ASSOCIATION FOR CONSUMER RESEARCH 1989 OFFICERS

BOARD OF DIRECTORS

President: Morris B. Holbrook, Columbia University
President Elect: Elizabeth C. Hirschman, Rutgers University
Past President: Richard J. Lutz, University of Florida
Treasurer: Terence A. Shimp, University of South Carolina
Director: John E. Calfee, University of Maryland
Director: Rebecca H. Holman, D'Arcy, Masius, Benton & Bowles Inc.
Director: Kent B. Monroe, Virginia Tech University
Executive Secretary: H. Keith Hunt, Brigham Young University

COMMITTEES

Conference: Marvin E. Goldberg, McGill University
Gerald J. Gorn, University of British Columbia
Richard W. Pollay, University of British Columbia

Newsletter: Peter Bloch, University of Massachusetts
James A. Muncy, Clemson University

ADVISORY COUNCIL

Richard T. Curtin, University of Michigan
Philip A. Harding
A. Marvin Roscoe, Jr., A T & T
Janet Wagner, University of Maryland

Preface

The research reported in this volume was first shared with the members of the Association for Consumer Research at their 17th Annual Conference, October 19-22, 1989 in New Orleans, Louisiana. This conference had record attendance, and a record number of submissions to the program, reflecting the continued growth of consumer research as a discipline.

The quality of the papers in this year's proceedings reflects both the discipline's development and the intensified competition to be on the program. Research papers became part of the program through one of two paths. They were either (1) proposed as a component part of a Special Session, or (2) submitted individually as a Competitive Paper. All competitive papers appear here, as revised by the authors following suggestions from the editors and the referees. Special Sessions are not as thoroughly represented in this proceedings volume, but participants and topics are listed, and Chairmen were encouraged to provide summaries in the absence of more complete documentation.

Proposals of both types were far more numerous than the available time would ever permit. For both competitive papers and special sessions, as a result, many interesting proposals, often by well known scholars, were rejected in deference to others that reviewers rated with even more enthusiasm. There was no "easy" way onto the program, as we could and did accept only about half of either type of proposal.

The papers included were accepted for the conference after a thorough peer review process involving another record number of participants. The Special Session proposals were each screened by one third of the program committee. All Competitive Papers were reviewed, with written comments and suggestions for revision, by as many as four referees. The reviewers were recruited by contacting those who had served in this capacity in recent years, except those already serving on the program committee or in other key ACR roles. To expand the number of referees, we also contacted those whose own work has appeared frequently in the previous three years' *Journal of Consumer Research* and/or *Advances in Consumer Research*. This involved a number of new people in the program's selection processes, especially younger scholars early in their careers, but already demonstrating research productivity and maturity.

We are, of course, grateful to a variety of people who helped us at various stages of the task of creating the program and this volume. Various ACR leaders provided advice and counsel generously whenever asked: Morris Holbrook recruited us and let us handle the job without being second guessed; Keith Hunt, as Executive Secretary, was our primary resource for mailing lists and many sundry organizational details, especially registration. This saved us from many headaches of management from another country (Canada) and the need for explanations to U.S. customs officials; Rich Lutz, *JCR* editor as well as a previous program chairman, helped us better understand the care and feeding of referees; Mike Houston, *JMR* editor and another previous program chairman, provided a variety of helpful suggestions along the way; and Jim Muncy coordinated and executed the production of this volume. Secretarial and administrative support was provided by Cynthia Ree (Vancouver - UBC) and Jean Hepworth (Montreal - McGill), who also supervised the many helping hands during peak efforts of receiving and mailing the multiple copies of the hundreds of manuscripts involved. Last, but far from least, we are grateful to each and every member of the program committee and the many reviewers listed on a separate page. They did their essential jobs conscientiously while still meeting our quick turnaround deadlines.

TABLE OF CONTENTS

ACR Officers and Conference Committee	iii
Competitive Papers Reviewers	iv
Editors' Preface	vi
Table of Contents	vii
Conference Program	xx
Presidential Address:	
"The Role of Lyricism in Research on Consumer Emotions: Skylark, Have You Anything to Say to Me?".....	1
Morris B. Holbrook, Columbia University	
Session 1.1	
"Regularities, Rules and Consumer Behavior: Tangencies Between Positivist and Interpretive Approaches to Research"	19
Eileen Fischer, York University	
"Eureka! and Other Tests of Significance: A New Look At Evaluating Interpretive Research"	25
Craig J. Thompson, University of Tennessee	
"Ritual, Ritualized Behavior, and Habit: Refinements and Extensions of the Consumption Ritual Construct".....	31
Mary A. Stanfield Tetreault, George Mason University Robert E. Kleine III, Arizona State University	
"To Everything There Is A Season: A Photoessay of a Farmers' Market"	39
Deborah D. Heisley, Northwestern University Mary Ann McGrath, Loyola University of Chicago John F. Sherry, Jr., Northwestern University	
Session 1.3	
"An Exploratory Study of the Effect of Imagery on Expectations and Satisfaction"	41
Deborah J. MacInnis, University of Arizona Linda L. Price, University of Colorado at Boulder	
Session 1.5	
"Generalization of the Market Maven's Information Provision Tendency Across Product Categories"	48
Mark E. Slama, Utah State University Terrell G. Williams, California State University, Northridge	
"An Assessment of the Moderating Effects of Market Mavenism and Value Consciousness On Price-Quality Perception Accuracy".....	53
Donald R. Lichtenstein, University of Colorado Scot Burton, Louisiana State University	

"Opinion Leadership, Enduring Involvement and Characteristics of Opinion Leaders: A Moderating or Mediating Relationship?"	60
Meera P. Venkatraman, Boston University	
Session 1.6	
"The Imperial Self"	68
Michael R. Solomon, Rutgers University	
Session 2.1	
"Beauty and Joy in Metaphorical Advertising: The Poetic Dimension"	71
Barbara B. Stern, Rutgers University	
"Market Metaphors for Meeting Mates"	78
Aaron Bernard, Northwestern University	
Mara B. Adelman, Northwestern University	
Session 2.3	
"Effects of Self-Reflection on Attitudes and Consumer Decisions"	79
Timothy D. Wilson, University of Virginia	
Douglas J. Lisle, University of Virginia	
Dolores Kraft, University of Virginia	
"Attitudes and Behavior: The Cognitive-Affective Mismatch Hypothesis"	86
Murray G. Millar, University of Wisconsin - Parkside	
Abraham Tesser, University of Georgia	
"Effects of Attribute Salience on the Consistency of Product Evaluations and Purchase Predictions"	91
Sharon Shavitt, University of Illinois	
Russell H. Fazio, Indiana University	
"Attitude Function: Is It Related to Attitude Structure?"	98
Mark P. Zanna, University of Waterloo	
Session 2.5	
"Brand Categorization and Product Involvement"	101
Jacques E. Brisoux, Universite du Quebec a Trois-Rivieres	
Emmanuel J. Cheron, Universite Laval	
"In Search of Brand Image: A Foundations Analysis"	110
Dawn Dobni, University of Houston	
George M. Zinkhan, University of Houston	
"Consumer Evaluation of Franchise Extension Products: A Categorization Processing Perspective"	120
Cathy L. Hartman, University of Calgary	
Linda L. Price, University of Colorado	
Calvin P. Duncan, University of Colorado	
"Brand Cognitions as Determinants of Brand Attitudes: The Influence of Measurement and Processing Involvement"	128
Randall L. Rose, University of South Carolina	
Paul W. Miniard, The Ohio State University	
Sunil Bhatla, Case Western Reserve University	

"The Role of Tangible and Intangible Attributes in Similarity and Preference Judgments".....	135
Roxanne Lefkoff-Hagius, University of North Carolina at Chapel Hill	
Charlotte H. Mason, University of North Carolina at Chapel Hill	
Discussion: "Involvement and Perceived Brand Similarities/Differences: The Need for Process Oriented Models".....	144
James A. Muncy, Clemson University	

Session 2.6

"The Information Processing of Televised Political Advertising: Using Theory to Maximize Recall".....	149
Annie Lang, Washington State University	
Patrick Lanfear, Washington State University	
"Effects of Commercial Complexity, the Candidate, and Issue vs. Image Strategies in Political Ads".....	159
Joan Schleuder, University of Texas	

Session 3.1

"Measuring Material Values: A Preliminary Report of Scale Development".....	169
Marsha L. Richins, University of Massachusetts - Amherst	
Scott Dawson, Portland State University	
"German and Canadian Data on Motivations in Ownership: Was Pythagoras Right?.....	176
Floyd W. Rudmin, Queen's University	
"Isolating the Effect of Non-Economic Factors on the Development of a Consumer Culture: A Comparison of Materialism in the Netherlands and the United States".....	182
Scott Dawson, Portland State University	
Gary Bamossy, Vrije Universiteit	
"Measuring and Comparing Materialism Cross-Culturally".....	186
Guliz Ger, Bilkent University	
Russell W. Belk, University of Utah	

Sessions 3.2 and 4.2

"Reducing Response Error in Consumers' Reports of Medical Expenses: Application of Cognitive Theory to the Consumer Expenditure Interview Survey".....	193
Leslie A. Miller, Bureau of Labor Statistics	
Theodore Downes-Le Guin, University of Michigan	
"Cognitive Aspects of Proxy Reporting of Behavior".....	198
Barbara A. Bickart, University of Florida	
Johnny Blair, University of Illinois - Urbana	
Geeta Menon, University of Illinois-Urbana	
Seymour Sudman, University of Illinois - Urbana	
"Cognitive Models for Behavioral Frequency Survey Questions".....	207
E. Marla Felcher, Northwestern University	
Bobby J. Calder, Northwestern University	
"The Disruptive Effects of Self-Reflection: Implications for Survey Research".....	212
Timothy D. Wilson, University of Virginia	
Dolores Kraft, University of Virginia	
Douglas J. Lisle, University of Virginia	

"The Influence of Survey Format on Judgment Processes: The Case of Ideals and Perceived Similarity"	217
Jack M. Feldman, Georgia Institute of Technology Scott Wesley, Georgia Institute of Technology Michael Hein, Georgia Institute of Technology Ann Gilmore, Georgia Institute of Technology	
Session 3.3	
"Measuring and Modeling Brand Interest as an Alternative A _{Ad} Effect with Familiar Brands"	223
Karen A. Machleit, University of Cincinnati Thomas J. Madden, University of South Carolina Chris T. Allen, University of Cincinnati	
Session 3.4	
"The Elaboration Likelihood Model (ELM): Replications, Extensions and Some Conflicting Findings"	231
Catherine Cole, University of Iowa Richard Ettenson, University of Maryland Suzanne Reinke, University of Iowa Tracy Schrader, University of Iowa	
"The Interaction of Peripheral Cues and Message Arguments On Cognitive Responses to an Advertisement"	237
Judith E. Hennessey, California State University, Northridge Shirley C. Anderson, California State University, Northridge	
"The Effect of Background and Ambient Color on Product Attitudes and Beliefs"	244
Susan E. Middlestadt, University of Illinois, Urbana-Champaign	
Session 3.5	
"The Effects of Missing Information on Decision Strategy Selection"	250
Sandra J. Burke, The University of Michigan	
"Knowledge and Context Effects on Typicality and Attitude Judgments"	257
Cynthia D. Huffman, University of Minnesota Barbara Loken, University of Minnesota James Ward, Arizona State University	
"Inferences About Missing Attributes: Contingencies Affecting the Use of Alternative Information Sources"	266
Carolyn J. Simmons, University of Illinois at Urbana-Champaign Nancy H. Leonard, University of Illinois at Urbana-Champaign	
"The Effects of Familiarity on Cognitive Maps"	275
Haim Mano, Washington University in St. Louis Scott M. Davis, Washington University in St. Louis	
Discussion: "In Search of the Elusive Consumer Inference"	283
Sarah Fisher Gardial, University of Tennessee David W. Schumann, University of Tennessee	
Session 3.6	
"AIDS Preventions Through Consumer Communication: Ideas from Past and Current Research"	288
Elizabeth Cooper-Martin, Georgetown University Debra Lynn Stephens, University of Maryland	

