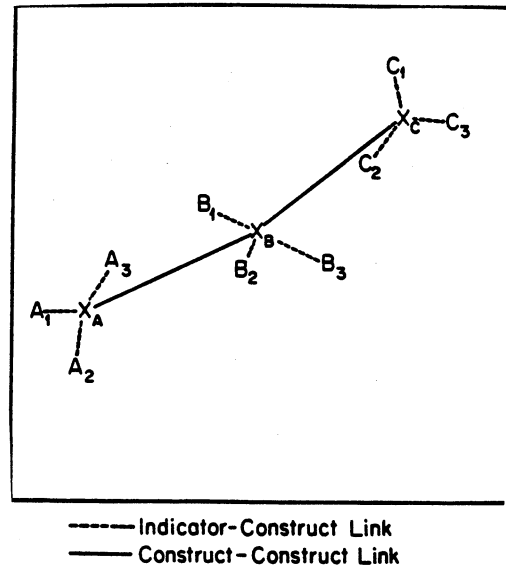

Figure 2 presents a two-dimensional configuration of a three construct model, where each construct has three indicators. X_A , X_B , X_C , are the geometric centroids representing the "true value" of each of the constructs. A_1 , A_2 , A_3 , are the three indicators of construct A. Euclidian distances between the indicators and constructs are analogous to factor loadings, and may also be taken as indications of measurement error. This system allows for the operationalization of indicator-construct relationships in a way that is conceptually quite consistent with the more sophisticated approaches used in the analysis of covariance structures.

Figure 2 also includes hypothetical estimates of relationships between constructs. The distance between X_A , X_B , for example, is a non-metric analogue to a path coefficient, and implies that the distance between the two constructs is a representation of the relationship between variables.

Thus, in a greatly simplified form, we have discussed the relationship between a theoretical model and a set of observed variables, and the manner in which confirmatory MDS techniques have attempted to conceptualize it using distance measures. MDS techniques also typically include an estimate of fit between a theoretical model and the data, to complete the range of considerations necessary for a causal modeling system. Now we turn our attention to a brief example of the application of these two types of techniques, followed by a broader discussion of the differences between these two approaches.

A Brief Example

Suppose that the same matrix represented by the two dimensional configuration in Figure 2 was analysed via LISREL. The matrix, presented in Table 1, was designed to produce an MDS configuration which would fit a CMDS model -- the clusters of indicators were clear, and the relationship between the clusters of indicators (and thus the underlying constructs) fit the theoretical relationships outlined in Figure 1. Will this matrix also fit the set of structural questions suggested by Figure 1?

TABLE 1.
SIMULATED CORRELATION MATRIX

A1	A2	A3	B1	B2	B3	C1	C2	C3
1.000	.770	.815	.611	.613	.775	.523	.508	.522
	1.000	.781	.659	.692	.707	.533	.523	.571
		1.000	.537	.585	.613	.481	.417	.493
			1.000	.875	.801	.740	.696	.668
				1.000	.820	.719	.659	.656
					1.000	.599	.578	.537
						1.000	.826	.825
							1.000	.808
								1.000

The answer, somewhat surprisingly, is no. Even though the parameter estimates are very strong, the LISREL fit is poor. With 25 degrees of freedom and a chi-square of 69.77 ($X^2/df=2.79$), the probability of these data actually fitting the theoretical model is .0000. The adjusted goodness-of-fit score is .791.

A second model helps to give further illustration of the differences between distance modeling and covariance structure analysis. Suppose that a matrix with an identical order, and an identical set of derived distances, but smaller correlations, was analysed via LISREL. How would this affect the fit of the covariance model?

When the correlations in Table 1 were multiplied by .5, there was a substantial improvement in the fit of the LISREL model. The chi-square fit measure dropped from 69.77 to 3.32 ($X^2/df=.13$) and the corresponding probability of fit rose from .0000 to 1.0000. The adjusted goodness-of-fit score also improved markedly from .791 to .993. Smaller correlations, with identical order and distance relations produced a markedly improved fit. Smaller correlations of course had no effect on the CMDS fit. The distance structure remained exactly the same since only the magnitude of the correlations was changed.

Comparing the Two Techniques

The first point of comparison must be the general conceptual similarity and purpose of the two techniques. Both require that a set of measures of a latent construct must converge on that construct, but that the measures must still show a relation to the measures of other constructs that is in keeping with a theory about the relation between the constructs. Both techniques are designed to solve a similar problem, and in most cases, give quite similar results. The example presented here was designed to highlight the type of situation under which the techniques would show different results.

Beyond this initial similarity the differences become much more apparent. These differences are outlined below:

First, the nature of constructs is quite different in the two systems. In CMDS constructs are represented by regions, and in the system developed by Denison and Fornell (1985) the "true value" of a construct is at least indirectly observable, since it can be approximated (assuming random error) by the central point (centroid) of the component measures of any construct. A construct, in LISREL terms is represented by a dimension, not a geometric region, and is truly unobservable. In practice, the "true value" of a latent variable is highly dependent upon the other constructs and indicators which are present in the system of equations.

Second, relationships in a CMDS model have no "functional form" per se. Proximity or similarity measures are converted to distances, but no functional form is implied by this procedure. LISREL, in contrast assumes a linear relationship, and both ordinal data and more sophisticated functional forms such as multiplicative relationships or polynomials violate the assumptions of the method.

Third, the two techniques differ enormously in the importance that they attach to inference. CMDS makes no claim to inferential power beyond that of the original proximity measures, and in general derives from a statistical tradition which places little faith in inference as a tool with which to develop theories. LISREL, in contrast, makes substantial claims to inferential power, and when the appropriate assumptions are met, allows for very powerful inference.

Fourth, one method responds primarily to ordinal relations among variables, whereas the other responds to interval relations. As the example illustrates, changing the size of the input correlations does not change the results of a CMDS analysis, unless the order relations are changed. While this insensitivity to changes in the size of input correlations is clearly one of the attractive features of this method, it can result in confusing examples. Negative correlations, extremely small or large correlations are all treated the same as long as the order relations are identical. LISREL, in contrast, is quite sensitive to changes in the size of input correlations, and relatively insensitive to changes in their order. Thus, larger correlations make a model more difficult to fit, and smaller correlations improve the fit tremendously.

This is in part due to a fifth consideration; the role of the null hypothesis. LISREL reverses the traditional role of the null hypothesis such that higher power leads to a higher (rather than lower) probability of rejecting a "true" model. Thus, a large sample size, and strong relationships among observed variables make it increasingly difficult to fit a model. By the same token, a small sample and weak relationships among observed variables make it very difficult to reject a faculty model. In contrast, CMDS takes a more traditional approach to hypothesis testing. Given a large sample, and strong relationships among observed variables, the convergence hypothesis is much more readily accepted for a given disparity between the model and the data.

Guidelines for Application

Several guidelines for the use of covariance and distance structure analysis seem to derive from the examples and discussion above. These can help to take advantage of the benefits of each of these methods, while avoiding some of their inherent problems.

1. CMDS is probably most useful when one is developing, rather than testing theories. Although the method does include a test, and an accept/reject decision rule, it is a less-precise, ordinal test rather than a metric test. If the data meet the assumptions necessary for covariance structure analysis, CMDS is still quite useful, but primarily as an exploratory technique.

2. CMDS is quite useful for assessing convergent-discriminant validity within the context of a multi-construct, multi-indicator model. The absence of a "true value" for a latent variable in LISREL sometimes makes this quite difficult. This guideline is related to the previous one, since convergent-discriminant validity should be resolved at the exploratory level, and should be a pre-condition for model testing.

3. Covariance structure analysis should be avoided when input correlations are either very small or very large. In these cases the outcome of the model testing is

largely determined by the size of the correlations, and CMDS presents an attractive alternative. An approach based on distance structures allows one to look at the structure of the data in relationship to a theory in a way which is unaffected by the magnitude of the correlations.

4. CMDS places very little weight on probabilistic inference, while retaining a good sense of the factors associated with the "efficacy" of a causal model. This combination has a lot of intuitive appeal, but nonetheless limits powers of inference. LISREL, in contrast, places tremendous emphasis on probabilistic inference, and offers lots of inferential power, when the assumptions are met. Inference is highly important at some points in the research process, and rather irrelevant at others.

Discussion

Research is basically a very disjunctive task; like a chain, a research design is only as strong as its weakest link. The tremendous interest generated by the development of covariance structure analysis, and the relative accessibility of LISREL, has probably resulted in the overuse of this very powerful and sophisticated technique in situations where a weaker, more intuitive technique with far less demanding assumptions would be more applicable. Our work on CMDS has attempted to develop this technique to fit the need for a less sophisticated technique that can be of greater utility at the theory-building stage of research.

A FACET THEORETICAL APPROACH FOR TESTING MEASUREMENT AND
STRUCTURAL THEORIES: AN APPLICATION OF CONFIRMATORY MDS

Lutz Hildebrandt, Technical University Berlin¹
West Germany

Abstract

The analysis of covariance structures has become a widely accepted tool to test measurement and structural theories in a holistic way. Due to underlying restrictive assumptions of the methodology, however, its usage is seldom justified in the analysis of behavioral data. This article proposes the use of facet theory and constrained multidimensional scaling as an alternative in confirmatory data analysis.

Introduction

During the last decade confirmatory methods in data analysis, especially methods which allow an integrative test of measurement and structural relations have attracted many social scientists. Marketing researchers have focused their attention particularly on one approach which is based upon the analysis of covariance structure (Joereskog 1981). The widely available software LISREL V/VI (Joereskog/Soerbom 1981, 1984) allows a simultaneous test of a measurement model and a model representing the causal hypothesis. In addition, Bagozzi (1980, 1984) provided philosophical arguments for the structural equation methodology and developed on this ground a general prospectus for theory construction in marketing. However, especially the LISREL approach in its maximum likelihood version has been widely criticized, due to its restrictive assumptions. Requirements like multivariate normal distributed variables or linearity etc. are seldom met by the data. The available test-statistic is affected by the sample size and violations of these assumptions (Fornell 1982, 1983). Later developed programs like EQS (Bentler 1984) or LVPLS (Lohmoeller 1985) do not have the restrictive distributional assumptions, but also assume linearity. The methods in general require metric data, although nonmetric extensions exist (Muthen 1983; Wold and Bartholet 1981).

The discussion about the application of the linear models is quite intensive. The facet theoretical approach, however, which is also based on an integration of measurement and theory testing is seldom discussed in consumer research. The methodology majorly is developed out of Guttman's (1954, 1957) work on scaling. Beginning with an investigation of the content of a theory, the statistical structure of the corresponding empirical observations can be predicted and tested by a multidimensional scaling procedure (see for instance Borg 1977, 1985).

Guttman's approach for theory testing can be distinguished from the methodology based on covariance structure analysis in two major instances. First, whereas the latter methodology begins with the integration of measurement and theory on the statistical and model specification level, Guttman's integrative approach starts on the research design level. Facet theory serves as a tool to explicitly define the measurement space on the basis of content. Metatheoretical rules additionally provide a set of structural hypotheses. Second, the proposed multivariate procedure to test the structural hypothesis is a nonmetric multidimensional scaling method based on soft assumptions. Correlations and other types of measures of contingencies and/or (dis-)similarities may serve to test the hypothesis. The method constrained monotone distance analysis (CMDA) to perform confirmatory multidimensional scaling (Borg and Lingoes 1980) is nonmetric and invariant to changes in the magnitude of the measures, as long as the order relation of the input data is maintained.

It should be mentioned that the methodology allows only derived causal interpretations of the results (see Denison and Fornell 1985). As in covariance structure analysis the available test-statistics should rather be interpreted as measures of fit. Instead of that a quasi-statistical model based on an efficacy coefficient can be used to evaluate a model (Lingoes and Borg 1983). In this article we will first introduce this methodology more closely. Then a worked-out example is performed, selecting items from an attitudinal study.

The Basics of Facet Theory

One element of Guttman's metatheoretical approach (1959) is the systematic research design based on facets as a prerequisite to test hypotheses. To clarify the concept of a facet or of 'facet theory', a definition outlined by Borg (1977, p. 65) can be used: "Facet theory is a general methodology for investigation in the social sciences: it provides a general framework for the precise definition of an universe of observations, which is directly related to both the specification of the various elements of empirical studies (stimuli, subjects, responses) and to theories about the structure of those observations".

The basic idea is that a theoretical problem can be decomposed into the number of underlying conceptual facets. The term 'facet' refers to a 'set consisting of a finite number of elements' (Foa 1965). The cartesian product of a finite number of facets for item construction corresponds to the factorial design for experimentation. Examples of facets include the set of components of an attitude, a set of attitudinal objects or a set of different methods to measure one attitude. As such the well-known design of an MTMM-matrix represents the combination of two facets: a method facet and a trait facet. The cartesian product of the two facets provides the basis for data collection (see also Mellenbergh et al 1979).

Based on facet theory Guttman also develops his concept of a theory as 'hypothesis of correspondence between a definitional system for a universe of observations and an aspect of the empirical structure of those observations, together with a rationale for such a hypothesis' (Gratch 1973, p. 35).

The definitional system has to explain the domain of observation and provides a meaningful basis for the replication of research and validation of results. The definitional basis for the measurement of the theoretical construct is provided by the use of a facet design related to the basis-paradigma of research in social sciences. This consists of three basic facets: a population (P), a set of stimuli or variables (S), and a set of responses (R). The population facet (P) describes the characteristics of the population. The second facet (S) defines the content of the variables under investigation. The third facet (R) specifies the categories of the answers.

As a framework to define the area under investigation serves the so-called mapping sentence (Guttman 1959; Shye 1978). A mapping sentence consists of a number of domain facets and a facet which represents the range of answers. The relation of the facets in the mapping sentence can be formalized as follows:

Let A_i be a set of elements and $S = A_1 \times A_2 \times \dots \times A_n$ be the cartesian set which can be built by A_k ($k=1, \dots, n$), then $s \in S$ holds, if and only if s is a structuple of the kind that

¹ Parts of the article were written while the author was a visiting professor at Auburn University in Alabama

$$s = a_{i1}, a_{i2}, \dots, a_{in}$$

having

$$a_{ik} \in A_k \quad (k=1,2,\dots,n)$$

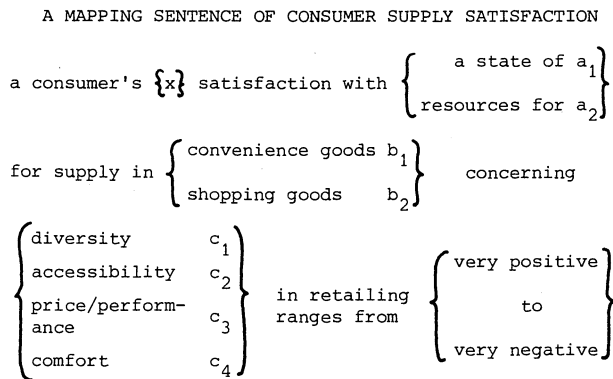

every A_k then is a facet of S . The whole mapping sentence can be formulated as:

where P is the population facet, $S = A_1 \times A_2 \times \dots \times A_n$ the cartesian set of the facets of content, which serves to define the stimuli, and R the range of answering. The elements of a facet are named structus, the elements of the cartesian product of the facets structuples.

The mapping sentence does not constitute a theory. The hypotheses are to be formulated according to the lawfulness of the empirical structure of the variables (Guttman 1959). An example of a mapping sentence from satisfaction research is given by figure 1. The construct under investigation is the consumer's satisfaction with different aspects of retailing in the consumer's area.

FIGURE 1

The cartesian product of the defined content facets $A \times B \times C$ provides all possible combinations of the facet elements which may be relevant to the domain under investigation. However, not all structuples (facet combinations) in general make sense (e.g. Jordan and Horn 1975). The system may serve as a basis for constructing items, but it can as well be used to select items from former empirical research. Using this approach, the researcher assures that also different types of studies are comparable on the general level, even if the focus of each single study may be different. The source of the construction of facets may be either theory or also ad hoc thinking (Borg 1985). Although the approach seems rather simple, it provides the ground to develop some metahypotheses.

Metahypothesis

The systematic definition of variables according to underlying substantive knowledge enables us to test their structural relations. In addition, it is assumed that some of the concepts of facet theory are so closely related to psychological processes that they provide meta-theoretical rules concerning the statistical relationships of the variables involved. Foa (1965) suggests two principles for predicting results from a facet structure of the variables: the principle of contiguity, and the concept of semantic principal components.

The principle of contiguity states that variables which are more similar in their facet structure (e.g. on the level of content) will also be more related empirically. An example is given by a combination of three facets, where each facet consists of two elements. The cartesian product of the facets - the space of content - results in eight structuples $(a_i, b_j, c_k; i, j, k = 1, 2)$ to define the varia-

bles. If one uses correlation coefficients to capture the relations of three variables, the contiguity principle (under the assumption of equal weights of the facets) has to lead to the following inequality, if the data are valid:

$$r(a_1 b_1 c_1; a_1 b_2 c_1) > r(a_1 b_1 c_1; a_1 b_2 c_2)$$

Using the principle it is possible to derive an ordering from the variables which in the simplest case is linear. In a study of Guttman (1959) four variables (items) are measured, because of the underlying structuples it was possible to arrange the items according to their contiguity. Each structuple is different to its neighbour by one element:

On the semantical (facet-)level we observe the following similarities: var 1 and var 2; var 2 and var 3; var 3 and var 4. Less similar are var 1 and var 3 or var 2 and var 4. Dissimilar are var 1 and var 4.

The principle of contiguity is confirmed empirically, if the correlation matrix of the variables shows a simplex structure. This structure is given if we have a decreasing ordering of the correlation coefficients in the off diagonal columns and rows toward the end points. The geometrical mapping of a simplex is a line or some linear ordering. This is exactly the same which is required if one builds a Guttman-scale. Therefore, the above example results in a scale, which is named 'semantic' Guttman scale by Foa (1965).

Contiguity, however, is only a necessary condition to predict a simplex structure. In a definitional system having three facets we are only able to define partial orderings. If we have dichotomous items, then the system of contiguity has the following structure (see also Guttman/Schlesinger 1967):

FIGURE 2

THE ORDERING IN A DEFINITIONAL SYSTEM OF THREE BINARY ITEMS

If all eight structuples are ordered so that each structuple is contiguous with its neighbour, and if there is only a difference in one element, then the first structuple becomes similar again with the last structuple. Each of the variables will correlate higher with its neighbours than with any other variable. The result is a circumplex structure in the data (Borg 1977 or Foa 1965). The geometrical representation of a circumplex is a circle.

In some cases, however, the principle of contiguity does not produce a unique order. If we assume equal weight of the facets, the facets are interchangeable. The order of the variables are dependent of the choice of the first facet and the first element. To solve this problem, Foa

Foa (1965) introduced the concept of the semantic principle component into facet theory, in analogy to Guttman's (1954) principle components of perfect scales. It states that in a sequence of several structures the facet which changes its elements the least (in general the first facet) serves as the first semantic principle component. If we have more than two facets, the frequency of the variation in the elements of a facet determines its relative weight. However, the concept of semantic principle components is defined very insufficiently. No order hypothesis can be derived without additional assumptions (Lantermann 1980).

Structural Hypothesis

Simplex and its extension, the circumplex, are basic structures and should be mapped only by using the relevant items (Borg 1981, p. 143). They have their importance primarily in scale construction.

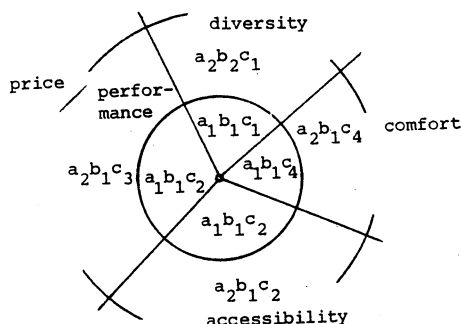

In consumer research it should be of more importance to test the more general hypothesis, if the discriminations created by the facets in S, P, and/or R correspond to empirical regularities. Less restrictive versions of contiguity serve as the basis to relate total configurations to the definitorial system of a facet design. In an ongoing study of Hildebrandt (1985) the mapping sentence of figure 1 served to define the domain of the items concerning supply satisfaction of convenience goods (b_1). The facet A can be regarded as ordered. Facet B is only represented by one element, and facet C is unordered. Using a weak conception of contiguity for a structural hypothesis it is required that

- a) items which have the same element in facet C should be represented in the same area or region of a two-dimensional MDS configuration, and
- b) facet A should discriminate items of type a_1 and type a_2 in this region. Both should lie in different partial regions. In addition a valid representation should discriminate facet A and facet C in a way that the areas or point clusters are non-overlapping and the representation is simple.

This spatial representation of the data is only possible in a two-dimensional space and a structure, which is called a radex (Guttman and Schlesinger 1967). The facet A serves as a modulating facet, facet C as a polarizing facet. The radex hypothesis which should be confirmed by the data using (N)MDS is represented in figure 3. The order expectation of the C facet is specified according to results from former studies.

FIGURE 3

A RADEX HYPOTHESIS OF SUPPLY SATISFACTION

Higher order facet structures and the development of complex spatial hypothesis as for instance the duplex, multiplex, cylindrex etc. primarily depend on Guttman's work and are discussed in a recent paper by Gorg (1985).

Testing Structural Hypothesis

Applying facet theory and developing a set of structural

hypotheses presents the first step to leave the stage of data reduction and exploration in multidimensional scaling. The hypothesized spatial structure based on a meta-hypothesis may be supplemented by some substantive assumptions about the relation of the constructs under investigation (see e.g. Fornell and Denison 1982). However, if we apply a classical (N)MDS method like MINISSA (Lingoes and Roskam 1975) to investigate if the empirical data confirm our structural hypothesis, we still remain in the theory formation process. Applying (N)MDS to our data, we leave the theoretical level and optimize a 'blind' stress which only accounts for the similarity structure. The resulting spatial representation then may satisfy the minimization criteria very well, but may not confirm our set of hypotheses. On the other hand we can not be sure whether there does not exist another configuration which satisfies the optimization criteria equally well and in addition confirms the structural hypothesis.

These interpretational difficulties in MDS solutions caused by local optima and indeterminacy are overcome by confirmatory MDS. Approaches for confirmatory MDS allow to put external constraints on a distance structure. The constraints might be derived from a facet design, from measurement requirements, and/or substantive theory (Fornell and Denison 1982). Constrained MDS solutions may be produced e.g. by programs like KYST (Carroll et al. 1980) or CMDA (Lingoes and Borg 1980). The last is applied in this article. Technically CMDA requires an acceptable ($K > .15$) solution of an unconstrained MDS, for instance by MINISSA. This unconstrained configuration is imposed by a set of constraints to produce a spatial solution according to our theory. In addition to the spatial representation of our data CMDA provides measures to decide, if the constrained and unconstrained distance configurations are equivalent representations of the original proximity data.

In their first approach Lingoes and Borg (1980) developed a statistical test based on Hotelling's t-test. This test is criticized because of its poor robustness against assumptional violations. In a more recent article instead of that Lingoes and Borg (1983) propose a set of decision criteria for the acceptance/rejection decision. However, it should be noted that the criteria are rather rules of thumb than strong statistical criteria. The following coefficients are relevant:

$\rho_c = \rho(X, Z, Y)$, the partial correlation between the order of the distances of the constrained solution (Z) and the unconstrained solution (X), where the order of the original proximity data is partialled out.

$K = \sqrt{1 - \rho_c^2}$, the coefficient of alienation defined as the proportion of variance not explained by the raw correlation ρ of X and Z.

As criteria for acceptance are proposed:

- ρ_c should be larger than $\sqrt{.5}$ (a good solution)
- ρ_c should exceed three times the alienation coefficient K or should at least be larger than 1

In cases where the ratio is between 1 and 3 additional criteria should be used to build a weighting factor A for K. For the calculation of this factor the reader is referred to Lingoes and Borg (1983, p. 47). The reason for the introduction of the multiplier A is that the condition of a larger sample size, larger matrix and a relative large number of constraints etc. should improve the chance for acceptance of a given model. It is proposed: If

$$\rho(X, Z, Y) \geq AK \quad (1)$$

we accept the equivalence hypothesis.

Applying the Facet Theoretical Approach

The clarify the holistic way of data analysis using the facet theoretical approach an item selection procedure is carried out to test hypotheses about the information behavior of young consumers. The research bases on the

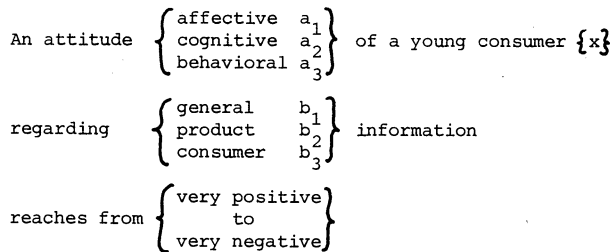

general hypothesis that consumers who are better informed in general are also better informed regarding product and consumer issues. A concept which tries to explain this relationship is 'the propensity to use information' (Wiswede 1975). In this study the concept is measured on the basis of attitudinal items toward different kinds of information. It is assumed that the better the attitude toward an information type, the better the information use behavior (resulting in a more rational buying behavior). The study then states a causal hierarchy for the 'propensity to use information' regarding three types of information :

Based on these conceptual considerations the following mapping sentence is used to define the area of investigation :

FIGURE 4

THE MAPPING SENTENCE

The attitude is defined as a three-partite concept. The cartesian product of the facets of content defines all possible combinations of facet elements. It serves as the frame of reference to select items out of an existing consumer study (Tschammer-Osten and Warnecke 1978).

FIGURE 5

THE CARTESIAN PRODUCT OF FACETS

Facet B \ Facet A		information		
		general	product	consumer
Attitude		b_1	b_2	b_3
cognitive	a_1	$a_1 b_1$	<u>$a_1 b_2$</u>	<u>$a_1 b_3$</u>
affective	a_2	<u>$a_2 b_1$</u>	<u>$a_2 b_2$</u>	$a_2 b_3$
behavioral	a_3	<u>$a_3 b_1$</u>	$a_3 b_2$	<u>$a_3 b_3$</u>

The items were selected by using a comprehensive system of categories with regard to the semantic meaning of cognitive, affective, and behavioral items. For the criterion set to distinguish different sources of information served the closeness of an information type to buying behavior. The selection procedure resulted in a set of nine items, which in part represent the same structuples, and on the other hand some of the structuples of the facet design were not available in the data set. The structuples covered by the available items are underlined.

We can now try to derive some structural hypotheses based on the facets represented by the items. The contiguity principle states that items with the same facet structure should be closest together. The derivation of an ordering depends on the definition of the first principle component and the specification of the first element in the ordering of the facets. Going back to our basic hypothesis we can assume that the facet B discriminating the information sources should be the dominant facet. Therefore, we specify that the attitude toward general information has

to be the first structuple of the ordering, and we derive the following scheme :

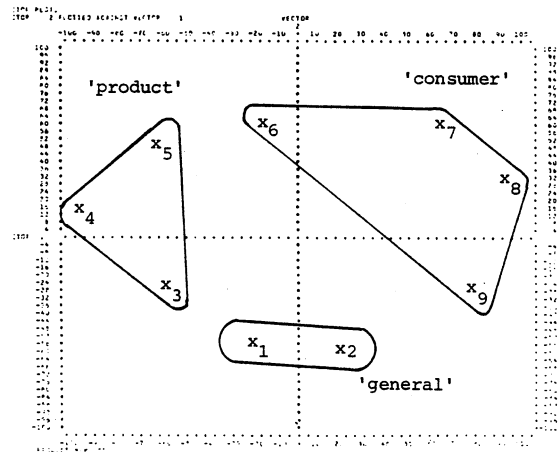

x_1	b_1	a_2
x_2	b_1	a_3
x_3	b_2	a_1
x_4	b_2	a_1
x_5	b_2	a_2
x_6	b_3	a_1
x_7	b_3	a_1
x_8	b_3	a_3
x_9	b_3	a_3

Variables with the same facet structures are x_3 and x_4 , x_6 and x_7 , x_8 and x_9 . They should be closest together. The largest dissimilarities are to be expected between x_2 and x_3 , and x_5 and x_6 . The facet structure in the items representing the same constructs are more similar than between the constructs. The information facet should generate clusters of items. If we apply the logic of an MIMM-analysis, we will get to the same assumption.

In addition we can formulate a simplex expectation between the items x_1 , x_2 , x_9 . To test the structural hypothesis we first generated a MINISSA solution, which produced a two-dimensional configuration based on an alienation $K = 0.9$, which is a good fit.

FIGURE 6

MINISSA-UNCONSTRAINED SOLUTION

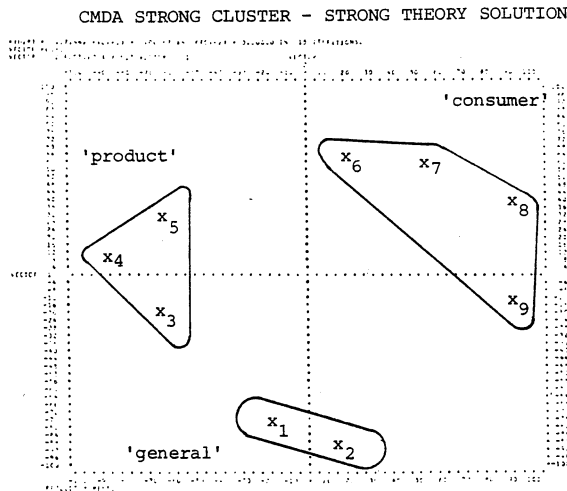

Analyzed were the Pearson correlations of the nine items of a 248 respondents' sample. The MINISSA solution does confirm the simplex expectation. Some of the expected similarities are also represented by the distances. However, the solution does not confirm a strong clustering expectation generated by the elements of the B facet. Especially for the item x_6 we can not decide, if it represents a 'product' related item or a 'consumer' related item.

For constraining the solution in a CMDA analysis according to our general research hypothesis and the structural expectation derived from the facet theory we use a strong concept of contiguity. The spatial solution should be constrained so that each point within an item cluster (representing the B facet) should be nearer to all other points within that cluster than to any point outside of that cluster. The relations between the clusters should

represent the assumed causal ordering. (see upper triangular in the correlation matrix).

FIGURE 7

The CMDA solution shown in figure 7 represents the clear clustering structure and also the stated hierarchical relation behind our three concepts. However, the solution does not satisfy the criteria for acceptance (see figure 8)

FIGURE 8

GOODNESS OF FIT CMDA SOLUTION

contiguity criteria	strong cluster strong theory	strong cluster weak theory
β_c	.67	.68
K	.42	.35
A	2	2

$\beta_c^2 \geq .5$	no	no
β_c/K	1.59	1.94
$\beta_c \geq AK$	no	no (borderline)

An additional analysis without relational constraints according to the assumed hierarchical structure generates a slightly better solution. However, the source of invalidity remains item x_6 . A possible strategy might be to accept a weaker type of Contiguity. If we find an acceptable solution we may calculate the centroids of the clusters as representations of the underlying constructs, and we can use (euclidian) distances to have a measure of their (causal) relations (see: Fornell and Denison 1982; Denison and Fornell 1985).

Discussion

The facet theoretical approach of Guttman integrates the basic steps of empirical research : design - measurement - hypothesis testing. It is more comprehensive than the 'holistic' methodology for the analysis of covariance structure. Shortcomings may be that there is only an indirect way for a causal interpretation of the results and the lack of a sufficient statistical test. But with regard to the last problem we should take into account that in social sciences the assumptions to apply a statistical test like the LISREL χ^2 are seldom met. If the assumptions however, are met, the theory testing part of the structural equation methodology is more powerful. The facet-theoretical approach using CMDA has its advantage if we can not assume linearity or if we do not have metric or quasi metric data. It also has advantages, if the researcher is involved in large variable sets.

THE MATRIX OF THE CORRELATIONS / ORDER RESTRICTIONS

x_1	.-	4	2	2	2	1	1	2	2
x_2	.38	-	2	2	2	1	1	2	2

GRAPHIC AND VERBAL PRESENTATION OF STIMULI: A PROBABILISTIC
MDS ANALYSIS

David B. MacKay, Indiana University
Mark Ellis, Indiana University
Joseph L. Zinnes, University of Illinois

Abstract

A probabilistic unfolding model is used to test a variety of hypotheses about the parameters underlying consumers' evaluations of graphic and verbal stimuli. Specific hypotheses concern the dimensionality of the space, the uncertainty with which stimuli are perceived by consumers, and the similarity of configurations derived from graphic and from verbal stimuli. Differences between configurations derived from graphic and verbal stimuli are explored.

Introduction

Applications of multidimensional scaling (MDS) implicitly or explicitly involve the assessment of a variety of hypotheses. Hypotheses concerning the dimensionality of the space that underlies the stimuli are perhaps most common. Other hypotheses might involve the equality of two or more configurations, order relations among stimuli on particular dimensions, and the nature of the distance function. Confirmation of such hypotheses requires the user to go beyond the calculation of a general loss function, such as Kruskal's stress, and to assess the "influence and balance of systematic and random effects in the data" (Heiser and Meulman 1984).

Statistical and quasi-statistical methods can be used for confirming MDS hypotheses. In the latter category, for example, would be the efficacy coefficient proposed by Lingoes and Borg (1983) for testing hypotheses with their constrained/confirmatory monotone distance analysis (CMDA) procedure. CMDA (Borg and Lingoes 1980) is a nonmetric MDS method which allows the user to impose order constraints on the distances among points in the estimated configuration. To determine if a constrained CMDA solution is equivalent to an unconstrained solution, the efficacy coefficient - a partial correlation of the ordered distances in the constrained and unconstrained configurations with the order of the original data partialled out - is computed. Unfortunately, the absence of an error model denies the authors the use of inferential statistical theory and requires them to develop a heuristic method for determining which values of the efficacy coefficient lead to the rejection of a hypothesis and which values do not.

To test hypotheses using the efficacy coefficient, a two stage decision model is used. In the first stage, the user compares the efficacy coefficient to the coefficient of alienation - the square root of one minus the squared correlation of the order of distances in the constrained MDS solution and the order of distances in the unconstrained MDS solution. The hypothesis of equivalence between the constrained and unconstrained MDS solutions is rejected if the efficacy coefficient is less than the coefficient of alienation. If the efficacy coefficient is more than three times the size of the coefficient of alienation the hypothesis of equivalence is accepted. If the efficacy coefficient is between one and three times the size of the coefficient of alienation, the user proceeds to stage two. Stage two reduces the value of the criterion required to accept the hypothesis of equivalence by computing instead an average of subjectively scaled factors which include items such as the sample size, configuration size, size of the matrix, etc.

Probabilistic models provide a different approach to confirmatory MDS. Development of probabilistic models has been motivated by the desire for an error model that will allow the use of test statistics for a wide variety of hypotheses. A number of probabilistic MDS models have been proposed, viz. (DeSoete and Carroll 1983), (DeSoete, Carroll and DeSarbo 1985), (Ramsay 1977), (Takane 1981),

(Zinnes and MacKay 1983). These models differ with respect to the types of judgments they handle, the measurement properties they assume, and the error models they posit. A review of several probabilistic models has been provided by Young (1984).

Instead of implicitly assuming a deterministic judgment process like CMDA, probabilistic models explicitly assume a probabilistic judgment process and make these assumptions intrinsic components of the model. A primary rationale for probabilistic models is the observed inconsistency of subjects' judgment processes. By assuming a probabilistic process, it is also often possible to make use of very powerful statistical procedures in the estimation of model parameters and the testing of a wide range of hypotheses. In addition, individual models may possess other attractive properties, such as the ability to account for Weber properties, asymmetric judgments, and nonisotropic spaces (Zinnes and MacKay 1981).

Probabilistic MDS models are, though, quite new and users are still faced with a number of open issues which are in need of further investigation. These issues include the sensitivity of the models to departures from their specific error assumptions and the effect of sequential hypothesis testing in accepting and rejecting hypotheses.

In this paper, a probabilistic model for consumer choice data is first defined. Then, an experiment is described which was designed to gather information on consumers' preferences for residential alternatives. Half of the subjects in the experiment received information on the stimuli in a graphic form and half of the subjects received information on the stimuli in a verbal (written) form. Finally, the probabilistic model is used to evaluate hypotheses concerning the dimensionality of the space, the homogeneity with which the stimuli are perceived by the subjects, and the equality of the configurations derived from graphic and verbal data.

A Probabilistic MDS Model

PROSCAL (MacKay and Zinnes 1982) is a probabilistic multidimensional scaling program for incomplete, complete or replicated data. The data are distance judgments between pairs of stimulus objects. PROSCAL represents stimuli as points in a multidimensional space and provides maximum likelihood estimates (MLE) of each point's location. In addition, dispersion parameters are estimated for the stimuli.

Originally defined only for proximity data, PROSCAL has recently been expanded to accommodate preference data as well (MacKay and Zinnes 1985). Preferences are evaluated by a probabilistic unfolding model in which the location coordinates of the stimuli and subjects are assumed to be normally and independently distributed in an isotropic r dimensional space. Standard deviations of the stimulus points are interpreted as measures of the heterogeneity of the subjects' evaluations of the stimuli. Standard deviations of the ideal points are interpreted as the amount of uncertainty in a subject's judgments.

Data for the PROSCAL unfolding model consist of preference ratio judgments. In collecting preference ratio judgments, subjects will typically be asked two questions for each pair of stimuli. First the subject will be asked to identify the stimulus of the pair which is more preferred and then to identify the degree to which that stimulus is preferred over the less preferred stimulus.

To use MLE methods, the density function (pdf) of the judgments must be computed. Given the probabilistic assumptions of the model, the squared standardized distance from an ideal point to a stimulus point can be shown to be distributed according to a non-central chi square distribution. If stimulus j is preferred to stimulus k by subject i , the preference ratio is represented by a ratio of distances d_{ki}/d_{ji} . Conversely, one may consider the ratio d_{ji}/d_{ki} as a measure of subject i 's disutility for stimulus j relative to stimulus k . Since the ratio of two noncentral chi-square distributions is a doubly non-central F distribution, F'' (Kendall and Stuart 1979), the pdf of the ratio $q = d_{ki}/d_{ji}$ can be defined (MacKay and Zinnes 1985).

Given the pdf, PROSCAL then finds the MLE of the parameters through numerical estimation. Initial estimates of the configuration are provided by a deterministic metric unfolding of I scales (Coombs 1950) estimated from the preference ratio data. The I scale for subject i 's evaluation of stimulus j is simply defined as the geometric mean of subject i 's preference ratio judgments involving stimulus j . Initial estimates of the variances are defined as a function of the squared differences between the preference ratio data and the initial configuration's estimates of the preference ratios.

An Experimental Evaluation of Graphic and Verbal Presentations

In a prior study (MacKay and Zinnes 1985), probabilistic MDS was used to evaluate subjects' residential preferences for residential alternatives that were defined on the basis of two dimensions, environmental level and time to work. Results from this prior study were the source of most of the hypotheses that were tested in the study that is described here.

Data

At the beginning of the experiment, subjects were told that they would be evaluating a new system designed to help realtors provide out-of-town clients with a list of residences for their consideration. After being introduced to the experiment, subjects were given a series of warmup tasks to assist them in making the required types of judgments.

To custom tailor the residential preference ratio questions to the prior interests of a subject, a graphic computer interactive data collection program was written. All information was conveyed to the subject by means of two color CRTs. One CRT was used for displaying instructions and receiving subjects' responses. A second high resolution CRT was used for displaying the stimuli.

Each subject expressed preference ratios for all pairs of twelve stimuli. A balanced incomplete block design was used to define the twelve stimuli on the basis of three variables commonly cited in the residential preference literature: environmental quality (three levels), price-quality (four levels) and distance to work (four levels).

The opening scenario told subjects that they were moving to a new town and that they would be working in the central business district (CBD) of a medium sized American city. In the warmup phase of the experiment, subjects were asked whether they were interested in renting or purchasing a house or in renting or purchasing an apartment (condominium). Specific values of the variables defining the stimuli depended upon the type of residence preferred by the subject. If the subject chose to rent or purchase a house, the four levels of time-to-work were 10, 20, 30 and 40 minutes. If the subject chose to rent or purchase an apartment (condominium), the travel times were 5, 10, 15 and 20 minutes.

Environmental level was conceptualized as a compound variable consisting of two parts - population density and level of local services (schools, parks, local retail outlets, etc.). For subjects stating a preference for a

house, the density levels were given as one, two and three thousand persons per square mile and the service levels were defined as low, medium and high. For subjects stating a preference for an apartment/condominium, density levels were stated to be three, four and five thousand persons per square mile and the service levels were again defined as low, medium and high. Density levels were described for the community in which the subjects resided to provide a benchmark.

The four price levels, utility costs plus mortgage payments or rent, were the same for all stimuli - \$300, \$450, \$600 and \$750 per month. Subjects were told that their desired level of quality should also be considered when evaluating the price level of a residence.

While the experiment constructed residential stimuli from only three variables, it was obvious from pretests and the literature that more than three variables were involved in actual residential decision making. To make the task more realistic, subjects were also asked to specify the number of bedrooms they required. All of the residences subjects evaluated were said to be drawn from a list of available properties that met their size requirements.

Thirty-eight subjects took part in the experiment. All of the subjects were graduate students in an MBA program. MBA students were selected because they were about to go into the housing market at salary levels which were high enough for many to contemplate purchasing a house or condominium. In addition, the scenario of working in a CBD and having to communicate with a realtor in a distant town was a scenario which many of the students would soon, if not already, experience.

In the main phase of the experiment, subjects were shown pairs of residential alternatives and asked to first indicate which alternative they preferred and then indicate the degree to which they preferred that stimulus over the other. Half of the subjects had the stimuli displayed graphically on a map of the city. The city was divided into different zones which contained different environmental levels. Time to work was proportional to the distance of the residence to the CBD. Price levels for the two residences in each pair was indicated in the legend. Subjects touched a light pen to the residence on the map they preferred more for the first part of the preference ratio judgment.

The other half of the subjects were presented with a verbal (written) description of the residences. For each judgment, two residences, A and B, were defined by the values of their three descriptive variables. Subjects indicated their preference by touching a small box underneath the description of the preferred residence with a light pen.

After designating their most preferred residential alternative, subjects indicated their degree of preference for the preferred alternative by touching the light pen to any position on a seven inch bar at the bottom of the screen. The bar was labeled on the left with a one and on the right with a five. The label one meant that they preferred the two residences equally and the five meant that they preferred one residence five or more times as much as the other residence. Each subject made these judgments for all sixty-six pairs of the twelve stimuli. Response times for all judgments were recorded.

To minimize anchor point problems, subjects rated extreme pairs of stimuli (very similar and very dissimilar residences) in the warmup phase of the experiment. Temporal bias was controlled by randomly ordering the pairs of stimuli and by balancing the order of the stimuli within each pair so that each stimulus appeared as the first stimulus to the subject approximately half the time. At the close of the session, subjects were asked to evaluate the realism of the experiment.

Analysis and Results

The experiment that has been briefly described above and the one that preceded it were designed to investigate both the nature of subjects' residential preferences and the impact of pictorial and verbal cue presentations. A large number of analyses were done using standard metric and nonmetric MDS procedures as well as PROSCAL for a variety of segments. Comparisons of multidimensional scaling analyses were also made to analyses using other multivariate methods, such as logit analysis.

A rather small subset of the analyses undertaken in the study are reported in this paper. Those that are used are chosen for their ability to illustrate the confirmatory use of probabilistic multidimensional scaling.

Tests of Dimensionality

With MLE programs, such as PROSCAL, tests of dimensionality are done quite easily. To compare a r and a $r+k$ dimensional solution, for example, solutions are derived in both r and $r+k$ dimensions. Log likelihoods of the two solutions are then compared in a likelihood ratio test. Since the quantity

$$Q = 2(L_g - L_s), \quad (1)$$

where: L_g = the log likelihood of the general $r+k$ dimensional solution

L_s = the log likelihood of the specific r dimensional solution

is asymptotically chi-squared distributed with the degrees of freedom equal to the difference in the number of free parameters estimated by the two models, a statistical test of the null hypothesis of a r dimensional solution is available. Thus, unlike most hypothesis tests in CMDA and confirmatory covariance structure analysis, the specific model is assumed to be true unless the data are strong enough to confirm that the general model is worth the cost of the added degrees of freedom it uses. In CMDA and confirmatory covariance structure analysis, the research interest is usually not in providing evidence for a more general model, but in showing that the simple constrained model with fewer free parameters is as good as the general model.

In this study, the data of the nineteen subjects who said they preferred apartments/condominiums, were evaluated in two, three and four dimensions. The resulting values of Q (1) are given in Table 1.

TABLE 1

LOG LIKELIHOOD DIFFERENCES FOR TESTS OF DIMENSIONALITY

Dimensions Compared	df	Q^1
2-3	31	58.54
3-4	31	8.44

¹ Q is defined by (1)

Critical values for Q include:
 $\chi^2(df = 31, \alpha = 0.01) = 52.21$
 $\chi^2(df = 31, \alpha = 0.99) = 15.64$

From Table 1, it is clear that there is ample evidence at the 0.01 level that the data are strong enough to reject a two dimensional model for a three dimensional model. However, there is almost no evidence for a four dimensional model and the three dimensional model is thus confirmed. Since the data were defined as three dimensional, one would not expect any more than a three dimensional solution, though a solution of lower dimensionality might be appropriate if subjects were combining dimensions in their evaluations of the stimuli.

Tests of Homogeneity

PROSCAL assumes that each stimulus and each ideal point has a variance that is the same on all dimensions but which may differ from point to point. (This restrictive assumption of an isotropic space that requires equal variances on all dimensions and independence of observations has been relaxed in the most recent version of PROSCAL. This generalization, which requires going to a distribution other than the double non-central F distribution described earlier, was not available when the analysis for this study was conducted.) In the preceding tests of dimensionality, it was assumed (though not stated) that the variances of all the stimuli were the same. Thus, only one variance was estimated. Other conditions could, of course, have been assumed.

The PROSCAL model allows great flexibility in modeling the variances of the stimuli and ideal points. Three general submodels for allocating variances exist; these are referred to as set, partition and distance submodels. More complex models can also be estimated (MacKay and Zinnes 1985).

In this study, the use of the set model for allocating variances is illustrated. The set submodel allocates variances to individual stimuli or ideal points. Each point may have its own unique variance estimated or the analyst may have a variance estimated for a set of points.

The set submodel was used here in two different ways. The first way was by appropriating a finding from the earlier study (MacKay and Zinnes 1985) on two dimensional residential stimuli that subjects attributed significantly different variances to stimuli according to their level of time from the CBD. This finding was evaluated in the present study by estimating five variances instead of one for the subjects choosing apartments/condominiums. Four unique variances were estimated for the stimuli, three stimuli in each set, and one variance was estimated for the ideal points. A likelihood ratio test then compared the log likelihoods of the five and one variance models.

The second application was to see if the variance for subjects exposed to graphic stimuli differed from the variance for subjects exposed to verbal stimuli. This was accomplished by simply dividing the ideal points into two sets and estimating one additional variance. A likelihood ratio test was again used to compare the likelihoods of the general six and specific five variance models.

Results of the likelihood ratio tests are given in Table 2. It is obvious that the increase in the number of variances from one to five was highly significant but that the increase from five to six was not. In the test of one versus five variances, it will be noticed that only three degrees of freedom are used instead of four. This is because only four of the five estimated variances are free parameters. The uniqueness properties of the unfolding model used by PROSCAL are such that ideal point variances cannot be uniquely distinguished from stimulus variances. The program accommodates this problem by scaling the minimum variances for stimuli and ideal points equally.

TABLE 2

LOG LIKELIHOOD DIFFERENCES FOR TESTS OF HOMOGENEITY

Number of Variances Compared	df	Q^1
5-1	3	103.84
6-5	1	0.50

¹ Q is defined by (1)

Critical values for Q include:
 $\chi^2(df = 3, \alpha = 0.01) = 11.34$
 $\chi^2(df = 1, \alpha = 0.01) = 6.63$

These results differ from those obtained in the earlier study of two dimensional stimuli where it was shown that the variance for graphic stimulus displays was significantly higher than that of verbal stimulus displays. A tentative explanation for this finding is that as the complexity of the stimuli increase, the relative benefits of the graphic display also increase, thus lowering the relative perceived heterogeneity of the stimuli. Estimated variances for the graphic and verbal stimuli were 0.42 and 0.41 respectively.

Tests of Configurational Similarity

An analyst will often want to determine if two or more stimuli or ideal points could indeed have the same estimated location. In product evaluation, for example, one would like to know if two or more brands are perceived to be the same. In this study, we were interested in determining if graphically displayed stimuli were perceived the same as verbally displayed stimuli.

To test the similarity of the configurations for verbal and graphic displays, separate PROSCAL analyses of subjects exposed to graphic and verbal displays were conducted for the apartment/condominium subjects. In both analyses, the configuration was constrained to be identical to the configuration obtained in the previous section when all apartment/condominium subjects were evaluated at once with a model involving five variances. Five variances were again estimated in both analyses. (These constrained analyses are the same as what is usually termed an external analysis. However, PROSCAL is able to keep any number of parameters free or fixed.)

Results of the hypothesis tests are given in Table 3. Here it is seen that the general unconstrained configuration of the verbally displayed stimuli differs significantly from the specific model in which the configuration of the stimuli was constrained to be the one obtained when subjects chose apartments or condominiums for all, graphic and verbal, stimuli.

TABLE 3
LOG LIKELIHOOD DIFFERENCES FOR TESTS OF
CONFIGURATIONAL SIMILARITY

Type of Display	df	Q ¹
Graphic	36	43.78
Verbal	36	82.19

¹Q is defined by (1)

Critical values for Q include:
 $\chi^2(df = 36, \alpha = 0.01) = 58.64$
 $\chi^2(df = 36, \alpha = 0.05) = 51.01$

Stimulus Display and Attribute Covariation

Figure 1 shows three configurations. In panel (A), the configuration of the objectively defined stimuli are portrayed. Panel (B) shows the configuration estimated from the judgments of the subjects exposed to the graphic displays and panel (C) shows the configuration of stimuli for subjects exposed to the verbal displays. Estimated ideal points are not shown.

Evaluation of the differences in the two display modes could proceed in different ways. Perhaps the simplest would be to select a single criterion, such as the correlation of interpoint distances between an estimated configuration and the known "true" configuration of physical coordinates in the first panel of Figure 1. If this is done, the resulting correlations are about equal, 0.56 for the graphic display and 0.62 for the verbal display, with a slight edge for the verbal display.

FIGURE 1
CONFIGURATIONS FOR (A) THE PHYSICAL STIMULI,
(B) THE GRAPHIC STIMULI, AND
(C) THE VERBAL STIMULI ALONG
THE DIMENSIONS OF PRICE,
ENVIRONMENT AND TIME

Examination of the configurations for the two sets of apartment/condominium subjects showed an interesting difference. For the subjects exposed to the graphic stimuli, the correlation between the attribute values of the stimuli on the environment and time axes was of a greater absolute magnitude than that for the subjects exposed to the verbal stimuli. For graphic and verbal displays, the respective correlations were -0.91 and -0.24. The corresponding covariances were -0.41 and -0.24 ($p < 0.05$).

Attribute covariation has been studied both in marketing and psychology, viz. (Chapman and Chapman 1971, Huber and McCann 1982, Jennings, Amabile and Ross 1984). A consistent finding is that even when presented with data which exhibit no covariation, subjects will report their pre-conceptions about covariation of the stimuli. The same phenomenon appears to be happening in this study, so the presence of covariation itself should not be taken as an indication that the graphic method is less satisfactory than the verbal method. It might even be argued that the abstractness of the verbal display dilutes the subjects actual preconceived covariation and that the greater covariation of the graphic display is a better representation. (How preconceptions overcome immediately available data is not known. Jennings, Amabile and Ross (1982) speculate on a number of possibilities - subjects may "see" the relations they report, subjects may weight subjective impressions and expectations, etc.)

Since the covariation affects the criterion of correlation among interpoint distances, other criteria, which are less affected by the covariation, should be considered. One criterion would be to simply correlate the projections of the stimuli on the axes with the corresponding physical values, after rotating the MDS configurations to maximum congruence with the physical configuration.

Results from correlating projections on individual axes, shown in Table 4, indicate that a primary difference in the graphic and verbal displays was that the verbal displays were much less successful in capturing the time dimension than the graphic displays. Correlations of projections on the other two axes are not significantly different from each other.

TABLE 4

PRODUCT MOMENT CORRELATIONS OF PROJECTIONS ON ESTIMATED AND PHYSICAL AXES

Axis	Graphic Display	Verbal Display
Environment	.87	.90
Price	.90	.97
Time	.82	.22

From Table 4, one might conclude that graphic displays enable subjects to retain a greater amount of information in their decision making. Such a conclusion, though, would be premature. Additional study of the effects of graphic and verbal displays are needed. To test hypotheses about the differences in graphic and verbal displays, the methods of confirmatory MDS are well suited.

AN EXCHANGE THEORY MODEL OF INTERPERSONAL COMMUNICATION

HUBERT GATIGNON, THE WHARTON SCHOOL, UNIVERSITY OF PENNSYLVANIA
THOMAS S. ROBERTSON, THE WHARTON SCHOOL, UNIVERSITY OF PENNSYLVANIA

Abstract

A new model of interpersonal communication is proposed based on social exchange theory. This conceptualization is proposed as an alternative to the prevalent "two-step" model and is offered in order to encourage new research directions.

Overview

The consumer behavior literature on interpersonal communication is dominated by the Katz and Lazarsfeld (1955) "two-step" model. This conceptualization represented a major contribution in dispelling the "direct effects" model, which was prevalent in the late 1940s and early 1950s and which attributed considerable unmediated power to the mass media. Katz and Lazarsfeld's research recognized the importance of horizontal communication among peer groups in mediating the effects of mass media.

Nevertheless, Katz and Lazarsfeld may also have overstated the role of social processes, especially for low involvement products where information-seeking and social legitimation may be minimal and direct media effects may be common (Krugman 1965; Ray 1973; Robertson 1976). They may also have overstated the role of social processes for innovators, who must rely to a greater extent on mass media sources of information about innovations--given the lack of information among peers (Bass 1969; Gatignon and Robertson 1985).

The two-step model is very one-sided in its structure. It suggests a dominant opinion leader in-touch with the mass media who exerts homophilous influence on a set of passive followers. The limitations of this model are well-documented (Weimann 1982; Gatignon and Robertson 1985) but central to these limitations is the one-way direction of influence. It assumes only opinion giving; however, opinion seeking and opinion sharing are also prevalent.

The model which we propose (Figure 1) has its foundations in social exchange theory (Homans 1961; Blau 1964, 1974). The central construct is reciprocity; that is, social interaction will continue only if mutually rewarding. In Blau's view: "Social exchange...is limited to actions that are contingent on rewarding reactions from others and that cease when these expected reactions are not forthcoming" (p. 6). As related to interpersonal communication, influence is an exchange relationship with associated costs and benefits for both parties. The continued occurrence of personal influence is contingent upon an exchange equilibrium whereby both parties benefit approximately equally from the influence transaction.

Personal Influence as Exchange

Most personal influence for consumer products and services occurs at an informal peer group level. There may be exceptions to this, particularly for visual influence (such as fashion and automobiles) which spans diverse social environments. It might be suggested, however, that even visual influence is most powerful at an informal peer or reference group level, rather than among strangers. For high technology innovations consumers may have to go beyond the boundaries of their peer group in order to find adequate information and expertise. In professional and industry domains, these consumers may be more likely to seek influence in an industry-wide social domain (Czepiel 1974; Leonard-Barton 1985).

The stability of personal influence over time depends on reciprocity. An individual who supplies information to another person obligates the recipient. The recipient must, therefore, furnish benefits in return. These benefits may be tied to providing information for other product categories, since most research suggests the situational nature of influence; that is, opinion leadership varies by product category. The reciprocal benefits might also be based on voicing explicit gratitude in order to reduce the level of debt.

Figure 1 schematically represents our exchange theory model of interpersonal influence. The left side of the model takes the role of the influencer and examines the benefits and costs of providing influence; the right side takes the role of the influencee and suggests the associated benefits and costs of seeking information from personal sources. The center of the model conceptualizes a set of factors which enhance the probability of interpersonal influence.

Information Giving

The transmission of influence is a function of the cost/benefit analysis by the potential influencer. This analysis is rarely explicit, as in economic transactions, but is subject to the same rules of utility maximization as in economic decisions. Indeed, Blau (1974) has suggested that diminishing marginal utilities apply, in that if an influencer is constantly asked for information, the social value of being asked declines over time. Similarly, from the point of view of the influencee, initial advice is worth more than later advice (diminishing marginal utility), assuming equivalent information content.

The potential rewards from assuming the influencer role relate to decision support and justification and to social status and power. The potential costs include the social obligation incurred, the time commitments made to information giving and the risks of providing inappropriate advice.

Benefits of Information Giving

A major incentive for assuming the influencer role is to gain support and justification for a purchase decision. In a sense, the information giver may be seeking the legitimation of friends in order to overcome cognitive dissonance. Previous research has tended to show that information giving is at its height immediately following purchase and declines with the passage of time.

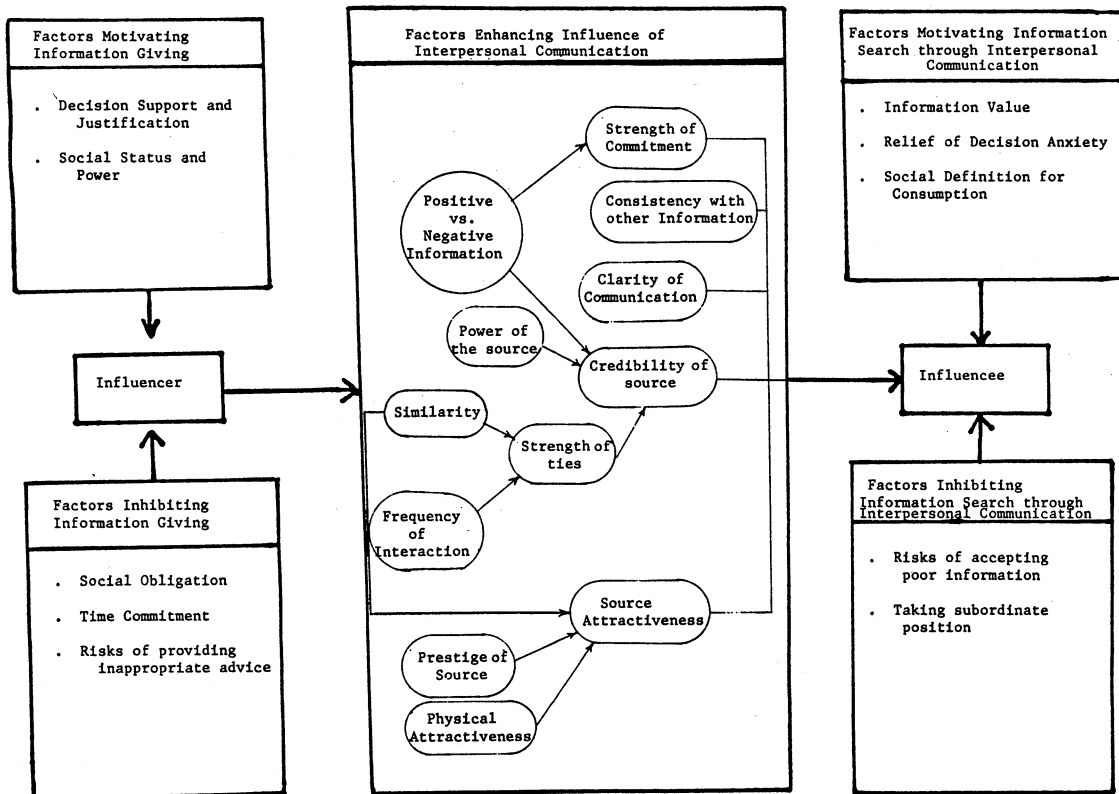

A second major benefit from information giving is social status and power. The act of information giving places the influencer in a superior position. By providing information, the giver makes a claim for recognition and status. Influencees, in turn, incur obligations and must demonstrate gratitude for information received or provide other services in return.

Costs of Information Giving

Much as influencees incur a social cost for receiving information, influencers may also incur a social cost "for being listened to." If the influencer has been given free rein to demonstrate knowledge in one domain of

FIGURE 1

AN EXCHANGE THEORY MODEL OF INTERPERSONAL INFLUENCE

consumption, it might be expected that he or she should reciprocate by receiving knowledge in another domain of consumption. Alternatively, any social relationship which is one-sided will be unstable, since the costs of information for the receiver will be too high. This will lead to resentment at constantly being in a subordinate position and to a breakdown in communication.

There are also time commitment costs associated with information giving. These costs may be high in a work environment, as studied by Blau, where "experts" may be accessed unduly and information giving may come to be resented. It is conceivable that this could also occur in certain high technology areas of consumer behavior. Rogers, Daley and Wu (1982), for example, found that the most likely influentials (persuaders) for personal computers had the highest levels of experience/expertise. Such individuals would seem least likely to receive purchase decision justification benefits and might be less interested in social status benefits. If so, the costs of continually providing personal computer advice could quickly exceed the rewards.

Finally, there are risks associated with the provision of information. These risks include the probability of inappropriate advice for a particular recipient and the resulting problems if recipients hold the influencer accountable. These risks may be assessed to be high for friends whose utility functions are unclear or for new technologies where long-run performance is unclear.

Information Seeking

The reception of information is also governed by cost/benefit analysis. The potential rewards relate to the value of the information, the relief of decision anxiety, and the social definition provided. The potential costs include the risk of poor information and the assumption of a subordinate position.

Benefits of Information Seeking

The most obvious benefit of soliciting information is the value which it provides for decision-making. Information from personal sources may be of particular value if objective non-social information is lacking or is conflicting. It may also be perceived that interpersonal communication is less biased than change advocate information, such as advertising and sales personnel.

Interpersonal communication may also relieve decision anxiety. The recipient may be able to gain confidence from the prior experience of peers, or may be able to avoid extensive information seeking and processing by relying on personal influence. Blau (1974) has suggested a decision value in simply being able to "think-out-loud" with a peer.

Information seeking from friends may also be important in defining group standards for the recipient. This suggests that various consumption domains are socially defined, as in fashion and automobiles. The individual may check with relevant others in order to determine the appropriateness of certain consumption decisions. Such information seeking, or social checking, will be most prevalent when the individual has high identification with the group or a high desire for assimilation with the group.

Costs of Information Seeking

As in all information seeking, the information gained may be poor; that is, erroneous, biased or incomplete. The decision value of personal sources for many products may be overstated due to the small sample sizes of experience which informal opinion leaders generally possess. This raises the interesting question of the relationship between opinion leadership and expertise. In consumer research on stereos, Jacoby and Hoyer (1980) found a

strong positive correlation between opinion leadership and expertise. In research on home computers, Rogers, Daley and Wu (1982) found that the opinion leaders most likely to persuade later adopters were those who were most experienced and highest on expertise. In research with a professional group (dentists), Leonard-Barton (1985) focused on national experts rather than local opinion leaders, implicitly suggesting that friendship-based opinion leadership may not correlate highly with expertise in this professional domain. The Leonard-Barton research is useful also in focusing on negative influence, whereas most research on interpersonal communication focuses on positive recommendations.

Information seeking also incurs the cost of assuming a subordinate position. Individuals may have different levels of tolerance for taking this position, but for almost all consumers it will be intolerable in the long-term unless reciprocity occurs. Such reciprocity could result from taking the opinion leadership role in other consumption domains or from more general patterns of social exchange and reciprocity, not necessarily tied to consumption.

Factors Enhancing the Influence of Interpersonal Communication

The relative influence of interpersonal information exchange is moderated by the set of factors specified in the center of Exhibit 1. The essence of these factors is that the potential for influence is a function of the level of motivation in information search combined with the level of incentive in information giving. The degree of influence depends on the perceived attributes of the source and the perceived nature of the communication message.

Perceived Source Characteristics

Two aspects of the source explain the extent to which an individual influences others. The first deals with the credibility of the source, and the second with the attractiveness of the source. Both notions have been developed in communication theory. However, the individual nature of interpersonal communication adds new elements to the theory, beyond those which are typically pursued in the mass communication context. In general, the degree of interpersonal influence increases as the source is perceived as more attractive and as the source credibility increases.

Source attractiveness. The attractiveness of a source is determined by the individual's prestige, similarity to the receiver, and physical attractiveness. The mechanism by which attractiveness enhances interpersonal influence is the greater attention paid to the communication (Sterthal and Craig 1982).

Source credibility. The source credibility literature borrows more from cognitive theories. A highly credible source is typically more persuasive than a less credible source (Brock 1965) because the high credibility of the source inhibits counter-argumentation (Sterthal, Dholakia and Leavitt 1978).¹ This corresponds also to the implications of a Bayesian model of information integration (Gatignon 1984). The two main determinants of credibility are the power of the source and the strength of ties between the source and the influencee.

The communication literature has concentrated on the power of the source as the major determinant of source credibility (Aaker and Myers 1982). The main type of power that has been studied is the expertise level of the source. It is clearly an essential determinant of the credibility of a source as the uncertainty associated with information is lower for a knowledgeable source than

generate a greater support argumentation in the receiver's cognitive responses.

a novice. However, although the source is an expert, the information must be communicated at a technical level which can be understood by the recipient. Therefore, personal influence will be more readily accepted if the information is communicated at the technical level at which the potential recipient is knowledgeable and comfortable.

Other types of power, such as coercive power, can also moderate the degree of influence of interpersonal communication when dealing with communication between parents and children or between group members (including family) where certain levels of coerciveness can exist. This type of power might not lead to a greater credibility of the source, but can determine the extent to which the information will be used by the recipient of the information.

Further determinants of the credibility of a source can be derived from the concept of the strength of ties (Granovetter 1973, 1983). The strength of an interpersonal tie is defined as the "combination of the amount of time, the emotional intensity, the intimacy (mutual confiding), and the reciprocal sources which characterize the tie" (Granovetter 1973, p. 1261). The stronger the tie, and therefore the greater the emotional intensity and intimacy between two individuals, the greater the credibility of each of these individuals to the other. According to Granovetter, the strength of the interpersonal tie is greater between individuals who are similar and between individuals that interact frequently. Consequently, personal influence will be more readily accepted from sources who are perceived to be similar to the recipient. Also, personal influence will be more readily accepted from sources who interact frequently with the recipient. These similarity and frequency of interaction concepts are, in fact, indicators of a more general level of social integration which provides an individual with access to information available within the social system. More specifically, the credibility of the source depends on the past experience that a recipient has with the advice and information given by the source. Therefore, personal influence will be more readily accepted from sources who have low variance in their previous recommendations. In other words, potential recipients will extrapolate from their previous experience and the accuracy of prior recommendations by the source (Barone and Byrne 1984).

Communication Characteristics

A message contains information which is being given to the recipient. However, there is uncertainty as to what the information really means. The degree of uncertainty or confidence associated with a piece of information acts as a weight determining the degree of persuasion of the message. There are three main determinants of the uncertainty associated with a message: the clarity of the message, the consistency with other information, and the strength of the source commitment.

Clarity of the message. Personal influence will be more readily accepted if the signals sent by the source are high in clarity. High in clarity refers here to the lack of ambiguity in the communication, or the absence of noise in the communication (Shannon and Weaver 1949). As indicated earlier, in terms of the power of the source, technical expertise is not sufficient for information to be used by the recipient. Adapting the message so that the information is communicated at the technical level at which the recipient is knowledgeable and comfortable leads to a clearer message and therefore to a lower uncertainty associated with the message.

Consistency with other information. The degree to which information from one source is compatible with other information that the receiver has is a determinant of influence potential. The consistency of the information with other information enhances the acceptance of the

1. Although Sterthal, et. al. (1978), have hypothesized an interaction of source credibility with prior opinions, a less credible source would be more persuasive if the receiver's prior opinion is positive because it would

information by the receiver (Howell and Burnett 1978). In fact, the recipient will evaluate new information against the prior opinion and the strength of (uncertainty associated with) this opinion (Wyer 1974). The consistency is important since previous information creates expectations and individuals react differently to confirmation or disconfirmation of expectations (Oliver 1977).

Strength of source commitment. The uncertainty attached to the message depends on the strength with which the information giver has committed himself or herself to the recommended behavior. The greater the commitment that the influencer has made to the recommended behavior, the greater the acceptance of the recommendation by the receiver. For example, if the source has bought the technology, the weight given to the information by the receiver will be greater. This, however, depends also on the type of information being given.

Positive information might be discounted, particularly, if the source has committed to the innovation. The reason for the discounting lies in the possibility of attributing the information to the source's motivation to reduce cognitive dissonance. This explains why negative information is more important in influencing the decision to adopt an innovation. In addition, the role of negative opinions of experts in blocking diffusion has been empirically demonstrated (Leonard-Barton 1985), as well as the importance of negative information when making a decision to adopt under time pressure or distraction (Wright 1974). Therefore, the nature of the information and whether it supports or negates an adoption decision has a major impact on the degree of influence.

Conclusion

This paper has developed a basic concept of diffusion theory: interpersonal influence. The proposed model offers explanations as to (1) why individuals give information to others, and (2) why individuals take information from others. The model also predicts the extent to which the information communicated influences recipient behavior.

We have systematically integrated a set of factors into a model explaining and predicting interpersonal communication effectiveness. This element of diffusion theory is crucial to understanding the rate of adoption of innovations, when affected by social imitation.

This model is the first stage in a research program centered on the role of interpersonal influence in the diffusion of innovations. The model remains to be tested. This can proceed in two complementary directions. The first direction consists of separately testing each of the relationships hypothesized in this paper. The second direction is an overall test of the model. Although the first approach would involve experimental research designs in the laboratory, the overall test of the model should be performed in the field to take advantage of the natural variation in the constructs of the model. This would also enhance the external validity of the model.

PRODUCT ENTHUSIASM: MANY QUESTIONS, A FEW ANSWERS

Peter H. Bloch, Louisiana State University

Abstract

Product enthusiasts represent significant marketplace forces because of their high levels of information seeking, innovativeness, and opinion leadership. Enthusiasm is described and placed within an involvement theory context. A number of additional issues are addressed, including differences among enthusiasts, motivations for product enthusiasm, and influences of the enthusiast on the marketplace. Particular emphasis is placed on enthusiasts' role in the diffusion process.

Introduction

The prevalence of low involvement among consumers has certainly attracted considerable research attention (see Bowen and Chaffee 1974; Houston and Rothchild 1978; Robertson 1976; Tyebjee 1979). This attention is not surprising since even casual observation will reveal that consumers do not deeply care about most of the products they own and use. Additional investigation, however, uncovers instances of high product interest and involvement. For example, consider the following statements by a person highly involved with guns:

The thing about shooting, you see, is that if you're serious about it, it tends to be an all-absorbing kind of sport. It's like you're a computer and its filling up all your memory, it's eating up all your thinking time. And after a while, shooting becomes the only thing that's interesting anymore. (Carr and Gardner 1985 p. 36).

Other examples of high product involvement include the personal computer buff who spends hours hooked into on-line bulletin boards and the clothes horse who owns 75 pairs of shoes. A simpler, generic term referring to high levels of product involvement is product enthusiasm.

Enthusiasts are significant for a number of reasons. First, they constitute important market segments. For example, cooking enthusiasts are predicted to spend over \$62 billion on gourmet foods and cooking equipment by 1990 (Zenka 1983).

Enthusiasts are also important for what they do as well as for how much they buy. These individuals tend to be information seekers, innovators and opinion leaders for the product classes of interest. As a result of these behaviors, enthusiasts play a potentially important role in the transfer of new product technology to other consumers. In exploring product enthusiasm, a number of questions arise including what is the nature of product enthusiasm, are there different types of enthusiasts, and what is the impact of this force in the marketplace. These and other questions are discussed below.

What Is Product Enthusiasm?

Product enthusiasm reflects product involvement at high levels. Thus in defining enthusiasm, it is necessary to define involvement which generally concerns the amount of interest or concern a consumer has with a product at a given time (Mitchell 1979). In considering the nature of involvement, Tyebjee (1978) devised a very succinct approach. He posited that levels of involvement are represented by the amount of time a consumer spends thinking about the product class. Thus, product involvement represents a continuum. Canned corn, scissors, light bulbs and the like have been termed low involvement goods and typically occupy one anchor of the continuum. Such

products may be depended upon or used frequently, yet the consumer does not care or think much about the product.

Durable goods such as freezers, office furniture, and cars are commonly termed high involvement products (see Chaffee and McLeod 1973). If one applies Tyebjee's rule, however, similarities between low involvement and high involvement items are often more striking than their differences. For consumers spending little time thinking about light bulbs and the corn, there is an almost permanent state of low involvement. For cars, freezers, and furniture, there is likely to be involvement, but only at certain times: when the product fails or a purchase is contemplated. High financial stakes are involved in such cases and most consumers will be concerned about the product class due to the high purchase risks. Outside of these specific situations, however, low involvement tends to dominate. Most of the time, freezers, cars, and furniture do not intrude on consumers' thoughts any more than the canned corn does.

Moving up from low involvement, there is a region characterized by moderate consumer interest. Here, the consumer thinks about the product more frequently and at occasions outside the purchase domain. For example, a person may enjoy taking photographs and using a camera; however, this activity may only occur during travel or special occasions. The person is not an avid camera buff, but has a moderate interest in photographic equipment and may occasionally enjoy talking about the product class with friends or looking at camera magazines.

Product enthusiasm, which is the focus here, refers to the high end of the involvement continuum. Webster's definition of enthusiasm helps provide a portrayal of the concept: "a strong excitement of feeling on behalf of a cause or subject; ardent zeal or interest." In the case of enthusiasm, the product in question plays an important role in the consumer's life. Product usage may be a hobby for the consumer and a source of pleasure along sensory or aesthetic dimensions. Another gun owner gave an example of the strength of the relationship between an enthusiast and the product:

My gun is practically my best friend. It goes with me from room to room...It's my buddy (Carr and Gardner 1985, p. 98).

Product ownership should also be considered in elaborating product involvement or enthusiasm. Very low levels of involvement may or may not be associated with product ownership. For example, interest or involvement in the product class of staplers may be low among those who do not own or use staplers as well as among those who do. On the other hand, product ownership is not required for enthusiasm. For example, a nine year old boy may care a great deal about motorcycles and many thousands of people maintain high enduring involvement with sports teams. In both of these cases, the object of the enthusiasm is not possessed or owned, yet high involvement exists.

Are There Different Types of Enthusiasts?

One way to examine whether different types of enthusiasts exist is by focusing on the duration of a particular enthusiasm. In particular, one might distinguish between a constant and rotating enthusiasms. In the first case, involvement with a particular product is maintained at high levels for a long period of time. In the latter case, a consumer may be prone to enthusiasm, but the target changes over time. For example, some consumers are technology buffs, enamored with a series of different

products as new types of electronics gear come on the market. For such consumers, enthusiasm may move over time from personal computers, to compact disc players, to video equipment. Here the involvement is based in the general characteristics of high technology products, rather than in the benefits of any one product class. In the case of constant enthusiasm, a product's benefits are highly valued and considered to be uniquely associated with that one good.

Other differences among enthusiasts may also be speculated upon. While research has not examined the question, it is doubtful that car enthusiasm is fundamentally different from camera or stereo enthusiasm. In these cases, the product is the focal point. However, there may be differences between product-based enthusiasm and activity-based enthusiasm. For example, automobile enthusiasm may have a different character or intensity than a skiing enthusiast's involvement with ski equipment. Enthusiasm for intangible products such as sports teams also may be different than other types of product attachments. The question of enthusiasm types certainly warrants additional study.

Why Become and Remain a Product Enthusiast?

Product Usage Satisfactions

Based on the work of Csikentmihalyi (1975) and other researchers (Bloch and Bruce 1984; Bryan 1977), several possible motivations for product enthusiasm may be proposed. The first motive reflects the satisfaction derived from product usage. A gun enthusiast described a first shooting experience as follows:

The first time, it was so funny, I never shook so hard in my whole life, about anything. The adrenaline rush is really something (Carr and Gardner 1985, p.8)

It is likely that wine connoisseurs and yachtsmen also arrive at their state of enthusiasm at least partially via the experience of product usage satisfactions. In these cases, the attachment to the product seems to be a conditioned response to the pleasure obtained during product usage.

Mastery Needs

Product attachment may additionally result from desires for skill development or competition with an ideal self (Fleishmann 1981). For example, if a person performs well at tennis, this satisfies an achievement need and the consumer may develop an enthusiasm for tennis equipment as well as for the game itself. Similarly, getting a difficult BASIC program to run successfully on a home computer may heighten levels of involvement with computer equipment. Thus, product enthusiasm can occur as a conditioned response to the feelings of mastery. The acquisition of a body of product information also may lead to feelings of mastery. The development of expertise can enhance the self and make the enthusiast feel more in control of his/her environment.