"AIDS and the Arts".....	294
Ronald Paul Hill, Villanova University	

Session 4.1

"An Exploratory Study of Lottery Playing, Gambling Addiction and Links to Compulsive Consumption".....	298
Alvin C. Burns, Louisiana State University	
Peter L. Gillett, University of Central Florida	
Marc Rubinstein, University of Central Florida	
James W. Gentry, University of Nebraska-Lincoln	
"Compulsive Buying Tendencies of Adolescent Consumers".....	306
Alain d'Astous, University of Sherbrooke	
Julie Maltais, University of Sherbrooke	
Caroline Roberge, University of Sherbrooke	
"Risk-Taking Behavior: Protecting Consumers from Themselves".....	313
Jef I. Richards, University of Texas at Austin	

Session 4.4

"Conceptualizing Argument Quality via Argument Structure".....	321
Gregory W. Boller, Memphis State University	
John L. Swasy, American University	
James M. Munch, University of Delaware	
"Mediators of Message Sidedness Effects on Cognitive Structure for Involved and Uninvolved Audiences".....	329
Manoj Hastak, The American University	
Jong-Won Park, University of Illinois at Urbana-Champaign	
"How Do Consumer Inferences Mediate the Effectiveness of Two-Sided Messages?".....	337
Cornelia Pechmann, University of California, Irvine	
"The Impact of Product-Related Announcements on Consumer Purchase Intentions".....	342
Raymond R. Burke, Wharton School, University of Pennsylvania	
Jaewun Cho, Arizona State University	
Wayne S. DeSarbo, University of Michigan	
Vijay Mahajan, Southern Methodist University	

Session 4.5

"Consumer Expertise and the Feature-Positive Effect: Implications for Judgment and Inference".....	351
Frank R. Kardes, University of Cincinnati	
David M. Sanbonmatsu, University of Utah	
Paul M. Herr, Indiana University	
"The Effects of Expertise on Preference and Typicality in Investment Decision Making".....	355
W. Steven Perkins, Penn State University	
Valerie F. Reyna, University of Arizona	
"Information Examination as a Function of Information Type and Dimension of Consumer Expertise: Some Exploratory Findings".....	361
Akshay R. Rao, University of Minnesota	
Eric M. Olson, University of Minnesota	

Session 5.1

"The Meaning of Custom-Made Homes: Home as a Metaphor for Living"367
C. B. Claiborne, Virginia Polytechnic Institute and State University
Julie L. Ozanne, Virginia Polytechnic Institute and State University

"T-Shirts as Wearable Diary: An Examination of Artifact Consumption and Garnering
Related to Life Events".....375
T. Bettina Cornwell, Memphis State University

"A Conception of Consumer Identity".....380
Richard A. Feinberg, Purdue University
S.J. Yoon, Purdue University
Lori Westgate, Purdue University
Charles Trappey, Purdue University
Jodie Monger, Purdue University
Peter Smith, Louisiana State University, Shreveport
Dennis Raphael, Ministry of Education, Toronto

"Symbolic Interactionism: Some Implications for Consumer Self-Concept and
Product Symbolism Research".....386
Dong H. Lee, Indiana University

Discussion: "Self-Identity and Symbolic Consumption".....394
Robert F. Kelly, University of British Columbia

Session 5.2

"How Regular is Regularity? An Empirical Test of the Regularity Assumption".....398
Thomas S. Gruca, University of Massachusetts

"Effects of the Mass Media News on Trends in the Consumption of Caffeine-Free Colas".....406
David P. Fan, University of Minnesota
Carol L. Shaffer, University of Minnesota

"A Structural Examination of Two Optimal Stimulation Level Measurement Models".....415
Russell G. Wahlers, Ball State University
Michael J. Etzel, University of Notre Dame

"Specifying Measurement Error in Structural Equation Models: Are Congeneric
Measurement Models Appropriate?".....426
Joseph A. Cote, Washington State University
Robert Greenberg, Washington State University

Discussion: "Varying Approaches to Data Analysis".....434
Stephen J. Arnold, Queen's University

Session 5.4

"Repetition, Social Settings, Perceived Humor, and Wearout".....438
George M. Zinkhan, University of Houston
Betsy D. Gelb, University of Houston

"Does Brand Attitude Moderate the Persuasiveness of Humor in Advertising?".....442
Kunal Basu, McGill University
Amitava Chattopadhyay, McGill University

Session 5.5

"Parallel Processing Models of Consumer Information Processing: Their Impact on Consumer Research Methods"443
Dawne Martin, University of Calgary
Pamela Kiecker, Texas Tech University

"The Effect of Imagery Processing and Imagery Content on Behavioral Intentions"449
Paula Fitzgerald Bone, West Virginia University
Pam Scholder Ellen, Georgia State University

"Style of Information Processing Differences in Relation to Products, Shopping, and Self-Consciousness"455
Stephen J. Gould, Rutgers, The State University of New Jersey

Discussion: "Studies in Imagery, Styles of Processing, and Parallel Processing Need Realtime Response Measures"461
G. David Hughes, University of North Carolina

Sessions 5.6 and 6.6

"Cigarettes in the Popular Press, 1930-60: Preliminary Research"467
Gary T. Ford, The American University
Debra Jones Ringold, University of Baltimore
Martha Rogers, Bowling Green State University

"What Would Happen If Cigarette Advertising and Promotion Were Banned?"474
John E. Calfee, University of Maryland
Debra Jones Ringold, University of Baltimore

"Banning Cigarette Advertising: A Cure That Will Aggravate the Disease"480
Paul N. Bloom, University of North Carolina-Chapel Hill

"The Regulation of Cigarette Advertising in the United States: Some Alternatives"482
Edward T. Popper, Bryant College

Session 5.7

"The Effect of Framing on The Choice of Supermarket Coupons"488
William D. Diamond, University of Massachusetts
Abhijit Sanyal, University of Massachusetts

"The Framing of Sales Promotions: An Approach to Classification"494
William D. Diamond, University of Massachusetts
Robert R. Johnson, College of William and Mary

"Overestimating Salesperson Truthfulness: The Fundamental Attribution Error"501
Robert Baer, Bradley University

Session 6.1

"Halloween: An Evolving American Consumption Ritual"508
Russell W. Belk, University of Utah

Session 6.2

"Toward Improving Household Consumption Behavior Research: Avoidance of Pitfalls in Using Alternative Household Data Collection Procedures"518
Alvin C. Burns, Louisiana State University
James W. Gentry, University of Nebraska - Lincoln

Session 6.3

- "Message Framing Effects on Product Judgement".....531
Joan Meyers-Levy, Northwestern University
Durairaj Maheswaran, New York University

Session 6.4

- "The Effects of Music in Conditioning Brand Preference: Replication and Extension".....535
Kunal Basu, McGill University
Marvin Goldberg, McGill University
Gerald J. Gorn, University of British Columbia
- "Classical Conditioning of Negative Attitudes".....536
Elnora W. Stuart, Winthrop College
Terence A. Shimp, University of South Carolina
Randall W. Engle, University of South Carolina

Session 6.5

- "Order Effects in Consumer Judgment, Choice, and Memory: The Role of Initial Processing Goals".....541
Frank R. Kardes, University of Cincinnati
Paul M. Herr, Indiana University
- "Selective Attention in Consumer Information Processing: The Role of Chronically Accessible Attributes".....547
S. Ratneshwar, University of Florida
David Glen Mick, University of Florida
Gail Reiting, University of Florida
- "Multiattribute Judgments Under Uncertainty: A Conjoint Measurement Approach".....554
Amiya K. Basu, University of Illinois at Urbana-Champaign
Manoj Hastak, American University
- "An Examination of the Effects of Attribute Order and Product Order Biases in Conjoint Analysis".....563
Michael Tharp, Kent State University
Lawrence Marks, Kent State University

Session 6.7

- "The Power of Affective Reports in Predicting Satisfaction Judgments".....571
Laurette Dube-Rioux, University of Montreal
- "Emotional States and Decision Making".....577
Haim Mano, Washington University in St. Louis
- "Product Type: A Neglected Moderator of the Effects of Mood".....585
Meryl P. Gardner, University of Delaware
John E. Scott, University of Delaware
- Discussion: "Feelings About Feeling-State Research: A Search for Harmony".....590
Carl Obermiller, Seattle University
April Atwood, University of Washington

Session 7.2

- "An Empirical Assessment of Multiple Operationalizations of Involvement".....594
Kapil Jain, University of Rhode Island
Narasimhan Srinivasan, University of Connecticut
- "When Do The Measures of Knowledge Measure What We Think They are Measuring?".....603
Rajesh Kanwar, San Diego State University
Lorna Grund, San Diego State University
Jerry C. Olson, Pennsylvania State University
- "Individual Differences in Value Stability: Are We Really Tapping True Values?".....609
L. J. Shrum, University of Illinois at Urbana-Champaign
John A. McCarty, University of Illinois at Urbana-Champaign
Tamara L. Loeffler, University of Illinois at Urbana-Champaign
- Discussion: "Issues in Measuring Abstract Constructs"616
Judith L. Zaichkowsky, Simon Fraser University

Session 7.3

- "Ad Affect, Brand Attitude and Choice: The Moderating Roles of Delay and Involvement".....619
Amitava Chattopadhyay, McGill University
Prakash Nedungadi, University of Toronto

Session 7.4

- "The Vicissitudes of Product Experience: 'Songs of Our Consuming Selves' in Drama Ads"621
Gregory W. Boller, Memphis State University

Session 7.6

- "A Citation Analysis of the ACR Proceedings: A Knowledge Development and Social Exchange Perspective"627
George Zinkhan, University of Houston
Mary Jane Saxton, University of Houston
Marty Roth, Boston College
Jerry Zaltman, University of Pittsburgh

Session 7.7

- "Metaphor In Promotional Communication: A Review of Research on Metaphor Comprehension and Quality"636
James Ward, Arizona State University
William Gaidis, Marquette University
- "An Introduction to Semantic Variables in Advertising Messages"643
Karen A. Berger, Pace University
Robert F. Gilmore, The City University of New York
- "Temporal Variations In The Evaluation Of Television Advertisements: The Role Of Key Nonverbal Cues".....651
Siva K. Balasubramanian, University of Iowa
- Discussion: "How Does an Advertisement Mean -- Cue, Claim, Metaphor, Resonance?"658
Edward F. McQuarrie, Santa Clara University