Uniqueness Needs

The role of enthusiast can augment an individual's feelings of uniqueness (Snyder and Fromkin 1980); that is, being known as an expert or enthusiast for a particular product is one way to feel distinctive and become noticed. For example, being introduced at a party as a wine connoisseur or a classic car collector can stimulate conversation, provide attention, and enhance feelings of superiority. In such cases, the enthusiasm, rather than the product, provides important benefits for the consumer.

Affiliation Needs

Product enthusiasm also seems to occur as a result of needs for companionship: interest in a product class can

provide convenient access to groups and a circle of friends. Membership in a computer users', garden, or canoeing club may be more important than the products themselves to many consumers. In addition, many people take on their spouse's involvement as a way to spend time with their otherwise preoccupied partner.

Enthusiasm also occurs as a response to reference group influence. As noted by Tauber (1972):

If group status is associated with one's knowledge of the product category and nature of holdings (e.g., size of record collection), then peer group influence may motivate the person to develop an interest in the product (p.48).

In such cases, the involvement may not be as high because it is less voluntary. Likewise, some product interests seem to result from sex role demands. Examples include fashion involvement for women and automobile involvement for adolescent males.

How Does Product Enthusiasm Affect Technology Transfer?

Although product enthusiasm itself may prove to be an interesting consumer state, its importance to consumer researchers is primarily based in its outcomes that influence the diffusion of new products and new technology. These behaviors include information search, innovativeness, and opinion leadership.

Information Search/Product Knowledge

As a result of strong product interest, the enthusiast engages in active and continuous information search pertaining to the product (Bloch and Richins 1983; Corey 1971; Csikentmihalyi 1975). For instance, the audiophile subscribes to stereo magazines, visits electronics stores frequently, and seeks product information from other stereo buffs. In terms of time expenditures, information seeking may be more significant than product usage for the enthusiast. The yachtsman, for example, may devote considerably more time to reading sailing books and magazines than in sailing itself. This ongoing information hunger underlies the success of special interest magazines such as Gourmet, Road & Track and Cycle. As a further example, consider the field of personal computers where new magazines were introduced at the rate of one per week in 1984 and where the top 25 computer magazines have a combined circulation of 5.9 million (Reiling 1984).

Information seeking provides significant satisfactions for the enthusiast. Besides developing expertise, search may substitute for purchase when budgets are tight. Hirschman (1980) suggests that information gathering allows vicarious adoption of new products that the enthusiast would very much like to own, but cannot for one reason or another. For example, car magazines are dominated by roadtests of new cars, many of which are expensive exotics (e.g. Ferraris and Lamborghinis costing \$75,000 or more). It is reasonable to assume that subscribers are not reading these roadtests to assist in upcoming purchase decisions, but to vicariously own and drive cars that arouse them. An even clearer portrayal of enthusiasts' innovativeness pertaining to information is provided by Infoworld, a weekly personal computer magazine (with an appropriate name), that recently began air shipment to subscribers in response to their demand for the most current product class information.

Along with the active information search noted above, enthusiasts also tend to be vigilant and sensitive for product information to which they are exposed in an accidental manner (Spence and Engle 1970). For example, the car enthusiast is often quick to spot new or unusual vehicles on the road that go unnoticed by others less involved in the product class.

Information seeking, whether through the media, retail visits or personal sources, results in increased product class expertise, a common distinguishing feature of the enthusiast. This specialized knowledge aids product

selection, provides negotiating power when in the marketplace (Brucks 1985; Moore and Lehmann 1980), and makes the enthusiast influential among other consumers (Leonard-Barton 1985). The expertise of the enthusiast also enhances the ability to recall and process product information (Johnson and Russo 1984; Sujana 1985). According to Alba (1983), product experts recall more advertising information and more sophisticated and important information than do less knowledgeable consumers. Product enthusiasts are also better able to evaluate new product information because they have superior understanding of how new information relates to their existing knowledge base (Beattie 1982).

Innovativeness

In addition to the vicarious innovativeness possible through information search, there is also a positive relationship between enthusiasm and actualized innovativeness (Baumgarten 1975; Feldman and Armstrong 1975; Tigert, Ring and King 1976). The involvement/innovativeness connection is not surprising because persons with strong product class interest are likely to learn of an innovation soon after it is introduced during the course of ongoing information gathering. Awareness of an innovation is, of course, the minimum prerequisite for adoption of the new product. In addition, the enthusiast's concern with the product class increases performance expectations that may only be met by the latest, most advanced products (Beattie 1982; Fleischmann 1981).

One may also speculate that innovativeness is influenced by a satiation effect on enthusiasm. Since the product class in question provides the enthusiast with satisfaction and excitement, frequent adoption of new product offerings may be necessary to renew the desired product "high." This need for the newest goods may be particularly pronounced in categories where product changes are noticeable and frequent (e.g., fashion goods, high technology goods).

It is not the purpose here to make product enthusiast a new term to describe innovators, however. When enthusiasm is centered on product classes where change is frequent and new product introduction is common, then the enthusiast is likely to be innovative due to high awareness levels, desires for the latest technology and high performance standards. There are cases, however, where product enthusiasm is not associated with innovativeness. An antique furniture buff may have a great deal of enthusiasm, but little apparent innovativeness. In looking at innovators, one may find individuals who are highly involved with products, individuals who are involved with newness, and individuals who are involved with both.

Opinion Leadership

Not only are enthusiasts likely to be innovative, but they also tend to disseminate news about the innovations they discover. A number of years ago, Dichter (1966) described how product enthusiasm results in opinion leadership.

Experience with the product (or service) produces a tension which is not eased by use of the product alone, but must be channeled by way of talk, recommendation, and enthusiasm to restore the balance (provide relief)... In many instances it is talk about the product which confirms for the speaker his ownership and joy in the product, or his discovery of it (p. 148-149).

Since this statement was made, several other researchers have examined the connection between product involvement and opinion leadership (Bloch 1981; Summers 1970; Tigert, Ring and King 1976). Corey (1971) reported that opinion leaders are distinguished by their:

...unique involvement with market topics. Compared to nonleaders in a particular topic, opinion leaders read more media about related consumer issues; they are more knowledgeable about related new consumer

product developments; they participate more often in related consumer activities; and they derive greater satisfaction from those activities (p. 52).

Researchers have long noted that consumers rely on opinion leaders for prepurchase information; only recently, however, has the extent of such reliance been noted (Hirschman and Wallendorf 1982; Leonard-Barton 1985; Price and Feick 1984). Because enthusiasts enjoy talking to others about the source of their enthusiasm, they are readily identifiable, and potential buyers may seek them out to borrow needed product information rather than conducting an extensive search from scratch. One could argue that the low levels of prepurchase search found in many studies are the result of consumers' efficient consultations with enthusiasts rather than reflecting a lack of motivation or effort.

Can Enthusiasm be Harnessed?

Product enthusiasts are considered here to be significant forces in the marketplace, particularly in the case of new product acceptance. This point begs the question of how enthusiasm can be harnessed to benefit providers of new products. In this vein, it is useful to consider ways in which marketing strategy can be tailored to enthusiast segments. It should be noted, however, that enthusiasm is not relevant to all product classes.

Enthusiast Products

While consumers can become enthusiasts for nearly any sort of good, certain product classes seem to generate a disproportionate number of aficionados. Complex products and hedonic products are two product categories that generate relatively high levels of enthusiasm.

For most consumers, a high level of product complexity is undesirable. Complexity increases buyer uncertainty and risks of disappointing product performance after purchase. In examining enthusiasts, however, one may find that these consumers are attracted rather than repelled by product complexity. In fact, product classes offering complexity and variety are among the most likely to attract enthusiasts (Fennell 1978). Such products offer considerable potential for knowledge acquisition and dissemination as well as for sensory stimulation. Since product enthusiasm implies a hobby-like interest in the product, more complex products would seem to hold the consumer's interest longer.

It is also expected that complex, high performance brands within a product class will be most appealing to the enthusiast. For example, the camera buff is likely to prefer Nikon's or Canon's 35mm models, with their many settings and accessories, over Kodak's Instamatics. While product complexity can be indicative of superior performance, complexity in and of itself may be a more important characteristic. This is particularly likely in product classes such as compact disc players or sports equipment where objective product performance is difficult to assess. For enthusiasts, complexity may be a surrogate indicator of quality much as price is used by many consumers. Product planners should also note that product complexity can be introduced to relatively simple products. Audio cassette manufacturers, for example, have successfully called attention to brand differences and complexity in a product class which at first glance appears quite basic.

Traditional theories of new product diffusion may have to be modified in the context of product enthusiasm. These theories posit a negative relationship between product complexity and new product acceptance, assuming that complex innovations puzzle consumers and forestall adoption (Derow 1982; Rogers and Shoemaker 1971). It might be a significant mistake, however, to direct research departments to design the simplest new products possible when the target market is comprised of a significant number of enthusiasts. The complexity of an innovation can in fact be the heart of its appeal to enthusi-

asts. For example, in 1984 the largest selling new video game for personal computers is a flight simulator that entails dozens of control functions and a thick manual of operations (Infoworld 1984).

Recreational or hedonic products are also likely targets of enthusiasm, provided that their usage is also varied, pleasurable, or stimulating (Csikentmihalyi 1975; Neulinger 1974). For example, a tennis buff may be highly involved with nearly every type of tennis gear except tennis balls because of the simplicity and uniformity of the product across brands. In sum, products having a recreational component that also offer novelty and complexity are strong candidates for product enthusiasm. Product Development

To successfully reach enthusiasts and take advantage of their influence, marketers must be prepared to innovate and improve their products or risk market share losses. Adidas and Puma, once strong competitors in the American running shoe market, lost considerable share in the late 1970's when they failed to keep pace with the technological advances offered by competing firms. On the other hand, enthusiasts' willingness to try a new brand if it promises superior performance helped a small firm, New Balance, move from obscurity to a strong competitive position in the running shoe industry (Merwin 1981). Brand name apparently does not offer a great deal of protection when serving enthusiasts. This is because enthusiasts' advanced knowledge of products and product attributes puts them in a good position to spot technological advances even in unfamiliar brands.

Other Strategic Issues

In encouraging enthusiast adoptions, pricing issues become salient as well. In some instances, enthusiast demand is inelastic. As noted by Kotler (1980), some buyers stand ready to pay a higher price than others because the product has high present value to them. The present value of new products to enthusiasts may be very high, being based on access to the latest product features and possible self-enhancement resulting from the scarcity of the product (Snyder and Fromkin 1980).

It is also possible that enthusiasts are relatively insensitive to price hikes. Once a desired performance level is achieved, it is doubtful whether price increases will cause an enthusiast to accept lower performance standards (Fleishmann 1981). In cases where performance gains are perceived as substantial at a concomitant price increase, the enthusiast also appears willing to make the additional outlay. State of the art running shoes now cost \$80 to \$120 as compared to \$50 or less a few years ago; nevertheless the avid running enthusiast has absorbed the price increase to remain at the leading edge of technology (Runner's World 1984).

New product developers are likely to find the task of reaching enthusiasts with promotional messages to be a relatively easy one. As noted earlier, product enthusiasts are distinguished from other consumers by their hunger for product information. Thus, messages targeted at an enthusiast audience are more likely to be attended to and can have higher information content than that aimed at general audiences (Beattie 1982; Tyebjee 1979).

In considering the importance of the enthusiast in the marketplace, the following statistic provides a summary example. A study by Car and Driver (1978) magazine found that 78% of its enthusiast readership gave automotive advice an average of 19 times a year. It is reasonable to assume similar rates of information transfer with other types of enthusiasts and other product classes.

Can Enthusiasm be Created?

Because of its impact in the marketplace, encouraging product enthusiasm can be a legitimate marketing objective. Chevrolet dealers sponsor Corvette clubs and Lotus Development, a major software producer, supports both a magazine and an on-line users group for personal

computer enthusiasts. These activities reinforce existing enthusiasts and provide resources and support for relative newcomers to the product involvement.

Note that pricing also plays a part in creating new enthusiasts in a product category. Obviously, the higher the initial outlay to become a product user, the smaller the number of participating enthusiasts. There are certainly fewer sailboat enthusiasts than movie or car stereo buffs. This conclusion results from the trialability attribute in determining adoption (Rogers and Shoemaker 1971). If a product is affordable and product usage proves especially enjoyable, enthusiasm can grow. Later, such enthusiasm elicits information seeking and increased expertise. This expertise may in turn raise performance demands and motivate the purchase of more advanced and expensive versions of the product in question. Simple power tools may be replaced by a woodworking shop, the aluminum tennis racket with a graphite model, and the video game machine with a home computer.

Conclusions

There are certainly other important questions regarding product enthusiasm that warrant research attention. Perhaps the most intriguing is the ways in which enthusiasm develops in a consumer. While some consumers become highly involved with a product as an adult for reasons noted above, others appear to develop significant product interests and attachments early in life. Therefore, concepts such as consumer socialization and family influence play a part in furthering the concepts of involvement and enthusiasm. For example, many car enthusiasts point to the origins of their interest in childhood, the building of car models or the racing of slot cars or go-karts. Clothing, gun, and sports enthusiasm also are likely to start in childhood. Speculating further, the extent to which enthusiasm begets enthusiasm bears investigation. It would be interesting to determine the proportion of product enthusiasts who have parents with the same interests.

Along with specific product enthusiasms, the issue of involvement proneness and its development are of interest. Some people seem to need an enthusiasm of some type, with the product choice being of less significance. Again the role of parental and peer group influence could be linked to this more generic question.

Taking the notion of enthusiasm to its highest extension may also provide important research directions, but more for sociologists or public policy makers than for marketers. At highest levels, product enthusiasm might be considered product obsession where the product is essentially all that the individual thinks about. Examples might include the somewhat mild case of a teenaged boy who thinks so much about his car, and cars in general, that his grades suffer, all the way to the bulimic who is preoccupied with food, and the drug addict who is obsessed with finding the next fix. In general, the study of high consumer involvement and product enthusiasm is one where there are many questions and many options.

THE EFFECT OF TV PROGRAM INVOLVEMENT
ON INVOLVEMENT WITH COMMERCIALS

C. Whan Park, University of Pittsburgh¹
Gordon W. McClung, University of West Virginia²

Abstract

The present study examines the effect of the audience involvement with TV programs on their involvement with the commercials. Two different types of TV program, cognitive and affective, were experimentally created with three different levels of involvement. The results strongly support the debilitating effect of a higher audience program involvement (both cognitive and affective) on their involvement with the commercials.

Introduction

The contextual facilitation of human information processing has been well documented in the area of cognitive psychology. Several studies have focused on how contextual aspects affect learning (Anderson & Ortony 1975; Barclay et al 1974; Tulving & Thompson 1973) and retrieval (Roediger 1983; Smith et al 1983; Glenberg et al 1973), illustrating the degree to which human memory and language understanding are sensitive to the context within which exposure to a message occurs.

The importance of contextual facilitation is particularly noted in assessing the program effect on audience reactions to advertising (Bandes 1983; Barclay et al 1965; Bello et al 1983; Crane 1964; Davis and Welsch 1983; Kennedy 1971; Krugman 1965; McConnell 1970; Mattes & Cantor 1982; Murphy et al 1979; Soldow and Principe 1981; Webb and Ray 1979; Worchel et al 1975). A principal goal of a television viewer is to view a program in order to fulfill certain underlying needs, rather than to view the commercials aired within the program. As an embedded element in the TV program, a commercial's effectiveness not only depends on its own production merit (initial effectiveness) but also greatly on the audience's reaction to the program. To the extent that contextual cues are important for human information processing and that a TV program affects the audience's commercial viewing, advertising research which is void of the program consideration suffers an ecological validity problem.

Hypothesis Development

The effect of a TV program on an advertisement's effectiveness can be understood with the consideration of: (1) the level of audience involvement with the program and (2) the congruence between program contents and commercial contents in terms of an audience's processing mode (e.g., cognitive and affective processing, Park and Mittal 1985; Park and Young 1986). The present study focused on the former while addressing the implication of the latter in the discussion section.

As audience involvement with a program increases, they are typically expected to allocate more attention to commercials embedded in the program. The relationship between audience program ratings and costs to air commercials in a program are essentially based on this expectation. Findings of television viewers' attentional inertia during program breaks (Anderson 1983) may justify this expectation. The present study suggests that this expectation should be, however, examined in terms of the moderating role of the audience's level of program involvement. Individuals do have control over the amount of attention devoted to a particular stimulus whenever such decision is deemed necessary (Kahneman 1973). Jacoby, for example, argued that consumers

will not generally be overloaded because they are highly selective in how much and just which information they access. When audience involvement with the program is high, thus requiring a greater processing demand, such needs become genuine. In this situation they will allocate higher levels of attention to the program at the expense of commercial attention. This will lead to lower involvement with commercials than would be expected on a pure attentional inertia basis. We therefore expect a curvilinear relationship between program involvement and commercial involvement: subjects' involvement with commercials will be highest at moderate rather than a low or high level of program involvement. (Subjects' commercial involvement initially increases with increases in program involvement up to a moderate level, thereafter commercial involvement decreases with increases in program involvement.)

This curvilinear pattern is expected to hold across the two types of program involvement. Specifically, previous studies distinguished two types of involvement: cognitive and affective (Park & Mittal 1985; Park & Young 1986). The cognitive motive is utilitarian in nature while the affective motive is experiential (Holbrook & Hirschman 1982). Describing these two motives in the context of a TV program, one watches a TV program to gain knowledge about the particular subject matter, to examine his/her perspective relative to others, to take one's position about an issue, and to entertain his/her intellectual curiosity in the case of the cognitive motive. In the experiential view, the reasons for watching a TV program are essentially aesthetic in nature and hinge on an appreciation of the program for its own sake, apart from any utilitarian function that it may or may not perform. The criteria for experiential viewing encompasses a wide spectrum of feelings and emotions which are not utilitarian in nature, including the value-expressive motive (Park & Mittal 1985; Park & Young 1986). When one indulges in fantasies and aesthetic thoughts by role playing of the character or self-identification with a character, he/she is affectively involved with the program. In an information processing context the cognitive motive fits well with piecemeal processing (Fishbein & Ajzen 1975; Anderson 1963) and the affective motive fits holistic processing (Gestalt school's field dependent processing). Emotional arousal is assumed to precede the information processing in the affective motive (Clark 1982; Bower and Cohen 1982; Leventhal 1982) while such is not assumed in the cognitive motive case. It should be noted that programs may not be clearly cognitive or affective and often they are mixed. The present study, therefore, approaches this more in terms of relative dominance rather than exclusive categorical classification.

When an individual's underlying motive for high program involvement is cognitive, the implication of difficulty in processing commercial information is evident. This is due to the heavy processing demand resulting from the piecemeal method of processing program information. When the underlying motive for high program involvement is affective, such processing difficulty will not be as extensive as is the case with cognitively motivated program involvement. This is attributable to the category-based information processing of program information (Fiske 1982; Mandler 1982). However, the emotional arousal created from the high affective program involvement will make it difficult for the viewer to get involved with the commercial (continuously paying attention to commercials). This is expected since high emotional arousal tends to last long (Clark 1982) and interferes with the adjustment process required for commercial information processing. Therefore, for two different reasons, we expect a curvilinear relationship between the level of program involvement and the level of commercial involvement for both types of program.

Methods

This section provides a general overview of the selection and assignment of subjects, the experimental design utilized, and the operationalization of involvement in terms of type and level.

Subjects for the Experiment

One hundred two female subjects were recruited from the general population for the experiment. Subjects were randomly selected from the telephone directory and contacted by phone. A follow-up letter with directions, confirmation of the scheduled time and reiteration of the level of remuneration for participation was then mailed.

Experimental Design

Two factors are examined in this study for the effects of the subjects' program involvement on their commercial involvement: the specific type of program involvement, and the intensity (level) of program involvement. The experimental design for this research is a 2 X 3 fixed-effects model employing two types of viewer involvement with the television program at three levels of involvement intensity. The subjects were randomly assigned to one of the six treatment conditions.

The two types of viewer involvement with the television program were operationalized as:

(a) Cognitive - where the subject is processing issue-oriented information from the television program. Subjects in the cognitive groups will be processing the specific position taken by the main character and/or evaluating the character's position.

(b) Affective - where the subject is identifying with the main character in the television program. Subject's role playing through identification with or projection into the character's situation was manipulated.

The program segments used in the experiment were selected after a review of a series of possible segments by three expert judges. The cognitive program selected for use in the experiment was a 30 minute sequence from Donahue. The affective program selected was a 30 minute sequence from a daily soap opera. The Donahue sequence was a discussion with Maureen Reagan regarding the political implications of the gender gap. The soap opera sequence was from Another World consisting of minimal dialogue with a series of love and relationship scenes embellished by a romantic musical score. The general contents of this program (from the early beginning to the end) consist of the main character recalling pleasant memories about her past love affair with her husband.

Three different television commercials, all representing different brands of hair shampoo, were inserted for each program. One commercial was a fictitious commercial which was created professionally while the other two were real ones. The commercial insertions in the program followed the same sequence as in the real program.

Experimental Manipulation

Experimental manipulations on the type and level of program involvement were performed by asking the subjects to follow the specific instructions noted below. For the low involvement manipulation, no distinction was made between the cognitive and affective program involvement (the same manipulation was performed as noted below).

(a) Low Involvement--cognitive and affective:

Thank you for agreeing to participate in this study. I am interested in what people select to read from magazines. To help create a more natural setting I will turn the television on while you are reading from the selection of magazines that have been provided. You may walk around and stretch if you wish, I only ask that you not leave the

room. Select two magazines and read at least one article from each of the magazines you have selected. I will return in about 30 minutes to ask you questions about your choice of reading(s) from the magazine(s) that you have selected.

(b) Moderate Cognitive Involvement:

Thank you for agreeing to participate in this study. While viewing the following program I would like for you to watch a discussion between Maureen Reagan and Phil Donahue. I would like for you to try to come to an understanding of Maureen Reagan's viewpoint.

(c) Moderate Affective Involvement:

Thank you for agreeing to participate in this study. I would like for you to watch a program where the main character is called Rachel. While you are watching the program try to identify with Rachel and think about how you feel. Rachel will be the first character you will see.

(d) High Cognitive Involvement:

Thank you for agreeing to participate in this study. While viewing the following program I would like for you to pay specific attention to the arguments advanced by Maureen Reagan and the sequence of events. Her arguments, the subsequent discussion with Phil Donahue, and your position concerning the discussion will be an important part of the questions I will ask you after the program.

(e) High Affective Involvement:

Thank you for agreeing to participate in this study. I would like for you to watch a program where the main character is called Rachel. While you are watching the program try to identify with Rachel and think about how you feel. Rachel will be the first character you will see. The program starts at a point in time where Rachel's husband is missing and assumed dead. Try to think about a situation in your past where your loved one has been missing. Imagine you are Rachel as you are watching the program and go through Rachel's experience to the fullest of your ability.

Measurement Instruments

Prior to the main experiment each subject was asked to indicate their level of interest in watching a particular type of programs. Subjects' level of interest in watching daytime soap operas, talk shows, television, movies, and business news were measured on a 7-point scale ranging from "very uninterested" (1) to "very interested" (7). In addition, subjects were asked their date of birth to determine their age.

After viewing the program subjects were asked a series of questions including the involvement measures. Subjects were asked to respond to a series of descriptive scales according to how they perceived the television program. The items consisted of 7-point semantic differential descriptors relating to irrelevant/relevant, means a lot to me/means nothing to me, matters to me/doesn't matter, uninterested/interested, significant/insignificant, vital/superfluous, essential/nonessential. Subjects were then asked to respond to the same descriptors according to how they perceived the commercials.

Results

Manipulation Check of the Subjects' Random Assignment

Tests for the randomization of subjects across the 2 X 3 design consist of measures in two key areas (1) the degree

¹It should be noted that at the beginning of this 30 minute sequence it became evident that her husband was still alive. The balance of the program was dedicated to a romantic memory sequence.

of interest in television watching, and (2) age. The mean differences (the degree of interest in television watching) across groups were not significant ($F = 1.00$, $p < .39$) with an overall mean value of 17.88 (28 represents the highest possible score). The respondent group's overall expressed interest in television viewing was slightly above the neutral level of 16. The second test of random assignment was to examine age differences between and within groups. A random distribution of age was thought to be important because of the possible difference in the sensitivity of the issues (both of cognitive and affective program issues) to subjects of different ages. The average age of respondents was 30 with 5 nonresponses. There was no significant difference in the age of respondents across the six treatment conditions ($F = .952$, $p < .419$).

Manipulation Check of the Experimental Group

Two experimental manipulation checks are called for in the present study. They are the type of program involvement (cognitive vs. affective), and the level of involvement (low, moderate, and high). Pretesting of the manipulations consisted of several stages from relying on 'expert' judgments for prescreening to pretesting with subjects which were not part of the main experiment. The results reveal support for a conclusion of effective manipulation as discussed in the following sections.

Type and Level of Involvement Manipulation. An array of approaches have been utilized in the manipulation of subject involvement from increased payoffs to levels of personal relevance. Measures of the effectiveness of these manipulations have consisted of single item measures of level of interest, importance, personal relevance, or multiple item scales (e.g., Zaichkowsky 1985). These traditional measures of involvement may not be equally sensitive to differences in the underlying motives for involvement such as cognitive and affective motives. These measures are expected to be more sensitive to cognitive involvement as opposed to affective involvement. For example, to go through emotional experiences by projection into the situation of a television character may not be viewed as 'important' though the intensity of emotion may be high when compared to the political ramifications of the gender gap. However, the emotional experience from projection into the characters role will still be sensitive to measures of importance across levels of increasing affective involvement. This leads to an expectation of higher scores on the measures of involvement for the cognitive involvement group than in the affective involvement group although the measures will still capture relative differences in the level of involvement.

A 7-item involvement scale, which was adapted from Zaichkowsky's recent work, was applied for the manipulation check of the type and level of program involvement. The results (Table 1) show higher involvement scores ($\bar{X} = 29.22$) for the cognitive group than for the affective group ($\bar{X} = 19.53$) with a significant effect ($F = 19.95$, $p < 0.001$). Equally interesting is the difference in the involvement scores across the three levels of involvement. For both types of program involvement there is a significant increase in the involvement score in accordance with the level ($F = 9.26$, $p < 0.001$).

TABLE 1
PROGRAM INVOLVEMENT

	Type		
	Cognitive	Affective	Mean
L Low	24.12	13.59	18.85
E			
V Moderate	29.18	18.82	24.00
E			
L High	34.35	26.18	30.26
Mean*	29.22	19.53	24.37

*maximum possible score 49.00

Hypothesis Testing

To test the hypothesis, analysis of variance was performed using the degree of involvement with the commercials shown during the television program as a dependent variable. The results (Table 2) reveal a significant main effect of level of involvement ($F = 4.03$, $p < 0.02$) and an interaction effect of level and type of involvement ($F = 5.113$, $p < 0.01$). An examination of the main effect reveals, however, that there is an overall curvilinear relationship between commercial involvement and the level of program involvement. The mean scores show an increase in involvement with the commercials as subjects' involvement with the affective program increases from the low (15.82) to the moderate level of involvement (29.29). There is a decrease in subjects' expressed level of involvement with the commercials at the high level of affective program involvement (to a level of 26.47). The mean scores show a marginal decrease in the level of commercial involvement as cognitive program involvement goes from low to moderate (24.88 to 24.82). There is then a decrease in the expressed level of commercial involvement (to 22.65) as program involvement increases to the high level.

TABLE 2

	COMMERCIAL INVOLVEMENT		
	Type		
	Cognitive	Affective	Mean
L Low	24.88	15.82	20.35
E			
V Moderate	24.82	29.29	27.06
E			
L High	22.65	26.47	24.56
Mean*	24.12	23.86	23.99

*a maximum possible score 49.00

The relationship between the cognitive program involvement and involvement with the commercials at the low and moderate levels is in an interesting contrast from that between the affective program involvement and involvement with the commercials at the same levels. The reason why there is no increase in involvement with the commercials from the low to the moderate level may be due perhaps to the subject's greater sensitivity to cognitive strain with the cognitive program than with the affective program. However, for the cognitive program the hypothesis of the present study concerning the effect of the high program involvement on involvement with the commercials is still supported.

The directional presence of the interaction effect is accounted for by the difference in commercial involvement between the subjects in the two types of programs and their level of involvement with the program. When the subjects watched the cognitive program at a low level of involvement, their involvement with the commercials was higher than those who watched the affective program ($t = 2.52$, $p < 0.0017$). This may be due to the fact that at a low level of involvement, it is easier to process information of the cognitive program than the affective program since the former does not require emotional arousal, which is difficult to achieve at a low level of involvement. This appears to have carried over into involvement with the commercials. However, at the moderate and high levels of involvement, the direction of involvement with the commercial is reversed ($t = -1.28$, $p < 0.211$, and $t = -1.27$, $p < 0.212$ for the moderate and high levels of program involvement, respectively). This is due perhaps to difficulty in maintaining attentional focus on both the program and its commercials by subjects who watched the issue-oriented TV program.

Summary and Implications

Program involvement and involvement with commercials do not necessarily coincide. The relationship between the two is subject to the level of involvement with the program.

At a high level of involvement with the program subjects, involvement with commercials was reduced, compared with subjects who were moderately involved with the program. The curvilinear relationship between program involvement and involvement with the commercial suggests that high involvement with the program has a mitigating effect on subjects' involvement with the commercials.

Several important implications for brand and advertising managers are evident from the results of the present study. Particularly at issue is the question of ad placement within a specific program to maximize ad effectiveness. This issue cannot be adequately addressed by utilizing program ratings and audience demographics since an essential aspect of program-commercial message processing relates to the intensity of viewer involvement with the program and advertisement. To address this issue the advertiser must carefully examine the intensity of viewers' involvement with the program within which an ad will be aired.

Although the results of the present study suggest that high involvement with the program has a mitigating effect on subjects' involvement with the commercials, their expressed involvement with the commercials and the effectiveness of the commercials may not necessarily be equated. The relationship between the two may be further mediated by the degree of congruence in processing mode between the program and commercial while being subject to the level of the subjects' program involvement. This needs to be addressed in future studies.

EFFECTS OF OVER-TIME MEASURES OF VIEWER LIKING AND ACTIVITY DURING PROGRAMS
AND COMMERCIALS ON MEMORY FOR COMMERCIALS

Esther Thorson, University of Wisconsin-Madison
Byron Reeves, University of Wisconsin-Madison

Abstract

Memory for commercial information was examined as a function of liking and change in liking measured over time during television viewing. Four categories of measures were taken during commercials and surrounding programs: mean liking; variance in liking, trend in liking across a segment; and change in liking between programs and commercials. Correlations were examined for simultaneous relations (memory and liking measures at the same point in time), and for proactive and retroactive relations. Significant variance in recall and recognition was explained by the over-time measures, independent of program or commercial content.

Introduction

There appears to be an inverse relationship between the cognitive involvement potential of material presented immediately prior to and subsequent to the critical message and retention of message content. (Bryant and Comisky 1978, p. 73)

Based on an initial sample of 18,000 viewers..., Burke found a direct correlation between the viewer's expressed opinion of the program and this viewer's ability to recall part of the test commercials. (Priemer 1983, p. 3)

Research about program-context effects on commercials is summarized by the two results described above. When program involvement was operationalized by viewer self-report, placement in highly involving programs inhibited memory for commercials (Kennedy 1971; Bryant and Comisky 1978; Soldow and Principe 1981). When liking was similarly measured, commercials in well liked programs showed stronger memory (Priemer 1983; Krugman 1983).

The present study was designed to reconcile these findings using an "on line" measure of program involvement and liking that could be matched with memory for embedded commercials. In addition to an overall assessment of the level of liking in surrounding programs, effects on memory were hypothesized to depend on three measures of activity during viewing: (1) the variability of surrounding judgments; (2) trends over time; and (3) changes in level, variance and trend that occurred between programs and commercials. Finally, effects were not limited to proximal influences of program judgments on memory. Three different processes were hypothesized: (1) simultaneous effects (influences of message involvement on memory for commercial information at the same point in time); (2) proactive effects (influences of prior programs on subsequent memory); and (3) retroactive effects (influences of later programming on memory for earlier commercial information).

Time-dependent analyses of television viewing are not new in marketing and communication research, although few citations can be found. The most typical application in mass communication has been the study of children's responses to television and movies. In an early study by Dysinger and Ruckmick (1933/1970), children's emotional responses were indexed over time by galvanic skin response during movie watching. More recently, Krull and Husson (1979) and Anderson and Lorch (1983) have correlated visual orientation (i.e., time when eye gaze was directed at the screen vs. competing stimuli) with memory and comprehension of television programs. Although most research on program-context effects in advertising has not used time-dependent analyses, the Bryant and Comisky study

cited above varied involvement of segments in a program, and noted their differential effects.

The scarcity of these studies stands in stark contrast to theoretical discussions about the importance of time-dependent processes in communication (Kline 1977; Krull and Paulson 1977). The extraction of meaning from television messages is best conceptualized as a series of interdependent evaluations. The successful uses of psychological concepts such as priming, serial position effects, and the processing of serial patterns (Jones 1974), attest to the importance of contextual information in encoding. Consequently, a primary assumption in this research is that mental activity occurring before, during and after the processing of a target message can dramatically influence the information retained, the length it is remembered, and the associations with past experience.

Lack of research about over-time processes probably results less from theoretical neglect than from a shortage of appropriate methods for assessing on-going reactions. The assumption that program and commercial messages are interdependent and that evaluations are mutually influential over time, suggests that exclusive use of post-viewing measures is inappropriate. Nevertheless, recording reliable evaluations of a quickly changing stimulus is difficult. In this study, subjects were asked to turn a dial as they watched television. They turned the dial up from 50 to 100 to indicate degree of liking and down from 50 to 0 to indicate dislike. A potentiometer setting was registered for each subject for every two seconds of viewing, and the over-time patterns of these mean settings comprised the measure of liking.

Two kinds of measures were examined in the dial patterns. The most obvious measure was the mean level of the settings. This level provided an indication of how much subjects liked what they were viewing during significant time segments. Mean level of liking was defined for commercials, commercial pods, and four different parts of programs (mean level for the entire program segment, and mean level for the last two minutes, one minute, and half minute before the commercials).

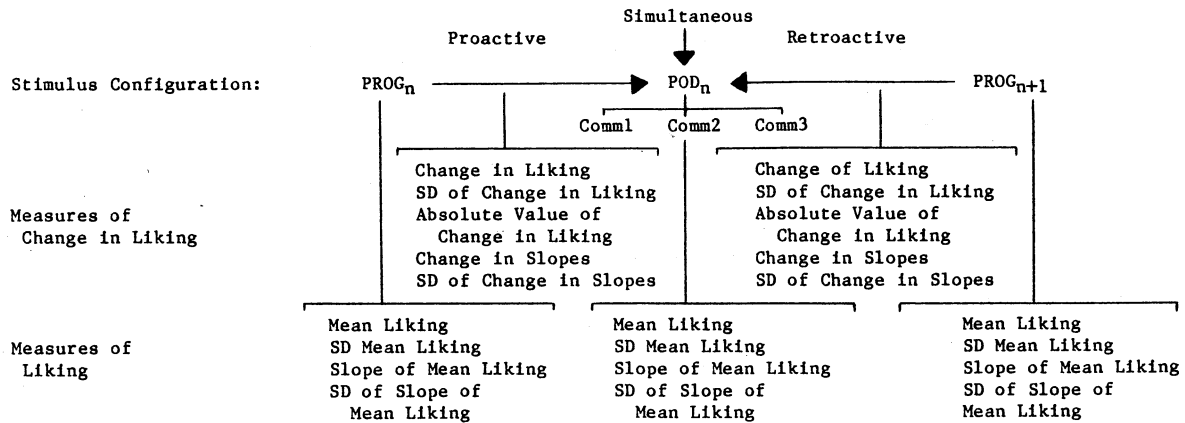

A second measure was how much dial-turning subjects showed during significant time segments. Except for the possibility that extremely riveting material might "freeze" or slow dial-turning, more turning seemed likely to index mental involvement in viewed materials. Change in liking was indexed by eight measures. The first was the standard deviation of mean liking, a measure of the over-time variation around the mean for each program and commercial. Subjects who exhibited large changes in how much they liked what they were viewing would have large standard deviations.

The second change measure was the difference between means for contiguous units. The time periods used were whole programs (PR), last two minutes (TM), last minute (1M), last half minute (HM), first (C1), second (C2), and third commercial (C3), and the commercial pods that combined three commercials (P). Rather than including all possible pairwise combinations, only the following pairs were examined: PRC_x, PRP_x, TMC_x, TMP_x, 1MC_x, 1MC_x, HMC_x, and HMP_x. All eight pairs were examined for each of the three program-commercial pairs in the experiment.

The third change measure was the standard deviation of each of the change scores. These were again defined for each of the eight time segment pairs mentioned above and for each of the three program-pod pairs.

FIGURE 1

PROACTIVE, SIMULTANEOUS, AND RETROACTIVE LIKING AND CHANGE IN LIKING MEASURES

The fourth change measure was the absolute value of the change scores. The previous change scores included both positive and negative values; however it may be important to consider the magnitude of the changes, regardless of valence. The absolute value measures provided this index.

The fifth change measure was the mean of the differenced series for liking, or, more intuitively, their slopes. The differenced series were calculated by subtracting contiguous time points. Positive values indicate increasing scores. Negative values indicate decreasing scores. The sixth measure was the standard deviation of the slopes or the amount of change in the slopes over different time periods. The seventh measure was the difference in slopes from one time segment to the next. These were defined for the same eight program-commercial or program-pod combinations as the change scores, and for each of the three program-pod pairs. The final measure was the standard deviation of the difference in slopes, which indicated how much the trend changed during each segment. High values for this measure indicate relatively more change in the upward or downward trend of evaluations during and between segments.

Over-Time Measures and Memory for Commercials

Over-time processes have not been similarly treated in past studies and consequently, expectations about effects of the over-time measures on memory were exploratory. All hypothesized effects were conceptualized in terms of a time relation with target commercials. Liking and change in liking could be correlated with memory for subsequent commercials (proactive influence), with preceding commercials (retroactive influence), or they could be correlated with memory for commercials at the same point in time (simultaneous influence). Figure 1 summarizes the design. There are three program segments and three commercial pods. The first, second, and third pods vary in numbers of proactive, retroactive, and simultaneous influences that can potentially occur. Hypothesized effects were also conceptualized in terms of valence (positive or negative correlations between the time-dependent variables and memory).

Predictions about direction and valence of memory effects were based on assumptions about how liking and change in liking operate at two different stages of information processing: attention and memory. Program liking should enhance attention to the television screen and hence increase attention to subsequent commercials. This would in turn lead to enhanced memory for the commercials. Program liking was hypothesized to operate on input processes, which should produce only proactive effects.

Hence,

H1: Mean liking should have positive proactive effects on memory for commercials.

The effect of level of liking during commercials (simultaneous effect) was harder to predict. To the extent that liking is determined by commercial execution, greater liking should be associated with stronger memory (Thorson and Friestad, in press). However, to the extent that liking commercials is determined by program context, level of liking during the commercials may be unrelated to memory. Ambiguity here precluded a specific hypothesis about simultaneous effects of level of liking.

Hypotheses about the effects of change in liking were also difficult because more dial turning (indicated by the variance and change measures) was assumed to affect both attention and memory. Viewers were presumably more attentive to television information when they showed greater dial activity (there were no instances where the programming became so compelling that the dials were "frozen"). At the same time, however, more dial turning may have indicated greater arousal, which could increase memory capacity. Dial changing during commercials, then, should be positively associated with memory:

H2: Indicators of change in liking simultaneous with commercials will be correlated positively with memory for the commercials.

Proactive and retroactive relations between change in liking and memory operate differently. Proactive effects are thought to result from interference between information in long-term memory and new material entering from a short-term buffer (Klatzky, 1980). Retroactive effects are thought to result from interference of new items with previous items in the limited slots of the short-term buffer or in the interference caused by the transfer of old items to long-term memory (Saltz, 1971). If dial-turning enhances encoding of commercial information occurring simultaneously, then when turning occurs before a commercial, it should lead to increased competition with the incoming commercial. Competing information could be either from previous material currently in short-term buffer or material in the process of being consolidated into long-term store. When dial-turning occurs after a commercial, it should also lead to more competition with prior information. Prior material is either occupying the short-term buffer or is itself being consolidated into long-term store. New information could preclude either of these processes and lessen the probability of creating a successful long-term trace of a previous commercial.

Hence:

H3: Proactive and retroactive indicators of change in liking will be correlated negatively with memory for commercials.

The predictions are constrained to the presentation of commercial pods in various program segments. Here, three pods of three commercials each were embedded in comedic, violent, and sexual program segments presented to viewers in counterbalanced orders (Thorson, Reeves, Schleuder, Lang, and Rothschild 1985). This allowed determination of degree, valence, and direction of relations between the time-dependent variables and memory.

Method

Subjects

Forty-six middle-class adults (number of males = 19), from Madison, WI, were tested. The subjects ranged in age from 20 to 50 and were members or friends of a community group. Payment for their participation was donated to the group.

Commercials and Program Sequences

The stimulus sequences consisted of 27.5 minutes of material: two minutes of TV black, 21 minutes of program segments (approximately 7 minutes each of comedy (Happy Days), violence (A-Team), and sexual content (segments from the movies Peter Proud and Shampoo), and 4.5 minutes of 30-second commercials. The order of presentation was: TV black (one minute), Program 1, Pod 1 (3 commercials), Program 2, Pod 2, Program 3, Pod 3, and TV black (one minute). Three orders of the programs and commercials were used to counterbalance for order effects.

Procedure

Groups of one to 10 subjects were instructed to use the potentiometer and were given the opportunity to practice. Before viewing the stimulus videotape, subjects watched two five-minute segments of feature stories and sports to acclimate to the viewing room. Each of the practice segments was followed by three thirty-second commercials.

After viewing the practice tape and the stimulus tape, subjects were asked to complete a questionnaire about the three program segments. A second questionnaire asked for free recall of the nine commercials in the stimulus tape. Subjects were asked to list for each commercial the appropriate product category, brand name, claims made, and executional information about the scenes, actors, and stories. Subjects were asked to include any information recalled even if not all information was available. To encourage thorough recall, a bonus of 10¢ was added to the participation fee for each commercial recalled.

A third questionnaire asked for recognition of the nine commercials. There were three pages for each commercial, each page presenting five selections, one of which was the target. The first page listed product categories, the second, brand names, and the third, claims.

In a final activity, subjects responded to an adjective checklist test for each advertised product (the results of which are not relevant to the present analysis). After completion of all the questionnaires, subjects were thanked and excused.

Analyses

The recall and recognition questionnaires were scored for accuracy. This resulted in eight memory measures for each commercial pod: total recall plus recognition score, recall of product category, brand name, claim, and execution, and recognition of product category, brand name, and claim.

The potentiometer data were standardized for each subject. Time series for each of the time-dependent

variables were then constructed. For mean liking, standard deviation of mean liking, trend, and standard deviation of trend, there was a score generated for each commercial, each pod, and four program means for each of the three programs: whole program, last two minutes, last minute, and last half minute. For changes in mean liking, absolute value of the changes, and standard deviations of the two variables, there were eight scores generated for each pod by combining the four program intervals with pods or the first commercial in each pod.

Results

Potentiometer Patterns Over Time

Figures 2 and 3 show the means of the potentiometer values across 825 2-second time intervals in the first order. These data are presented to illustrate visually the nature of the over-time changes in liking. In each series there is a clear distinction between the commercials and the program segments. These aggregate changes indicate that program-commercial break points represent significant shifts in the series and that there is substantial individual variation in the type of change present. For the males, there was always a large drop at the beginning of each commercial pod, with a slow rise across the ensuing 90 seconds. The pattern was more complicated for the females. The first pod produced a marked drop, the second pod, a marked increase, and there was a small drop in the third pod. There were also differences in the mean level of the standardized readings, with females lower for sex and violence and higher for comedy. The figures also show more up and down movement for females than males.

Recall and Recognition as a Function of Pod Position

Mean memory levels also varied across commercial pods. There was a strong serial position effect, with memory significantly higher ($p < .05$) for Pods 1 ($\bar{X} = 8.0$) and 3 ($\bar{X} = 9.1$) than for Pod 2 ($\bar{X} = 6.4$).

Mean Level of Liking and Memory

Hypothesis 1 suggested liking would have positive proactive effects. Because change scores from the whole program, the last two minutes, one minute, and half-minute were highly correlated, only one of the four was counted if there was a significant correlation with memory. As can be seen in Table 1, 15 mean level of liking variables were correlated significantly with the memory measures, and all were positive. There were, however, also simulta-

Total Change Scores	9	29	7	2	9	22

neous and retroactive correlations, and while the retroactive ones were primarily positive, the simultaneous relations were both positive and negative. This result is inconsistent with the notion that liking operates only proactively on attentional processes. The simultaneous effects are particularly puzzling because liking during a commercial can apparently damage memory for it. It may be, however, that if the memory measures had been at the level of the individual commercial rather than pods, the liking would have been positively correlated with one or two of the commercials, and the negative correlations have resulted from within-pod retro- or proactive relations.

Changes in Liking and Memory

Hypothesis 2 suggested that change in liking simultaneous with commercials should be positively associated with memory for them. Again, Table 1 shows support for the hypothesis. Because change scores from the whole program, the last two minutes, one minute, and half-minute were highly correlated, one of the four was counted if there was a significant correlation with memory. While there were only nine significant correlations between simultaneous change in liking variables and memory, seven of them were positive.

Hypothesis 3 suggested that retroactive and proactive change-in-liking values would be negatively associated with memory. As can be seen in Table 1, this prediction was supported. Of 38 significant proactive correlations, 29 (76%) were negative. Of 31 retroactive correlations, 22 (71%) were negative.

Comparison of the number of significant correlations for each of the eight change measures shows absolute value of the change scores and the standard deviation of mean liking to be strongest (15 significant correlations each). Both the change in liking and standard deviation of change in liking showed 11 significant correlations. The standard deviation of the difference in slopes had 9 significant correlations. The other three measures were weaker.

Prediction of Memory from Mean Liking and Change in Liking

Table 2 shows the squared multiple correlations for each of the preference measures. To reduce the number of independent variables entered in the equations, only scores for entire programs, commercial pods, and changes between programs and pods were used. These variables were entered stepwise into the equations (F-to-enter criterion was $p < .05$). Each multiple correlation was significant with between one and ten predictors of performance. These

variables accounted for between 11 and 83 percent of the variation in performance ($R^2 = .51$). The predictions for recall were marginally better than those for recognition (R^2 for recall = .52; R^2 for recognition = .48) even though there was greater variation in how well recall performance could be predicted in the three different pods. Most notably, the predictions of recall performance in Pods 1 and 3 were better than for Pod 2 for information about product, brand, and scene. As noted before, Pod 2 also had the lowest level of performance in all three viewing orders.

Discussion

The most important results in the present study were the strong proactive and retroactive relations between memory and the time-dependent variables, mean level of liking,

All equations were significant at $p < .05$; $n = 31$ for all equations

and measures of change in liking. Mean liking showed predominantly positive effects, while the change in liking measures showed mostly negative effects. Further, liking and change in liking predicted significant percentages of the variation in performance scores, independent of commercial or programming content.

Most research in advertising and mass communication assumes that evaluations of messages as they occur are independent of prior and subsequent judgments, and that memory for media information can be predicted by consideration of simultaneous judgments alone. In contrast, the present study emphasized the influence of the viewing process. The time-dependent effects argue that watching television is best conceptualized as a series of interdependent program segments and messages, each influential backward and forward in time, as well as at the same point in time. In fact, the present study showed a greater number of significant predictions that were distant compared to predictions that were proximal.

It is also important to note that the success of the performance predictions was not dependent on the products, brands, arguments, or executions of the commercials. The results were unchanged for three different viewing orders in which each of three programs and nine commercials occupied different positions. A substantial amount of variation in performance was attributable merely to the position of messages relative to other content, and to the nature of an individual's reaction to surrounding messages. It is likely, therefore, that studies that do not approximate a natural viewing situation by providing a context for the evaluation of messages could possibly overemphasize content effects at the expense of effects attributable to over-time processes.

Evaluations of commercial messages are typically assessed using judgments attributable to entire messages or to a portion of particular interest (usually content features like language, judgments of people, etc.). These evaluations are similar to the calculations of mean levels of liking in the present study. These are not the only relevant judgments, however. The present results indicate that the structure of evaluations--regardless of the particular messages to which the evaluations apply--are also significantly related to performance. The important structural evaluations were variability in response (standard deviation measures), trend of response (mean of differenced responses), and the change measures.

EFFECTS OF THE COOPERATIVE GROUP DECISION-MAKING CONTEXT
ON THE TEST-RETEST RELIABILITY OF PREFERENCE RATINGS

Kim P. Corfman, New York University

Abstract

An approach to modeling test-retest measurement error as a function of contextual factors is presented. Two situational factors are proposed that may contribute to low reliability when a subject provides preference ratings independently and then with the knowledge that he or she will be making a decision on the same stimuli as a member of a cooperative group. These factors are the group's decision history and empathy.

Introduction

Unless the reliability of measures used in studies of consumer behavior is established, it is not possible to demonstrate the validity of the instruments used or determine the reason for low correlations among constructs (Peter 1979). The test-retest method of reliability assessment is designed to establish the proportion of systematic variance in a measure by administering it twice to the same subjects under conditions that are as similar as possible. As it is rarely possible to exactly duplicate measurement conditions, it is useful to attempt to identify the differences in context from one administration of an instrument to the next. This paper proposes that the inconsistency found in test-retest measures can be partly explained by identifiable changes in the measurement context.

Specifically, it suggests that preference ratings that members of long-term cooperative groups (e.g., families and buying committees) provide when they are questioned individually (with no reference to the group) will differ from those they provide when they know they will shortly be making a decision about the same stimuli with their group. The latter situation will be referred to as the cooperative group decision-making context. It is proposed that these differences are due to the group's decision history -- the effect of the outcomes of the group's past decisions on the way a group member values or rates the alternative he or she prefers in future decisions (Corfman, Lehman and Steckel 1985) -- and to the empathy members may have for each other and each other's preferences (Burns and Granbois 1977, Davis 1976).

Reliability

Classical reliability theory suggests that a subject's observed response to a measurement scale is composed of two parts, a true and an error component (Guilford 1954, Kerlinger 1973). The true component is presumed to be stationary over time and neither component can be observed alone. What is observed is the true score plus or minus an error score.

This error has been termed either random or nonrandom (systematic) error (Carmines and Zeller 1979). Nonrandom error has a systematic biasing effect on measuring instruments, causing them to register consistently high or low scores. Test-retest measures of reliability cannot assess the level of this kind of error because it is present in both the test and retest settings. They can, however, measure the amount of random error. This is because it is assumed that random error is equally likely to move the observed score up or down from the true score, so that over a very large number of admini-

strations of an instrument the mean score will be very close to the true score.

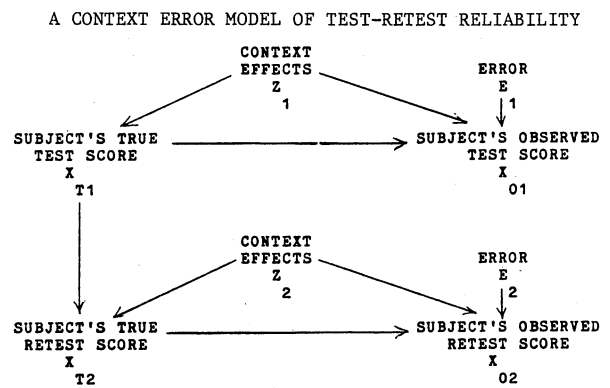

In this paper another kind of error, context error, is discussed which tends to show up as random error in test-retest methods. This error is not a consistent biasing of responses either higher or lower than the true score, nor is it random and equally likely to move the observed score higher or lower than the true score. It is caused by factors which vary from one administration of the instrument to the next (and, perhaps, from subject to subject). Context error is systematic in the sense that it is a function of changes in the situation or context.

Basic Model

Figure 1 represents the basic model. It differs from the usual representation of the test-retest method (Carmines and Zeller 1979) in two ways. First, due to changes in the context, what we are attempting to measure in the retest may be the true score of another phenomenon -- a different set of preferences for a different situation. Preferences may have changed due to the measurement context. (An alternative way to view this is that the true score has changed.) Therefore, there is a potentially different true score for each period. The second difference is that in both the test and retest conditions the context may affect how the subject reports his or her true score. If the contexts are different, even if the same true score is being measured, the observed score may change. (Random error will also contribute to changes in observed scores).

For example, a husband may have a different true preference score when questioned alone than when he is questioned with the knowledge that he will shortly be evaluating the same stimulus with his wife. Concern for her preferences may cause him to incorporate what he thinks she would prefer into his own rating. This may reflect either genuinely different preferences or simply a desire to accommodate his spouse.

FIGURE 1

If X_{T1} and X_{T2} are the subject's true test and retest scores, and X_{O1} and X_{O2} are the subject's observed scores, the traditional model is,

$$X_{O2} = b_1 X_{T1} + e \quad (1)$$

If changes in context affect response, the model in (1) is underspecified. If these changes are measured, their con-

¹The author wishes to thank Donald R. Lehmann and Punam Anand for their helpful comments on earlier drafts of this manuscript.

tribution to lower test-retest reliability can be estimated. Z_1 is the effect of the context in the first administration of the instrument. Since the difference between the contexts of the two tests is of interest, Z_1 is set to zero and the value of Z_2 indicates the change. (Clearly, as many context factors as are appropriate may be specified.) The following equations result from the model depicted in Figure 1:

$$X_{01} = b_1 X_{T1} + e_1 \quad (2)$$

$$X_{T2} = b_2 X_{T1} + b_3 Z_2 \quad (3)$$

$$X_{02} = b_4 X_{T2} + b_5 Z_2 + e_2 \quad (4)$$

Substituting (2) and (3) into (4) produces (5).

$$X_{02} = b'_1 X_{01} + b'_2 Z_2 \quad (5)$$

It will not be possible to determine whether the new context is eliciting a new true score or whether it has simply changed the way the subject reflects the true score in his or her rating. It will, however, show the relative importance of different environmental or contextual factors to test-retest reliability.

Group Decision-Making

Many models of group choice weight individual preferences with the group members' relative influence to predict what the group will choose (Choffray and Lilien 1978, Davis 1973, Keeney and Kirkwood 1975, Krishnamurthi 1981, March 1966). Whether individual preferences are assessed alone or in the presence of the group will lead to important differences in interpretation of results if the context affects the observed preference scores.

The cooperative group context often causes a subject to give different responses than he or she would in an independent (non-group) context. In a recent examination of how individual preferences relate to group decisions, Corfman (1985) had 124 spouses (62 married couples) individually rate a set of 54 stimuli by assigning from 0 to 100 points to each. These ratings were used to create a unique set of 12 to 18 stimulus pairs for each couple so that the items in each pair were ranked differently by the spouses (i.e. one spouse preferred the first alternative and the spouse preferred the second). An average of 19 days later the experimenter met with the couple and presented the stimulus pairs one by one. As each pair was presented, the spouses first rated the alternatives individually on 100-point constant sum scales (group context ratings) and then made a joint decision on which of the two to acquire.

All together the spouses rated 1668 stimulus pairs (124 spouses each rating 12 to 18 pairs). Since the first set of ratings was on a different scale from the second (a 0 to 100 point scale for each stimulus vs. a 100 point constant sum paired comparison of the stimuli in the pair) only the cases in which the preferred alternative changed are examined. Of the 1668 rankings, 541 (32%) changed from the first to the second test. This undoubtedly underrepresents the total number of rating changes, some of which did not result in rank changes.

Some of these changes may have been due to the differences in the way subjects used the two rating scales or to changes in preference with time, although the number is large enough to suggest there are other explanations. To investigate this possibility, 24 spouses provided extra sets of individual group context ratings on the 100-point scales used in the first test. Immediately before the sequence of decision pairs was presented to the spouses in each of the 12 couples, they provided extra ratings of those stimuli which were about to appear in

decision pairs. These couples provided a total of 312 pairs of individual ratings (24 spouses each rating an average of 13 pairs). The average point change from the first to the extra test was 21.47 points. The following rank changes occurred for this group of 24 subjects in their ratings of the decision pairs used in the group task:

Between the	AVERAGE TIME BETWEEN RATINGS	RANK CHANGES	PERCENT OF POSSIBLE CHANGES
Test ratings and extra ratings	19 days	51	16 %
Extra ratings and retest ratings	1/2 hour	56	18 %
Test ratings and retest ratings	19 days	96	31 %

This illustrates the potential importance of context to the correct interpretation of the scale responses. If subjects are questioned alone and the group context affects their true scores, a model's parameter estimates may be biased and it may not perform as well as it would were the relevant preferences measured. If subjects are questioned in the group context and the model estimated, it should not be assumed that preference ratings obtained from members in isolation will predict as well. This paper suggest two factors, decision history and empathy, that may affect members' preferences and preference ratings in the cooperative group decision-making context.

Decision History

The first situational factor that is considered is the group's decision history. Assuming our interest is in groups that are not newly formed (such as families, committees, and buying centers) a particular decision made by a group is likely to be one of a sequence the group has made in the course of its existence. If there has been conflict, the outcomes of past decisions will represent wins and losses and may affect members' feelings about future decisions. Specifically, decision history is the effect of the outcomes of past decisions on the way the group member values the alternatives he or she prefers in future decisions. As a result of having lost in the past an individual may exaggerate the value of his preferred alternative in a subsequent decision and rate it more highly than he would have out of the context of the group decision (Corfman 1985, Corfman, Lehmann and Steckel 1985). Conversely, having had his choice adopted by the group, an individual may express future preferences less extremely. These effects may occur because individuals genuinely value the alternatives differently -- their preferences have changed -- or because the desire to win or restore equity (Adams 1965) is being reflected in the preference ratings. In either case, the preference ratings will differ from those provided outside the context of decisions made by the group.

Decision history can affect preferences and preference ratings in another way. A group member who has had his selection adopted by the group in the past may place higher values on the alternatives he prefers the more he gets his way. Having his preferences confirmed may give him confidence and lead him to express his preferences more firmly, or winning may be addictive and the desire to win reflected in the ratings. Similarly, a member who has lost in the past may respond with decreased confidence or a sense of futility and rate his preferred alternatives more moderately. Again, changes in ratings may be due either to real changes in preferences or to the reflection of desire to win.

Empathy

The other context effect that will be considered here is the empathy group members may have for each other and each other's preferences (Burns and Granbois 1977, Davis 1976, Greenhalgh, Neslin and Gilkey 1984, Olson 1969). This effect will be particularly important in primary groups

(Faris 1937), such as families, and other groups such as social clubs and even some work groups that are characterized by strong commitment or attachment bonds (McCall 1970). In these groups, the satisfaction of other members and preserving relationships with them may be as or more important to a member than having his way in a decision. When asked alone which of several alternatives a husband (or wife) prefers, he may give a different response than he would in the context of making a decision with his wife where he may be less able or willing to distinguish his preferences from hers. Empathy may actually cause changes in individual preferences or it may just reflect the desire to accommodate a spouse. In either case it will contribute to the difference between ratings given independently and those given in the group context.

If a decision history or empathy effect is present and important, then use of independent preference ratings in models of group choice is not appropriate. Even if true independent preference scores are the same, these independent ratings will not reflect subjects' preferences at the time the joint decision is made, due to the group decision-making context.

Model

The general model in (5), modified to include the effects of decision history and empathy in a two-person group, appears in (6). It may be generalized to larger groups by using the subject's perceptions of other members' average preference if the analysis is performed across groups, or by adding a term for each additional member if the analysis is performed across decisions made by a single group. Presented this way, decision history is a variable and empathy is b_3 , the parameter associated with the member's perception of the other member's preferences.

$$X_{02} = b_0 X_{01} + b_1 \text{ DECISION HISTORY} + b_2 \text{ PERCEPTION OF OTHER'S PREFERENCES} + e \quad (6)$$

X_{01} and X_{02} are the subject's ratings of the stimulus alone and in the group context, respectively. If an experiment is used and the group context ratings are provided all together before the group decisions begin, no effect of decision history will be apparent, although it may well play a part in the group's decisions. For the most accurate measures of the individual preferences that will contribute to the group decision, the ratings should be provided immediately preceding the corresponding group decision.

Given that the outcomes of a sequence of decisions made by each group have been recorded, decision history may be operationalized in at least two ways. It may be simply whether the member had the alternative he or she preferred chosen by the group in the preceding decision. Alternatively, it may be the proportion of preceding decisions in which the alternative he or she preferred was chosen.

The subject's perception of the other member's preferences may be solicited directly, although reactivity may present a problem. If the subject is asked first what he believes the other member prefers it may encourage the use of this information in the subject's reporting of his own preferences. If asked afterward, the subject may bias his report of the other member's preferences. An alternative approach would be to use the other member's self-reported preferences. In a pre-existing cooperative group whose members are well-known to each other and have established preferences for the decision alternatives, this may be a better solution.

Hypotheses

H1: The subject's initial observed score, X_{01} should clearly account for the largest portion of the variation in the rating he gives in the group context, X_{02} . The

parameter b_1 is an indication of the measure's reliability and should lie between zero and one. It should be less than one because when looking across a large number of ratings, a regression to the mean effect is more likely than consistently more extreme ratings.

H2: The DECISION HISTORY parameter, b_2 , should be negative: the less the subject's preferred alternative has been chosen in the past, the more highly he will rate his choice in future decisions (and vice versa). The alternative hypothesis suggested earlier is also plausible: the more the subject has had his way in the past the more highly he will rate his choice in the future. Exploratory research indicates that the former is the more likely phenomenon in cooperative groups (Corfman 1985, Lehmann and Steckel 1985).

H3: Due to empathy, b_3 should be positive -- the subject's rating of his preferred alternative in the group context will be positively related to the way he perceives the other member's preference for the alternative. If member A believes that member B likes the alternative A prefers even more than A does, A will rate the alternative more highly in the group setting than he does independently. If he thinks B likes the alternatives less, he will rate it lower in the group setting.

It is possible that "empathy" will be stronger for some subjects and groups than others due to personality and relationship characteristics. Subjects who are generally more caring, accommodating, or dependent, or who dislike conflict may tend to alter their preferences or preference ratings more. The more cooperative group (due to a longer relationship or greater interdependence) may be generally more empathetic. These possibilities could be investigated through interaction terms with the perceived preference of the other group members.

Conclusions

Although the data requirements for estimating group choice models are great, collecting the additional preference data needed for this analysis seems reasonable when the added insights that can result are considered. If the context factors examined here contribute to the change in preference ratings given by group members when they are moved from the independent to the group setting, it is clearly important to measure preferences in the appropriate context and to understand how measurements taken in other contexts differ.

There may be other context factors affecting preferences and preference ratings in these and other kinds of groups which have yet to be identified -- a useful direction for further research. In some organizational groups, for example, the threat of veto or possession of much greater influence by another member may result in preference rating changes similar to those associated here with empathy. The group context may also affect the riskiness or conservatism of individual ratings provided in anticipation of a group decision on the same issues. In a non-cooperative bargaining situation it may be to a participant's strategic advantage to misrepresents his or her preferences. This might be reflected in individual ratings provided before the exchange begins.

This kind of investigation into the effect of context on test-retest reliability may be useful in areas other than group decision-making. Depending on the instrument, stimuli, and subjects, such factors as differences in the time of day (relating to fatigue), recency of consumption of or contact with the stimuli, and discussion or consideration of the stimuli or instrument may affect true retest scores and the way they are reported. If some of the measurement error produced in situations in which the environment cannot be completely controlled is found to be systematic in the sense that it can be modeled, data may be adjusted to accordingly and, hence, more reliable measures used.

PERSUASION AS DIRECTED INFERENCE

John Deighton, Dartmouth College

Abstract

The paper argues that persuasion by advertising is, at least in part, the result of directing an audience's inferences from evidence. Points at which inference is vulnerable to this influence are identified. Studies offering empirical support for the model are reviewed.

Introduction

There is ample evidence that some messages, under some contingencies, will persuade their audiences more after the lapse of time than at the moment of exposure. The phenomenon is intriguing, because it offers the possibility of insight into at least some of the processes of persuasion. When message exposure can be temporally separated from persuasion, we can examine to what extent persuasion depends on the intervening contingencies.

The contingency studied in this paper is evidence. The paper presents a model of a process of persuasion in which the message acts to direct the path of the audience's subsequent inferences from evidence that bears on the message's claim. Phrased differently, the model envisages that one of the ways messages can persuade is by shaping the sense we make of data.

This model of persuasion seems, on the face of it, to have application to persuasion by advertising. It may account for some odd properties of advertising. The contradiction is often noted, for example, that consumers deny that advertising affects them, yet advertisers see value in using it. To the extent that advertising is influencing sensemaking, rather than presenting argumentation, its influence will not be accessible to introspection by its audience and these contradictory reports can be reconciled.

Another curious property of advertising is the fact that it is often used to promote low-cost, frequently purchased products and services to consumers who are already users. The use of advertising to retain the loyalty of existing consumers has been noted by Ehrenberg (1974) and Harper (1976) among others. To the extent that advertising acts by shaping the interpretation of experience, it is plausible that its most responsive audience will be those who are already users of the advertised product or service. Thus the marketing of high-share brands like McDonald's or Coke will be more successful if it can influence existing customer's satisfaction with the next purchase than if it can persuade the small proportion of their market who have never tried the product to do so. The question addressed in the next section of this paper is: how can persuasive communications influence the experience of consuming a product or service?

The Model: How Inference is Directed

The model applies to ambiguous consumption environments: those in which the consumer is not compelled by the event itself to attach to the event one meaning or another. The sense a consumer makes of an ambiguous consumption experience owes more to promotion than to the native event. Consider two kinds of ambiguity to illustrate this claim.

In the first, ambiguity is the result of the bland, uncontroversial nature of the experience. No prominent features of the product intrude themselves on the consumer's attention: there is little information available from the experience. Eating a slice of bread might be such an experience. Unpromoted, the event has little meaning. Promoted, the very blandness of the event allows it to support many assertions: "builds bodies seven ways," or "see how light and airy it is!," or "taste the wheat!"

In the second, the experience is not bland, but its distinctive features may serve as evidence for a variety of interpretations without conclusively eliminating any of them. Here, in contrast to the previous example, the experience offers considerable information, but little diagnosticity. The purchase and wearing of clothing, for example, generates for the wearer a complex set of data. By asserting claims consistent with some of this data and not contradicted by others, a marketer may shape the experience of wearing the clothing in directions not guaranteed by the experience itself.

The purpose of the model is to explain how advertising shapes the meaning consumers ascribe to such ambiguous events. By "meaning" is meant a set of beliefs and evaluations inferred inductively by the consumer from the consumption event. The ascribing of meaning is modeled as the inducing of inferences. The model seeks to identify points in the inductive process at which advertising can be said to direct inference, or influence it to deviate from the canons of classical statistical induction.

To decide what an experience means, the stream of sense data that makes up the experience must be broken into units needing interpretation, and one potential interpretation must win favor over others. In this model of the sensemaking process, advertising plays at least two roles. First, during exposure, it forms an expectation. Second, during experience with the product, it directs inference toward confirmation of the expectation.

In the first step, the audience learns, rather passively, what the advertiser is claiming. It would be wrong to assume that the audience accepts the claim, and probably more accurate to describe the claim as merely entertained. One interpretation of the experience of using the product becomes more salient than others. As McCombs and Show (1977) claimed of the press with respect to politics, advertising cannot determine what we think. But it can influence what we think about.

Because the expectation aroused in the first step is weak, particularly if the audience is sensitive to the partisan nature of advertising, measurement of the expectation is difficult. A subject who fails to report the expectation may do so either because the ad failed to create it, or because the ad succeeded but the subject was reluctant to admit to belief in the claim on such slight evidence. If the subject does report the expectation, it may not exist as a psychological state of expectation but merely as demand-induced verbal compliance. Thus simple pre-post exposure copy testing is likely to be a poor predictor of advertising performance.

John Deighton is Assistant Professor of Business Administration, Amos Tuck School, Dartmouth College, Hanover, New Hampshire 03755.

The second step, from "thinking about" to "believing," depends on experience. Without wholly accepting the claim, the consumer may find it plausible enough to act on it, at least to the extent of a trial purchase. In this second step, provided the claim is not sharply repudiated by experience or contradicted by prior beliefs, it influences the sense made of experience in several ways. It affects the choice of evidence to be encoded in memory, strategies for interpreting the evidence, the process of combining information to form impressions, and/or the retrieval of evidence from memory. In this manner the claim gradually becomes a belief: external influence feels like learning from experience.

A number of studies have found that the salience of cause influences their use in judgment. Reyes, Thompson and Bower (1980) found that, in a mock jury decision, evidence made disproportionately available in memory had a correspondingly disproportionate influence on the jury's verdict. In the field of person perception, several studies have found effects of salience on causal attribution (Lepper and Greene 1975, Taylor and Fiske 1978, and see Ross and Anderson 1982 for a survey). Wyer and Srull (1981) induced shifts in impression formation by manipulating the availability of relevant concepts. Schindler and Berbaum (1983) found that salience influenced choice.

Media-induced salience has been shown to influence behavior. Suicide reports in the press were associated with increases in the population suicide rate (Phillips 1974), publicized prize fights affected the incidence of homicide (Phillips 1983), radio reports of prosocial behavior induced subjects in a bargaining experiment to be more co-operative (Blackman and Hornstein 1977), and the rate of violent crime rose after the spate of assassinations in the early and mid-1960's (Berkowitz and Macaulay 1971). More generally, a view of the mass media as agenda-setters for the public's evaluations have been advanced by Shaw and McCombs (1977), and forms the basis of Sutherland and Galloway's (1981) argument that agenda-setting is an important part of the process by which advertising communicates.

Advertising usually makes salient two aspects of a consumption experience: an outcome and an associated cause. The goal may be to make the brand a candidate cause for the outcome, for example when Ritz crackers are given as the reason for a successful party. Or it may be to draw attention to the outcome: the 'quicker picker-upper' advertising for Bounty paper towels tells consumers to notice absorbency among the many other aspects of the consumption experience that might capture their attention. In either event, the advertising invites its audience to test one cause-outcome link among the many they might otherwise consider.

Another relevant research stream has to do with the way such candidate cause-outcome links are tested. A number of studies have found that, in inferring the strength of association between causes and outcomes, lay perception of correlation is disproportionately influenced by confirmatory instances (Beyth-Maron 1982, Hamilton and Rose 1980, Smedslund 1963, Ward and Jenkins 1965. See Crocker 1981 for a comprehensive review of lay covariation assessment). This work suggests that the confidence with which a claimed cause comes to be accepted as a true cause will increase with the number of times the cause and the outcome co-occur, with too little regard for the number of times the outcome occurs without the cause or the cause without the outcome. Thus, for example, belief in the claim that a paper towel was more absorbent because it bore the brand name Bounty would be strengthened whenever a consumer used Bounty and found it absorbed well. Lack of evidence on the absorbency of other brands, or even occasional evidence that other brands pick up quickly too, if not made salient by advertising, would not interfere with the experiential confirmation of the claim for Bounty.

Combining these two sets of findings, we propose that advertising (1) sets the consumer's diagnostic agenda and (2) benefits from the self-fulfilling nature of consumer inquiry into that agenda. In situations that would otherwise be bland or confusing, its claims become the questions consumers ask. By making one interpretation of an experience more salient or available than others, an advertiser disposes the consumer to confirm it, so the consumer comes to accept it.

Empirical Tests

The research reviewed in this paper comprises three studies. The first examined how an advertising claim influenced the inferences drawn from evidence of product performance. The second study examined how a claim affected inferences from product experience. The final study sought to identify characteristics of the consumer's information search and analysis that might explain the confirmatory diagnosis phenomenon.

1. Directing Inference from Evidence. The first study (Deighton 1984) examined how advertising for Ford cars would affect the sense made of evidence of automobile reliability. The advertising stimulus was print advertising from Ford's "Quality is Job 1" campaign which claimed that Ford paid particular attention to quality in its assembly plants. Evidence of reliability took the form of two pages of data from Consumer Reports' Frequency of Repair Records for 1976 to 1981 for sixteen models of car. This data was rather overwhelming, and in the time subjects had to examine it they could do no more than form a rough impression of its meaning.

The experiment can be thought of as a kind of inkblot test: subjects saw a rather ambiguous stimulus (evidence relevant to Ford's claim) and in the value they placed on it they indicated the extent to which the advertising had been effective in prefiguring the sense-making process.

The experiment took the form of a 2x2 factorial design: subjects were assigned to one of four conditions obtained by crossing advertising (present or absent) with evidence (present or absent). Dependent measures were the shifts in ratings of the reliability of six car manufacturers following exposure to the experiential condition.

The result of this experiment is summarized in Figure 1. The Ford advertising had a significant ($p=0.03$) effect on belief change, but only when subjects had the opportunity to see evidence. Without this 'grist for the mill of inference', the advertising had no measurable persuasive effect. If the no-evidence conditions of the experiment had been run alone, as in a conventional copy test, the test result would have suggested rejecting the campaign. In fact, the campaign appears to have the capacity to shape the sense made of evidence.

FIGURE 1

By using the evidence contained in Consumer Reports tables, this study was able to control the amount and kind of experience consumers could bring to bear on the advertised claim. This tactic enhanced the internal validity of the study. However, it did little for external validity. If an advertisement can direct inferences from a table of data, does that mean it can alter the experience of using a product? Further research was needed to establish whether inference from experience was similarly responsive to advertising.

2. Directing Inference from Experience. The second study (Deighton and Schindler 1985) examined how belief in an advertised claim was affected by experience with the product. The finding was very similar to that in the first study: that although the claim itself was not persuasive, the claim in the presence of experience did induce belief to shift. Thus this study supports the notion that expectancy-confirming inference is not just characteristic of consumers' reading of evidence, but extends to the way they form impressions of their own experiences with advertised products.

In this study, advertising was developed for each of three Boston rock music radio stations, claiming that each played 'the most new music'. Subjects were assigned to one of three groups, and each group heard advertising for a different station. The study measured shifts in belief in the claim before hearing the advertising, after hearing it, and two weeks later. Subjects reported how much exposure they had had to the stations over the two weeks that followed exposure to the advertising.

Figure 2 summarizes the results of this experiment. Again, advertising for a station had no effect on beliefs for subjects who did not subsequently listen to that station. However, subjects who heard the advertising and also listened to the station did respond positively to the claim, and this effect was greater the more experience they had (subject only to a scale ceiling effect). It appears that the audience found confirmation of the claim in their experience with the advertised station, but did not find this confirmation when their interpretation of the experience had not been prefigured by advertising.

3. Mechanisms in Directed Inference. The first two studies showed that advertising's persuasive effect is sometimes delayed: that the claims of advertising sometimes become more plausible over time, and not just because they are objectively correct. The third study (Deighton 1983) examined why. How is it that a consumer can acquire a strengthened belief in an advertised claim in the face of inconclusive or even occasionally contradictory evidence?

This study sought the answer in the way consumers test claims about products: in characteristics of consumer inquiry that might discourage or impede accurate learning from experience. This is not to say that we imagine a world of very methodical consumers who set out deliberately to test claims. All we propose is that the learnt claims of advertising become the default opinions that consumers entertain about the state of affairs in markets, and as they operate in these markets they encounter experience which either repudiates or endorses the default opinions. The question then is how experience updates beliefs.

The general answer proposed in this study was that consumers use heuristics (cognitive short cuts) to form the impressions they depend on the make choices among products. These heuristics lighten the burden of thinking, but they systematically reduce the odds that advertised claims will be discredited. Thus impressions are biased toward confirmation of prior expectations.

The first hypothesis tested in this study was that consumers employ positive confirmation as a reliable guide to covariation: that when they form impressions about causation, positive confirmatory evidence is overweighted. What is positive confirmation? When consumers believe that a cue causes an outcome (such as that Crest gives better checkups), they can meet with four kinds of experience. They can use Crest and have better checkups (cue and outcome both present: a positive confirmatory experience) or they can have good checkups while using another brand (outcome present, cue absent), or use Crest but not have good checkups (outcome absent, cue present). Finally they can have poor checkups with another brand (outcome and cue both absent). Normatively, consumers should compare the frequencies of occurrence of all four kinds of experience to infer the strength of the association between Crest and checkups. In practice, we argue, consumers who hold Crest's claim as their default opinion will give too much weight to the occasions when Crest works. They will take too little account of the times when Crest fails to work or of the success rates of other brands.

The second hypothesis dealt with the way consumers gathered information bearing on an advertised claim which they had learnt. Consumers, seeking successful purchase outcomes rather than knowledge for its own sake, will expose themselves to evidence in which the advertised cue is present more than evidence in which it is not. In so doing, however, they shield themselves from evidence that might prove the claim false. The study sought empirical support for this proposal. Einhorn and Hogarth (1978) showed that, as long as there is any correlation above chance between a cue and an outcome, the restriction of evidence to instances in which the cue is present will bias the gathered sample to report higher correlation than is present in the population.

The third hypothesis was for a primacy effect in impression formation: that in the interpretation of a sequence of experiences, early evidence contributes more to the impression than later evidence (Asch 1946, Tversky and Kahneman 1973). If a consumer is persuaded to try a brand and finds support for its advertised claims, this impression will, it is hypothesised, withstand subsequent experience that other brands deliver the same benefit.

The study tested for these sources of confirmatory bias. It examined how a sample of mothers made inferences about the breakfast cereal preferences of a group of children. The mothers saw advertising that built in them expectations about the childrens' cereal preferences, and then were shown data on the childrens' actual cereal choices. Although the data shown to the mothers neither supported nor contradicted the advertised claim, the mothers interpreted them as confirmatory when the hypothesised factors, positive confirmation and primacy, were experimentally manipulated. They also displayed a preference for evidence in which the advertised cue was

present over evidence in which it was absent. Because the study dealt with advertising's effect on the inferences subjects drew from the behavior of others, some caution is needed in extrapolating this result to inferences from the performance of products.

Conclusion

This paper suggests one reason why persuasion may be delayed beyond the moment at which an audience is exposed to a message. It presents a model in terms of which message exposure merely establishes the salience of a particular interpretation of experience with a product. Actual experience, or at least some dispassionate evidence, must be available to the audience before the persuasive consequences of salience can be observed.

Abstract

The schema-copy-plus-tag (SCT) memory paradigm is tested in a 2x2 (typical vs. atypical arguments; immediate vs. two-day recall) design in the context of print advertising. Since mixed results do not fully support the model, suggestions for its more effective testing are offered.

Introduction

How advertising is represented in memory is of considerable interest to those in the field of marketing communication. Not only is this representation thought to have an immediate influence on advertising response, but it is also thought to have a longer-term influence on memory. The study undertaken here attempts to address this issue by testing a schema-based model of memory, in which message comprehension and representation are viewed as being largely under the control of pre-existing knowledge structure.

The model, based on Graesser and Nakamura's (1982) schema-copy-plus-tag (SCT) hypothesis, begins with the notion that message recipients engage in certain cognitive processes as a result of anticipating the receipt of a persuasive message (cf. Cialdini, Petty and Cacioppo 1981). Based on pre-message source, contextual, and thematic cues, these processes are thought to involve the retrieval of a generic schema that best relates to the communication issue. In that the schema is supposedly a stored representation of information typical of similar persuasive messages gained through experience, its presumed role is one of guiding message comprehension. In addition, it is thought to serve as an organized structure that facilitates message representation and storage. According to this line of reasoning, memory for ads is constructive and, thus, frequently incomplete and occasionally even highly distorted. In the encoding process, message arguments typical of the schema are thought to merge with similar arguments contained in the ad so as to produce a coherent, unified, expectation-confirming and knowledge-consistent representation of the message (see Alba and Hasher 1983). As a consequence, the memory trace makes no distinction between "typical arguments" that actually appeared in the message and those that did not (Schmidt and Sherman 1984). Arguments that are not typical of the schema are said to be represented separately from the schematic portion of the trace by a "unique tag." In essence, this tag distinguishes the item from schematically typical items within the trace.

Whether this model adequately depicts memory for ads is the focus of the study reported here. An experiment was conducted in which both immediate and delayed effects of advertising were assessed in the context of print media. Initial findings are reported in terms of both recall and recognition as well as related measures of attitude.

Background

Although memory for complex events can be quite accurate, it is frequently found to be subject to distortions and omissions. These errors, of course, pose a problem for any theory of memory. One

theoretical perspective that appears capable of accounting for such errors, however, is that of schema theory (see Alba and Hasher 1983). This perspective views memory of complex events as reconstructive, consisting of a generic schema together with certain abstracted event-related details thought to guide reconstruction. The term schema refers to the general knowledge structure a person possesses about a particular domain (Alba and Hasher, p. 203). According to this formulation, recall of a complex event is likely to contain little in the way of actual detail. Instead, it frequently produces such things as paraphrases (of prose passages), thematic intrusions, and interpretations and elaborations that are more in line with the generic schema than with the target event. Alba and Hasher (1983) give a more thorough account of this perspective in terms of four central encoding processes: selection, abstraction, interpretation, and integration.

A schema theory which asserts that all four processes occur would state that from any environmental event, only the information that is relevant and important to the currently activated schema will be encoded. Of the information selected, the semantic content of the message will be abstracted and the surface form will be lost. Further, the semantic content will then be interpreted in such a way as to be consistent with the schema. The information that remains will then be integrated with previously acquired, related information that was activated during the current encoding episode. The operation of one or more of these processes is likely to result in a representation that is less than totally accurate (p. 204).

As already pointed out, another hypothesized schema-related process is that of reconstruction. Occurring at retrieval, reconstruction is thought to combine selected event-related abstracted details with an activated schema to arrive at a probable recounting of the target event. One current and well articulated representation of schema theory is the schema-copy-plus-tag (SCT) model proposed by Graesser and Nakamura (1982), which attempts to explain memory for narrative descriptions of action sequences for which people possess prototypic schemata (essentially scripts). According to the SCT model, comprehension and storage of prose passages are carried out in terms of a generic schema that best fits the passage's main theme. Items that are most typical of the schema are "copied" directly from the schema into the memory representation. Thus, the memory trace may include some items that were not explicitly stated in the passage; there is no distinction between very typical statements that were actually in the passage and those that were not. In essence, typical message statements may actually be forgotten--i.e., typical information need not be stored, since it can always be derived from the prototypic script, or schema. On the other hand, statements that are atypical of the schema are thought to receive special attention in memory. Specifically, it is thought that such statements cannot be represented in the schematic portion of the trace. Instead, they are said to be linked to the representation by a "unique tag" by which they are distinguished from typical and other atypical items.

Schmidt and Sherman (1984) have extended this model to persuasive communication by opining a generic schema position--i.e., a generic schema containing typical arguments (as opposed to action sequences) related to a

¹ Completion of this research was made possible by a grant from the George A. Ramlose Foundation.

familiar communication issue. Thus, representation of a persuasive message is thought to entail the copying of typical schema-related arguments directly into the schematic portion of the trace and tagging atypical arguments as deviations from the schema.

If this formulation is correct, it has several implications for persuasive communication in general and advertising in particular. First, typical arguments should hold an advantage in retrievability because of their placement in the generic schema. Atypical items should suffer in that they are not strongly associated with the schema. In a general recall task, individuals are thought to recall message content by accessing the generic schema. This being so, typical items are more likely to be recalled than atypical items. Further, this difference should increase over time because of a faster decline in the retrievability of atypical, or tagged, information. A final effect has to do with intrusion errors. Since the memory trace for persuasive messages is thought to be undifferentiated in terms of typical arguments--i.e., whether they were actually contained in the message or not--there should be a greater likelihood of schema-based intrusions, and this should increase over time.

Although the constructivist position advocated by Schmidt and Sherman is based on a popular perspective of memory, it does not form an easy amalgam with other literature which seems to demonstrate that recall can be surprisingly accurate. It has been shown, for instance, that under certain recall conditions--instructions that stress accuracy or change subjects' retrieval strategies and situations that permit successive attempts at recalling the same material--schema-based recall errors can be eliminated (See Alba and Hasher; Hasher and Griffin 1978). Further, the Schmidt and Sherman formulation does not seem to mesh well with research showing that depth of message processing is enhanced by the use of unexpected atypical message arguments (Hunt and Kernan 1984). If this latter finding is correct, atypical arguments may become a more (not less) memorable part of the message representation. Because of these apparent discrepancies, an experiment was conducted to test the schema-copy-plus-tag formulation in the context of print advertising. This involved the manipulation of argument typicality and recall interval over two levels (typical vs. atypical; immediate recall vs. two-day delayed recall). In accordance with schema theory, it was anticipated that subjects exposed to ads containing only typical arguments would exhibit better recall and more schema-based intrusions than subjects exposed to ads containing atypical information. Further, atypical items were expected to suffer more in terms of being recalled over time than typical items. Finally, information-based attitudinal data were expected to exhibit patterns that paralleled the hypothesized information decay.

Method

Subjects

Female and male undergraduate students (N=41) from two eastern universities participated in a study to evaluate a new student magazine. Ages ranged from 20 to 47; average age was 22. Most of the subjects were either business majors (78%) or communication majors (15%). In addition, thirty-one subjects served in an argument-generation phase designed to ascertain typical and atypical arguments for the test advertisement.

Stimulus Material

For purposes of external validity, the experimental ad was embedded in a bogus test magazine supposedly designed for area college students. The ad promoted a new brand of ball-point pen, called the "Accupoint Pen," and consisted of picture and text. The picture showed a group of three business-like executives (two males and a

female) examining a computer print-out. One person, who appeared to be the supervisor, had pen in hand. Next to this picture was a close-up of the pen. The text described these people as "brand managers."

Arguments used to construct the text of the ad were created by asking subjects in the generation phase to list typical and atypical arguments regarding the promotion of ball-point pens. Half the subjects in this phase were asked to list the arguments they thought would be typical of a normal pen ad. The other half was asked to list atypical arguments. This produced a set of fifteen general statements, eleven of which were designated typical, and four of which were designated atypical.

Two versions of the pen ad were constructed, a typical version and an atypical version. Each of these contained five of the eleven typical arguments. In addition, they both contained six filler statements. One argument was reserved for the typicality manipulation; this had to do with the pen's effect on the writer's handwriting. In the typical ad, the pen was represented as one that would "fit your handwriting," while in the atypical version it was described as "actually improving your handwriting." The textual location of this argument was identical in both versions--midway through the text.

Dependent Measures

Recall of the ad was obtained by asking subjects to write out as many of the statements from the Accupoint pen ad as they could remember. This task followed a short questionnaire dealing with subjects' overall impressions of the test magazine. It was felt that this questionnaire would serve as a distraction task for the immediate recall group and provide a realistic format for subjects whose recall was delayed.

Recognition was tested via seven items (5 typical and 2 atypical). Two of the typical items involved arguments that actually had been presented; the remaining three pertained to unrepresented arguments. Of the two atypical items, one related to an unrepresented argument, while the other involved the manipulated argument. Thus, this second item represented material that was unrepresented to typical subjects and presented to those in the atypical group. Subject rating of each statement was performed on the following six-point scale 1 = definitely not in the ad; 2 = fairly sure it was not in the ad; 3 = uncertain, but think it was not in the ad; 4 = uncertain, but think it was in the ad; 5 = fairly sure it was in the ad; 6 = definitely was in the ad. The instructions indicated to subjects that some of the statements had not actually appeared in the Accupoint ad.

The final set of dependent measures consisted of two attitudinal statements. The first involved subjects' "attitude toward the Accupoint Pen ad;" the second involved "attitude toward the Accupoint Pen itself." Both items were rated on a 7-point bipolar scale, ranging from "very favorable" to "very unfavorable."

Procedure

Because of certain physical constraints, subjects were selected and assigned to treatment cells on a class, rather than individual, basis--i.e., each of the four classes constituted one of the four treatment cells. Subjects were informed that the purpose of the experiment was to assess the concept of a new student magazine called Campus Week. This test vehicle consisted of a cover, calendar-of-events at various area campuses, a full-length feature article, and several ads dispersed throughout. General instructions requested subjects to read the entire magazine as though they had an interest in all of its content. No mention was made of a subsequent memory test. Subjects then received a

magazine containing one of the two Accupoint ad versions. Eight minutes was the allotted reading time, after which subjects completed the questionnaire dealing with their general impressions. Following this, subjects in the immediate treatment group received a questionnaire containing the dependent measures. Subjects in the delayed group completed this latter questionnaire two days after their exposure to the stimulus material. At the outset of the questionnaire, both groups were told that because of the length of the magazine, they would be required to evaluate only a portion of it. No mention was made of which portion that would be until subjects opened the questionnaire. It was then that they learned they would be evaluating the Accupoint ad. It was felt that this procedure eliminated any presensitization error. To reduce possible communication between the immediate and delayed groups, subjects from different schools were used for these groups.

Results

Recall

Recall data consisted of correctly-recalled items, as well as errors and additions. Errors were placed into one of three categories: (1) thematic intrusions--statements that were consistent with the ad's overall theme, but not actually presented; (2) schematic intrusions--statements that corresponded to typical statements from the generation phase, but not actually presented; and (3) generalizations--statements that combined actual arguments into a more general assertion about the text. Additions included statements about the pen that were unrelated to the text. Scoring of protocols was conducted by having two judges independently classify the recalled items. The judges agreed on 96% of these classifications. Disagreements were resolved through discussion between judges.

Four separate ANOVAs were carried out on correct recall and error scores. As expected, a significant main effect of recall interval was found for correct recall ($M = 2.00$ and 0.72 for immediate and delayed intervals respectively), $F(1,38) = 11.23$, $p < .002$. However, no significant effect of typicality was found; nor was there a significant interaction effect. Of the three analyses involving error scores, only one was found to contain results that approached significance. That pertained to schematic intrusion scores. As might be expected, recall interval had a main effect (marginally significant), with means declining over the interval ($M = .46$ and $M = .17$), $F(1,38) = 3.15$, $p < .08$. Somewhat surprisingly, however, the typicality factor was found to have a main effect (again marginal) on the schematic intrusion scores in which the mean for typical subjects was $.16$ as compared with $.48$ for atypical subjects; $F(1,38) = 3.83$, $p < .06$. No significant interaction effect was found. Further analysis of thematic intrusion and generalization scores revealed no significant results.

Recognition

Mean scores for both recall and recognition items are reported in Table 1. Items pertaining to recognition are reported in terms of their typicality and whether they were actually presented in the test ad. Results related to the manipulated typicality argument appear in item 5. Consistent with the manipulation, an ANOVA revealed a significant main effect of typicality for this item, $F(1,38) = 4.91$, $p < .03$. As expected, subjects who received an ad claiming the pen would "actually improve their handwriting" scored significantly higher ($M = 4.00$) than those who received the "fit your handwriting" version ($M = 3.00$). In addition, a marginal main effect of retention interval was found for this item ($M = 3.92$ and $M = 3.06$ for immediate and delayed intervals, respectively), $F = 3.63$, $p < .06$. No significant interaction effect was

Toward Product	4.27	4.92	4.63	4.40

Found.

Items 2 and 4 pertain to schema-typical items that actually appeared in the test ad. An ANOVA on item 2 revealed a significant main effect of typicality, $F = 8.07$, $p < .007$. Subjects exposed to the atypical ad version exhibited better recognition scores ($M = 5.09$) than those who received the typical version ($M = 4.00$). Analysis of the fourth item produced a marginally significant two-way interaction effect ($F = 3.47$, $p < .07$), with atypical/immediate recall subjects exhibiting better recognition than their typical counterparts. This ordering was reversed for delayed recall subjects. No other significant effects were found with regard to typical presented arguments.

Items 1, 3, and 6 involved schema-typical arguments that were unpresented. Of the three related ANOVAs, only one produced a main effect approaching significance. In responding to item 6, atypical subjects surprisingly scored higher ($M = 3.17$) than did typical subjects ($M = 2.47$), thus indicating a greater intrusion likelihood, or false recognition rate, on the part of the former group, $F = 3.00$, $p < .09$. An ANOVA pertaining to the first recognition item produced somewhat similar results. A significant two-way interaction effect ($F = 4.57$, $p < .04$) was found in which immediate recall subjects exposed to the atypical ad exhibited higher false recognition scores than typical ad subjects. This ordering was slightly reversed for delayed recall subjects. No significant results were found in conjunction with item 3.

Only one item, the seventh, was used to represent false atypical arguments. Analysis of the data pertaining to this item failed to produce any significant results.

Analysis of subjects' ability to discriminate between presented and unpresented information was performed by calculating the proportion of correct "yes" (ratings of 4, 5, and 6) and "no" (ratings of 1, 2, and 3) responses on the recognition test for atypical subjects. The mean percentage score for typical arguments was 0.62 for both immediate and delayed retention subjects. Respective means for atypical arguments were 0.77 and 0.75. Contrary to expectations, a two-way ANOVA on these scores produced no significant main or interaction effects.

Related attitudinal data also failed to exhibit significant differences between typicality groups or over the retention interval. These data appear in Table 1.

Discussion

According to the results of this study, there is only modest evidence to support the proposition that the

processing of print ads follows an SCT framework. It should be noted, however, that the experimental task represented a fair amount of external validity. Given the assignment of evaluating an entire magazine, subjects received no forewarning as to the exact experimental stimulus. Further, they were kept unaware that the study involved a memory test. This lack of focus raises the possibility that the experimental impact or effect size was slight, and this might explain why the SCT model received little support.

However, the study's design requirements seem to have been met. Subjects exposed to predetermined atypical argumentation, concerning the pen's effect on handwriting, apparently attended to and processed that information. Their reported recognition of the presence of that information in the ad was significantly greater than that of their typical counterparts. Thus there is little doubt that the atypical information was in some way represented in memory. The effects of that information, however, deviated from what would be expected from an SCT-based representational process. Specifically, subjects exposed to the highly typical ad made fewer (not more) schema-based intrusions than subjects exposed to an atypical ad stimulus. This finding prevailed for subjects' recall protocols and, to a lesser extent, their responses to recognition items--i.e., item 6, with a marginal main effect and item 1, with an interaction effect unfavorable to the SCT model. Further, the typical subjects exhibited no better memory performance in terms of recall and recognition accuracy than did atypical subjects. In fact, on one of the recognition items (the second item involving an actually presented schema-typical argument), the findings were opposite of SCT expectations. Typical subjects performed considerably worse than atypical subjects.

In addition to the recall and recognition items, analysis of subjects' discrimination scores do not mesh with an SCT prediction. According to the SCT model, subjects should be better able to discriminate between presented and unpresented atypical information than typical information. This prediction is derived directly from the SCT notion that memory for a prose passage is partitioned into two segments: a schematic portion and a portion related to tagged items. Since the schematic portion is thought to consist largely of typical items imported from previously formed knowledge structures, its contents are viewed as relatively indistinguishable in terms of whether they originated from previous knowledge or some target event. Thus, subjects should have more difficulty in discriminating between presented and unpresented typical information than discriminating between "tagged" information and unpresented atypical items--i.e., tagged items are thought to be represented in a separate portion of the trace. Accompanying this line of reasoning is a second SCT prediction having to do with the ability to discriminate between presented and unpresented information over time. Since tagged information is thought to decay more rapidly than typical items, the SCT model predicts that over time differences in ability to discriminate between various forms (presented/unpresented) of typical and atypical information should decrease. That is, as tagged atypical information is lost, it tends to merge with unpresented atypical items. Thus, atypical items should lose their advantage in discriminability. Neither of the above predictions were upheld by the data. Although a slight advantage in discriminating atypical items was noticed ($0.76 > 0.62$), this difference was far from being significant.

In sum, although many interesting findings emerged, a conservative conclusion must be that a schema-copy-plus-tag hypothesis does not account well for the data of this study. Precisely why this is so is not apparent, since no clear pattern of results emerged. In fact, the mixed findings make it difficult to offer alternative formulations. For instance, a depth-of-processing

approach would predict better memory performance for subjects in the atypical groups. This did not occur, however. Another schema-based paradigm suggests that unless a schema is fully activated, incoming information is difficult to encode. As a consequence, memory performance suffers and reconstruction is more likely (see Alba and Hasher). It is possible that this occurred in the atypical group. That is, the presentation of atypical information in some way disarmed subjects, depressing schema activation. If this is so, these subjects would be more likely to exhibit schema-related reconstructions at retrieval time. Although there is some evidence of this occurring, the data do not square entirely with the notion of an encoding deficit. That is, if atypical information inhibited encoding, then these same subjects should have also exhibited poorer recall and recognition of presented items. This, however, did not occur.

It should also be noted that the SCT formulation might resist explication because of its failure, in reference "retrieval" predictions, to distinguish adequately between recognition and recall. As Krugman (1985) reminds us, these are measures of different kinds of memory, and to lump them together might be to mask the individual effects of either.

Finally, as suggested earlier, the unclear results likely have something to do with the efficacy of the study's manipulation. Although requiring subjects to read a lengthy test magazine may have improved external validity, it may simultaneously have suppressed experimental impact. If this is so, the schema-copy-plus-tag model may yet prove to be a viable representation of memory for ads. A more powerful test of SCT will be necessary, however, to determine whether the representation and recall of ads can be made to lie comfortably on this procrustean bed.

Abstract

The four papers in this session represent two independent lines of research which have been converging on the conclusion that, in addition to whatever immediate persuasive effects an ad may have, it may also cause persuasive effects which accrue over time. Further, these papers contain indications of the conditions under which such delayed effects are most likely to occur and suggest some directions for future research.

The Importance of the Delayed-Effects Issue

The issue of whether at least part of the persuasive effect of an advertisement can be seen only after a delay of days or weeks is of importance for both practical and theoretical reasons. The practical side concerns the adequacy of current copy-testing methods. Since most copy-testing questioning occurs within a day after the consumer is exposed to the ad (Aaker and Myers 1982; Schlinger 1979), the measures are blind to delayed effects. Since copy-testing is usually used to compare the effectiveness of alternative ads, this insensitivity to delayed effects would not be a problem as long as all ads had equivalent delayed effects. But if ads differ in their ability to cause delayed persuasive effects, then the inability of current copy-testing methods to detect such effects could cause erroneous conclusions about the relative effectiveness of alternative ads.

On the theoretical side, researchers who are studying the psychological processes behind delayed advertising effects are likely to propose advertising mechanisms which would not have been considered by researchers who assume that the entirety of an ad's persuasive effect can be measured immediately after the ad is presented. Several of the papers in this session have proposed such mechanisms and thus enrich the study of how advertising works.

Research on the Consumer as a Naive Scientist

The papers by Hoch and Ha (1985) and Deighton (1985) are rooted in the tradition of considering the everyday person a "naive scientist" who uses predictable (and sometimes erroneous) strategies in his or her attempts to make sense of the world.

Deighton reviews two studies where subjects who experienced both product advertising and ambiguous product evidence gave more positive product evaluations than did subjects who experienced only one or the other or neither. Through a third study and a review of the literature, he concludes that this ability of product experience to enhance an ad's persuasive effect is due to two factors. First, the ad increases the availability of the ad's claim in the consumer's memory, and thus increases the chances that the consumer evaluates this claim against the evidence. Second, since consumers tend to evaluate a claim by checking for the presence of confirming instances (without taking into account the number of disconfirming instances), they will come to believe a claim they are evaluating if they encounter any confirming instances at all in the product evidence.

Hoch and Ha confirm Deighton's finding that the persuasive effects of an advertisement can be enhanced by subsequent product experience, but argue that the ambiguity of the product evidence is necessary for this effect to occur. They support this argument by showing that the effect occurs for a product category which

provides ambiguous evidence as to product quality (polo shirts), but does not occur for a less ambiguous product category (paper towels). Although it is possible that differences between polo shirts and paper towels other than ambiguity could be responsible for their results (e.g., level of involvement with the category), it is extremely plausible that it would be more difficult to persuade someone, by any means, when that person has access to unambiguous evidence.

Hoch and Ha also found that advertising caused their subjects to spend more time examining the advertised brands. They conclude, as does Deighton, that advertising leads to the evaluation of the advertised claim when subsequent product experience is available. However, they suggest that consumers may often try to disconfirm the claim. When the product experience is ambiguous, such disconfirmation becomes difficult, and the claim tends to be accepted.

Only one of the four studies described in these two papers actually observes the change in advertising effects over a sizable (two-week) delay. However, the mechanisms proposed in both papers suggests that when an ad is followed by product experience (e.g., during external research or routine brand switching), the persuasive effects of the ad may increase. Further, the results suggest that such delayed persuasive effects are most likely to occur if the product experience is ambiguous or at least contains some confirming instances.

Differential Memorability of Information in Ads

The papers by Kisielius (1985) and Hunt, Kernan, and Bonfield (1985) concern the likelihood that all parts of an advertisement will not be remembered equally well. This research could be considered to follow in the tradition of the sleeper effect, which has commonly been attributed to a tendency to remember the content of a persuasive message but to forget its source (Pratkanis and Greenwald 1985; see also Hasher, Goldstein, and Toppino 1977).

Kisielius investigates the view that parts of an ad which receive more cognitive elaboration when the ad is first seen (i.e., are associated with a larger number of items in long-term memory) will be more likely to come to mind after an extended delay than will parts of the ad which receive less cognitive elaboration. She expects, for example, that pictures in ads tend to receive more cognitive elaboration than verbal statements. This implies that if the pictures in an ad are more favorable to the advertised product than the verbal parts of the ad, the persuasive effect of the ad will be greater after some delay than at the time the ad is originally presented.

While Kisielius relies on the concept of cognitive elaboration to account for memory of an ad, Hunt, Kernan, and Bonfield report a test of the value of the "schema plus tag" notion for predicting what parts of an ad will be more memorable. Although they conclude that they have found little evidence to support the schema-plus-tag view, the delay vs. typicality interactions for both their recall (Correct) and recognition (Item 5) conditions were in the direction predicted by schema theory. The failure of these interactions to reach statistical significance can hardly be considered conclusive given the small sample size in the study (n=42). Moreover, computing the mean recognition score for the typical/unpresented items (3.11) and comparing it to the mean recognition score for the atypical/unpresented item

(1.66) indicates that among the unrepresented items the typical ones were considerably more likely to be rated as having been presented in the ad. This also is just as a schematic view of memory would predict.

While these two studies are far from conclusive, they do suggest that an ad is more likely to have a delayed persuasive effect if, (1) the cognitively elaborated parts are more positive than the non-cognitively elaborated parts, and (2) if the parts that are typical of a consumer's existing knowledge structure are more positive than the parts that are not typical of any of the consumer's existing knowledge structures. Further, if the Hunt et al. result of more false positives for the typical items than for the atypical items can be replicated, it would suggest that the deceptive persuasive effects of advertising might also accrue over time (see Sawyer and Semenick 1978).

Future Research Needs

There are obviously many interesting variables yet to be explored in both the naive scientist and differential-memorability lines of research. But there is also value in research directed at integrating these two research traditions. In both lines of research, it is essential that at least one positive claim in the ad be remembered. In the differential memorability research, the delayed persuasive effects result from this positive claim being more memorable than negative information which was also present in the ad. The naive scientist research also involves a remembered claim which is positive toward the brand. Here, however, forgetting of negative information in the ad isn't necessary because the delayed persuasive effect results from the way the consumer actively tests the claim during experience with the brand. But will a consumer always actively test a remembered claim if the opportunity arises? Or is it necessary that the claim be salient, i.e., very memorable? If the memorability of a claim is related to the probability of its being actively tested, then both types of delayed persuasive effects have a causal variable in common. Moreover, the memorability of the positive claim of an ad is something which can easily be measured. Of course, day-after recall probably wouldn't do. It might take something more like "week-after recall" to have an effective practical measure of an ad's delayed persuasive effects.

Another research direction which could lead toward integrating these lines of research would involve studying how a consumer's environmental input affects his or her response to ads. Cues in the environment certainly can enhance retrieval of advertised information (see Hutchinson and Moore 1984), but they may also enhance delayed persuasive effects in other ways. For example, if a manufacturer coordinates an advertising campaign (e.g., one claiming increased product effectiveness) with a change in product appearance (e.g., the addition of "blue action crystals"), the confirming instances that the consumer happens to experience would tend to become more salient and thus more memorable. Increasing the availability in memory of confirming instances of an advertised claim should enhance delayed persuasive effects of the ad, and suggests another route by which basic memory principles may be able to provide a unified explanation for delayed advertising effects.

MATERIALISM AND INDIVIDUAL DETERMINISM
IN U.S. AND JAPANESE PRINT AND TELEVISION ADVERTISING¹

Russell W. Belk, University of Utah
Wendy J. Bryce, University of Utah

Abstract

Hypotheses that Japanese advertising would approach or surpass U.S. advertising in the level of materialism evinced since World War II were supported. Hypotheses that U.S. advertising would be more likely to stress actively changing the environment (primary control) rather than adapting to it (secondary control) were also supported, but more strongly in print than in television advertising. Cross-cultural and cross-media differences in consumption appeals are discussed.

Economic Growth and Consumer Materialism

Materialism is defined by Belk (1983) as the tendency to view possessions as the primary sources of satisfaction and dissatisfaction in life. As Belk and Pollay (1985b, 1985c) have shown, twentieth century U.S. print advertising has increasingly depicted and appealed to a materialistic lifestyle among American consumers. Although it is unclear whether such advertising is leading or following cultural value changes regarding materialism, it cannot be denied that advertisements at least support and reinforce materialistic values. The present study sought to further explore materialism and related values as displayed in magazine and television advertising in the U.S. and Japan since World War II. Differences over both time and culture were of interest.

While there are many reasons for cultural differences based on factors such as religion, political history, geography, language, and traditions, an even more important factor shaping materialism and derivative consumption aspirations may be the ratio of economic growth to work force growth. This ratio is important for at least two reasons. One is that it reflects the relative increase or decrease in the availability of goods and services, which in a free market system thereby affects prices and consumer expectations of what they will be able to acquire. Secondly, given a level of technology and a relatively fixed ratio of imports to exports, economic growth relative to work force growth also reflects the surplus or scarcity of available jobs and an individual's potential rate of job advancement as older more or less numerous workers retire and as new jobs are created through economic growth.

The impact of these factors on consumer materialism was seen by both Inglehart (1971, 1977) and Easterlin (1980), although they reached opposite conclusions about its effects. Both agreed that the economic climate when one is growing up should have a strong impact on adult consumption aspirations. However, Inglehart concluded that growing up during the post-war economic growth decades in the U.S. and Japan (as well as Europe) should satisfy lower order consumer needs (Maslow 1954) so that less materialistic higher order needs would gain prominence. Easterlin on the other hand concluded that one who, for instance, grows up in the suburbs and is driven or drives to school, friends, movies, and stores will come to regard an automobile as a necessity along with all of the other products of affluence. Thus Inglehart predicted decreasing materialism among a generation raised in a time of abundance, while Easterlin predicted increasing materialism. While the value changes of the 1960's made it appear that Inglehart was correct, subsequent increases in materialism among the U.S. and British baby boom generations and the parallel Japanese "bulge" generation (which quit bulging about a generation earlier in Japan---Reischauer 1977) contradict Inglehart's predictions and appear to support Easterlin's predictions of increasingly

materialistic attitudes (Ike 1973, Marsh 1975, Flanagan 1979).

It is also necessary to consider the relative rates of economic growth in the U.S. and Japan in order to make predictions about the relative rates of growth in materialism that are expected in these two countries. Between 1960 and 1975 the U.S. economy grew at an average real dollar growth rate of 3.7 percent per year while the Japanese economy grew at a rate of over 10 percent per year (Yoshino 1975). Since 1975 Japanese real growth has only been about 5 percent, due in part to high inflation in 1976-1978, but U.S. growth has also slowed and as U.S. trade deficits climb, Japanese trade surpluses rise (Morton 1984). All this means that Japanese buying power has risen much more rapidly than U.S. buying power since World War II and there have also been considerably greater opportunities for jobs and job advancements in Japan than in the United States. Given the much stronger growth in the Japanese economy, we expected to find a much greater rise in materialism reflected in Japanese advertising than in U.S. advertising.

These are predictions about the relative growth rates in materialism in America and Japan. To make predictions about the relative levels of materialism displayed in one country versus the other it is also necessary to consider additional cultural differences. The U.S. has long been known as a highly materialistic nation (e.g., De Tocqueville 1835), but apart from some imperial and feudal splendor lasting into the mid-nineteenth century, Japan has not traditionally been known as a highly materialistic nation--until lately. There are several reasons for Japan's less materialistic traditional reputation. One is that since its feudal era, there have not been wide income disparities in Japan. In addition, conspicuous consumption has generally been viewed as violating egalitarian norms (Cassassus 1985, Christopher 1983, De Mente and Perry 1967). And the devastated state of the Japanese economy at the close of World War II left limited discretionary incomes and a scarcity of consumer goods on which to spend them. However, with the unprecedented economic gains of post-war Japan, as well as a period of openness to Western influences (Belk and Pollay 1985a), materialism began to grow. By the 1960's it became popular to joke that the three imperial regalia (mirror, sword, and jewel) had been superceded by three greater treasures for the Japanese consumer: the car, color TV, and cooler (air conditioner), or the three C's (Fukutake 1974, 1982). Cleaver (1976) suggested that even these, now owned by the majority of the population, have been replaced in consumer aspirations by newer treasures such as the summer cottage, electric oven, and central heating. This rise in materialism has not gone uncriticized in Japan (Burton 1985; Fujiwara 1985; Fukutake 1974, 1982; Guerin 1981; Kikusawa 1979). While the level of consumption by the Japanese consumer is still short of that of the American consumer (due to smaller incomes, smaller dwellings, and greater savings for house and retirement), we expected that the level of advertising emphasis on materialistic themes would be as high or higher in Japan during the current period.

Individual Determinism in the U.S. and Japan

Individual determinism is used here to mean the belief that one's acts as an individual determine one's outcomes; that is, the belief that we are each masters of our own fate and we succeed or fail based on individual initiative. This is a particularly western view that is related to individualism and has been studied recently as "standing out" and "primary control" (Bairy 1967, Rothbaum, Weisz, and Snyder 1982,

¹The authors would like to thank the History of Advertising Archives at the University of British Columbia for access to the U.S. print ads.

Weisz, Rothbaum, and Blackburn 1984). There are two aspects to these beliefs. One is the desire to stand out from the group and be perceived as personally responsible for one's actions. The other related aspect is the desire to actively control situations, people, and events in order to produce desired outcomes. If these are the patterns that characterize Americans, it should not be inferred that the Japanese lack any concern with individual identity and trust their futures to fate. Both of these would be mistaken assumptions. However, the Japanese are believed to prefer "standing in" over standing out and "secondary control" over primary control. Standing in refers to seeking to be a part of the group and derive nurturance and feelings of identity through this association and its collective actions. Secondary control is the preference for adapting to one's environment rather than trying to change it; thus producing harmony rather than challenge and conflict. Producing this harmony is seen as a matter of character and strength and not, as it would more likely be seen in America, as an absence of character and a weakness (Reischauer 1977).

Such differences in individual determinism between the U.S. and Japan were expected to be reflected in advertising in two major ways. First, we expected to find fewer Japanese advertising appeals to use a product or service because it would make one unique or successful as an individual. Secondly, we expected that the U.S. ads would be more likely than the Japanese ads to claim or show that the product could help one do or change things by affecting others or the environment. Unlike the materialism predictions, these differences were not expected to increase or decrease over the time period studied.

Other Differences

A number of other cultural differences were examined in the comparisons of U.S. and Japanese advertising (see Belk, Bryce, and Pollay 1985 and Belk and Pollay forthcoming), but only a few will be presented here and these will be restricted to the television advertising samples. These differences may be grouped under the headings of advertising execution styles and interpersonal relationships, including sex roles. Because there are some important and somewhat subtle differences between the U.S. and Japan in terms of norms for interpersonal relationships, they require some comment.

As Reischauer (1977) points out, the public display of affection and emotion, even with a spouse, is considered inappropriate in Japan. Thus we expected to see fewer intimate glimpses of family life and less physical contact in Japanese ads. At the same time, as Morley (1985) and Trucco (1984) note, Japanese advertising portrayals of females in ways that would currently be regarded as sexist in the U.S., are not regarded as unusual or objectionable in Japan. Such sex role attitudes have also been used to explain the greater use of female spokespersons in Japanese television commercials as a way to defuse what would otherwise be an inappropriate status challenge in an ad suggesting that the viewer take an action such as buying the brand advertised (Smith 1983). For instance, the imperative tone of a message such as "Drink Coca Cola!" would only be appropriate for a superior speaking to a subordinate within the structure of Japanese language and status hierarchy. To avoid such a condescending tone (demanded by the language), in addition to coquettish women, Smith (1983) found the use of children and ingratiating comedians in commercials designed to avoid offending the viewer.

Such subtle differences in communication reflect the relatively greater burden placed on nonverbal communication in Japan (Barthes 1982) and suggest a reason why television advertising, with its greater ability to convey such messages, is even more popular in Japan than in the U.S. In 1980 just over one-third of Japanese advertising dollars were spent on television versus somewhat under one-third in the U.S., (J. Walter Thompson 1982). We were not certain what other differences might be found between television and print advertising in Japan, but it seemed likely that there would be some.

Methods and Results

Study 1: Magazine Advertising

Methods and results for the U.S. sample of magazines have been described elsewhere (Belk and Pollay 1985b, 1985c). Briefly, a systematic random sampling procedure was used to select 250 ads per decade from the ten largest circulation magazines for that period. Of these ads, those retained for the present analysis had illustrations showing the interior or exterior of a home. This resulted in 220 ads distributed as follows:

1943-1947	100 ads
1953-1957	59 ads
1963-1967	32 ads
1973-1977	29 ads
Total	220 ads

The comparison sample of Japanese ads was obtained, also using the criterion of illustrations of the home, from the three largest circulation Japanese magazines since World War II: Bungei Shunju (Literary Digest), Chuo Koron (Central review), and Shukan Asahi (Weekly Asahi). In this case a census of all such ads was taken from each issue of these magazines every fifth year, resulting in the following sample of 332 ads:

1953	40 ads
1958	29 ads
1963	40 ads
1968	55 ads
1973	45 ads
1978	75 ads
1983	48 ads
Total	332 ads

Coding also was done comparably to that for the American ads with three judges, except in this case all were fluent in reading Japanese. One was a Japanese graduate student and the others were American graduate students who had each spent at least five years in Japan. Inter-judge reliability (percent agreement--Kassarjian 1977) averaged .85 and disagreements were arbitrated by majority rule. In addition, these judges coded ten of the U.S. ads and produced an average agreement level of .84 with the coders for these ads (who were about comparably consistent within the ads they coded). Coding definitions for the themes reported here were:

Luxury/Pleasure: Explicitly mentions luxury (or related terms such as leisure, pleasure, regal, or pampered) or else depicts such pleasures visually.

Status/Prestige: Shows or discusses prestige or social standing relative to others or uses high prestige source or association.

Having: Either a person is displaying or referring to owned object(s) or a house or room is shown from eye level into which the viewer seems to be invited.

Being: Shows or discusses what the reader can become or how people will treat the reader with the help of this product or service.

Doing: Shows or discusses a reader activity that is aided or provided by the product or service.

There were some differences in the portions of the two ad samples involving various product categories, but comparisons with product category held constant produced no meaningful disparities in results to those from the overall sample. Materialism was measured in the ads by the frequencies of appeals involving luxury and pleasure, status symbolism, and "having" the product or service advertised for its own sake (rather than for the person it will help one be or become or the activities it will help one do). Table 1 shows that each materialistic theme was less frequent in Japan for the earliest years and grew to become the more frequent in

either the sixties or seventies. Appeals stressing

TABLE 2

TABLE 1

PERCENTAGE OF U.S. AND JAPANESE ADS USING VARIOUS THEMES

YEAR*	Luxury		Status		Having		Being		Doing	
	U.S.	JAPAN	U.S.	JAPAN	U.S.	JAPAN	U.S.	JAPAN	U.S.	JAPAN
1943-										
1947	21.0%		4.5%		31.0%		58.0%		76.0%	
1953-										
1957	27.1	2.5%	6.8	0.0%	50.8	27.5%	39.0	45.0%	86.4	17.5%
1958		0.0		0.0		24.1		37.9		10.3
1963-										
1967	25.0	25.0	4.2	20.0	31.3	45.0	37.5	22.5	84.4	12.5
1968		32.7		30.9		47.3		9.1		1.8
1973-										
1977	48.3	42.2	4.8	40.0	51.7	35.6	31.0	11.1	72.4	15.6
1978		52.0		36.0		25.3		22.7		6.7
1983		29.2		35.4		43.8		22.9		12.5

*Underlined years apply to Japan

the status symbolism of the advertised brand were far more frequent in Japan starting in the 1960's, even in comparison to the height of U.S. status appeals in the 1930's (Belk and Pollay 1985b, 1985c). High status persons from prominent occupations are typically used in this advertising in order to impart symbolism to the advertised brand. Thus, as predicted, Japanese materialistic appeals not only grew more rapidly than U.S. materialistic appeals, but exceeded U.S. levels at some point before the end of the sample period. Recent apparent declines in Japanese materialistic appeals may be responding to the same changes in values creating the recent journalistic criticism of such traits in Japan.

The last two columns of Table 1 show two alternate existential states to having (Sartre 1956). The more interesting of the two is doing which reflects the primary control hypothesized to be more common in the U.S.. On the basis of these results the hypothesis is strongly supported.

Study 2: Television Advertising

Because an historical archive of Japanese and U.S. television advertising was not available, television advertising for both countries was only studied for the year 1984. The U.S. advertising was recorded off the air in late summer and early fall in Spokane. The Japanese sample was recorded for a similar time period in Tokyo. A random sample of times of day, days of week, and stations was obtained in both cases. These ads were not restricted to those showing a home.

Japanese television saturation is comparable to the U.S. and programming is also similar (Gardner 1961). Generally, television advertising is not as regulated in Japan as it is in the U.S. (Ward, et al. 1985), but an exception is the prohibition of comparative advertising. Nevertheless, all of the Japanese advertising in our sample could have been shown on U.S. TV, although the use of cartoon characters in some of the children's advertising might meet with some criticism.

There were again some differences in the frequency of ads for various product categories as shown in Table 2, with the most extreme case being that 30 of the 191 Japanese ads were for non-alcoholic beverages while only 3 of 203 U.S. ads were in this category. But when analyses were done within a single product category (health and beauty products), results were similar to the overall results presented below.

TELEVISION AD PRODUCT CATEGORIES

PRODUCT CATEGORY	NUMBER OF ADS	
	U.S. Sample	Japanese Sample
Automobile and Related	24	10
Clothing and Related	3	2
Food and Food Related	31	35
Alcoholic Beverage	18	7
Non-alcoholic Beverage	5	30
Health and Beauty	37	31
Household Cleaning/Care	16	10
Electrical Appliance	1	5
Electronics	33	12
Home Furnishings	8	7
Retailers	3	13
Other	24	29
Total	203	191

Coding of the television ads was similar to coding of the print ads, with similar coding categories and two sets of three graduate student coders for each country's ads (in this case one coder overlapped in the two sets of judges). Partly because of a reduced number of coding categories compared to the print ads, inter-judge reliability averaged over .95 for the television ad coding.

In terms of format, 68% of Japanese commercials were 15 seconds in length whereas over 90% of U.S. commercials were 30 seconds long. The only other major difference was that more Japanese commercials used music throughout (83.8% versus 69.5%) and fewer used no music at all (3.1% versus 24.1%). Differences in the thematic content and styles of these commercials are shown in Table 2.

TABLE 3

FREQUENCY OF U.S. AND JAPANESE 1984 TELEVISION ADVERTISING THEMES AND STYLES

APPEAL/FEATURE	PERCENT OF ADS	
	U.S.	JAPAN
Luxury/Pleasure Appeal	19.8%	16.8%
High Status Spokesperson	11.8	41.3
Having Theme	64.1	79.3
Being Theme	31.5	11.5
Doing Theme	56.5	55.0
Demonstration	38.4	53.9
Be Unique Theme	7.9	5.3
Be Successful Theme	28.6	2.6
Superlatives Used	17.7	4.7
Product Test Results	12.8	4.2
Product Ingredients Touted	40.9	22.5
Product Performance Touted	63.6	34.5
Price Noted	3.0	19.0
Voiceovers Used Throughout	77.3	26.2
Superimposed Writing	58.6	98.5
Female Announcer	16.8	37.7
Sexy Female Featured	4.9	13.6
Family Featured	25.1	8.9
People Shown Touching	62.6	38.7

Again the comparable use of materialistic themes and especially high status spokespersons is seen in the Japanese ads. However, the primary control doing theme is no more common in the U.S. TV ads than in the Japanese TV ads. The reason for this is largely the greater number of product demonstrations in the Japanese ads, often involving demonstrations by high status spokespersons. Clearly the U.S. ads were more likely to use individualistic appeals to be unique or successful however, and were more likely to employ superlatives. In addition to not encouraging viewer individuality, the Japanese ads seemed not to stress brand uniqueness or relative advantage to any great degree. By law, no Japanese

ads were comparative, while 7.4 percent of U.S. ads used a comparative format. Toshio Yamaki (1984) in a comparison of Japanese and U.S. print ads also found that U.S. ads were more likely to be comparative and to stress individuality, success, and the enhancement of consumer performance.

Differences in stylistic execution are also seen in the greater tendency of U.S. ads to stress test results, ingredients, and product performance, and the Japanese ads' greater tendency to stress price. Also while the U.S. ads more frequently used voiceovers throughout, the Japanese ads more frequently used superimposed writing throughout. Finally, some anticipated sex role differences are seen in the Japanese ads' greater use of sexy female models and the U.S. ads' greater tendency to show families and people touching one another.

Discussion

It is a basic premise of advertising that a successful ad must appeal to the values and needs of its intended audience (McNeil and McDaniel 1984). If the ads studied here have explicitly or implicitly adhered to this premise, then it is clear that differences remain in Japanese and U.S. consumer values. While there has been some convergence in the amount of materialism displayed in these ads, Japanese emphasis on status symbolism remains substantially higher and U.S. emphasis on individualism and standing out remains higher as well. The predicted U.S. preference for primary control over secondary control was evident in the print ad sample, but less so for the television ad sample. It may be that this difference is brought about by the near necessity of television to show action of some sort, but it is also possible that the greater nonverbal communication potential of television makes it more amenable to expressing new values than more traditional print media (Barthes 1982).

Cross-cultural value differences also bear on the likely effectiveness of advertisements dubbed from one culture to be presented in another. Such ads were relatively rare in the present sample. In the Japanese TV ad sample, while 11.5% of the ads were for U.S. products, only about one-third of these were dubbed from English language versions. In the U.S. TV ad sample only 2.0% of the ads were for Japanese products and none of these were dubbed from Japanese. Nevertheless, given the recent calls for universal advertising appeals by Theodore Levitt and others, some comment might be made from the present results. Given the value differences noted above we are very skeptical of the potential for universal advertising appeals. Furthermore, more subtle communication differences such as sex of the announcer, amount of touching, and prevalence of active "doing" appeals, make universal advertising campaigns a more difficult proposition still. If such differences are present in the few appeals examined here, they are undoubtedly present in others as well.

THE CULTURAL PERSPECTIVE IN CONSUMER RESEARCH

John F. Sherry, Jr., Northwestern University

Abstract

The use of a cultural perspective to interpret behavior and direct investigation in consumer research has been sporadic, despite its profound potential. "Culture" has imprecise and unwieldy connotations which make traditional consumer researchers hesitant to employ it as an interpretative frame. This paper proposes a conception of culture designed to assist researchers in understanding consumer behavior. Some suggestions for using a cultural perspective are provided.

In his review of the benchmark study of culture conducted by Kröeber and Kluckhohn (1952) - the one cited so often in despair or derision by contemporary consumer researchers - which provided us with 164 definitions and almost 300 conceptions of the term "culture," the late cultural theorist Leslie White (1954) celebrated its thorough detail but lamented the confusion such a study would engender. In our quantitative investigations of consumer behavior, culture frequently represents "the unexplained residuum of rigorous empirical analysis, an area of darkness beyond the reach of currently available scientific searchlights" (LeVine 1984). That many researchers operate in a "world of variables with frequencies of less than 70%, and arbitrarily assign certain characteristics to the J-curve has profound implications for our understanding of consumer behavior: mere "background parameters" from one perspective become topics of "revealing cultural inquiry" from another (LeVine 1984). In the spirit of Tucker's (1966) call for help in the search for "useful questions," this essay discusses the cultural perspective in consumer research.

Defining Culture

To understand the complexity of the term "culture" in modern usage, beyond the literal continuity of physical process (as in sugar-beet culture or germ culture) Williams (1983) wisely insists that we recognize three broad categories of active usage. The first is the independent abstract noun describing a general process of intellectual, spiritual and physical development, which has its origins in the 18th century. The second is the independent noun indicating a particular way of life, which has its origins in the late 19th century. The third is an applied form of the first sense, an independent abstract noun describing the works and practices of intellectual and artistic activity, which has its origins in the late 19th and early 20th centuries. Each usage is currently colored by every other. While usage number three is perhaps the most widespread, I will use the second sense as the foundation of this essay.

Perhaps the oldest "terminological wrangle" in anthropology centers around the term "culture" (D'Andrade 1984). It has been treated both as a class of "things," often with a very particular content, and as a process. Of all the classificatory schemata used by anthropologists to describe and analyze cultural systems, a "universal pattern" proposed by Harris (1971) has proven effective for researchers of varying theoretical bent. This universal pattern of culture has three major functional sectors: ecology, social structure, and ideology. Ecology is the way a system is adapted to its habitat. This adaptation is shaped by the technology used to obtain, transform, and distribute resources. Demographic factors also govern the relationship between cultural system and environment. This component of the universal pattern is the infrastructure. Social structure is the way that an orderly social life is maintained. Domestic and political groupings are funda-

mental social structural units, the order within and between which permits economic transaction. Neither the production, consumption, or exchange of resources, nor the structure of social groups performing these functions can be satisfactorily understood in isolation. This component of the universal pattern is the structure. Ideology is the set of mental characteristics that fit a people to its ecology and social structure; it encompasses all socially patterned thought. Ideology as Harris (1971) understands it can be explicated using a set of concepts discussed by Geertz (1973): world view and ethos. World view is the cognitive, existential aspect of culture, embodying the most comprehensive ideas of order. Ethos is the moral, aesthetic, evaluative aspect of culture, embodying a people's mood or character. Together, world view and ethos impart meaning to experience. This component of the universal pattern is the superstructure. A functional unity between these sectors of culture has been a basic postulate of many culture theorists (Harris 1971). The universal pattern can be used effectively to understand consumer behavior as a cultural system.

World system theorists (Rollwagen 1980) have criticized traditional anthropological treatments of culture as isolationist insofar as the adaptive interaction among cultures has been ignored. Recent work by Wolf (1982) has provided a much needed corrective, and has recast culture as "a series of processes that construct, reconstruct and dismantle cultural materials, in response to identifiable determinants." Thus, it is inaccurate to speak of the instrumental forms and the ideological codes which constitute "culture" as existing *in vacuo*. Culture is not so much a property of society as it is a process of creation and interpretation that occurs when people interact over time (Rollwagen 1980). Mintz's (1985) masterful interpretation of the role of sugar in modern history is a striking example of the culture-as-processing viewpoint.

Culture can be viewed in Williams' (1977) scheme as an interrelated configuration of archaic, residual and emergent dimensions. At the level of archaic culture, past patterns are generally no longer effective in the present, although they may serve as sources of historical identity. Residual culture is comprised of lived patterns originating in the past, but affecting interactions in the present. Emergent culture consists of existing expectations, values and interactions, along with the process through which new meanings and relationships are continually created. Thus, culture is not uniform, in the sense that it is a continual synthesis of old and new. Given the many modes of exchange between societies, every culture can be understood as an amalgam (Ulin 1984).

The properties of culture that LeVine (1984) experiences as central are collectivity, organization, multiplexity and variability. Culture is collective in that, within a community, consensus exists about meaning, consensus is related substantively to the importance of social communication, and that consensus produces redundancy across individuals. Culture is organized in that a coherence or connectedness, regardless of degree and of kind, exists between its elements; it is not a random assemblage of discrete elements. Culture is multiplex in that it cannot be reduced to its explicit or implicit dimensions, and that it can integrate rational and nonrational elements into a workable rationale. Culture is variable in that the patterns by which people live their lives vary widely by place and time. We will discuss variability in considerable detail directly.

D'Andrade (1984) has identified three major views about the nature of culture, which can be arrayed along a continuum. At one pole, culture is conceived of as knowledge, or accumulated information, which is not necessarily widely shared nor necessarily highly integrated. The volume of information in the cultural knowledge pool is extremely large. At the other pole, culture consists of "conceptual structures" that create the "central reality" of a people, and which are inter-subjectively shared. The entire system is highly inter-related, despite any contradictions which might exist. The volume of information in the cultural knowledge pool is relatively small. Between these polar conceptions of the nature of culture lies the third, or institutional, conception which views culture as clusters of norms defining the roles which attach to statuses; integration, while important, is problematic. The amount of information in the cultural knowledge pool is considerable.

It is often remarked that nothing so divides researchers seeking to generalize about human behavior as the issue of cultural variability (LeVine 1984). How do we interpret the facts of cultural variation in generalizing about variability? LeVine (1984) identifies three perspectives commonly assumed on this issue. Again, the idea of a continuum is useful. At one pole, the reductionists (Marxists, neoclassical economists, cultural materialists, orthodox Freudians, sociobiologists, etc.) promote such basic premises as uniformities of structure and content in human life, culture and motivation across time and place. They minimize variability and dismiss variation as surface manifestations concealing deeper uniformities. At the other pole, phenomenologists insist on the uniqueness of each culture, the local pattern of meaning with which apparent universals are invested, and the impossibility of constructing useful cross-cultural categories. They view similarities in behavior as superficial, and feel comparative methods will obscure the diversity of meanings that defines a particular culture. Between these poles is the centrist position, which posits no a priori theoretical position forecasting the results of inquiries into variation and demands a larger, more appropriate theoretical frame than those currently available. It is this centrist position that LeVine (1984) champions in his advocacy of ethnographic and comparative methods.

While we have abandoned the anarchic "shreds and patches" concept of culture once popular, in favor of conceptions based upon pattern, we have not moved significantly beyond the search for an appropriate metaphor in attempting to define culture. For our present purposes, I will inelegantly proclaim that culture at once is constituted and constituting. It is composed of, and in turn, composes two significant human phenomena: meaning systems and material flows (D'Andrade 1984). Meanings represent the world, create cultural entities, direct people to behave in particular ways, and evoke particular feelings. Material flow denotes the movement of potentially countable entities - goods, services, messages, genes, etc - in space and time. Human groups adapt to their environment and structure interpersonal activity through these two phenomena. Meaning systems and material flows are mutually influential and differentially distributed across persons (D'Andrade 1984).

The challenge to consumer researchers - the majority of whom are firmly embedded in and actively constructing a culture of consumption - is to describe and interpret both the meaning systems and material flows underlying consumer behavior, as well as to analyze the relationship between meaning and flow. That worlds of goods exist within which culture is created and cognition structured is recognized; how these processes unfold across cultures remains to be determined (Douglas and Isherwood 1979, Agnew 1983). Cultural analysis can improve our understanding of consumer behavior as trivial as the new Coke debacle and as profound as the Third World infant formula complex. The fruits of such analysis might then be used to maintain or transform consumer culture.

A Prescription for Consumer Research

Because this essay was drafted to amplify the voice of a disaffected and growing minority of researchers interested in moving beyond the traditional positivist, cognitive psychological orientations in consumer behavior studies, some programmatic remarks are required. We are living in an era in which cultural diversity is alternately accelerated and eroded by the diffusion of consumer ideology. The fragmentation of the domestic marketplace, the allure of a global marketplace, the spectre of protectionism, the renaissance of organizational climate concerns, the critique of development, the new international division of labor and dozens of other critical trends virtually compel us to adapt a cultural perspective in our research. Whether "subculture," "ethnicity" or "segment" becomes our interpretive frame, whether "corporation," "household" or "family" becomes our laboratory, or whether "normative," "idiographic," or "eclectic" becomes our orientation are all subsidiary to our decision to focus on meaning systems and material flows within and between groups.

Without undertaking a critique of naive empiricism, or proclaiming the primacy of the centrist perspective - enterprises we may be unwilling or unable to support - what steps can a consumer researcher take in adapting a cultural perspective? The first is to negotiate a working conception of culture, in terms of your preferences regarding variability and nature as discussed above. The investigator who views culture as "a non-rational, extralogical, arbitrary partitioning of the world that is "framed," talked about, acted upon, even labelled and is handed over from one generation to the next" (Shweder 1984) will generate questions and findings that a consumer researcher with an opposing perspective can employ, advancing the field in the bargain. The second is to select a consumer research issue, and frame it in terms of meaning systems and material flows. Gauging the impact of differential time allocations upon the household meal complex lends itself to such a framing: "role," "family," "time," "food," and "meal" are just a few of the culturally constructed entities that must be interpreted. The third is to identify an accessible group that would become your fieldsite, or natural laboratory. Urban nomads, middle managers, rural black families, flea market dealers, yuppie neighbors and other "naturally" occurring groups in their traditional contexts are exemplary units. The fourth step - and one best left to another paper, is the selection of an appropriate methodology. The tailoring of research design to problem and setting is a challenging and ongoing enterprise. Cultural perspectives have been guided by ethnographic and ethnologic procedures, traditionally. (The merits and shortcomings of ethnography in consumer research will be discussed at our next Annual Conference, if the proposed Consumer Behavior Odyssey Project is successfully launched.) It is important to note that many theorists' conceptions of culture have emerged as a direct result of their ethnographic work.

Conclusion

A cultural perspective assists the researcher in achieving a comprehensive understanding of the consumer behavior he or she is attempting to interpret. That interpretation is a synthesis of the consumer's native intuition and the analyst's understanding. Recent forays into cultural hermeneutics, semiotics, discourse analysis, structural anthropology, historical materialism and other "nontraditional" disciplines have rewarded consumer researchers with novel insights into their subjects.

EFFECTS OF STEREOTYPING IN CROSS CULTURAL RESEARCH:
ARE THE CHINESE REALLY CHINESE?

James McCullough, Washington State University
Chin Tiong Tan, National University of Singapore
John Wong, Washington State University

Abstract

Previous research has identified consumer segments in both Western and Oriental societies exhibiting attitudes and behaviors associated with traditional Chinese values. These consumers were said to exhibit high levels of Chineseness. This paper examines the consequences of these findings for the study of ethnicity in consumer behavior. Research results indicate Chineseness is more likely to exist in non-Asian households than in Asian families. Patterns of Chinese attitudes and consumption behavior found in Singapore differ significantly from those found in the United States. This raises questions about the nature of ethnic segmentation and the definition of ethnicity as it is commonly used marketing and consumer behavior, indicating the need for alternate operationalizations of ethnicity.

Introduction

Interest in ethnic research in marketing and consumer behavior has been stimulated by the growth of large market segments with strong ethnic affiliations. Interest in the characterization and analysis of Black, Hispanic, and other ethnic groups within the American marketplace has been driven by the strong economic impact of these groups on American society. Consumer behaviorists have become interested in the relationship between ethnicity and consumption largely because of the diversity of behavior found in ethnically affiliated consumers and the usefulness of the ethnic consumer as a vehicle for examining other important consumer behavior constructs.

In another context, ethnic research has been undertaken to provide insight concerning international markets and the international dimensions of consumer behavior. Tan and McCullough *et al.*, for example (McCullough, Tan, and Teoh, 1984; Tan, Teoh, and McCullough, 1984; Tan and McCullough, 1985; Ellis *et al.*, 1985), have examined the relationship between affiliation with Asian or Chinese ethnic groups, family decision making, and consumption behavior. This series of studies and subsequent discussions of ethnic behavior at the American Marketing Association meeting in August 1985 have led to this paper.

Understanding Ethnicity

Values and Ethnicity

Central to any ethnic group is a set of cultural values, attitudes and norms since culture represents the social heritage and distinctive life style of a society. According to Linton (1973) it is a configuration of learned behaviors which are shared within a society. Since few ethnic groups exist in homogeneous societies, they commonly represent sub-groups holding a common set of cultural values, attitudes and norms. Since they develop within a larger environment over a period of time, it is often difficult to identify the values of the ethnic group and to separate the group values--the underlying determinants of behavior--from other elements of culture.

Ethnicity-Value-Behavior Measurement

Rokeach has done a great deal to clarify the conceptual issues surrounding the study of attitudes and values. Careful conceptual distinctions are drawn among belief, belief

belief systems, ideologies, values, value systems, faith, sentiments, and attitudes. An attitude for example is defined as a relatively enduring organization of interrelated beliefs that describe, evaluate, and advocate action with respect to an object or situation, and with each belief having cognitive, affective and behavioral components. Each of these beliefs is a predisposition response toward the attitude object or situation or towards others who take a position with respect to the attitude object or situation or toward the maintenance or preservation of the attitude itself. Since an attitude object must always be encountered with some situation about which we must also have an attitude, a minimum condition for social behavior is the activation of at least two interacting attitudes, one concerning the attitude object and the other concerning the situation (Rokeach 1970, p. 132).

A value by contrast is a type of belief, centrally located within one's total belief system about how one ought or ought not to behave, or about some end-state or existence worth or not worth attaining. Values are thus abstract ideals, positive or negative, not tied to any specific attitude object or situation, representing a person's belief about ideal modes of conduct and ideal terminal goals... (Rokeach 1970, p. 124).

If the definition of ethnicity goes beyond geographic terms, the values, attitudes, and behaviors of the ethnic group should be studied. In attempting to determine what are valued between ethnic groups, either observed behavior or verbalizations concerning behavior are usually examined. From observations of individuals, consistent behavior patterns in given situations can often be noted. When a consistency can be established, it is then possible to infer a degree of liking, commitment to certain kinds of behavior. Thus the different elements of value, attitude, and behavior among ethnic groups can be established.

Chineseness

The Chinese exist as ethnic subgroups in most countries and as the dominant group in many parts of Asia. Although the Chinese are culturally diverse, comprising a wide variety of dialectically defined groups, there are some unique cultural characteristics to describe the values and behavior of the Chinese in general. These unique cultural characteristics have been documented in the anthropology, sociology, and political science disciplines (Greenblatt, Wilson, and Wilson, 1981; Greenblatt 1979, Wilson 1970). For example, Hsu (1981) has proposed that in comparison to the American, the Chinese are by and large situation-centered, the Chinese are inclined to be socially or psychologically dependent on others. They are tied closer to the world and their fellow men. Thus their happiness and sorrow are milder since they are shared. Other values that are general to human social existence but have been operated differently within the Chinese are family loyalty, filial piety, group orientation, the concept of face and the concept of reciprocity in social exchange. Bennett (1979) has generated a list of 34 identifiable value statements peculiar to the Chinese. Some examples are shown in Figure 1.

FIGURE 1

TYPICAL CHINESE VALUE STATEMENTS

1. Age should be respected over youth.
2. Established authority is preferred over innovation.
3. The public welfare should be placed ahead of individual welfare.
4. Social classes and severe inequality are desirable if not natural.
5. Conspicuous consumption and material possessions should be taken as leading indicators of status.
6. Favors must be repaid equivalently, otherwise one is under obligation and loses face.
7. Men should go to work to support their families, and women should stay home and take care of household duties.
8. The building blocks of interpersonal relationships should be connections--a confident feeling of reliability arising from accumulated obligations.
9. Face is the prestige and reputation one achieved through material or social success, ostentation or generosity. Also, having face is the respect from others for a person or a family with a good moral reputation.
10. Filial piety is a virtue.

Measuring Chineseness

The study of Chineseness was begun in Singapore in 1982 as part of a study to explain differences in patterns of family decision making. The scale used to measure Chineseness that was developed for that study is shown in figure 2. Before examining the problems caused by the use of the scale, it is important to understand the origin of the elements. Singapore is a complex society composed of several significant ethnic groups dominated by the Chinese. The elements of this scale were extracted from a list of statements proposed by a group of predominately Chinese university students for use in consumer behavior research in an Honors (graduate course) in consumer behavior and marketing research. The ten elements used in the studies were identified by consensus from among the elements originally proposed.

FIGURE 2

CHINESENESS SCALE

The following items were identified as possible indicators of Chinese attitudes. Beginning with a list of stereotypical Chinese belief and input from Chinese students in Singapore, focus groups modified the items to arrive at the following scale items:

1. A woman's place is in the home. (Agreement).
2. Caring for one's aged parent is the duty of every person. (Agreement).
3. I often do the right things so as not to lose face. (Agreement).
4. I feel strongly about returning favors to others. (Agreement).
5. Every family should have a son. (Agreement).
6. My relationship with my parents is formalized. (Agreement).
7. I interact frequently and closely with my relatives. (Agreement).

8. Showing your affections openly is acceptable. (Disagreement).

9. Marriage should be a lifetime commitment. (Agreement).

10. One should not go to the extremes in one's behavior. (Agreement).

Subjects respond to the above statements using a Likert scale (agree-disagree) and after item 8 is reversed in the scoring a summed score is calculated for each respondent. Low scores (i.e.: high agreement) are termed highly Chinese.

Clearly, in the case of Chineseness, the measurement of ethnicity became largely an evaluation of values, although the elements relate to both beliefs and behaviors. Once the scale was developed, it was used to try to explain differences in family decision making activity (Tan and McCullough, 1984) and in consumption behavior (Tan and McCullough, 1984) among consumers drawn from the Chinese community in Singapore. This work was extended to consumers in the United States who were compared with the Singaporean sample (McCullough and Tan, 1984). It was from these studies that a disquieting result emerged--ethnically white consumers living in the United States were as Chinese as ethnically Chinese consumers living in Singapore based on scores on the Chineseness scale. The Chineseness scale was no longer measuring uniquely Chinese characteristics, but an underlying construct common to both groups.

Why Study Ethnicity?

Increased interest in the international dimensions of consumer behavior has spawned a number of studies of "cross-cultural" consumer behavior. Most of these have examined the differences in behavior between to national markets chosen more for the convenience of the researchers than for their scientific justification.

Ethnicity provides a vehicle for examination cultural difference in a systematic fashion across national boundaries by identifying similar subgroups in a variety of countries rather than by describing specific groups in selected environments.

What Is Ethnicity?

From a marketing perspective, ethnicity was initially a demographically defined concept. A consumer was defined as a member of an ethnic market segment on the basis of race. This concept was reasonable in an operational sense as long as the black consumer was identified as a reasonably isolated, homogeneous consumer within the American market. The integration and fractionation of ethnic groups within this market has made segmentation based on race less useful, and the emergence of other large, but less easily definable groups presents even greater problems.

In looking at the Hispanic market, for example, Valencia (1984) points out the difficulty in defining "Hispanicness" due to the wide variance in acculturation. Hirschman (1981) discusses the same problem in the American Jewish group. Although the relationship between ethnicity and acculturation can be discussed in conceptual terms, it is difficult to develop a useful framework for using ethnicity in the study of consumption.

The fact the similarities in values and behavior associated with ethnicity can be found in apparently unrelated and diverse groups in different international environments provides a clue to an operational definition of ethnicity: affiliation with a group of individuals in a cultural holding similar values, attitudes, and beliefs, and exhibiting similar behaviors without regard for race, religion, or national origin. Ethnicity becomes, therefore, not a demographic, but a psychographic characteristic, and similar ethnic groups would be expected in a variety of cultures, regardless of the demographic structure of the society.

Using this definition, it is not surprising to find Americans who are as Chinese as the Singaporean. Both groups hold the same values, attitudes, and beliefs, and exhibit similar behaviors. Although their social role may be different--the Chinese in Singapore are the dominant group while the traditionalist in the United States does not play as strong a role--they exhibit similar consumption behaviors and may serve as target markets for similar marketing programs.

How Can Ethnicity Be Determined?

There appear to be three approaches to evaluation of ethnicity offering potential in the study of consumer behavior.

Demographic Measures

Demographic measures of ethnicity are the easiest to use as they are by definition objective characteristics. The increased intermingling of races and nationalities, however, makes these traditional ethnic determinants less reliable. More significantly, if ethnicity is a behavioral construct, using demographic variables may prove unreliable.

Values and Attitudes

Culture is usually defined in terms of values and behaviors, and ethnicity is generally considered to be closely related to culture. As the Chineseness studies indicate, however, there can be wide acceptance of "ethnic" values among individuals who are obviously not part of the ethnic group of interest. This approach should facilitate extension of marketing programs and consumer behavior concepts internationally, facilitating identification of important subgroups which are "ethnically" similar.

Self Reports

Ethnic assimilation is an important parameter in the evaluation of ethnicity. As the demographic determinants of ethnicity are discarded, individuals become free to adopt a wider variety of ethnicity. Their assessment of their own ethnicity may be the best measure to their true ethnicity. The degree of affiliation with the group in question is a good measure of ethnically related consumption.

Conclusion

In Asian cultures, young, modern consumers (demographically defined) commonly adopt Western values and behaviors, but report themselves as belonging to a particular dialectical ethnic group. This indicates the complexity of the issue. In order to understand international consumer behavior in an age of mixing and change, ethnic behavior needs to be better examined and better understood. A redefinition and reevaluation of ethnicity and ethnic stereotypes will be necessary before we can understand and evaluate white, Anglo-Saxon Chinese.

ACCULTURATION: THE IMPACT OF DIVERGENT PATHS ON BUYER BEHAVIOR

Thomas C. O'Guinn, University of Illinois
Wei-Na Lee, University of Illinois
Ronald J. Faber, University of Texas

Abstract

The concept of acculturation is central to the study of subcultures and their interaction with host societies. Yet, while buyer behaviorists have given this topic some attention, actual investigations involving subcultures have been largely descriptive, and conducted without the aid of a substantive theoretical model of the acculturation process. While this paper stops short of presenting a truly comprehensive model, and is developmental in nature, it does, however, suggest a fundamental reconceptualization of existing consumer acculturation theory. The thesis presented by this paper is that the consumer acculturation process may take multiple, simultaneous and less direct paths than previously modeled, the most significant of which may be the path offered by mass media.

To understand human behavior we must specify its social origins and the process by which it is learned and maintained." (McLeod and O'Keefe 1972, 127-8).

"I watch TV." Chance the Gardner

Introduction

The United States is presently becoming more ethnically heterogeneous. This is due, in large part, to high levels of Asian and Hispanic immigration. Both of these ethnic groups have brought with them languages other than English, as well as culturally bound attitudes, values and behaviors. Some of these cultural differences may be expressed in terms of buyer behavior. In response, many marketers are having to reconsider the manner in which they have traditionally approached and segmented their markets. Unfortunately, marketing researchers have paid relatively little attention to the concepts of ethnicity, subculture and consumer acculturation.

Previous research grounded in the so-called "melting pot" model has left us without any clear understanding of the agents and forces involved in the consumer acculturation process. For the most part, American social scientists modeled the acculturation process in terms of the immigrant's direct contact with the people and social institutions of the new host society; the greater the contact, the greater the acculturation. This approach, however, ignores the American immigrant as a consumer and tends to overstate the importance of the workplace and the school as agents of socialization. This model may have been adequate when it was developed, but in a consumer culture now pervaded by commercial mass media it is in clear need of revision. A workable model of consumer acculturation must, at a minimum, incorporate the indirect path offered by mass mediated socialization, as well as the traditional path of direct social contact.

Consumer Acculturation

A central and primary mechanism involved in the interaction of ethnic subcultures and host societies is the process of acculturation. Acculturation may be

defined as the immigrant's adoption of the dominant society's attitudes, values and behaviors. Consumer acculturation is a subset of this process comprised of those attitudes, values and behaviors which collectively comprise what we call buyer behavior.

While some immigrants will retain a great many culturally bound attitudes, values and behaviors, others will more quickly and enthusiastically adopt those that define the dominant host culture. Some of this variance will undoubtedly be expressed along dimensions of buyer behavior. For this reason, level of consumer acculturation could begin to play an increasingly important role in marketing efforts targeted at ethnic populations. Marketers, for example, who now view the Hispanic market as one homogeneous and monolithic segment may have to re-evaluate their thinking and approach. Yet far more important than any application, is the hope that investigation of the consumer acculturation of immigrants may give us a better understanding of the larger consumer socialization process. By studying those new to a society, we are provided with a unique opportunity to investigate the mix of social forces which affect us all.

Certainly there is no doubt that what it means to become acculturated as an American includes learning the culturally accepted attitudes toward material goods and possessions. Much of who and what an American is is determined by what he or she possesses, and the values those possessions express and convey to others. Immigrants who want to become acculturated must learn what things they should desire, and to a lesser extent, why.

While this paper does not represent a complete remodeling of the consumer acculturation process, it does suggest one major revision: the incorporation of the indirect path offered by mass mediated consumer socialization. Historical examples and cultural artifacts are used to support and illustrate this thesis. The paper also presents some developmental propositions regarding the effects of these divergent paths, as well as suggestions and implications for future research.

The Traditional Model

What buyer behaviorists use as a sort of working model of acculturation is largely the sociological model developed in the late 1920's and early 1930's (see Kimball 1955). It represented a major break with the anthropological functionalism and natural history of Boas, Benedict, Sapir and others (Hymes 1967). This sociological model is grounded in logical positivism and focused on the European immigrant to the United States. The psychological factors of acculturation were never explored much beyond a rather narrow view of social facilitation. It is, in short, an incomplete and outdated model. It is incapable of satisfactorily encompassing and dealing with such things as enduring ethnic subcultures, the institutionalization of biculturalism, and the pervasive and powerful effects of the mass media.

According to this facilitation model, the "successful" immigrant takes on the values, attitudes and behaviors of the host society through direct social contact with, and observation of its people and institutions. In the case of immigrant children, the public school system was viewed as the dominant agent of acculturation. There,

immigrant children were taught the new ways by both teachers and peers. For immigrant adults, the Anglo-dominated workplace was thought to be the primary institution of acculturation. Even though the immigrant may have worked alongside other immigrants, they typically worked within the confines of an institution dominated by, and operated in accord with the norms of the dominant Anglo society. In these institutional settings the immigrant learned the formal as well as the informal rules of the new culture. Presumably, the old eventually succumbed to the new.

While significant theoretical revision seems warranted on many fronts, this paper will focus primarily on only one. It is, however, one of the most significant. In the United States there has been, ever since the turn of the century, a new path to acculturation via the pictorial mass media. This path was immediately accessible. The pictorial mass media were, and still are, enormously powerful and incredibly pervasive. Some argue that they have, in fact, become central in our everyday lives. Their incorporation into any contemporary model of consumer acculturation is an absolute essential. The development and the diffusion of the pictorial mass media have been described as nothing short of the single most important mass socialization event in this century (McCluhan 1964; DeFleur and Ball-Rokeach 1975). Certainly, their impact upon merging cultures should be considered as well.

It's Almost Like Being There

Acculturation can be viewed as a subset of socialization. Socialization is a process by which the individual learns, adapts and conforms to society's norms, rules and expectations. However, when the situation involves a foreigner learning a new set of societal values rather than a native born person learning the expectations for a novel role, we tend to call the process acculturation rather than socialization.

In a society dominated by mass media, mass mediated socialization seems a virtual certainty. In the motion picture *BEING THERE*, Chance the Gardner (a.k.a. Chauncie Gardner) exemplifies a man totally socialized by television. Outside of the people in his master's home, he has only experienced the world through indirect means, or as Chance puts it: "I watch TV." Yet, Chance believes that he understands the world. Chance's social reality has been constructed by television and he lives by the rules of television logic. However, when he encounters the world directly, his behaviors set him apart. He behaves differently, still trying to operate according to the norms and social conventions acquired from television. While Chance is a fictionalized and extreme example, the point remains. Someone new to a society can derive a considerable degree of socialization via the electronic mass media. They need not always take the riskier path of direct contact with the host society and its institutions. Prior to Mass Media America this simply wasn't the case. Successful acculturation was solely dependent upon direct contact and observation. First films, and then television made a safer, more indirect path for acculturation. Yet, due to its contrived, hyperbolic, materialistic and blatantly commercial nature, its effect upon the way in which immigrants become "American consumers" must be significant.

Communication scholars have, for quite some time, been concerned with the effects the mass media have on the socialization process. However, their work has generally been limited to children. Originally, researchers concerned with childhood socialization looked only at the influence of individuals and institutions with which the child had direct contact. These included parents, schools and churches. However, as interest in mass media grew, scholars recognized that indirect mass mediated contact could also be a socialization agent. Research evidence indicated that children could not only learn and

model behaviors from watching television, but also learn societal values (e.g., DeFleur and DeFleur 1967).

More recently, mass communication researchers have suggested that media socialization may not be limited to just children, but may also occur with adolescents and adults (Faber, Brown and McLeod 1979; Ward 1972). In fact, for any novel role in which people do or expect to find themselves, some degree of socialization will occur. To the degree that direct experience or learning is difficult, or involves greater risk, anticipatory or concurrent socialization may occur via the mass media. For the immigrant who is faced with learning a new cultural value system, especially when a foreign language is involved, the pictorial media may play an extremely important role in socialization.

While not discounting the importance of direct experience, twentieth century America offered the immigrant something novel, acculturation not solely dependent upon direct experience and observation. Yet, current models of acculturation, particularly consumer acculturation, have largely failed to take this into account. Media content should be included in any attempt to explain the process by which those new to America, or to any mass mediated society, learn to "appropriately" behave as consumers of that culture.