Session 8.1

- "The Animal 'Other': Self Definition, Social Identity, and Companion Animals"662
Clinton R. Sanders, University of Connecticut
- "The Role of Possessions in Constructing and Maintaining a Sense of Past".....669
Russell W. Belk, University of Utah
- "To Me From Me: A Descriptive Phenomenology of Self-Gifts"677
David Glen Mick, University of Florida
Michelle DeMoss, University of Florida

Session 8.4

- "The Effect of Donor-Recipient Involvement on Consumer Gift Decisions".....683
Janet Wagner, University of Maryland
Richard Ettenson, University of Maryland
Sherri Verrier, University of Maryland
- "Gift Giving: Consumer Motivation and the Gift Purchase Process".....690
Cathy Goodwin, University of Alaska
Kelly L. Smith, Georgia State University
Susan Spiggle, The University of Connecticut
- "Motivations and Symbolism in Gift-Giving Behavior".....699
Mary Finley Wolfinbarger, University of California, Irvine
- Discussion: "Symbolism, Obligation, and Fiber Choice: The Macro to Micro
Continuum of Understanding Gift Giving"707
Scott D. Roberts, Old Dominion University

Session 8.5

- "Choose Your Own Price: An Exploratory Study Requiring an Expanded View of
Price's Functions"710
Michael Lynn, University of Missouri - Columbia
- "Assessing the Relationship Between Perceived and Objective Price-Quality: A Replication".....715
Scot Burton, Louisiana State University
Donald R. Lichtenstein, University of Colorado
- "Tipping As A Consumer Behavior: A Qualitative Investigation".....723
John A. McCarty, University of Illinois at Urbana-Champaign
L. J. Shrum, University of Illinois at Urbana-Champaign
Tracey E. Conrad-Katz, University of Illinois at Urbana-Champaign
Zacho Kanne, University of Illinois at Urbana-Champaign

Session 8.7

- "Consumer Market Beliefs: A Review of the Literature and an Agenda for Future Research".....729
Calvin P. Duncan, University of Colorado-Boulder
- "A New Perspective on Choice".....737
Kathleen M. Rassuli, Indiana-Purdue University at Fort Wayne
Gilbert D. Harrell, Michigan State University
- "Capricious Consumption and the Social Brain Theory: Why Consumers Seem Purposive
Even in the Absence of Purpose".....745
Joseph Cherian, University of Illinois - Chicago
Barbara Harris, University of Illinois - Chicago

Discussion: "A Commentary on New Theoretical Perspectives on Consumer Behaviour".....750
David W. Stewart, University of Southern California

Session 9.1

"The Effects of Situational and Intrinsic Sources of Personal Relevance on Brand
Choice Decisions".....755
Simeon Chow, University of South Carolina
Richard L. Celsi, California State University, Long Beach
Robin Abel, University of South Carolina

"Effects of Individual Difference Variables on Responses to Factual and Evaluative Ads".....761
Meera P. Venkatraman, Boston University
Deborah Marlino, Simmons College
Frank R. Kardes, University of Cincinnati
Kimberly B. Sklar, Pugh-Roberts Associates, Cambridge

"Situational Product Relevance and Attitude Persistence".....766
Curtis P. Haugtvedt, Ohio State University
Alan J. Strathman, Ohio State University

Session 9.2

"Further Validation of the Consumer Susceptibility to Interpersonal Influence Scale"770
William O. Bearden, University of South Carolina
Richard G. Netemeyer, Louisiana State University
Jesse E. Teel, University of South Carolina

"The Conceptual Organization of Behavior and Attitude-Behavior Consistency".....777
Mahmood M. Hajjat, The Ohio State University

"Constructing A More Difficult Recognition Test For Television Commercial Scenes".....785
Michael L. Rothschild, University of Wisconsin
Lisa Qualheim, University of Wisconsin
Brian Deith, University of Wisconsin
Yong J. Hyun, University of Wisconsin

Session 9.3

"Affect Intensity as an Individual Difference Variable in Consumer Response to
Advertising Appeals".....792
William D. Harris III, Ohio State University
David J. Moore, University of Michigan

Session 9.5

"Consumer Socialization Research: Content Analysis of Post-1980 Studies, and Some
Implications for Future Work".....798
Scott Ward, University of Pennsylvania
Donna Klees, University of Pennsylvania
Daniel B. Wackman, University of Minnesota

"An Investigation of Mothers' Communication Orientations and Patterns".....804
Les Carlson, University of Arkansas
Sanford Grossbart, University of Nebraska
Carolyn Tripp, University of Arkansas

"Children's Influence in Purchase Decisions: A Review and Critique"813
Tamara F. Mangleburg, Virginia Tech

Session 9.6

"Toward an Understanding of Social and World Systemic Processes in the Spread of Consumer Culture: An Anthropological Case Study".....826
Janeen A. Costa, University of Utah

"An Empirical Update and Extension of Patronage Behaviors Across the Social Class Hierarchy".....833
Scott Dawson, Portland State University
Bruce Stern, Portland State University
Tom Gillpatrick, Portland State University

"An Empirical Study of the Effects of Ethnicity on Consumption Patterns in a Bi-Cultural Environment".....839
Chankon Kim, Concordia University
Michel Laroche, Concordia University
Annamma Joy, Concordia University

Discussion: "Cultural Interpenetration: A Critical Consumer Research Issue for the 1990s".....847
Alan R. Andreasen, California State University, Long Beach

Session 10.1

"Consumption Styles of the Rich and Famous: The Semiology of Saul Steinberg and Malcolm Forbes".....850
Elizabeth C. Hirschman, Rutgers University

Session 10.2

"A Relational Model for Category Extensions of Brands".....856
Peter H. Farquhar, Carnegie-Mellon University
Paul M. Herr, Indiana University
Russell H. Fazio, Indiana University

Session 10.4

"The Cognitive Representation of Services Varying in Concreteness and Specificity".....861
Laurette Dube-Rioux, University of Montreal
Dennis T. Regan, Cornell University
Bernd H. Schmitt, Columbia University

"Testing a Theory of Crowding in the Service Environment".....866
Michael K.M. Hui, Concordia University
John E.G. Bateson, The London Business School

"The Effect of Positioning on the Purchase Probability of Financial Services Among Women with Varying Sex-Role Identities".....874
Lynn J. Jaffe, Northeastern University

Session 10.5

"The Antecedents of Cognitive Age".....880
Caroline Chua, Student, National University of Singapore
Joseph A. Cote, Washington State University
Siew Meng Leong, National University of Singapore

"Attitudinal and Leisure Activity Differences Across Modernized Household Life Cycle Categories".....886
William D. Danko, State University of New York
Charles M. Schaninger, State University of New York

"The Intensions and Extensions of the Time Concept: Contributions from a Sociological Perspective"	895
Carol J. Kaufman, Rutgers University	
Paul M. Lane, Western Michigan University	
Discussion: "Aging, Life Cycles and the Sociology of Time"	902
Elaine Sherman, Hofstra University	

From Hawaii

"Computer-Controlled Experimentation in Consumer Decision Making and Judgement"	905
Merrie Brucks, University of North Carolina	
"Product Category Perceptions, Elaborative Processing and Brand Name Extension Strategies"	910
Dipankar Chakravati, University of Arizona	
Deborah J. MacInnis, University of Arizona	
Kent Nakamoto, University of Arizona

ASSOCIATION FOR CONSUMER RESEARCH

ANNUAL CONFERENCE

**NEW ORLEANS MARRIOTT HOTEL
NEW ORLEANS, LOUISIANA
OCTOBER 19-22, 1989**

ACR PROGRAM

Conference Chairs:

**Marvin E. Goldberg
McGill University**

**Gerald J. Gorn/Richard W. Pollay
University of British Columbia**

THURSDAY, OCTOBER 19

REGISTRATION: 1:00 P.M. - 8:00 P.M.

10:00 A.M. - 5:00 P.M.	ACR EXECUTIVE BOARD MEETING	Balcony I (4th Floor, River Tower)
1:00 P.M. - 8:00 P.M.	REGISTRATION.....	Galerie Booth (2nd Floor)
6:00 P.M. - 8:00 P.M.	EARLY BIRD RECEPTION.....	Bissonet Room

FRIDAY, OCTOBER 20
REGISTRATION: 7:00 A.M. - 3:00 P.M.
1ST SESSION: 8:30 A.M. - 10:00 A.M.

1.1 Competitive Papers: *Qualitative Research and Its Evaluation*

Friday 8:30 A.M. - 10:00 A.M.....Galerie 1

Chair: Laurel A. Anderson, Arizona State University

"Regularities, Rules and Consumer Behavior: Tangencies Between Positivist and Interpretive Approaches to Research"
 Eileen Fischer, York University

"Eureka! and Other Tests of Significance: A New Look At Evaluating Interpretive Research"
 Craig J. Thompson, University of Tennessee

"Ritual, Ritualized Behavior, and Habit: Refinements and Extensions of the Consumption Ritual Construct"
 Mary A. Stanfield Tetreault, George Mason University
 Robert E. Kleine III, Arizona State University

"'To Everything There Is A Season:' A Photoessay of a Farmers' Market"
 Deborah D. Heisley, Northwestern University
 Mary Ann McGrath, Loyola University of Chicago
 John F. Sherry, Jr., Northwestern University

Discussant: Rebecca H. Holman, D'Arcy, Masius, Benton & Bowles Inc., New York

1.2 Special Session: *Psychophysiological Observations of Cognitive and Affective Processing*

Friday 8:30 A.M. - 10:00 A.M.....Galerie 2

Chair: Michael L. Rothschild, University of Wisconsin

"EEG as an Indicator of Micro Information Processing and a Predictor of Memory"
 Michael L. Rothschild, University of Wisconsin

"Physiological Indices of Communication Involvement and Attention to the Analysis of Broadcast Commercials"
 James E. Fletcher, University of Georgia
 John A. Shimell, Jr., Inner Responses Inc.

"Heart Rate as an Index of Attentional, Attitudinal and Memory Responses to Commercials"
 Esther Thorson, University of Wisconsin - Madison
 Brian Deith, University of Wisconsin - Madison

"Inferring Psychological Significance from Physiological Signals: A Theory of Psycho-Physiological Relationships"
 John T. Cacioppo, Ohio State University
 Louis G. Tassinary, University of Iowa

1.3 Special Session: *Imagery in Consumer Choice: Definitions, Predictions, and Measurement*

Friday 8:30 A.M. - 10:00 A.M.....Galerie 3

Co-Chairs: Deborah J. Mitchell, University of Pennsylvania
Richard L. Oliver, University of Pennsylvania
Thomas S. Robertson, University of Pennsylvania

"Imagery and Preference"
Paul Slovic, Decision Research

"An Exploratory Study of the Effect of Imagery on Expectations and Satisfaction"
Deborah J. MacInnis, University of Arizona
Linda L. Price, University of Colorado at Boulder

"Imaging/Analyzing Behavior and Choice"
Richard L. Oliver, University of Pennsylvania
Thomas S. Robertson, University of Pennsylvania
Deborah J. Mitchell, University of Pennsylvania

"Image Processing: Multiple Paths to Multiple Outcomes"
Julie A. Edell, Duke University

Discussants: John R. Rossiter, Australian Graduate School of Management
Susan E. Heckler, University of Michigan
Terry L. Childers, University of Minnesota

1.4 Special Session: *Pictures, Music and Humor: Stimulus Factors and Advertising Effectiveness*

Friday 8:30 A.M. - 10:00 A.M.....Galerie 4

Chair: Dipankar Chakravarti, University of Arizona

"Music as a "Peripheral Cue" in Advertising; Varying Dimensions and Influences on Ad and Brand Attitudes"
Deborah J. MacInnis, University of Arizona
C. Whan Park, University of Pittsburgh

"Humor in Advertising: Facilitation/Inhibition Effects on Memory for Brand Name and Message Claims"
Harishankar Krishanan, University of Arizona
Dipankar Chakravarti, University of Arizona

"Pictures and Words in Advertising: Memory and Selection Information Use in Consumer Choice"
Carolyn L. Costley, Texas A&M University
Merrie Brucks, University of North Carolina

1.5 Competitive Papers: Market Mavens and Opinion Leaders

Friday 8:30 A.M. - 10:00 A.M.....Balcony L
(4th Fl., River Tower)

Chair: Wesley J. Johnston, University of Southern California

"Generalization of the Market Maven's Information Provision Tendency Across Product Categories"
Mark E. Slama, Utah State University
Terrell G. Williams, California State University, Northridge

"An Assessment of the Moderating Effects of Market Mavenism and Value Consciousness On Price-Quality Perception Accuracy"
Donald R. Lichtenstein, University of Colorado
Scot Burton, Louisiana State University

"Opinion Leadership, Enduring Involvement and Characteristics of Opinion Leaders: A Moderating or Mediating Relationship?"
Meera P. Venkatraman, Boston University

Discussant: Robin A. Higie, University of Connecticut

1.6 Special Session: Service Encounters: Episodes & Entanglements Topic-of-Opportunity for the 1990's

Friday 8:30 A.M. - 10:00 A.M.....Galerie 6

Chair: Peter Wright, Stanford University

"Critical Service Encounter Events: Consumer and Employee Perspectives"
Mary Jo Bitner, Arizona State University

"Emotional Response to Service Encounters"
Marian Friestad, University of Oregon
Peter Wright, Stanford University

"From One Night Stands to Long-Term Relationships: Surrogate Consumers as Marketing Partners"
Michael Solomon, Rutgers University

"Service Encounter Research Opportunities: Views from Industry and Academia"
Peter Webb, Pacific Consulting Group

Discussant: Valerie Zeithaml, Duke University

<p style="text-align: center;">FRIDAY, OCTOBER 20 2ND SESSION: 10:30 A.M. - NOON</p>
--

2.1 Special Session: To Be Or What To Be: Theoretical and Methodological Approaches to the Study of Metaphor in Advertising and Promotion

Friday 10:30 A.M. - NOONGalerie 1

Co-Chairs: Jacqueline C. Hitchon, University of Wisconsin - Madison
Peter A. Dacin, University of Wisconsin - Madison

"Examining the Effects of Metaphor in Advertising: A Categorization Based Approach"
Peter A. Dacin, University of Wisconsin - Madison

"Beauty and Joy in Metaphorical Advertising: The Poetic Dimension"
Barbara Stern, Rutgers University

"The Use of Sensory Metaphors in Product Evaluation"
Trudy Kehret-Ward, University of California - Berkeley

"Market Metaphors in Meeting Mates"
Mara B. Adelman, Northwestern University
Aaron Bernard, Northwestern University

"The Metaphor of the Exotic: A Textual Analysis of the Banana Republic Mail Order Catalog"
Elli Lester-Massman, University of Georgia - Athens

2.2 Special Session: *Implication of Variety Seeking: Understanding the Link Between Satiating and Choice*

Friday 10:30 A.M. - NOONGalerie 2

Chair: David Schmittlein, University of Pennsylvania

"Market Share Response When Consumers Seek Variety"
Fred M. Feinberg, Duke University
Barbara Kahn, UCLA
Leigh McAlister, University of Texas

"Satiating and Switching: The Dynamic Attribute Satiating Model Meets Observed Choice Patterns"
Emine Sarigollu, McGill University
David Schmittlein, University of Pennsylvania

"Variety Seeking at the Group Level"
Joel H. Steckel, New York University

Discussant: Leigh McAlister, University of Texas

2.3 Special Session: *Toward a Redefinition of "Attitude" in Consumer Research: Lessons From the Study of Attitude-Behavior Relations*

Friday 10:30 A.M. - NOONGalerie 3

Chair: Sharon Shavitt, University of Illinois

"Effects of Self-Reflection on Attitudes and Consumer Decisions"
Timothy D. Wilson, University of Virginia
Douglas J. Lisle, University of Virginia
Dolores Kraft, University of Virginia

"Attitudes and Behavior: The Cognitive-Affective Mismatch Hypothesis"
Abraham Tesser, University of Georgia
Murray Millar, University of Wisconsin - Parkside

"Effects of Attribute Salience on the Consistency of Product Evaluations and Purchase Predictions"
Sharon Shavitt, University of Illinois
Russell H. Fazio, Indiana University

Discussant: Mark P. Zanna, University of Waterloo

2.4 Special Session: Social Network Approaches to Linking Individual Action and Market Processes

Friday 10:30 A.M. - NOONGalerie 4

Chair: Harry L. Davis, University of Chicago

"Cognition and Social Behavior"

Peter Reingen, Arizona State University
James Ward, Arizona State University

"Information Characteristics and the Impact of Social Ties on the Flow of Information in Markets"

Jonathan K. Frenzen, University of Arizona
Kent Nakamoto, University of Arizona

"Agreements in Dyadic Interactions"

Dawn Iacobucci, Northwestern University

"Market Consequences of Social Processes Unleashed: The Case of the Home Party"

Jonathan K. Frenzen, University of Arizona
Harry L. Davis, University of Chicago

Discussant: Wayne Baker, University of Chicago

2.5. Competitive Papers: Brand and Product Perceptions

Friday 10:30 A.M. - NOONBalcony L
(4th Fl. River Tower)

Chair: David K. Tse, University of British Columbia

"Brand Categorization and Product Involvement"

Jacques E. Brisoux, Universite du Quebec a Trois-Rivieres
Emmanuel J. Cheron, Universite Laval

"In Search of Brand Image: A Foundations Analysis"

Dawn Dobni, University of Houston
George M. Zinkhan, University of Houston

"Consumer Evaluation of Franchise Extension Products: A Categorization Processing Perspective"

Cathy L. Hartman, University of Calgary
Linda L. Price, University of Colorado
Calvin P. Duncan, University of Colorado

"Brand Cognitions as Determinants of Brand Attitudes: The Influence of Measurement and Processing Involvement"

Randall L. Rose, University of South Carolina
Paul W. Miniard, The Ohio State University
Sunil Bhatla, Case Western Reserve University

"The Role of Tangible and Intangible Attributes in Similarity and Preference Judgments"

Roxanne Lefkoff-Hagius, University of North Carolina at Chapel Hill
Charlotte H. Mason, University of North Carolina at Chapel Hill

Discussant: James A. Muncy, Clemson University

2.6 Special Session: Political Effects of the Talking Lamp: Individual Processing of Political Advertising on Television

Friday 10:30 A.M. - NOONGalerie 6

Chair: Esther Thorson, University of Wisconsin - Madison

"The Information Processing of Televised Political Advertising: Using Theory to Maximize Recall"
Annie Lang, Washington State University
Patrick Lanfear, Washington State University

"The Role of Cognitive Schemata in Determining Candidate Characteristics Effects"
Gina M. Garramone, Michigan State University
Michael E. Steele, Michigan State University
Bruce E. Pinkleton, Michigan State University

"Political Commercials: Issue-Image Strategies, Attack vs Support Appeals, and the Impact of Music and Visual Background"
Esther Thorson, University of Wisconsin - Madison
William G. Christ, Trinity University
Clarke Caywood, Northwestern University

"Effects of Commercial Complexity, Party Affiliation, and Issue vs Image Strategies in Political Ads"
Joan Schleuder, University of Texas

Discussant: James Farwell, Fauchaux Farwell Associates

**FRIDAY, OCTOBER 20
NOON - 1:30 P.M.

Luncheon

Presidential Address
Morris Holbrook, Columbia
(Bissonet Room)**

**FRIDAY, OCTOBER 20
3RD SESSION: 1:45 P.M. - 3:15 P.M.**

3.1 Special Session: Cultural and Measurement Issues in the Study of Materialism

Friday 1:45 P.M. - 3:15 P.M.....Galerie 1

Chair: Marsha L. Richins, University of Massachusetts

"Isolating the Effect of Non-Economic Factors on the Development of a Consumer Culture: A Comparison of Materialism in the Netherlands and the United States"
Scott Dawson, Portland State University
Gary Bamossy, Vrije Universiteit

"German and Canadian Data on Motivations for Ownership: Was Pythagoras Right?"
Floyd W. Rudmin, Queens University

"Measuring and Comparing Materialism Cross-Culturally"
Guliz Ger, Bilkent University
Russell W. Belk, University of Utah

"Measuring Material Values: A Preliminary Report of Scale Development"
Marsha L. Richins, University of Massachusetts
Scott Dawson, Portland State University

Discussant: Melanie Wallendorf, University of Arizona

**3.2 Special Session: *Substantive Theory in Social and Consumer Judgments:
Implications for the Validity of Measurement***

Friday 1:45 P.M. - 5:15 P.M. (Double Session).....Galerie 2

Co-Chairs: Carolyn J. Simmons, University of Illinois - Urbana
Lauranne Buchanan, University of Illinois - Urbana

"Cognitive Models for Behavioral Frequency Survey Questions"
E. Marla Felcher, Northwestern University
Bobby J. Calder, Northwestern University

"Reducing Response Error in Consumers' Reports of Medical Expenses: Application of Cognitive Theory to the Consumer Expenditure Interview Survey"
Leslie A. Miller, Bureau of Labor Statistics
Theodore Downes-Le Guin, University of Michigan

"Cognitive Aspects of Proxy Reporting of Behavior"
Barbara A. Bickart, University of Illinois - Urbana
Johnny Blair, University of Illinois - Urbana
Geeta Menon, University of Illinois-Urbana
Seymour Sudman, University of Illinois - Urbana

"Informant Reports of Dependence: Can We Get the Real Story?"
Lauranne Buchanan, University of Illinois - Urbana

"The Disruptive Effects of Self-Reflection"
Timothy D. Wilson, University of Virginia
Dolores Kraft, University of Virginia
Douglas J. Lisle, University of Virginia

"The Influence of Survey Format on Judgment Processes: The Case of Ideals and Perceived Similarity"
Jack M. Feldman, Georgia Institute of Technology
Scott Wesley, Georgia Institute of Technology
Michael Hein, Georgia Institute of Technology
Ann Gilmore, Georgia Institute of Technology

"Response Modes in Market Research"
Scott A. Hawkins, University of Chicago
Stephen J. Hoch, University of Chicago