A Little History

This thesis can best be illustrated with the aid of historical examples. These examples will focus on two very significant periods of American immigration, the corresponding mass media environments, and the lessons of American materialism and consumption implicit in these messages. While making too strong a causal argument through the interpretation of cultural artifacts is an admitted danger, so too is overlooking or discounting them. Art and the artifacts of popular culture represent the creation and the expression of the men and women who collectively define cultures. They have meaning; it's not essential that we absolutely and definitively distinguish reflection from cause. The argument is in fact superfluous (Belk 1986).

Filmed in the USA

Shortly after the turn of the century the United States experienced unprecedented levels of immigration. In the first decade of the twentieth century one out of every one hundred Americans had been in the country one year or less (Bureau of the Census 1976). Upon arrival, these immigrants were met with a novel entertainment medium: the motion picture. While some European immigrants may have seen early motion pictures in their native lands, it was in her indigenous films that the consumption ideals of America found vivid expression and portrayal.

American immigrants, at least at a functional level, had to learn the appropriate values and behaviors of their new host society, many of which were tied to notions of ownership and consumption. For some, this was essential for survival, for others it was a desired end in itself. In both cases, the motion picture offered assistance without requiring direct, and thereby, riskier, contact with mainstream America.

It was no accident that the motion picture found its first audience in the urban immigrant population. During its formative years the silent short was generally shown in a converted storefront (nickelodeon) located on the edge of the business district for an average price of five cents. It required no knowledge of English, and was an inexpensive diversion from the drudgery of everyday industrialized existence. For the immigrant, the movie also provided a very functional service by acting "as a guide to the newcomer on the manners and customs of his new environment" (Jowett 1976, 38). Gilbert Anderson who played the enormously popular silent screen cowboy "Broncho Billy," summed up this effect by saying that his

films "taught young immigrants their first values of American manhood...shoot straight and build railroads" (May 1980, 101). While this statement may appear facetious, underlying it is the notion that the typical Western conveyed the values of honesty and hard work. What Broncho Billy forgot to mention was that just as these early American films told immigrants to work hard and earn wages, they more often demonstrated a myriad of attractive ways for the disposal of these very same wages. So while the work ethic was a common theme, the consumption ideal was an imperative.

While it would be grossly unfair and inaccurate to classify all American films of the silent era under one heading, they did collectively assist in the birth of what has become known as "consumer culture" (May 1980). Through these films immigrants were given more than a casual glance at "the good life." The immigrants who came here during the first decade of the century were, for at least the next twenty years, literally barraged with a group of movies which overtly glorified consumption. Their impact upon consumer behavior had to have been significant. As film historian Garth Jowett points out (1976, 139):

"American industry lost no time in using this power for its own advantage, and the movies were soon turned into a potent medium for the "mass" merchandising of clothing, furniture, soft drinks and even new hairstyles."

Excellent examples are the films of the enormously popular Mary Pickford (a.k.a. "America's Sweetheart") and Douglas Fairbanks. While both were sympathetic to the plight of the exploited industrial worker, their films often made the point that one should still work within the system in order to purchase happiness through the pleasure that only consumption could give you.

In HIS PICTURE IN THE PAPERS and the advertisements Fairbanks made, we see the new code of success. Men continued to achieve in the world of production; but now they strove equally hard for the money to purchase goods and leisure pursuits to compensate for boredom on the job. The Fairbank's hero was thus expanding the necessities of life... mass produced but high class consumer goods became a reward for tolerating the modern economy (May 1980, 117).

While the immigrant was attempting to learn the ways of America, Hollywood and the star system became American institutions. America began to glorify and more importantly emulate the "beautiful people" of the silver screen, and Hollywood had literally become a metaphor for self indulgence and conspicuous consumption. Commenting on the socializing force of American film, Ferguson (1932) noted:

Equal opportunity came not merely to mean that each of us had a right to protect his interest with his vote, but that each of us had a right to stalk around in public places and live vicariously the life of the rich.

The early motion picture may have in effect helped us to institutionalize a consumer fantasy life similar to that discussed by Holbrook and Hirschman (1982). We too could be "stars," and the easiest way to do so was to look like they looked, and act as they did. In other words, to be a star in one's own mind, one had to consume what the real stars consumed, and do it in a visible way.

Still, films' influence did not stop with mass vicarious consumption. They actually guided people in purchases and product choices. This was often accomplished by demonstrating the purchasing process itself, the

"important" attributes of a good or service, as well as its fashionability.

No longer does the girl in Sullivan, Indiana, guess what the styles are going to be in three months. She knows because she sees them on the screen. ...the head of the house sees a new golf suit. The housewife a lamp of a new design...down they go to the dealer to ask for the new goods. (Hays n.d.)

So even though their impact was unquestionably felt by all of society, early American films must have had a considerable impact upon the consumer behavior of the immigrant. The immigrant could, for the first time, and without the necessity of the English language, sit in a darkened theater and experience the consumption ideals of the dominant society without the inherently greater risks of direct contact and interaction.

And It Really, Really Works

The more things change, the more they stay the same. While the jerky silent film has given way to 70mm color prints, VCR's and remote control, the dominant theme of American pictorial mass media has remained amazingly consistent. This presents a particularly interesting parallel since the U.S. is now experiencing another large wave of American immigration.

In the last fifteen years there has been a steady and significant rise in the immigration rate of the United States. If films allowed the earlier immigrants to taste the consumption values of the new land, television, with its pervasive place inside the home, now force-feeds the current immigrants a steady diet of American cultural values and attitudes regarding consumer behavior.

Content of U.S. television during the 1970's and 1980's is much the same as films of the silent era. The themes are of opulence and the glorification of conspicuous consumption. An informal content analysis of network television of the past fifteen years reveals messages which predominantly glorify the possession of wealth and its use in consuming everything imaginable. The most popular shows in America tell us about the lives of the wealthy, and the pursuit of happiness through consumption. Consider DALLAS and DYNASTY; two of the highest rated shows in American television history. What messages do they convey about what it means to be an American consumer? They tell us that even the most decadent dreams can come true, and that simply owning something is never enough. For something to be truly useful, it must be prominently displayed and frequently discussed.

Daytime television is more of the same, much more. It consists largely of game shows and soap operas. Game shows portray an environment where "common folk" can mingle with the stars and take home a bunch of cash and goodies. The American soap opera is the ultimate glorification of conspicuous consumption and consumer fantasy. Everyone is either successful in a materialistic sense or rapidly trying to get there through whatever means necessary.

Then you have commercials, institutionalized and ritualized mini-messages explicitly designed to stimulate consumption. Everyone knows the intent; no apologies are offered. Commercials not only point out the attributes of a product, they often focus on their value expressive nature, and their status conferring qualities. They are not merely statements of objective information, they too are agents of consumer socialization (Ewen 1976). They may, however, be far more effective at helping perpetuate a mass consumer culture, than effectively increasing demand for a specific brand.

No matter what the genre, all this adds up to a type of mass mediated consumer culture. For the immigrant, it is an indirect path of acculturation. The pictorial mass media are literally windows through which the immigrant may view a society's most important ideals and cherished values.

Contrasts and Suspected Differences Related to Path

It is the contention of this paper that the medium may very much be the message (McCluhan 1964), and that people who's socialization is predominantly through the mass media will think and behave differently as consumers than those who more directly experience the world about them.

We believe this because the paths are so different. They differ not only in what they say, but how they say it. Because of this, we can suggest a sort of Mary Hartman-Mary Hartman hypothesis. In other words, a person who is predominantly socialized via the American mass media will think about material possessions and consumption in a very different way than someone who chooses other routes of acculturation. Those new to a society give us an excellent opportunity to test this hypothesized effect.

No matter what tragedy befell Mary Hartman, consumer problems were always foremost on her mind. Mary's world was her kitchen and her television. Mary was the embodiment of American televised values. To her "waxy-yellow-buildup" was the greatest menace to civilization since "ring-around the collar." While she, like Chance the Gardner, are narrative exaggerations, they are not as far removed as we might expect. A society whose members watch an average of six hours of commercial television per day (Comstock et. al. 1978) cannot hope or pretend to be immune from its socializing influence. Mary Hartman lives.

The pictorial media are powerful. This power is a result of both form and function. Janis (1982) demonstrated how extremely persuasive and effective pictures could be in terms of influencing expected outcomes and behaviors. The repetitive nature and the pairing of attractive outcomes with advertised products, and unattractive outcomes with failure to use these products have lead some to suggest that learning from television can even be linked to classical and instrumental conditioning (Bandura 1971; Ward 1974).

As an example of this power consider O'Shaughnessy's 1972 study of Canadian school children. Even though these children were taught in grade school accurate information of the plight of modern day Canadian Indians, most eight to nine year-olds still believed that current day Indians wear little or no clothes and have feathered headbands, live in tents or teepees, and survive by killing people and stealing. This image of native Canadians is remarkably similar to that presented by the typical Western. Apparently years of formal education did not effectively compete with years of mass mediated socialization.

The mass media emphasize different values than the school and the workplace. Gans (1974) argues that the mass media emphasize upper middle class values and a culture of consumption, possessions and leisure, whereas more direct paths such as the workplace and the school offer a more diverse and realistic picture. Direct paths place greater emphasis on lower middle class values which stress job skills, and the ethic of hard work.

The school preaches a culture of production and participation; the media one of consumption and spectating...

The mass media differ most sharply from the school in that they train children in how to consume and play and how to be

family members, whereas the schools emphasize the ability to produce and work, and how to be colleagues and citizens." (Gans 1974, 63-64).

Ward (1974, 41) pointed out that "motivations for consumption acts differ as a function of different socialization practices." It may be that critical differences in path are related to differences in consumption motivations. Television may lead to a desire for conspicuous consumption, whereas interpersonal and direct contact to more utilitarian motivation.

While television may provide greater breadth of knowledge, it is usually somewhat superficial and subject to misinterpretation. It has a greater focus on visual attributes, and offers only shallow understanding about any given topic. This is one reason why warranties and complex product information are rarely found in television advertising. Resnick and Stern (1977) found that 49% of commercials studied contained no information, only 4 out of the 378 contained three or more information items. Relevant information is rarely synonymous with information obtained via television commercials. The problem with learning from television is that it is not good for teaching complex behaviors, only simple ones. This is true of observational learning in general.

Interpersonal communication produces a greater depth of understanding, more detailed knowledge about a given topic, or knowledge about complex topics. It gives one a more realistic view of product attributes and benefits. In other words, richer information from interpersonal communication helps one to put products in proper contexts.

Television demonstrates a highly constrained decision process. A content analysis of network programming by Faber (1978) revealed that while 78% of sit-coms and dramas showed at least one purchase decision per episode, 25% were resolved immediately, 25% within a one day period, 40% within a week, and only 9.1% took longer than a week. This would certainly give the impression that American consumers make rapid purchase decisions. In summary, televised learning leads to a superficial view of products, their importance, their attributes, and the decision making process.

Research Implications and Summary

Consumer acculturation via the mass media offers a safer and less riskier path than direct contact. One doesn't have to worry about making embarrassing mistakes when one doesn't interact. It is certainly the path of least resistance. Paths of least resistance are often the most popular paths. In order to accurately model the process by which immigrants learn to become consumers within their new host societies, we cannot ignore this important agent of mass socialization.

Research utilizing this revised model should further our understanding of not only the acculturation process, but the larger consumer socialization process as well. Immigrants are of particular interest in this regard because we may investigate the consumer socialization process without the confounding effects produced by the developmental processes of native individuals. Most importantly, consumer behaviorists are in need of a more contemporary model of acculturation.

While this paper has offered only a developmental and partial theoretical revision, future research should attempt to expand this conceptualization. While empirical testing of some of the developmental constructs would be advisable, so too would be more anthropological and qualitative approaches. The examination of cultural artifacts seems particularly appropriate.

METHODS TO RESEARCH SHOPPERS' KNOWLEDGE OF SUPERMARKET PRICES

Peter R. Dickson, The Ohio State University
Alan G. Sawyer, University of Florida

Much marketing research studies the effect of relative price or price reductions or promotions in the grocery store. These studies implicitly presume that consumers pay careful attention to price in order for it to affect their purchase behavior. Psychological studies of price perception explicitly posit the existence of referent prices in consumers' minds. These referent or usual prices are posited to form the basis for perceptions of new prices as low or high. Knowledge of referent prices also helps the consumer to recognize both the presence and extent of a price discount. Of course, any attempts to help educate consumers to be more conscious of costs and values would benefit from knowledge of the accuracy of shoppers' knowledge of prices of purchased items.

The purpose of this paper is to review past research about consumers' knowledge and use of price information. After a review and a critique of past methods, a new procedure is described. This method has been designed to correct the problems of past research and preliminary results indicate the method is a useful improvement.

Past Research

Gabor and Granger

In their frequently quoted study, Gabor and Granger (1961) examined consumer in-home price awareness. In November, 1958 they studied a random sample of housewives living in the City of Nottingham, in England. In 82% of the 5,276 purchases across a sample of 428 households, the housewife named a price. This price "consciousness" was higher than the researchers expected and was reported to be inversely correlated with a social status measure. The accuracy of the price estimate was checked for seven of the 15 commodities that had been purchased in the last week. Overall, 57% of the estimates were correct, 25.4% were wrong and 17.6% gave no answer. The exact price recall accuracy was highest for tea (79.3%), coffee (68.1%) and sugar (67.0%) and lowest for margarine (46.1%), flour (35.6%) and breakfast cereal (34.8%). If latitudes of $\pm 10\%$ around the actual price were allowed, the overall percentage of correct price estimates would have risen to at least 60% and 70%, respectively.

At the risk of being accused of taking some cheap shots at a truly classic study undertaken over two decades ago, it is important to discuss some of its weaknesses, precisely because of the impact it has had on later researchers' and theorists' thinking about consumer price awareness. Gabor and Granger's measure of willingness to simply volunteer a response to a price estimate question was a suspect operationalization of "price awareness." The measure clearly depended very much on the consumer's desire to cooperate as well as her price knowledge and would have included many "best guesses." The extent of this "desire to cooperate" bias might have been inferred by observing the nonresponse variability across the 44 student interviewers some of whom no doubt elicited more "cooperation" than other interviewers.

Regardless, the observed relationship between reporting a price and social status was, in fact, not statistically significant. Gabor and Granger did not report any statistical tests but a chi-square test and correlational test that can be computed from the percentages given in Table 1 (Gabor and Granger 1961, p. 177) and both fail to reject the null hypothesis despite more than adequate statistical power.

Measurement and analysis criticisms aside, the fact remains that over half of the subjects accurately recalled

the price. This finding, however, must also be qualified. On the one hand, no allowance was made for special offer prices, deviations from the manufacturers' recommended price and the fact that shop assistants may have quoted and charged an incorrect price. Consequently the consumer's price estimate may have been correct and the "actual" checked price incorrect. But on the other hand, eight of the 15 commodities were not used in the price accuracy study because they were sold at "such a variety of prices." This made it impractical to check the answers. It also introduced a serious commodity selection bias that led to an overstatement of price awareness. Consumers will be more accurate in the recall of commodity prices that are stable across time and place. It should also be noted that this recall accuracy was for items purchased in the last seven days. The researchers acknowledge that they were really interested in studying attention paid to the price at the time of purchase and that even someone who paid great attention to price would likely forget it after more than seven days. In other words, their findings speak more to attention paid to price in the past and recall of that price rather than to attention paid to price at the point of purchase or whether price last paid will be accurately recalled at the time of the next purchase.

A further concern is the uniqueness of some of the shopping circumstances and consequent behavior. An unidentified percentage of the shopping was undertaken at stores where the commodities were not directly accessible to the buyer and were not priced on the package. The buyer had to ask for the particular commodities often by brand but they were in the habit of asking for the product by price in some instances. For example, Gabor and Granger note that housewives frequently described and ordered their favorite tea by the price and not by a brand name. It is therefore not surprising that tea had the highest recall accuracy (79.3%), some 10% higher than the next commodity.

A budget conscious buyer has a greater need to know the price of a commodity outside the store in circumstances where such knowledge cannot be readily gathered inside the store. Alternatively the consumer could set a limit on the price she is willing to pay for an item and ask the shop assistant to provide an item at, or below, that price. Either way the unique shopping situation studied by Gabor and Granger encouraged the learning of the prices of frequently purchased goods. The low inflation rate and stable pricing climate that existed at the time maintained the relevance of these learned prices and ensured frequent rehearsal of the unchanging prices in memory. All in all, the relevance of the findings of the study to supermarket shopping in the United States in the 1980's is very suspect.

The Food Marketing Institute

In a study undertaken in the mid 1970s, interviewers intercepted 1,500 shoppers at the checkout (Allen, Harrell and Hutt 1976). They randomly selected three items from the shopping cart and asked the shopper to name the price. The percentage of exactly correct response for the three items was 55.8% and the average price estimates were off by 8.0%. The same shoppers were also asked to select and price three items that they had purchased on previous shopping trips (but not the day of the interview) from a display of 40 commonly purchased products. Only 16.8% of the shoppers were able to correctly name the price even with the selection bias that inflated the perception accuracy. These same researchers interviewed another sample of shoppers at the point of purchase but

the price accuracy estimates of this group were grossly inflated (to the point that they were meaningless) because the interviewers allowed the shopper to check the price on the item or on the shelf label before answering.

A third phase of this study involved noting products at the time of the checkout interview. Some two weeks later subjects were asked to recall the price of these items. The shopper was not aware items had been noted so item specific sensitization was avoided. However, the interviews and some expectation of future questioning may have increased general sensitivity to item prices in the home. The in-home price awareness was 31.4% and the price estimates were off by an average of 14.5%. The results of this study are particularly interesting for they suggest that price awareness is higher the closer you get to the time and place of the past purchase.

Progressive Grocer

A variation of the Gabor and Granger price awareness study was undertaken in the United States in 1963. Colonial Stores and Progressive Grocer (1964) selected 59 frequently advertised and very price competitive items. Tables were set up in the stores and several thousand customers played a version of "The Price is Right" TV game. They had to estimate the price of a subset of six of the 59 items. The shoppers were reported to have been cooperative and interested. They were not very accurate at estimating price. For all but one item, fewer than 40% of the shoppers could name the exact price. Less than 20% could name the exact price for 41 of the items. The extraordinary exception was that 86% of the customers correctly named the price of a six pack of Coca-Cola.

When some slight error in the estimate was allowed, the percentage of correct answers increased but even then for only 7 of the 59 items could a majority of the shoppers give a price estimate within $\pm 5\%$ of the actual price. The variation in their price accuracy measure across the item was considerable ($\bar{x} = 31.4\%$, $s.d. = 14.9\%$). The research reported that item users (and presumably therefore item buyers) were, overall, twice as knowledgeable about the correct price as non-users. While the evidence for this assertion and even the criteria upon which it was based was not explained, it does make the findings more consistent with the British study. Sex age and household income of the shopper was not related to the accuracy of the estimates.

The relationship between exact price accuracy and approximate price accuracy was not as high as might be expected. Excluding the Coca-Cola result (because of the ceiling effect) the correlation, across the 59 items, between the percentage of shoppers who could exactly name the price of the item and the percentage of shoppers who could name the approximate (within $\pm 5\%$) price of the item was only 0.58. The following examples explain why the correlation was low. Twenty-three percent of the shoppers could exactly state the price of Pillsbury Pancake Mix. When the accuracy was relaxed, 25% of the shoppers could estimate the price within 5%. By contrast 20% of the shoppers could exactly price 5 lbs. of Domino Sugar, but a much higher 67% could estimate the price within 5%. In short, shoppers' exact and approximate price accuracy are not necessarily related. This could be due to the high likelihood that frequent purchase of the product group will result in a high approximate accuracy and frequent purchase of a brand in a product group will result in high exact accuracy. But these two frequencies are not necessarily related, in part because brand loyalty and brand share within product groups varies.

The 1964 study was replicated in 1974 using subsets of 11 product brands from a total of 44 items and 560 shoppers (Heller 1974). The consumers who said they bought the item were on average more likely to give the correct price (within 5%). However, for 7 of the 44 items the percentage of the non-buyers who gave a correct price estimate was surprisingly higher for non-buyers than buyers. As might be expected, the more price conscious

buyers of private labels were more aware of prices than buyers of national brands.

The variation for item buyers in accuracy of price estimates (within 5% of the actual price) across the products was again extraordinary, ranging from highs of 71% for Marlboro cigarettes, 54% for Land-O-Lakes butter and 52% for Scott paper towels down to 10% for Crest toothpaste, 9% for Maxwell House Instant Coffee and 8% for Saran Wrap. The prices of cornflakes, frozen orange juice, canned corn and fruit cocktail were heavily overestimated. The prices of instant coffee, shortening, sugar, salad dressing, and facial tissue were heavily underestimated. Although it might have been expected that price accuracy would be greater for higher priced grocery items, this was not found; the 10 private label items enjoyed higher price recognition than the 34 nationally branded products. These private labels may have been more notable in consumers' memories because of their low price.

The accuracy of price perceptions was lower in 1974 than in 1963. Only 8% of the 1974 shoppers estimated the exact price compared to 20% exact in 1963. Across the matched pairs of 35 common items there was a significant ($p < 0.05$) 6% average decline in price estimation accuracy, estimated within 5%. This effect was product specific and may have reflected changes in price associated with the recent lifting of price controls.

Two further price awareness studies have been undertaken by Progressive Grocer. A study undertaken in late 1976 (Dietrich 1977) found that only 30% of the time could buyers of 12 popular items name the price within 5%. For five of the items a significantly greater number of buyers overestimated the price but for another five items a significantly greater number underestimated the price. In the most recent study (Zbytniewski 1980), 27% of the buyers were able to estimate the price of 16 items, within 5%. The most accurately recalled price was for Perrier Bottled Mineral Water (46% amongst buyers compared to 14% amongst non-buyers). The least accurately recalled price was for Maxwell House Instant Coffee (11% amongst buyers and 12% amongst non-buyers).

Only 8% of the shoppers in the 1977 and 1980 studies knew the exact price. Age and shopping time did not influence awareness but self-labelled price aware shoppers were a little more accurate (24% to 20.5%, within $\pm 5\%$ of actual price). A comparison of price awareness changes for particular products between 1980 and 1977 revealed that Scott paper towels dropped from 38% to 29% (it was 52% in 1974), Coca-Cola went from 39% to 25% and Tide XK detergent from 34% to 25%. Price accuracy did not increase for any of the eight comparable items.

Over recent years Progressive Grocer has provided a good deal of evidence that price has become a much more important consideration in supermarket shopping. The percentage of households using particular items has changed as household have switched from expensive product groups to cheaper substitutes. The fact that the incidence of one-brand users has dropped over the years suggests less brand loyalty and greater price sensitivity. Low prices was ranked the fifth most important characteristic in choosing a supermarket in 1973, rose to the third most important in 1975, became the second most important in 1979 and was number one in 1981 (Progressive Grocer 1975, 1981; Zbytniewski 1979). Shoppers have also greatly increased their reported use of shopping lists, ad reading and coupon clipping.

Despite all of this evidence of increasing focus on the price of products, buyers have not become more aware of prices. There are several possible explanations for this apparent anomaly. It can be argued that inflation and the increase in price specials have made the task of price estimation much more difficult. It is true that price awareness dropped significantly between the 1963 and 1974 study and 1974 was a year when, according to Progressive Grocer, even the store personnel had trouble

remembering the latest operative shelf price. However, the effect of inflation should have shown itself in a general tendency for buyers to underestimate the price of items. Across the 59 items in the 1974 study, 38% of the buyers underestimated the price but 33% overestimated the price. This is not a substantial difference, and the higher percentage who overestimated cannot account for the overall drop in accuracy between 1963 and 1974. It should also be noted that estimation was more likely to be under than over the correct price for 26 of the 44 items, a result only slightly higher than chance. The 1977 and 1981 studies both reported tendencies for buyers to overestimate rather than underestimate the price. One possible reason for this could be a tendency for shoppers to intentionally guess high as a way to include any recent inflation. The increase in couponing and offering of price specials would also be expected to produce a bias toward understating rather than overstating price. Consequently, the results do not obviously support increased price promotions as an explanation for the lack of improvement in price awareness over a period when the salience of price has increased.

The compelling conclusion is that many buyers do not learn the current exact price of the many hundreds of items they purchase. They probably do not attempt to learn and retain this information because they do not need to learn and retain this information even if they are very price conscious. The point of purchase shopping setting provides all of the price information they need for making an item or brand choice within a product group. This reduces the need to bring any information about exact prices paid in the past to the point of purchase. The increased volatility of prices resulting from inflation and the increased use of price promotions has encouraged shoppers to rely on price information at the point of purchase. Such a theory assumes that evaluations of an item's price are made relative to the immediate set of alternatives. Buyers use an external rather than internal reference frame to evaluate the price of an item within a product group. Buyers do use an internal reference frame to evaluate the general price level of a product group.

In-store Price Checking Behavior

Consumers have a number of ways of becoming aware of the price of items. Advertising often presents information about the price of an item. But a reduced special price is frequently featured rather than the standard price. Such advertising may actually lower consumers' price expectations for a product group or brand to a level below the normal price. Of course, if most purchases are made at a special price, then that price rather than the manufacturer's list price should be rightly considered the "normal" price. It is then the manufacturer and not the consumer who has a price expectation problem. This situation probably exists today for many products, ranging from home appliances to soft drinks, where a significant proportion of retail sales are made at a Sale or Special price.

Prices may also be noted in the home when actually using an item. If price awareness were solely based on such in-home price checking, then consumer's price awareness might tend to lag behind actual prices of products because the stock item was purchased some time ago and prices have risen over the inventory holding period.

It is most logical to assume, however, that price information is obtained at the point of purchase. It is current, unbiased and relevant. This information may be so useful that it dramatically reduces the need to remember specific prices and for consumers to possess fine-tuned internal price standards. The question of immediate interest is what patterns of search behavior do occur at the point of purchase.

Wells and Lo Sciuto (1966) undertook one of the first, if not the first, observational study of supermarket shopping behavior. In the research tradition of Barker

(1965), 1,500 behavioral episodes were recorded. An episode began when the shopper entered an aisle and ended when the shopper left the aisle. The advantages of an observational study over a self-report study are obvious. It does not depend on a subject's ability to recall a rather mundane individual purchase from among many. Nor does it depend on the subject's understanding of the meaning of a question. It is also not biased by the subjects' desire to cast themselves in a favorable light and delude both themselves and the researcher.

The observers attempted to assess how much attention shoppers paid to prices. It was admitted that it was hard to tell whether the shoppers were looking at price when examining a package, the implication being that the results perhaps understated price checking behavior. The authors also imply that prices were not provided on the shelf facings of the supermarkets. This is an important issue in evaluating the relevance of their findings to today's supermarket shopping environment. Three product purchases (cereal, candy and detergent), two types of stores (urban, suburban) and four shoppers characteristics (adult male, adult female, adult couple with or without children, children alone) were studied. The highest observed price inspection activity was among adult females shopping for detergent in an urban store; one third were observed checking the price. The lowest reported price checking activity was observed for couples shopping for cereal in a suburban store (8%). The store and shopper differences were less than the product differences. Adult females did the most checking (in 17% of the events averaged across the products and stores) and children the least (10%). Surprisingly, a brand loyalty explanation for the lower price search activity for the cereal purchase was not supported by other evidence.

Allen, Harrell and Hutt (1976) reported a number of measures of price search behavior obtained from subjects at the point of purchase. In contrast to the Wells and Lo Sciuto study, their statistics may overstate the price search activity because they are self-report and subject to a possible self-presentation bias. Seventy-one percent of the shoppers in a conventional supermarket reported checking the price of the item before placing it in their shopping basket. However, only 31.5% reported checking the prices of other items and 12.9% reported using unit price information. The shoppers, interviewed at the checkout, were asked whether they had referred to an item already in their cart when considering another later purchase. Thirty-one percent of shoppers indicated that they had made such between product comparisons and, in 81% of such cases, a price comparison was made. Another question revealed that 86% of the shoppers had checked the prices of substitutes within a product category (i.e., canned, fresh or frozen peas).

In summary, the above two studies present conflicting findings on point of purchase price checking activity. The study undertaken in the mid-sixties reports a low incidence of price checking compared to the study undertaken a decade later. The difference may be partly the result of the research approach but it also could be a consequence of changes in the shopping environment. By 1975, supermarkets were presenting the price of items on the shelf facing along with, for some stores, the unit price of items. Where previously an item often had to be handled to establish its price, now the price of all of the brands and sizes could be easily assessed in a few seconds. Reducing the cost of seeking price information (in terms of effort) seems to have encouraged greater use of point of purchase price information. As already mentioned, the spurt of inflation that occurred in 1974-75 and a higher incidence of price specials may also have made the shoppers in the later study more conscious of price and yet less certain about the price of individual items, leading to more point of purchase price checking. To summarize, the increased value and reduced cost (in effort) have very probably over time contributed to more point of purchase price.

Proposed Method

A survey procedure was designed to provide the following advantages:

1. Ask shoppers about their knowledge of and use of price information in the store at the point-of-purchase immediately after they had selected the item in question. This would alleviate most of the problems due to decay in memory of delayed questions. It is very reasonable to expect rapid decay immediately after and also minutes after choice since most consumers will be focusing their attention on their next choice and have little need and to retain incentive the price information.
2. Combine observation of shopper's behavior at the point of purchase with verbal reports.

Observers were stationed at the point of purchase with a clipboard and were instructed to give the appearance of undertaking some stocktaking activity, a not unusual sight in a supermarket. On the next tenth minute of the hour the observer recorded the behavior of the first shopper to select a brand and size of the target product. This involved estimating the time spent at the point of purchase (the interval between when the shopper turned her attention to the display and when the chosen item was placed in the shopping cart or basket), noting the number of different brands physically touched and inspected (including the chosen brand), and observing the number of different sizes physically touched and inspected (again including the chosen size). Any other unusual behavior was noted.

The shopper was intercepted immediately after she had placed the item in her cart. The interviewer pointed to an Ohio State Lapel label and said "Excuse me, I am from Ohio State University. May I ask you a few questions about the item you just chose. In return as a token of our appreciation I would like to give you this one dollar bill." The refusal rate was less than 1% and was primarily because the shopper was in a hurry. The interviewer then asked: "Off the top of your head, without checking, can you tell me what the price is of the (coffee/margarine/cereal/toothpaste) that you just chose?" This meant that the shopper was asked to recall the price of the item just selected within about 15 seconds of having placed the item in her shopping basket.

Any answer was coded as to its immediacy and was followed by an open ended question: "How did you know that price?" If no answer to the latter was offered, respondents were prompted with a list of possibilities. Respondents were then asked if the price of the just selected item was lower than the usual price. A positive answer to that question was followed by asking how much the price was below the regular price. Subjects were then asked several questions about their recognition and usage of shelf price information including the meaning of the shelf tags which were color-coded by the store chain to indicate whether the price was a regular price, an everyday low price, or an even further discounted special price. Respondents were then asked about their shopping patterns, usual use of price information and why they did or did not check the price of the item in question. The full interview took some 4-5 minutes. On completion the interviewer recorded the actual price of the item, whether it was on special and the amount of any price reduction.

Four products were chosen after discussion with the supermarket chains's regional marketing and advertising managers. They were meant to be representative of relatively low (coffee and toothpaste) and high (margarine and cold cereal) turnover products and infrequently (cold cereal and toothpaste) and frequently (margarine and coffee) promoted product groups. Very low turnover items (such as shoe polish) were not chosen because we expected that price recall accuracy for such items would be very

poor and a very long time would be required to gather a sample size of 50 observations per product per store. An attempt was made to balance the time of observation according to peak shopping times so that the sample reflected the same proportions of shoppers by time period as can be observed shopping over the week in the stores. Effectively this meant that very few observations were made through Monday-Wednesday and most observations were made in the afternoon and early evening on Thursday and Friday and morning and afternoon on Saturday and Sunday. Stores were chosen to represent different extremes of demographic composition of customers and store display of price information.

Except for measures of purchase frequency and use of coupons, we did not ask for or record any demographic information. In hindsight this was perhaps a mistake but we faced store imposed concerns over the inconvenience to the shopper of undertaking an extended personal interview at the point of purchase. In the future we would recommend giving the subject a questionnaire to complete at a later date and drop mail to receive a further gift. Apart from some fairly predictable effects of age and extremes of income, previous studies have found demographics not to be very powerful determinants of instore, supermarket shopping (e.g., Zeithaml and Furst 1983; Zeithaml 1984) and since our intent was to focus on product effects this also discouraged us from asking a battery of demographic and psychographic questions.

Discussion

We have implemented and analyzed the results of a study using the procedure described above. The method appears to work quite well. Subjects seem to be relatively free from attempts to present themselves as more rational than actual. The few seconds interviewing between when the respondent placed the item in the shopping cart and when the interviewer asked the first question about the price of the chosen item all but eliminated memory loss since the purchase as a problem. Analysis of answers to the several questions in addition to the ones about knowledge of the price paid enabled several insights about the antecedents of price knowledge and how it relates to other aspects of information processing (Dickson and Sawyer 1985).

This method could be improved. One aspect that went unmeasured in this study was the possession of coupons for chosen items and the intention to use them. Demographics and other unmeasured characteristics of the shoppers might be best assessed in a followup mail questionnaire. Finally, this measurement procedure might be combined with manipulations of such marketing variables as coupons, featured item advertising, product displays, shelf items and flags, and price specials.

THE ACCURACY OF PRICE KNOWLEDGE: ISSUES IN RESEARCH METHODOLOGY

Jerry N. Conover, Northern Arizona University

Abstract

Two studies exploring shoppers' awareness of prices of products they had selected found that price awareness was better than indicated by previous research. Methodological considerations in such research are addressed, and preliminary findings concerning price awareness are reported.

Introduction

The idea that consumers know the prices of products on the market is a key assumption of economic theory. The idea is also implicit in marketers' manipulation of price as a key strategic tool. This assumption has been challenged, however, by data from consumer surveys (Harrell, Hutt and Allen 1976; Heller 1974; *Progressive Grocer* 1964, 1982; Zbytniewski 1980). These studies reported a surprisingly large number of shoppers who could not very accurately report the prices of common grocery products, even when asked about products they use regularly (typical figures indicated about two thirds or more of shoppers were off by more than 5% in their price judgments).

Given the importance of price as a major marketing variable, it would be very useful to gain a clearer understanding of what consumers know about prices, and how they use that information in their purchase decisions. Unfortunately, the literature concerning price knowledge is quite sparse (see Dickson and Sawyer [1986] for a review), and several scholars have called for research to clarify this area (Conover 1984; Monroe 1973, 1976; Olson 1980; Zeithaml 1984). The two studies presented below were conducted to address these questions.

Both studies were designed to assess the accuracy of consumers' price knowledge, and to determine whether such accuracy is related to shopper characteristics or practices, marketing practices, and product variables. The present paper reviews the procedures employed in each study, and discusses methodological issues in this type of research. Additionally, some key findings concerning price knowledge accuracy are discussed. However, a full elaboration of the complex relationships between price knowledge and the numerous other factors investigated is beyond the scope of this paper, and will appear in a later report.

Study 1

The first of these investigations was designed to assess the accuracy of supermarket shoppers' price knowledge for a variety of products. In addition, the study explored several aspects of participants' perceptions, preferences, motivations, demographic status, and general shopping behavior, as possible factors influencing their price knowledge.

Method

Subjects. Participants were recruited from adult shoppers in a large supermarket that is part of a major national grocery chain. This particular store was chosen for the representativeness of its clientele, upon the advice of the store's regional manager. The 168 shoppers whose data are reported below were systematically sampled to provide a balanced cross section of the local market population in terms of age (median = 32 years), education (median = "some college"), household size (median = 2.2), and income (median = \$18,354). Females accounted for 80.8% of the total, a figure approximating that of the store's overall clientele. Sixty-six percent of respondents worked full-

or part-time, and 58.6% were married. Distributions of each of these classification variables (except sex) were quite similar to those in the metropolitan area in which the store is located.

Procedure. Data from shoppers were obtained through individual personal interviews in the store. Shoppers were eligible to participate if they had in their cart at least one product from any of nine categories (white milk, white bread, mayonnaise, cola, stick margarine, ground coffee, powdered laundry detergent, frozen orange juice concentrate, or paper towels). Efficiency in data collection was enhanced by the selection of these high-volume categories (as indicated by store management) as the target products. Only a small proportion (less than 10%) of shoppers who were asked to participate declined, usually due to time constraints.

Shoppers were recruited while within the aisles of the store. The time elapsed from selection of a target product until they were intercepted for the interview was not explicitly monitored, but probably ranged from several seconds (when product selection was directly observed) to perhaps 20-30 minutes.

Upon consenting to participate in the survey, the shopper was asked a variety of questions concerning grocery shopping habits (store patronage; shopping frequency; use of newspaper ads and coupons; general preferences for national, private, and generic brands; etc.). The shopper was then asked several questions about the target product (from the categories above) she/he had already selected. These questions began with the shopper recalling, without looking at the item, the price marked on that product. Next, the shopper named all the brands he/she could think of in that product category, and specified the factors he/she considered important in choosing such a product.

The shopper was then asked to rank all the brands carried by the store in that category from low to high in price. This task was accomplished by sorting cards, each bearing a different brand name, on a board that had a long line labeled, at opposite ends, "Most Expensive Brands" and "Least Expensive Brands". Shoppers were permitted to omit brands about whose price they had no idea, and to place multiple brands at the same position on the ranking line if those brands were thought to be identically priced.

Following the ranking task, the shopper answered several questions about his/her perceptions of the product, factors influencing this particular choice, and usage patterns for the product. Finally, the shopper completed a brief demographic questionnaire. Upon completion of the interview, the shopper was thanked and received a coupon redeemable in the store for a free dozen eggs. Each interview took from seven to ten minutes to complete.

Results

Exact Price Recall. The absolute value of the difference between the subject's estimate of the product price ("exact price recall") and the actual marked price was divided by the actual price, to provide a measure of the proportion of error in price recall. Each price judgment was also classified as an overestimate, an underestimate, or a correct recall. These results are shown in Table 1.

The mean error in price judgments, pooled across all products, was 6.1% of the actual price. Mean exact price recall was most accurate for margarine and milk, and

TABLE 1

EXACT PRICE RECALL FOR NINE GROCERY PRODUCTS
(Study 1)

	MILK	BREAD	MAYON- NAISE	COLA	MARG- ARINE	COFFEE	DETER- GENT	ORANGE JUICE	PAPER TOWELS	ALL PROD'S POOLED

$$* \text{"Error"} = \frac{|\text{Estimated Price} - \text{Actual Price}|}{\text{Actual Price}}$$

Discussion

least accurate for colas. However, pooling the over- and under-estimates into a single mean error score obscures some interesting variations across products in the nature of errors. For example, the percentage of shoppers who correctly recalled the exact prices of milk and margarine were among the lowest for any product. Therefore, Table 1 also shows the mean size of over- and underestimates for each product, as well as the percentage of shoppers who gave such erroneous responses.

Of all the products, shoppers were most likely to correctly recall the price of bread (65% correct). The price of the product with the highest percentage of errors, milk, was correctly recalled by 36.8% of shoppers. And correct prices were recalled by at least half the shoppers for six out of the nine products. Thus, the exact price recall by shoppers of these products was substantially better than that of shoppers in earlier studies cited above. Erroneous price recalls were fairly evenly divided across products between over- and underestimates, although no one underestimated the price of bread.

Relative Price Recall. The price rank order of brands as sorted by the shopper was assessed for accuracy against actual price rankings by computing a Spearman rank-order correlation coefficient for each shopper. In these computations, any brands omitted by the shopper were also omitted in determining the actual rankings. Thus, each shopper's relative price recall accuracy was indexed by this correlation coefficient. Overall, as shown in Table 2, shoppers' relative price recall was rather accurate; the mean correlation, with all products pooled, was 0.579, $p < .0001$. There was some variability among products in relative price accuracy, but all correlation coefficients were significant at $p < .0001$. Moreover, the variability in relative price recall does not seem to be an artifact of the number of brands available in a product category to be ranked (see Table 2).

Relative and Exact Price Recall Compared. Shoppers' accuracy in relative price recall was only slightly related to their accuracy in exact price recall ($r = 0.121$ across products, $p < .06$). No substantial product differences were found in the correlation between exact and relative price recall. Pooled across products, shoppers who correctly recalled the exact price had a mean relative price recall coefficient of 0.550; those who overestimated exact price had a mean relative price recall score of 0.597; those who underestimated exact price had a relative price recall mean of 0.626. These values are not significantly different from each other ($F[2,165] = 1.30$, $p > .30$). Thus, exact price recall was not a reliable predictor of relative price recall.

Implications of the above results are addressed following discussion of the second study, below. The present discussion focuses on issues of measurement and analysis of price recall accuracy.

Assessing Exact Price Recall. The proportional deviation of price recall from the actual price, expressed as an absolute value, has been used by Harrell et al. (1976) and Zeithaml (1982) to index the accuracy of exact price knowledge. This measure has the advantage that it is easily interpreted as the relative deviation of price recall from the correct price. However, several potential limitations should also be considered:

1. The absolute value obscures the directionality of any errors.
2. The proportional nature of the measure makes its magnitude dependent on the base (correct) price, whereas it might be informative to explore the actual deviation in cents of the recalled price from the correct price.
3. The number of shoppers who correctly recall the exact price is unavailable from such a measure. Thus, it obscures qualitative differences that may exist between those who err and those who correctly recall prices.

These concerns should not eliminate the exact price recall measure from use. Rather, it should be supplemented by measures that do reveal something about the nature of recall errors, such as percent of shoppers over- and underestimating the price.

TABLE 2

CORRELATIONS BETWEEN JUDGED AND ACTUAL PRICE RANKINGS
(Study 1)

Product	Number Brands Possible	Mean Corr.	Std. Dev.
MILK	9	0.590	0.334
BREAD	7	0.568	0.242
MAYONNAISE	7	0.429	0.385
COLA	5	0.773	0.381
MARGARINE	13	0.649	0.254
COFFEE	14	0.451	0.195
DETERGENT	20	0.518	0.177
ORANGE JUICE	6	0.707	0.229
PAPER TOWELS	14	0.492	0.275

Assessing Relative Price Recall. The brand sorting task for indicating the shopper's relative price judgments has both advantages and disadvantages. It is easy for the shopper to understand, and it can reveal the degree of differentiation of price levels within a product category perceived by the shopper. The only previous measure of price recall error employed a conceptually similar task, but computed an index from the sum of the differences between each brand's correct and recalled ranks (Zeithaml 1982). The present correlation coefficient measure has an advantage over Zeithaml's "price comparison error" index in that it can be easily compared across categories with different numbers of brands. Drawbacks of this method of assessing relative price recall include:

1. The procedure is cumbersome to administer. The board must be large enough to hold many brand cards, and shuffling the cards between interviews can be awkward. Also, considerable time is spent in recording the rank ordering of the brands, especially for large categories.
2. Establishing the "correct" ranks of the various brands is confounded by the fact that many brands come in multiple sizes and prices. The correct rank of a brand thus depends on its size. One could compare it only against other brands of the same size, but not every category has standardized package sizes. The present study determined correct ranks on the basis of unit prices, averaging across sizes for each brand. (It should be noted that this problem is not limited to this one measure; it also applies to other similar approaches to assessing relative price recall when multiple package sizes exist.)

In conclusion, Study 1 produced substantial data showing considerable ability of shoppers to recall both exact and relative prices. Study 2, reported below, extended the investigation of consumer price knowledge in several ways.

Study 2

Like Study 1, the second study was designed to investigate the influence of numerous factors on the recall and use of price information. Again, the complex pattern of interrelationships among these factors will not be addressed in the present paper. Instead, this report will focus on the general nature of price recall findings, and also will address methodological considerations in such research.

Given the unknown effect of time delay between initial processing of price information and subsequent questioning in Study 1, the second study was designed to control that effect by closely monitoring consumer choice processes; price recall questioning began immediately after product choice. Additionally, this study sought to determine any possible change in price recall over time by including both immediate and delayed recall tests. Another extension beyond Study 1 was provided by obtaining price processing and recall measures for several products from each shopper, thus allowing investigation of the generalizability of price awareness across products. Finally, Study 2 explored the nature of processing of price information both at the time of choice and at recall.

Method

Grocery shoppers were recruited for Study 2 in the same supermarket described in Study 1. They participated in a simulated shopping task that allowed good control over the choice situation and close monitoring of responses.

Subjects. Sixty-six adult women participated in this study. Their demographic profile closely matched that of the market area as a whole: median age = 36.5; median educational bracket = "some college"; median income = \$18,438; median household size = 2.5. Full- or part-time

workers comprised 68.2% of the sample, and 59.1% were married.

Procedure. Shoppers entering the store were randomly selected and asked to participate in a study of "grocery shopping habits". Those who consented (the large majority of those approached) were led to an isolated room in which was located a section of store shelves stocked with several common products. Products were taken from the actual store shelves, and current prices were marked on both shelves and individual packages. Each product category included national brands, private label and generic products, and at least one item in each category was identified by a shelf talker as being on a temporary price deal.

Facing the shelves, the shopper was instructed to choose one brand from a particular product category (mayonnaise), basing her decisions on the same considerations she would normally apply in such a choice. She was instructed to "think out loud" while she made her selection, mentioning anything she thought about with respect to the decision. Her words were recorded on tape for later analysis.

This first brand choice was a practice trial, to confirm comprehension of the instructions and get the shopper used to the procedures. Once the procedures were established, the shopper was asked to make similar choices from four other product categories (colas, flour, toothpaste, and peanut butter), one at a time upon instruction from the experimenter. As each brand was selected, the shopper placed the item in a shopping cart and proceeded to the next choice. Order of item selection was systematically varied across subjects so that each product category was chosen first, second, third, and fourth approximately the same number of times.

Immediately following the last item choice, with the tape recorder still running, the shopper was asked to state, without looking at either the cart or the shelves, the price of the item she had just placed in her cart. She then recalled the prices of any other brands in that category that she could remember, and indicated whether she in fact had noticed any prices at all. She was also asked whether she had noticed whether any brands were offered at a special price. Next, she identified (from a list of brands) all the brands that she had actually considered in making her choice.

The shopper indicated her relative price recall by a procedure somewhat different than in Study 1. A similar board labeled "most" and "least expensive brands" was used, but no cards representing the brands were sorted. Instead, the line from "least" to "most expensive" was evenly graduated with a series of numbers from 1 to 9. The shopper was asked to point to the place on that line representing where the price of her chosen brand stood relative to all the other brands in the category. The nearest number on the line was recorded as an index of the brand's perceived relative price.

This same procedure was replicated for each of the other three product categories, in reverse chronological order. Verbal protocols were recorded throughout.

Following the exact and relative price recall tasks, the shopper was asked a series of questions about the brands and categories used in the tasks. For each category, she indicated brand repeat purchase behavior and preference, category purchase frequency, perceived similarity among brands, lowest-price buying tendency, and perceived price volatility over time. The questioning then proceeded to general shopping behaviors and tendencies. The shopper rated her store loyalty; percentage of the household's grocery shopping that she does; general national/store/generic brand preferences; and tendencies to notice grocery prices in general, to read grocery ads, to use coupons, to notice grocery price changes, and to remember prices after buying groceries. Finally, she completed a standard demographic questionnaire. The entire procedure took approximately 20 minutes. Upon completion, partici-

TABLE 3

IMMEDIATE AND DELAYED EXACT PRICE RECALL FOR FOUR GROCERY PRODUCTS
(Study 2)

	IMMEDIATE RECALL				DELAYED RECALL			
	COLA	FLOUR	TOOTH PASTE	PEANUT BUTTER	COLA	FLOUR	TOOTH PASTE	PEAN BUTT

% Underestimates	46.3	5.6	47.2	42.6	37.0	7.4	34.0	42.6

* "Error" = |Estim. - Actual Price| / Actual Price

pants were debriefed, thanked, and given a coupon for a free dozen eggs. (Shoppers did not keep the items they had selected.)

Two days after completing the above tasks, each shopper was telephoned, without advance warning, and was asked to recall the exact prices of each of the four target products she had selected. The response latency in seconds was also recorded at that time for each recalled price.

Results

Exact Price Recall. Shoppers' exact price recall was analyzed as in Study 1. As shown in Table 3, errors in this task were somewhat larger than in Study 1, averaging 16.5% of the actual prices across products during immediate recall, and 13.4% during delayed recall. Correct recalls were provided by no more than 44.4% of the shoppers for any product, and more than 90% of the shoppers erred in immediate recall of the price of peanut butter.

The magnitudes of errors in 2-day delayed recall were generally similar to those in immediate recall, except in the case of flour, for which delayed recalls improved considerably. In no case is there evidence for a substantial worsening of price recall after a 2-day delay. The correlations between immediate and delayed recall were: cola = .774; flour = .607; toothpaste = .518; and peanut butter = .604; all of which are highly significant. Thus, those shoppers who were more accurate in immediate exact price recall tended to be more accurate in delayed recall as well.

The question of whether individuals vary in a general tendency to recall prices accurately was addressed by comparing each shopper's immediate exact price recall for each of the four products. Table 4 reveals the correlations between these recall figures, and shows that there was very little consistency in recall accuracy across products. None of the correlations was significant at $\alpha = .05$.

Relative Price Recall. The accuracy of shoppers' recall of relative price of each brand they chose was computed from the correlation between their judged position of the brand on the numbered scale from "lowest" to "highest" price and its actual position. The actual relative position for each brand was converted to a 9-point scale by the formula:

$$8 \left(\frac{P_b - P_l}{P_h - P_l} \right) + 1$$

where P_b = the actual price of the brand, P_h = the highest price in its category, and P_l = the lowest price in its category.

The resulting correlation coefficients for relative price judgments were: cola = .687; flour = .843; toothpaste = .691; and peanut butter = .881. All are significant at

$\alpha = .00001$, indicating very good relative price recall by these shoppers.

Discussion

Many measures collected in Study 2 are not reported above, as they are beyond the scope of this report. The discussions that follow again focus on issues of measurement and analysis, as well as presenting some preliminary interpretation of the findings.

Relative Price Index, Study 2. The revised approach to assessing the shopper's relative price knowledge used in this study is much easier and quicker to administer than the procedure used in Study 1. Consequently, it probably is more enjoyable for the consumer, as well. Given the similar magnitudes of relative price recall correlations in the two studies (the one common product, cola, produced very similar results), the advantages of the latter procedure should be strongly considered for future such research.

The design of Study 2 also eliminated another problem found in assessing relative price recall in Study 1. By including in the simulated choice situation only products of the same size within each category, no ambiguity as to correct relative prices occurred.

General Discussion

Jacoby and Olson (1977) pointed out that price information may be retained in memory in various possible ways, including exact representation of the actual price and also a representation of the product's price relative to other brands. The present research confirms that consumers can and do maintain price knowledge in both of these fashions. However, as those authors noted, price information as tested by recall might be directly retrieved from a stored representation, or it might instead be reconstructed on the basis of other product knowledge at the time of testing. Data from the present study are currently being analyzed to shed some light on this issue.

Whatever the nature of production of responses to price recall questions, the measures employed in this study seem to offer reasonably valid, manageable procedures for assessing consumers' price knowledge. Certainly, as Monroe et al. (1986) argue, there may be cases in which recall measures will not reveal memory traces of prices that consumers could possibly maintain, and the additional use of more sensitive measures such as recognition tests is encouraged. However, recognition tests cannot provide, as can recorded protocols from recall tests, much clue to the nature of price information encoding and retrieval.

Finally, some comments should be made about the price recall results of the present studies. These data suggest that shoppers are more knowledgeable about prices of products they have recently selected than earlier studies indicate. The poorer price recall revealed in Study 2 may

reflect the artificiality of the situation (the shoppers were not given any forewarning that price was a focus of the study, and they were clearly being closely observed, which may have altered their normal decision-making style somewhat). Or it may result from sampling of different product categories than in Study 1. The failure to find a drop in price recall over two days in Study 2 may reflect heightened attention to those prices once price questions began, and rehearsal of them afterward.

The impact of methodological variations on price recall measures is a topic that should clearly be addressed in future research. The more obtrusive the data collecting procedure, especially if it affects the choice process itself, the more likely price recall will be influenced by factors unrelated to the development and use of price knowledge in real shopping situations. Extending the present studies with such investigations, and exploring the impact that stored price knowledge has on consumer behavior, are worthy objectives for future research.

Abstract

Drawing upon memory and information processing theories, this paper develops the conceptualization and analytical procedures for measuring price awareness. Based on the premise that much of consumer shopping is low involving, without elaborate information processing, the paper demonstrates that recognition memory tests are more appropriate for measuring price awareness at the time of purchase. Theoretical propositions are derived by analogical reasoning from signal detection theory, and the supporting dependent measures are discussed.

Overview

One of the factors often stated as important in making purchase decisions is price. Much research has been done in the area of price, and it has been shown that consumers have price limits and acceptable ranges of prices that influence whether or not they will pay a certain price for a product (Gabor and Granger 1964, 1966; Monroe and Venkatesan 1969; Monroe 1971). Although this past research shows that consumers perceive prices in terms of the degree to which they may be willing to pay for an item, nonetheless it has been shown that, when asked, consumers have difficulty recalling the correct price for a previously purchased product (Gabor and Granger 1961, 1964). It has been inferred that since people cannot recall the price paid for a recent purchase, they could not have paid much attention to the price at the time of purchase (Gabor and Granger 1961). Previous price awareness research has relied on recall as a measure for price awareness and has not addressed how memory and human information processing should be considered when measuring price awareness.

Contemporary thinking about the role that price plays in influencing purchase behavior has evolved from the classical stimulus-organism-response model to a cognitive or information processing model. In the past decade, price researchers have offered descriptive models of how the price stimulus may actually be perceived, stored in memory, and recalled at a later time. Thus, it is recognized that buyers' purchase behaviors may be influenced not only by the price of a product, but also by price information stored in their memories, and by what they have learned about price relationships from previous shopping experiences. Therefore, to enhance our understanding of how price may influence purchase behavior, it is necessary to increase our knowledge about how price information is acquired, perceived, stored in memory, and retrieved. Also, since learning is concerned with how a relatively stable behavior potentially becomes a part of memory (Adams 1980), how buyers learn about prices is also of interest.

Price Awareness vs. Price Consciousness

Before the issue of price awareness is fully developed, the difference between price awareness and price consciousness needs to be discussed. The issue of whether buyers "know" the prices they pay has been called either price awareness or price consciousness. However, there are differences in the meanings of these two concepts.

Often times the term price consciousness has been used interchangeably with price awareness, even though the terms are not synonymous. In this research price awareness refers to the ability of the buyer to remember prices, whereas price consciousness refers to the buyer's sensitivity toward price differentials (Monroe and Petroschius 1981). For example, someone who remembers the price paid for a jar of peanut butter is aware of price. On the

other hand, someone who may or may not remember the exact price but knows the price has gone up from last week and, therefore, will not buy that brand is price conscious. That is, buyers who use price or price differentials to guide their purchase decisions are classified as price conscious. While it is likely that price-conscious buyers may also be able to remember specific prices, it is not necessary that price-aware buyers use price as a purchase decision criterion to the same degree. That is, price-aware buyers may know that brand A is higher in price, yet will buy that brand for other reasons.

Learning, Memory and Price Awareness

Learning and memory are different sides of the same behavioral coin, and, therefore, it is necessary to relate the different ways of processing information to learning. A key issue in the psychology of learning is the difference between intentional and incidental learning. Incidental learning is learning that happens by chance, or where there is no active information search. It can be compared to intentional learning which is learning resulting from an active search for information. Extending this notion to consumer behavior, intentional learning is a result of an active search for information before, during, or after actual shopping. During actual shopping, the active search for information would include comparing alternative choices on their different attributes including price. Interitem processing, or the attention to lists of items in memory, has been said to be the type of information processing used in intentional learning. The key point here is that the method and depth of information processing used during learning is critically important when using memory tests to determine the extent of prior learning. However, researchers have concluded that learning can occur under conditions of low attention and of passive information processing. Hence, there has been a renewed interest in a second type of learning: incidental learning.

Incidental learning has been called low-involvement or low-commitment learning by consumer researchers, and these researchers suggest that most of consumer behavior learning is incidental in nature (Bettman 1979a; Robertson 1976). Therefore, this research proceeds on the premise that most grocery shopping situations are of an incidental learning nature. The primary distinction between intentional or incidental learning is the degree the shopper consciously attempts to acquire and process relevant information concerning the choice to be made.

The evidence to date is compelling that memory performance (and learning) is influenced more by the nature of the processing activities engaged in by the individual than by the intention to learn per se (Eysenck 1982). Therefore, if a shopper engages in activities that include the comparing of prices of several items in a choice set, this interitem processing serves as an elaborative function between the chosen item and other product and price information. It is this forming of associations in memory that tend to facilitate the recall of specific information at a later time. On the other hand, if a shopper attends to only information about the chosen or preferred item, then associations are not formed as readily in memory, and the information about the item is more distinguishable from other encoded information in memory. This intraitem processing is of more importance for recognition memory (Eysenck 1982).

Recall vs. Recognition

These two types of learning can have different effects on the recall and recognition of price information, but first, the distinction between recall and recognition must be made.

Recall is the mental reproduction of a response or item that has been experienced or learned before, whereas recognition is deciding (or awareness) that a stimulus has been experienced before (Adams 1980). The distinction between the two measures involves whether or not the alternatives are presented to the subject. If we ask, "What is the capital of X?" we are testing recall, but if we ask, "What is the capital of X: A, B, C, or D?" then we are testing recognition (Murdock 1982). Recognition gives cues to the subject which can trigger the memory to retrieve the desired information. Recall gives no such cues. Therefore, although the information might be in memory, there are no cues given to start the retrieval process for that information.

Recall has been the most common method used in the past for measuring learning effectiveness. With respect to the price awareness literature, recall has been used to determine whether or not consumers are aware of prices they pay for items in grocery stores. Some of the studies used aided recall in that products were shown to consumers who were then asked to give the price of the product (Heller 1974; Progressive Grocer 1977). Several studies used free recall where no product or cue was given to the consumer and subjects were simply asked to give the correct price for a particular item (Gabor and Granger 1961).

Information Processing and Price Awareness

An important aspect of the information processing perspective concerns the actual way humans actively process incoming stimulus information. This process depends on the amount of attention focused on the incoming information and the degree people attempt to associate this new information with other incoming information and/or with information already stored in memory.

Interitem processing, which has been said to be the type of processing used in intentional learning, is the attention of lists of items together in memory and is especially important for recall (Eysenck 1982, p. 204). Shoppers who are comparing alternative items or comparing available information about items are likely engaging in interitem processing. These comparison shoppers therefore are involved in a form of intentional learning.

Intraitem processing, which has been said to be the type of processing used in incidental learning, is the attention to one item at a time in memory. In the usual shopping situation, shoppers probably are processing one item at a time as they shop. Therefore, most of the learning occurring in such a situation is probably incidental learning.

Retrieval Processes

The implicit conceptual model used in previous price awareness studies assumes a common sequence of activities. That is, exposure to a price leads initially to perceptual activities, then information processing, and finally to a memory trace. Price awareness research has focussed on the output of this process, the memory trace, without regard to the internal structure or process of memory. Recently, a number of researchers have called attention to the relevance of modern theories of memory for understanding the role of price in consumer behavior.

Overall, these theories hold that there is a degree to which a piece of information can be retained. The more attention or rehearsal given the information or event, the more likely it will be permanently stored and become available for processing at some later point in time. It is also important to learn how information is retrieved from memory to select the best test of price awareness for consumers.

Retrieval processes, or the utilization of stored information, can range from immediate access for familiar items to involved search processes for other items. The more familiar the item, the faster the retrieval. The retrieval process interacts with the way in which the individual structured the information for rehearsal (coding), what is stored in memory and the form in which it was stored

(transfer), and where the information was stored (placement (Bettman 1979a)). These memory control processes are the strategies people use to control the flow of information into and out of memory.

Retrieval of information from memory is an important memory control process. The previously mentioned control processes interact with retrieval. If the decision strategies used for the structuring and placing of an item of information in memory cannot be retrieved, then the item may not be accessible. Therefore, forgetting is not necessarily a decay or loss of items, but a failure of the retrieval process (Murdock 1982).

Certain cues can initiate the retrieval process if they are similar to the information stored in memory. If they are not similar, retrieval may be inhibited. Other things which may affect the retrieval process are searching in the wrong "part" of memory (i.e., the wrong set of associations), running out of time to perform the search, or losing one's place in the search (Bettman 1979b, p. 59). Therefore, when testing for price awareness it is imperative to consider the type of learning involved and to select the memory test appropriate for the retrieval task.

The way in which information is processed should dictate whether a recall or recognition test of learning is necessary (Bettman 1979b). For example, a brand choice decision made in a store may need only a recognition type test because the choice may be distinguishable without searching through a network of associations (Singh and Rothschild 1983).

Current research results tend to support the generalization that intention to learn has little effect on recognition memory. However, as discussed above, interitem processing serves as an elaboration function by developing associations between the item of interest, price, and other information. It is this type of processing that is of greatest value for recall. The inference then is, for incidental learning situations, recognition memory tests may be more appropriate for measuring awareness. Since there is a consensus among consumer researchers that much of purchasing behavior is incidental learning involving intraitem processing, then recognition would seem to be a better measure of consumer price awareness.

Methods for Studying Recognition

There are two basic research methods for recognition memory: method of single stimuli, and forced choice. Both methods begin with stimuli exposure to respondents and then, later, require the respondents to identify the previously exposed stimuli, old, from among new stimuli. The differences in the methods arise in how the recognition test is conducted.

Method of Single Stimuli

In the method of single stimuli the old and new stimuli are mixed and presented one at a time to the respondents. The respondents judge each stimulus as "old" or "new". The problem with this procedure is that response bias easily can occur. For example, a subject could designate all stimuli as "old" or all stimuli as "new". In each instance, the subject will have correctly "recognized" all old stimuli, or all new stimuli. In the first situation, the subject would achieve a 100 per cent recognition score, while in the second situation a zero percent score would result. Thus, percent correctly recognized is an inadequate measure for this method. Although it is possible to correct statistically for guessing, the response bias resulting from a subject's motivation to respond remains an issue. Currently, the motivation to respond taken by the subject is called the subject's decision criterion.

To overcome the problem with the percent correct measure and to consider the subject's criterion, psychologists have applied the Theory of Signal Detection. Applying this theory to recognition memory assumes that a subject has a psychological continuum of familiarity for items. It is

also assumed that the subject sets a criterion along the continuum and uses it during the recognition test to judge whether an item is familiar or not. If the item is judged to be "more familiar" than the criterion, the subject responds "old", otherwise the response is "new". There are four types of responses: hits, false alarms, correct rejections, and misses. Hits and correct rejections are correct responses, while misses and false alarms are errors.

The use of signal-detection analysis may be justified on both empirical and theoretical bases (Murdock 1982). From an empirical basis, in most cases the data meet the underlying assumptions, in particular, that the underlying distributions are normal with equal variances. From a theoretical basis, the conceptualization underlying Signal Detection Theory is congruent with contemporary information processing view of cognitive psychology. In particular, the strength of the memory trace of the old items is what influences the decision to judge old or new when the stimulus is presented.

The measure for sensory-perceptual discrimination is

$$d' = z(\text{false alarm}) - z(\text{hit}), \quad (1)$$

where z is the standard (or z) score corresponding to the false alarm and hit rates. If $d' = 0$, then the implication is the subject could not discriminate between the old and new items. If $d' < 0$, then either there is measurement error, or the subject is intentionally giving incorrect responses. If $d' > 0$, then the subject has been able to discriminate between the old and new items. Since d' is a standard score it is comparable to other d' scores, and the larger the score, the stronger was the discriminability of the subjects.

Forced-Choice Method

In the forced-choice method, the old stimulus item is presented simultaneously with one or more alternative new stimuli and the subject must discriminate the old item from the new ones. Since the subject is forced to discriminate between several stimuli and declare one as "old", the response bias problem no longer applies. Thus, percent correct is an acceptable measure of recognition for this method. In an m -alternative forced-choice test, the subject is assumed to be choosing the strongest of the m alternatives. Essentially, criterion effects are absent, and percentage correct is an acceptable measure. Tables are available to convert the percentage correct measures to the d' statistic, if desired (Hacker and Ratcliff 1979).

However, while the percentage correct measure is acceptable, it does not give a "true" measure of recognition because different ways of defining the test will give different recognition scores. Recognition accuracy has been shown to be affected by the number of alternatives, m , and the similarity of the stimuli. Further, although the problem of response bias has been removed, the problem of guessing remains. As might be expected the greater the number of alternatives in the forced-choice test, the lower the recognition accuracy. Since recognition testing essentially tests discriminability, it is intuitive that the more similar the alternatives, the lower the recognition accuracy. The more similar the alternatives are, the more difficult it will be to discriminate the old item from the new items.

The third problem associated with the forced-choice method is the possibility that the subject will guess which item is "old". Assuming the subject does guess, then each of the m alternatives has $1/m$ chance of being selected. Thus, the traditional correction formula for guessing gives the "true" recognition score as

$$P_T = (mp_m - 1) / (m - 1), \quad (2)$$

where p_m is the recognition accuracy score. However, this correction for guessing depends directly on the number of

alternatives, m , and, therefore, reduces the comparability of scores from different m -size tests. Thus, it has been suggested that the accuracy scores for different size tests could be equated by computing the correction score using a standard alternative size, $m = 10$ (Clarke 1964):

$$P_{10} = (m-1) p_m / [9+(m-10)p_m]. \quad (3)$$

Measures of Recognition Memory

The three main measures in the study of recognition memory are accuracy, latency, and confidence (Murdock 1982). Accuracy is determined by the proportion of correct responses, latency is the length of time elapsing between presentation of the testing item and the time of test, and confidence judgments are the subjects' assessment of their own accuracy.

Accuracy. One of the main advantages of using signal-detection theory is that it provides an economical summary statistic (d') to characterize overall accuracy (Murdock 1982). The d' statistic combines the measures of performance on old and new items. The subject is given an item and must search memory to determine whether the item is an old or new one. In a forced-choice procedure, the subject is choosing the strongest of m -alternatives and since criterion effects are absent, percentage correct is an acceptable measure (Murdock 1982).

Latency. Latency, or the time between presentation of the test and the response, is a supporting measure of accuracy. It is a function of the size of the test set, the serial position of the correct item in a forced-choice test, and the time lag between initial exposure to the item and the test itself.

The larger the test set, or number of choices in a forced-choice test, the longer the latency score. In addition, the subject who scans the list item by item until the correct answer is found will have a lower latency score than the subject who makes a complete scan of all the items and then goes back and chooses the correct answer. Furthermore, as the time between initial exposure and the test increases (time lag) the latency score tends to increase.

The latency measure is important because it gives some support to the accuracy measure. The longer the latency, the lower the accuracy. Without latency data, only partial measures of performance would be obtained (Murdock 1982).

Confidence. Confidence is another supporting measure for accuracy and is usually measured on a rating scale. The general relationship between the two measures is positive. That is, as accuracy increases, so does the level of confidence. In addition, the confidence scores give some idea as to whether the subject happened to guess the correct answer. If guessing does occur, the confidence rating would be low thereby indicating that the high accuracy score was just a lucky guess.

Obtaining Price Recognition Measures

As explained above, there are three main measures of recognition memory: accuracy, latency, and confidence. Both latency and confidence are supporting measures of accuracy, and enhance the interpretability of the accuracy measure. To use price recognition as an indicator of price awareness requires the selection of either the method of single stimuli or the forced-choice method. Traditional laboratory research on recognition memory proceeds on the basis that respondents are given specific instructions about a later memory test and are given the prior probability for the "hit" rate. On the other hand, a field study might entail approaching a shopper in a natural setting without prior instructions or probability information. Thus, using a m -alternative forced-choice test provides a subject with the prior probability of a correct response ($1/m$) and does not require prior learning instructions. Therefore, if the research setting is

outside the laboratory, it would seem that the forced-choice method is more appropriate.

Data Collection. To illustrate how the price recognition measures can be obtained, the following test procedure is assumed. Shoppers are approached singly after a purchase selection has been made and are asked to indicate which of five alternative prices is the actual price for the selected item. Then the shoppers are asked to rate how confident they are that the chosen price is correct. It is also possible to ask the shoppers to indicate their degree of confidence that the non-chosen prices are incorrect. (Another variation would be to ask the shoppers to make a second choice and to rate their confidence that the second choice is correct.) The latency measure is obtained by timing the shoppers' responses from presentation of the stimuli set to price selection.

Data Analysis. To illustrate the analytical procedures, assume 500 shoppers are approached and asked to choose the actual price of a previously selected item using a 5-alternative forced-choice method. Also assume that the respondents then rate their confidence that the chosen price is correct using the four-point rating scale shown in Table 1A. The sample data in Table 1A correspond to a 90 percent price accuracy score. The confidence rating scale provides additional information about a shopper's criterion for accepting a given price as correct. Also, the confidence rating is directly related to the accuracy of the recognition task.

TABLE 1

ILLUSTRATION FOR DATA ANALYSIS

A. Sample Data	$C_r \cdot R_i$	$I_r \cdot R_i$	R_i
Scale Category			
R_1 : Very sure price is correct	270	5	275
R_2 : Moderately sure price is correct	112	20	132
R_3 : Slightly sure price is correct	45	17	62
R_4 : Not at all sure price is correct	23	8	31
Totals	450	50	500

B. Probability Definitions

$P(C_r \cdot R_i)$ is the joint cumulative probability of a correct price response and a given confidence rating or better.

$P(I_r \cdot R_i)$ is the joint cumulative probability of an incorrect price response and a given confidence rating or better.

$P(R_i | C_r)$ is the cumulative conditional probability of a confidence rating i , or better, given a correct price response (hit rate).

$P(R_i | I_r)$ is the cumulative conditional probability of a confidence rating i , or better, given an incorrect price response (false alarm rate).

$P(C_r)$ is the unconditional probability of a correct price response.

In a m -alternate forced-choice experiment with confidence ratings, the independent probabilities $P(R_i | Cr)$, $P(R_i | Ir)$, and $P(Cr)$ give a complete description of the behavior of the shoppers in the price-recognition task. When using a confidence rating scale, the cumulative conditional probability at any rating given a correct or incorrect response is assumed to represent the decision criterion of the subjects. Thus, the rating approach assumes that humans are capable of adopting multiple decision criteria. The conditional probability $P(R_i | Cr)$ assumes that people would select a price only if they were very sure it was the actual price. Continuing in this manner the cumulative conditional

probability $P(R_2 | Cr) = \sum_{i=1}^2 p(R_i | Cr)$. Assuming that R_2

represents a less strict criterion, then the observations using a more strict criterion (R_1) would also be accepted for R_2 . The value of d' can be determined from the table

in Hacker and Ratcliff (1979) using $P(Cr)$ and the m . For the illustrative data in Table 1, $P(Cr) = 450/500 = 0.90$, $m = 5$, and from the 1979 table, $d' = 2.60$.

Latency. The above discussion has focussed primarily on response accuracy. However, another important dependent variable in recognition memory tests is latency - the length of time elapsing between presentation of the test items and subject's response. As has been presented here, most models of recognition memory employ the decision orientation of signal detection theory. However, it is likely that a more complex process than simple direct memory access is occurring.

At issue is the nature of the retrieval process used to extract information from long-term memory. It seems clear that retrieval processes involve some form of memory scan or search. Successful search for an item depends on the properties of the trace and the amount of information available to the individual during retrieval (Mandler 1980). Although the retrieval processes involved in recall and recognition are not inherently different, they do differ to the extent that the retrieval information present at the time of recall is different from that at the time of recognition.

In a forced-choice recognition test, the use of latency (or response time) allows for inferences about the retrieval process being used. Assuming that a price recognition task can be separated into four stages, these stages might be: stimulus encoding, comparison, decision, and response. The comparison stage involves a scan or search of memory to determine whether a test price can be matched to information in memory. If for a recognition memory test, subjects serially scan and compare the entire set of test items before decision and response, then response time will be an increasing function of set size. On the other hand, if there is no relationship between response time and set size, the implication is that subjects were involved in parallel scanning, in which all items of a set are searched simultaneously. If the serial scanning model is correct, then the slope of the latency function is a measure of the scanning rate in the comparison stage. If the experimental manipulations affected either of the other stages, these differences should show up in the intercept of the latency function.

While generally, latency and accuracy would be expected to be negatively correlated, it is sometimes found that they are positively correlated. Such a positive relationship has been called the speed-accuracy trade-off. This trade-off relationship makes it important to collect both accuracy and latency data when testing recognition memory. For if only accuracy measures have been obtained, there is no opportunity to determine if subjects have compensated either for serial position of the correct test item or are simply guessing without performing a retrieval process.

Independent Variable Issues

There are several independent variables that should be considered when measuring price awareness through recognition memory tests: time lag, serial position, relative price position, and products included in the study. The time lag is the elapsed time from when the subject picks up the product to the time of the price awareness test. The time lag can vary across each subject if several products are used for each person. The time lag is important in order to get an idea of its effect on price awareness accuracy. Assuming additional shopping occurs during the time lag, then the longer the time lag the more there will be distractions, making it more difficult to retrieve the correct price.

The serial position is the actual position of the price in the forced-choice recognition test and should be varied to prevent a potential bias toward the actual price. That is, the actual price should not always be in the same position. Further, as noted earlier, if serial scanning occurs, the serial position may influence the latency measure.

The relative price position is the numerical value the actual price has relative to the other alternatives in the forced-choice test. For example, the actual price could be the highest number, the middle number or the lowest number of the choices in the test. The relative price position should be changed randomly to avoid any selection bias towards a particular relative value affecting the accuracy measure.

The actual grocery products used in any price awareness accuracy study employing recognition tests should be at least \$1.25 in price or more per item. This price is chosen so as to exclude those items that do not allow for a sufficient range of incorrect prices to be offered in the recognition test. Prices that are under \$1.25 create a problem in that some of the incorrect prices would be over \$1.00 while some incorrect prices might be under \$1.00. As mentioned above, the more similar the test items, the more difficult it is to recognize the correct price. Therefore, the alternative prices should be in the same general price range.

There are several product categories which would be difficult to include in an in-store intercept recognition memory test. These categories include meats, produce, and some dairy products. The reason for this is that it would be difficult to determine the actual prices of these products before administering the test unless the interviewer checked into the subjects' shopping carts.

Conclusions

According to traditional price theory, buyers are assumed to know the prices they pay, and are assumed to be price sensitive in that they will search for lower-priced alternatives. The research evidence reviewed earlier suggest that buyers may not be knowledgeable about the prices they pay, particularly for frequently purchased and relatively low-priced goods. Moreover, buyers do not always purchase lower-priced alternatives and buyers do not always buy less at higher prices. The inability of this limited evidence to verify the simple explanation of the influence of price on buyer behavior means a more careful study of buyers' (1) price awareness, (2) price perceptions, and (3) price sensitivity is necessary. The extent that buyers are aware of the prices they pay influences the way prices are perceived and the degree that buyers are sensitive to price differences and price changes. Therefore, a necessary first step is to develop a better understanding of the degree buyers are aware of the prices they pay.

Research measuring buyers' price awareness typically has used a form of recall. That is, buyers have been asked to recall the prices they have paid for selected items familiar to them. The percentage of prices correctly remembered has ranged from two percent to 86 percent. For most product categories, the frequency of correctly remembered prices fell below 50 percent. Thus, this evidence seems to imply that few buyers know the prices they pay, and moreover, buyers do not seem to be sensitive to differences in prices for alternative comparable choices.

Essentially, previous price awareness research can be classified as a type of memory research emphasizing intentional learning. That is, the use of some form of unaided recall assumes that the behavior being assessed represents buyers' intent to notice and commit to memory (learn) the prices of the products being purchased. Yet, current thinking regards most of human learning as incidental rather than intentional. Also it has been determined that the level or depth of information processing is critically important for the later retrieval of that information. The depth of processing is determined by the extent to which meaningfulness is extracted from the material. Finally the deeper levels of processing are associated with elaboration that involves associating or organizing the material information in some way (interitem processing).

From the perspective of memory research, the issue of whether buyers are aware of prices of the products they purchase may not be answered correctly using only a recall methodology. Moreover, the relative inability to recall prices paid should not lead to the inference that buyers do not attend to price and are unaware of the prices they pay. An obvious issue with a recall memory test is whether the correct retrieval cues have been used. It seems plausible that most buyers can be classified as incidental learners. That is, they may attend to purchase information such as price, but do not elaborate on the information. The paying attention to a single item, such as price, without elaboration is called interitem processing, and is less likely to be retrieved using a recall methodology. Instead, recognition methodology would be a better approach to determine the degree buyers are aware of the prices they are expected to pay. Therefore, the relative inability to recall prices paid should not be used to infer that buyers do not attend to price and are unaware of the prices they pay.

The objective of this paper has been to provide the conceptual framework for research seeking more definitive answers to the question of whether buyers are aware of prices they pay. Previous research has been both sketchy and, based on memory research, may have used inappropriate and incomplete measures of price awareness. Before we can address the issue of how people perceive prices, i.e., encode price information with a degree of meaningfulness, it is important to have a clearer perspective on price awareness. Finally, the issue of buyers' price sensitivity to price changes and price differences can be addressed when we have better information on price awareness and price perception.