Discussant: John G. Lynch, Jr., University of Florida

**3.3 Special Session: *Emerging Theoretical and Methodological Issues in the
Study of AAd and AB***

Friday 1:45 P.M. - 3:15 P.M.Galerie 3

Chair: Timothy B. Heath, University of Pittsburgh

"Accessibility as a Determinant of A_{Ad}'s Mediating Role"

Douglas M. Stayman, University of Texas
David A. Aaker, University of California

"Moderating Influences on the A_{Ad}-A_B Relationship"

Marian C. Moore, Duke University
Julie A. Edell, Duke University

"Measuring and Modeling Brand Interest as an Alternative A_{Ad} Effect with Familiar Brands"

Karen A. Machleit, University of Cincinnati
Thomas J. Madden, University of South Carolina
Chris T. Allen, University of Cincinnati

"An Experimental Investigation of Ad and Brand Effects After a Single Ad Exposure"

Timothy B. Heath, University of Pittsburgh

3.4 Competitive Papers: *The ELM Model: Central and Peripheral Factors in Persuasion*

Friday 1:45 P.M. - 3:15 P.M. Galerie 4

Chair: Alan S. Dick, SUNY at Buffalo

"The Elaboration Likelihood Model (ELM): Replications, Extensions and Some Conflicting Findings"

Catherine Cole, University of Iowa
Richard Ettenson, University of Maryland
Suzanne Reinke, University of Iowa
Tracy Schrader, University of Iowa

"The Interaction of Peripheral Cues and Message Arguments On Cognitive Responses to an Advertisement"

Judith E. Hennessey, California State University, Northridge
Shirley C. Anderson, California State University, Northridge

"The Effect of Background and Ambient Color on Product Attitudes and Beliefs"

Susan E. Middlestadt, University of Illinois, Urbana-Champaign

"Effects of Odd-Even Price Endings on the Image Communicated by an Advertisement"

Robert M. Schindler, University of Chicago
Thomas Kibarian, Stanford University

Discussant: Daniel J. Howard, Southern Methodist University

3.5 Competitive Papers: *Incomplete Information and Prior Knowledge*

Friday 1:45 P.M. - 3:15 P.M. Balcony L
(4th Floor River Tower)

Chair: Siew Meng Leong, National University of Singapore

"The Effects of Missing Information on Decision Strategy Selection"

Sandra J. Burke, The University of Michigan

"Knowledge and Context Effects on Typicality and Attitude Judgments"

Cynthia D. Huffman, University of Minnesota
Barbara Loken, University of Minnesota
James Ward, Arizona State University

"Inferences about Missing Attributes: Contingencies Affecting the Use of Alternative Information Sources"

Carolyn J. Simmons, University of Illinois at Urbana-Champaign
Nancy H. Leonard, University of Illinois at Urbana-Champaign

"The Effects of Familiarity on Cognitive Maps"

Haim Mano, Washington University in St. Louis
Scott M. Davis, Washington University in St. Louis

Discussant: David W. Schumann, University of Tennessee

3.6 Special Session: *The Impact of AIDS on Society: Future Directions and Potential Consumer Reactions*

Friday 1:45 P.M. - 3:15 P.M.....Galerie 6

Co-Chairs: Ronald Paul Hill, Villanova University
Debra L. Stephens, University of Maryland

"Emotional Response to AIDS Messages: The Use of Fear Appeals"
Pat Stout, University of Texas - Austin

"AIDS and the Arts"
Ronald Paul Hill, Villanova University

"Increasing Condom Consumption: Ideas from Past & Current Research"
Debra L. Stephens, University of Maryland
Elizabeth Cooper-Martin, Georgetown University

Discussant: Meryl Gardner, University of Delaware

FRIDAY, OCTOBER 20
4TH SESSION: 3:45 P.M. - 5:15 P.M.

4.1 Competitive Papers: *Compulsion, Risk Taking and Regulation*

Friday 3:45 P.M. - 5:15 P.M.....Galerie 1

Chair: Russell Lacznik, University of Vermont

"An Exploratory Study of Lottery Playing, Gambling Addiction and Links to Compulsive Consumption"

Alvin C. Burns, Louisiana State University
Peter L. Gillett, University of Central Florida
Marc Rubinstein, University of Central Florida
James W. Gentry, University of Nebraska-Lincoln

"Compulsive Buying Tendencies of Adolescent Consumers"

Alain d'Astous, University of Sherbrooke
Julie Maltais, University of Sherbrooke
Caroline Roberge, University of Sherbrooke

"Risk-Taking Behavior: Protecting Consumers from Themselves"

Jef I. Richards, University of Texas at Austin

4.2 Special Session: *Substantive Theory in Social and Consumer Judgments: Implications for the Validity of Measurement*

Friday 3:45 P.M. - 5:15 P.M.....Galerie 2

(Double Session Continued)

4.3 Special Session: *Context Effects in Consumer Choice*

Friday 3:45 P.M. - 5:15 P.M.....Galerie 3

Co-Chairs: Rashi Glazer, University of California, Berkeley
Itamar Simonson, University of California - Berkeley

"Context Effects in Search"
Joel Huber, Duke University
Itamar Simonson, University of California - Berkeley
Eluise Coupey, Duke University

"Choice in Context"
Itamar Simonson, University of California - Berkeley
Amos Tversky, Stanford University

"Context Effects and Measurement Indeterminacy in Consumer Judgments"
Rashi Glazer, Columbia University
Morris Holbrook, Columbia University

4.4 Competitive Papers: *The Structure of Persuasive Messages: Positive and Negative Information*

Friday 3:45 P.M. - 5:15 P.M.....Galerie 4

Chair: Fleming Hansen, The Copenhagen School of Business Administration and Economics

"Conceptualizing Argument Quality via Argument Structure"
Gregory W. Boller, Memphis State University
John L. Swasy, American University
James M. Munch, University of Delaware

"Mediators of Message Sidedness Effects on Cognitive Structure for Involved and Uninvolved Audiences"
Manoj Hastak, The American University
Jong-Won Park, University of Illinois at Urbana-Champaign

"How Do Consumer Inferences Mediate the Effectiveness of Two-Sided Messages?"
Cornelia Pechmann, University of California, Irvine

"The Impact of Product-Related Announcements on Consumer Purchase Intentions"
Raymond R. Burke, Wharton School, University of Pennsylvania
Jaewun Cho, Arizona State University
Wayne S. DeSarbo, University of Michigan
Vijay Mahajan, Southern Methodist University

Discussant: Wendy Bryce, Western Washington University

4.5 Competitive Papers: Consumer Expertise in Search and Preference

Friday 3:45 P.M. - 5:15 P.M.....Balcony L
(4th Floor, River Tower)

Chair: Jolita Kisielius, University of Illinois - Chicago

"Consumer Expertise and the Feature-Positive Effect: Implications for Judgment and Inference"
Frank R. Kardes, University of Cincinnati
David M. Sanbonmatsu, University of Utah
Paul M. Herr, Indiana University

"The Effects of Expertise on Preference and Typicality in Investment Decision Making"
W. Steven Perkins, Penn State University
Valerie F. Reyna, University of Arizona

"Information Examination as a Function of Information Type and Dimension of Consumer Expertise:
Some Exploratory Findings"
Akshay R. Rao, University of Minnesota
Eric M. Olson, University of Minnesota

Discussant: John G. Myers, University of California, Berkeley

4.6 Special Session: Research, Teaching and Professional Issues for Women in Consumer Behavior: Do Women Have a Different Experience?

Friday 3:45 P.M. - 5:15 P.M.....Galerie 6

Co-Chairs: Valerie Folkes, University of Southern California
Henriette Sanft, University of Southern California

Panel: Elizabeth Hirschman, Rutgers University
Deborah Marlino, Simmons College
Mita Sujun, Pennsylvania State University
Alice Tybout, Northwestern University
Melanie Wallendorf, University of Arizona
Valerie Zeithaml, Duke University

SATURDAY, OCTOBER 21
5TH SESSION: 8:30 A.M. - 10:00 A.M.

5.1 Competitive Papers: Self Identity and Symbolic Consumption

Saturday 8:30 A.M. - 10:00 A.M.....Balcony I
(4th Fl., River Tower)

Chair: Timothy P. Meyer, University of Wisconsin

"The Meaning of Custom-Made Homes: Home as a Metaphor for Living"
C. B. Claiborne, Virginia Polytechnic Institute and State University
Julie L. Ozanne, Virginia Polytechnic Institute and State University

"T-Shirts as Wearable Diary: An Examination of Artifact Consumption and Garnering Related to Life Events"

T. Bettina Cornwell, Memphis State University

"A Conception of Consumer Identity"

Richard A. Feinberg, Purdue University
S.J. Yoon, Purdue University
Lori Westgate, Purdue University
Charles Trappey, Purdue University
Jodie Monger, Purdue University
Peter Smith, Louisiana State University, Shreveport
Dennis Raphael, Ministry of Education, Toronto

"Symbolic Interactionism: Some Implications for Consumer Self-Concept and Product Symbolism Research"

Dong H. Lee, Indiana University

Discussant: Robert F. Kelly, University of British Columbia

5.2 *Competitive Papers: Varying Approaches To Data Analysis*

Saturday 8:30 A.M. - 10:00 A.M.....Galerie 2

Chair: Allan D. Shocker, University of Minnesota

"How Regular is Regularity? An Empirical Test of the Regularity Assumption"

Thomas S. Gruca, University of Massachusetts

"Effects of the Mass Media News on Trends in the Consumption of Caffeine-Free Colas"

David P. Fan, University of Minnesota
Carol L. Shaffer, University of Minnesota

"A Structural Examination of Two Optimal Stimulation Level Measurement Models"

Russell G. Wahlers, Ball State University
Michael J. Etzel, University of Notre Dame

"Specifying Measurement Error in Structural Equation Models: Are Congeneric Measurement Models Appropriate?"

Joseph A. Cote, Washington State University
Robert Greenberg, Washington State University

Discussant: Stephen J. Arnold, Queen's University

5.3 *Special Session: New Directions in Research on Memory Based and Mixed Judgment*

Saturday 8:30 A.M. - 10:00 A.M.....Galerie 3

Co-Chairs: Manoj Hastak, The American University
John G. Lynch, University of Florida

"Competitive Advertising and Consumer Choice"

Raymond R. Burke, University of Pennsylvania
Hubert Gatignon, University of Pennsylvania

"Memory and Evaluation Effects in Competitive Advertising Environments"

Kevin Lane Keller, Stanford University

"Judgment Updating Strategies: Effects of New Information on Existing Product Evaluations"
Manoj Hastak, The American University

"On-Line Cognition in Consumer Memory and Judgment"
Thomas K. Srull, University of Illinois

5.4 Special Session: *The Role of Humor in Advertising*

Saturday 8:30 A.M. - 10:00 A.M.....Balcony J
(4th Floor, River Tower)

Chair: Amitava Chattopadhyay, McGill University

"Humorous Advertising: An Assessment of the Affect Transfer Hypothesis"
Thomas J. Madden, University of South Carolina

"The Importance of Humor Type in Humor-Dominant Commercials"
Paul Speck, University of Tennessee

"Humor in Advertising: The Moderating Role of Prior Brand Evaluation"
Amitava Chattopadhyay, McGill University
Kunal Basu, McGill University

"Repetition, Perceived Humor, and Wearout"
George M. Zinkhan, University of Houston
Betsy Gelb, University of Houston

Discussant: Calvin P. Duncan, University of Colorado

5.5 Competitive Papers: *Approaches to Understanding Information Processing*

Saturday 8:30 A.M. - 10:00 A.M.....Galerie 5

Chair: Anthony D. Cox, Indiana University

"Parallel Processing Models of Consumer Information Processing: Their Impact on Consumer Research Methods"
Dawne Martin, University of Calgary
Pamela Kiecker, Texas Tech University

"The Effect of Imagery Processing and Imagery Content on Behavioral Intentions"
Paula Fitzgerald Bone, West Virginia University
Pam Scholder Ellen, Georgia State University

"Style of Information Processing Differences in Relation to Products, Shopping, and Self-Consciousness"
Stephen J. Gould, Rutgers, The State University of New Jersey

Discussant: G. David Hughes, University of North Carolina

5.6 Special Session: *In The Name of Consumer Welfare: The Proposal to Ban Cigarette Advertising and Promotion*

Saturday 8:30 A.M. - NOON (Double Session).....Galerie 6

Chair: John E. Calfee, University of Maryland

"Tobacco in the Popular Press: 1925-60"
Gary T. Ford, The American University
Debra Jones Ringold, University of Baltimore
Martha Rogers, Bowling Green State University

"What Will Happen If Cigarette Advertising and Promotion are Banned?"
John E. Calfee, University of Maryland
Debra Jones Ringold, University of Baltimore

"The Regulation of Cigarette Promotion in the U.S.: Some Alternatives"
Edward T. Popper, Bryant College

"The Ban of Tobacco Products Advertising: The Canadian Experience"
Richard W. Pollay, University of British Columbia

Panel: Paul Bloom, University of North Carolina
Joel B. Cohen, University of Florida
Richard A. Daynard, Northeastern University
Harold H. Kassarian, UCLA
Joseph Mulholland, Federal Trade Commission
Judy P. Wilkenfeld, Federal Trade Commission
William Wilkie, University of Notre Dame

5.7 Competitive Papers: Information Processing Issues in Promotion and Sales

Saturday 8:30 A.M. - 10:00 A.M.....Balcony K
(4th Fl., River Tower)

Chair: Peter Bloch, University of Massachusetts

"The Effect of Framing on The Choice of Supermarket Coupons"
William D. Diamond, University of Massachusetts
Abhijit Sanyal, University of Massachusetts

"The Framing of Sales Promotions: An Approach to Classification"
William D. Diamond, University of Massachusetts
Robert R. Johnson, College of William and Mary

"Overestimating Salesperson Truthfulness: The Fundamental Attribution Error"
Robert Baer, Bradley University

Discussant: Harish Sujana, Pennsylvania State University

<p>SATURDAY, OCTOBER 21 6TH SESSION: 10:30 A.M. - NOON</p>
--

6.1 Special Session: Holiday Rituals and Consumption

Saturday 10:30 A.M. - NOON.....Balcony I
(4th Floor, River Tower)

Chair: Eric J. Arnould, University of Arizona

"Thanksgiving Day Feasts: A Pictorial Analysis of Consumption"
Eric J. Arnould, University of Arizona
Melanie Wallendorf, University of Arizona

"Halloween: An Evolving American Consumption Ritual"
Russell W. Belk, University of Utah

"'Tis the Season to be Jolly?: Tensions and Trends in Christmas Shopping"
Eileen Fischer, York University

**6.2 Special Session: *The 1989 Household Consumption Behavior Research Forum
Toward Improving Household Consumption Behavior Research:
Avoidance of Pitfalls in Using Alternative Household Data
Collection Procedures***

Saturday 10:30 A.M. - NOON.....Galerie 2

Co-Chairs: Alvin C. Burns, Louisiana State University
James W. Gentry, University of Nebraska-Lincoln

"Methodological Problems in Survey and Experimental Research on Family Choice"
Kim P. Corfman, New York University

"Pitfalls in Obtaining Family Purchase Research Data"
Ellen R. Foxman, Washington State University
Patriya S. Tansuhaj, Washington State University

"A Simulation Game as a Family Research Paradigm"
James W. Gentry, University of Nebraska-Lincoln
Jeffery J. Stoltman, Wayne State University
Kevin R. Coulson, University of Nebraska-Lincoln

"Information Integration Theory Approach to Husband-Wife Decision Making"
James Shanteau, Kansas State University
C. Michael Troutman, Charles & Associates

"Longitudinal Methods for Family Consumer Research"
Alladi Venkatesh, University of California - Berkeley

Discussants: William J. Qualls, Massachusetts Institute of Technology
Michael D. Reilley, Montana State University

6.3 Special Session: *Message Framing Effects on Product Judgments*

Saturday 10:30 A.M. - NOON.....Galerie 3

Chair: Alice M. Tybout, Northwestern University

"Framing of Attribute Information in Product Descriptions"
Gary J. Gaeth, University of Iowa
Irwin P. Levin, University of Iowa
Susan Combs, University of Iowa

"Investigating Message Framing Effects on Consumer Judgments: The Influence of Personal
Relevance and Product Risk"
Joan Meyers-Levy, Northwestern University
Durairaj Maheswaran, New York University

"Individual Differences in Preferences for Numeric/Verbal Framing"
Nancy Artz, University of Southern Maine

"Exploring Temporal Perspective Framing Effects"
Carolyn Yoon, Duke University
Joan Meyers-Levy, Northwestern University
Alice M. Tybout, Northwestern University

Discussant: Christopher Puto, University of Arizona

6.4 Special Session: *Opportunities and Challenges in Empirical Research Using an Associative Learning Paradigm*

Saturday 10:30 A.M. - NOON.....Balcony J
(4th Floor, River Tower)

Chair: Chris T. Allen, University of Cincinnati

"The Effects of Music in Conditioning Brand Preference: Replication and Extension"
Kunal Basu, McGill University
Gerald J. Gorn, University of British Columbia
Marvin Goldberg, McGill University

"The Reinforcement Properties of Music Videos: I Want My ... I Want My ... MTV"
Basil G. Englis, Rutgers University

"Assessing the Impact of Cartoon Characters Using an Associative Learning Paradigm with Preschool Children"
Chris T. Allen, University of Cincinnati
M. Carole Macklin, University of Cincinnati

"Negative Conditioning of Attitudes: Implications for Consumer Research"
Elnora W. Stuart, Winthrop College
Terence A. Shimp, University of South Carolina

6.5 Competitive Papers: *Consumer Judgements: Primacy Effects, Attribute Uncertainty and Attribute Accessibility*

Saturday 10:30 A.M. - NOON.....Galerie 5

Co-Chairs: Tina Kiesler, University of Southern California
Michael A. Kamins, University of Southern California

"Order Effects in Consumer Judgment, Choice, and Memory: The Role of Initial Processing Goals"
Frank R. Kardes, University of Cincinnati
Paul M. Herr, Indiana University

"Selective Attention in Consumer Information Processing: The Role of Chronically Accessible Attributes"
S. Ratneshwar, University of Florida
David Glen Mick, University of Florida
Gail Reiting, University of Florida

"Multiattribute Judgments Under Uncertainty: A Conjoint Measurement Approach"
Amiya K. Basu, University of Illinois at Urbana-Champaign
Manoj Hastak, American University

"An Examination of the Effects of Attribute Order and Product Order Biases in Conjoint Analysis"
Michael Tharp, Kent State University
Lawrence Marks, Kent State University

Discussant: Wes Hutchinson, University of Florida

6.6 Special Session: *In The Name of Consumer Welfare: The Proposal to Ban Cigarette Advertising and Promotion*

Saturday 10:30 A.M. - NOON.....Galerie 6
(Double Session Continued)

6.7 Competitive Papers: *Affective States and Consumer Preferences and Decision-Making*

Saturday 10:30 A.M. - NOON.....Balcony K
(4th Fl., River Tower)

Chair: April M. Atwood, University of Washington

"The Power of Affective Reports in Predicting Satisfaction Judgments"
Laurette Dube-Rioux, University of Montreal

"Emotional States and Decision Making"
Haim Mano, Washington University in St. Louis

"Product Type: A Neglected Moderator of the Effects of Mood"
Meryl P. Gardner, University of Delaware
John E. Scott, University of Delaware

Discussant: Carl Obermiller, Seattle University

SATURDAY, OCTOBER 21
NOON - 1:30 P.M.
Luncheon
Business Meeting
Award Presentations
Salons D & E

SATURDAY, OCTOBER 21
7TH SESSION: 1:45 P.M. - 3:15 P.M.

7.1 Special Session: *The Forest or the Trees?: Perspectives on Product Complementarity*

Saturday 1:45 P.M. - 3:15 P.MBalcony I
(4th Floor, River Tower)

Chair: Michael R. Solomon, Rutgers University, New Brunswick

"Charting Consumption Constellations: A Role Theory Perspective on Product Complementarity"
Michael R. Solomon, Rutgers University, New Brunswick

"The Diderot Effect: Reflections on Why Goods Run in Packs"
Grant McCracken, University of Guelph

"Variety, Complementarity, and Similarity: An Investigation in the Context of the Performing Arts"
William J. Havlena, Rutgers University, Newark
Susan L. Holak, Rutgers University, Newark

Discussant: Morris B. Holbrook, Columbia University

7.2 Competitive Papers: *Improving Construct Measurements: Involvement, Knowledge and Values*

Saturday 1:45 P.M. - 3:15 P.M.Galerie 2

Chair: J. Michael Munson, Santa Clara University

"An Empirical Assessment of Multiple Operationalizations of Involvement"
Kapil Jain, University of Rhode Island
Narasimhan Srinivasan, University of Connecticut

"When Do The Measures of Knowledge Measure What We Think They are Measuring?"
Rajesh Kanwar, San Diego State University
Lorna Grund, San Diego State University
Jerry C. Olson, Pennsylvania State University

"Individual Differences in Value Stability: Are We Really Tapping True Values?"
L. J. Shrum, University of Illinois at Urbana-Champaign
John A. McCarty, University of Illinois at Urbana-Champaign
Tamara L. Loeffler, University of Illinois at Urbana-Champaign

Discussant: Judith L. Zaichkowsky, Simon Fraser University

7.3 Special Session: *Research Linking Advertising Exposure to Choice*

Saturday 1:45 P.M. - 3:15 P.M.Galerie 3

Chair: Andrew Mitchell, University of Toronto

"Ad Affect, Brand Attitude and Choice: The Moderating Roles of Delay and Involvement"
Amitava Chattopadhyay, McGill University
Prakash Nedungadi, University of Toronto

"Advertising and Consumer Choice: A Look at the Logic and Psychologic"

PRESIDENTIAL ADDRESS
**The Role of Lyricism in Research On Consumer Emotions: Skylark, Have
You Anything to Say to Me?**
Morris B. Holbrook, Columbia University¹

ABSTRACT

This paper examines the role of lyricism in research on consumer emotions. It associates lyricism with the songlike expression of feelings and suggests that, as the content of consumer research deals increasingly with emotional phenomena, its style must adapt accordingly. In this, our work must incorporate aspects of singing. Herein, it may depart from some traditional canons of science narrowly conceived, but may retain consistency with a broader conception of scholarship. Additional support for this point emerges from postmodern and feminist perspectives on the philosophy of science. Further, the paper itself illustrates the lyrical style and thereby exemplifies the phenomenon of which it speaks. In sum, it expresses the hope that consumer researchers may find a new voice so as to transcend some limitations of their conventional impoverished language by drawing on the force of lyricism in research on consumer emotions.