AN IDIOTHETIC ANALYSIS OF ATTITUDE-BEHAVIOR MODELS

Abstract

Limitations of nomothetic treatments of psychological data are discussed relative to consumer decision making. A framework is described for circumventing the limitations.

Introduction

The need to develop methods for studying individuals has been evident for nearly fifty years. The vast majority of research in the social sciences has focused on aggregate level analyses, in which inferences are drawn about groups of individuals, considered as a whole. As Allport (1937) noted, the understanding of behavior at the aggregate level does not necessarily yield understanding of behavior at the individual (idiographic) level. When nomothetic (aggregate-based) principles are applied to individuals, there frequently exists considerable error. Because of such limitations, Allport suggested the creation of methodologies that would allow the social scientist to study the behavior of individuals.

Allport's call for the development of idiographic methods was greeted with skepticism. At the time, logical positivism and behaviorism were the dominant paradigms within the social sciences, and both approaches viewed the primary aim of science as the development of universal laws. Because of this, many critics felt that idiographic explanations of behavior were outside the realm of science. This skepticism was fueled by Allport's linking of idiographic approaches to disciplines such as history and literature, with the suggestion that methods for collecting data in these domains (e.g., analysis of letters, subjective biographical reports) be used in developing an idiographic science of human behavior. Allport's approach was criticized because of (a) the inability of the researcher to develop generalizable results, (b) difficulties with using single subject experimental designs, and (c) a lack of adequate methods for conducting idiographic research (for a review of these criticisms, see Runyan 1983). Despite these criticisms, Allport's motivation for suggesting new methodologies remained: Explanations of behavior based on aggregate or nomothetic methods of analysis fell short of explaining why a given individual performed behavior X in response to stimulus Y in context Z.

Since 1937, the terms "idiographic" and "nomothetic" have taken on a wide variety of meanings in the scientific literature. This proved so confusing that in 1962, Allport clarified his goals for the study of individual behavior in personality and labeled methodologies developed toward this end as "morphogenic." However, this new methodological description did not receive wide acceptance, and the terms "idiographic" and "nomothetic" are still used in a multitude of ways in the current literature (see Jaccard and Wood 1985 for an elaboration). The term "idiographic" invites controversy because of the multiple meanings attached to it. In the present paper, we will follow the suggestion of Lamiell (1981) and label the methodologies discussed in this chapter as idiotic, a blending of the terms "idiographic" and "nomothetic." In the spirit of Allport, we recognize that idiotic methods should help us to understand and to predict the behavior of individuals. The researcher should be capable of demonstrating the reliability and validity of findings derived from these methods. Further, these methods should not rely on group norms or other nomothetic information in their analysis of

the individual. We do not deny (or minimize) the important contribution of nomothetic procedures to the social sciences and the analysis of consumer behavior. Ideally, information collected and analyzed at the individual level should be capable of later analysis at the nomothetic (aggregate) level. In the sections that follow, we will discuss some of the limitations of nomothetic procedures in constructing theories about the individual consumer. We will then briefly outline an idiotic approach to consumer decision making which we have found to be useful in numerous applied settings.

Limitations of Nomothetic Treatment of Data

Consider the following experimental design in a study of consumer attitudes: A researcher is interested in whether social class is related to attitudes towards a given product and whether this attitude is differentially influenced by perceptions of the cost of the product in upper class as opposed to lower class individuals. The researcher begins by developing a set of questions that will measure attitudes towards the product in two groups, one consisting of upper class individuals and the other consisting of lower class individuals. He/she does this by consulting Osgood's tables of adjective descriptors that load on an evaluative factor via the semantic differential technique (e.g., good-bad, beautiful-ugly, clean-dirty, tasteful-distasteful). Each individual rates the product on the scales and an overall attitude score is derived by summing the responses across items. In addition, the product is rated on an inexpensive-expensive dimension. The mean attitude scores are contrasted in the two groups via a t test, and a statistically significant difference is observed, with lower class individuals revealing a higher (more positive) mean score. A correlation between the attitude score and the inexpensive-expensive rating is calculated for each group, separately. For lower class individuals, there is a moderate negative correlation between the two variables, whereas for upper class individuals, there is a moderate positive correlation between the variables. The difference in correlations is tested by means of the appropriate statistical test, and is found to be statistically significant. The investigator concludes that social class is related to attitudes towards the product, such that lower class individuals evaluate the product more positively than upper class individuals. In addition, the researcher concludes that the data support the proposition that perceptions of expense affect the attitudes differentially in the two groups. Upper class individuals' attitudes are favorably influenced by cost, whereas lower class individuals' attitudes are unfavorably influenced by cost.

Comparison of Mean Scores. A number of assumptions are required to compare mean scores to assess the relationship between social class and attitudes. First, one must assume that the rating scales are valid for both groups of individuals. To the extent that validity coefficients are low in magnitude for either group, any conclusions are called into question. Assuming valid measures (in a traditional psychometric sense), a second issue arises in the comparison of the mean scores. When an individual is asked to make a judgment about an object on a dimension, he/she must first make the judgment cognitively, and then translate that judgment onto the rating scale provided by the investigator. Two individuals might make the same cognitive judgment, but differ in their observed ratings, if they translate that judgment differently onto the rating scale. At issue is whether group differences

reflect differences in the true underlying attitude or whether they reflect differences in the way individuals in the groups use and experience the rating scale. Research in psychophysics (e.g., Wegener, 1982; Upshaw 1962) suggests that the problem of response translation may be more serious than applied researchers realize.

How might an individual translate a judgment onto a numerical rating scale? One strategy suggested by psychophysicists is that the individual will position the center of the scale to correspond to the average subjective value of the stimuli he/she expects to judge. In this case, individuals who expect to evaluate stimuli with generally high values will make lower ratings than individuals who expect to rate stimuli with generally low values on the dimension in question. A second strategy, suggested by Parducci (1965), is that the individual will position the scale so that the two most extreme categories correspond to the most extreme values he/she would assign to stimuli of the type being studied. Having done this, the individual equates the intermediate categories with a range of judgments between these extremes. Parducci discusses several situations in which this strategy would produce different ratings for two individuals, even though their cognitive judgment is the same. In fact, Parducci has used such an interpretation as an alternative explanation for several "established" psychological phenomena. Although other plausible strategies could be elaborated, the point is that observed mean differences may reflect systematic differences in the response translation process. The assumption that all individuals use the rating scales in the same fashion, with similar experiences in mind, is required (or one must assume that the differences cancel or are irrelevant to the question at hand).

In the above example, suppose the product being rated was a certain type of appliance. One might reasonably assume that upper class individuals have had experiences with, on the average, better appliances than lower class individuals. If individuals use the first strategy identified above for response translation, then one would predict a lower mean attitude score for upper class individuals as opposed to lower class individuals. This was, in fact, observed.

Analysis of Correlations. The same issues discussed above apply with equal vigor to the analysis of correlations. First, one must assume that the scales are equally valid indicators within groups. Otherwise, differences in observed correlations may be an artifact of differential validity. Second, one must assume that all individuals within a group (but not necessarily between groups) use the response scale in the same fashion and with the same experiences as a referent. For example, consider the negative correlation between attitudes and perceived expense for the lower class individuals. Suppose individuals with more positive attitudes have tended to encounter more expensive appliances in their experiences. If all individuals within this group adopt the first response translation strategy mentioned above, then individuals with more positive attitudes would tend to rate the appliance as being less expensive than individuals with more negative attitudes (even though true differences in expense judgments might be minimal). This would yield the observed negative correlation, where possibly none exists.

These examples illustrate a frequently neglected requirement of nomothetic analyses in consumer research; namely, the assumption of a common response language across individuals. Violations of the assumption can affect either mean scores or correlations. The issue is particularly germane to consumer research that uses rating scales.

Inferences About Individuals. If the measurement assumptions noted above are met, then the theorist may still be restricted to aggregate level conclusions. To illustrate the problem in the case of correlation coefficients, consider the above study, but assume that

observed correlations within social class groups are not artifacts of response language. Suppose, also, that the investigator did not measure social class. For all individuals considered together, the correlation between perceived expense and attitude would probably be near zero (assuming common mean centroids), since the investigator has mixed two groups, one exhibiting a positive correlation and the other a negative correlation. The implication would be that a change in perceived expense would not result in a change in attitude. On an aggregate level, this would be true. Shifting perceived expense downward would cause the lower class individuals to revise their attitude upward and the upper class individuals to revise their attitude downward. The net change in attitude would be minimal. But at the individual level, considerable change would occur, contrary to what one might infer from the correlation coefficient. In this instance, the correlation coefficient would only have been descriptive of individuals if all individuals "weighted" expense in the same way (sign and magnitude) in forming an attitude toward the product. This phenomenon has obvious implications for popular regression-based approaches of intention and attitude formation in the consumer literature (e.g., models such as Fishbein, Sheth, etc.).

A second example of potentially misleading aggregate analysis for correlations is illustrated using market segments versus total market in Figure 1. In this example, the focus is on market segments versus the total market. There are three market segments (S1, S2, and S3), each of which exhibit a strong negative correlation between variables X and Y. If a correlation is computed ignoring segments, a strong positive correlation between X and Y results. One might infer from the across-segment analysis that positive changes in X will yield positive changes in Y, when exactly the opposite would occur, as revealed by the within-segment analyses.

FIGURE 1

EXAMPLE OF MISLEADING AGGREGATION IN CORRELATION

Inferences about individuals may also be problematic in the comparison of group means. This can be illustrated from an example in the family area. Researchers have asked newlyweds the number of children they intend to have in their completed family and then contrasted the expected mean number with the mean number of children the couples actually have. The correspondence is remarkably close, indicating that at the aggregate level, little change has occurred. At the individual level, however, expectations prove to be a poor match with actual behavior. Some couples have fewer children than expected, while others have more children than expected. The "overs" cancel the "unders" and the aggregate level means are quite similar. Simple examination of the means, in this case, does not permit accurate statements about the individual level. This process probably characterizes several marketing phenomena, such as the strong correspondence observed between actual prices of products and the average (calculated across individuals) perceived prices of those products (Louviere and Meyer 1981).

A second example of misleading aggregation for mean scores is illustrated in Table 1. There are four distinct segments of a market, the members of which were asked to rate each of three brands (A, B, and C) on a 10 point, "strongly dislike" (1) to "strongly like" (10) scale. Assume that each segment is homogeneous in its ratings and that individuals purchase the brand that they like the most. In this case, brand B would have a zero market share, yet if ratings are averaged across segments, brand B is the most liked. Mean score analysis would lead to the conclusion that preferences are unrelated to purchase behavior, when, in fact, a marketing strategy that changed preferences might have considerable impact on purchase behavior.

TABLE 1

EXAMPLE OF MISLEADING AGGREGATION WITH MEANS

	Brand A	Brand B	Brand C
Segment 1	10*	9	1
Segment 2	9*	7	3
Segment 3	1	7	8*
Segment 4	2	9	10*
Means	5.5	8.0	5.5

* = most preferred option

A final example of potentially misleading aggregate analyses focuses on proportions. Consider two segments of a market in the analysis of brand switching, as illustrated in Table 2. For each segment considered separately, purchases at time 2 are independent of those at time 1. If the data for the segments are pooled, however, the brand switching matrix suggests a first-order process.

TABLE 2

EXAMPLE OF MISLEADING AGGREGATION WITH PROPORTIONS

	A-A	A-B	B-A	B-B
Segment 1	.64	.16	.16	.04
Segment 2	.04	.16	.16	.64
Aggregate	.34	.16	.16	.34

(A-A = use of brand A at time 1 and time 2, A-B = use of A at time 1, B at time 2, etc. Assume equal N segments)

In sum, inferences about individuals from group level data can encounter problems with respect to reliability, validity, response language used in interpreting scales, and within group variability. The above comments should not be taken to imply that means, proportions, and correlations in traditional consumer studies, when calculated on the aggregate level, will always be misleading about individual cases. However, they can be misleading and must be interpreted carefully when making inferences about individual behavior.

An Idiopathic Approach To Behavioral Decision Making

Jaccard and Wood (1985) describe three facets of an idiopathic approach to consumer decision making that circumvents many of the above problems. The first facet focuses on describing how consumers perceive different options and identifies idiographic perspectives on product space analysis. The second facet considers brand preferences, integrating aspects of choice theory with traditional attitude theory. The third facet concerns trade-off analyses and describes idiopathic methods for identifying how consumers trade-off the positive and negative features of a product in forming product preferences. Space limitations do not permit a discussion of each facet. We will focus our attention on the second facet.

Preference Structures. An individual's preference structure refers to his or her attitude toward each of the decision options. The preference structure is a key concept in our theoretical framework, because a person's choice is conceptualized as being, in large part, a function of the preference structure. An attitude is conceptualized in very restricted terms in our framework. It refers to the extent to which an individual feels favorable or unfavorable toward enacting a given behavioral option. A preference structure is measured by asking the individual to rate each decision option on a -10 to +10 unfavorable-favorable scale. Consistent with subjective-expected-utility (SEU) theory, it can be argued that an individual will choose to perform that option toward which the most positive attitude is held (exceptions to this principle will be discussed shortly). Thus, the attitude measures are analogous to global measures of SEU, without requiring the measurement of specific probabilities and utilities (see Jaccard, 1981). The essence of preference structure analysis is quite simple and certainly is not new to consumer psychology. Unlike traditional decision theory, however, the concept of attitude is a central construct in the framework. And, in contrast to traditional attitude theory, the focus is on within individual analysis of attitudes across competing brands, as opposed to across individual analysis. On a conceptual level, preference structure analysis represents a theory of the relationship between attitudes and behavior. It is quite distinct from traditional, nomothetic-based consumer models that attempt to explain discrepancies between attitudes and behaviors. We will elaborate these differences and then consider the applied implications of preference structure analysis.

Theoretical Implications. Several theorists have attempted to explain attitude-behavior discrepancies by suggesting that variables other than attitudes may influence behavioral decisions (or behavioral intentions, as they are called in most theories). These theories are typically stated in the form of a multiple regression equation such that

$$BI = w_1 X_1 + w_2 X_2 + \dots + w_n X_n \quad (1)$$

where BI = the intention to perform the behavior; X_1 through X_n = the relevant predictor variables, of which the attitude toward performing the behavior is X_1 ; and w_1 through w_n = empirically determined regression weights which are said to reflect the importance of the respective variable in determining BI. According to these models, discrepancies between traditional measures of attitude and behavior occur because (1) the traditional attitude measured is usually not specific to the behavioral criterion (i.e., it is an attitude toward an object and not an attitude toward a behavior), (2) there may be other factors (e.g., normative beliefs) determining the behavior such that attitude is irrelevant, and (3) attitude may only determine intentions to perform a behavior and thus, should be predictive of the action only to the extent that these intentions are highly related to the behavioral criterion. The present approach is consistent with point 1 (since the preference structure consists of a set of attitudes towards behaviors) and point 3. However, several differences can be highlighted with regard to point 2 and equation 1.

First, the preference structure approach differs from the regression approach in terms of an emphasis on behavioral predictability from a within-subject versus between-subject perspective. This difference may best be illustrated by considering only the first component of equation 1 (i.e., we will assume that weights 2 through n are zero). The regression model would involve measuring different people's attitudes toward performing a behavior (e.g., using brand A) and correlating these measures with a behavioral criterion (e.g., use of brand A). It is assumed that the more favorable the attitude, the more likely it is the behavior will be performed. Table 3 presents a hypothetical example of three individuals and

their attitudes towards brand A. According to the regression model, individual 1 should be most likely to use A, followed by individuals 2 and 3, respectively. In contrast, the preference structure approach suggests that behavioral prediction requires knowledge of the distribution of attitudes across decision options. If a person possesses a positive attitude toward A, and an even more positive attitude toward B, it is unlikely he will choose A even though he has a positive attitude toward it. In Table 3, the preference structure approach would predict that individual 3 will use brand A, whereas individuals 1 and 2 will use brand B (given that the most positive attitude dictates the choice). In the regression model, it is assumed that the more positive the attitude relative to other people's attitudes, the more likely it is the individual will perform the behavior. By contrast, in the preference structure approach, it is assumed that the more positive the attitude relative to the person's attitude toward other decision options, the more likely it is the person will perform the behavior.

TABLE 3

PREFERENCE STRUCTURE ANALYSIS FOR THREE INDIVIDUALS

Individual	Brand A	Brand B
1	6	9
2	4	8
3	2	-5

A second difference in the two approaches concerns the specification of factors other than attitudes that are relevant to behavioral prediction. A number of social scientists (e.g., Wicker, 1969; Triandis, 1977) have argued that a person's attitude toward an act is only one of a number of variables that influence behavior or behavioral intent. Several models have been proposed which investigate such additional factors as attitude toward the situation (Rokeach and Kliejunas, 1972), morals (Triandis, 1977), and normative beliefs (Fishbein, 1972). In the preference structure approach, the "additional variables" are attitudes towards performing the other decision options. Most regression based models do not focus on different decision options. Thus, the approaches differ in where they direct the theorist to look for other variables that can account for attitude-behavior discrepancies.

A third difference between the two approaches concerns the way in which the "other variables" are used within the theoretical network. In the regression model, the predictor variables are given weights representing the importance of the variable in determining intention. Generally, these weights are estimated via multiple regression procedures. The weighted predictor variables are summed to yield an index of predicted behavior. In the preference structure approach, no such weighting parameters are employed nor is there a summative relation among the weighted predictors. Rather, the attitudes toward performing each of the decision options are compared with one another and the option toward which the most positive attitude is held represents the predicted behavior.

One might be tempted to extend regression models of behavioral intention to include decision options, thus resulting in a more "complete" model of decision behavior. Such an approach was suggested by Ajzen and Fishbein (1969, 1980). In the context of Fishbein's model, this involves measuring Aact (attitude towards the behavior) and SN (subjective norm) toward each option and regressing an intention measure for each option onto the appropriate Aact and SN. The combination of Aact and SN would then be dictated by the results of the various regression equations.

There are several problems with this approach relative to the present one. First, the preference structure approach is idiotic and allows prediction of an individual's

behavior knowing only that individual's attitudes toward the decision options. The regression approach, in contrast, is not idiotic. It requires that a group of individuals be studied so that least squares estimates of the weights (w_1 and w_2) can be obtained for any given option. This approach requires that all individuals within the group be homogeneous in terms of how they weight Aact and SN for a given option and also requires some rather stringent measurement assumptions (e.g., all individuals interpret the rating scales in the same way). Thus, deriving accurate estimates of how to weight the multiple predictors is problematic from the standpoint of psychological explanation (see Gordon 1968 for additional issues in this respect). These assumptions are not requisite in the preference structure approach, because no weighting parameters are involved. Second, if behavioral predictions are based on Aact and SN, the regression approach requires that the standard errors of estimate be low and homogeneous across all options. If the regression analysis yielded a poor goodness-of-fit for just one option, the entire analysis could be jeopardized. Finally, there is no empirical evidence to indicate that normative factors, when used in the context of the preference structure approach, will yield increased behavioral prediction over and above Aact. Initial research efforts therefore might best employ the more parsimonious perspective of focusing on just the attitude construct. This practice would be consistent with the literature on decision making and makes the assumption that the influence of other variables on behavioral decisions is mediated by attitudinal variables. Empirical support for the preference structure approach relative to regression models is presented in Jaccard (1981) and Jaccard and Becker (1985).

Preference structure analysis can also be contrasted with other formal choice models proposed in the consumer literature. Space limitations do not permit detailed comparisons. However, some general observations can be made. First, the importance of measuring attitudes (or some related concept) towards alternative brands has been widely recognized in consumer research (as opposed to psychological theories of behavioral intention which have tended to focus on the analysis of a single option). However, many applications (e.g., Wilkie and Pessimer 1973) use cross-sectional, regression-based strategies for relating the attitude indices to brand choice. Such strategies are subject to the limitations discussed above and contrast with the preference structure approach which uses a purely idiotic method for generating predicted choice.

Second, the majority of applications in the consumer area have focused on attitudes towards "objects" as opposed to attitudes towards "behaviors" (Ajzen and Fishbein 1977). Thus, the attitude toward the brand per se (e.g. a Rolls Royce) is measured as opposed to the attitude toward actually purchasing (i.e. choosing) the brand. Research in psychology has demonstrated the superior predictive power of attitudes towards behaviors (e.g., Jaccard, King, and Pomazal 1977; Ajzen and Fishbein 1977). The preference structure approach uses attitudes towards behaviors.

Third, the preference structure approach conceptualizes attitude as the extent to which the individual feels favorable or unfavorable toward choosing the option in question. Measures of attitude follow directly from the attitude scaling literature, in which the attitude is measured on an unfavorable-favorable rating scale (Jaccard, Weber and Lundmark 1975). Many applications in the consumer area estimate attitude by use of compositional methods, in which perceptions about individual attributes of an option are combined (frequently using a variant of expected-utility theory) to yield an index of attitude. These approaches are generally inferior to the present measurement strategy, because they (a) make strong measurement assumptions (e.g., the presence of ratio level properties), (b) assume that all relevant attributes and no irrelevant attributes have been included in the analysis, (c) vary in the

conceptualization of what the relevant attribute-level measures should be (e.g., measures might include indices of certainty, probability, evaluation, importance, salience, relevance) and/or (d) impose a combinatorial rule on the individual attribute measures which may not be valid. The resulting measures may not reflect the relevant attitude, as conceptualized in the preference structure approach.

Fourth, the preference structure approach states that an individual will choose to perform that option toward which the most positive attitude is held (however, see exceptions discussed later). Several models of choice functions have been suggested in the consumer literature (e.g., Louviere and Woodworth 1983; Currim, 1981; Batsell and Lodish 1981; Reibstein 1978), the most popular being a form of the Luce multinomial logistic function. The model states that the probability of choosing an option A from a set of options can be expressed as the (natural log) evaluation of option A divided by the sum of the (natural log) evaluations of all options considered. This function has primarily been evaluated for aggregate level phenomena, as opposed to individual choice functions. Batsell and Lodish (1981) evaluated the model at the individual level for repeat purchase decisions over time. Psychological research on the model at the individual level has found it to be unsatisfactory (e.g., Becker, DeGroot, and Marschak 1963; Tversky 1972). In its present form, the choice function of the preference structure approach is crude, but has proven to be effective. Future research is needed to better quantify and conceptualize preference structure choice functions.

Applied Implications. Preference structure analysis has numerous applied implications. Consider the case where a consumer psychologist is attempting to influence an individual to perform one of four behavioral options (purchase product A from the class A, B, C, D). The attitude toward each of the options can be measured. Depending on the distribution of the attitudes, different influence strategies would be dictated. First, it may be found that the attitudes toward options C and D are quite low and, hence, these options can be ignored. Three strategies are then possible: (1) make the attitude toward A more positive, (2) make the attitude toward B more negative, or (3) some combination of the above. The attitude scores will, in part, dictate the strategy used. For example, if the attitude toward option B is highly positive, the psychologist would be ill-advised to make the attitude toward alternative A more positive. There would probably be a "ceiling effect" and the only effective strategy would be to lower the attitude toward alternative B in conjunction with raising the attitude toward A. In contrast, if the attitude toward B was moderately positive, with the attitude toward A being slightly less positive, then any of the three strategies could be effective.

If one wanted to strengthen the decision to perform A (i.e., make the decision resistant to change), then this would involve maximizing the discrepancy between option A and option B. This could be accomplished by using any of the three influence strategies outlined above.

The preference structure approach also has implications for the selection of target populations. If the psychologist is trying to increase the number of individuals who perform A, then those individuals most likely to change their behavior will be those whose attitudes towards options A and B are roughly equal (i.e., those who are only slightly more positive toward B than A). In contrast, individuals who have much more positive attitudes toward B than A should be relatively difficult to influence because the discrepancy between attitudes is large. Initial change efforts therefore might be focused on the former group. The strategies used to induce change could differ for one group as opposed to the other. (Parenthetically, the size of the discrepancy between the two most positive options should be related to the stability of behavior over time: The larger the discrepancy, the more likely it is the behavior will be stable.)

The above comments are theoretical approximations, at best, and are made in the spirit of suggesting potential applied implications of preference structure analysis. More precise statements will be possible as research on the choice function is forthcoming.

Error Theory for Preference Structure Analysis. The comparison of attitudes across options for a single individual should address the problem of measurement error. Consumer research which has used individual choice functions to predict choice behavior has ignored the problem of unreliability of measures. In our research, we typically obtain ratings of attitudes on three separate occasions, and use the mean attitude score as an index of the "true" score. Differences between mean scores for any two options are then evaluated relative to an index of the average unreliability across options. This is accomplished using a one way analysis of variance model, in which the different options define the levels of the analysis, and replicates are the ratings in each session. Tukey-based (Kirk 1968, p. 88) critical differences are defined for pairwise comparisons of options to isolate attitude differences that can not be attributed to measurement error. This strategy is similar to the error theory of functional measurement (Anderson 1981, 1982). The major assumption is that within-cell variation reflects only random measurement error. The approach becomes problematic if the number of options is small, because the statistical tests may lack power. This can be offset by increasing the number of repeated assessments.

Non-Optimizing Decision Rules. Thus far, our statement of preference structure analysis assumes an optimizing choice process: The individual chooses that option towards which the most positive attitude is held. Although this will generally be the case, there are instances where behavior will not correspond to the most positive option. One such case can occur when the behavior is not volitional and is controlled by other people or events. In this instance, individuals may be unable to enact the option that they are most positive toward.

Our research on choice of banks has revealed a second moderating variable on the use of an optimizing rule. When individuals first move to a community, they choose the bank towards which they feel most positive. Over time, they might acquire information about a competing bank which leads them to be more positive toward that bank relative to their own bank. However, their behavior does not change because of the costs (both economic, social, and psychological) of switching from one bank to another. This suggests that the costs of switching options relative to the benefits to be gained will be an important mediator of attitude-behavior consistency from an optimizing perspective.

Nomothetic Analyses. Nomothetic (mean) level analyses, requiring minimal assumptions about a common response language, can be conducted on preference structures, if the mean comparisons are between two or more decision options (i.e. between "repeated measures" means). The necessary assumption is one of an approximately common scale unit across individuals (the origin being irrelevant). This assumption will probably be met if the measurement practices described in Jaccard and Wood (1985) are effected. Subgroup comparisons can also be made without recourse to common origin assumptions, if the focus is on group differences in the differences between means (e.g., the difference in mean attitude scores between options A and B for upper class individuals as compared with the difference between mean attitude scores for options A and B for lower class individuals).

Conclusions

We have outlined some of the difficulties with using aggregate level or across individual analyses in testing theories of consumer behavior. We have also briefly described one facet of an idiothetic approach to consumer decision making. Space limitations forced us to deal with the most simplistic aspect of our framework. However,

even this facet has implications for much of the current consumer research using regression based attitude models to explain consumer behavior.

A REVIEW OF META-ANALYTIC TECHNIQUES

David Brinberg, Baruch College, CUNY
James Jaccard, SUNY - Albany

Abstract

A number of statistical procedures have been developed in recent years to integrate a set of empirical findings. This paper provides a review and synthesis of the strengths and weaknesses of these techniques.

Introduction

With the rapid growth of empirical findings in consumer behavior, there is a need to integrate research results into a coherent body of knowledge. In this paper, we will discuss an approach that can provide the researcher with the tools to integrate a body of literature. The paper will be divided into two sections. In section one, we will present a brief historical overview of the procedures used to integrate research findings. In section two, we will discuss the types of statistical procedures that can be used for the integration of research findings and we will present examples of the use of these procedures.

Integrating Research Findings: A Brief Historical Review

Statistical procedures for the integration of research findings have been available to social science researchers for over 50 years (cf. Pearson 1933; Pearson 1938; Wallis 1942; Fisher 1948; Mosteller & Bush 1954). Those procedures focused primarily on the development of transformations (e.g., natural log, z score transformation) and strategies for weighting individual studies and allow the researcher to combine or to compare the probability levels obtained from independent studies. Recent work on these statistical procedures (e.g., Rosenthal 1978; Glass, McGaw and Smith 1981; Hunter, Schmidt, and Jackson 1982; Hedges 1982, 1983) has extended the work on transformations and has focused on the estimation of the nature and strength of a hypothesized relation. Meta-analysis has been the term developed to describe the use of these statistical procedures for the integration of a set of empirical findings across independent studies (Glass, McGaw and Smith 1981).

In recent years, meta-analytic procedures have been introduced to consumer researchers. Sawyer and Peter (1983) discuss issues associated with meta-analysis in their presentation of statistical significance testing. Substantive applications of meta-analysis have examined the relation between research design and response rates to questionnaires (Yu and Cooper 1983); research design and the reliability of rating scales (Churchill and Peter 1983); and advertising and sales (Assmus, Farley, and Lehmann 1984). Several researchers have discussed the strengths and weaknesses of meta-analysis (Houston, Peter, and Sawyer 1983; Monroe and Krishnan 1983), although those authors do not provide a discussion of the analytic procedures. In section two of this paper, we will focus on a detailed discussion of these procedures.

Limitations of Literature Reviews

Two types of reviews will be discussed: (1) narrative reviews and (2) meta-analytic reviews. In our view, the primary feature that distinguishes narrative from meta-

This paper is a condensed version of a chapter entitled "Meta-Analysis: Techniques for the quantitative integration of research findings" to appear in D. Brinberg & R.J. Lutz (Eds.) Perspectives on Methodology in Consumer Research. New York: Springer-Verlag.

analytic reviews is that the latter uses precise and formal procedures whereas the former uses the reviewers' subjective judgments to address the following set of questions: (1) Is there a relationship between two (or more) variables? (e.g., consumer attitudes and purchase behavior) (2) What is the strength of that relationship? and (3) Under what conditions (e.g., subjects, behaviors, measures, and contexts) will the findings hold?

Narrative reviews can be characterized as an integration of findings by either itemizing each result or by some vote-counting technique (i.e., by tabulating the number of studies consistent with a particular hypothesis). Proponents of meta-analysis have described narrative reviews as limited in their potential for useful information. For instance, Axelson, Federline and Brinberg (1985) conducted a meta-analysis on the relation between food attitudes and food related behavior. In their review, nine studies were found that examined this relation. Seven of those nine studies had a nonsignificant correlation between attitude and behavior. Using a vote counting procedure, these authors would have concluded that no relation exists between food attitudes and food related behavior. Using meta-analytic procedures, however, these authors found a statistically significant (though small) relation between food attitude and food behavior. Thus, the meta-analytic procedures reduced the likelihood of these authors making a Type II error.

There are several limitations associated with the narrative approach. First, when the number of studies is large, the reviewer may have difficulty estimating: (a) whether there is a relationship among the variables being examined and (b) the strength and nature of that relationship. Second, there are losses of information that may occur if information is integrated incorrectly (Light and Smith 1971): (1) weak inferences; that is, the relation under study is stronger than the reviewer infers; (2) overlooked inferences; that is, the reviewer ignores systematic variation in the set of findings and (3) wrong inferences; that is, the reviewer integrates the set of findings in a manner that is inconsistent with the more accurate statistical integration. Third, reviewers may ignore the impact of statistical power when using just the level of significance in their integration of a set of findings (Cook and Leviton 1980). A finding may not reach statistical significance because of a lack of power but still be consistent with the direction of the hypothesized relation. Ignoring that finding or treating it as non-support for the hypothesis may result in a misleading conclusion as illustrated above.

Several researchers have presented limitations that apply to both narrative and meta-analytic reviews, although the discussion by these authors focus on meta-analytic techniques. Wilson and Rachman (1983) and Mintz (1983) have argued that bias can occur in the selection of studies both in terms of the specification of the sampling frame (e.g., only published studies or only those studies with quantified results) as well as in the specification of hypothesized relations. For instance, studies that examine the attitude-behavior relation may measure attitude several ways (e.g., semantic differential, set of belief statements). The reviewer needs to make a judgment concerning what studies are appropriate for inclusion in the literature review; that is, he/she needs to determine what studies will be treated as replicates (and thus, included in the review) and what studies will be treated as different (and thus, excluded from the review).

Another major source of controversy in conducting reviews is the integration of seemingly unrelated studies. For instance, Glass, McGaw and Smith (1981) report a meta-analysis in which they combined a wide variety of psychotherapy treatments and a wide variety of illnesses. A single, overall effect size estimate concerning the effectiveness of psychotherapy was computed. That estimate, however, can be misleading because it may mask ineffective treatments. These authors point out that useful information concerning psychotherapy can be gained when the set of studies are partitioned into different groups and the scope and limits of treatments can be identified.

For most research, we assume those units we treat as a replication factor are homogeneous (e.g., subjects in a between-subject factorial design). The reviewer makes a similar assumption concerning the set of studies to be integrated because the studies are treated as the replication factor. Procedures (to be discussed in section two) are available to determine the uniformity of these studies and to test the viability of this assumption.

The impact of poor quality studies is another source of controversy when conducting literature reviews. Glass and Kliegl (1983) argue that all studies should be included in a review and that the quality of the study should be coded and correlated with outcome variables to determine their relation. If there is a non-significant correlation, the researcher might then conclude that study quality is unrelated to study outcome. Mintz (1983) and Wilson and Rachman (1983), however, argue that including poor studies provides no useful information because no accurate inferences may be made concerning their outcomes. Further, Mintz (1983) argues that coding the quality of the study assumes the researcher is able to develop a valid coding system. Mintz suggests that the reviewer not include all studies but make explicit his/her reasons for excluding any particular study from the review.

A final source of controversy concerns the treatment of studies as independent replicates of a hypothesized relation. If a single study includes more than one piece of information concerning the hypothesized relation and each piece of information is included separately in the review, the researcher is faced with the problem of biasing the integration of the set of studies by placing undue weight on findings from the same study and violating statistical assumptions of independence. Two approaches have been suggested to deal with this problem (Light and Pillemer, 1984). First, the researcher may develop a single statistic for that study. Second, the researcher can include each piece of information in the review but weigh the information in such a way that it receives the same overall weight as the findings from a single study. We do not recommend the use of the second approach because it violates the assumption of independence, although some techniques have been developed recently to adjust for nonindependent findings (Strube 1985).

The Role of Meta-Analysis in the Conduct of Research

Our position is that meta-analytic procedures should be viewed as one strategy within a general research program for studying a focal problem. The primary advantages of the meta-analytic procedures are two-fold: (1) statistical procedures are more precise than intuition in identifying the presence, strength and nature of a hypothesized relation and (2) these procedures can be used to identify the scope and limits of the hypothesized relation.

Several sources of controversy were raised concerning literature reviews which we would like to address. First, in our view, the researcher conducting a meta-analysis is faced with many of the same "subjective" choices as the narrative reviewer (e.g., specification of the sampling frame, the hypothesized relation, the quality of the study, factors that potentially interact with the study outcomes, the scope and limits of the findings). We view both procedures as subjective, although we acknowledge that the meta-analytic procedures may help the researcher

be more explicit in his/her assumptions and be more precise in the integration of probability levels and effect size estimates. Second, the issue concerning the integration of unrelated studies is a question concerning the conceptual clarity of the original hypotheses. A researcher may be interested in only combining studies that operationalize a concept similarly or may be interested in examining all studies that claim to examine the same concept (even if they are operationalized differently). There is no single approach that is correct because the selection of studies depends on the purposes of the reviewer. Each reviewer needs to choose and make explicit the criteria he/she has used to select a set of studies. Third, poor quality studies (i.e., those studies with design flaws or poor execution that result in confounded findings) should not be included in an integration of a set of findings because the outcome of those studies are unclear and will add uninterpretable variation in a review. We have argued to exclude poor quality studies for two reasons: (1) poor quality studies have confounded (i.e., ambiguous) outcomes; thus, no reasonable inference can be made concerning the relation between those studies and other "external" variables, and (2) if the number of studies is sufficiently large to examine the difference between poor and good quality studies, then the researcher is likely to have a sufficient sample size to simply use the good quality studies to examine the hypothesized relation. Fourth, to reduce the problems that occur when including multiple findings from a single study, we recommend that only a single finding from any one study be included in a review. A conservative approach (in terms of Type I errors) is to select the weakest relationship, and a liberal approach is to select the strongest relationship.

The major source of information in any literature review is not in single summary statements concerning the relation but in identifying its scope and limits. Knowing the overall significance level and the overall effect size of a set of studies provides the reviewer with limited information. Only when the reviewer is able to fit it into some nomological network will he/she come to a deeper understanding of that relation.

Statistical techniques have been developed to estimate the impact of partition variables on the presence or absence of a hypothesized relation, across a set of independent studies, and on the strength and nature of that relation. A detailed, and somewhat formal presentation of these techniques will be the topic of discussion for the remainder of this paper.

Quantitative Procedures

This section describes statistical methods for analyzing multiple research studies. We begin by considering the characteristics of effect size measures used in most meta-analyses. After describing the statistical focus of meta-analytic techniques, we consider approaches to the quantitative analysis of multiple studies.

Measures of Effect Size

Numerous indices of effect size have been proposed in the social sciences. One of the more popular indices has focused on the proportion of explained variance in the dependent variable relative to the independent variable. Statistics such as t , r , F (where $df = 1$), and χ^2 (where $df = 1$) can be converted to measures reflecting the proportion of explained variance (EV) in a set of data as follows:

$$\begin{aligned} EV &= r^2 & (1) \\ EV &= \chi^2/N & (2) \\ EV &= F/(F + df \text{ within}) & (3) \\ EV &= t^2/(t^2 + df) & (4) \end{aligned}$$

Meta-analytic techniques typically use two indices of effect size. The approach advocated by Rosenthal (1983) uses an index, r_a , which is the square root of any of the EV measures. The second index is based upon Glass et al.

(1981) and Cohen (1977) and concerns the case of mean scores in two conditions. This index, called d , is defined

$$d = (M_1 - M_2) / s \quad (5)$$

where s is a pooled standard deviation from the two conditions. Cohen (1977) suggests that a d of .2 represents a "weak" relationship, a d of .5 represents a "moderate" relationship, and a d of .8 represents a "strong" relationship (however, see Cohen 1977, p. 24 for additional perspectives on this problem). d is mathematically related to r_r (e.g., d values of .2, .5, and .8 equal r_r values of .10, .25, and .37 respectively. See Cohen (1977) for the mathematical translation of d to r_r and vice versa).

In equation 5, there is some controversy as to the optimal method for defining s in sample data. The value of σ in the population parameter $\delta = (\mu_1 - \mu_2) / \sigma$ is assumed to stem from populations with equal variances. It follows that the best estimate of σ will be based upon traditional formulas used in t tests. In cases where the two groups in question represent a treatment and control group, Glass, McGaw and Smith (1981) recommend the use of the control group standard deviation as the estimate of σ . In contrast, Hunter, Schmidt, and Jackson (1982) advocate the traditional pooled estimate of σ . For most consumer applications, the pooled estimate of σ will be the most appropriate. Discussions in the sections that follow will therefore assume an s based upon a pooled standard deviation estimate. For further consideration of this issue, see Glass et al. (1981), Hunter et al. (1982), and Hedges (1981).

Few studies report the information necessary to compute d directly. However, it can be derived from the t statistic by $d = t \sqrt{(1/n_1 + 1/n_2)}$.

Analyzing p values

Methods for estimating the statistical significance of a relationship across independent studies as a function of p values have been reviewed by Rosenthal (1978) and his associates (Rosenthal and Rubin, 1979). The two most popular methods are the method of adding z 's and the method of adding weighted z 's (also called Stouffer's method). Table 1 presents five hypothetical studies that examined the relationship between an independent and dependent variable by means of a t test. Column 2 of the table presents the t values observed in each study and column 3 indicates the direction of the mean difference (+ means $M_1 > M_2$, - means $M_1 < M_2$). Column 4 reports the df on which each t was based. Column 5 is the one tailed p associated with each t reported in column 2. A one tailed p is always used in this approach by virtue of statistical considerations. Most statistics texts do not provide tables that readily provide these p values. A FORTRAN program for computing the p associated with a t , r , F , or χ^2 statistic is presented in Veldman (1968, p. 222). Extensive tables of p values are provided by Sherman (1984). Column 6 of Table 1 presents the z score equivalents of the p values in question. These are obtained from tables of the standard normal distribution.

TABLE 1

NUMERICAL EXAMPLES FOR ANALYZING p VALUES

Study	t	Direction of difference	df	One tail p value	z
A	1.19	+	40	.12	1.17
B	2.39	+	60	.01	2.33
C	.60	-	10	.72	-.58
D	1.52	+	30	.07	1.48
E	.98	+	20	.17	.95

The method of adding z 's involves summing the scores in column 6 and dividing by k . This calculation yields a z of 2.39. The one tailed p value associated with a z score of

2.39 is obtained from a table of the standard normal distribution and in this case, $p = .009$. For an alpha level of .05, the null hypothesis of no effect or no relationship would be rejected because $.009 < .05$. Note that if the vote counting procedure was applied to these studies, the result would be a failure to reject the null hypothesis.

The method of adding weighted z 's is similar to the above, but each z in column 6 is weighted by the degrees of freedom. This approach gives greater weighting to studies with large N . The critical z uses columns 4 and 6 of Table 1 such that

$$z' = \left(\sum_{j=1}^k df_j z_j \right) / \sqrt{\left(\sum_{j=1}^k df_j^2 \right)} \quad (6)$$

In this case, $z' = 3.01$ with an associated p of .0013. Again, the null hypothesis is rejected. Note that the method of adding unweighted z 's is more conservative than the method of adding weighted z 's. This results from the fact that studies with smaller N typically will observe larger p values, and these are weighted equally in the unweighted case.

When analysis focuses on p values associated with chi square, p values are, by definition, two tailed. Column 5 of Table 1 must therefore be derived by dividing the p value in half. Also, for purposes of executing the weighted z method, the weights are the respective sample sizes (N) rather than df .

One problem with the above meta-analysis procedures is the potential bias introduced by editorial policies of journals. It is commonly believed that statistically non-significant results are less likely to be published, the result being a tendency to underestimate the true value of p . Rosenthal (1980) has referred to this as the "file drawer problem," because numerous unpublished studies with large p values may be tucked away in the researchers' file drawers. One method for addressing this issue is to calculate the number of studies that would have to exist whose mean z is zero such that the observed z' would become marginally non-significant at the .05 alpha level. This can be calculated by

$$NS = \left(\left(\sum z_j \right)^2 / 2.706 \right) - k \quad (7)$$

where NS is the number of studies. As an example, Rosenthal estimated that approximately 3,444 studies with a mean z of zero would have to exist in file drawers for doubt to be cast on the existence of experimenter bias effects. In the current example, the number of such studies would be six.

The above approach assumes that all p values are generated from a common population. This assumption may not be correct in certain instances, in which case it is inappropriate to combine p values. If the individual p values in the studies are quite heterogeneous (holding constant df), then the assumption of a common population is questionable. The procedures outlined in the next section provide a mechanism for testing this assumption.

Analyzing Effect Size Indices

The analysis of effect size indices across studies typically involves a two stage analysis. Given k independent investigations, the first stage is to determine if the population effect sizes across the k studies are equal. If the effect sizes are homogeneous, then the second stage focuses on estimating the size of the effect, based on the k investigations. If the effect sizes are heterogeneous, then the second stage focuses on isolating the sources of heterogeneity.

Stage 1: Testing Homogeneity of Effect Sizes

Many approaches have been suggested for testing homogeneity of effect sizes. We will focus discussion on the analysis of the d statistic and correlation

coefficients, emphasizing approaches that, at present, seem to have the most desirable statistical properties.

Analysis of Mean Differences. Hedges (1981, 1982, 1983) has developed an approach that is applicable to the case of independent means. The technique uses the effect size measure d . Table 2 presents an example with six studies that examine the difference between two means on a common dependent measure. The t was converted to a d statistic by $d = t\sqrt{1/n_1 + 1/n_2}$. The first step involves translating each sample d to an unbiased estimate of δ by multiplying the d by $1 - (3/(4w-1))$ where $w = n_1 + n_2 - 2$. This has been done in column 5 of Table 2. Let \tilde{d}_j be the unbiased estimate of δ in study "j". The intermediate statistic, V , is computed for each study such that

$$V = \frac{n_1 + n_2}{n_1 n_2} + \frac{\tilde{d}_j^2}{2(n_1 + n_2)} \quad (8)$$

Column 7 of Table 2 presents the corresponding V . Then,

$$TS = \sum \tilde{d}_j^2 / V - \frac{(\sum \tilde{d}_j / V_j)^2}{\sum 1/V_j} \quad (9)$$

and TS is approximately distributed as a chi square with $k - 1$ degrees of freedom. For the present example, $TS = 14.212 - (8.889/217.79) = 13.84$. The null hypothesis of homogeneous effect sizes is rejected.

TABLE 2

NUMERICAL EXAMPLE FOR ANALYSIS OF HOMOGENIETY OF d SCORES

Study	n	n	t	d	\tilde{d}	V
A	30	30	.71	.183	.181	.06694
B	30	30	-2.04	-.528	-.521	.06893
C	280	290	-1.56	-.131	-.131	.00703
D	6	11	1.99	1.011	.959	.28462
E	44	40	.45	.098	.097	.04778
F	37	55	2.00	.429	.425	.04619

Correlation Coefficient. Rosenthal (1983) has described an approach which can be used to test the homogeneity of a set of correlation coefficients. Table 3 presents an example with six studies that report the correlation between two variables. r is first converted to Fisher's Z using the transformation $Z = .50 (\ln(1+r) - \ln(1-r))$, where \ln = the natural logarithm. Most statistics texts provide tables for converting r to Z . The relevant Z appear in column 4 of Table 3. An average Z is computed as follows:

$$\bar{Z} = \frac{\sum (N_j - 3) Z_j}{\sum (N_j - 3)} \quad (10)$$

where N = the sample size for study "j". TS is calculated by

$$TS = \sum (N_j - 3) (Z_j - \bar{Z})^2 \quad (11)$$

TABLE 3

NUMERICAL EXAMPLE FOR THE ANALYSIS OF HOMOGENIETY OF CORRELATIONS

Study	N	r	Z	(N-3) Z
A	50	.30	.310	14.57
B	60	.33	.347	19.78
C	40	.25	.255	9.44
D	50	.28	.288	13.54
E	60	.44	.477	27.19
F	40	.46	.497	18.39
				<u>102.91</u>

For the present data, $Z = 102.91/282 = .365$ and $TS = 2.24$. TS is approximately distributed as a chi square with $k-1$ degrees of freedom. For a chi square of $6-1 = 5$ degrees of freedom, the critical value of chi square for $\alpha = .05$ is 11.07. Because 2.24 does not exceed this

value, the null hypothesis of homogeneous correlations is not rejected.

Measurement Error. The above techniques do not take into account fallible measures. Hedges proposes modifications to his formulas to incorporate the effects of measurement error when good reliability estimates are available. Hedges modification involves multiplying the pooled standard deviation estimate, s , in equation 5 by the square root of the reliability coefficient for the dependent variable. The adjusted d scores are then analyzed instead of the observed d scores, using formulas 9 and 10. Because s is rarely provided in research reports, a simpler approach is to multiply the observed value of d by $1/\sqrt{r_{yy}}$, where r_{yy} is the reliability coefficient for the dependent variable.

For the analysis of correlations, the original r 's are multiplied by $1/\sqrt{(r_{xx} r_{yy})}$. Equation 9 is then applied to the adjusted r .

The problem with the above approaches is that they assume accurate estimates of reliability are available. This is rarely the case in consumer research. The most frequently used reliability estimate, test-retest correlation is subject to considerable sampling error and, at best, represents a crude approximation to reliability. This creates a dilemma. On the one hand, the analyst can use the crude reliability estimate, with the knowledge that sampling error in the estimate could undermine the validity of the conclusions made from the analysis. On the other hand, the analyst can ignore the reliability adjustments, which is tantamount to assuming perfectly reliable measures.

We recommend a two step approach in which the test is performed first without the reliability adjustment and then with the reliability adjustment. The reliability estimates used should be a best-guess (based upon theory, past research, and present reliability data) of the lower bound of the reliability of the measures in question. If the results of both analyses lead to the same conclusion, then one has increased confidence in that conclusion. However, if the results of the analysis are discrepant, then any conclusions must be tentative.

Stage 2: The Case of Homogeneous Effect Sizes

If one is confident that homogeneous effect sizes exist, then it is reasonable to average the effect sizes in some manner to estimate the population effect size.

Mean Differences. Hedges has suggested several methods for estimating δ . We will describe the approach advocated in Hedges (1982). The estimate of δ , d' , is calculated from

$$d' = \frac{(\sum \tilde{d}_j / V_j)}{\sum 1/V_j} \quad (12)$$

where all terms are as previously defined. Approximate 95% confidence intervals can be formed by first defining the constant $c = 1.96 \sqrt{(1/1/\sum V_j)}$, and then forming the lower limit by $d' - c$, and the upper limit by $d' + c$.

Correlation Coefficients. Viana (1980) has described a method for estimating ρ from a set of k correlation coefficients across k studies. Table 4 presents five studies reporting correlation coefficients that will serve as a numerical example. Column 2 presents the sample size for each study and column 3 presents the observed sample r . Column 4 presents an approximation to the minimum variance unbiased estimate of ρ , \tilde{r} (Olkin and Pratt, 1958). \tilde{r}_j is computed from r by $\tilde{r}_j = r_j + ((r_j(1-r))/2(N_j - 4))$. The estimate of ρ , r' , is then $\sum (r_j(N_j - 1))/(TN - k)$, where $TN = \sum N_j$. For the data in Table 4, $r' = .312$.

An approximate 95% confidence interval can be constructed for cases where $\rho < .70$, a common situation in consumer research. This involves transforming each observed sample

r to Fisher's Z and then calculating a weight, w, for each Z. w is defined as follows:

$$w = \frac{(N_j - 3)(1 + .5(N_j - 1))}{(TN - 3k)(1 + .5(N_j - 1))} \quad (13)$$

The approximate 95% confidence interval is constructed by defining the 2 constants $c = 1.96 (\sum (w_j^2 / (N_j - 3)))$, and $f = 1 + \sum (w_j / (2(N_j - 1)))$. The lower limit of the interval is $((\sum w_j Z_j) - c)/f$ and the upper limit of the interval is $((\sum w_j Z_j) + c)/f$. This yields values of .088 and .520 for the data in Table 4.

TABLE 4

NUMERICAL EXAMPLE FOR ESTIMATING THE POPULATION CORRELATION

Study	N	r	\tilde{r}	Z	w
A	15	.450	.466	.484	.156
B	16	.191	.198	.193	.169
C	30	.303	.308	.312	.346
D	15	.395	.410	.417	.156
E	16	.193	.200	.195	.169

Measurement Error. Estimates calculated in the above techniques can be adjusted for measurement error using procedures discussed earlier. This involves calculating an adjusted d or an adjusted r, and applying the formulas to the adjusted values rather than the observed values.

Biased Estimates. The validity of all estimation procedures are subject to editorial policies of journals. To the extent that journals only accept articles reporting "large" effect sizes and reject articles reporting "weak" effect sizes (and which are methodologically sound), then estimates will be biased upward. This possibility should be considered when interpreting effect size estimates. Recent perspectives on this problem, and methods for addressing it, are discussed in Hedges (1984).

Orwin (1983) has developed an analogy to Rosenthal's "file drawer" formula for measures of d. One can compute the number of studies ("fail-safe" n) whose mean d is zero that would have to exist in order to reduce the sample mean d to some specified value (e.g., .2 corresponding to a "weak" effect in Cohen's analysis, .5, a "medium" effect, or a .8, a "strong" effect). The estimated number of studies is defined by

$$NS = (k(\bar{d} - d_c))/d_c \quad (14)$$

where NS = the number of studies in the "file drawer," k = the number of studies on which the mean sample effect size is based, \bar{d} = the absolute value of the unweighted mean of the observed d scores across the k studies, and d_c = the criterion value (e.g., .2, .5, .8).

There are several limitations to equation 14. First d must always be greater than zero. At best, the investigator can compute the "fail-safe" n for some trivial criterion effect size (e.g., .01) but not for an effect size of zero. Second, the formula assumes that the k studies have equal N. If the N are not very discrepant, then equation 14 should give a reasonable approximation to the "fail-safe" n. We therefore recommend equation 14 be used cautiously and as a rough guideline.

A similar formula can be derived for correlation coefficients. The formula is

$$NS = (k(\bar{Z}_o - Z_c))/Z_c \quad (15)$$

where \bar{Z}_o is the Fisher Z transform of the mean sample correlation across the k studies, Z_c is the Fisher Z transform of the criterion correlation value, and NS and k are as previously defined. Equation 15 has the same limitations as equation 14.

Stage 2: The Case of Heterogeneous Effect Sizes

When the effect sizes are found to be heterogeneous, it is not appropriate to average them to estimate the relevant population parameter. Instead, additional analyses are required to determine which subsets of effect sizes are heterogeneous. This can be accomplished from either an exploratory perspective or a theory driven perspective. We will consider each, in turn.

Exploratory Analyses. Hedges and Olkin (1983) discuss exploratory procedures for the analysis of d and the correlation coefficient, r. One procedure is based on the Bonferonni multiple comparison procedure developed in analysis of variance. We will first consider the case of d.

The procedure begins by rank ordering effect sizes for the k studies from smallest (rank = 1) to largest (rank = k). This has been done in column 2 of Table 5, which presents d measures (column 3) for five studies. The d_j are first transformed to U statistics by $U_j = 2 c_j n_j$, where $c = \log \sqrt{(d + 8)} - 1.0536$ and $n = (1/k (\sum n_j))^2$. n refers to the number of subjects per group in a given study, assuming equal n in the two groups (the case of unequal n will be considered shortly). Column 4 presents the U measure for each d. The absolute difference between two effect sizes is tested against zero by comparing the absolute difference between corresponding U's with a critical value. The critical value is determined by specifying the number of "steps," ns, between the effect sizes. ns will equal the larger of the two ranks minus the smaller of the two ranks plus one. For example, to compare effect sizes for study F and D, $ns = 5 - 3 + 1 = 3$. The absolute difference between U_F and U_D is .69 and the critical value (alpha = .05) is 3.68. Because .69 does not exceed 3.8, we fail to reject the hypothesis of homogeneous effect sizes for these studies. Using this approach, exploratory comparisons can be made with the possibility that post hoc analyses of differences in effect size will make substantive sense when study characteristics defining "similar" and "different" effect sizes are considered.

TABLE 5

NUMERICAL EXAMPLE FOR ANALYSIS OF d MEASURES BASED AND HEDGES AND OLKIN

Study	Rank	d	U
G	1	-.587	-2.257
E	2	-.494	-1.907
F	3	-.235	-.910
A	4	-.079	-.307
D	5	-.058	-.220
C	6	.091	.350
B	7	.699	2.563

For correlation coefficients, the r is transformed to U by first transforming the sample r to Fisher's Z and then multiplying the Z by $\sqrt{(N-3)}$, where $N = (1/k (\sum N_j - 3))^2$.

Both approaches formally assume equal N across studies, although Hedges and Olkin suggest that unequal N will not drastically affect the outcome. Further, the analysis of d assumes that the two conditions within a study have equal n. In cases of unequal n within a study, a conservative approach is to define n by the smaller n of the two, a liberal approach is to define n by the larger n of the two, and a compromise is to define n as the mean n.

Theoretical Analysis. Hedges (1982) discusses a useful approach for analyzing heterogeneous d measures when the measures can be grouped into clusters a priori on the basis of theoretical concerns. For the data in Table 5, assume the first three studies were conducted with upper class individuals whereas the second three studies were conducted with working class individuals. Using equation 9, the overall chi square, TS is calculated to test the null hypothesis of homogeneous effect sizes across all k studies. The total chi square is then decomposed into two

components, one due to between group differences (as defined by social class) and the other due to within group differences. This procedure is analogous to the partitioning of variance in analysis of variance problems. The chi square for between group differences is calculated as follows: Let p = the number of clusters (in this case $p = 2$, upper and working class), m_i = the number of studies in cluster i , \bar{d}_{ij} = the unbiased estimated effect size of study j in cluster i , V_{ij} = the V measure for study j in cluster i , and d'_i = the average d measure in cluster i (note: the mathematical definition of d' is given shortly). Then, the between groups chi square, TSB, is

$$TSB = \frac{\sum_{i=1}^p \sum_{j=1}^{m_i} d'_{ij} / V_{ij}}{\sum_{i=1}^p \sum_{j=1}^{m_i} 1 / V_{ij}} - \frac{\left(\frac{\sum_{i=1}^p \sum_{j=1}^{m_i} d'_{ij} / V_{ij}}{\sum_{i=1}^p \sum_{j=1}^{m_i} 1 / V_{ij}} \right)^2}{\sum_{i=1}^p \sum_{j=1}^{m_i} 1 / V_{ij}} \quad (16)$$

$$\text{where } d'_i = \frac{\sum_{j=1}^{m_i} d_{ij} / V_{ij}}{\sum_{j=1}^{m_i} 1 / V_{ij}} \quad (17)$$

TSB is distributed as a chi square with $p - 1$ degrees of freedom. For the data in Table 5, $d' = -.137$, $d' = .317$, and $TSB = 7.50$. The chi square for within group differences is $TSW = TS - TSB = 13.84 - 7.50 = 6.34$. TSW is distributed as a chi square with $k - p$ degrees of freedom.

The critical value for TSB, $\alpha = .05$, is 3.84. Because 7.5 exceeds 3.84, the null hypothesis of homogeneous population d is rejected. It is useful to calculate 95% confidence intervals for each d , (see discussion of equation 12). For upper class studies, these are $-.286$ to $.012$. For lower class studies, they are $.028$ to $.606$. Non-overlapping confidence intervals indicate statistically significant differences.

The critical value for TSW, $\alpha = .05$ is 9.49. Because 6.34 is less than 9.49, we fail to reject the null hypothesis of homogeneous effect sizes within clusters, indicating that the calculations of d for the clusters is meaningful. If TSW is statistically significant, then equation 11 can be applied to each cluster separately to determine which group(s) has heterogeneous effect sizes.

The above procedures hold for the case of d measures. Analogous procedures are applicable to the case of correlation coefficients. Each correlation coefficient is converted to Fisher's Z . The total chi square, TS , is computed using equation 11. The between group chi square involves calculating an average Z , Z_i , for each cluster separately using equation 10. Let N_i = the sum of the sample sizes across studies in cluster i , and $Z_{..}$ = the average Z (using equation 10) across all studies. Then

$$TSB = \frac{\sum_{i=1}^p (N_i - 3m_i) (\bar{Z}_i - Z_{..})^2}{\sum_{i=1}^p (N_i - 3m_i)} \quad (18)$$

and $TSW = TS - TSB$. TSB is approximately distributed as a chi square with $p-1$ degrees of freedom. TSW is approximately distributed as a chi square with $k-p$ degrees of freedom. Significance tests are applied, as above. Approximate 95% confidence intervals about each mean r can be calculated, as described earlier.

Summary and Conclusions

In this paper, we have discussed two basic features in the use of meta-analytic techniques. First, we described the strengths and weaknesses of literature reviews, in general, and meta-analytic reviews in particular. Second, we discussed a set of statistical techniques that can be used for summarizing the findings across a set of independent studies. In that discussion, we described two basic summary statistics; a correlation coefficient between an independent and dependent variable and a d statistic (Glass, McGaw and Smith, 1981) as well as discussed the impact of unequal sample size and measurement error on those statistics. Researchers are currently examining the statistical properties of these meta-analytic techniques in great detail (e.g., Hedges, 1984).

In many areas of the social sciences, meta-analytic techniques are receiving increased use as a tool for the systematic integration of a body of literature. Our goal in this paper is two-fold: (1) to make the reader aware of current statistical advances in meta-analytic techniques and (2) to describe how meta-analytic techniques can be used to increase a researchers' understanding about the many facets that can influence a set of findings. Our hope is that the reader will make greater use of these techniques in their own area of interest.

OBTAINING MSI SUPPORT: THE CASE OF THE PRICING RESEARCH COMPETITION

Diane H. Schmalensee, Marketing Science Institute

Abstract

This paper describes the process for obtaining MSI support for scholarly marketing research. Support may be financial, or it may be in the form of data or expertise. The paper illustrates this process with the case of the four winners of MSI's pricing research competition.

Introduction

Much of the research done by consumer researchers is eligible for support from the Marketing Science Institute (MSI). While not all subjects of interest to marketing academics are pertinent to MSI and marketing practitioners, there are many areas where their interests do overlap, and these subjects may merit MSI support. For instance, research on the effects of advertising on individuals, on the factors affecting consumer demand for durables, and on consumer response to price and to price changes falls within MSI's highest research priorities.

MSI supports academic researchers in several ways. It can offer grants of a few hundred dollars earmarked for surveys or small experiments. It can provide seed grants (of up to approximately \$5,000) to support the early stages of research. It can give larger grants (of \$10,000 to \$50,000 or more in a few cases) to support major projects of particular interest to MSI member companies. It can provide a forum for researchers to share their ideas with business people and receive constructive feedback and advice. It can provide access to corporate or commercial data, and it can open doors for interviews.

This paper has two objectives. First, to describe the process for obtaining MSI support for academics needing research funding, data, or advice. Second, to illustrate this process with the case of the four winners of MSI's 1984 pricing research competition.

The Process of Obtaining MSI Support

Step 1: Matching Researchers' Interests with MSI Priorities

The starting point for obtaining MSI support is the MSI Research Priorities, a booklet which describes the research topics of greatest interest to MSI. Every two years, MSI member company representatives and academics serving on various MSI committees select the priorities, or the topics with the greatest gaps between what marketers need to know and what is already known. These topics become MSI's research objectives, and all research proposals are judged by how well they match the priorities.

The topics listed in the Research Priorities do not cover all aspects of marketing: They cover only topics of potential relevance to marketing practitioners. Researchers are advised to read the questions listed in the booklet closely and to call MSI for clarification or detail as needed. Generally, every researcher will have some interests in common with MSI's research priorities, but it is unlikely that all of a researcher's interests will be relevant to MSI.

Regardless of topic, all research supported by MSI is scholarly (intended to lead to publication) rather than consulting in nature. MSI does not favor one type of approach or methodology over another and supports all forms of research (such as theory or model development, case studies, or empirical or experimental work) as long as the form is appropriate for the study. Finally, MSI will consider supporting research on topics not listed in the Research Priorities if the proposed topics are innovative and have potential relevance for marketers.

As part of the evolving research priorities, international implications of MSI-supported research are increasingly important. Proposals should show awareness of existing research outside the U.S., as well as implications of the methodology and results of the proposed research for non-U.S. settings.

Step 2: Preparing the Proposal

MSI accepts two types of proposals. One is a pre-proposal letter that outlines the topics to be studied and the researchers' preliminary hypotheses. The purpose of this pre-proposal is to let the researcher obtain MSI's reaction to the topic and research concept before investing the time required to write a full proposal, but the more complete the thinking in the pre-proposal, the more likely it is to receive encouragement.

The second type is the full proposal. MSI does not have a required standard format or length, although brevity is appreciated by reviewers, and five to ten pages are usually sufficient. Successful proposals tend, however, to have a number of common elements. These elements are presented as aids to researchers and not as requirements:

1. Background. — includes a brief review of the relevant literature and statement of why the proposed research will advance knowledge. Typically, it also positions the research with regard to MSI's research priorities.
2. Research questions or hypotheses. — describes the issues to be studied, the researchers' initial insights or beliefs, and what should be learned from the study.
3. Research design and methodology. — describes in detail the approach to be used, including sampling and interviewing methods, experimental designs, and analysis plans as appropriate. If the research is to be divided into phases (qualitative research and theory development are sometimes treated as a first phase, with quantitative research as a second phase); this is spelled out here.
4. Timetable and funding or support needs. — includes key research dates and an expected completion date, along with the researchers' needs for funding, data, or other support from MSI.
5. Expected outcomes or new knowledge. — proposals that include this section list expected outcomes, such as a new definition or framework, a new methodology, a better understanding of how key variables affect the marketing process, or new information to assist managers in making better marketing decisions.
6. Vita of the researcher.

Step 3: Evaluating Proposals

All proposals are reviewed by MSI's review committee composed of the President, Executive Director, and Director of Research Operations. Proposals passing this initial screening are usually sent for further review by selected reviewers with a special expertise in the field or by one of MSI's steering groups.

MSI has six steering groups covering topics related to advertising, marketing strategies, services marketing, packaged goods marketing, consumer durables marketing, and industrial marketing. It also has a special interest group concerned with international or global marketing. All groups have both business and academic members.

The following criteria are considered when evaluating proposals:

1. Fit of the proposed topic with MSI priorities
2. Importance of the topic
3. Originality and intellectual appeal of the proposed research
4. Quality of conceptual development
5. Appropriateness of the methodology for the research
6. Feasibility or doability of the research
7. Qualifications of the researchers for that project

The evaluation process is intended to help researchers with their work rather than just offering a yes or no decision. Reviewers' comments and constructive suggestions are shared with the researchers when possible. Frequently, researchers are asked to revise proposals or to meet personally with interested business people to discuss their ideas before beginning work. Most researchers feel their work is improved as a result.

Step 4: Defining Mutual Responsibilities

When a proposal is accepted, a letter of agreement is prepared that outlines the responsibilities of the researchers and of MSI. Researchers select the dates for the halfway point and for the completion of the study. Researchers agree to prepare a written progress report at the halfway point, a working paper describing the results of their research for MSI, and a short (ten-page maximum) Management Summary of the working paper suitable for quick reading by managers. (Having a management summary and working paper printed and distributed by MSI in no way interferes with publication in a scholarly journal.) Typically, the papers will appear in the MSI working paper series before reaching journal publication.

MSI commits to supply funding, access to data or executives, or other support as requested in the proposal. It also often organizes mini-conferences or meetings between the researchers and interested business marketers. In some cases these mini-conferences provide a forum for enlisting the extra financial or data support needed by the researchers. In other cases, they provide the researchers with early feedback on their work or enable the researchers to share their results personally with MSI member companies.

The Case of the Pricing Research Competition

At the 1984 ACR conference, MSI announced a competition for letters of research interest dealing with consumer response to pricing and price changes. This was an unusual step for MSI, undertaken by its Packaged Goods Steering Group to call attention to its eagerness to support research on pricing. Although the competition is a special case of winning MSI support, it illustrates how MSI researchers can work together with MSI to develop projects of mutual interest.

The process began early in 1984 when MSI's Packaged Goods Steering Group selected the subject of pricing as its top priority for research. The group identified five pricing issues on which it particularly wanted to sponsor research:

1. Factors affecting consumer perceptions of "cost" and the role of cost in purchase behavior
2. How price discounting affects consumers' expectations, perceptions, and behavior
3. Measuring the "value" of a brand and how it is affected by changing prices
4. Factors influencing the way retailers determine prices
5. Pros and cons of a price discounting versus an everyday low price strategy

In September, the steering group announced its competition to draw attention to its pricing topics and to initiate a stream of pricing research. The competition (which offered up to four prizes of \$300 each plus a trip to meet with the steering group and discuss mutual research interests) asked academics to prepare a short letter of research interest describing their interests, hypotheses, and methodologies. These were not full-fledged proposals but general statements of which of the five pricing issues the researchers would like to address and how. This competition was announced at conferences such as the annual ACR and TIMS/ORSA conferences, and by mail.

Fourteen letters of research interest were received by the December 1984 deadline. These were reviewed by members of the Packaged Goods Steering Group (including representatives from Beatrice, Campbell, General Foods, General Mills, Gillette, Lever, Nabisco, Polaroid, Quaker and Warner-Lambert as well as Wharton, M.I.T., Vanderbilt, the University of Chicago, and the University of Florida). Four winners were then selected and invited to meet in February 1985 with the members of the steering group.

Two of the winners, Professors James Lattin (Stanford) and Sridhar Moorthy (Yale), were interested in how discounting strategies affect consumers, while the other two winners, Professors Carl Obermiller (University of Washington) and Valarie Zeithaml (Texas A&M), focused on new approaches for studying the relationship among price, quality, and value. At the steering group meeting, each winner described his or her interests and general approach and received feedback from the steering group. Based on this interaction, the winners then individually prepared complete proposals for MSI that incorporated the changes in emphasis or detail suggested at the meeting.

None of the final proposals remained exactly as originally conceived, and all four winners felt the process helped them improve and focus their work. For instance, Professor Lattin narrowed his focus from a general study of factors affecting discount depth and duration to the narrower study of the dynamics (specifically wearout) of consumer response to price discounts. And, after meeting with the group, Professor Valarie Zeithaml split her research on price, perceived quality, and perceived value of packaged goods into two phases (the first for executive interviews and qualitative research and the second for a laboratory experiment to develop measures and test the theory from the first phase).

As of Fall 1985, three of the proposals are under review by the Packaged Goods Steering Group. Professor Zeithaml's project has been approved and the first phase of the research is underway.

The process of obtaining support for marketing research through MSI is clearly a dynamic one, as the case of the pricing competition shows. The researchers and MSI work together to find the overlap in their interests and to strengthen the research. Marketing practitioners from MSI member companies are involved as reviewers and research sponsors or data sources. And, the process benefits all those involved.

I'M HIP:
AN AUTOBIOGRAPHICAL ACCOUNT OF SOME MUSICAL CONSUMPTION EXPERIENCES

Morris B. Holbrook, Columbia University¹

A...lack of rapport was noted by Down Beat in connection with an attempt by Paul Desmond to buy a dacron blanket.

"I'm sorry sir," said the salesgirl, "We seem to be all out of dacron blankets. But wouldn't you like to look at this one?"

"No. I don't think so. I want dacron."

"But, sir, this one is down. It's real down."

"I'm hip," said Desmond. "But I still want dacron."

--Leonard Feather and Jack Tracy (1963),
Laughter from the Hip, New York:
Da Capo Press, pp. 152-153.

I'm hip; I'm no square;
I'm alert, I'm awake,
I'm aware....
Like dig: I'm in step;
When it was hip to be hep, I was hep

Omnisound Jazz

Music's my life,
And ev-'ry day I live it,
And it's a good life too

--Billy Preston,
"Music's My Life,"
Music Is My Life,
A & M Records

For most of my life, I have tried very hard to be hip. Growing up, I was never the smartest student at school, the best football player on the team, the most popular guy in the class, the most successful in winning student

¹I present this highly egocentric narrative in the spirit of Beth Hirschman's special ACR session and with the hope that it may encourage other consumer researchers to reflect systematically and deeply on their own consumption experiences. I take Beth's autobiographical account of her WASP roots as an example and proceed in the manner of W. T. Tucker's Foundations for a Theory of Consumer Behavior (1967), a work that probably deserves more attention than it has received. Anyone needing a rationale for this kind of storytelling should refer to Beth's recent JCR article on styles of consumer research and to Geraldine Fennell's session on phenomenology at last year's ACR conference (especially the paper by Wertz and Greenhut). Others may choose to regard this effort as one more tedious example of Morris being reprehensibly self-indulgent. Between these extremes, some may simply view my saga charitably as an attempt to convey something quite subjective about a little-studied consumption phenomenon--namely, the ethos of hipness. I thank Sandy, May, Kate, and Teenie; Helen and Tommy; Johnny and Steve; Howie, Kenny, and Stu; Peter and Susie; Sally and Chris; Bob; Paul and Zoey; Lila; and all the others...even Valerie, Barbara, and Dave. They know who they are and what they have meant to me. Finally, I gratefully acknowledge the financial support of the Columbia Business School's Faculty Research Fund. I hope they still would have given me the money had they known that I would spend it on jazz records.

elections, nor the biggest hit with the girls at the small female prep school down the street. But I had one consolation. Even if I wasn't better than my classmates at anything important, I was hipper than at least 99 percent of the other students at the Milwaukee Country Day School. I knew that just as surely as I know that vanilla tastes better than tutti-frutti.

Very early, I learned that the rules for being hip are actually quite simple. They follow a straightforward four-step procedure:

- (1) Find out what most people like
- (2) Treat that with complete indifference (or, when pressed, with scornful contempt)
- (3) Ferret out some obscure treasure admired by at most a few cognoscenti (or, if necessary, by some other group of weirdos)
- (4) Elevate that piece of obscurity to a lofty status of extravagant admiration and treat anyone who cannot appreciate it with pity (sometimes mixed with disdain)

In Milwaukee, Wisconsin--where Lawrence Welk and Liberace were born and raised, where weekday-afternoon radio consisted mostly of polka bands and Hawaiian guitars, and where the Braves were unanimously regarded as the town's greatest cultural achievement--being hip was easy. The four steps come naturally to someone inhabiting a city whose fame depends on the reputation of its leading brand of beer.

At home, things were different. Some of the earliest sounds that I can remember hearing were the tinkling notes of my father's piano as he played Teddy Wilson and Fats Waller arrangements of songs like "China Boy" and "Just a Girl that Men Forget," transcriptions he had painstakingly read and scrupulously committed to memory when he was probably still himself scarcely more than a young boy. On many evenings, I fell asleep with those sweet sounds ringing gently in my ears. Thus, I learned to love jazz at a very early age. I suppose you could say that, for a little kid, I was pretty hip.

I also remember my grandmother effortlessly sight-reading Chopin with her long delicate fingers skimming across the keys of her beautiful black ebony Steinway. And I recall Teenie, our beautiful black housekeeper, pouring out her soul in melodious spirituals as she glided through her housework. Everywhere, I was surrounded by graceful music. Soon I wanted to make some music of my own.

My dad, Sandy, taught me some simple one-finger tunes, but realized very soon that, for the sake of my development and his nerves, I needed some more professional instruction. So, at the age of six, I started into lessons with Helen, a friend of my parents who came from the old school of piano teaching. Helen awarded a gold star if you practiced faithfully and learned your lesson for that week, or a red star if you did not. She lived by the rule that three red stars meant termination. Thanks to gentle but constant prodding from my mother, I never received one of those dread stigmata, but even then I was hip enough to know that red stars belonged in Moscow, not Milwaukee. Later, much later, I learned the difference between extrinsic and intrinsic motivation and that musical activities properly belong in the latter category where even positive external rewards can exert disincentive effects. Meanwhile, Helen taught me to play a few

classical pieces, dragging me through such bleak exercises as Mozart's "Piano Sonata in C-Major." After four years, I could stumble through about three pages of its first movement, but the main lesson I learned from Helen was an abiding sense of what the experience curve means when it says that you need to double the number of trials in order to attain a 20 percent improvement in performance. This doubling and redoubling of effort grew increasingly tedious. Somewhere between the ten and twenty thousandth repetition, my spirit broke. Increasingly, in my frustration, I would lean forward and bite our piano. This noble Steinway still bears ancient teeth marks along its front edge. Realizing that this modus operandi was noticeably less than hip--with support from Sandy and May (who had doubtless grown tired of reminding me to practice)--I asked for a new instructor, someone a little closer to jazz.

By this route, I came to study with Tommy, Milwaukee's leading jazz musician and, purely and simply, the greatest teacher that I have ever known. Since then, I have attended various schools, studied under innumerable professors, and watched many academic colleagues, but I have never encountered Tommy's equal in communicating his vast knowledge and love of his subject matter. Tommy lived and breathed jazz. His students lived and breathed jazz with him.

Tommy started me on boogie-woogie versions of "St. Louis Blues" and "Basin Street," moved me into jazzier swing and show tunes like "Moonglow" and "A Foggy Day," and gradually began showing me chords, harmonic progressions, and the techniques of improvisation. His empathy, patience, and enthusiasm deeply conveyed his passion for music. They instilled in me a lasting faith in his credo: "If it sounds right, it is right." Tommy was the quintessence of hipness, the prototype. He approached the Platonic Form for Hip. Tommy sounded right. Tommy was right.

So, under Tommy's guidance, I marched to the tune of a different drummer, one with a rhythmically advanced sense of time. While everybody else was listening to Rosemary Clooney's "Come On-A My House," Patti Page's "How Much Is That Doggy In The Window," and Doris Day's "Che Sera Sera," I cultivated a devoted attachment to Sandy's collection of Benny Goodman records--precariously breakable 78's and scratchy old 33's that even he had largely forgotten about. I found exactly two other contemporaries, Johnny and Steve, who shared my worshipful fondness for singers like Bing Crosby, Ella Fitzgerald, or Louis Armstrong and for musicians like Lionel Hampton, Gene Krupa, or the King of Swing himself. Johnny and I memorized the Bing-and-Gary duets by singing them with each other for hours over the telephone. Steve and I played and replayed Goodman's 1938 Carnegie Hall Concert in amazed admiration for the intricacies of the wonderful trumpet solos by Harry James and Ziggy Elman. When the film of the Benny Goodman Story appeared, Steve and I were in ecstasy. I tried to learn to play the trumpet, but this task proved impossible for a young man with a horn, an entire mouthful of braces, and an orthodontist whose weekly machinations vividly presaged Sir Laurence Olivier's sadistic performance in The Marathon Man. (I still have my shiny Holton trumpet hanging in our bookcase--unused but not forgotten.) For a while, I even persuaded some of my friends to call me Ziggy. They cooperated but probably did not understand that it was my way of retaliating against society's devotion to Eddie Fisher and "Oh, My Papa."

The arrival of Elvis Presley gave me something new and much more formidable to detest. At this critical moment, Johnny left town to attend Deerfield. Steve--my confrere in vintage-1938 tastes--deserted me, bought a black leather jacket, grew ducktails, and practiced wildly gyrating dances on the tiptoes of his white sweat socks. Things got lonely. I was the only one in my eighth grade class who thought--no, knew!--that Elvis was terrible. Cherishing my adolescent musical iconoclasm like a rare diamond, I searched for a way to remain hip.

Two things saved me. The first involved my discovery of the cool school of West Coast jazz. Gerry Mulligan, Chet Baker, Paul Desmond, Stan Getz, and their cohorts brought me into an ethereal world of restrained, cerebral, progressive music that none of the other eighth graders knew, cared about, or could understand--even if they had been willing to listen to it, which they weren't. I was in orbit. I had found something wonderful that no one else liked. In fact, I had found something supremely beautiful that everyone else hated. I had reached the outer sphere of hipness where few ever tread.

My second salvation came from forming a band or what, in those days, we called a "combo." This combo consisted of Howie on guitar, Kenny on bass, Stu on drums, and me on piano. We learned tunes like "How High the Moon," "Pick Yourself Up," and "Jumpin' With Symphony Sid." In other words, we shunned anything remotely popular. Sometimes we played for parites or for dances, but mostly the combo just practiced by ourselves on Sunday afternoons that were long and arduous for us, as we fumbled and argued our way through incorrect chord changes and botched melody lines, and no doubt even longer and still more arduous for our bewildered parents. The other guys in the combo came from public school. I only saw them on weekends. The rest of the time, surrounded by preppy little eighth graders who showed an ironic fondness for Elvis and other hip-swinging hillbillies, I pursued my own splendid musical isolation. My classmates thought that "hip(s)" was a (plural) noun. I knew that, for me, it was a (singular) adjective. Sometimes, I felt a little outcast in my wayward tastes. But, if you let that sort of thing bother you, then you're not really very hip.

Then, in the first year of high school, Peter arrived. Pete came from across town where he had pursued a roughly parallel development of musical sensibilities. The major difference was that Pete had listened to a wider array of the new jazz than I had heard. Peter exposed me to Miles Davis, Sonny Rollins, and Horace Silver. I had to scramble to compete. I dug back into the recent past and came up with Charlie Parker, Thelonius Monk, and Dizzy Gillespie. Pete reciprocated with Art Pepper, Lee Konitz, Jimmy Giuffre, and Zoot Sims. I countered with Clifford Brown, Milt Jackson, Hampton Hawes, and the Modern Jazz Quartet. These were days of great growth in our evolving musical tastes. Even someone who is very hip needs a kindred spirit. Peter and I spurred each other on.

Once a week or whenever we could pry some allowance money from one of our parents, Pete and I traveled downtown to Radio Doctor's--our mecca--Milwaukee's best record dealer and the finest jazz outlet I would see until I reached New York and found places like Sam Goody's and King Karol or, later, J & R and Tower Records. These weekly pilgrimages to Radio Doctor's invariably produced some great discovery. After hours of sampling every new release in sight and driving the store's otherwise amiable owner nearly crazy, we would triumphantly make our purchase, climb back on the bus, and head for the turntable at my house. (Those recordings usually cost \$4.98. Today the same items, in reissues faithful to the originals, typically cost \$4.99. I can think of no other consumer product with as low a rate of inflation.) I began to think of record stores as my homes away from home. Years later, on the traumatic afternoon when John F. Kennedy was shot, I went straight to the nearest music shop and stood there for three hours, with my ears buried in headphones, listening to all the new jazz releases. Once again, the owner thought that I was very strange, but it made me feel better, like a visit home.

Of course, Peter and I alienated all of our classmates--after all, as I've said, that is part of the point of being hip. While everyone else in our high school was enjoying Harry Belafonte and the Kingston Trio, I entertained myself by writing editorials for the school newspaper, pointing out the inanity of lyrics such as "Banua. Banua,/Banua, Oh-Oh;/Banua, Banua,/Baby I don't know." During our last year at Country Day, Peter and I brought

some 45 r.p.m. jazz records to school and played them incessantly on the little phonograph in the senior room to the exasperated distraction of our fellow students. One day, while we were gone, Dave (captain of the football, hockey, and baseball teams) used our entire collection of cherished 45's as frisbees and sailed them, one by one, out the senior room window into the cool spring daylight. These gems, including one or two rare items like Oscar Peterson's unavailable recording of "The Golden Striker," were never recovered nor replaced. Dave's crime will forever live in infamy and serve as my touchstone for the apotheosis of Anti-Hip.

At graduation, partly because Pete wrote the descriptions, my school yearbook confirmed that I had achieved the status of "the class' leading nonconformist." But clouds had begun to form on the horizons of my hipness. First, I had spent part of the previous summer at the Lenox School of Jazz where some of my greatest idols (John Lewis, J.J. Johnson, George Russell, Gunther Schuller, and Milt Jackson, to name a few) had made it very clear to me that they did not exactly consider me ready for the Jazz Big Time. Needless to say, they were right. Most of those distinguished leaders in the field could not even find enough work to keep their own bands together. And they were musical geniuses! Certainly, that bitter economic reality did not augur well for me. I realized that eventually I would need some other profession.

Second, Ornette Coleman had burst onto the jazz scene, with his little white plastic alto sax, playing music that was too far advanced even for our studiously abstruse tastes. Listening to Ornette's honks and squeaks, Peter and I began to wonder if we would be hip to the jazz wave of the future.

Third, my self-proclaimed hipness had earned me acceptance at Harvard College. I have already confessed that I was not the most intelligent, popular, or athletic student at Country Day. But these were not the criteria of major importance to Harvard's admissions office. Harvard was looking for people who were hip. I was hip, so they took me. The only trouble was that they also admitted about 1,246 other freshmen, every one of whom was at least as hip as I was...or hipper. This staggering competition doubtless accounts for the miserably stressful pressure that I encountered in college. In the land of the blind, the man with one eye is king. In Milwaukee, the person who dug Charlie Parker was hip. I had spent my first eighteen years achieving a blissful degree of utter hipness in my own narrow little world. But, suddenly, I found myself in the midst of hipsters in every domain--music, art, literature, films--claiming interests so esoteric that they tapped levels of nonconformity whose existence I had scarcely suspected. Suddenly, surrounded by the Harvard intelligentsia, I felt positively square by comparison.

Surviving this threat to my unconventionality with my hipness intact proved difficult, but I did it. My *deus ex machina* was the Beatles. Everybody--the Yale men, the Princeton boys, and even the Harvard students--everybody loved the Beatles. It was impossible to dislike their insouciant blend of good spirits and hard-driving rock. Impossible, that is, for everyone but me. With total dedication and fierce perseverance, I managed to accomplish this unexampled feat. I practiced by playing myself Bill Evans and Jim Hall records through earphones while everyone else in the dormitory was blasting "I Want to Hold Your Hand" or "I Saw Her Standing There" at peak volumes on their portable stereos. I had triumphed. At last everyone at Harvard enjoyed something immensely popular that I could detest with self-righteous scorn.

This ploy sustained me through my difficult college years and brought me into the late 1960's to face the new traumas of Columbia University's MBA program, the rigors of life in New York City, the Vietnam War, and a draft board who simply did not understand that I was much too hip to serve in the Army. Through this pain, I was

sustained by Sally, my wonderful new bride, who served not only as a great comfort and shelter against world chaos, but also as a constantly reassuring model of pristine squareness. She hated jazz and loved the Beatles. I loathed the Beatles and adored Paul Desmond. We preserved this delicately balanced symbiosis throughout the terrifying years of the Johnson Administration. I sympathized with those involved in the Columbia sit-ins and riots. I admired the guts of the student protestors, even the ones who disrupted my academic training. They worked for peace. But except for attending a few peace marches and demonstrations in Central Park, I remained aloof. After all, Mark Rudd and the other student protestors were merely yippies and hippies. By contrast, I myself was hip.

Then something terrible happened. Jazz died--or at least it went into deep hibernation for a while. Peter, who had come to New York to earn his MA in English at Columbia and had then returned to Milwaukee to marry my next door neighbor Susie and to teach at Country Day, now moved with Susie to Dublin to write his Ph.D. dissertation on Wilkie Collins. Meanwhile, all our favorite jazz musicians entered semiretirement (Paul Desmond, Gerry Mulligan); went to jail (Art Pepper, Chet Baker); or moved to Europe (Art Farmer, Dexter Gordon). I was left with nothing to listen to, nobody to listen to it with, and a baby on the way.

The sudden total eclipse of jazz in my life, the consciousness raised by impending fatherhood, the agony of the Vietnam Era, and deep doubts about whether it was hip to pursue an MBA career produced two momentous consequences--first, a decision to enter Columbia's Ph.D. program in marketing and, second, an embarrassing regression in my musical tastes. I clung to what little security I could find, sought safety in numbers, and began listening to the Stones, the Who, Traffic, Cream, Simon and Garfunkel, Jefferson Airplane, and--yes--even the Beatles. Just before the Beatles broke up, I fell in love with Abbey Road and started working my way backwards through their oeuvre, buying all their recordings in the retrograde order and finishing with Meet the Beatles, the album that features "I Want to Hold Your Hand." When the rumor started that Paul was dead, I was as concerned as their most loyal fan. Soon the group itself had perished and I had to look elsewhere for musical sustenance. Thus does hipness founder when it crashes against the rocky shores of the Principle of Irony.

Christopher, weighing eight pounds and thirteen ounces and replete with adorable charm from the moment he was born, arrived to fill the breach. His delivery was three weeks late, but we finally induced labor by taking him in utero to a Procol Harum concert at the Filmore East and letting the ear-shattering, belly-thumping sounds of "Salty Dog" and "Whiter Shade of Pale" disturb his peaceful slumber in the womb. Suddenly, my world was filled with new life in the form of Christopher and countless rock groups and artists that were springing up like wildflowers: the Band, Joe Cocker, Cat Stevens, Blind Faith, James Taylor, Blood-Sweat-and-Tears, Van Morrison, Jackson Browne, and so on. Bob, an old classmate from Country Day, moved to New York, entered a partnership with Albert Grossman, and began managing rock stars like Dylan, the Band, Janis Joplin, Seatrain, Blood-Sweat-and-Tears, and Procol Harum. Sally and I were flooded with free lp's and concert tickets. Whenever we could find and afford baby-sitters, we went down to the Filmore. We heard everybody. Maybe it wasn't very hip, but at least it was fun.

I even learned to play a sort of watered-down version of rock on the piano. My fumbling efforts in this direction led to constant feuds with our downstairs neighbors, Valerie and Barbara, who were themselves struggling young musicians and who did not appreciate my musical assault on their folkly sensibilities. On the very afternoon that my new baby grand arrived, Valerie paid me a nasty visit within ten minutes after I started practicing. We endured many such unpleasant scenes, letters to the landlord from

both sides, poundings on their ceiling (our floor), and (once) the arrival of the police (whom I called in a brilliant stroke of oneupmanship). But, in spite of this harassment, I finally learned to play songs like "Ruby Tuesday," "Both Sides Now," and "Bridge Over Troubled Water" in a kind of compromise jazz-rock style.

For a while, I took this reawakened interest in performing into All Angels, the Episcopal church near where we lived. Paul and I showed up there at about the same time, filled with an urge to play some jazz-tinged rock or rock-tinged jazz and convinced that religious services provided an appropriate milieu for that activity. The easiest thing to find was piano players; so I learned to play the Fender bass and let Zoey handle the piano chores. Mac, a marketing professor at Columbia, played electronic keyboards in the band. I wrote countless jazz-rock arrangements of old Episcopal hymns like "Holy, Holy, Holy," "Praise to the Lord," and "Children of the Heavenly King." Moreover, I adopted the philosophy, which I still hold, that any music is suitable for church as long as it is played with the right religious feeling (a subtle variation on Tommy's old doctrine that if it sounds right, it is right). This credo worked well for tunes like "Let It Be" and "Morning Has Broken" (popularized by Cat Stevens and subsequently incorporated into the new Episcopal Hymnal), but it broke down when, on one inspired Sunday morning, I played "Ben" (Michael Jackson's theme music for the movie about a large rat) during Holy Communion. This song deals with the themes of friendship and loyalty and sounded right to me at the time. However, besides establishing my credentials as one of the first Michael Jackson fans, this experience (and many others like it) prompted increasing attempts by the clergy to control my selection of material. Angered, however unreasonably, I rationalized that I was too hip for organized religion.

I turned instead to psychotherapy. In five years of Freudian analysis (four times a week on the couch), Lila listened in about equal proportions to stories about (1) my musical adventures, (2) my trials in the Ph.D. program and tribulations in beginning my first teaching job at Columbia, and (3) the rest of my many problems and interests. Needless to say, thanks to the first of these content areas, Lila has become the hippest psychoanalyst in New York. She has witnessed endless attempts to unravel the mystery of the tingle that starts at the base of my spine and charges upward into goosebumps on the back of my neck. For example, I spent months on the couch trying to figure out why Ray Charles moves me so deeply, deciding that it has something to do with Teenie and those spirituals I heard as a child, but concluding that these revelations only begin to scratch the surface. Similar, still-unresolved questions surround my responses to Paul Desmond, Art Pepper, Bill Evans, and Hampton Hawes. The closest I ever came to understanding my rapturous reactions to Milt Jackson was the analogy that, for me, he does on the vibraphone what Earl Monroe did on the basketball court. As they used to say, Earl the Pearl was a magician--so loose and free, yet deadly accurate. Finally, after such speculations had run rampant for two or three years, Lila pointed out to me that, if I ever wanted to finish psychotherapy, I had better move on to other matters.

Though Lila (like a true Freudian) seldom spoke, a few of her rare and incredibly perceptive comments changed my life forever. One day, after listening to about forty minutes of diatribe on my agonies concerning a particularly difficult and unrewarding piece of marketing research, she innocently asked why I did not do more work like the project for a jazz radio station (WRVR) that I was enjoying so much. I decided that she was right and extrapolated her comment to cover most of my research activities. As my guiding principle, I adopted the goal of getting the names of my favorite singers and musicians into the major journals. Thus did Roberta Flack and Ray Charles soon find their ways, respectively, into the Journal of Consumer Research (1977) and the Journal of Applied Psychology (1978). Encouraged by this initial

success, I have continued to seek homes for my musical heroes in the various publications related to the field of consumer research.

Thanks to Lila, jazz reentered my life in a big way. Along with other aspects of my youth, I began reexamining my musical roots and learned that they were stronger than my branches into church music and rock 'n' roll. Moreover, many of my long-lost jazz idols had awakened from their slumbers and were returning to the recording studios. Recordings by Desmond, Evans, Hawes, Mulligan, Baker, Farmer, Pepper, Sims, and others--sometimes with the masters playing rock tunes as in Desmond's Bridge Over Troubled Water or Baker's Blood, Chet, and Tears--flooded onto the market. I began writing guest reviews for a short-lived jazz publication called Different Drummer. These reviews paid a mere \$4.00 apiece, barely enough to cover the purchase price of the recording, but somehow their appearance in print always cheered me up as a token of my reemerging jazz consciousness. A typical example was my review of Oscar Peterson's Great Connection (MPS MC 21281):

Most of Oscar Peterson's more successful albums recently have been collaborations with other gifted and forceful soloists such as Herb Ellis (MPS), Milt Jackson (MPS), or Joe Pass (Pablo). Somehow, when Oscar sinks comfortably into the cozy familiarity of the conventional piano-bass-drums trio, he seems to lose the urge to experiment with new ideas and begins to wallow in predictability. Indeed, there is a joke circulating that, on such occasions, you can recognize Peterson's virtuosity chiefly by the way he plays the same clichés over and over without making a mistake. The present disc documents this less interesting facet of Peterson's pianistic personality. We are offered routine run-throughs of old chestnuts like "Younger Than Springtime," "Soft Winds," "Just Squeeze Me," and "On the Trail."

Aside from bassist Pedersen's heroic comping and finger-bruising solos, the most captivating moments on the disc occur in Peterson's intriguingly lugubrious reading of "Smile." Elsewhere, Oscar simply reaffirms his supreme technical command over the keyboard. And that's not exactly faint praise.

Meanwhile, my old friend Peter had abandoned Wilkie Collins, moved to London, written Ghost Story, and earned so much money that the British tax system compelled his return to the U.S. He arrived in New York full of ideas about new people worth hearing (Scott Hamilton, Warren Vaché) and old people worth rehearing (Billie Holiday, Lester Young). As always, his instincts were infallibly right. I spent days pawing through second-hand record bins in search of Holiday and Young recordings I had been too ignorant to buy when I was a child and they had been easy to find. Tantalized and encouraged by these events, I entered a new period of hipness from which I hope never to recover, as hipness ripens into eccentricity.

But another force had also emerged on my musical scene: Christopher. Somehow, amidst all these other happenings, Chris has reached the age of 16 years, has learned to play Mozart and Bach like an angel, has stubbornly repudiated jazz, and has built a passionate devotion to rock. Moreover, he has developed the strong conviction that he is a lot hipper than his old man. Can I passively withstand this new questioning of my hipness? Of course not.

So I have tried to catch up by listening to Christopher's favorite recordings of U2, The Smiths, the Minutemen, Talking Heads, and Killing Joke. What generally greets my ears when I play the albums Chris lends me is somewhere between a wailing screech and a screeching wail. Synthesizers appear to have banished real musical instruments, and vocal noises seem to have replaced language. I hate this music instinctively. Listening to it is nearly torture. But I must force myself to do it. I must keep up

with the times. After all, I'm hip, and I need a constantly replenished supply of popular music that I can hate.

Occasionally, however, Chris finds something about which we can enjoy a meeting of the minds. The recent videotape of "We Are the World" (reputed to be the largest-selling single recording of all time) served as a spectacular case in point. Chris can justifiably proclaim the virtues of heartfelt performances by Michael Jackson and Bruce Springsteen. We can both agree on the merits of Stevie Wonder's impassioned outpouring and Cyndi Lauper's two seconds of pure brilliance. And I can have the satisfaction of insisting that the whole production should be interpreted not only in light of its worthwhile social cause, but also as a crowning tribute to the work and spirit of Ray Charles. The entire piece builds ineluctably toward his style and reaches its culmination in his melismatic embellishments of the refrain.

Before concluding, I feel I should recount what has happened to the characters in my egocentric little saga. My grandmother has passed away; her magnificent ebony Steinway now sits unused and gathers dust. Teenie has moved back home to Tuskegee, Alabama. I still sometimes hear Sandy play the old Wilson and Waller arrangements that May and I will always cherish. Helen has mercifully given up teaching by the star system, and Tommy has retired and moved to the Wisconsin Dells, where he remains prototypically hip. Johnny has returned to Milwaukee and lived for a while in my grandfather's old house; but he doesn't listen much to Bing Crosby any more. Steve teaches aviation at the University of Illinois; I doubt that he remembers Ziggy's solo on "And the Angels Sing." Kenny the bassist went into medicine, I believe, and Stu the drummer wound up in LA with no forwarding address. Howie the guitarist came to New York, changed his name to Hod, worked as a musician, and even made some recordings with his own groups, but died tragically in an automobile accident after moving out to California. By a strange turn of coincidence, Hod's younger brother, Michael, now serves on the policy board for the Journal of Consumer Research. Peter's novels, always cluttered with the names of jazz musicians, have reached fabulous success. In Shadowland, he provided the ultimate description of life at Country Day circa 1960 and even included a flattering but fictional account of my own struggling efforts as a jazz pianist:

Morris, standing on the side of the room with the other members of his trio, looked crippled with stage fright.... The three of them filed up the stairs to the stage. Brown picked up his bass, Morris said, "One...one...one...one," and they began playing "Somebody Loves Me." It sounded like sunlight and gold and fast mountain springs, and I switched off everything else and just listened to the music.... During Morris' last number I heard...him insert a quote from "Hail, Hail, the Gang's All Here" into his solo.... He was having, under trying circumstances, the best time he could, which is one definition of heroism (pp. 115-116).

Peter and Susie have moved back to New York permanently and, to my joy, have once again become our near neighbors. They now number many great jazz musicians among their friends and lend these artists their unstinting support. Dave reappeared as my classmate in Columbia's MBA program and has since moved to Connecticut where he now works for a headhunting agency. Ornette, who still specializes in honks and squeaks, showed up in my office one day wanting to know how to reach a wider audience. I told him I didn't think someone as hip as he could do that. The Modern Jazz Quartet--perhaps after being as mean to each other as they had been to me--broke up but have since regrouped and play as miraculously as ever. Harvard still stands on the banks of the Charles, and a recent directory of my classmates confirms their continued hipness; almost all of them are teachers. Sally, still very precious to me after 20 years, continues to hate jazz; we have finally

reached a compromise in our mutual fondness for Bach and black gospel music played at peak volume on the car stereo. Bob left rock management and went into investing in other types of commercial properties; he also manages Peter. Valerie and Barbara still live in the same building and probably still infuriate their new neighbors in our old apartment. Paul and Zoey remain active in church music; both have learned to fit themselves into the liturgy better than I ever could; Mac has become a dean. Lila still practices psychoanalysis in New York and, in fact, now sees one of the other characters in my story; I remain grateful to her insights and for the suggestion that resulted in my populating some of the journals with the names of my favorite singers and musicians. Christopher continues as a source of joy in our lives; I marvel at his ability to absorb Bach and Mozart while simultaneously admiring U2 and The Smiths.

For the past few years, Chris and I have made Christmas tapes containing some samples of our playing and distributed to a few long-suffering friends. Typically, Chris plays some of his classical repertoire. I rattle through a few dimly remembered jazz pieces and end with a reworking of some old Episcopal hymn. The words to one of these hymns remind me of the place for music in my life. Literally, they refer to the eternity and everlasting nature of God Himself. But, for me, they also convey something of the power of music to last forever. Like other artistic forms, music in general and jazz in particular are ultimate consumer durables. They endure from year to year and from generation to generation. They are spiritual and nearly godlike in their permanence:

Abide with me: fast falls the eventide;
The darkness deepens; Lord, with me abide:
When other helpers fail and comforts flee,
O thou who changest not, abide with me.

--William H. Monk (1861),
"Abide With Me,"
Hymn Number 467,
1940 Hymnal

DEEP-SEATED MATERIALISM:
THE CASE OF LEVI'S 501 JEANS¹

Michael R. Solomon, New York University

Abstract

A small number of products possess extraordinary symbolic significance to consumers; they are an integral part of popular culture. This paper is a case-study of one such product, Levi's 501 jeans. Quantitative and qualitative data from a variety of sources is employed to examine the social functions performed by this icon of material culture. Functions discussed include social reassurance, consumer personalization, attributions of "magical" qualities, mnemonic capabilities, and ceremonial rites.

Introduction

One way to view products is as material artifacts of social life (Solomon 1983). The use of products as vessels to define and enact social relationships, aspirations, fantasies, and so on leads us away from the emphasis on the products bought by society and toward an emphasis on the products valued by society (cf. Belk 1984a). Consumers form deep and complex attachments to some products; such phenomena deserve greater attention by consumer researchers and other social scientists.

In this spirit, the present paper is a case study of a product which is a cultural icon. A select number of products are such an integral part of contemporary culture that they attain an almost archetypal status. At the least, consumers' allegiance to these material artifacts certainly transcends conventional wisdom regarding brand loyalty or the product life cycle. A list of such products would probably include the Ford Mustang, "Star Wars," the Hershey Bar, Elvis Presley, Marlboro cigarettes, and Coca-Cola (the old version). The recent outcry over the changing of the Coke formula by loyal consumers attests to the "special" place such products occupy in our social system.

In the apparel category, Levi's 501 jeans occupy a dominant (and almost mythical) position in American material culture. The jeans are worn by a cross-section of society, and while it is tempting to regard the product as just another fashion item, its endurance as a staple for over 130 years belies the common vicissitudes of fashion. The unique stature of Levi's as a cultural emblem becomes apparent when one considers that this product is represented in the Americana collection of the Smithsonian Institution, and that the name "Levi's" is included as an entry in Webster's Collegiate Dictionary.

This paper will begin to explore the relationship between Levi's 501 jeans and their wearers. It will focus upon the iconic functions played by the jeans via an examination of several sources of data. These sources include a national telephone survey of 501 owners, an archival examination of letters written to the company by consumers over the last thirty years, information supplied by the company, and data on company performance. Examination of subject verbatims, aggregate responses, letters, etc. will be combined to examine some social and intrapersonal benefits ascribed to the product by consumers.

The intent of this short paper is not to provide a complete history of the product, nor a satisfactory explanation for its popularity. Instead, it is an initial attempt to profile an example of a relationship between consumers and a product which cannot be fully explained by a logical positivist approach to consumption. Despite

its subjectivity, this attachment and kindred phenomena deserve a place in the realm of consumer research.

Company Background

Levi Strauss & Co., based in San Francisco, is the world's largest branded apparel manufacturer. Its motto is "Quality never goes out of style." According to the annual report, net income in 1984 was \$41.4 million on sales of \$2.5 billion. As of the end of 1984, the company employed 37,000 people in over 100 manufacturing and distribution centers.

Product lines are sold in more than 40,000 retail outlets in the U.S. and in over 70 foreign countries. The company spent \$153 million on advertising in 1984; much of this expenditure was associated with sponsorship of the Olympics (the entire 750-member U.S. team was provided with Levi's outfits). The New York Times (7/19/84) estimates Levi's market share at 21%. Its closest competitor is Lee, which holds 12% of the denim jean market.

The company notes that last year's net income fell to its lowest level since 1974. This decline was attributed to such factors as a shift in taste away from basic jeans and toward fashion jeans, weak foreign currencies, expanded production capacity coupled with a flattened jeans market, and strained relationships with some retailers.

Many of the company's problems can be attributed to shifts in clothing symbolism desired by consumers. The major manufacturers, encouraged by a boom beginning in 1981 (and spurred by the release of the movie "Urban Cowboy"), increased production and became complacent about a market which would become flat in later years (The New York Times, 7/19/84). The overall sluggishness of this market is often attributed to the maturing of the baby boom generation. According to industry sources, consumers over 24 tend to buy fewer jeans, and to wear them longer. As will be seen, the extraordinary longevity of Levi's is a mixed blessing for the company.

Despite attempts to diversify product offerings (e.g., a new line designed by Perry Ellis), the original 501 line is still the strongest performer. This is the "basic" blue jean, which is distinguished by a number of features, including the shrink-to-fit fabric which is guaranteed to shrink, wrinkle and fade, the button fly, a waistband patch, the red tab on the right-hand back pocket, and a watch pocket.

The company at some level seems to grasp that its competitive advantage lies in consumer loyalty to its core product --as evidenced by its frequent use of the copy point "We put a little blue jean in everything we make." Levi's 501's continue to be the best-selling jeans in the world, according to the 1984 annual report. In an effort to expand the popularity of this style east of the Mississippi, the company in 1984 launched a \$36 million advertising campaign, which it claims is the largest program ever undertaken on behalf of a single apparel product. The annual report states that unit sales of 501 jeans were up almost 20 percent from the previous year.

Product Background: The 501 Blues

The product was invented by Levi Strauss (1829-1902), an Austrian immigrant who peddled dry goods to prospectors in California during the gold rush. He originally intended to sell rolls of canvas for tents and wagon covers, but realized that the material he had brought with him from New York might serve a better purpose. Strauss seemed to

¹The author would like to thank Levi Strauss & Co. for its cooperation in the preparation of this paper.

exhibit a real marketing orientation, as he responded to the complaints of miners that they could not find pants which would last. The first pants he sold were tailored from heavyweight brown canvas, and they were assigned lot number 501. Strauss switched during the 1850's to a tough cotton fabric made in Nimes, France called "serge de Nimes," which Americans soon came to pronounce as "denim." The term "jeans" originated with the French as well, who identified sailors from Genoa by their heavy cotton pants. These pants were called "genes," a derivation of the French word for Genoa.

Product evolution. Over the years, the pants acquired such distinguishing trademarks as copper rivets, a leather patch depicting two horses struggling to pull the pants apart, and a stitched pattern on the back pockets. This pattern, according to company literature, has been in use longer than any other American apparel trademark. The copper rivets on the back pockets were later replaced due to complaints about the scratching of school desks, saddles, and automobile paint. In the late 1930's, the rivet in the crotch was removed when the president of the company crouched too close to a campfire and the flames heated the rivet to the point of discomfort.

Product diffusion. The jeans remained a purely Western phenomenon until the late 1930's, where cowboys would keep one pair for work and one pair for dress. The onset of the Depression prompted many ranchers to entertain Eastern "dudes" to produce extra income. These vacationers bought the jeans to emulate Western chic, and then co-opted the style by bringing the pants home (perhaps as an ostentatious symbol of ability to travel during the Depression).

During World War II, the production of 501 jeans was declared an essential industry, and only those engaged in defense work were permitted to purchase them. The back stitching was, however declared to be an unnecessary use of thread by the War Production Board. The company substituted orange paint, which led to some concern by consumers that they were receiving counterfeit jeans.

After the war, the company shifted its marketing efforts to a younger segment. The product's symbolic status was transformed by its identification with James Dean, whose moodiness and independence bordering on rebellion captivated many members of this generation.

The company has at times attempted to encourage this association, as evidenced by the successful advertising campaign centered around the mysterious "Travis" and based on a still from the movie "Giant." Nonconformist values were also catalyzed by Marlon Brando, who appeared in the 1954 film "The Wild Ones" with the symbolic entourage of leather jacket, motorcycle, and Levi's 501 jeans.

The independence associated with the jeans was carried over into the politicized era of the 1960's. The pants were intimately associated with the youth culture of that time. An emphasis on the core value of individuality was abetted by the numerous personalizing operations performed on the jeans. Many permutations of tie-dyeing, stitching and patchwork proliferated, with many consumers using Levi's 501's as a common symbolic canvas.

This overlaying of meaning is consistent with Belk's (1984b) observation that symbolism is often added to a product after its purchase. A possible irony here is that this trend toward the embellishment of pants as a form of status display laid the foundation for the popularity of signature goods and other forms of elaborately-detailed designer jeans, which until recently posed a major threat to the basic Levi's.

Product benefits. The set of objective product benefits associated with Levi's 501's may help to explain the psychic benefits which account for their popularity, longevity, and consumer loyalty. The company stresses that 1) the design has virtually remained unchanged for well over a century; 2) the pants shrink-to-fit, which

allows consumers to create their own personal fit; and 3) the fabric softens and becomes increasingly comfortable with each washing. These proclaimed benefits can be used to infer a set of higher-level benefits: The product offers 1) the reassurance of tradition, 2) the capacity for personalization, and 3) it appreciates in (psychic) value as it ages.

These three benefits are the opposite of many contemporary fashion products, which are characterized by novelty, social acceptance, and inevitable obsolescence. In this sense, the jeans may be thought of as "anti-fashion" and these properties may begin to explain the unique attachment of many consumers to them over the years.

Some Social Functions of Levi's 501's: Bases of Attachment

Instrumentality

Confidence. The function of clothing and other expressive products as facilitators of social role-playing has been discussed elsewhere (e.g., Solomon 1983; Solomon and Anand 1985). According to this perspective, product symbolism is used by consumers to place themselves in the correct role and thus retrieve the script appropriate to that role. Unimpeded access to this script results in confidence regarding one's ability to play the role; inappropriate or absent symbolism impedes role performance.

Various disciplines and perspectives have acknowledged the role of material objects in creating or reinforcing security. For example, object-relations theorists in clinical psychology feel that attachment to objects stems from their use as compensation for separation from a mother figure (e.g., Fairbairn 1954). Developmental psychologists have found that the soft, comfortable aspects of a security blanket or article of clothing are the most effective means of reinforcing a sense of security and play a role in identity formation (e.g., Belk 1984b; Weisberg and Russell 1971). Similarly, Furby (1978) notes that control is the main reward quality of objects. Attachment makes salient the role of possessor, which enhances self-confidence. In a recent phone survey of 200 Levi's 501's owners, 10% of the males and 23% of the females used the word "confident" when asked to describe how they felt when wearing the pants. The reliance on the products as a social prop is highlighted by some examples of individual responses to the question: "How do you feel when you wear your Levi's 501's jeans?":

*"Like I don't have to worry about what I'm wearing." (#2017)

*"You don't feel like an outsider." (#2076)

*"I usually feel like I'm 'with-it'...I look as good as any chick there...I feel confident." (#1052)

*"I feel comfortable, self-confident and composed... Like a second skin...I feel that I don't have to be aware of how I look. I don't have to be self-conscious because I know I look good." (#2020)

Magic. While many consumers value this product for the social rewards it offers, for some the attachment seems to go beyond the realm of rational product benefits. Both socially and functionally, some consumers seem to value the "magical" qualities of the jeans. One respondent in the survey noted that she felt like she "...could do anything in them" (#2022), while another (perhaps influenced by the James Dean mythos) attributed life-like qualities to the pants: "They are confident because they walk like they are confident" (#1015).

The jeans also seem to be valued for their (literally) life-saving properties. A survey participant, when asked about any important experiences he had had when wearing the product, replied:

One time I had a horse and I jumped off and got caught in some wire and if I hadn't been wearing Levi's I would have been ripped to pieces. (#1024)

Examination of unsolicited letters which have been written to the company over the years revealed similar stories. There are numerous testimonials to the product's strength, which has reportedly saved people from a variety of serious injuries resulting from accidents in traffic, on construction sites, and even one account of a consumer wearing the jeans for months in a prisoner-of-war camp with no appreciable damage. The following account is representative of this experience:

I was working on a 52 story bank building...and a crane hook caught me in underneath my pocket and the crane swung me out in open air which [sic] I thought I was gone but the hook had me caught so that the Levi's didn't rip until another man brought me back to the side...I wanted to tell you in plains [sic] words that I'll buy when I can your Levi's...Levi's save [sic] my life so I pass it around they are getting their money's worth when they buy Levi's...."

M.H.
Fort Worth, TX
February 1, 1965

Personalization

Interviews with wearers emphasize the role adaptability of the product; they can be worn in a wide variety of situations, with a wide range of other clothing styles, and by a cross-section of subcultures. In this regard, the jeans may be seen as highly individuating. They do not force the wearer to conform to a specific life-style statement, but rather may be molded to the whims of the wearer. Compared to other, more role-specific clothing, they can accompany the wearer in a broader range of role performances. One survey respondent noted, "They feel like part of me -- I'm bare without them" (#1004). Consumers, in a sense, do not have to put on airs when wearing the jeans; the jeans form a sartorial blueprint of the individual instead. As another purchaser noted, "I feel like I can relax. I don't have to be stiff and proper" (#3050).

Mnemonic value. This individuation appears to prompt some 501's owners to regard the jeans as companions, and to value them because they accompanied the wearer during cherished or stressful life experiences. In one study of people's reasons for cherishing objects, 15% of the subjects interviewed reported that such objects embodied past memories (Csikszentmihalyi and Rochberg-Halton 1981). Objects which are retained for long periods of time thus provide a record for the continuity of the self. The value of such products may lie in their ability to modulate arousal during times of social stress. In other contexts, it has been argued that an overstimulated organism values familiar objects (cf. Mehrabian 1976). In the Levi's survey, one respondent observed that "...they be [sic] a good friend...always with me, know me pretty much, like your best friend" (#2076).

Approximately 25% of respondents in the phone survey did in fact associate special memories with their 501 jeans. The majority of these memories were related to romantic encounters. The following are some representative examples of the memories elicited:

- *"The first time I went out with the guy I'm still with" (#1010)
- *"I went to a bar, met my spouse, we got married..." (#2079)
- *"I asked my wife to marry me in 501 jeans" (#2069)
- *"...first time I got laid" (#2075)

*"I got married in them" (#1033)

*"I wore them on my wedding night" (#1020)

Continuity

It seems clear that a significant component of the Levi's phenomenon is the longevity of the product. This attribute poses a bit of a quandary for the company, in that it is somewhat problematic to simultaneously promote staying power and to remind consumers about the desirability of repeat purchase. Unlike most fashion items which (by definition) lose their appeal when they lose their novelty, 501's go through a seasoning process whereby their meaning and value increases with the passage of time. This value seems to endure even after the product has deteriorated; its "essence" is often retained in the form of cut-offs, scraps in a quilt, and so on. Like a trusted horse or sword, the jeans seem to prove themselves on the social battlefield. In the telephone survey of Levi's owners, for example, 35% of respondents said that their oldest pair of 501's were more than two years old, 13% said that they were more than 4 years old, and 4% owned the same pair for more than six years.

The tendency to hold on to the pants is also supported by an examination of letters written to the company. Some excerpts from this (admittedly biased) sample should suffice to make the point:

*"Would you believe a 21-year-old pair of Levis?" (A.M., Cos Cob, CT, 9/18/74)

*"I graduated from high school in May of 1955, and at that time received two pair of Levi jeans. My purpose in writing to you is to inform you that I am still wearing one pair of those jeans..." (R.H.H., Phoenix, Az, 2/25/81)

*"I just wanted you to know after laundering your Levi's for 43 years my husband's Levi jeans still pair up with him for fishing trips, and hang lovingly in the garage --although a little fishy smelling." (G.S., Aptos, Ca, 2/11/81)

*"In October of 1939, my new husband bought a pair of your Levi jeans. He died this last February. After all these years, those jeans are still in very good condition." (R.A.B., Toledo, Oh, 8/15/83)

*"On my first trip to California, while learning engineering on the old ship Madison in the winter of 1913...I bought two pair... of a very heavy blue jeans called Levi's....In spite of all the hard wear, grease and our practice of washing them in lye and steam from the ship's boilers, mine are still good right in 1960. I am sending one pair to you that you may see for yourself. The other will take care of me." (T.R.E., Ophelia, Va, 5/15/60)

Ceremonial rites. Although the examples above are certainly extraordinary, they do hint at the product's staying power. Consumers do more than just hold onto the pants, however. There seem to be at least three distinct ceremonial rites associated with 501's. First, there is the "breaking-in" process, where the consumer repeatedly washes the jeans until they soften and conform to his or her body. This rite resembles those practiced in some other cultures where the self and an object undergo a literal incorporation, such as the practice of licking new possessions or shedding one's blood on them (cf. Beaglehole 1932). It is interesting to note that consumers' desire for aged jeans has spawned an ancillary industry; some companies now sell pre-faded jeans and others sell a detergent additive to "break-in" new jeans.

Second, the jeans seem to take on the status of an heirloom for many consumers. That is, there is a tendency to "hand down" the jeans to one's children. The worn jeans, imbued with memories and experience, seem to provide a

link between generations-- a comforting sense of continuity not provided by many contemporary products designed for everyday rather than ornamental use. The following letter exemplifies this function:

When I was 14 years old, my brother-in-law gave me an old pair of his jeans....The next summer I was in a serious automobile accident and my mom almost threw away my "favorites," thinking they would bring back bad memories. I remember being quite upset about it, and I wasn't happy 'til they were saved and I had them on again.

...Many years went by...and then I married a man with four children...His 12-year-old son wanted to swim in the river...and he needed some shorts. I got out the old reliables and they fit ---...I lost them permanently to him...

The long and the short of it is, those old jeans are Levi's. As nearly as I can determine, they are at least 20 years old...

I watch my boy, and realize that he is the third generation enjoying those Levi's, and I thought you might like to know what fans we are of your product!... (L.W., Chehalis, Wa, 7/1/83)

The third phase is burial. According to the company, there have been a number of instances where a pair of tattered 501's arrive in the mail with a note attached requesting a proper burial. These occurrences illustrate the anthropomorphic attachment generated by a simple product which costs less than \$25, yet which occupies a privileged position in the American psyche.

Conclusions

The preceding discussion is an attempt to highlight by way of example the richness of relationships that consumers form to significant others, even if those "others" are inanimate objects. Some products are deeply engrained in the cultural psyche, and have meaning far beyond that unearthed by concept tests, conjoint analyses, and so on. To better understand such complex relationships, it is necessary to be open to nontraditional forms of inquiry and explanation.

The case study method is one way to approach this issue. It, too, has its problems. It is difficult to rule out alternative explanations, and the researcher must be sensitive to the bias inherent in selecting consumer protocols, etc. Also, this technique treats as legitimate information supplied by the symbol's creator (in this case, the company) or other interested parties -- such sources must always be viewed with some skepticism. This bias highlights the desirability of collecting data from a number of different sources.

Regardless of the problems with this approach, consumer researchers must come to appreciate the special stature of products which are cultural icons. Their effects on consumers can be significant. Levi's 501's are one example of a basic and inexpensive product which is nonetheless the object of considerable attachment by many consumers.

By virtue of its physical properties and the mythology which has come to surround it, the product is used by consumers to perform many social functions, some of which almost resemble those normally performed by other people. The intensity and nature of the bonds formed between consumers and product icons is certainly worthy of further exploration, as a final letter to Levi's indicates:

I...just wanted you to know how my family feels about Levi Strauss. My husband has worn absolutely nothing but Levi's jeans for 35 years.

All he ever asks for, for Christmas and Father's Day...are Levi's. This year I thought I would surprise him and take some of his old and too small Levi's and put them into a quilt, so not only can he wear them all day, but he can sleep with them at night. I guess he would say, "Next to Levi's, I love my wife the best." (K.K., Cincinnati, Oh, 6/21/82)

SOME ISSUES SURROUNDING RESEARCH ON THE EFFECTS
OF "FEELING ADVERTISEMENTS"

Andrew A. Mitchell, University of Toronto

Abstract

It is argued that our current models of advertising effects are inadequate for explaining the effect of 'feeling' advertisements. A number of theoretical issues concerning affective states are discussed as well as a number of issues concerning alternative hypotheses of how 'feeling' advertisements may work and possible boundary conditions on their effects.

Introduction

There has been increased interest recently in understanding the role of emotion, feelings and affect on human behaviour in both psychology (e.g. Bower 1981; Zajonc 1980) and consumer behaviour (e.g. Holbrook 1985; Kassarian 1985). To some extent, this increased interest may be viewed as a reaction against strict information processing models which implicitly (or explicitly) view human behaviour to be largely based on the processing and interpretation of verbal information. Humans, however, also experience various affective states such as happiness and sorrow, so these states would also seem to comprise a critical element of human behaviour. Unfortunately, there is no general consensus as to the functional role of these affective states. Simon (1967), for instance, has argued that emotions should be regarded as an interrupt in the human information processing system, while others have argued that affective states directly affect the processing of information (e.g. Bower 1981; Isen 1984). Others view affective states as a behavioural homeostatic process as well as a fundamental signaling system (e.g. Plutchik 1984).

In studying affective states, there are two distinctly different approaches that may be taken. First, affective states may be treated as a phenomenon in and of itself. Research using this approach is directed at developing a taxonomy or categorization of different affective states (e.g. Tomkins 1982) or at understanding what variables cause the various affective states to be evoked (e.g., Weiner 1982; Roseman 1983). In this latter case, affective states are treated as a dependent variable. Alternatively, research may be directed at understanding the effect of affective states on some other human activity. For instance, does an individual's affective state effect decision making? Under this approach affective states are treated as an independent variable.

In this paper, we will primarily be concerned with the second approach. More specifically, we will be concerned with the effect of affective states within an advertising context. However, as we will argue in this paper, we will need to have some theoretical understanding of affective states in order to understand their possible effects. Finally, in this paper the term affective state will be used in a generic sense to include all emotional and feeling states. Mood specifically will be viewed as a less intense form of emotion (e.g. Isen 1984).

The issue of how affective states within an advertising context may affect consumer behaviour seems to be an important one since we are faced with a basic contradiction. Most of our current theories of how advertising works are strict information processing models. In these models, consumers must make either verbal responses to advertisements (support arguments) or acquire knowledge about the advertised brand in order to change attitudes which, in turn, are viewed as the primary (only) mediator of behaviour. On the other hand, a very large proportion of the advertisements that appear on television and in magazines contain little product attribute information. Many seem to be designed simply to create an emotional reaction in

the consumer. Following Zielski (1982), we will call these 'feeling' advertisements. In doing so, we wish to differentiate them from advertisements which contain emotional appeals. The effects of these latter types of advertisements presumably can be explained with our current models.

In order to explain the effect of 'feeling' advertisements with our current models, we have to either (1) assume that individuals make considerable verbal responses to these types of advertisements, or (2) assume that these advertisements don't have any affect on consumer behaviour. Alternatively, we can recognize that our current models do not adequately explain the effects of these types of advertisements. At this particular point in time, this latter alternative seems to be the most appropriate since there is both anecdotal evidence that 'feeling' advertising campaigns may increase sales and evidence from laboratory research that the affective states of individuals have an affect on attitude formation in an advertising context. Consequently, the first and second assumptions do not seem to be tenable.

Theoretical Issues

Research on moods and emotions and theories of emotions remains a rather murky area in psychology, both conceptually and in terms of empirical results. The purpose of this section is to briefly review some theoretical issues concerning affective states and some critical empirical results that are the most relevant with respect to developing a model that will explain the effects of 'feeling' advertisements. This review is not meant to examine all the critical conceptual issues surrounding emotion nor to necessarily cover all the various theories of emotion. In this discussion, we will focus primarily on theories and research that attempt to integrate emotion and mood into our current understanding of the human information processing system. Since we have good understanding of this system, it would seem the most fruitful to understand how moods and emotions may affect this system instead of attempting to develop a new model of how 'feeling' advertising may work. In addition, we will only be concerned with how 'feeling' advertisements may work given exposure to the advertisement. It should be noted, however, that other researchers have suggested that consumers may be more likely to attend to these types of advertisements (e.g. Ray and Batra 1983).

The first issue that will be discussed and certainly one of the most critical concerns the conceptualization and measurement of emotion. At least some of the confusion surrounding emotions occurs because it has been measured in many different ways. For instance, emotional states have been measured by using facial expressions (e.g. Ekman 1984), specific behaviours (e.g. Schachter and Singer 1962) and physiological measures (e.g. Lazarus et al. 1965).

Most emotion theorists agree that an emotion has four different elements: (a) subjective feelings, (b) physiological arousal, (c) expressive behaviour (e.g. facial expression) and (d) a behavioural response (e.g. shouting at someone). Following Plutchik (1982), we would like to conceptualize emotion as a hypothetical construct and the different elements as possible measures of the hypothetical construct. Since it is well known that individuals can mask their true emotional state with their expressive behaviour and their behavioural response, and may not correctly report their subjective feelings, measures of affective states based on these three elements will probably contain measurement error and may, in some cases, be biased.

There are also problems with physiological measures. First, cognitive-arousal theories of emotion (e.g. Mandler 1975, 1982; Schachter and Singer 1967) indicate that physiological arousal is a necessary, but not a sufficient condition for someone to be in an affective state. In other words, someone may be in a state of physiological arousal, but not in an emotional state. Second, the empirical evidence indicates that the relationship between physiological arousal and emotion does not appear to be as strong as once thought (e.g. Reizenstein 1983). Finally, there is considerable disagreement as to the type of arousal that accompanies an emotion. Mandler (1985), for instance, argues that it is automatic arousal while others argue that cortical arousal must also be considered in emotional reactions (e.g. Izard 1982). Of all these possible measures, then, measures of subjective feeling states, would seem to be the most appropriate as long as there is no reason for subjects to misrepresent their feelings. In addition, this review suggests that physiological measures should only be used in conjunction with measures of subjective feeling states.

A second issue concerns emotion as motivation or drive. The behavioural school viewed emotion as a drive or a motivator to action. According to this view, affective states, with the accompanying increase in arousal, motivated the individual into action. For instance, a state of anger, would motivate the individual to strike at the target of the anger. In the persuasion literature, this view of emotion resulted in the fear drive model of Janis and Feshbach (1953). Under this model, increases in the level of fear should provide motivation to reduce the cause of the fear. For instance, increasing the fear associated with lung cancer should increase the motivation to stop smoking. As is well known, however, experimental research indicated that in some situations high levels of fear may be less effective than low levels of fear. Consequently, an inverted U shape relationship was hypothesized to exist between fear levels and behavioural compliance.

A number of experimental findings within the fear appeal literature has cast doubts on this model of emotion as drive or motivation. For instance, most studies have been unable to find an interaction between level of fear and efficacy of suggested behaviour (e.g. Mewborn and Rogers 1979; Leventhal 1970). If fear acts as a motivator, then higher levels of fear should cause more behavioural compliance when the suggested behaviour is efficacious. In addition, no effects on behavioural compliance have been found when the fear appeal precedes or follows the message suggesting the appropriate behaviour for reducing the cause of the fear (e.g. Leventhal and Singer 1966). If fear acts as a drive, one would also expect more behavioural compliance when the fear appeal precedes the suggested behaviour. These findings have led Leventhal (1970) to propose an alternative to the fear-drive model, his Parallel Response Model. According to this model, individuals make two parallel responses to a fear appeal message. The first is a response to the cause of the fear (e.g. lung cancer) while the second is a response to the emotion or fear itself. When the level of fear is low, individuals devote most of their energy to reducing the cause of the fear and behavioural compliance is high. However, when the fear is high, individuals focus on strategies for coping with or reducing the level of fear and little energy to the cause of the fear, so behavioural compliance is low. Consequently, this model also results in an inverted U shaped relationship between level of fear and behavioural compliance.

The view of emotion as drive or motivation has also declined in most theories of emotion, but this is probably due more to the decline of the behaviourist school in psychology as opposed to contrary empirical evidence. Exceptions are Tomkins (1984), who views emotions as enhancing the behavioural response of the individual and Buck (1985) who has recently presented a model that

integrates both motivation and emotion.

The third issue concerns the number of different emotions and the relationship between emotions. As might be expected there is no general agreement as to the number of different emotions that exist or, for that matter, a precise definition of emotion and now it differs from other psychological constructs. There seems to be general agreement concerning the fundamental emotions of happiness, sadness, fear, anger, interest, contempt, disgust, surprise, shame and guilt (e.g. Izard 1977; Tomkins 1982), however, other theorists have suggested that others such as pride and hope may also exist (e.g. Lazarus et al. 1980).

A related issue concerns the structural relationship between affective states. A number of studies using a number of different methodologies have examined this issue. In most of these studies, subjects evaluated either facial expressions of subjective feeling states along a number of dimensions. This data was then factor analyzed or submitted to a multidimensional scaling program. Although the number of dimensions found varies across studies, the two dimensions of pleasantness and level of activation seem to consistently appear across studies (e.g. Frijda 1969; Russell 1980). Other researchers, focusing on how the appraisal of the environment affects emotional response, have suggested additional dimensions of attentional activity, control, depth of experience, legitimacy and certainty (e.g. Roseman 1984; Weiner 1982). A recent empirical study by Smith and Ellsworth (1985) which attempted to control for methodological problems in previous empirical studies, found five dimensions underlie different emotional states. These are pleasantness, responsibility/control, certainty, amount of attention, amount of effort and situational/control. The results of these studies are important because we need to understand what dimensions underlie different affective states in order to produce these states with advertising or in the laboratory. As will be mentioned later, most of the current research examining the effect of affective states in an advertising context have examined affective states along the pleasantness dimension only.

The fourth issue concerns the extent to which affective states affect cognitive processing. As mentioned earlier, one approach to understanding the effect of affective states is to understand how these states may affect the processing of information. Currently, there is a growing literature on these effects. For instance, affective states have been found to affect decision making (e.g. Isen and Means 1983), the categorization of ambiguous stimuli (e.g. Isen and Daubman 1984), perceptions of risk (Johnson and Tversky 1983), the helping of others (e.g. Isen and Levin 1972; Moore Underwood and Rosenhan 1973) and the evaluation of objects (e.g. Isen et al. 1978). In addition, a number of studies have found asymmetric effects due to pleasant and unpleasant affective states (e.g. Isen 1984).

What is less clear is why these effects occur. Here a number of different hypotheses have been proposed (e.g. Isen 1984). One is a retrieval hypothesis. Here it is hypothesized that an individual's affective state will effect what information is retrieved from memory. For instance, a number of studies indicate that when individuals are in a pleasant affective state, they are more likely to retrieve positively toned information (e.g. Teasdale and Fogerty 1979). The second is an encoding hypothesis. Here it is hypothesized that the affective state of the individual effects what information is encoded in memory. For instance, individuals are more likely to encode positively toned material when they are in a pleasant affective state (e.g. Bower et al. 1981). However, direct tests of these hypotheses have yielded conflicting results. A further clouding of the issue is caused by the use of different manipulations in the studies to create affective states, so there is some concern

that these different manipulations may confound the results. For instance, Bower et.al. (1981) used hypnosis to induce an affective state and found an encoding effect, while Hasher et.al. (1985), used naturally occurring affective states and found no effects.

In summary, the issue here is, if different affective states cause differences in evaluations and judgments, to what extent can these differences be explained by differences in cognitive processes. For instance, if subjects in a pleasant affective state form more positive evaluations of products, to what extent are these differences caused by differences in the encoding or retrieval of more positive product related information.

The final issue concerns the representation of emotions in memory. There are a number of empirical studies that indicate that memory for affective states persist over time. For instance, Bower (1981) has found evidence for state dependent learning. Individuals that learn information in a particular affective state will retrieve more of the learned information if they are in the same affective state at retrieval.

The current, though somewhat controversial approach to the representation problem is that affective states may be represented as a node in a semantic network (Clark and Isen 1981; Clark 1982; Bower 1981). An extension of this model is that the arousal state of the individual is also represented in memory. Clark, Milberg and Ross (1983), present empirical evidence supporting this proposition.

The main argument against this representation is that the number of linkages between a particular affective node and all the related nodes would be large and if a spreading activation model is used to explain information retrieval, there would be only a very small probability that a particular linked node would be activated. This would make the finding of state dependent learning very unlikely. Given the robustness of semantic network models of memory, however, one could always create refinements in the model that could handle these objections. For instance, one might hypothesize some other type of retrieval process for information linked to an affective node or one might argue that there are many different nodes for a particular emotion that may be differentiated by other contexts that occurred at learning.

Although there are a number of critical unresolved issues in psychology surrounding both the conceptualization of affective states and their effects on information processing, we should not let this deter us in investigating the effects of 'feeling' advertisements. There are a number of critical issues that can be examined given the present state of theoretical development on affective states. These will be discussed in the next section.

Advertising Issues

In this section, a number of theoretical issues concerning the effect of affective states within an advertising context will be discussed. In general, there is increasing evidence that the affective state of individuals affects their responses to advertising messages (e.g. Milberg and Mitchell 1985; Srull 1984). The issues that will be discussed in this section focus on understanding the boundaries and causes of these effects.

The first issue is whether or not these effects can be explained by differences in cognitive processes. For instance, a number of studies indicate that individuals form more positive evaluations of advertised brands when they are in a pleasant affective state (e.g. Srull 1984). These effects might be explained by either the encoding and retrieval hypotheses. If individuals are in a pleasant affective state during exposure to an advertisement they may encode more favorable information about the advertised brand which, in turn, may cause them to evaluate

the advertised brand more favourably. Alternatively, if the retrieval hypothesis is valid, then individuals in a pleasant affective state when evaluating a brand would retrieve more positive information which would also cause them to evaluate the advertised more favourably. Obviously, the encoding hypothesis has the most relevance for the advertiser since advertisers have some control over consumers' affective states through the design of advertisements and the placement of advertisements in specific television shows. In addition, if the encoding hypothesis is valid, it suggests that 'feeling' advertisements will have an effect only if the advertisement contains product information.

In a study designed to examine the validity of the encoding and retrieval hypotheses, Milberg and Mitchell (1984) manipulated the affective state of subjects at both encoding and retrieval. In addition, each product message contained both positive and negative information. The results of the study indicated very strong effects due to the affective state of the subject, however, no differences were found in the valence of the information recalled across conditions. These results suggest that the encoding and retrieval hypotheses cannot explain the attitudinal differences that were found, so that we must now look elsewhere for an explanation of these effects.

The second issue is whether attitude toward the advertisement (e.g. Mitchell and Olson 1981) can explain these effects. First, it might be expected that advertisements that create a pleasant affective state will be liked more than advertisements that create a neutral or unpleasant affective state. If this is true, then attitude toward the advertisement may explain advertisement induced affective state effects. This of course, needs to be demonstrated empirically. An alternative hypothesis is that affective states may produce a response bias. Whenever individuals are in a pleasant affective state they may simply evaluate everything more positively. Consequently, both attitude toward the advertisement and brand attitudes would both be evaluated more positively.

There are a number of ways of testing these rival hypotheses. First we might be able to find some experimental stimuli that could be used in an advertisement (e.g., music) that would have differential effects on the valence of the affective state and the evaluation of the advertisement. For instance, we might be able to find music that would create pleasant affective states, but would cause a neutral evaluation of the advertisement. Alternatively, we might create two experimental conditions where an experimental stimuli is used to induce an affective state prior to and during an advertising message. If attitude toward the advertisement were the same in both conditions, a response bias explanation would seem appropriate.

The third issue concerns the stability of these effects. All the studies that have found that affective states affect the evaluations of the advertised brand have taken measures of brand attitudes shortly after the affective state manipulations. Consequently, although these effects occur in the laboratory, they may disappear shortly after subjects leave the laboratory.

One boundary condition that may affect the stability of these effects is whether or not the subject forms an evaluation of the brand during exposure to the advertisement. Srull (1984), for instance, manipulated whether or not subjects formed an evaluation of an advertised brand during exposure to an advertisement. In this study, pleasant, neutral and unpleasant affective states were induced prior to seeing the advertising message. The results of this study indicated that pleasant and unpleasant affective states had an effect on brand attitudes only when subjects formed an evaluation of the advertised brand during exposure to the advertisement.

The fourth issue is whether affective states have an effect on brand attitudes in an attitude change situation. All of the recent research that has obtained affective state effects on brand attitudes is an attitude formation situation. Previous research (e.g. Janis et.al. 1965) has found attitude change effects with different affective states, however, these studies contain methodological flaws. Consequently, it still is necessary to demonstrate unambiguously that affective states can have an effect in an attitude change situation.

A fifth issue concerns possible differences in effects if the affective state is induced prior to seeing the advertising message or during the message. These differences would be analogous to whether the affective state was induced by the program content prior to the advertisement or whether the affective state was induced by the advertisement. As mentioned previously, Srull (1984) found that when the affective state is induced prior to receiving the advertising message, the affective state has an effect only when subjects form an evaluation of the brand during exposure to the message. It is hypothesized here, that if the affective state is induced during exposure to the message, it will have an effect regardless of whether or not a brand attitude is formed during exposure to the advertisement. Under these conditions, the affective state will become linked to the brand in memory. Consequently, when this attitude is formed at a later point in time, the affective state will still have an effect. As the time period between exposure to the advertisement and the formation of the attitude increases, however, these effects might be expected to weaken since it is generally believed that affective states induced by recalling a particular event where that affective state was present, will be weaker than the affective state that occurred at the time of the event.

The sixth issue concerns the effect of different types of affective states. All of the previous research examining the effects of affective states on brand attitudes in an advertising context has induced either a pleasant or unpleasant affective state. However, as was discussed earlier, pleasantness is only one of the dimensions that has been found to underlie different affective states. It may well be that other dimensions of affective states will also have an effect on brand attitudes, purchase behaviour, or the evaluation of a product usage experience. This will be more likely to occur if it is found that affective states formed during exposure to an advertisement continue to have an effect even if the subject did not form an evaluation of the brand during exposure to the advertisement. It is also hypothesized that if these other dimensions have an effect, they are most likely to occur at the point of purchase or in the evaluation of the usage situation. In addition, it is hypothesized that if the different dimensions of affective states have an effect, these effects will be very product class specific.

The final issue concerns the differential effects of attitudes with a strong cognitive base and attitudes created through pure affect. Theoretically, we can now construct the same attitudes, in terms of valence, based on either product information or affective reactions. These latter reactions may be created either through the creation of an affective state during exposure to the advertisement or by using affect inducing non-informative photographs in the advertisements (e.g. Mitchell 1985). The issues here involve potential differences in the stability of the attitudes that are formed and differences in the attitude-behaviour relationship. Here, it might be hypothesized that attitudes with an informational base will be more stable, but have a weaker attitude behaviour relationship.

Discussion

In this paper, I have provided reasons why it is important to understand the effect of 'feeling' advertisements and briefly outlined some important theoretical issues

concerning affective states that are critical in developing theoretical models of how 'feeling' advertisements may work. In addition, a number of important issues were presented surrounding the effects of 'feeling' advertisements.

A number of problems should also be pointed out that may occur in conducting research in this area. First, it is difficult to develop pure experimental manipulations of affective states. Most manipulations of affective states will also have some other effect on the information processing system. For instance, the use of music in an advertisement to induce a particular affective state may also act as a distractor. This means that there will be alternative explanations for the results that are found. Consequently, it is important to design tightly controlled experiments or use converging operations to rule out alternative explanations (e.g. Gardner, Harke and Erickson 1956). Second, it may be difficult to develop pure manipulations of different affective states since most theories of emotion are cognitive. This means that we need to create different cognitions in order to create different affective states. Consequently, if different effects are found, it will be difficult to determine what is causing the effect, the different cognition or the different affective states. The final problem is that individuals may experience many different emotions at the same time (e.g. Ekman 1984). This will probably be especially true if we use complex stimuli such as advertisements. If we want to investigate the effect of specific affective states with advertising, we will probably need to create advertisements to make sure that we are inducing only the affective state that is of interest. It also means that if we want to measure affective states induced by actual advertisements, we will need to use measurement procedures that are able to measure combinations of emotions.

CHILDREN'S PURCHASE REQUESTS AND PARENTAL YIELDING:
A CROSS-NATIONAL STUDY

Scott Ward, University of Pennsylvania
Thomas S. Robertson, University of Pennsylvania
Donna M. Klees, University of Pennsylvania
Hubert Gatignon, University of Pennsylvania

Abstract

This study explores patterns of children's purchase requests and parental responses to those requests across three cultures. These patterns are found to vary by culture, child's age and amount of television viewing.

Introduction

The purpose of this study is to examine patterns of children's requests for products, and parental reactions to those requests, in three cultures: the United States, Japan, and Great Britain. The topic is an important one, since regulations have been proposed in many countries to affect television advertising targeted at child audiences. These proposals are based, in part, on concerns voiced by critics and activists that television advertising stimulates children to ask their parents to buy things for them, and that such requests may be dysfunctional for parent-child relations. The basic issue seems to be that, since children have relatively little disposable income, they usually must ask parents to buy things. Television advertising may stimulate children to make more requests than they would absent television advertising, and advertising-engendered requests may be more "intense" than requests which do not result from a child's exposure to advertised products. The frequency and intensity of such requests is thought to lead to a corresponding increase in family tensions when parents--especially those in lower socioeconomic brackets--deny the requests.

In addition to regulatory issues, patterns of children's purchase requests and parental responses would seem to be an important part of children's consumer socialization processes. These processes generally refer to the development of consumption-related knowledge, attitudes and skills, and they are influenced by many factors, including advertising, peers, children's experiences, and parental behavior.

Consumer socialization processes will vary depending on the children's experiences resulting from the pattern of reinforcements as children request products and parents respond to these requests. For example, parents who agree to buy most things their children request probably encourage their children to be attentive to advertising and to request things frequently. On the other hand, parents who routinely discuss children's requests with them may encourage children to develop particular skills in selecting and interpreting product information, and in defining product needs carefully. We also expect consumer socialization processes to differ markedly across cultures, due to differences in the marketing environments, broadcast systems, and most importantly, differences in basic patterns of parent-child interaction.

Previous Research

Research in two areas is pertinent to this study: research on patterns of children's product requests and parental responses, and cross-national research comparing aspects of parent-child interaction which may be related to these request-response patterns. Research in the first area has been conducted in the United States. One diary study found that 3-12 year-olds request an average of 14 products a month, and that mothers most often agree to buy what their children request, although they are more likely to buy less expensive items (such as snack foods) than

more expensive items (bicycles, games, etc.) (Isler, Popper and Ward 1979). Other studies (summarized in Adler et al. 1980) have found that the frequency of children's purchase requests varies with age, product category, and, to a lesser extent, social class. Generally, explicit purchase requests decrease when children approach teenage years. This finding has been attributed to a number of factors, including the increased independent spending power of children as they grow older, and to the fact that older children do not need to make many explicit requests, since their parents know favorite products and brands.

Findings also suggest age-related differences in the kinds of products children request. Food products are requested across age groups, but younger children are more likely to request toys and games, while older children request clothing, records and tapes, and the like (Adler et al. 1980). Some evidence of a link between television viewing and purchase requests has been reported. In one study, heavy viewers of Saturday morning television were more likely than light viewers to report asking their parents to make purchases of both breakfast cereals and toys (Atkin 1975). The correlations between frequency of requests and viewing dropped, but remained significant, when age, sex, race, and scholastic performance were controlled. The same study reported that this effect was especially marked among younger children.

Parental agreement to purchase requested products has been found to depend on the knowledge levels and attitudes of parents, the type of product and its expected use, and seasonal factors. Children of mothers who have a good understanding of nutrition have been found to express fewer preferences and request fewer food products than those whose mothers lack this understanding. This finding could be attributable to the children's feeling that such requests would go unheeded, given their mothers' concern for nutritional factors. Studies have found high levels of yielding (about 70% of the time) for inexpensive products children consume (snacks, cereals), but there is some evidence which suggests that mothers act as gatekeepers for children's cereal requests by limiting choices to a few acceptable brands (Robertson 1979).

Parent-child interaction concerning products is especially high around holidays, particularly Christmas. Yielding levels for relatively expensive products are high--about 40%--during holiday seasons. Research on parental responses to children's requests shows that very few parents simply deny their children requests without an explanation. The most frequently-offered explanations for denial were "expense" and "poor value" in one study.

Research among American families has not explicitly examined more general patterns of parent-child interaction which may underlie patterns of purchase requests and parental responses. Socialization researchers agree that the family unit is the primary agent for socialization among pre-adolescent children. Moreover, evidence suggests that family orientations and behaviors differ markedly across cultures. We believe that three particular aspects of parent-child interaction should be strongly related to patterns of children's requests and parental responses: the degree and nature of affect linking parents and children; patterns of dependence; and types of control mechanisms.

Based on various studies, the primary differences in these three areas of socialization across countries are summarized in Exhibit 1. Regarding affective relations, American families are more likely to be verbal and expressive, while

Japanese families are less likely to express affect verbally, despite the fact that Japanese children are more indulged than children in other cultures (Caudill and Schodler 1973, Conroy et al. 1980). Harmony is stressed in Japanese families (Shigaki 1983), while conflict is expected in American families (Conroy et al. 1980). In contrast, relatively low levels of affect characterize British families, which score lowest on nurturance and warmth.

EXHIBIT 1

A CROSS-CULTURAL COMPARISON OF SOCIALIZATION PRACTICES

Socialization Variables	U.S.	England	Japan
Parental warmth	high	low	high for mothers; low for fathers
Parental control	low	high	high
Parent-child contact	high	low	high
Association with peers	medium	high	medium
Time child spends alone	low	high	medium

Sources: Devereux (1970); Fischer (1970); Condon and Saito (1974).

Regarding dependence, American families seek to encourage children to be independent and to "stand out" from the crowd; in contrast, Japanese children are encouraged to "stand in" with culturally-defined groups and lifelong emotional dependence on the family is encouraged (Weisz et al. 1984). Among British families, independence is stressed, and British children come to identify with peer groups at an earlier age than children in the other cultures (Devereux et al. 1969, Devereux 1970).

Finally, families in the three cultures differ in the extent and nature of control exerted. American families are more likely to use psychological rewards and punishments, and to employ guilt-inducing methods (Devereux et al. 1969). Japanese families are least likely to employ direct physical punishments and guilt-inducement. Rather, Japanese parents rely on persuasion and reasoning (Conroy et al. 1980). One author notes that American children are often punished by forced realignment with the family (being "grounded"), while an extreme punishment in a Japanese family might be to lock the child outside the house (Weisz et al. 1984). British families are unlikely to use guilt-inducing mechanisms, but most likely to employ physical punishments (Devereux et al. 1969).

Hypotheses

Based on these streams of research, and using past U.S. research as a benchmark, we pose the following hypotheses:

H1: Japanese children should make fewer requests of their parents, but their parents should most often agree to buy requested products, compared to children in the U.S. or in Britain.

More than American or British children, Japanese children are encouraged to be respectful and harmonious in the family, and purchase requests may be viewed as "pushy"; however, since Japanese parents are highly indulgent of their children, they should most often agree to buy requested items. (It may be that there is a threshold effect, in that too many requests by Japanese children may be viewed as disrespectful, and threatening to parental authority and family harmony.)

H2: Parental agreement to buy requested products will increase with age.

Children become more skillful in their asking behavior with age: they more clearly define products they want, and probably become more adept at asking for things they want. We expect this skill to develop with age among all chil-

ren, regardless of culture.

H3: Heavy-viewing Japanese and British children should request more products than heavy-viewing American children.

American children are more likely to be exposed to television advertising than their Japanese or British counterparts, since commercial broadcast is far more prevalent in the U.S. than in Japan or Britain. Heavy television viewing has been related to frequency of requests (Atkin 1975). However, American children should be satiated with television commercials, compared to children in the other countries. Television advertising may still be relatively novel to Japanese and British children. Consequently, we expect heavy-viewing children in these countries to be more affected by television advertising, and to make more requests than heavy-viewing American children.

H4: Parental responses of "discussion" and "negotiation" should decrease with age.

Research among American children suggests that parents of young children--up to about age seven--are more likely to discuss consumption issues with their children than are parents of older children. For older children, parents most often expect direct and indirect modelling to affect children's consumer socialization. Although there may be some differences in the degree of "expressiveness" among families in the three cultures studied here, we do not expect differences by country in the relative incidence of negotiation and discussion as children mature.

Research Design and Measures

Mothers kept diaries to record one child's purchase request behavior and parental responses over a two-week period in the spring and summer of 1984. A separate diary was maintained to record the focal child's TV watching behavior, and a separate questionnaire was administered at the end of the two-week period to collect demographic information and other data relating to parent and child attitudes and behaviors.

The sample consisted of 267 families in three countries: the U.S. (n=84), Japan (n=118) and Great Britain (n=65). All were two-parent, middle- to upper-middle class households with 2-4 children present. In each family, one child's behavior was observed. The age ranges were 3-4, 5-7 and 8-10 years old, roughly corresponding to pre-operational and concrete operational stages of cognitive development.

Measures and procedures were based on an earlier diary study among American children (Isler, Popper and Ward 1979). Japanese and British colleagues served as study coordinators in their own countries. The diaries were translated into Japanese, and selected portions back-translated; the British questionnaire was adapted slightly. Mothers were asked to record each purchase request made by the child, and to indicate the nature of responses via closed-end items. Measures included how children asked, and, of interest in this study, how parents responded: positive yielding includes "unqualified yes," "yes with discussion," and "yes, with negotiation." Negative responses include "absolute no," "no with discussion," "no with negotiation," and "deferment." Children's television viewing was measured in terms of total minutes of commercial broadcasting recorded over the two-week period by the parent completing the diary.

Results

We hypothesized that Japanese children should make the fewest requests of their parents, but their parents should most often agree to buy requested products, compared to children in other countries.

Purchase request levels in the three countries were compared by a one-way analysis of variance, which revealed a significant main effect by country ($p < .05$). Mean requests for the total sample were 8.81 requests over the study

period in Japan, 19.17 in the U.S. and 14.66 in Great Britain.

Regarding parental agreement to buy requested products, results were as hypothesized: Japanese parents agreed to their children's purchase requests more than U.S. or British parents. This relationship holds when total number of requests is controlled by assessing agreement to buy as a percentage of total requests (see Table 1). The data indicate that Japanese parents are particularly likely simply to agree to buy ("unqualified yes") compared to parents in other countries, while the incidence of discussion and negotiation are roughly comparable across the three countries.

TABLE 1
PARENTAL AGREEMENT TO BUY AS A
PERCENTAGE OF CHILDREN'S TOTAL REQUESTS

Response	Age	U.S.	Japan	Great Britain	All Countries
Unqualified Yes	3-4	29.3	45.1	21.7	33.0
	5-7	32.9	52.0	36.1	38.8
	8-10	35.8	58.6	35.7	41.5
Yes, with Discussion	3-4	14.9	20.6	15.4	17.1
	5-7	11.3	13.4	16.2	13.2
	8-10	17.1	15.9	16.6	16.7
Yes, with Negotiation	3-4	2.6	2.5	3.0	2.6
	5-7	5.8	1.3	4.3	4.2
	8-10	3.9	1.2	3.0	3.0
Total "Yes"	3-4	46.8*	68.2	40.1	52.7
	5-7	50.0	66.7	56.6	56.2
	8-10	56.8	75.7	55.3	61.2
Refused to Buy	3-4	53.2	31.8	59.9	47.3
	5-7	50.0	33.3	43.4	43.8
	8-10	43.2	24.3	44.7	38.8

*To be read: Of total requests made by 3-4 year-old U.S. children, parents agreed to buy in response to 46.8% of the child's requests.

The second hypothesis was that parental agreement to buy would increase with age, and this relationship would hold across cultures. Data in Table 1 show results in the expected direction. Differences between agreement to buy products requested by youngest children (3-4 years old) and oldest children (8-10 years old) are as hypothesized, and significant in each country ($p < .05$).

Greater parental agreement to buy products which older children request may reflect the fact that they make fewer, and perhaps more selective requests. Also operating may be the "passive dictation" phenomenon (Wells 1966), i.e., that parents come to know children's favorite products and brands, so that older children do not have to make requests as frequently.

The third hypothesis was for differential effects of "heavy viewership," since American children may be satiated with commercials, while British and Japanese children may find them more novel, and consequently, may be more sensitive to increased exposure to commercials.

In Japan, only 3-4 year-olds show significant differences in frequency of requests as a function of amount of commercial viewing, and in Great Britain, only 5-7 year-olds show such effects. It may be that, in Japan, the higher levels of requests among youngest children reflect the greater propensity of Japanese parents to yield to young children's product desires, while in Great Britain, the failure to find differential effects may simply reflect the tendency for British children to become more peer-centered, and less family-centered, than children in other countries (Devereux 1969).

TABLE 2

MEAN REQUESTS BY HEAVY AND LIGHT VIEWERS BY COUNTRY AND AGE

Country	Age	Purchase Requests over 14 Days		
		Heavy Viewers	Sig.	Light Viewers
U.S.	3-4	20.2	-	20.6
	5-7	19.3	-	18.2
	8-10	22.9	<.05	12.4
	Total	21.3	<.05	17.7
Japan	3-4	12.6	<.05	8.0
	5-7	10.7	-	9.3
	8-10	5.9	-	6.7
	Total	9.6	-	8.0
Great Britain	3-4	22.0	-	17.9
	5-7	22.4	<.05	11.4
	8-10	12.8	-	9.6
	Total	17.1	-	13.2
Total	3-4	15.3	-	14.5
	5-7	15.7	-	13.4
	8-10	13.5	<.05	8.8
	Total	14.6	-	12.6

The final hypothesis was that parental responses involving "discussion" and "negotiation" should decrease with age. Previous research among American children has shown that verbal interaction is more prevalent with younger children, while older children should be expected to understand parental reasoning, and to be responsive to more indirect cues, viz., modeling parental consumer behaviors (Ward, Wackman and Wartella 1972).

Results are shown in Table 3. While ANOVA results indicate age-related differences in the uses of discussion ($p = .006$) and negotiation ($p = .02$), significant differences were found only between 3-4 and 8-10 year-olds in Japan for discussion ($p = .03$) and for negotiation ($p < .01$).

TABLE 3

MEAN USE OF "DISCUSSION" AND NEGOTIATION" BY PARENTS IN RESPONSE TO CHILDREN'S REQUESTS, BY AGE AND COUNTRY

Country	Age	Mean Responses over 14-Day Period	
		Discussion	Negotiation
U.S.	3-4	8.1	.71
	5-7	6.1	1.5
	8-10	5.8	1.1
Japan	3-4	2.6	.80
	5-7	1.7	.66
	8-10	1.2	.13
Great Britain	3-4	6.8	.81
	5-7	5.2	1.0
	8-10	3.7	.65
Total	3-4	4.9	.78
	5-7	4.1	1.1
	8-10	3.2	.53

Although we did not hypothesize differences between countries in the use of "discussion" and "negotiation", results in Table 3 suggest that Japanese parents are less likely than American and British parents to use these verbal responses.

Conclusions

Previous research among U.S. children has shown that many aspects of consumer socialization vary strongly by age. The present findings indicate that these age differences hold across cultures, and that culture itself is an impor-

tant variable determining differences in parent-child interaction regarding consumption. Literature contrasting parent-child relationships in different countries suggests that Japanese parents are more indulgent of their children, and our data support this notion, and suggest that one form of indulgence is to agree to buy things which children request. Another age-country interaction is seen in the incidence of negotiation and discussion. While the trend across countries is for less negotiation and discussion among older children, American parents are more likely to use these responses than are British and Japanese parents.