God guard me from those thoughts men think
In the mind alone;
He that sings a lasting song
Thinks in a marrow-bone
[W. B. Yeats (1935), "A Prayer for Old Age,"
Collected Poems, p. 281].

... Now my ladder's gone,
I must lie down where all the ladders start,
In the foul rag-and-bone shop of the heart
[W. B. Yeats (1936-1939), "The Circus
Animals' Desertion," *Collected Poems*, p.
336].

We know truth not only by reason but more
by the heart [Blaise Pascal, quoted by Scruton
(1981), p. 45].

The feelings expressed in music are incapable
of articulation, not because they are too
vague for words, but on the contrary because
they are too specific [Felix Mendelssohn,
quoted by Crutchfield (1987), p. 1].

the lyric poet...through the medium of the
emotions...has enabled us to glimpse
spiritual depths which until now were closed
and inaccessible to himself as well as to

us.... every great lyricist gives us knowledge
of a new feeling for the world. He shows us
life and reality in a form in which we feel we
have never known it before.... All this "is"
and "endures"; it discloses to us a *knowledge*
which cannot be grasped in abstract concepts,
which stands before us, nevertheless, as the
revelation of something new, something
never before known or familiar [Ernst
Cassirer (1961), *The Logic of the Humanities*,
p. 85].

Somewhere afield here something lies
In Earth's oblivious eyeless trust
That moved a poet to prophecies --
A pinch of unseen, unguarded dust:

The dust of the lark that Shelley heard,
And made immortal through times to be --
Though it only lived like another bird,
And knew not its immortality....

Go find it, faeries, go and find
That tiny pinch of priceless dust,
And bring a casket silver-lined,
And framed of gold that gems encrust;

And we will lay it safe therein,
And consecrate it to endless time;
For it inspired a bard to win
Ecstatic heights in thought and rime
[Thomas Hardy (1887), "Shelley's Skylark"].

*

Today is a very *emotional* day for me. It is
also a very emotional day for *you*. And, indeed, it
is a very emotional day for *all consumers*
everywhere because emotion, I would argue, lies at
the heart of the consumption experience as an
inextricable part of the basic human condition. This
faith in the importance of emotional responses in
the lives of consumers has sustained me for a
number of years and has, I'm happy to say, begun to
win acceptance as a fairly conventional point of
view shared by others, too numerous to mention,
who are doing excellent work in this area of
investigation.

In short, it seems safe to say that,
collectively, we have now accepted emotion as an
important topic for study. The remaining questions
concern not whether but rather how to proceed when
conducting research on the emotional aspects of the
consumption experience. In this connection (to
preview briefly), I wish to argue that -- contrary to
our age-old devotion to a pseudo-scientific style of
writing -- our discourse on emotion must show more
feeling. We must, I believe, replace our typically
cold, impersonal, dispassionate, literal mode of

¹The author thanks Steve Bell, Beth Hirschman,

their helpful comments on earlier drafts of this
paper. He also gratefully acknowledges the
support of the Columbia Business School's
Faculty Research Fund.

2 / The Role of Lyricism in Research on Consumer Emotions

communicating with warmer, more colorful, richer, and more metaphoric uses of language. In other words, when speaking about emotional consumption experiences, we must adopt a style more lyrical (by which I mean more expressive) than that to which we have grown accustomed.

This conviction accounts for the first part of my title -- namely, "The Role of Lyricism in Research on Consumer Emotions." But you may still wonder how to explain my subtitle -- "Skylark, Have You Anything to Say to Me?" That phrase refers, of course, to the first line of "Skylark," a wonderful old ballad written in 1941 by Hoagy Carmichael and Johnny Mercer, recently repopularized by such singers as Bette Midler and Linda Ronstadt, and characterized by Alec Wilder in his book on the *American Popular Song* (1972) by such adjectives as "superior," "remarkable, distinguished," and "extraordinary" (p. 383). Further -- reflecting the location of ACR's 1989 Conference in New Orleans, the birthplace of jazz -- "Skylark" has long been a favorite tune of jazz musicians. Indeed, I might best account for my subtitle by telling you a brief story about a jazz singer whom I once heard on a trip to the South.

*

A few years ago, Sally, Chris, and I visited Charlotte, North Carolina, where our friends took us to a concert to hear a marvelous singer named Marlene Ver Planck, who commands a voice as pure and soft as mountain snow. As Marlene sang her first song, accompanied by the Loonis McGlohon Trio, I was in seventh heaven and only barely noticed a large white-haired lady who entered and sat down on the seat in front of me. Then the musicians began their version of "Skylark." After some slow, pensive chords from Loonis on the piano, Marlene stepped to the microphone, closed her eyes, tilted back her head, and sang: "Skylark..., have you anything to say to me?"

As she began this phrase, her words hit the air like bells ringing sweet and clear above the crowd. The concert hall fell as quiet as a church. And, in this reverent silence, the large white-haired lady on the seat in front of me let out a clearly audible gasp of appreciation -- "aaahhh."

After the intermission, Marlene began her second set by introducing a few old friends from Charlotte who were seated in the audience. She mentioned a couple of local celebrities whose names I no longer remember, and then she called on the great operatic soprano, Eileen Farrell. The spectators broke into a thunderous ovation. And the large white-haired lady on the seat in front of me stood up and took a bow.

*

Clearly, what I had witnessed in that spontaneous gasp of appreciation was the immediate but deep emotional reaction of one great artist to another. My intimately shared view of Eileen Farrell admiring Marlene Ver Planck represents a facet of the consumption experience that usually occurs more privately. It represents a profound aesthetic response far deeper than anything that might be

characterized as simple hedonic pleasure. It represents a state of nearly spiritual ecstasy duplicated elsewhere only in elevated levels of exalted rapture or cosmic consciousness.

It also raises questions about how we can account for such transcendental consumption experiences. In the present case, I suspect that this magic resulted from the utter perfection in Marlene Ver Planck's rendering of Hoagy Carmichael's achingly beautiful tune and Johnny Mercer's poignantly tender lyrics. In short, I suspect that it resulted from a brief but nearly quintessential manifestation of what we might call *the power of lyricism*.

*

For years, as a student of English, I wondered what people meant when they talked about "lyricism." What makes a lyrical poet "lyrical"? Why do we call the words to a song its "lyrics"? What is the connection of lyricism with the small stringed instrument, the little ancient harp, that we refer to as a "lyre"?

In Greek mythology, Hermes (the messenger of the gods who gave his name to hermeneutics or the theory of interpretation) received credit for inventing the lyre (a stringed instrument whose name provides the root for the word "lyrical"). The great musician Orpheus used his lyre to soothe the wild beasts, to move the rocks, to make the trees dance, and to stop the river of time. Thus, the book on *Greek Myths* by Robert Graves (1981) calls Orpheus "the most famous poet and musician who ever lived" (p. 44). A review by Andrew Porter (1988) sees Orpheus as the "embodiment of music's power over the emotions" (p. 106); points out that this has made him a favorite protagonist in operas by great composers ranging from Monteverdi and Gluck to Stravinsky to Hans Werner Henze and Lukas Foss; and concludes that

Orpheus, who demonstrated that song can override the stern rules of the physical world -- moving mountains, bringing the dead to life -- remains the musician's greatest hero (p. 111).

Indeed, in appreciation for these gifts, Apollo placed the lyre of Orpheus in heaven among the constellations of stars.

The lyre has lent its name to the lyrical form in poetry. According to Northrop Frye and his colleagues, "Lyrical poetry began in ancient Greece in connection with music, as poetry sung, for the most part, to the accompaniment of a lyre" (Frye et al. 1985, p. 268). In general, as suggested by M. H. Abrams (1988):

the term is now used for any fairly short, nonnarrative poem presenting a speaker who expresses a state of mind or a process of thought and feeling.... the lyric is uttered in the first person.... A lyric poem may be simply a brief expression of a mood or a state of feeling (pp. 97-98).

Thus, "the majority of lyrics consist of thoughts and feelings uttered in the first person" (Abrams 1953, p. 85).

A book entitled *The Idea of Lyric: Lyric Modes in Ancient and Modern Poetry* by W. R. Johnson (1982) emphasizes the first-person aspects of the classical (as opposed to the modern) lyric as found in the "pronomial patterning" of the "I-You poem" (p. 3) before its evolution in the direction of more meditative forms. Johnson argues that "when the lyric poet casts his poem in the first-person singular..., the integrity of lyric form and lyric impulse remains intact" (p. 149):

What is essential, then, to lyric is rhetoric, and essential to this lyrical rhetoric...is the pronomial form and lyric identity, the dynamic configuration of lyrical pronouns that defines and vitalizes the situation of lyrical discourse (p. 23).

This first-person discourse in "lyric poetry...about our feelings" (p. 13) lends itself to the creation of "lyric poems where emotions...are distilled to their richest purity" (p. 13):

The most usual mode in Greek lyric (probably) and in Latin lyric (certainly) was to address the poem (in Greek, the song) to another person or to other persons. What this typical lyric form points to is the conditions and the purposes of song: the presence of the singer before his audience; his re-creation of universal emotions in a specific context...; and, finally, the sharing, the interchange of these emotions by singer and audience (p. 4).

In the romantic tradition celebrated by M. H. Abrams in *The Mirror and the Lamp* (1953), the lyrical poem expresses "the spontaneous overflow of feeling" (p. 97):

Poetry is the expression or overflow of feeling, or emerges from a process of imagination in which feelings play the crucial part (p. 101).

Along similar lines, *The Logic of the Humanities* by Ernst Cassirer (1961) describes the lyric as follows:

Indeed, the lyric appears to be, of all the arts, the most fluid and fleeting.... If there is an attempt here to hold fast to anything, it is to change as such -- the coming and going, the emerging and the vanishing, the suggestion and tantalization of the subtlest stirrings of the soul, and the most transient of the sentiments.... For there are, after all, only a few great and fundamental themes to which lyric poetry may apply itself.... lyric poetry never leaves the sphere of human feelings....

Always lyric poetry resolves itself into the "natural forms of humanity" (pp. 209-210).

In *The Roots of Lyric*, Andrew Welsh (1978) acknowledges the Wordsworthian conviction that "poetic language arises from occasions of particular excitement and passion" (p. 3) and ties this poetic impulse to the *melos* (meaning song or music) of Aristotle (p. 135), the *melopoeia* (meaning musicality) of Ezra Pound (p. 15), and the *melos* (meaning the musical principle in verbal organization) of Northrop Frye (p. 18):

The melopoeia of song and the melopoeia of speech...recall...the lyre and the lute of the Greek Melic poets and the medieval troubadours as emblems of the lyric grace to be heard within (p. 195).