On the other hand, some aspects of parent-child interaction involving consumption appear to hold across cultures: our data indicate that parents of older children are more likely to agree to buy requested products, and this holds for all countries in our study.

In future research, we plan to analyze some further determinants of patterns of parent-child interaction within and across cultures. We gathered data concerning general aspects of parent-child interaction, and these measures should add to our understanding of the determinants of children's request behavior and parental responses in different country settings.

CHILDREN'S RELATIONSHIPS BETWEEN REPETITION AND AFFECT

Theo B.C. Poiesz, Tilburg University, the Netherlands¹

Abstract

In this paper an attempt will be made to gain a better understanding of children's affective reactions to brandname repetition. For this, reference will be made to differences in cognitive development. These differences are presumed to affect the conditions that are deemed necessary for positive repetition-affect relationships to take place. One of these conditions is specified by the functional exposure hypothesis. Empirical evidence is presented suggesting that age does influence the type of relationship between repetition and affect.

Introduction

Over the years, repetition-affect phenomena have received a great deal of attention in the psychological and consumer behavior literature. For a recent and comprehensive review on these so-called 'mere exposure phenomena' see Obermiller (1985). Empirical results that were reported in the literature were obtained almost exclusively with adult subjects. It seems justified, however, not to limit research to adult subjects only, as one may assume that also children are frequently and repeatedly exposed to marketing stimuli. For example, when considering the case of brandnames as one type of these stimuli, Atkin and Heald (1977) calculated brandname exposure to be an average of 3.65 times per children's television commercial. In order to get an impression of the total number of children's brandname exposure opportunities, this figure would have to be multiplied by the number of commercials over time and supplemented with brandname exposure through other media. For adults, in (dated) literature some estimates of the number of exposures to marketing stimuli are presented (e.g. Advertising Age, 1970; Bauer and Greyser 1968, Ebel 1957), but for children no such estimates are known to be available. Anyway, apart from the practical significance and methodological problems of such figures, we may safely assume that the number of children's brandname exposures is impressive.

The few studies that were reported on repetition-affect relationships of non-adult subjects produced conflicting results (e.g. Cantor 1968, Heingartner and Hall 1974). Reviewing the available evidence, Rossiter (1980) concludes that a persuasive effect of brandname repetition within a children's commercial is unlikely (p.177). However, one may argue that in its effect upon behavior, the issue of repetition within commercials is less critical than the number of repetitions over commercials. The present paper will address the latter issue, thus not confining itself to the effect of the number of repetitions per advertising message.

The 'mere exposure' hypothesis (Zajonc 1968) states that the mere repeated exposure of an individual to a stimulus object enhances his/her attitude toward it. By 'mere exposure' is meant: a condition which just makes the stimulus accessible to the individual's perception. To put it briefly, empirical studies on exposure effects produced conflicting results. Also, the mere exposure hypothesis directly contradicts the existence of a different phenomenon well established in the literature: the preference for novel as opposed to familiar stimuli (e.g. Berlyne 1980, 1970).

Recently, the 'functional exposure' hypothesis was introduced (Poiesz 1983, and elsewhere these Proceedings) which attempts to provide a consistent explanation for the seemingly contradicting empirical results. This

hypothesis states that positive repetition affect relationships will occur only and to the extent that repetition, or its psychological counterpart: familiarity, may be considered psychologically functional.

The function of familiarity is to be understood as its possibility to help a person reach a desired psychological state. In an ambiguous experimental situation, for example, this would be the possibility to reduce subjective uncertainty - but only to the extent that uncertainty is associated with apprehension as an undesired psychological state. Whether uncertainty will be associated with apprehension can only be ascertained by the simultaneous consideration of the person, the object(s) and the situation involved. If uncertainty/apprehension is reduced by the more familiar stimuli, these stimuli will be evaluated more positively. As another example take an ambiguous laboratory consumer choice situation in which Ss are requested to make a selection out of a number of alternative brands. Also here, the function of the familiarity of brandnames is dependent upon the specific combination of subject, (choice-)objects and situation. If Ss perceive little risk in the choice situation, familiar stimuli can not be functional by reducing that risk. Therefore, the more familiar stimuli will not be evaluated more positively. If perceived risk increases, so does the function of familiarity. However, if perceived risk is high, also the need for choice-relevant information is high. As mere brandname familiarity itself is not choice relevant, its functionality will be low under conditions of high perceived risk. Therefore, in a functional exposure interpretation it is expected that there will be a preference for familiar brandnames only in a condition of intermediate perceived risk and not/less under conditions of low and high perceived risk. The functional exposure hypothesis differs from other uncertainty reduction hypotheses by its emphasis on the function of familiarity as determined by the interaction of person, object and situational variables. According to the functional exposure hypothesis uncertainty reduction alone is neither a sufficient nor a necessary condition for positive repetition-affect relationships to occur.

The empirical evidence supporting the functional exposure hypothesis is of two types (see Poiesz 1983). The first type of evidence was obtained in the social psychological laboratory. Empirical results supported the hypothesis that positive repetition-affect relationships will be found only in task situations in which subjects are uncertain (and apprehensive) with regard to their personal performance on a task. The second type of evidence concerned laboratory subjects' choice behavior in a 'consumer task'. Some support was found for the hypothesis that under conditions of perceived risk (as the consumer behavior counterpart of the concept of subjective uncertainty/apprehension) more familiar brandnames are preferred to less familiar brandnames, and that this preference will be absent/smaller under conditions of high and low perceived risk.

The functional exposure hypothesis does imply some (pre- or sub)conscious cognitive activity. First, the task demands must be well perceived and understood. Second, the assessment of functionality requires some cognitive activity by which familiarity, as a relevant stimulus characteristic, is related to the requirements of the task.

In the developmental literature, strong evidence is provided for the existence of age differences with respect to the conditions stated above. With regard to the first condition, older children (13, 14 years of age

¹The author wants to thank Jan van Gerwen for his valuable contributions.

and up) have been reported better capable of selecting useful (i.e. functional) information from stimulus components and of tailoring attention to task demands (e.g. Roedder 1981, Hale 1979, Flavell and Wellman 1977, Ross 1976, Stevenson 1972).

Regarding the second condition, Piagetian theory and research (see e.g. Chestnut 1979 for a reconsideration of Piagetian theory in children's consumer behavior research) suggest that children of about 14 years of age may be expected to differ from younger children (up to about age 12) in their capacity to cognize about the significance or functionality of events. This should also hold for events taking place in an experimental setting such as the occurrence of exposure frequency differences. Also, the older children are better capable of thinking in terms of self-generated hypothetical propositions, of theorizing about new relationships, and of thinking abstractly (see Roedder 1981). Combining the evidence we may expect the probability of observing positive repetition affect-relationships among experimental subjects in an ambiguous, apprehension-generating situation to increase with age (in the range from 9 to 14 years of age). It is hypothesized, therefore, that children of 13/14 years of age will show more positive repetition-affect relationships in such a situation than children of 9/10 years of age. Parenthetically, reference is made here only to levels in the developmental trend, and not to a strict stage theory of cognitive development. In the developmental trend, levels have been identified that are supported by research and theoretical consensus (Fischer and Silvern 1985). For sake of clarity, the abovementioned hypothesis relates to the difference between age levels on the basis of a global distinction with regard to cognitive development. The hypothesis does not pertain to any particular single aspect of cognitive development as a determinant of the expected effect.

Experiment 1

Method. Subjects: 70 children of 9/10 years of age and 76 children of 13/14 years of age (resp. primary and secondary school) participated in the present experiment.

Stimulus material. The stimuli were 6 slides, each showing the set of eyes of 12 year old children. This type of stimulus was chosen for to exclude the possibility that the nature of the stimulus, such as, for example, its subjective complexity, would interact with age level. The 6 stimuli were selected out of a large set of eye pairs on the basis of their relative affective neutrality which was established by a small group of children at the two age levels; these children did not participate in the experiment. Slides had a standard format, eye pairs had been photographed from a standard distance and only eyes were shown (no hair, etc.). The photographed children all looked straight in the camera and had a "neutral" facial expression when being photographed.

Equipment. The equipment consisted of a Kodak carousel slide projector, a projection screen placed in front of the subjects, a white instruction board with text in brown. The instruction could be easily read by all subjects.

Design and procedure. The design involved two experimental groups of subjects distinguished on the basis of age, and a control group for each of the age levels. The experiment was carried out at the schools of the subject groups, in the respective classrooms. Per condition, subjects participated collectively. Each of the two experimental groups was confronted with the procedure typically employed in repetition-affect studies. That is, there was no explicit task related instruction prior to the exposure frequency manipulation. The affect rating of all stimuli immediately followed this manipulation. For the two control groups, there was no exposure frequency manipulation and subjects in these groups rated affect associated with the various stimuli on the basis of a single exposure to each stimulus only.

Instructions. 'In a few moments I will show you a number of slides of the eyes of children. Later on I will explain you the reason why. The eyes are those of children of the ... school in Eindhoven (a nearby city - note by the author). These children are in the same grade and are of your age. Please look at the screen now'. Subjects in all conditions received these instructions. It was assumed that the combination of the absence of unambiguous instructions and the exposure of unknown stimuli would generate apprehension, an assumption proved valid in comparable experimental situations (Poiesz 1983). A particular stimulus was shown 0, 1, 2, 5, 10 or 20 times. Subjects in the control conditions saw each stimulus once only. Frequencies were intermixed, so that each stimulus did not follow itself. Stimuli were exposed for 2 seconds each. Interstimulus intervals were 4 seconds. Because of practical constraints, the stimulus presentation and the affect rating had to take place for all subjects per condition simultaneously. As a result, the order of the frequency levels in the rating phase was fixed: 5, 0, 20, 1, 10 and 2 (exposure time: 2 seconds each). Stimuli were rated on the 7-point "smiling-faces" scale (Jolibert and Baumgarten 1979). Subjects were instructed how to interpret the scale. They were requested to 'indicate how nice you think the child is whose eyes you just have seen'.

Results and discussion. Assuming psychologically equal intervals at the exposure frequency continuum, linear trendscores were calculated per condition (see Winer 1971). This was also done for the two control conditions, although, in fact, the equal exposure frequencies in these conditions can not be subjected to a trend interpretation. However, for reasons of comparison, trendscores could be calculated without violating analytical rules. A linear trend analysis showed an unexpected significant interaction between the base lines of the two control groups ($F_{1,87} = 15.95, p < .01$), implying that, apparently, stimuli were not equal in affective neutrality and differing for both groups. Consequently, a direct comparison between the two age groups was not possible. The only prudent comparison that could be made was, per age level, the one between the experimental repetition affect relationship and the respective baseline. Then, for children of both age groups, it was observed that repetition-affect relationships differed significantly from the baselines. However, for the younger children the trend of the experimental group was negative relative to its baseline ($F_{1,68} = 7.04, p < .01$), while for the group of older children this trend was positive relative to its baseline ($F_{1,74} = 5.08, p < .05$). Even though these results confirmed the hypothesis - the younger children (9/10 years of age) would show less positive repetition-affect relationships than children of 13/14 years of age - the interpretation is hampered by the significant difference between the control groups of both age levels and by limitations in the set-up of the present experiment: it did not allow for a counterbalancing of stimuli over stimulus repetition levels. Nor could the order of the stimuli in the rating phase be varied. Therefore, a second experiment was set up, in which procedural flaws of the first study were eliminated.

Experiment II

Basically, the theoretical background of Experiment II was identical to the one of the Experiment I. Again, two age groups were confronted with a manipulation of exposure frequency, and it was hypothesized that the repetition-affect relationship of children 13/14 years of age would be more positive than the relationship of children 9/10 years of age.

Method. Subjects: 60 children participated in this experimental study. 30 Children of about 9/10 years of age, and 30 children of about 13/14 years of age (primary and secondary school, respectively).

Stimulus material. For sake of simplicity, in this experiment a less 'multidimensional' type of stimulus was used than in the previous experiment. Stimuli were 6 nonsense words, formed by four consonants and one vowel.

These words has been selected out of a set of 33 words on the basis of their affective neutrality for both age levels. This was done in a study, prior to the actual experiment, with a group of 13 children per age group. These children evaluated stimuli on the "smiling faces" scale referred to earlier. The selected words were DONJW, VINCB, RETBG, SBETG, SGLIB, and FUPKZ. The stimuli were presented on slides, all in the same format.

Equipment. Employed were a KODAK caroussel slide projector and a projection screen, placed at a distance of about 15 ft. from the subjects.

Procedure. In this experiment, subjects participated individually. After entering the experimental room, the subject was requested to sit in front of the screen. The standard instruction was: 'In a few moments, I will show you a few slides. Later, I will explain you why. Each slide shows the name of a child. The names are all unknown to you - you probably never saw them before. Now, look at the screen and I will show you the slides. Please watch them closely'.

During the stimulus presentation, each stimulus was exposed for two seconds. Interstimulus intervals were 4 seconds. The stimuli were presented in random order, but so that each stimulus did not follow itself. A particular stimulus was shown 0, 1, 3, 5, 10 or 15 times. The exposure phase was followed immediately by the rating phase, in which stimuli had to be rated one by one on the 7-point "smiling faces" scale.

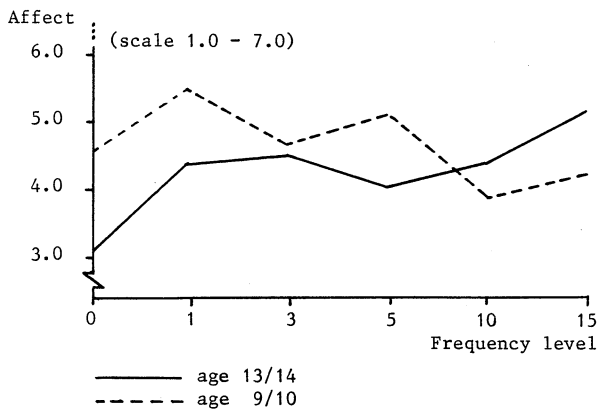

Subjects were instructed how to interpret the scale. In the rating phase, repetition levels were rotated over the exposure positions 1 through 6.

Results. Table 1 and Figure 1 show the average affect score per exposure frequency level and per age group.

TABLE 1
MEAN AFFECT SCORES PER AGE LEVEL AND PER FREQUENCY LEVEL (N=30 PER AGE LEVEL)

Frequency level:	0	1	3	5	10	15
Age 9/10	4.57	5.47	4.67	5.07	3.93	4.23
Age 13/14	3.10	4.37	4.50	4.03	4.40	5.17

FIGURE 1
MEAN AFFECT SCORES PER AGE LEVEL AND PER FREQUENCY LEVEL

The results indicate that there is a difference between the age groups with regard to the slope of the repetition-affect relationship. The tendency for the older children is positive, and for the younger children negative. The difference is significant ($F_{1,58} = 10.28$, $p < .005$), confirming the hypothesis.

General discussion

The results of the two experiments combined provide support for the argument that cognitive development differences co-determine differences between repetition-affect relationships.

The results may be worthwhile in that they suggest that

age level (level of cognitive development?) may have an autonomous influence on the repetition-affect relationship.

Several critical questions remain to be answered, however. One of these questions is whether age related differences exist with regard to the perception of the experimental situation. A second question is whether other age related differences than cognitive development differences can be held responsible for the obtained results. For example, a point that received possible too little attention in the reported experiment is the one concerning the subjective uncertainty/apprehension assumed to be generated by the experimental situation. Yet another question concerns the interpretation of the slopes (positiveness/negativeness) of the observed relationships. Note that no explicit hypotheses were formulated on the slope of the relationship of each of the group - only on the nature of the difference between the two. The average relationship of the older children was found to be more positive than that of the younger children, as expected. For the latter group, the relationship was negative, however. A possible explanation for this effect is that if the more familiar stimuli are not psychologically functional for the younger children, the repeated exposure of these stimuli may generate boredom or even irritation. This would have expressed itself in more negative affect towards these more familiar stimuli.

It would be premature to consider the external validity and significance of these findings, considering the artificial nature of the controlled experimental situation in which they were obtained and the importance of yet unanswered questions. However, two points suggest the possible relevance of additional research. First, although the stimuli employed in both studies were not marketing stimuli in the strict sense, there may not be a fundamental difference between the nonsense words as used in the second experiment and real life brandnames. Second, even though the experimental situation with which subjects were confronted here was not a consumer choice situation, the behavior in both situations may often be conceived of as problem-solving behavior involving perceived risk or uncertainty as conceptualized here.

Converging the evidence on adult repetition-affect relationships and the obtained (limited) evidence on children's repetition-affect relationships, three hypotheses may be formulated:

- 1) Children of age 13/14 on (including adults) will show positive affect towards frequently exposed brandnames in buying situations with a moderate degree of perceived risk (which is to be interpreted as determined by the interaction of consumer, product and situational variables).
- 2) Children up to age 9/10 will show no positive affect towards frequently exposed brandnames in buying situations with a moderate degree of perceived risk.
- 3) Children (and adults) of all ages will show no positive affect towards frequently exposed brandnames in buying situations with either a very high or a very low degree of perceived risk.

BRAND FAMILIARITY AND ADVERTISING:
EFFECTS ON THE EVOKED SET AND BRAND PREFERENCE

William Baker, University of Florida

Introduction

It is a well known fact that brand awareness, or familiarity, and brand choice are highly correlated (Axelrod 1968; Haley and Case 1979). This relationship undoubtedly reflects the fact that choice increases awareness, if for no reason other than people will be exposed to the brands they choose more often than brands they leave on the shelf. Of greater interest is the proposition that brand awareness plays some causal role in the choice process. This is implied by the classic hierarchy of effects model of advertising effectiveness (Lavidge and Steiner 1961; Palda 1966) as well as the low involvement hierarchy proposed by Ray, Sawyer, Rothschild, Roger, and Reed (1973). In this paper we explore the theoretical and empirical bases of this proposition.

The Brand Familiarity Construct

In order to facilitate the present discussion, we will adopt a very particular working definition of brand familiarity and examine its viability.

DEFINITION. Brand familiarity is a unidimensional construct that is directly related to the amount of time that has been spent processing information about the brand, regardless of the type or content of the processing that was involved.

Thus, brand familiarity is the most rudimentary form of consumer knowledge. Moreover, this definition specifically assumes that brand familiarity is context-independent and is affected in more or less the same way by advertising exposures, purchase behavior, and product consumption or usage. This seems to be the simplest definition possible and is therefore a reasonable starting point for our investigation. In the remainder of this paper we examine two principal ways in which brand familiarity might affect brand choice: (1) by increasing the likelihood that the brand is included in the evoked set, and (2) by contributing to brand preference.

Brand Familiarity and the Evoked Set

Wright and Barbour (1975) list three stages of a consumer decision - defining the pool of alternatives, reviewing relevant information in memory and applying a decision rule. The pool of alternatives has been referred to as an evoked or consideration set (Howard and Sheth 1969; Urban 1975). Evidence suggests that while consumers may have knowledge of a large number of brands in a product class, they may consider only a few of these for purchase on any particular occasion Bettman and Park 1980; Lussier and Olshavsky 1979). The composition of such an evoked set has important influences on subsequent probabilities of brand choice. First, a brand that is not considered cannot be chosen. Further, probability of choice is a function of both the number and nature of the other brands included in the evoked set (e.g., agenda effects, Tversky 1972). It is, therefore, important to examine in some detail factors that determine inclusion of a brand in the consumer's evoked set.

Brands can be included in an evoked set either by being recognized in the environment (in the case of a stimulus-based choice) or by being recalled from memory (in the

case of memory-based choice; Bettman 1979; Lynch and Srull 1982). In both instances, the cues available to the consumer could determine the set of brands considered for choice. The traditional role ascribed to brand familiarity in such instances may be summarized in the following propositions:

PROPOSITION 1: In stimulus-based choice situations, brand familiarity enables quicker and easier perceptual identification of a brand and, therefore, facilitates inclusion in the evoked set.

PROPOSITION 2: In memory-based choice situations, brand familiarity increases the probability of a brand being recalled and, therefore, facilitates inclusion in the evoked set.

In the following sections we shall examine these propositions in greater detail.

Brand Recognition

Simple item familiarity, or strength, is no longer widely accepted as an explanation of recognition in the typical list learning tasks frequently studied by psychologists (see Crowder 1976, ch. 11; Mandler 1981). However, it can be argued that this is because the task requires items to be discriminated on the basis of the context at the time of encoding (i.e., the list in which they occurred). This task does not seem especially relevant for determining which brands will be included in a stimulus-based evoked set. More directly relevant are perceptual identification tasks, such as reading words and naming objects. For instance, word recognition tasks typically present words in some perceptually degraded fashion (e.g., visually masked, extremely brief duration, with missing letters, etc.) and require subjects to read the word aloud or simply indicate whether, or not, it is an actual English word. It seems plausible that the perceptual processes involved in such tasks are quite similar to those involved in quickly scanning a store shelf for brands to consider.

One of the most influential accounts of word recognition has been the logogen model of Morton (1969). This model originally assumed that words are represented by entities, called "logogens," that correspond to the meaning constituents of words (i.e., morphemes). The appropriate logogens must be activated in order for a given word to be identified and each activation lowers the threshold for subsequent activations. These lowered thresholds were intended to account for the fact that previous exposures to a word facilitate later word recognition (referred to as a "priming" effect). Thus, the logogen model provides a natural theoretical basis for brand familiarity on perceptual identification.

A number of recent empirical findings have questioned the validity of the logogen model, however. Morton (1979) found that facilitation occurred only at input. Specifically, if a subject was given the definition of a word and asked to produce the word in response, this did not facilitate later recognition of the word when visually presented. Further, he found that priming in the auditory modality did not generate facilitation in the visual modality. Morton (1979) extended his model by separating the input and output systems and by hypothesizing that the logogens for each modality were independent and distinct.

Recent research has found, however, that priming effects can be even more context-specific. Of special interest is the finding that changes in the surface features of the stimulus, such as upper vs. lower case letters or identical vs. similar pictures of the same object, can significantly reduce the effectiveness of priming (Jacoby and Brooks 1984). This effect is most evident when initial processing is merely perceptual and does not involve naming the stimulus. We suspect that such merely perceptual processing is also more characteristic of advertising exposures. Some authors have interpreted this evidence as supporting the idea that the cognitive procedures in operation during encoding form some part of the memory trace (see Jacoby and Brooks 1984; Kolers and Roediger 1984; Tulving 1984, 1985). Thus, advertising exposures will be most effective if the viewer engages in the same mental operations that will be required at the time of purchase (e.g., comparing brands, recognizing packaging and store displays, etc.).

The above information should not be overinterpreted. There is still considerable evidence that context independent familiarity can affect perceptual identification (again see Jacoby and Brooks 1984). What has been learned from recent research is that this is not the only, or even dominant, source of familiarity effects on perceptual identification. In fact, context independent familiarity may simply be the aggregate result of many context-specific traces. Such context-specific traces may correspond to lower-order logogens (Morton 1979), episodic memories (Jacoby and Brooks 1984; Tulving 1984, 1985), or activation patterns in a distributed memory network (McClelland and Rumelhart 1985).

Brand Recall

Most current accounts of recall postulate that information in memory is accessed via retrieval cues (Crowder 1976). Such cues may originate in the immediate environment, or they may be internally generated by the individual. In general, two types of retrieval cues could render a brand accessible on a particular choice occasion: (1) specific attributes or benefits, and (2) product class cues.

Specific attributes or benefits. Recent research on the usage situation suggests that a large percentage of variance in choice may be accounted for by considering the situation in which the product is purchased or consumed (e.g., Belk 1975; Day, Shocker and Srivastava 1979; Ptacek and Shanteau 1979). Currently, usage situations are believed to influence consumer choice by altering the importance weights of attributes in a multiattribute framework (e.g., Miller and Ginter 1979). In addition to affecting attribute utilities the usage situation exerts an important influence on choice by providing retrieval cues, specific to the situation. A consumer faced with product choice in a usage situation makes use of these retrieval cues to recall and consider brands strongly associated with them. Thus, for the product class of beverages, the usage situation of "lunch" may render the attributes "light" and "refreshing" salient, while the usage situation of "a wild party" may render "mixable with alcohol" and "popularity" salient. In both situations, beverages high on these attributes will be retrieved and included in the evoked set.

As this discussion suggests, whenever situation specific cues trigger retrieval, a general familiarity with the brand may not be as important as familiarity with the brand in that situation. A beverage that is not "light and refreshing" may never be recalled in the context of lunch, although the consumer may be very familiar with it. On the other hand, a beverage with which the consumer is less familiar may have a higher probability of being recalled merely because it is perceived as being light and refreshing. As discussed earlier, the probability of retrieval will then have important influences on the probability of final choice. In many instances then, situation-specific familiarity may exert a greater

influence on probability of choice than brand familiarity in general.

In an exploratory study subjects were given usage situational cues and asked to list the brands that came to mind, within specific product classes. Low correlations were obtained for probability of brand recall across situations, specially when the most salient or familiar brands were excluded from the analysis. The study was replicated across a number of product classes. While one or two major brands (e.g., MacDonalds in the case of restaurants, Coke in the case of non-alcoholic beverages, or Burdines and Sears in the case of stores), tended to be recalled consistently whenever the product class was mentioned, probability of recall of other brands tended to be driven by situational cues. This suggests that except in the case of extremely familiar brands such as Coke, overall brand familiarity may influence recall less than context-specific considerations. Further work is in progress to study the important role of contextual cues on choice (Nedungadi 1985).

Brand familiarity, devoid of context may still play an important role in retrieval in a number of instances. This is most certainly the case in product classes where the usage-situation does not account for large amounts of variance in choice. In addition, cues other than attributes sought often guide retrieval in a purchase context.

Product-class cues. The product class or subcategory to which the brand belongs could serve as a retrieval cue in many instances. A consumer may seek a "fruit juice" to have with a meal or a "soda" to mix with alcohol. Research on categorization processes has established the importance of "prototypicality" as a determinant of the strength of association between a category concept and members of the category (e.g., Rosch 1975; Smith & Medin 1981). Prototypicality of a brand is a measure of how representative the brand is of its product category. Operationally, prototypicality is measured by individuals' ratings of how "good an example" they consider the object of a category. When the product class serves as a retrieval cue, brands that are prototypical are likely to be recalled faster and more often (Nedungadi and Hutchinson 1985; also see Barsalou 1985; Rosch and Mervis 1975). This should lead to a higher probability of inclusion in the evoked set and probably to higher probability of choice.

Research on typicality has examined the influence of overall familiarity on representativeness. Ashcraft (1978) and Malt and Smith (1982) found that typicality increased as exemplars became more familiar. However, Barsalou (1985) compared the relative effects of overall familiarity (subjective estimates of frequency of encounter across all contexts) and context-specific frequency (subjective estimates of the frequency of category instantiation) information on prototypicality ratings and output dominance (frequency of production) of category members. Frequency of instantiation was found to be a better predictor of both prototypicality and output dominance than overall familiarity, across a large number of categories. In addition, an exemplar's similarities to the "average" and the "ideal" members of the category were found to be independently correlated with both measures.

Brand Familiarity and Preference

This section of the paper will explore two processes by which brand familiarity may directly mediate choice behavior through brand preference formation. The first of these processes is the exposure effect which is directly related to Zajonc's (1968) mere exposure hypothesis. The second of these processes is the frequency effect which is derived directly from the automatic frequency counting mechanism proposed by Hasher and Zacks (1984).

In the present section we explore two propositions related to this thesis:

PROPOSITION 3: Brand familiarity generates a positive affective response to the brand that requires no effortful information processing, only brand perception. This affect may serve as an input to brand choice.

PROPOSITION 4: Brand familiarity can directly mediate choice behavior, but only when mediators which are the product of higher level information (i.e., performance attributes) are not available or cannot discriminate between brand alternatives.

The Exposure Effect

Zajonc (1968) has demonstrated that exposure to a stimulus can enhance the liking for that stimulus independently of cognitive evaluations or contextual associations. Basically, this stream of research has demonstrated that affect is a linear function of the logarithm of exposure frequency (see Harrison 1977). So, as exposure to a brand increases affective reactions to the brand become more favorable.

Zajonc takes the extreme position that the exposure effect can mediate liking without increasing subjective recognition, the perception of being more familiar with the stimulus object. Causal path analyses demonstrating significant mediational effects of exposure beyond subjective recognition (Moreland and Zajonc 1977, 1979) and experimental evidence of the effect occurring without subjective recognition (Wilson 1979) provide the supporting evidence for this position (Wilson 1979). The Moreland and Zajonc research, however, has been convincingly critiqued (see Birnbaum and Mellers 1979) and attempts to replicate the Wilson results have failed (Obermiller 1985).

Thus, while there is strong, consistent evidence of an exposure effect mediated by perceived familiarity with the stimulus, there is contradictory evidence regarding the mere exposure hypothesis. The key point for marketers is that subjective familiarity does mediate the exposure effect (Obermiller 1985; Stang 1975; Moreland and Zajonc 1977) and that brand directed attention without elaboration will generate this subjective familiarity (Obermiller 1985; Greenwald and Leavitt 1984).

Potential Causes of Exposure Induced Preference. The cause of the exposure effect is likely to be closely linked with the concept of stimulus habituation (Harrison 1977; Zajonc 1968, 1980; Berlyne 1970). Essentially, novel stimuli generate high levels of arousal that trigger an avoidance response. Repeated exposure decreases arousal, facilitating stimulus habituation, affect formation, and an approach tendency. Therefore, the exposure effect may be considered a very basic, adaptive mechanism that on the basis of prior encounters tells us what is and is not safe to approach. Stimuli which have been encountered many times without ill effects are safer and, hence, more approachable than new, untested stimuli. In a marketing context, this approach may be perceived by consumers as perceived risk or what Obermiller (1985) refers to as uncertainty reduction, a component of perceived risk.

The unique factor in this "persuasion process" is the absence of any required cognitive or contextual elaboration to generate the affective response. The response occurs effortlessly and automatically as a natural consequence of exposure. Cognitive requirements are limited to stimulus-directed focal attention (Greenwald & Leavitt 1984). Thus, the exposure effect may be a product of the automatic processing system (Posner and Snyder 1975; Schiffrin & Schneider 1977; Bargh 1984).

The Frequency Effect

Research by Hasher and Zacks (1984) suggests another process by which brand familiarity may mediate brand preference. It suggests that effects of automatic processing can provide the input to evaluative inferences consumers draw about brands. This research strongly suggests that

an automatic frequency counting mechanism exists in memory. Basically, the mechanism effortlessly provides relative frequency information which can be the basis for consumer inference-making (i.e., "I've seen this more than other brands. It must sell well. It must be good. I'll buy it").

It requires only focal attention to operate and is not facilitated by higher order cognitive processing. This mechanism, like the habituation effect, is adaptive in that it allows individuals to effortlessly assess the subjective probability of one event over another. To differentiate this process from the exposure effect, it will be dubbed "the frequency effect".

Like the habituation process, the automatic accessibility of frequency information is adaptive in that it allows individuals to effortlessly assess the subjective probability of one event over another and to react accordingly. And, like the habituation process, it requires only sufficient attention to generate brand perception to operate.

The key difference between this process and the exposure effect is the cognitive requirement of a deliberate, pre-choice evaluative inference based on the accessed frequency information. The amount of cognitive effort required to generate an evaluation through this process is greater than the exposure effect because it explicitly requires comprehension of the source of the affect (the frequency information) and an evaluative inference derived from that source. The evaluation generated by the exposure effect requires no such inference, only retrieval of affect.

Given this difference, from a marketing point of view the exposure effect may be operative when consumers are completely uninvolved in the decision process, while the latter process may be accurate when consumers are more involved, but either have no substantive information on which to judge alternatives or perceive no difference between alternatives on available information.

Moderators of Brand Familiarity Effects

Empirical research suggests that the duration of attention, not the number of prior exposures facilitates the exposure effect. Crandall (1972) demonstrated an exposure-effect relationship at two exposures when exposure duration potential was 50 minutes. At the other extreme Zajonc, Crandall and Kail (1974) did not find evidence of a significant exposure effect until a frequency of 243 exposures when the exposure duration was a fraction of a second.

Research by Obermiller (1985) suggests that the exposure effect is also facilitated by attentional strength. In this research, a greater average liking for brands occurred when attention towards the stimulus was facilitated rather than distracted. When cognitive elaboration (e.g., stimulus is not only perceived, but is given meaning) of the stimulus was facilitated, however, average liking decreased. Thus, the level of focal attention increases the strength of exposure-induced brand liking, but cognitive elaboration is inhibitory. This finding is consistent with the principle of higher order dominance which asserts that effects of elaboration (e.g., formation of performance beliefs) inhibit effects of focal attention (e.g., effortlessly retrieved affect) on brand evaluation (Greenwald and Leavitt 1984).

In summary, the exposure effect seems to be mediated by attentional duration and attentional level, not the rate of exposure and not by cognitive elaboration of the stimulus. Therefore, if the communication goal is facilitation of the exposure effect, then advertising should be designed to maintain focal attention towards the brand name or package without causing the consumer to negatively elaborate on the message.

In contrast, if the communication goal is facilitation of the frequency effect, then the critical determinant of advertising success is to have more total exposures than the competition. Since the frequency effect operates through the automatic counting mechanism (Hasher and Zacks 1984), attentional strength and duration are irrelevant. Advertisements which are short, but effective in generating sufficient attention to cause brand perception will operationalize this strategy at the minimum cost in advertising dollars.

Attitudinal Versus Choice Effects

Since brand attitude formation does not require explicit interbrand comparisons, the absolute level of affect generated by brand familiarity will directly influence the level of brand liking. Except in the cases of habitual purchase behavior, however, brand choice explicitly requires interbrand comparisons. Thus, the relative level of brand familiarity among brand alternatives is the critical independent variable. The extent of the comparison is dependent on factors such as prior product class knowledge and decision involvement (Bettman 1979; Bettman and Park 1980).

With regard to the exposure effect, the nature of the exposure-frequency function suggests that both absolute and relative effects may be difficult to achieve if the brand(s) involved in the evaluation have high brand familiarity prior to subsequent exposures (Harrison 1977). In these cases, brand position on the frequency-affect curve may be at the asymptote. In the case of brand attitude, increased exposure may not be sufficient to generate a perceivable change in affect. In the case of brand choice, increased exposure may not create greater liking of a brand over an alternative. This suggests that the viability of the exposure effect as a communication goal may be limited to situations where subjective brand familiarity of the advertised brand is not on the asymptote of the frequency-affect curve.

With regard to the frequency effect, perceivable between brand differences in exposure-based habituation is not the issue. Operation of the frequency effect depends only on the recognition that one brand has been seen more than another. The only requirement for an effect on either choice or attitude is that the difference in frequency of exposure between alternatives is large enough to perceive. The required size of this difference as total frequency of exposure increases among all alternatives is an empirical issue (e.g., 5 versus 1 exposure is very noticeable, but is 105 versus 101 exposures perceptible?).

Evidence Directly Relevant to Marketing Applications

If brand familiarity can motivate purchase behavior, then it must be considered to be a viable marketing communications strategy in and of itself. Validation of brand familiarity effects in marketing contexts and the establishment of their limits are prerequisites to strategic applications. Below, evidence relating to marketing applications of brand familiarity is briefly reviewed.

Three early experiments that tested the generalizability of the exposure effect provided the first evidence that brand familiarity can directly mediate consumers' purchase decisions. First, "advertisements" consisting solely of Turkish words were placed in a school newspaper. Exposure frequency mediated attitude toward the words (Zajonc and Rakecki 1969). Second, nonsense syllables were differentially exposed to subjects and subsequently identified with boxes containing nylon stockings. Exposure generated familiarity significantly influenced brand preference and brand choice (Becknell, Wilson and Baird 1963). Finally, posters of fictitious candidates were placed about a university campus in varying frequency. No information other than the candidate names and the contested elected position were on the posters. Students who had seen the posters most fre-

quently were most likely to vote for the most publicized candidates (Stang 1974, in Harrison 1977).

These three studies are important because they demonstrate that (1) brand name familiarity is a sufficient condition to enhance brand attitudes and brand choice and (2) that these effects occur in natural settings. One limiting characteristic of all three studies, however, is that no information was available to form evaluations other than exposure related information. Thus, these experiments support the potential for brand name familiarity based marketing strategies, but they were achieved in informationally sparse decision environments.

Recent studies have attempted to generalize effects of brand name familiarity into decision contexts where other evaluative information is present. Using an advertising format, Moore and Hutchinson (1985), measured subjects' reactions to affective associates to the brand (e.g., advertising background visuals) and levels of brand familiarity. Two days after exposure to advertisements, subjects' reactions to the ads' affective associates were the strongest mediators of brand liking. One week after exposure, however, brand name familiarity ratings were the dominant attitudinal mediator. The pattern of findings strongly suggests that brand name familiarity became the dominant mediator in delay because affective reactions to the ads were forgotten.

In another advertising experiment, subjects were provided brand attribute information, affective associations to the brand, and varying levels of brand name exposure (Baker 1985). Significant effects of brand name familiarity on purchase intention occurred, but like Moore and Hutchinson (1985), only after a week's delay from advertisement exposure. Interestingly, the significant effects of brand name familiarity occurred only when (1) the accessibility of advertisement execution information and brand attribute information was at its lowest level and (2) relative brand name familiarity (brand name familiarity relative to competing brand alternatives) was at its highest level.

Evidence from these two experiments suggests that if meaning is conferred to the stimulus through a complex cognitive process such as attribute belief formation (Lutz 1975) or simple process such as source evaluation (Petty, Cacioppo and Schumann 1983; Sternthal, Dholakia and Leavitt 1978; Holbrook 1978), then the direct effects of brand name familiarity on evaluation will be attenuated. The findings are consistent with the principle of higher order dominance (Greenwald and Leavitt 1984).

On the positive side, both sets of the results also suggest that higher order effects of advertising decay much more rapidly than effects of brand familiarity. This suggests that when information from advertisements are not effortfully integrated into brand memory structures, simple effects such as brand familiarity may dominate advertising-based brand evaluation, especially if there is any significant delay between the time of message exposure and brand evaluation.

Finally, neither the Moore and Hutchinson (1985) nor the Baker (1985) experiments provided evidence to discriminate whether the exposure effect or the frequency effect was the operative brand familiarity based process. Future research must (1) empirically discriminate between these processes and (2) identify the factors that determine which of these processes will be operative in a given situation.

The Viability of Brand Familiarity Based Strategies

Given the evidence to date, it appears that brand familiarity is a viable independent mediator of brand liking and choice, but only in limited decision contexts. If sources of evaluation (i.e., brand attribute beliefs or source credibility) which require greater information processing intensity are not accessible or cannot discriminate between brand alternatives, then brand famil-

ilarity may be a viable marketing communications strategy. Two likely indicators of these types of situations are product class knowledge and decision involvement.

When a consumer has no prior product class knowledge then by definition there can be no memory-based opportunity for higher order knowledge to inhibit the accessibility of exposure-based affect (Greenwald and Leavitt 1984; Bargh 1984). And, if decision involvement is so low that automatically retrieved affect is likely to be the only input into the preference formation process at the point of decision, then facilitation of the exposure effect may be a viable advertising strategy.

If on the other hand, prior knowledge exists and is likely to be accessed and there is sufficient decision involvement to expect cognitive elaboration in the decision process, but there is no perceived difference between brand alternatives on performance dimensions, the facilitation of the frequency effect may be a viable advertising strategy.

Concluding Remark

The thesis explored in this paper is that brand familiarity exerts important effects on brand choice. The magnitude of brand familiarity effects and the processes mediating such effects have received little empirical and theoretical attention. The intent of the present paper was to discuss mechanisms that may account for familiarity effects and to examine the generality of such effects. After examining relevant literature we are led to the conclusion that brand familiarity is a viable, albeit limited, marketing tool for influencing consumer decisions.

Brand familiarity is likely to: 1) Enhance perceptual identification of a brand, 2) increase the probability of inclusion in the evoked set, 3) generate positive affect toward the brand, and 4) motivate purchase behavior. The primary caveat to these conclusions is that brand familiarity effects may be highly context dependent. Specifically, perceptual identification will be impaired if cues present in the environment during purchase do not match those present during previous exposures to the brand. Evoked sets are dependent upon the usage situation and hence, inclusion in the evoked set will be determined more by brand/situation associations than by overall familiarity with the brand. Finally, brand familiarity is unlikely to exert a robust effect on consumers' brand attitudes and decisions when extensive product knowledge is available or when involvement is high.

Footnote

1. Berlyne (1970) theorized that novelty is pleasing, but familiarity is not. This is clearly a direct contradiction of the exposure effect thesis. Berlyne developed a two-factor theory of exposure effects. The first factor is stimulus habituation, which mediates positive affect. The second factor is tedium/irritation and leads to attitude attenuation. Berlyne argues that initial exposure leads to a positive habituation, but continued exposure promotes tedium/irritation, which attenuates affect. This process describes an inverted U-shaped relationship between exposure and affect.

The two factor process explanation is not really inconsistent with the exposure effect. The difference is in factor emphasis, which has led to different framework conceptualizations. Berlyne observed a large effect of tedium/irritation and gave the effect status equal to the habituation effect in his model. Exposure effect supporters view habituation-based affect as the "true" effect and consider situational tedium a moderator of the fact. The position taken in this paper is that the one-factor exposure effect model not only offers the most parsimonious explanation of exposure-based affect, but is also more relevant to explaining advertising exposure effects because:

1. It centers on the relationship between the stimulus and the individual, which is a central marketing concern. Situational irritation is an association to the stimulus, but not a reaction to the stimulus itself.
2. The effect of the tedium/irritation factor is apparently short-lived relative to the effect of familiarity. The temporary nature of irritational effects suggests its role is an exposure effect moderator rather than a central factor in the model.

A MODEL OF CONSUMER MEMORY AND JUDGMENT

Thomas K. Srull, University of Illinois

Abstract

One of the most perplexing problems in advertising research over the past several decades has been a failure to find any consistent relationship between memory for information presented in an ad and product evaluation. A general model of the relationship between recall and judgment is outlined, and several empirical tests of the model are reported.

The purpose of the present paper is to consider carefully the relationship between consumer memory and judgment. Many psychological theories assume implicitly that there should be a close correspondence between the specific facts that can be recalled about an object and any global evaluation that is made of that object. This is true in most theories of attribution, impression formation, and other areas of social judgment. In general, the person is assumed to recall specific episodic events involving the target, and then determine the implications of these events for the judgment to be made. Theorists differ on how elaborate the intervening combinatorial process is hypothesized to be, but there is almost universal agreement that there should be a strong relationship between the evaluative implications of whatever events are recalled and the extremity of any evaluative judgment that is made. The extent of this agreement is so strong that Hastie and Carlston (1980) have referred to this as the "traditional model."

While theorists have been nearly universal in stating what should happen, empirical examinations have painted quite a different picture. For example, there are approximately fifty published experiments in the psychology literature that have examined the relationship between memory and judgment (Hastie and Park 1985). The typical procedure is to present subjects with information, wait for some period of time, and then ask them to recall as much of the information as possible and make some type of judgment of the target. The average evaluative implication of each item recalled is then correlated across subjects with the judgments that are made. Do subjects who recall the most favorable information make the most favorable judgments? Usually not; the correlations described above are invariably quite small, and seldom statistically different from zero.

It is somewhat surprising from current psychological theory that one would ever find such a lack of correspondence between the specific facts that are recalled and the judgments that are made. It is even more surprising how general and robust this finding appears to be. For example, in a classic impression formation study, Anderson and Hubert (1963) provided subjects with trait adjectives. Their essential finding was that there are strong primacy effects in impression formation, but reasonably large recency effects in recall. The authors concluded from this that the impression judgments and memory for the trait adjectives must be independently stored and accessed in memory. In a later study, Dreben, Fiske, and Hastie (1979) replicated these effects, and also found that temporal delays had a large effect on recall but very modest changes in impression ratings. They also concluded from this that there must be some independence between episodic memory and abstract evaluative impressions (see also Riskey 1979).

There is also a long line of persuasion studies that have found a very weak relationship between memory for information in a persuasive communication and attitude formation and attitude change. A good illustration of this is a classic set of studies reported by Greenwald (1968). Subjects were presented with arguments concerning two separate controversial issues. Subjects first received an opinion pretest followed by the presentation of the commu-

nication. Upon reading the communication subjects were asked to write a one-sentence reaction to the main point of the paragraph. Subjects' opinions were again assessed followed by an unexpected recall test. Following a one week interval, the opinion posttest and the recall test were unexpectedly readministered again. Greenwald found no correlation between posttest opinion and retention of communication content at either of the delay intervals. He concluded from this that memory for information in a persuasive communication is not a mediating variable of subject attitude change. A number of other studies are also consistent with this general conclusion (see e.g., Insko 1964; Miller and Campbell 1959; Watts and McGuire 1964). These failures to find the predicted relationship represent the type of concern that led to the "cognitive response" approach to the study of persuasion that is so dominant today.

The same essential conclusion has been reached in the study of attributions of causality. For example, Fiske, Taylor, Etcoff, and Laufer (1979) conducted a series of studies examining whether imagery accounts for the effects of empathy on attributions. No correlation between what was remembered and the attributions that were made was observed in any of these studies. Similar to many other experiments, there was no evidence for any recall-attribution link. Fiske et al. concluded that these results parallel those found in the other domains, a conclusion that has also been reached in more recent reviews (Hastie and Park 1985; Lichtenstein and Srull 1985).

A very similar situation exists in the psychology of advertising (Beattie and Mitchell 1985; Lichtenstein and Srull 1985). Most theorists have assumed that there should be a close correspondence between the specific facts that are recalled about a product and any general evaluative judgment that is made of that product. Because of this, one of the most popular measures of advertising effectiveness is recall. Again, however, the empirical evidence is quite different. There have recently been four separate reviews of the relationship between recall and judgment within an advertising context. In each case, the relationship has been found to be very small, and only in rare cases was it significantly different from zero (Gibson 1983; Ross 1982; Stout 1981; Young 1972).

It is seldom that theory and data stand in such stark contrast. Is it possible for so many theorists to be misguided on such a fundamental issue? It may be possible, but it is also doubtful. In the following sections of the paper, recent advances in cognitive psychology are used to explicate the conditions under which a strong correspondence between memory and judgment should and should not be expected on conceptual grounds. In the process, a general model that can be used to conceptualize the judgment process will be outlined. Several lines of empirical evidence bearing on the model will then be summarized.

The model proposed is based on a more comprehensive theory of information processing developed by Wyer and Srull (1980; 1985). The Wyer and Srull theory is relatively complex and well beyond the scope of the present discussion. However, two aspects of it are of particular importance. First, the theory suggests that the mental representation of product information will often differ as a function of the initial processing objectives of the consumer. The importance of differing mental representations in understanding the recall-judgment relationship will soon become apparent.

The second noteworthy aspect of the Wyer and Srull theory concerns its broad scope. Because it is intended to

trace the flow of information from the initial encoding stage to the final response stage, it makes specific statements about how any given mental representation should be reflected in various performance measures. Although different representations may "look the same" on the basis of some dependent measures (e.g., overall levels of recall) they can be differentiated on the basis of others (e.g., probe reaction time or the types of judgments that are made). As just one example, Lichtenstein and Srull (1986) have used the theory to generate predictions for six separate measures of performance: (1) overall levels of recall, (2) the extremity of evaluative judgments, (3) the relationship between the episodic facts that are recalled and the judgments that are made, (4) serial position order effects in recall, (5) serial position order effects in judgment, and (6) the relationship between spew recall order and judgment. The underlying assumption of this work is that our understanding of the recall-judgment relation will be best advanced by simultaneously considering all six aspects of performance in conjunction with one another.

An additional virtue of the Wyer and Srull theory is that it incorporates the distinction between "retrieval" and "computational" processes. Imagine a consumer is asked, "Is the Ford Thunderbird a luxury automobile?" A retrieval model would suggest that, at least for some people, the answer to such a question has already been determined and stored in memory. Thus, one simply needs to "retrieve" it from memory in order to answer such a question.

In contrast, a computational model would suggest that, at least for some consumers, the answer to such a question has not already been determined. That is, the mental representation of Ford Thunderbird does not contain any propositional knowledge indicating a value along some luxury dimension (or membership in some luxury-related category). In order to answer such a question, one would need to retrieve as much information about the Ford Thunderbird as possible, compare it to one's referent for "luxury automobile," and then "compute" or figure out an answer on the spot. Of course, if one were asked the same question again he/she would no need to re-compute an answer but simply retrieve the previous judgment (Wyer and Srull 1985).

Although the distinction between retrieval and computational processes is not often discussed, a number of researchers in both social cognition (e.g., Allen and Ebbesen 1981; Ebbesen and Allen 1979) and consumer behavior (e.g., Bettman 1979; Burke 1980; Brucks and Mitchell 1981; Mitchell and Smith 1982; Smith, Mitchell, and Meyer 1982) have recently found it to be useful. This distinction turns out to be crucial in understanding when there will and will not be a relationship between recall and judgment. In particular, the model proposed suggests that the consumer's information processing objectives or "goals" are a critical mediating variable that determines the nature of the relationship between recall and judgment. The reason for this is that such processing objectives often determine whether product evaluations have been pre-stored or need to be computed on the spot.

The model postulates that when a consumer acquires ad information with the (implicit or explicit) objective of making an evaluative judgment of the product, the global evaluation will be made at the time of information acquisition and stored in memory separately and independently from the specific episodic facts that are learned. If the consumer is later asked to make a specific judgment, the evaluation will have already been "computed" and will simply be accessed at that time. This is consistent with a large body of literature that suggests self-generated evaluations are much more accessible in memory than externally presented information (Johnson and Raye, 1981; Ostrom, Lingle, Pryor and Geva 1980; Slamecka and Graf 1978). Thus, under these conditions, there is no reason to expect any strong relationship between the specific facts that are recalled and the global evaluation that is made. One can see that this is a very straightforward retrieval model in which the previous judgment and the specific episodic facts on which it is based are independently stored and accessed. It is a process that is consistent with the conceptualizations outlined by Anderson and Hubert (1963) and Dreben et al.

There are occasions in which an alternative process will apply. Specifically, when a person acquires ad information with no specific objective in mind, or only a very general objective such as to comprehend the information being presented, a global evaluation of the product will not be made at the time of information acquisition. Thus, no evaluation will be incorporated into the resulting mental representation. If later asked to make a specific judgment, the consumer will be forced to retrieve the previously acquired information, or some subset of it, and use it as a basis for his/her evaluative judgment of the product. In other words, a judgment will have to be computed on the spot. Under these conditions, a strong relationship would therefore be expected between the global evaluation and the evaluative implications of the information that is recalled.

As an initial test of the model, Lichtenstein and Srull (1985) presented undergraduate students with print ads that: (a) were as complex as possible in the sense that they contained a large amount of attribute information, and (b) pertained to products with which subjects were likely to have little prior familiarity. Three separate stimulus replications were used. Half of the subjects, who participated in what is typically called an on-line processing condition, were told to read the ad with the purpose of forming an evaluation of the product so that they would later be able to judge how desirable it would be relative to other competing brands. The other half, participating in a memory-based processing condition, were told that the ad was written by an undergraduate advertising major. Their task was to read the ad in order to judge how grammatical, coherent, and interesting it was.

After reading the ad, there was either a 5-minute or 48-hour delay. Then subjects were asked to recall as much of the information as possible and make a general evaluative judgment of the product, half of the subjects completing the recall task first and the other half beginning with the judgment task.

The typical way to analyze such data is to have a separate group of subjects rate the evaluative implication of each proposition or "idea unit" in the ad. Then the mean evaluative rating for each proposition recalled by any given subject is determined. These values are then correlated, across subjects, with the product evaluation ratings.

Lichtenstein and Srull found in 12 out of 12 independent comparisons that the correlation between recall and judgment was higher in the memory-based than on-line conditions. Moreover, the correlations in the memory-based conditions were universally large and statistically different from zero. The mean correlation across 12 conditions was .64 in the memory-based condition and .22 in the on-line condition.

More recently Hastie and Park (1985) replicated these effects by using a slightly different paradigm. The on-line condition was very similar to that described earlier. However, for a memory-based condition, they had subjects anticipate making one judgment, but later asked them for a different, unrelated judgment. Across four separate experiments, the average correlation between recall and judgment was .51 in the memory-based condition and .16 in the on-line condition. Srull (1985) also reported several conceptual replications using slightly different orienting tasks.

These findings are very strong and replicate across a variety of laboratories, stimulus sets, content domains, and delay intervals. They suggest that past studies have consistently found only a weak relationship between recall and judgment because subjects have tended to use some type of on-line processing strategy. In the few studies that have included memory-based conditions, however, a strong correspondence between recall and judgment has indeed been found. For example, Sherman, Zehner, Johnson, and Hirt (1983) provided subjects with current information about two historically rival football teams. In one case the goal was to remember the information as well as possible. In

another case, the goal was to form an impression of the potential outcome of an upcoming game between the two teams. Sherman et al. found a very weak relationship between memory for the information and subjects' judgments of the outcome when they had formed their impressions at the time of information acquisition. However, this relationship was quite strong among subjects who had initially been given a memory set. The authors suggest that the "availability" of information in memory will only affect judgments when they are initially unanticipated. A similar finding has recently been reported by Reyes, Thompson, and Bower (1980).

Although the model proposed predicts that the level of correspondence between consumer memory and judgment will vary considerably as a function of the person's initial processing objectives, much more subtle tests of the model are also possible. Srull (1985) reported one experiment that was specifically designed to tap into the intervening processes that are postulated to occur. The presumed difference between a "product evaluation" group (who theoretically are forming their evaluations on-line) and a "comprehension" group (who theoretically are not) is in the amount of computational activity required at the time of judgment. This was tested by examining the amount of time required to make a judgment.

Subjects were presented with a series of 12 print ads. One group was told to read the ads and form an evaluation of each product described. Another group was told to simply comprehend the information presented. The judgment task was then administered either 5 minutes or 48 hours later. The subject sat in front of a computer screen and was probed with "Please rate the desirability of each of the following products." On each of the 12 trials, the screen would display after a rest interval the brand name and a 10-point rating scale, ranging from 0 ("very undesirable") to 9 ("very desirable"). The time interval between stimulus onset and response was recorded on each trial.

The mean reaction time for the product evaluation group was approximately 5 seconds in the 5-minute delay condition, and approximately 6 seconds under the 48-hour delay condition. The mean reaction time for the comprehension group was approximately 10 seconds in the 5-minute delay condition and nearly 20 seconds in the 48-hour delay condition.

The most parsimonious interpretation of these results is that the on-line processing group formed their evaluations of the product at the time of information acquisition. At the time of judgment, they simply needed to access the appropriate evaluation in memory. It took them slightly longer after 48 hours than after 5 minutes. But they were very rapid in both cases. In contrast, the memory-based group must retrieve the episodic facts that were learned, or at least some subset of them, integrate the items that are retrieved into a global evaluative judgment, and finally make an overt response. These subjects took twice as long as the on-line group to make their judgments after 5 minutes, and nearly four times as long after 48 hours.

The most diagnostic test of the process model proposed in the present paper was reported by Lichtenstein and Srull (1985). The experiment was based on the fact that prior retrieval attempts typically aid subsequent recall. For example, consider a group of subjects who attempt to recall information at Time 1 and then again at Time 2. Their performance at Time 2 will generally be better than that of a control group who only recalls at Time 2. This is a very robust phenomenon (see e.g., Modigliani 1976), and it is usually interpreted to mean that prior attempts to recall strengthen the memory traces of the retrieved items.

Lichtenstein and Srull used this phenomenon as a diagnostic tool to determine what information is retrieved from memory under various conditions. Three separate experimental groups were created, each of which was exposed to the same sequence of print ads. One hour after receiving the ad information, one third of the subjects attempted to

recall the information in as much detail as possible. Then, after a 48 hour delay, they tried to recall the information again. A second group made a global evaluative judgment after one hour. Then, after a 48 hour delay, they also tried to recall the information in as much detail as possible. Finally, as a control condition, one third of the subjects were not asked to complete any task after one hour but were asked to recall as much of the original information, in as much detail as possible, after 48 hours. The dependent variable of theoretical interest is the number of attribute units recalled by subjects after 48 hours.

One can consider the group that had no intervening task as a baseline control condition. Lichtenstein and Srull report that levels of recall were essentially the same for on-line and memory-based subjects in this condition. However, subjects who recalled after one hour showed much higher levels of recall after 48 hours than did the control subjects, providing a replication of earlier findings reported in the literature. Moreover, this was true for both the on-line and memory-based subjects and, as before, there was very little difference between them in terms of overall levels of recall.

The most important condition in terms of the underlying theory is that where intervening judgments were made after a one hour delay. The model suggests that memory-based subjects will need to retrieve the original information in order to make such a judgment. If this is true, the same type of recall advantage after 48 hours as is seen with the "recall" group should be observed. In other words, the model suggests that the ultimate recall of memory-based subjects in the "intervening judgment" condition should be: (a) greater than that in the "no intervening activity" condition, and (b) not significantly different than that in the "intervening recall" condition. This is exactly what was found.

The model also makes specific predictions about the on-line subjects in the "intervening judgment" condition. The model suggests that the on-line subjects will have already formed the evaluation at the time of information acquisition. Thus, after one hour, they need not review the original information in order to make the judgment, but simply retrieve their original evaluation from memory. If this process occurs, however, the ultimate memory performance of such subjects should not be as great as that of subjects in the "intervening recall" condition. This was also found.

The results of this experiment are subtle and provide strong converging evidence in support of the model proposed. The fact that intervening product evaluations increase levels of recall (compared to a no-intervening-task control group) for memory-based subjects but not for on-line subjects is difficult to explain without postulating different retrieval mechanisms.

One of the most perplexing problems in advertising research over the past several decades has been the general failure to find any consistent relationship between memory for information presented in an ad and product evaluation. These failures have been met with surprise, discouragement, and some have even used them to question why researchers need to be concerned with memory processes in the first place. The research presented here should help to frame the problem in a somewhat new perspective.

There are three assumptions that are central to the present approach. First, it is assumed that different types of mental representations can only be distinguished by simultaneously examining different aspects of performance. The reason for this is that different underlying representations will often react to experimental manipulations in the same way. Thus, they may appear to be the same even though they are not. In one study reported by Lichtenstein and Srull (1985), for example, the overall levels of recall and the overall levels of judgment were identical for on-line and memory-based subjects. It is only by looking at a range of measures that one can discover con-

verging evidence for how the underlying mental representations must be different from one another.

The second assumption is that theories must be developed to the point at which they have implications for multiple dependent measures if they are going to be distinguishable empirically (see Srull 1984). While plausible alternative interpretations of any single effect can be numerous, building alternative, internally-consistent theories that are capable of accounting for a large array of data is much more difficult. Moreover, even when such alternative accounts are devised, subsequent attempts to distinguish between them are nearly certain to produce substantial theoretical growth (see Srull and Wyer 1984 for an elaboration of this point).

Finally, the model outlined in the present paper is a very general one, within which a variety of more specific theoretical commitments can be made. For example, the exact format of knowledge representation has been left unspecified in the present report. Similarly, there is no commitment to a particular type of retrieval process. At this level of analysis, for these purposes, such commitments are unnecessary. However, as new constraints are added to the model, more sensitive predictions will emerge. Future work should be directed toward examining some of the more subtle implications of the model that emerge when a more specific set of theoretical assumptions are imposed.

UNDERSTANDING YOUNG CONSUMERS:
COGNITIVE ABILITIES AND TASK CONDITIONS

Deborah Roedder John, University of Wisconsin-Madison

Abstract

Over a decade of research has been devoted to assessing the extent to which children can understand advertising messages and product claims, evaluate and judge product alternatives, and make informed product choices. The majority of studies in this area have focused on the issue of whether or not children are able to perform consumer tasks such as evaluating advertising and judging advertised products. In doing so, evidence has accumulated which supports the view that many children, particularly young children, cannot critically evaluate advertising claims and advertised products, cannot direct their attention to important aspects of commercial messages, cannot adequately judge the value of product alternatives, and cannot use product information effectively in making product choices. Findings such as these have contributed to our understanding of children's consumer abilities and have also provided valuable input into public policy concerns regarding children.

Despite the contributions of this line of inquiry, current research in developmental psychology suggests that we should shift our research focus from the question of whether or not children have certain abilities to the issue of when children can be expected to exhibit these abilities. This view is supported by a large body of developmental research which documents the fact that children's abilities are seldom exhibited in an all-or-none fashion--children perform well under some task conditions but not others. In consumer settings, for example, children's ability to understand advertising claims may depend on the terminology used to describe the claim and the amount of commercial time devoted to describing the claim.

By failing to investigate potential factors such as these which may affect children's performance, it is quite possible that we have either underestimated or overestimated children's consumer skills and abilities. This possibility is particularly unsettling due to the fact that past results regarding children's abilities have been the cornerstone for regulatory policies toward marketing to children. Thus, there is a need to extend our scope of investigation beyond the current focus to one which includes a consideration of conditions under which children's abilities can be expected to surface.

This paper examines several classes of factors or conditions which have the potential to influence children's consumer abilities. Based on recent findings from developmental psychology, four types of task factors appear to be influential in this regard: information quantity, information format, instruction set, and response format. Information quantity refers to the number of informational units or chunks that must be processed in completing some task. Large amounts of information are typically more demanding and require more processing skill. Information format pertains to the manner in which task-relevant information is presented. Some formats are more conducive to processing information than others. Instruction sets refer to instructions or directions given to subjects regarding task performance. Instruction sets often provide guidance and suggest strategies to enhance performance on the task. Finally, response format pertains to the manner in which subjects are required to respond to the task. Some methods for measuring performance place greater processing burdens on subjects than others. Evidence pertaining to each of these factors is reviewed and implications for future research are identified.

THE IMPACT OF TASK CONDITIONS ON YOUNG CHILDREN'S PERFORMANCE

M. Carole Macklin, University of Cincinnati

Abstract

Every researcher working with children has observed that an average 7-year old is cognitively more mature than the average 4-year old. In recent years, however, developmental psychologists have increasingly recognized the negative slant of traditional research depicting the cognitive abilities of preschoolers. Gelman (1978) argued that the developmental literature is biased by descriptions of what young children cannot do. The younger child typically appears incompetent when stacked up against the older child.

An underlying reason for this slant emanated from the field's reliance on Piagetian research. A distinguishing characteristic of Piaget's procedures, both his instructions and elicited responses, was their highly verbal nature. For example, tasks designed to assess a child's understanding of conservation were filtered through such words as "same," "less," "more," and "number." Preschoolers allegedly failed to conserve; namely, they focused on the states of objects rather than on the transformations linking the states. Thus, young children did not realize that some quantitative property of an object did not change by a change in perceptual appearance.

With Piaget's number conservation task, young children believed that the number of objects in a row changed when the items were pulled together or spread apart. Gelman (1972) developed a more age-appropriate task that eliminated such ambiguous (at least to the preschooler) terms as, "number," "more," and "less." Displays of values, for example, 2 and 3, were labeled with the words "the winner" and "the loser." The child had to find the winner and tell why one value was so labeled. Further, when the experimenter altered one of the displays, such as by addition, and the child was queried about the transformation. The results from the "magic task" indicated that preschoolers understood that the lengthening or shortening of an array did not change the numerical value.

Piaget also believed that the young child is necessarily egocentric, meaning the child interprets the world in terms of self. For example, in a communications task, children were labeled egocentric because they could not repeat explanations about the workings of watertaps. Shatz and Gelman (1973) argued that the difficulty of the task might prohibit the child's ability to account for the listener's needs. That is, the failure was not due to language insufficiency and/or narrow perspective-taking, but because of task complexity requiring discussion about an unfamiliar object. These researchers asked preschoolers to describe the workings of a toy. Children tailored their speech appropriately; indeed 4-year-olds altered the complexity of syntax and the content of the messages when talking to 2-year-olds versus adults. Thus, young children were shown not be necessarily egocentric communicators.

Therefore, two Piagetian conclusions about the young child were successfully challenged: 1) a failure to conserve and 2) to interpret the world beyond self. Those challenges, briefly illustrated by the preceding examples, suggested the importance of task difficulty, task instructions, and required responses for successful completion. All three factors influence outcomes and subsequent conclusions about the child.

The Piagetian influence has been likewise felt in applied research. Adopting this framework, early researchers on advertising effects found that children's responses meshed with Piaget's stage-like view of

development. One important conclusion about the young child was that he/she did not understand the persuasive intent of television commercials. The conclusion about children's lack of commercial understanding was based on numerous studies that incorporated the stage perspective (e.g., Blatt, Spencer, and Ward 1972). Early works relied upon open-ended questioning to assess abilities. The reader can surmise the limitation of this approach. As developmental psychologists discovered, tasks requiring mature expository skills are slanted towards the older child's success and the younger child's failure.

Advertising researchers have begun to acknowledge the limitation of survey techniques; however, preliminary evidence with other types of techniques indicates that much work is needed to determine the appropriateness of tasks for measuring children's responses. Donohue, Henke, and Donohue (1980) reported results from a picture selection task which indicated 2- and 3-year olds understood commercial intent when asked to pick one of two sketches. Macklin (1985) reported a failure to replicate such indications when the alternatives were widened to include additional product display. It was argued that the original task may have been simply too easy, and that other types of nonverbal measures are needed.

The necessity of multiple measures of commercial understanding is straightforward and reinforces what developmental psychologists have found about the child. Namely, the appropriateness of the task in terms of design, instructions, and required responses affect assessment of children's abilities. Not just one task nor just one measure of abilities can be expected to be definitive of children's skills. Just as children's abilities to conserve quantity or to assume the perspective of another are determined by multiple efforts, an accurate view of children's processing of commercials will require multiple approaches. Advertising researchers must be prepared to provide a converging web of evidence about children's skills in an advertising context.

CHILDREN'S COGNITIVE RESPONSES TO ADVERTISING¹

Merrie Brucks, University of North Carolina
Marvin E. Goldberg, McGill University
Gary M. Armstrong, University of North Carolina

Abstract

We advocate a cognitive response approach for researching children's reactions to advertisements. We suggest that the factors especially likely to influence children's use of cognitive defenses include state of cognitive development, knowledge about advertising, knowledge about the product, spontaneous information processing abilities, emotional involvement with the ad or product being advertised, and verbal ability. Each of these factors and its hypothesized relationship to children's counterarguing is discussed.

Introduction

The long debate over the fairness of television advertising to children hinges on whether advertising messages unfairly manipulate children. To address this issue, researchers have explored the extent of children's "cognitive defenses," generally defined as children's knowledge of the selling intent of commercials and an associated distrust of commercials. But the fact that cognitive defenses exist does not mean that children actually use these defenses when exposed to advertising. We advocate a cognitive response approach for researching children's actual use of cognitive defenses.

Prior Research on Children's Cognitive Defenses

Much research has examined children's acquisition of "cognitive defenses," or more specifically, comprehension of the selling intent of advertising (e.g., Donohue, Henke, and Donohue 1980; Rossiter and Robertson 1974; Ward, Wackman, and Wartella 1977). It appears that most children do not develop a conceptual understanding of the selling intent of advertising until at least 8 years of age. Full comprehension may not occur until 11 years of age. However, it should be noted that research findings concerning the age at which these cognitive defenses are acquired differ, depending on the researcher's definition and operationalization of cognitive defenses. (See Goldberg and Gorn 1983; Roberts and Bachen 1981; and Wartella 1984 for reviews of this literature).

The existence of cognitive defenses does not mean that children actually use these defenses when they are confronted with advertising. To address this issue, several studies have examined children's judgments and preferences as a function of viewing television commercials. These studies suggest that children do not use their generalized understanding of selling intent as a cognitive defense in many situations.

In one study, Ross et al. (1981a) assessed the accuracy of judgment of children from kindergarten to sixth grade regarding the presence of actual fruit in three types of cereals and beverages advertised on television: "real fruit"; "non-fruit" and "artificially fruit-flavored" products. Showing the children these commercials resulted in greater accuracy (regarding the presence of actual fruit) in the "real fruit" and "non-fruit" conditions but greater inaccuracy for the artificially fruit-flavored product condition. These effects were noted regardless of age. The authors concluded that the strategies employed in the commercials for artificially flavored products appeared to overwhelm children's

growing general skepticism, resulting in miscomprehension of the messages.

Similarly Ross et al. (1981b) reasoned that if an understanding of the selling intent and strategies of commercials and a corollary distrust of them is sufficient "defense", older children should be less influenced by extraneous information in a commercial, such as the use of a racing car celebrity or real racing footage in selling a toy racing car. In fact, manipulating the presence or absence of these extraneous factors in commercials shown to older and younger boys resulted in a main exposure effect: the celebrity endorser and real racing footage were effective regardless of age of the boys. No interactions were noted. Older children were no more accurate than younger children in processing the extraneous information presented in the commercials. The researchers concluded that, at least in this television viewing situation, the older children failed to employ the television-related cognitive defenses they may have acquired.

Another study suggests that commercials may cause children to act inconsistently with their established set of preferences (Roedder, Sternthal, and Calder 1983). This study indicated that fourth grade children may respond solely to the momentary influence of a commercial when making product choices, ignoring their prior product preferences. By eighth grade, children appear to select their preferred alternative regardless of advertising. These results may be interpreted as evidence of an "overwhelming" effect of advertising on young children.

To examine the use of cognitive defenses acquired through consumer education, Roberts et al. (1980) showed children an instructional film, which was designed to teach children to adopt a more analytical/critical perspective when viewing TV commercials. A control group saw an irrelevant film. Several days later the researchers returned to show children some commercials. In order to assess the effectiveness of the instructional film, they posed questions to the children regarding each commercial they saw. For example, for a commercial with Bill Cosby endorsing Jello, they asked: "Does Bill Cosby know more about Jello than most people? (Responses could vary along a 4 point scale). Results showed that children who viewed the instructional film were more skeptical than those who viewed the control film. However, this approach begs the question as to whether the issue (in this instance, of celebrity endorsers) was actually salient for the children as they watched the commercials. Specifically, a child who indicated skepticism about Bill Cosby's expertise in response to the researchers' questions may not have questioned Cosby's expertise while viewing the Jello commercial. More generally, we contend that research that poses direct questions to a child may evoke in the child a vigilant, critical orientation, regardless of whether this orientation existed prior to questioning.

In the Roberts et al. (1980) study, larger differences between control and experimental groups were found for the younger as opposed to the older children. Older children in the control groups provided responses skeptical of the commercials even in the absence of the training film. It may be, however, that all we can safely conclude from this type of direct question is that as children grow older (at least by age 11) they learn to give socially "correct" responses:

¹This research was partially supported by a grant from the Business Foundation of North Carolina through the University of North Carolina.

Children's increasingly negative attitudes toward TV advertising do not mean much...they merely acquire an adult-like attitude against TV advertising as a social institution; an attitude which bears little relationship to advertising's actual effects (Rossiter, 1979, p. 232).

The Role for Cognitive Response Measures

The evidence available suggests that "going into" a commercial viewing situation children have a generalized awareness of the selling intent of commercials. Yet there is also evidence that "coming away" from a commercial, children tend to manifest attitudes and behavior suggesting that any generalized awareness has not operated as an effective defensive mechanism. What appears to be missing is evidence of children's actual cognitive experience while watching commercials. What thought processes do children engage in during the TV viewing situation? To what extent and under what conditions do they generate the counterarguments that would be the main substance of a cognitive defense? Moreover do attempts to teach children to adopt an analytical/critical perspective (as with the instructional film in the Roberts et al. 1980 study) succeed in generating counterarguments? Cognitive response measures (responses to a probe such as "What thoughts and feelings were going through your mind as you watched the commercial?") would appear to be an ideal measure in this regard. Counterarguments, which require using prior knowledge to "argue" against implicit and explicit advertising messages, indicate the actual use of cognitive defenses. Other elaborative cognitive responses include support arguments, which are thoughts in favor of advertising messages, and source derogations, which are thoughts critical of advertisers or advertisements (Wright 1973).

Cognitive response measures avoid the potential biasing effect of overly direct questions, and provide data that are directly pertinent to the ongoing processing of information. These data may complement the more inferential findings reviewed above (i.e., Roberts et al. 1980; Roedder, Sternthal, and Calder 1983; Ross et al. 1981a,b).

Some researchers have suggested that cognitive response measures may not fully capture a child's thoughts because children cannot always articulate what they think (e.g., Calder, Robertson, and Rossiter 1976). On the other hand, other researchers contend that cognitive response measures may be the most valid indicator of a child's capacity to defend himself/herself against persuasive TV messages, that unless the child can articulate a concept, he or she cannot really understand it.

...language and cognition are closely related. Without words a child cannot escape from his or her own egocentrism; he or she cannot grapple with concepts as opposed to merely feeling emotions. More specifically the message in advertising (persuasion, selling) cannot be understood or defended against without the use of language (Geis, as cited in FTC, 1981, p. 29; emphasis added).

Factors Affecting Childrens Cognitive Responses

What conditions are most likely to facilitate the use of cognitive defenses by children? We might assume that the situational and source factors found to be related to counterarguing in adults (e.g., time pressure, source credibility, etc.) will also be related to counterarguing in children. More interesting, perhaps, are individual factors (e.g., knowledge, involvement), which usually differ widely between the adult and child context.

Specifically, we suggest that the factors especially likely to influence children's use of cognitive defenses when exposed to advertising include stage of cognitive

development, knowledge about advertising, knowledge about the product, spontaneous information processing abilities, emotional involvement with the ad or product being advertised, and verbal ability.

Stage of Cognitive Development

The traditional cognitive development approaches view progress in children's cognitive skills as a series of stages through which children pass as they grow from infancy to adulthood. Piaget's theory is the best known of the stage theories. (See Flavell 1963, Piaget 1983, Piaget and Inhelder 1969). According to this theory, cognitive development occurs in four main stages: the sensorimotor stage (0-2 years), the preoperational stage (2-7 years), the concrete operational stage (7-11 years), and the formal operational stage (11 through 15 years).

In the sensorimotor stage, the infant's behavior is not at all mediated by thought. In the preoperational stage, the child develops the ability to think in terms of symbols (language and mental imagery), but has poorly organized ways of thinking about objects, events, and ideas. The preoperational child tends to focus on dominant perceptual attributes of objects (e.g., height) while ignoring other attributes (e.g., width). Thought is guided almost entirely by the perceptual characteristics of the immediate environment. Thus it is highly unlikely that elaborative cognitive responses to advertising messages would occur in this stage.

In the concrete operational stage, the child may consider several attributes of an object simultaneously. The child has conceptual skills that allow effective cognitive mediation of perceptual activity, but these thoughts are generally limited to the domain of concrete objects. In contrast, in the formal operational stage, the individual's thoughts may be guided by abstractions (e.g. theories, values, and ideas) that are not directly related to the child's perception of the physical environment. It appears likely that individuals in the formal operational stage would be able to draw upon prior knowledge to generate elaborative cognitive responses.

The question remains, however, whether 7 to 11 year olds (concrete operational stage) are capable of elaborative cognitive responses. Based on Piaget's theory, one might expect concrete operational children to produce elaborative cognitive responses only when concrete knowledge of the product exists in memory. For example, when viewing a commercial for a robot toy that uses closeups to make the toy look bigger, a child who knows the toy is only 6 inches tall may think "They're not that big." In the absence of such product knowledge, however, the child may be unable to apply the abstract concept that advertising is biased (and uses special techniques to show products in the best possible light) in order to generate the counterargument, "It may not be very big." The hypothesis that product knowledge (which is relatively concrete) is more effective in the concrete operational stage than advertising knowledge (which is more abstract) in producing elaborative cognitive responses in children has yet to be empirically tested.

Although Piaget's theory has proved useful in describing age-related cognitive activities, it lacks sufficient mechanistic detail to explain what causes these age-related differences (Roedder 1981). The information processing perspective suggests that age differences in children's cognitive activities result from differing abilities to store and retrieve information. Based on an extensive review of the children's information processing literature, Roedder (1981) proposed three stages of development: limited, cued, and strategic processing. Limited processors do not have the capability to use storage and retrieval strategies as a means for processing information. Cued processors do not spontaneously use such strategies, but they can do so when

prompted or cued. Strategic processors possess and use the skills necessary to store and retrieve information. The ages associated with these stages depend on the cognitive activities involved. For the latest-developing activity, the allocation of attentional effort to central rather than incidental material, the suggested ages are: limited, under 8 years of age; cued, 8-12 years; and strategic, 13 years of age and older. Thus, we may not expect children to be fully able to focus attention on important message arguments and spontaneously counterargue until they are 13 years old. Children 8 to 12 years old may need prompting to focus their attention and to counterargue, while children under 8 may be incapable of doing so at all. Thus, Roedder's theory leads to an empirically testable hypothesis regarding the effect of cueing or prompting on elaborative cognitive responses in the three stages. Specifically, cueing should improve children's use of cognitive response strategies in the middle age group, but it should have little or no effect in the youngest and oldest age group.

The view that post-infancy changes in cognitive activities are "fundamental, qualitative, and stage-like" has been increasingly questioned in recent years (Flavell 1985). The alternative view is that children make continuous progress in their cognitive activities. If this is true, then the role of stage theories like Roedder's and Piaget's is to simplify communication, rather than to provide an accurate description of developmental progress.

Whether or not progress occurs in stages, it is well-documented that children become more and more adept at information processing activities as they grow older. But is this increased facility for cognitive activities due to biological development or can it be explained by other factors? It has been argued that the acquisition of knowledge, rather than age itself, causes the observed increase in facility for information processing (Chi 1981, Flavell 1985).

This distinction is particularly important regarding the public policy issue of advertising to children. If children's ability to defend themselves against persuasive attempts can be substantially affected by acquiring knowledge, then consumer education for children is a potentially useful option. On the other hand, if children's ability to defend themselves against persuasive attempts is blocked by age, then protective regulations may be appropriate. In the next section of the paper, we discuss children's knowledge and its role in cognitive responses.

Children's Knowledge

As children develop, they acquire factual and conceptual knowledge about themselves and the world around them. This is termed "declarative knowledge." In an advertising context, the relevant aspects of declarative knowledge are knowledge about the product being advertised and knowledge about advertising in general. Children also acquire "procedural knowledge", knowledge about how to solve problems and accomplish tasks. In this context, the relevant aspect of procedural knowledge is knowledge of elaborative cognitive responses as a strategy for processing advertising messages. Children must have both declarative and procedural knowledge in order to form cognitive elaborations in response to advertising.

Based on a review of research in cognitive development and cognitive psychology, Siegler (1983) suggested several conclusions about the effects of a child's knowledge on information processing activities. First, knowledge influences the recall of newly presented material. Second, memory improves during periods of development in which there is little improvement in procedural knowledge but substantial improvement in declarative knowledge. Third, age-related differences in measures of basic capacities and information processing strategies may be attributable to changes in declarative

knowledge. Fourth, in some circumstances, differences in declarative knowledge outweigh all other age-related differences.

Product Knowledge. It has been shown that product knowledge facilitates cognitive responses in adults (Edell and Mitchell 1978). However, empirical research on the role of product knowledge on children's cognitive responses to advertising has not been published (although at least one study is currently underway (Costley 1985)). In the light of Siegler's conclusions, it is likely that Edell and Mitchell's results will extend to children as well as adults.

Advertising Knowledge. Much research has been conducted on children's knowledge of the purpose of advertising. The implicit assumption is that children who know that advertising is a biased source will critically evaluate advertising messages, and thus be no more persuasible than adults. Roberts (1982) suggests that children must understand four concepts about advertising before their advertising knowledge can provide them with a usable cognitive defense. Children must recognize (1) that the advertiser and viewer have different perspectives and interests; (2) that the advertiser intends to persuade; (3) that all persuasive messages are necessarily biased; and (4) that biased messages demand different interpretation strategies that do informational, educational, or entertainment-oriented messages. Note that this last concept is procedural rather than declarative knowledge. Roberts further suggests that all four aspects of knowledge typically do not occur until age 10 to 11. Earlier research suggested that children "understand" the persuasive intent of advertising by 7 or 8 (Wartella 1984), but this research generally considered only the first one or two of these four advertising concepts.

The role of advertising knowledge is different from the role of product knowledge in affecting children's cognitive responses to advertising messages. Product knowledge provides a reference point with which to compare information provided in advertising. For example, a child with prior knowledge of Auto-bots who sees close-ups of Auto-bots in a TV commercial may think "Auto-bots aren't really that big." Advertising knowledge, on the other hand, alerts the child to the possibility of hyperbole, puffery, and exaggeration. Advertising knowledge might elicit a cognitive response like, "There they go again, using special techniques to make a product look bigger than it really is."

Procedural Knowledge. As Roberts (1982) implied, procedural knowledge is necessary in order for declarative knowledge to have an effect on cognitive responses. If a child does not know how to critically evaluate messages, then his or her store of declarative knowledge cannot be used. Unfortunately, it seems difficult to instill procedural knowledge about information processing strategies in children. For example, in one study, young children were taught the mnemonic strategy of verbal rehearsal, but used it only when told to do so (Keeney, Cannizzo, and Flavell 1967). This finding has been replicated under a number of conditions (Flavell 1985). This robust finding led Roedder (1981) to define a class of "cued-processors," children who do not use sophisticated information processing strategies spontaneously. In order to provide cued processors with an adequate cognitive defense it may be necessary to provide a cue (perhaps in the form of a public service announcement) during children's TV viewing hours in order to remind them to adopt a critical processing strategy.

It has yet to be empirically determined at what ages children become capable of producing elaborative cognitive responses under cued conditions. Below this age, children are incapable of cognitive responses even if they do have product knowledge and know the selling intent of advertising, since they lack the necessary procedural knowledge. Eventually, children become capable of spontaneous cognitive responses, but this age, too, remains to be empirically determined.

The term "involvement" has come to mean several different but related concepts. In this paper, involvement means degree of "personal relevance" of the message or consequences (Petty, Caccioppo, and Schumann 1983). Petty and Caccioppo (1981) proposed the Elaboration Likelihood Model as a way to understand the effects of involvement on attitude change in adults. This model contends that "as an issue or product increases in personal relevance or consequences, it becomes more important and adaptive to forming a reasoned and veridical opinion. Thus, people are more motivated to devote cognitive effort required to evaluate the true merits of an issue or product when involvement is high rather than low." If this adult model is also appropriate for children, we would hypothesize that children will produce more elaborative cognitive responses when a commercial is personally relevant than when a commercial is not relevant.

We might imagine, however, that children (particularly very young children) might not be motivated to form a "reasoned and veridical" opinion when an advertised product is personally relevant to them, say, for example, Cabbage Patch dolls or Transformers for 9 year old girls and boys, respectively. Casual observation suggests that emotional reactions dominate reasoned and veridical thinking in such situations. In fact, the relationship between level of involvement and number of elaborative cognitive responses may be negative if affective reactions replace cognitive reactions. One might speculate that children need experience with budget constraints and purchasing in general in order to understand the importance of carefully considering purchase alternatives. Thus, we hypothesize that the ELM model does not extend to young children. Specifically, high involvement results in equal or fewer elaborative cognitive responses than low involvement.² This hypothesis remains to be empirically tested. If true, further research on what factors affect the child's transition to the adult model would be interesting and important.

Verbal Ability

It is believed that verbal ability affects the measurement of cognitive responses in adults (Wright 1980). Children display a much wider variance in verbal ability than do adults, most obviously between age groups, but within age groups as well. Thus, it is argued that verbal ability is a particularly important factor to control for in studies of children's cognitive responses. Alternatively, it may be insightful to assess the degree of convergence between level of verbal ability and extent of counterarguing.

Summary and Conclusion

We have argued that cognitive responses are an appropriate measure of the use of children's cognitive defenses to advertising. The individual factors believed to moderate the use of cognitive responses in this context are stage of cognitive development, knowledge about products, knowledge about advertising, knowledge about how to process biased information, degree of involvement, and verbal ability.

²Note, however, that this hypothesis is dependent on the "personal relevance" definition of involvement. According to Batra and Ray (1983), lack of cognitive response is associated with low involvement by definition.

CHASING THE WUNDT CURVE:
AN ADVENTURE IN CONSUMER ESTHETICS

Punam Anand, New York University
Morris B. Holbrook, Columbia University¹

Abstract

This paper provides a brief progress report on research investigating the effects of musical tempo on perceived activity and affect. After introducing some key issues, we describe our experimental procedures and report preliminary support for (1) a logarithmic or power function relating tempo to perceived activity, (2) a nonmonotonic Wundt curve relating perceived activity to affect, and (3) a shift in this Wundt curve in response to a change in arousal. We conclude with a discussion of remaining issues that deserve investigation.

Introduction

Many marketers and designers of advertisements have traditionally employed music in their programs to encourage consumer purchasing and to enhance persuasiveness. In particular, music has been used to improve store image (Milliman 1982) and to increase message acceptance (Galizio and Hendrick 1972). Despite the widespread use of music, research documenting its effects has remained limited. One reason for this gap in the literature is that the study of music as a form of communication poses several difficulties. The term "music" denotes a wide range of stimuli (for example, pitch, frequency, density, modality, and tempo) that hang together in an extremely complex gestalt. One pulls apart this gestalt only at one's peril. Nevertheless, through the isolation of individual variables, some provocative findings have begun to emerge. Our general impression is that such findings have appeared most frequently and reliably in work exploring the effects of tempo on perceived activity and affect.

Zimny and Weidenfeller (1963) measured subjects' heart rate and skin resistance to three pieces of music, found that faster music decreased skin resistance, but detected no such changes for neutral or calming music. They interpreted their data as indicating that more exciting music produces an increase in physiological arousal. Similarly, Seidman (1981) found that fast music tends to elicit happiness and excitement, whereas slow music tends to elicit more somber moods such as calmness and sadness. However, there is some evidence that fast tempos may also have debilitating effects. Wakshlag, Reitz, and Zillmann (1982) found that, although faster background music increased selective exposure to an educational program, slower music yielded less decrease in visual attention and information acquisition. In an applied setting, Milliman (1982) found that slower background music resulted in longer in-store traffic flow and increased sales volume.

In the field of consumer research, several studies have shown effects of musical tempo on perceived activity (e.g., Holbrook 1982, 1983; Holbrook and Huber 1983, Huber and Holbrook 1979) and of tempo or perceived activity on affect (e.g., Holbrook 1981, 1983; Holbrook and Corfman 1985; Huber and Holbrook 1980). However, most of the effects reported in the consumer literature have been only directional (e.g., perceptual responses to two levels of tempo) or linear (e.g., affective responses to a range of perceived activity). Yet these linear monotonic effects inadequately represent the underlying theory from conventional psychophysics positing a logarithmic relation between tempo and perceived activity (Fechner 1860, Stevens 1975). Moreover, linear or

¹The second author gratefully acknowledges the support of the Columbia Business School's Faculty Research Fund.

monotonic relationships may seriously distort the nonmonotonic impact of perceived activity on affect (Wundt 1874) described by psychobiologists (e.g., Berlyne 1971, 1974). Both these aspects of the work on musical tempo in consumer esthetics therefore require repair. In addition, further aspects of the effects of tempo deserve exploration.

Tempo and Perceived Activity

Briefly, psychophysics is concerned with the quantitative measurement of sensation. Fechner's Law (1860), modeling the relationship between the strength of an external stimulus and subjective impressions of intensity, is an extension of Weber's Law (1846). Weber proposed that a fixed percentage must be added to a stimulus in order to produce a just noticeable difference (JND). Fechner assumed that each time the stimulus is increased by one JND, the sensation increases by a constant increment. These assumptions imply that perceived activity is a linear function of the logarithm of tempo. By contrast, Stevens (1975) has argued vehemently that magnitude estimates are related to stimulus intensity by a power law by which equal percentage increases in the stimulus produce equal percentage increases in the response so that (for our purposes) a linear relationship would exist between the logarithm of tempo and the logarithm of perceived activity. Baird and Noma (1978) show that, in accord with the debate between Fechner and Stevens, the relative appropriateness of the logarithmic and power laws depends on whether one measures sensation or perception on an equal-interval or a ratio scale. Hence, when scale properties remain in doubt (as in the present case), the choice of models becomes at least partly an empirical issue. The difference between the logarithmic and power functions appears in Figure 1.

FIGURE 1

PSYCHOPHYSICAL RELATIONSHIP BETWEEN TEMPO AND PERCEIVED ACTIVITY

Perceived Activity and Affect

Abundant evidence connects affect to fluctuations in arousal (Berlyne 1967, 1971, 1974). Stimulus patterns that give rise to very low or very high levels of arousal will be unpleasant, aversive, and disliked, whereas those that lead to moderate arousal levels will be more pleasurable. Given a direct connection between perceived activity and arousal, the resulting relationship should follow the Wundt curve presented in Figure 2.

FIGURE 2

The Moderating Effect of General Arousal

In addition, esthetic theory (Berlyne 1971) also suggests that the nonmonotonic Wundt curve should shift toward the right as general arousal increases (due to changes in the situational context). This hypothesized relationship appears in Figure 3.

FIGURE 3

To test these propositions, we varied the tempo of a piece programmed for a Casio keyboard. This instrument was selected because it permits a carefully controlled and precisely replicable range of speed settings. The fourteen tempo levels ranged from 56.6 beats/minute (the Casio's slowest speed) to 348.3 beats/minute (judged to be faster than any tempo likely to be encountered in everyday experience). In the spirit of Weber's Law, each tempo level was determined by adding a constant percentage increment (15%) to the preceding level. Subjects heard all fourteen different levels of tempo in randomly determined orders (cf. Stevens 1975).

General arousal was manipulated by assigning different distraction tasks to different subjects. One group of subjects sat still with their eyes closed while the experimenter changed tape cassettes. The other group worked on four anagram puzzles (related to musical terms and intended to be mildly arousing) between tempo presentations. Thus, in the manner typical of work in psychophysics, tempo varied within subjects (cf. Stevens 1975). By contrast, general arousal was manipulated between treatment groups. Forty-four subjects participated in the experiment. After subjects listened to each tempo, they filled out two instruments intended to measure perceived activity and affect. The affect measure consisted of six bipolar adjectival scales (e.g., unpleasant/pleasant). The perceived activity measure contained eight bipolar adjective scales (e.g., slow/fast). After listening to all the tapes, subjects also provided information on demographics, familiarity with the music, and past musical training.

Extensive data analyses have generated preliminary results that appear strongly to support the three hypothesized relationships. Specifically, (1) perceived activity varies directly with the logarithm of tempo; (2) affect responds nonmonotonically to perceived activity (and to the log of tempo) with a peak at moderate levels of tempo; and (3) this peak shifts from a lower to a higher position on the perceived activity continuum with increases in general arousal. By contrast, demographic variables, familiarity, and past musical training have shown no impact on perceived activity, affect, or the moderating effect of arousal.

Remaining Issues

Amidst these promising preliminary findings, some important issues remain for further analysis. Three appear to deserve special attention.

First, the superiority of the logarithmic versus the power law should depend on whether our index of perceived activity behaves as a category (equal interval) scale or as a scale of numerical magnitude (ratio) estimation (Baird and Noma 1978, Stevens 1975). We can muster arguments for either interpretation of the activity index and therefore feel that the issue should be decided by a careful comparison of the fits obtained by logarithmic and power functions. This analysis still awaits completion.

Second, though most psychophysicists work with group averages based on within-subject designs (Stevens 1975), we shall be more comfortable with our results for the moderating effect of general arousal on the relationship between tempo and affect if these findings retain their significance when tested by the appropriate repeated-measures design (cf. Latour and Miniard 1983).

Third, theory and previous studies suggest the likelihood of sequence effects on both perceived activity (Stevens 1975) and affect (McClelland, Atkinson, Clark and Lowell 1976). Specifically, one's impression of speed or liking for a piece of music should depend in part on the tempo of the last piece heard. The results of preliminary regression analyses suggest that such order effects do indeed occur, but our statistical procedures need further refinement.

In sum, these and other issues still await investigation before we can report our results in full. More generally, the glimpse provided here appears to argue for the more widespread and systematic exploration of the psychophysical aspects of consumption experiences. With rare exceptions (Buchanan and Morrison 1984; Moskowitz, Jacobs, and Firtle 1980), psychophysics has remained a neglected area in consumer research. We hope this study encourages a broader adoption of psychophysical methods to increase our understanding of the relationship between different aspects of music and sensations in particular, the nature of consumer esthetics in general, and ultimately the full spectrum of experience involved in the phenomena of consumption.

TOWARDS A MODEL OF CONSUMER POST-CHOICE
RESPONSE BEHAVIOR

J. D. Forbes, University of British Columbia
David K. Tse, University of British Columbia
Shirley Taylor, University of British Columbia

Abstract

A process model of consumer post-choice response behavior is developed from four components which include the type of post-choice response, as the dependent variable, and as the independent variables, attribution of the cause of satisfaction/dissatisfaction, the subjective probability of a successful response, the expected consequences of a response, and the characteristics of individual consumers.

Introduction

Two distinct approaches to model consumer post-choice processes have been attempted. The first, called comprehensive models in this paper (Hunt 1979, Wilton and Tse 1983), conceptualizes consumer post-choice processes through flow chart diagrams. This approach describes post-choice activities and their feedback loops, but it fails to specify how determinants of post-choice response interact to affect the consumer's choice of one or more post-choice responses.

The second approach, pioneered by Day and Landon (1977) and subsequently modified by Day (1980, 1984), attempts to specify how post-choice determinants interact through mathematical models. These attempts to model post-choice processes mathematically, plus a desire to use consumer satisfaction/dissatisfaction research and related concepts to help in the development of consumer policy, stimulated our project. The model proposed in this paper represents a first step towards this goal.

A Model of Consumer Post-Choice

The behavioral processes included in this model encompass more of the total behavior and experience of the subject's performance of psychological and behavioral activities than previous formulations. We view the process as the psychological and behavioral activities the subject performs on an object within an environment to attain some specific goals. The activities involve costs and effort, generate feedback and take time. In short, behavioral processes consist of a subject, an object, an environment, the activities, the motives and goals underlying the activities, the costs incurred and the benefits derived, the feedback generated and the time elapsed in the attainment of those goals. The major elements of the model developed in this paper is a vector of post-choice responses as the dependent variable, the attribution of the source of satisfaction or dissatisfaction, the subjective probability of a successful response, the expected consequences of a particular response, and an individual's predisposition to respond. A formulation of the model is as follows:

The relationships specified in the model include the multiplicative nature of the standard expectancy model of subjective probability and expected consequences of a response in the two middle terms. We are not sure of the nature of the functional form of the attribution part of the model. And the individual differences portion is similarly unspecified as discussed near the end of the paper. The subcomponents of the expected consequences component are standard economic theory relationships, with the addition of psychological and social costs and benefits. While not especially wedded to the functional forms, we wanted to include hypothesized relationships where the theory would seem to support them.

The model differs from existing conceptualizations in three ways; it includes responses of both satisfied and dissatisfied consumers, while previous models are generally of complaint behavior by dissatisfied individuals; it is a process model which incorporates feedback from consumers' previous choice and post-choice experiences; and it incorporates consumer's expected psychological, monetary, time and physical costs and benefits as variables in predicting the choice of a variety of possible post-choice responses. Each component, and ways to measure and validate them, are discussed below.

Post-Choice Responses

The model's first component, its dependent side, contains a vector of consumers' psychological and behavioral post-choice response alternatives. It includes the responses of both satisfied and dissatisfied consumers ranging from expressing one's thanks for a good meal at a restaurant by thanking the chef or leaving a tip, to taking a defective product back to the store for an exchange, to bringing suit for a million dollars in damages caused by the faulting engineering design of an automobile. These responses may be complex. They may be engaged in simultaneously, or they may be sequential in nature, one being used after a previous response has been ineffective. Three complexities of this component are discussed below.

First, the literature indicates that satisfied and dissatisfied consumers may engage in a wide variety of psychological and behavioral responses subsequent to their consumption experience. The psychological responses may include changing one's overall belief, attitude, product attribute salience, and repurchase intent towards the product. Behavioral responses include private actions, legal actions, and compensatory behavior.

$$\left[\begin{array}{c} \text{Consumer} \\ \text{Post-Choice} \\ \text{Responses} \\ \text{time } t+1 \end{array} \right] = F \left[\begin{array}{c} \text{Attribution} \\ \text{of Source of} \\ \text{Satisfact./} \\ \text{Dissatisfac.} \\ \text{time } t \end{array} \right] \times \left[\begin{array}{c} \text{Subjective} \\ \text{Prob. of} \\ \text{Successful} \\ \text{Response} \\ \text{time } t \end{array} \right] \times \left[\begin{array}{c} \text{Expected} \\ \text{Consequences} \\ \text{of Particular} \\ \text{Response} \\ \text{time } t \end{array} \right] \times \left[\begin{array}{c} \text{Predisposition} \\ \text{of Individual} \\ \text{to} \\ \text{Respond} \\ \text{time } t \end{array} \right]$$

(see expansion of
this term below)

$$\left[\begin{array}{c} \text{Expected} \\ \text{Consequences} \\ \text{of Particular} \\ \text{Response} \\ \text{time } t \end{array} \right] = \left[\begin{array}{c} \text{Expected} \\ \text{Economic} \\ \text{Soc-Psych} \\ \text{Physical} \\ \text{Time} \\ \text{Gain} \\ \text{time } t \end{array} \right] - \left[\begin{array}{c} \text{Accumul.} \\ \text{Economic} \\ \text{Soc-} \\ \text{Psych} \\ \text{Time} \\ \text{Loss} \\ \text{time } t \end{array} \right] + \left[\begin{array}{c} \text{Expected} \\ \text{Cost} \\ \text{Successful/} \\ \text{Unsuccessful} \\ \text{Response} \\ \text{Social-} \\ \text{Psych} \\ \text{Time} \\ \text{Loss} \\ \text{time } t \end{array} \right]$$

Second, the choice of a specific post-choice response is not discrete. Dissatisfied consumers frequently engage in a number of post-choice responses rather than a single activity (Wilton and Tse 1983, Day and Ash 1979). For example, we know that some dissatisfied consumers have and continue to lower their evaluation of the brand, AND to tell their friends about it, AND complain to the retailer AND to the manufacturer.

Third, Nicosia's (1981) study of how consumers cope with product failure shows that consumers may possess a "hidden agenda" of post-choice responses. Some actions, especially the less extreme activities such as complaining to the sales clerk, are taken first. If the complaints are not favorably received, then other activities are likely to be undertaken.

The number of previous studies of post-choice behavior is skewed towards complaint behavior for obvious reasons. However, recent findings in the TARP (1984) study for the Coca-Cola Company suggest that satisfied consumers engage in psychological and behavioral responses towards the company that are different from the responses of dissatisfied consumers. Further, previous studies tend to concentrate on predicting specific post-choice activities while little or no effort has been expended on predicting the choice of specific sets of responses or the possible sequence development of an agenda of response activities.

Measurement of Post-Choice Responses

Measures of post-choice responses are well established. Psychological responses can be measured by changes in belief, product attribute salience, brand attitude, and repurchase intention. Behavioral responses can be assessed through measuring the activities and the responses in which consumers engage.

This model component is probably best studied by longitudinal consumer surveys, consumer panels and process design experiments in which consumer post-choice responses are simulated to occur in predetermined sequence (Tse 1984). In such designs, consumer's beliefs, attitudes, and repurchase intentions can be measured before and after their consumption experience. In addition, the post-experience questionnaires should include intention measures of various post-choice behavioral activities. Follow-up to validate the behavioral activities are also indicated.

Attribution of Satisfaction/Dissatisfaction

Consumers have expectations about their consumption experiences. The satisfaction/dissatisfaction literature hypothesizes that if these expectations are either positively or negatively disconfirmed, consumers may feel confused and stressed (stress is defined as a general state of arousal (Selye 1976)). The emergent stress is likely to motivate consumers to engage in an attribution process. Attribution studies in psychology suggest that consumers may engage in attribution to reduce their dissonance in addition to conventional dissonance reduction strategies. Models of consumer post-choice behavior (Tse 1984) suggest that consumers who experience dissonance may engage in attribution before adopting other dissonance reduction strategies. We believe that further research on this area will be a part of our task. That is, the research process is directed toward explaining the underlying causes for the disconfirming experiences and how consumers cope with them.

Consumers engage in the attribution process for three major reasons. First, they wish to restore control over their confused environment. Knowing the underlying causes of disconfirmation is a beginning step in this direction. Second, knowledge of the underlying causes of dissatisfaction offers important guidance for subsequent activities. Third, disconfirmed consumers may use the attribution result to reduce their stress, such as reducing their responsibility for the dissatisfaction (Krishnan and Valle 1979, and Tse 1984).

Previous studies of attribution in post-choice processes investigated the concepts of locus - who should be responsible (Valle and Wallendorf 1977), stability - the dynamics of the locus (Folkes 1983), level of specificity - by chance or if the experience can be generalized (Lawther, Krishnan and Valle 1979), and controllability - whether or not the locus is in control of the outcome (Folkes 1984).

Attribution is a process where consumers act as intuitive scientists who develop and test hypotheses about the underlying causes of their experience from the available information. They actively seek evidence to validate their hypotheses and/or revise their prior hypotheses. Feedback from attribution activities are likely to change the consumers' beliefs, attitudes and repurchase intentions. The attribution result has sometimes appeared to be unstable (Folkes 1983) and seldom does there appear to be a clean dichotomy where the attribution is completely recognized to be internal to the individual or the fault of manufacturers, sellers or other external factors (Tse 1984). Because of the process nature of attribution, to fully understand measurement results, researchers need to know if consumers are still in a stage of the attribution process or whether they have already decided on how to attribute a situation.

Measurement of Satisfaction/Dissatisfaction Attribution

The four different attribution dimensions listed above may be measured by either surveys or experiments. Measurement scales may also be developed. Longitudinal surveys or process design experiments are needed to study the notion of an attribution process, that is, to observe how disconfirmed consumers are simulated to engage in attribution, to measure the attribution activities undertaken and the results of those activities, to identify the factors that terminate the attribution process, and, last and most important to our model, to determine how the attribution result influences the choice of subsequent post-choice responses.

Subjective Probability of Success

The second determinant in the model is the subjective probability of success the consumer associates with a specific post-choice response. While this construct has not been incorporated formally into models of post-choice behavior, except in Day (1983), there is evidence in previous studies that this construct is important in consumer's decisions. For example, in complaint behavior surveys, dissatisfied consumers explained that they did not engage in specific form of redress because: "it wouldn't do any good", (Warland, Herman and Willits 1975); they "didn't think it would make any difference" (Leigh and Day 1979); or they "didn't think anything they could do would make any difference" (Day and Ash 1979). It is likely that consumers develop these subjective probabilities from information and/or prior experience.

Measuring Perceptions of Success

In a recent paper, Day (1984), developed some measures of the consumer's subjective estimates of the possible consequences of specific post-choice responses. His measures, for example, the chances of recovering out of pocket costs of complaining, seem to combine both the subjective probability assessment and the consequences of a particular redress activity. Our model is designed to isolate the consumers' subjective estimates of the probability of the success of a particular post-choice response.

Timing of measuring this component is an important issue. Ideally, the measure needs to be administered before the consumer engages in a post-choice response activity if that activity is not to bias the results. Finding an adequate sample of dissatisfied consumers, given that satisfaction/dissatisfaction studies generally have shown that consumers are satisfied with most purchases, appears to be a non-trivial problem. Being able to find and measure their psychological state before any response has been made appears even more difficult.

Subjective Estimate of Consequences of Response

The third determinant in the model is designed to test our hypothesis that the choice of post-choice response is a function of the consumers' expected consequences of that particular response. The model adopts an "holistic" approach to expected costs and benefits by including the effects of the current choice and all previous post-choice activities. The model overtly recognizes the possible importance of feedback from previous responses on the present response. We think this component is the model's most important contribution. It differs from previous and more conventional approaches which have used only the effects of the current product/service experience on post-choice decisions.

For example, a person may bring suit for an apparently trivial matter which on its face seems illogical. However, the sales clerk was rude and unhelpful when they tried to return a faulty product to the department store. A hot argument with the store manager concluded with the manager's parting comment casting doubt on the consumer's parentage. A telephone call to the manufacturer's consumer affair department was put on hold for fifteen minutes and then disconnected. And to add insult to injury, the company ignored their letters of complaint. While this and similar scenarios are infrequent, they have happened. The post-choice response to sue in court is likely the result of the totality of the results of the unfortunate experiences and we feel an attempt should be made to overtly include and accumulate such matters in the model.

The expected consequences component of the model is the net result of summing the expected benefits of a response and subtracting both its expected costs as well as the accrued costs of all previous post-choice responses. The problems associated with these concepts are discussed below.

Expected Costs and Benefits

This component has been considered by others. Different costs and benefits include time (Day 1980), money (Richins 1979), and psychological costs and benefits (Bearden and Teel 1980). We attempt to include within this component responses beyond complaining behavior which include things such as physical costs, e.g., the costs consumers may incur trying to repair their broken appliances, the travel costs to return merchandise and similar costs seldom considered in previous studies. The major challenge in this element is not that of conceptualization, since the ideas are the concepts basic to micro economics. The challenge is how to measure and combine these disparate types of costs into a few measures that are mathematically tractable in the model. A further problem is how to accrue such costs and benefits, as perceived by the consumer, over a number of time periods.

Measuring Expected Costs and Benefits of Response

Measures of each type of cost and benefit has been developed to some degree (Richins 1979). As stated above, what needs to be developed is a method to combine them. Nicosia's (1981) coping study pioneered the use of conjoint analysis in this area. This technique merits further study. Economists have been using tradeoff techniques to measure relative utility of two or more goods or services. We are in the process of investigating whether these techniques, similar in some respects to conjoint analysis, may provide some help in measuring this component. Measuring, incorporating and combining values of psychological costs and benefits with more conventional monetary and time costs presents an additional challenge that will have to be addressed.

Accrued Costs and Benefits

This model component contains the key difference of the proposed model from existing models of consumer complaint behavior. Accrued costs and benefits are defined as the accumulation of the time, monetary, psychological and physical costs and benefits of consumers from all their previ-

ous post-choice responses. The construct is meant to be a "reservoir" or "storage tank". That is, it is a system that captures and records the feedback of all previous post-choice activities and attacks the problem in other models which do not overtly recognize that few consumers enter transactions without previous experience and without existing attitudes towards the exchange transaction. We expect to have to include a forgetting (decay) function in this component as there is much evidence that the salience of both positive and negative feelings about product/service choice and use experience decline over time (Oliver 1981).

Measuring Accrued Cost and Benefit Experience

We have not found previous attempts to measure consumer feedback systems of post-choice response experiences. In this relative void of empirical measurement we presently plan to proceed as follows.

Measures designed to understand behavioral processes must be able to capture consumers' activities and psychological states at different time slices. Having obtained these time series data, we may be able to make inferences about the process(es) through which consumers have gone. Previous studies and discussions on how consumers may change after product experiences suggest studying the following variables in feedback mechanisms. They include attitudes (Nicosia 1966), beliefs (Engel, Kollat, and Blackwell 1978), confidence (Howard and Sheth 1969), salience (Tybout and Yalch 1980), and choice heuristics (Bettman 1979). The above constructs are likely not to be exhaustive. Nonetheless, the idea that there exists a feedback system within consumers which enable them to remember and be changed by their experiences is intuitively realistic. Studying these feedback processes is crucial to understanding and modeling post-choice response behavior.

Individual Consumer Characteristics

This component of the model will either become an error term or will be the pool of data from which one or more characteristics specific to individuals or to groups of consumers will be found that can help in explaining post-choice response. Given the frequent failure of both psychological and consumer behavior research to identify individual differences capable of explaining a significant proportion of variation among individuals, we do not expect much from this variable and expect it will be mainly the error term. However, we could be surprised.

Summary and Future Directions

A process model to explain and predict consumer choice of post-choice behavior in response to satisfied and dissatisfied consumption experiences was outlined. The authors are presently engaged in finding existing data bases to test some portions of the model. A series of research designs are in the planning process to test other aspects of the model.

THE ROKEACH VALUE SURVEY AND CONSUMER
BEHAVIOR: THEORY, METHOD, AND
RESEARCH GUIDELINES

Royce Anderson, Baruch College, CUNY
David Brinberg, Baruch College, CUNY

Abstract

The Rokeach Value Survey (RVS) has been the primary instrument for the measurement of values in Consumer Behavior. There are, however, theoretical and methodological difficulties involved with the application of the RVS to consumer research. This paper uses an historical perspective derived from the marketing literature and Rokeach's writings to examine these difficulties. The primary argument, in keeping with Rokeach's original development, is that research should emphasize the structure and function, rather than merely the content, of value systems. Of particular concern is the question of the dimensionality of the value system. Specific methodological guidelines are provided to suggest directions for future research.

EFFECTS OF RECREATION USAGE SITUATION AND PREVIOUS
EXPERIENCE ON SETTING CHOICE

David A. Boag, University of Saskatchewan

"Abstract"

This research focuses on recreation usage situation influences on the choice of recreation setting. The argument presented is that recreation takes place within a specific recreation usage situation and is likely to have been aided, inhibited or guided by the conditions of that situation and the recreationist's previous recreation participation in it. The paper reports the results of an on-site survey of 379 recreationists who reported their preferences toward ten recreation settings in each of ten different usage situations. A two-way analysis of variance indicated that preferences toward recreation settings varied across usage situations. Comparing correlation coefficients for preferences on the basis of a test-retest for high and low participation frequencies in each situation provided no support for the theory that more experienced individuals are more stable in their preferences than those less experienced.

CLOTHING-RELATED RISK PERCEPTIONS OF DISABLED PEOPLE

Paula Bounds-O'Bannon, K-Mart, Incorporated
Betty Feather, University of Missouri-Columbia
John W. Vann, University of Missouri-Columbia

Abstract

Wheelchair-bound consumers face special clothing-related problems in dressing, in comfort, and in appearance. The risks which these disabled consumers perceive in buying clothing were examined along the physical, performance, psychological, economic, and social dimensions. Physical risk was rated as the highest clothing-related risk dimension, followed, in order, by the performance, psychological, economic, and social dimensions. The relative positions of physical and social risk were the reverse of what had been reported in earlier studies of able-bodied consumers. Only the performance and social risk dimensions were significantly correlated with an overall risk measure. Collectively, all the dimensions explained only 12% (n.s.) of the variance in overall risk. The highest interdimensional correlation was between economic and performance risk. Those with congenital disabilities perceived greater overall risk than those who had acquire their disabilities.

THE EFFECT OF STRUCTURAL MODIFICATION ON HOMEOWNERS'
ENERGY CONSERVATION BEHAVIORS

Jeanette A. Brandt, Oregon State University
LaRae Chatelain, Utah State University
Becky O. Beck, Eagle River, Alaska

The hypothesis that homeowners' energy conservation behaviors decrease once structural energy saving modifications are added to residences was refuted by the findings of this study. Using a longitudinal sample from eight western states, the energy conservation behaviors of homeowners who added specific structural energy saving modifications were compared with those who did not by t-tests. Three significant ($p < .05$) positive relationships between the addition of specific structural modifications and concomitant energy conservation behavior change were found. Although no significant difference in behavior change was found for the remaining six hypotheses, the addition of five of the structural modifications were accompanied by increases in energy conservation behavior. Knowledge of the positive relationship between structural modification and concomitant energy conservation behavior may be used by professionals to educate consumers and as a basis on which policy decisions can be made.

**SUBSTANCE ABUSE IN SPECIAL POPULATIONS:
ALCOHOL USAGE AND THE SENIOR CITIZEN**

Victor A. Christopherson, University of Arizona

Abstract

Interviews were conducted with 444 individuals aged 65 years and older throughout the state of Arizona in order to determine the patterns and amounts of alcohol usage in this group. Respondents were grouped into categories on the basis of the quantity and frequency of alcohol consumption--abstainers, light drinkers, moderate drinkers, and heavy drinkers. Light, moderate, and heavy drinkers were differentiated according to reasons for drinking, as were the various age groupings. Findings indicated that the rural elderly's alcohol use is generally at an acceptable level and style, that alcohol use diminishes with age, and that drinking patterns and reasons generally remain consistent into old age. The fact that life styles prior to age 65 were more instrumental in determining drinking patterns in the later years than any other single factor, gave strong support to the continuity theory of senescence.

THE IMPACT OF PERCEIVED RISK ON BRAND PREFERENCE

Mark G. Dunn, University of Notre Dame
Gerald U. Skelly, University of Mississippi
Russell G. Wahlers, University of Notre Dame

Abstract

This paper examines the relationship between perceived risk and brand preference in four supermarket product categories. One hundred and three individuals were surveyed and the findings suggest that perceived risk is significantly associated with brand preference. A closer examination of the aggregated risk model indicates that disaggregation of the model (i.e., breaking the model into its individual risk dimensions) will likely improve its ability to explain brand preference. The results also suggest that the perceived risk of competing brands should be considered in the analysis. Extending the risk model to include the perceived risk of competitive brands improves the usefulness of the perceived risk construct.

MODELING THE PROCESS OF ATTRIBUTE BELIEF FORMATION

Gary M. Erickson, University of Washington
Carl Obermiller, University of Washington

Abstract

A model of belief formation is developed to account for beliefs based on interpretation of data, inferences from other beliefs, and halo effects from overall attitudes. The processes are discussed and the following hypotheses are proposed:

- H1: When data-based information is available, beliefs will be formed by a process of interpretation of the data.
- H2: When data-based information is not available, people will infer target beliefs from other belief values.
- H3: When neither interpretation nor inferences are possible, affective halo effects will occur.

The hypotheses are tested with two-stage least squares regression on survey data, which shows some support for a hierarchy of belief formation processes, depending upon the availability of relevant information. It is suggested that controlled experimental settings are needed to more thoroughly investigate the complex processes contributing to belief formation.

**THE DEVELOPMENT OF CONSUMER AND
NON-CONSUMER SCRIPTS IN CHILDREN**

Audrey Guskey Federouch, University of Pittsburgh

Abstract

The purpose of this research was to study the development of consumer and non-consumer scripts in children of different ages across several varied event contexts. Five scripts (morning, recess, supertime, McDonald's, and grocery shopping) from three age groups of children, representing the Piagetian developmental stages, are compared and contrasted. The five event contexts were chosen because they vary in terms of frequency of experience, participation in the experience, the age of initial exposure, and the role of others in the experience. Using standard procedures, scripts were elicited, recorded and analyzed for 67 children. The results are primarily descriptive and illustrate the early development and salience of consumer scripts. It is shown that there are not always substantial developmental differences between children of different ages for the various scripts on the set of standard development criteria employed. Implications of the findings suggest the temporality of the script, the cultural basis of script knowledge, and the transition from observer to participant within the script. Future research should address the degree of script development and its relationship to the mindless script.

USING LOG LINEAR MODELS TO EXAMINE THE RELATIONSHIP
BETWEEN PURCHASE INFLUENCER AND INFLUENCEE

Lawrence F. Feick, University of Pittsburgh
Jo Ann Novak, University of Pittsburgh

Abstract

In this paper we illustrate the use of log linear models for analyzing the relationship between opinion leaders and seekers. We show how these models can be used to test three general hypotheses about this relationship. We also illustrate how combinations of these hypotheses can be tested and show how to test product-specific effects on the relationship. To illustrate the use of these models we analyze a classic data set due to Katz and Lazarsfeld (1955). Analyses suggest that in the purchase of common household products, consumers seek advice from individuals of the same social status. For fashion products, more than one model adequately describes the relationship between opinion leader and seeker. While the small dimensions of the table limit our ability to analyze product-specific effects, the models discussed provide a richer interpretation than simple chi-square tests.

THE DEVELOPMENT OF THE BOUNDARIES
OF GEOGRAPHIC SUBCULTURES

James W. Gentry, Oklahoma State University

Segmentation on a geographical basis has received some support in the literature and much usage in practice. Garreau's (1981) book The Nine Nations of North America has stimulated many marketers to rethink the boundaries of various geographical subcultures. The empirical basis for the Eight Nations in the United States is investigated in this study. Cluster analysis was used to group 53 U.S. cities on the basis of 30 demographic, marketing, and political variables. While the empirically-derived maps have some similarity to that developed by Garreau (1981), consistent differences were uncovered also.

A DISAGGREGATE NONCOMPENSATORY CHOICE MODEL

Dennis H. Gensch, University of Wisconsin-Milwaukee
Joseph A. Svestka, Cleveland State University
Rajshekhar G. Javalgi, Univ. of Wisconsin-Milwaukee

Abstract

Empirical research work modeling consumer multi-attribute choice problems using logit, probit, regression, conjoint, and LINMAP, which are derived from the utility maximization principle, are currently used in almost all applications. However, in their work, Russ (1971), Tversky (1972), Newell and Simon (1972), and Tversky and Sattath (1979) indicate that for many problems, choice behavior appears to be context dependent and hierarchical. The disaggregate hierarchical choice modeling approach has been restricted due to the lack of an efficient operational algorithm. This paper discusses a disaggregate noncompensatory model which estimates threshold tolerances (cutpoints), eliminates nonchosen alternatives, provides choice probabilities, and finally offers diagnostic information regarding the key attributes that are responsible for making a final decision.

AMPLIFICATION OF THE BIPOLAR SCALE RESPONSE:
WHY UNIPOLAR SCALES SHOULD BE USED

Robert Gilmore, New York University

Abstract

It was argued that when consumers decide between conflicting alternatives, they will appear to have stronger attitudes than indicated by multiattribute measures. An impression formation experiment demonstrated that the bipolar scale response was more extreme (amplified) than predicted by the sum of the positive and negative unipolar scale responses and by the average of the individual attribute evaluations. Amplified responses only occurred when the attributes were affectively inconsistent. It was suggested that opposing response tendencies were simultaneously elicited when subjects responded on bipolar scales, but opposing tendencies were not simultaneously elicited when responses were made on unipolar scales. These conflicting tendencies produced processes which caused the amplified response. Unipolar scales should be used because they avoid conflict processes and because they provide additional information that bipolar scales can not provide.

PHYSICAL FITNESS: AN INVESTIGATION
OF CONSUMER INVOLVEMENT

Kent L. Granzin, University of Utah
Janeen E. Olsen, University of Utah

Abstract

Physical fitness is a growing area of consumer activity. This study investigates the nature of consumers who participate in activities that aid fitness by distinguishing among three consumer segments based on their expenditures for products and services to support physical fitness activities. The results show the segments can be characterized in terms of their patterns of relatively passive and relatively active leisure pursuits, their attitudes, and their demographics and media habits.

MODELING MULTIATTRIBUTE GROUP CHOICE

Sunil Gupta, Columbia University
Duangtip Tantiwong, Fairleigh Dickinson U.

Abstract

This paper proposes a model of multiattribute group choice. The model explicitly accounts for differences among group members regarding: i) the power structure, and ii) the interest of each group member in each attribute. These differences lead to divergent views regarding how much influence each group member should have on the final outcome. So, a consensus mechanism, similar to the Delphi process, is provided to reconcile these differences. The final result is a set of predictions of the influence of each group member over each attribute.

MENTAL IMAGERY VIVIDNESS IN MARKETING COMMUNICATION

Evelyn Gutman, Boston University

Abstract

This study explored how individual ability in mental representation interacts with presentation modality to affect belief strength and accuracy of recall. Experiments were conducted with health care consumers at a major urban medical center. The same imaginal information was presented in four different modes, i. e., audio, visual, audiovisual and audiokinesthetic. The findings expand our knowledge about imaginal processing. First, imagery vividness was a multidimensional construct by sense. That is, imagery vividness by sense was associated with response outputs, while imagery vividness aggregated across the senses was not useful for evaluating imagery effects. Second, the effects of imagery vividness varied according to type of cognitive response, i. e., belief strength versus accuracy of recall. Third, imagery vividness interacted with presentation modality. The results emphasize the importance of studying imaginal processing in separate senses, suggest that processing among the senses may interact in identifiable ways, and provide direction about how to design, package and communicate information.

DERMATOLOGICAL PROBLEMS ASSOCIATED WITH
CLOTHING AND HOUSEHOLD TEXTILES

Kathryn Hatch, University of Arizona

Abstract

Wearing clothing is a necessary and also a pleasurable experience. However, consumers sometimes complain of intolerance to certain fabrics and on occasion the dermatologist diagnoses that clothing has caused an adverse skin reaction. This research investigates the types of dermatitis that are caused or aggravated by fabrics, the specific aspect of the fabric (fiber, dye, finish, etc.) responsible for the reaction, and incidence of occurrence. Case histories as given in the medical literature were assessed. Results show that various fibers, dyes and finishes are associated with adverse skin reactions, though incidence rates cannot always be deduced. Evidence of consumer awareness of such reactions is also limited, and research in these areas is needed.

REPORTED BEHAVIOR AND FUNCTIONAL
MOTIVES: SOME SELF-PERCEPTION INSIGHTS

Paula J. Haynes, University of Tennessee
at Chattanooga

Abstract

This paper examines the use of self-perception attributions within Katz' functional approach. A two stage experiment was employed. First a list of 52 frequently purchased or used items was developed. Then a group of 105 undergraduates was given the list of items and four descriptions corresponding to Katz' four functional motives. Subjects were asked to categorize, if possible, their use or purchase of each item to one of the four descriptions. These responses were treated as self-perception attributions of reported behavior. Two questions were examined: 1) Would the four functions be useful in self-perceptions of past behavior, and 2) Would single functions tend to dominate these reports for each item? An across-subject analysis suggested the four functions could be meaningfully employed in a self perception context. Single motives dominated attributions for only six of the 52 items. The paper concludes with some suggestions on further research involving the functional motive approach with self-perception attributions.

THE ROLE OF EMOTION IN THE CONSUMPTION EXPERIENCE:
ACTIONS AND REACTIONS IN CONSUMER BEHAVIOR

Morris B. Holbrook, Columbia University

Abstract

Recent progress in consumer research has moved toward a fuller understanding of intentional consumer actions. Multiattribute attitude models, decision models, models of buying choices, and other ways of studying rational purchasing behavior have all taken us further toward explaining reasoned action as one type of consumption activity. However, the study of consumer reactions has remained a relatively neglected area of investigation. For example, a prototypical reaction might involve emotional responses to advertising messages or to other symbolic offerings and the types of customer value that result therefrom. This paper proposes a conceptual scheme for integrating such reactive components into an expanded model of consumer behavior and thereby clarifies the role of emotional responses in the consumption experience.

APPROACH TO LIFE SCALES

Richard Heslin, Purdue University
Blair T. Johnson, Purdue University

Abstract

This study presents initial conceptual and empirical background to the Approach to Life (AL) scales (Heslin and Johnson 1985). These nine scales were developed to assess major behavioral orientations that underlie or facilitate consumer behavior. The scales are entitled (1) Aware of Other's Possessions, (2) Decision Confident, (3) Desires Sensuous Experiences, (4) Seeks Variety, (5) Impulse Buyer, (6) In the Communication Network, (7) Innovator, (8) Materialist, and (9) Go First Class. Care has been taken to avoid common personality inventory mistakes and pitfalls and to build on the procedures of the more careful instrument developers. Indications based on theory and data are that the scales are adequately separated yet all of them relate to the same general construct: Enjoys being a consumer and is likely to spend money. Results from a telephone survey reveal good initial support for the validity of the scales.

A STATE VARIABLES REFORMULATION OF THE
HOWARD AND SHETH MODEL

Pamela M. Homer, University of Oregon

Abstract

Howard and Sheth's Model of Buyer Behavior has been the topic of both empirical investigation and criticism (e.g., Farley and Ring 1970; Engel, Kollat and Blackwell 1968, 1982; Zaltman and Wallendorf 1983). A reformulation is presented with primary focus on (1) increased parsimony, (2) designation of the precise relationships among the variables, and (3) complete empirical testability. Specifically, 13 variables are classified as either an antecedent, process, inference, or output variable and interrelated with 22 propositions based on past empirical findings. Suggestions of a causal approach for empirical testing are provided. An evaluation of the reformulated model as a theory implies it could ultimately be accepted as a theory of buyer behavior.

SURREALISTIC ADVERTISING: A SOCIAL
ADAPTATION PERSPECTIVE

Pamela M. Homer, University of Oregon
Lynn R. Kahle, University of Oregon

Abstract

Surrealistic art techniques, an outgrowth of the early 20th century artistic movement, are often visible in modern day advertisements. Although these methods are quite widely used, research concerning their effectiveness and persuasive capabilities is virtually nonexistent. In an experiment subjects were exposed to print ads in which surrealism and priming (i.e., leading subjects to expect forthcoming messages with product-relevant information) were manipulated. Results found that priming influenced recall of message arguments, surrealism led to less incorrect recall of message arguments, and purchase likelihood was significantly related to the interaction of surrealism and priming. These findings were interpreted as supportive of Social Adaptation Theory.

DISCORDANCE WITHIN CONCORDANCE AMONG MARINE
RECREATIONAL FISHERMEN IN THE SOUTHEAST

Jeffrey Johnson, East Carolina University
David Griffith, East Carolina University

Recreational fishermen target and use or reject fish on the basis of a variety of criteria. Many fish caught incidentally are discarded because of myth, rumor, or perceived negative characteristics that mask the positive values of the fish. To discover how fishermen make consumer decisions about saltwater species, we collected judged similarity data in Florida, North Carolina, and Texas, analyzing these data with multidimensional scaling, hierarchical clustering, and item-by-use matrices. We found that the general perceptions fishermen use to target, use, or discard species were uniform from region to region, but that the specific species which met these broad cognitive criteria varied from region to region. Fish regularly utilized in one region were considered "trashfish" in another. This study demonstrates that, despite general agreement among fishermen, specific decisions based on local information may result in different consumer behaviors toward the same consumer good.

THE EFFECT OF COLOR VERSUS BLACK AND WHITE
ADVERTISING FORMATS ON AFFECTIVE RATINGS AND
PERCEPTIONS OF PRODUCT QUALITY

Wayne D. Hoyer, University of Texas
Robert P. Leone, University of Texas
Cathy J. Cobb, University of Illinois

Abstract

A problem with the academic research on color vs. b/w advertisements is that the majority of studies was conducted several decades ago, when the use of color in advertising was quite novel. A further problem is the overwhelming emphasis on the cognitive domain (attention, recognition, recall) in studying consumer response to advertising formats. Yet, there is now some evidence that advertising may work on more of an affective as opposed to a cognitive level. Thus, the present study takes a new look at the effect of color vs. b/w advertising formats, using variables of more current interest to marketers--affect toward the ad and perception of product quality. The study also examines several exploratory issues, such as variations in response across different types of appeals, product categories, levels of product intensity, and amounts of copy. The major finding was greater liking and slightly better ratings of quality for color versions; however, the differences were quite small.

SOCIAL ADAPTATION THEORY IN CONSUMER BEHAVIOR

Lynn R. Kahle, University of Oregon
Pamela M. Homer, University of Oregon
Sharon E. Beatty, University of Oregon

Abstract

Social adaptation theory applies neo-Piagetian concepts to such content areas as attitude change and advertising effectiveness. The theory assumes that schemata grow as a result of dynamic adaptation through assimilation and accommodation, as well as through internal organization of information. Adaptation rather than rationality animates change. This paper elaborates on the theory, compares and contrasts it with other, competing theories, and describes applications of the theory in the research areas of advertising effectiveness, attitude-behavior consistency, self concept, values, and philosophy of science.

CONDITIONING EMOTIONAL BENEFITS IN SATURATED MARKETS
STRATEGIES AND EMPIRICAL RESULTS

Franz-Josef Konert, University of Paderborn

Abstract

The increasing number of saturated markets in highly industrialized countries creates a considerable number of problems to marketing-management. This paper tries to generate an effective marketing-strategy for firms which are confronted with such markets. This strategy which uses techniques of conditioning is based on results of imagery research and activation theory. The first study examines the conditions of an emotional benefit strategy. These conditions are saturated markets, homogeneous products and the highly perceived quality of life. The empirical results (n=262; survey research) support these conditions. The more pronounced these conditions are the more important are emotional benefits. The second empirical study (n=200; 2x2 experimental design without repeated measurement) tries to verify the effectiveness of this strategy. The experiment was limited to print advertisements. The empirical findings corroborate the strong effect of the strategy for all measures (activation, product evaluation, ad evaluation and memory performance measures).

CONSUMER ATTITUDES AND PARTICIPATION IN A VOLUNTARY
ENERGY CONSERVATION PROGRAM

Duncan G. LaBay, University of New Hampshire
Cynthia J. Frey, Boston College

Abstract

Participation behavior in a voluntary energy conservation program sponsored by an electric utility firm in New England is evaluated. Participants, who received low-cost home insulation devices free of charge on request, are compared to non-participants on the basis of energy conservation attitudes and prior behaviors, attitudes toward utility firms, dwelling-specific situational differences, and demographic and lifestyle factors. Data were collected through a mail survey utilizing a probability sample of program participants and a matched control group. Response rates of 75% and 51%, respectively, yielded a total of 707 respondents. Significant differences are found to exist between the two groups in a number of energy conservation attitudes and behaviors. Dwelling-specific factors and demographic differences also exist. The results have implications for consumer researchers evaluating the effectiveness of such energy conservation incentive programs, from a private sector and public policy viewpoint.

PRODUCTS FOR SPECIAL NEEDS:
PROBLEMS EXPERIENCED BY DISABLED CONSUMERS

Roger M. Kramer, University of Arizona

Abstract

This paper examines the need to bring disabled consumers into closer contact with the products they need to make independent living possible. There is a decided lack of information about where to find products. A literature review and a survey of disabled consumers concludes that seldom are they able to secure or find the products they need to alleviate the effects of their disabilities. Traditionally, the disabled are considered customers of the medical-institutional-commercial market. Consequently, many of the products they need are not available in the open market. Architectural, attitudinal, transportation and communication barriers are also restricting their role as consumers. There is a need to advocate for long overdue improvements in their products. Essential goods are lacking altogether in many instances; in others, they may be unreliable or exorbitantly expensive.

CULTURAL DREAMS, CULTURAL NIGHTMARES:
THE SYMBOLIC DIMENSIONS OF NUCLEAR POWER

John W. G. Lowe, Planmetrics, Inc.

Abstract

The failure to adequately recognize the symbolic dimensions of nuclear power and act accordingly has led to progressive polarization in the nuclear debate, to the ultimate disservice of the consumer. Symbolic attributes associated with nuclear power - timelessness, abnormality, invisibility, and concentrated power - are characteristics of the sacred or spiritual world. To many people, the opposition to nuclear power comes down to "I don't trust having this god-like power in the hands of fallible human beings." The symbolic connotations of nuclear energy require forceful notions of authority and legitimacy among those most intimately associated with it. This is just what is called into question by construction delays and cost overruns, and the adversarial nature of the legal process. The result, a series of feedback loops such as that between legal action and reduction in legitimacy, has been largely responsible for the morphogenesis in nuclear programs around the world, some seemingly quite successful, others, as in the U.S.A., mired in fiscal disaster.

INTERSPOUSAL INTERACTIVE ROLES ACROSS DECISION STAGES

Oswald A. Mascarenhas, University of Detroit
Ram Kesavan, University of Detroit

Abstract

This research reports interspousal role estimations across prepurchase, purchase and postpurchase decision stages involved in the recent buying of two new jointly used products : TV and car. Forty four evening MBA student couples participated in the study. Roles across prespecified 20 decision substages were estimated on a 100-point constant sum scale, first individually, and then jointly, by the couples, amid much individual reflection and joint interaction. The questionnaire was pretested, and fully explained to the participants for uniformity of understanding of the decision stages and their content, thus assuring the reliability and the validity of the research instrument.

Given the student sample results may not be fully generalizable. Major findings reveal that given the male expertise for these products the husbands did express dominant roles through most of the decision substages. However, the interactive process that lead to the final decision seemed to have been controlled by the female spouses.

AN INVESTIGATION OF THE RELATIONSHIP
OF BEHAVIORAL, AS COMPARED TO EXPERIENTIAL,
MEASURES OF MUSIC INVOLVEMENT
WITH CONSUMER MARKET RESPONSES TO NEW ROCK MUSIC

Richard Mizerski, Florida State University
Marya J. Pucely, Florida State University
Lori Baldwin, Florida State University

Abstract

This study experimentally tests the relationship of several measures of music involvement to a select group of consumer responses to new rock music. Two measures of music participation and two measures of experiential involvement are evaluated in terms of reliability, and their relationship to affect toward, attention paid, and intention to purchase new rock music. The two usage-based involvement measures were found to have relatively poor internal reliability and a low to nonexistent relationship to memory, evaluation and intent to purchase measures. The experientially-based involvement measures had a significant relationship to evaluative and purchase intent measures, but these relationships were song specific. In total, these results suggest that experientially-based involvement measures outperform usage-based measures in all criteria, and that music involvement appears to be song specific rather than general in nature.

UNDERSTANDING INVESTMENT FRAUD:
IN SEARCH OF THE POT OF GOLD
AT THE END OF THE RAINBOW

James H. McAlexander, University of Utah
Debra L. Scammon, University of Utah

Abstract

Investment fraud is an increasing problem in the American economy. Spurred on by economic turbulence, high inflation and unemployment, business and investment frauds are siphoning dollars from consumer budgets and rarely do consumers ever recoup their investment. The financial hardship created for fraud victims is perhaps greatest for the elderly. For this reason both the U.S. Senate and House have recently held investigations into the problem of investment fraud. This attention highlights the need for an understanding of the investment decision. Knowledge of the decision process should facilitate the formulation of a solution(s) to the problems created by investment fraud and suggests some lines of research and some research methods that might help elucidate the investment fraud situation.

SEXUAL APPEALS IN ADVERTISING: THE
DETERMINATION OF RECALL

P. J. O'Connor, Baruch College, CUNY
Aylin Bahar, student, Baruch College, CUNY
Bosco Gong, student, Baruch College, CUNY
Elyse Kane, student, Baruch College, CUNY

Abstract

While there have been a number of investigations of sexual appeals in advertising, the results of this research have been somewhat equivocal in nature. In part, this may be due to an oversimplification of the character of sexuality in advertising. A whole host of issues can contribute to the perception of sexual content in an advertisement. Four dimensions of sexuality; functional, fantasy, symbolism, and inappropriate, are employed in the current research. The focus is on the effects these dimensions have on the level of recall of the advertisement. The results indicate that both the level of sexuality and its appropriateness appear to be important characteristics for enhancing recall of the respondents.

THE EFFECTS OF COMPARATIVE ADVERTISING ON THE
EVALUATION OF INFORMATION

P. J. O'Connor, Baruch College, CUNY
Joan Rosenberg, student, Baruch College, CUNY
Ira Bloom, student, Baruch College, CUNY
Lorraine Abruzzo, student, Baruch College, CUNY

Abstract

In general, research that has been conducted in the area of comparative advertising has focused upon the attitudinal and/or behavioral effects. Also, the comparisons have been made in terms of attributes of the product class. The present study uses "real", i.e. non-student, consumers to investigate the information value of comparative advertising. Specifically, the content, usefulness, and believability of information presented in comparative versus non-comparative formats is analyzed. In addition, pricing superiority as a dimension is explicitly considered. The results indicate that while comparative advertising tends to be superior, the effects are dependent upon the specific type of comparison being made.

FUNCTIONALISM AND CONSUMER BEHAVIOR RESEARCH

Charles Pickett, Mattel Corporation
George M. Zinkhan, University of Houston
Scot Burton, University of Houston

Abstract

The New Functionalism arose as a philosophy of psychology in the mid-1960's and has become an increasingly important philosophy of science for that discipline. Generally, the New Functionalists view mental states in terms of their causal roles in relation to sensory stimulation, behavioral outputs, and other mental states. Emphasis is placed on the causal role of mental states in the mental life of an organism. Several features of the New Functionalism, including ontological neutrality and the avoidance of teleological explanations and normative claims, make it quite appropriate for theory development in consumer behavior research. Unlike more restrictive perspectives, such as Behaviorism and Physicalism, theories of consumer decision making based on the New Functionalism can incorporate relationships between environmental stimuli, mental events, and behavioral outputs. All entities which can be functionally defined are admissible in theories based on the New Functionalism.

THE RELATIONSHIP OF BRAND LOYALTIES TO COGNITIVE
DISSONANCE: SOME NEW QUESTIONS TO THE OLD ANSWER

Kathy L. Pettit, Washington State University
Thomas A. Johnson, University of Idaho

Abstract

Brand loyalty has long been of interest to marketing practitioners and academicians. One explanation for its causation concerns Festinger's notion of postpurchase cognitive dissonance. Specifically, the old wisdom was that postpurchase dissonance leads to choice justification and, ultimately, to increases in loyalty to the selected brand, accompanied by decreases in loyalty to the nonselected brand(s). However, results of the current soda-tasting experiment, which explored the effect of dissonance on brand preferences and postdecisional confidence, raise some new questions concerning the effects of dissonance on repeat purchasing and/or brand switching behavior. That is, when higher dissonance was aroused (through tasting of more identical "brands"), and subjects were allowed to justify the choice through an intervening attribute evaluation task, postdecisional choice confidence declined in the final rating task. Thus, future brand considerations and/or loyalties may have been similarly affected for both the selected and "closely-rejected" brands.

DESIGNING PRODUCTS FOR THE DISABLED:
THE CASE OF CLOTHING

Naomi Reich, University of Arizona

Abstract

The state-of-the-art in clothing for the disabled will be presented from both national and international perspectives. Information and research findings from past and present research, their impact and conclusions from a 1984 study leave abroad investigating the clothing and textile field in relation to the special needs of physically disabled consumers will be discussed. Research work will be discussed under eight main topics; design impact on clothing and aids, potential use of resource centers, research emphasis and its impact on manufacturers, need for improved sizing systems, developments in the use of computers to improve communications and education for disabled people, and the role of source organizations and importance of conferences. The problem-solving approach utilized in the apparel design process, selection of ready-to-wear in the market place and possible garment modifications to meet the special needs of disabled people, especially arthritics, will be outlined. Availability of clothing and related resources for the disabled consumer will be discussed.

RETAIL PATRONAGE BEHAVIOR

Maija Rökman, University of Tampere

Abstract

Consumers' choice of the purchasing place has several impacts on the surroundings, retailers and civil servants. In this study consumers' purchases are examined by developing a framework to describe and explain patronage behavior in alternative areas. Distance between two areas explains a part of this shopping movement, but the reasons of the other part should be explored to understand the total phenomenon. Store image and area image are the main components of the developed framework. After two mailings the whole data set consisted of 1015 questionnaires representing 17% of all families in the town. The analysis of variance was used to reveal the connections between different components. Results indicate that consumers' perceptions of stores and areas (image) have significant effects on purchases of different products. Negative perceptions have greater effects than positive. This would imply more like "pushing out" than attracting a trading area. This is useful empirical support for retailers.

WHEN DOES TELEVISION PROGRAMMING AFFECT CONSUMER ATTITUDES TOWARDS AN ADVERTISED PRODUCT?: EXPLAINING CONTEXT EFFECTS USING THE ELABORATION LIKELIHOOD MODEL

David W. Schumann, University of Tennessee

Abstract

With the growth of the television industry in general, the ever increasing number of cable stations, and the staggering cost of television advertising, the relationship between the program and the commercial has become a topic of increasing concern to the marketing and advertising disciplines. How does the context in which a commercial appears, affect the influence an advertisement has on the consumer? Research interest in this topic has grown steadily yet many questions remain unanswered. This paper provides a review of the marketing research concerning context effects, and proposes the use of the Elaboration Likelihood Model (Petty & Cacioppo, 1979, 1981) as a theoretical basis for explaining an important segment of the reported findings.

HEALTH AS A DETERMINANT ATTRIBUTE IN CONSUMER DECISION MAKING

Joel Rudd, University of Arizona
George B. Sproles, University of Arizona

Abstract

Health-consciousness is one of the major consumer trends of the 1980's. An increasing number of products and services are marketed with consumer health as a central feature, e.g. "health" foods, exercise equipment, sportswear, pharmaceuticals and related personal care products. To what extent is health-consciousness a determinant attribute in consumer decisions? We examine this question by 1) reviewing evidence of the extent to which health is actually considered in consumer choices across product categories, and 2) identifying evidence of the circumstances in which consumers should be encouraged to be health-conscious in decision-making. Findings indicate a substantial literature dealing with central aspects of consumer health, e.g. nutrition, exercise, and hazardous substances. However, published literature on health as a determinant attribute in consumer behavior is limited. Research is needed to further examine health as a major variable in contemporary consumer decision-making.

DETERMINANTS OF PRODUCT VALUE-EXPRESSIVENESS

M. Joseph Sirgy, Virginia Tech
J. S. Johar, Cal State U San Bernardino
Michael Wood, CUNY, Hunter College

A study was conducted testing the hypothesis that product value-expressiveness is a function of product conspicuousness, differentiation, and common usage. A 3-way repeated measures ANOVA design was used representing the effects of the three factors on value expressiveness. Eight products representing the eight cells in the repeated measures design were selected. Manipulation checks showed that the products did indeed represent conspicuousness, differentiation, and common usage. As expected, the ANOVA results showed three significant main effects and no interaction effects. That is, conspicuousness, differentiation, and common usage were found to significantly contribute to the predicted variance in value expressiveness. This finding was argued to be instrumental in developing future reliable and valid product value-expressiveness measures to be employed in consumer self-concept research.

CONSUMER RESEARCH FOR THE GLOBAL MARKET: SEGMENTS AND THEMES

Lynette S. Unger, Miami University
Teresa J. Domzal, George Mason University

Abstract

This paper examines some of the reasons for the strong resurgence of interest in global marketing and some implications for consumer research. A distinction between multinational and global marketing is made and the extent to which major corporations are already employing global branding and advertising strategies is discussed. Consumer research currently takes a multinational rather than global approach to cross-cultural similarities as well as differences. Emphasis on psychographic rather than geographic segmentation would be more appropriate to global marketing. Two universal themes, play and leisure and prosocial behavior, are presented, which might be employed in cross-cultural promotion.

CONSUMER INVOLVEMENT RELATED TO APPAREL PURCHASE BEHAVIOR

Anne L. Vreeman, University of Illinois
Michelle A. Morganosky, University of Illinois

Abstract

The concept of involvement as it relates to apparel products is discussed and developed. A telephone survey was done utilizing systematic random sampling procedures for all names listed in a north central city telephone directory. Results indicate that apparel involvement attitudes and behaviors, such as time spent searching for information about apparel from media sources, time spent looking at apparel in stores, importance of merchandise assortments, brand awareness, brand importance, store displays prompting purchases, and shopping for pleasure or leisure, in part depend upon the extent to which the consumer views apparel as close to his/her "self." These findings give added support to the concept of involvement, and indicate that consumers do evaluate products based on centrally held values, as proposed by many involvement researchers.

SITUATIONAL CONTEXT AND BUYER PREFERENCES

E. K. Valentin, Weber State College
Kent L. Granzin, University of Utah

This study investigated the influence of situational context, conceptualized as the sum of the object of consumption, intended usage, and user type, on product attribute preferences. Operationally, the object of consumption was represented by three food items and intended usage by three alternative recipients of food. Users were classified as one of three types using a psychographic scale developed prior to the reported study. Data were gathered from 200 subjects via questionnaire and were analyzed using a repeated-measures analysis of variance model. The choice object, intended usage, user type, and object-situation interactions were found to affect preferences for product attributes significantly. The results were found to contain several implications for further research as well as for marketing management.

NUTRITIONAL EVALUATION AND SAFETY OF VARIOUS FOOD ITEMS

Charles W. Weber, University of Arizona

Abstract

The food consumed daily is essential to life, but it also is a mixture of thousands of chemicals, any one of which, in sufficient quantities could be hazardous or fatal. Even essential nutrients such as zinc, copper, vitamins D and A are toxic in excess, but one can not live without them.

The public in demanding an absolutely safe food supply, free of harmful "chemicals" is mistaken and misdirected as all foods consist exclusively of chemicals. It is equally mistaken to demand a food supply that contains no harmful substances. The chief concern is the amount of material ingested.

Nutritional evaluation of food items are needed on a consistent yearly basis. As new food dishes are prepared, their nutritional evaluation is also needed. For example, the public changes its taste in foods by shifting from hamburgers to Mexican food dishes which are prepared differently from the hamburger.

APPLYING DISENGAGEMENT THEORY FROM SOCIAL
GERONTOLOGY TO PREDICT AND EXPLAIN
SEGMENTS WITHIN THE SENIOR MARKET

William A. Weeks, Washington State University

Abstract

The purpose of this paper is to explore the social gerontological Disengagement Theory's ability in predicting and explaining segments within the Senior Market. The research approach consisted of an analysis of 20 interest and opinion items from Needham, Harper, and Steers's 1982 consumer panel. Senior consumers are shown to follow one of three retirement adjustment patterns: "disengagement," "re-engagement," or "realignment." The results of this study support the hypothesis that the Senior Market is comprised of unique segments that must be targeted accordingly. Future researchers may want to use an alternative indicator of behavior such as one's use of time.

A NOTE ON ACR STYLE

Over the course of publishing thirteen volumes of Advances in Consumer Research, The Association for Consumer Research has established a consistent format. Because the style sheet for the conference proceedings does not change much (if at all) from year to year, I decided that it would be useful to include it here and thus make it more widely accessible.

The next two pages reproduce the standard style sheet that was sent to the contributors to this volume. Minor inconsistencies in the appearance of papers result from failure to adhere closely to the guidelines (authors were responsible for providing their own final copy).

Some oversights were particularly common among this year's submissions:

1. ACR does not use commas or other punctuation within an in-text citation, e.g., (Bartels 1979), NOT (Bartels, 1979).
2. ACR uses full names in the reference list. Initials are not considered adequate unless that is the way the author's name appears on the cited article.
3. Consistent alignment and capitalization of headings are necessary to provide a paper that is well-organized in appearance.
4. Each figure and table should have both a label and a title typed in all capital letters and not reduced, even if the figure or table is reduced to fit the available space (i.e., type in the label and title after reducing the table or figure itself).
5. Margins must be treated as firm. This includes the requisite spacing on the first page.
6. Selection of a single typeface (in this case IBM prestige elite) allows minor editorial corrections to be made after submission, rather than returning the entire paper to the author(s) for retyping.

Together with the Journal of Consumer Research style sheet (see, for example, the March 1985 issue) the ACR typing guide provides sufficient detail to ensure an aesthetically pleasing set of published papers.

I hope that publishing the format information in this volume leads to increasing consistency in the appearance of the conference proceedings.

Richard J. Lutz
Editor

ASSOCIATION FOR CONSUMER RESEARCH
GUIDE FOR AUTHORS AND TYPISTS¹

Richard J. Lutz, University of Florida²

Abstract

This sheet provides instructions to authors and typists concerning the format and style of manuscripts to appear in Advances in Consumer Research, Vol. XIII. The volume will be printed by photographing the "oversize" sheets on which you submit your final paper. It is critical that each author follow all instructions very carefully; deviations cannot be accepted.

Instructions to Authors

This guide specifies the format of the paper to be submitted for publication. The 1986 proceedings will be identical in format to Advances in Consumer Research, Vol. XII. If you have questions left unanswered by this sheet, please consult last year's volume.

Papers may not exceed six oversized pages corresponding to about 24 double spaced typewritten pages. This is an absolute limit; no exceptions will be made. With each original oversized manuscript, the author should submit two copies that have been photoreduced to 8½" X 11" (i.e., to 67% of original).

Title

The title should be in all capital letters and centered at the top of the first page (not centered over the left column), starting on the fourth line from the border at the top. If more than one line of title is required, single space between the lines (as illustrated above).

Authors

The author(s) and affiliation(s) should be centered and single spaced, beginning on the second line below the title. Do not use professional titles. Follow the format shown at the top of this page.

Headings

First level headings should be centered and in caps and small letters. Do not underline. (See the "Instructions to Authors" heading.) Second level headings should be left adjusted, in caps and small letters. Do not underline. (See "Title" heading.) If a third level of heading is absolutely necessary, use the run-in side head, underlined and followed by a period. Do not place a heading at the bottom of a column if there is not room to begin the relevant text.

Abstract

An abstract of approximately 50 words should be placed before the body of the text. The word "Abstract" should be centered and treated as a major heading.

Figures and Tables

Figures and tables should be placed as close as possible to the location where they are cited. Labels should be

¹Here, you may wish to give acknowledgements regarding financial support or other help received. For example, I wish to thank Elizabeth Hirschman and Morris Holbrook, on whose "Guide for Authors" this version is based.

²Further details about authors' affiliations or addresses can be given here, if desired.

centered, typed with all solid caps, and located above the table or figures as follows:

TABLE 1 (or FIGURE 1)

A title, typed in all uppercase letters, and describing the content of the table or figure should be centered on the second line following the label.

All figures and tables must be photo-reproducible. Any symbols or parts of a figure which cannot be typed should be carefully drawn in with black ink. If possible, please format your tables and figures to fit within a single column. You may photo-reduce figures to fit within a single column to save space, but keep in mind that the manuscript will be reduced again for printing. If you reduce a table or figure, do not reduce the label and title. In exceptional instances of very large tables or figures, both columns may be used. Without exception, the oversized sheets should not be turned sideways for typing of tables. If necessary, use rubber cement to paste a figure or table produced on a separate sheet of paper within the blue rectangle. Do not use cellophane tape.

Footnotes

Explanatory footnotes should be numbered consecutively and placed at the bottom of the page and column in which they appear. They should be separated from the body of the text by a line one inch long. (A one-inch line is twelve spaces.) Footnotes should not be attached to equations. Please avoid footnotes wherever possible.

Equations

All equations should be placed on separate lines and numbered consecutively. These consecutive numbers should be placed within parentheses and aligned against the right margin:

$$A = f(X_1 + X_2 + \dots + X_n) \quad (1)$$

$$A = \sum_{i=1}^n b_i e_i \quad (2)$$

References

Citations in the text should be according to the current practice of the Journal of Consumer Research. Footnotes should NOT be used for reference purposes and, in general, should be avoided. (see above).

Citations in the text should be by the author's last name and year of publication enclosed in parentheses WITHOUT PUNCTUATION, e.g., (Bartels 1979). If practical, the citation should stand by a punctuation mark. Otherwise, it should be inserted at a logical sentence break. If you use the author's name within the sentence, there is no need to repeat the name in the citation; just use the year of publication in parentheses, e.g., "the paper by Ferber (1976)."

If a particular page, section, or equation is cited, it should be placed within the parentheses: (Olson 1979, p. 127).

The bibliography should include all and only those references cited in the text of the paper and should be entitled "References." This section should appear at the end of your paper. The word "References" should be

centered above the list of references and entries should be in alphabetical order by last name of first author. Follow current JCR practice.

Book reference form should be:

Dean, John P. and Alex Rosen (1955), A Manual of Inter-Group Relations, Chicago: University of Chicago Press.

Journal reference form should be:

Lutz, Richard J. (1975), "Changing Brand Attitudes Through Modification of Cognitive Structure," Journal of Consumer Research, 1 (March), 49-59.

Resolve any additional documentation problem by consulting the Journal of Consumer Research "Style Sheet" published in the March, 1985 issue.

Appendices

Appendices, if needed, should immediately follow the body of the paper preceding the references. The word "Appendix" should be centered at the top of the appendix.

Instructions to Typists

An IBM electric typewriter must be used. The type (freshly cleaned) must be Selectric Prestige elite. Only carbon ribbons may be used.

Corrections

White opaque corrections fluid must be used for corrections. Corrections must be complete and neat. The corrections fluid must be kept thin, be spread evenly, and be thoroughly dry before corrections are typed. No strikeovers can be accepted.

Paper

The camera-ready copy will be prepared by typing on the special oversized paper provided. Type the left-hand rectangle first, then type the right-hand rectangle.

Margins

All paragraphs should begin flush with the left margin, not indented. Please take special care to make right margins as even as possible. Appropriately hyphenating words when feasible is important in obtaining an even right margin. The border serves as the top margin, and except for the title page, typing should begin immediately under the border; do not skip two or three spaces down before starting to type. The border also serves as the bottom margin, and the last line of each column should be as near to it as possible.

The proper margins are outlined with a border on the special "oversized" paper. The border will not reproduce when the pages are photographed; it serves only as your guide to proper margins. Except for the title and author name(s) and affiliation(s) and possible tables and figures, all typing must be within these borders.

Spacing

Single space the body of the paper. Double space before and after first and second level headings, between paragraphs, before and after the words "Appendix" and "References," between the last line of the text and the first line of the footnotes; between footnotes, and between references.

Page Numbers

Do not type in the page numbers, but to keep your paper in the right sequence, please pencil them in on the back. Page numbers to be printed will be inserted by the editor prior to printing.

Special Note to Typist

Please see the section, "Instructions to Authors," for detailed information on the format for titles, headings, figures and tables, footnotes, equations, references (bibliography), and appendices.

Mailing Instructions

Please return the completed oversized manuscript in the same oversized envelope it came in or a similar replacement envelope. Please use the cardboard stiffeners. Bending can cause problems. If you are mailing it within the United States, clearly mark the envelope in several places as FIRST CLASS MAIL and be sure that the full First Class postage is put on it. If you are mailing it from outside the United States, please mark it AIR MAIL and attach sufficient postage.

Please follow all instructions in the accompanying letter and return your manuscript with all the other requested materials to:

Richard J. Lutz
ACR Program Chairman
205 Matherly Hall
University of Florida
Gainesville, Florida 32611

Final Checklist:

- () Manuscript on oversize sheets (no more than 6 pages)
- () Cardboard stiffeners to prevent bending
- () Two (2) photo-reduced copies of paper
- () Copyright form signed by all authors
- () Topic Index form
- () Self-addressed, stamped postcard to notify you of receipt of your package

Your manuscript must arrive before September 15, 1985.