However, Welsh also emphasizes the magic, incantatory, enchanting charm by which lyrical discourse acquires the power to move:

The point is that charms are first and foremost concerned with power, with the use of magic words.... It is the sense of sacred formality, the *necessity* for the compelling, incantatory quality, that produces the rich webs of sound in charms. At the roots, the words of a charm are themselves magic actions...of words which move (p. 145).

In search for words which move, then, the language of magic sought out what became the melopoeia of charms, a special language of webs of sound and irregular rhythms different from the language used to communicate ordinary meanings.... The language of the charms is a language of power, and that power comes primarily...from other meanings hidden deep in the sounds and rhythms (p. 153).

*

In sum, though a variety of different meanings have attached to the term, the adjective "lyrical" (with all its suggestions of emotive power) literally means "suitable for singing." Thus, it would be redundant to apply the term to a song itself because that is what the word denotes in the first place. Rather, we say that some other discourse is lyrical when we mean that it is *like* a song. In this sense, lyricism connotes songlike qualities associated with the sharing of personal feelings. Like some primordial urge that gives birth to singing and that (in the views of Vico and Rousseau) is perhaps associated with the origins of language itself, lyricism expresses emotion. In the song by Carmichael and Mercer, the primary emotion expressed concerns a deep yearning for romantic love.

*

Skylark, have you anything to say to me?

4 / The Role of Lyricism in Research on Consumer Emotions

Won't you tell me where my love can be?
Is there a meadow in the mist,
Where someone's waiting to be kissed?

*

I believe that such emotions -- as captured by the lyrical voice -- deserve a place in consumer research, in at least two senses. As already mentioned, the first sense involves the way in which consumption activities prompt emotional responses. Clearly, as consumers, we feel joy, sadness, anger, and fear. To paraphrase the words of "Just Friends" by Sam Lewis and John Klenner, we love, we laugh, we cry. In short, we knit the fabric of our consumption experiences around their emotional consequences, around our appreciative responses. In this, how we *act* as consumers in making purchase decisions becomes less important than how we *react* in the resulting emotions that move and stir our lived experiences. A valid body of consumer research must reflect this fact. It must reflect the importance of emotion in its *content* or *substance*.

This insight has won fairly wide acceptance in our discipline by now. But I would add that consumer research must also increasingly reflect the importance of emotion in its *form* or *style*. This second point on the matching of matter and manner is a bit more controversial and probably requires a few words of justification. Here, I refer to what I perceive as the need for more lyricism in consumer research -- the need to create a mode of communicating that sounds less matter of fact and more expressive, less humdrum and more songlike, less "scientific" and more "poetic."

*

Under the sway of our concern for scientific rigor, most of us engage in a rarefied, depersonalized, colorless, desiccated, rational, dreary, cold, and dispassionate sort of rhetoric. Indeed, for a long time, many thinkers have distinguished sharply between scientific and poetic forms of discourse. According to this distinction, the former conveys facts whereas the latter expresses feelings. Thus, a literary critic such as I. A. Richards (1926, 1935, ed. 1970) contrasted science (logical, factual) with poetry (emotional, feelingful). Linguists like Roman Jakobson (ed. 1976) have separated lyricism (emotive, songlike, first-person, metaphorical) from epic or narrative (referential, prosaic, third-person, metonymic). Semioticians have followed Charles Morris (1946) in emphasizing the difference between scientific discourse (designative-informative) and poetic discourse (appraisive-valuative):

the language of empirical science is adapted to expressing the truth and not the importance of its statements. Lyric poetry...uses terms...for...values and evaluations (p. 58).

Similarly, the early Roland Barthes (1964) pursued Hjelmslev's contrast between denotation and

connotation. More recently, Pierre Guiraud (1975) has distinguished the referential (logical, denotative, objective, scientific) from the emotive (aesthetic, connotative, subjective, artistic):

The two principal modes of semiological expression are the referential (objective, cognitive) function and the emotive (subjective, expressive) function. They stand in antithetical opposition to one another to such an extent that the notion of a "double function" of language can be extended to all modes of signification. In fact, *understanding* and *feeling*, mind and soul, constitute two poles of our experience and correspond to modes of perception which are not only opposed but are inversely proportional, so that one could define *emotion* as an incapacity to understand: love, pain, surprise, fear, etc., inhibit the intellect, which is incapable of comprehending what is happening (p. 9).

M. H. Abrams (1979) draws a related distinction between scientific and humanistic demonstrations:

A humanistic demonstration, unlike a scientific demonstration, is rarely such as to enforce the consent of all qualified observers. For it to carry the reader through its exposition to its conclusions requires some grounds for imaginative consent, some comparative ordering of values, some readiness of emotional response to the matters shown forth, which the reader must share with the author even before he begins to read; and these common grounds are no doubt in part temperamental, hence variable from reader to reader (p. 194).

Meanwhile, a psychologist like Jerome Bruner (1986) contrasts the paradigmatic with the narrative (p. 12) and scientific writing with the language of poetry (p. 22). Even the humanistically inclined sociologist Peter Berger (1963) suggests that one should not mix the scientific with the subjective but rather should keep them as meticulously separate as meat and milk in a kosher kitchen (p. 124). And, speaking of humanism, the self-proclaimed generalist C. P. Snow (1959, ed. 1964) once inflamed his colleagues by pointing to a rift between "the two cultures": the sciences and the humanities.

I suggest, then, that a basic dichotomy -- reference versus emotion, facts versus feelings, science versus poetry, logic versus lyric -- has won wide acceptance and informs the literary efforts of virtually every serious writer. Further, in our eagerness to achieve the status of scientists, most of us have learned to pursue the former and to shun the latter.

Yet we pay a price for this attempt to retreat into a coldly dispassionate form of discourse. Often, our gains in factual accuracy and freedom from

value-based biases are partially offset by an atmosphere of bland indifference that prompts many of our readers to wonder, in effect, "So what?" or "Who cares?"

We may be prepared to pay this price when we study such phenomena as brand choice or purchase decisions. But, when we come to phenomena related to consumers' emotions, we run the risk that our scientific rhetoric may actually falsify the phenomena we claim to illuminate. Even Charles Morris (1946) admits this danger:

Since scientific language is pre-eminently designative in mode and informative in use, the tendency is strong to place reliance upon scientific discourse and to avoid, or even derogate, the other types of discourse. In so far as such "scientism"...discourages the use of non-designative signs it is theoretically questionable and culturally dangerous (pp. 116-117).

Thus, the study of emotions seems to call for an expressive mode of discourse. Along these lines, in *The Logic of the Sciences and the Humanities*, F. S. C. Northrop (1947) notes the power of art to convey reality (pp. 173-186, passim); and, in *The Philosophy of Rhetoric*, I. A. Richards (1936) acknowledges the "mysterious power" of *exemplifying* what one describes (p. 121).

*

That false attempts at scientific rigor and quantification in the realm of the emotions can do more harm than good appears clearly in Act I of Shakespeare's *King Lear* (ed. 1970). The king immediately establishes his affinity with consumer researchers by announcing that he has "a constant wish to publish" (I.i.43). However, what he wants to "publish" or to proclaim is a clarification of his daughters' dowries. And, toward that end, he asks the three girls to be precise in stating their feelings toward him in quantitative terms: "Which of you shall we say doth love us most/That we our largest bounty may extend" (I.i.51-52). The only true response comes from Cordelia, who recognizes that she *cannot* weigh and objectify her emotions in this manner and therefore vows to say "Nothing" (I.i.87-89): "Love, and be silent.... my love's/More ponderous than my tongue" (I.i.62 and I.i.77-78). Lear's cruel and foreboding response -- "Nothing will come of nothing" (I.i.90) -- fails to recognize the folly of reducing the emotions to the scientific mode of discourse and thereby lays a foundation for the tragedy that follows. Consumer researchers concerned with emotion might wonder whether we, in our quest for a dispassionate language of facts and numbers, might also rush headlong into the arms of tragedy.

*

In a postmodern conception of science -- perhaps one drawing on something close to the post-Cartesian, antifoundationalist, arepresentational view (or *nonview*) of epistemology articulated by Richard Rorty in *Philosophy and the Mirror of*

Nature (1979) -- knowledge is socially constructed and depends on the consensus of people interacting in dialogues and discussions so that the community becomes the primary source of epistemic authority:

justification is not a matter of a special relation between ideas (or words) and objects, but of conversation, of social practice. Conversational justification, so to speak, is naturally holistic, whereas the notion of justification embedded in the epistemological tradition is reductive and atomistic.... The crucial premise of this argument is that we understand knowledge when we understand the social justification of belief, and thus have no need to view it as accuracy of representation.... So holism produces...a conception of philosophy which has nothing to do with the quest for certainty (pp. 170-171).

Via such conversations, we feel emotions. Those emotions must affect our work, whether we admit it or not. To deny this is to threaten our own humanity:

The fear of...scientism...is the fear that all discourse will become normal discourse.... This is frightening because it cuts off the possibility of something new under the sun, of human life as poetic rather than merely contemplative (pp. 388-389).

To try to write research reports devoid of emotion is to try to smuggle one's feelings past one's colleagues undetected. By contrast, those reports might more honestly reflect the emotional underpinnings from which they spring.

This need for research to carry the expression of its own emotional foundations becomes especially apparent when the focus of the study is emotion itself. In other words, if we want to write about love, about joy, about ecstatic moments of profound aesthetic rapture -- or alternatively about hate, about sadness, about anger verging on white-hot fury -- we may need to adopt a mode of discourse that lets the audience *feel* what we are saying. If we want to claim that emotions matter, we may need to *show* that they matter in the way we tell about them.

*

Few philosophers of science (Rorty, perhaps, included) would readily agree with this argument. Those such as Hanson (1958), Koestler (1964), Bronowski (1965), or Brannigan (1981) -- who have much to say about the scientist's intuitive, playful, and creative but always socially embedded subjective personal introspections -- tend to see the researcher's own emotions as a mode of discovery rather than justification. In this quasi-Reichenbachian spirit, they consign emotions to the front end of a hypothetico-deductive process (where the propositions get formulated) rather than to the back end (where the results get reported).

To this, I have two responses.

*

First, if we wish to resist the scientists and to avoid watching our discipline drained of its emotional fervor, perhaps we ought to re-examine our position. Here, in agreement with an article by Herbert Rotfeld entitled "Marketing Educators Must Become More 'Scholarly'" (1985), I believe that academicians owe an allegiance to their profession above and beyond that which they owe to science narrowly conceived. Specifically, they owe a paramount obligation to *scholarship*. The *sine qua non* for the academic profession is scholarship, not science. Perhaps, then, what we need in consumer research on emotions is not so much science as scholarly work that somehow manages to preserve the researcher's emotions and to keep them intact.

*

Second, perhaps the conventional views of science are themselves wrong. Perhaps one cannot explain the world in a discourse stripped of its affective content. Perhaps we lose too much when we try to reduce our feelings to facts, our emotions to cognitions, our passions to thoughts.

Some of the more conventional perspectives on consumer research -- for example, the focus that uses rational choice models to represent purchase decisions -- demand a self-consciously logical and dispassionate approach. After all, in such a world view, we can state axioms, derive propositions through the application of logic, and test those hypotheses empirically. This degree of precision proves comforting to the scientist and scholar alike.

But, as we turn to an increased interest in the role of emotion in the consumption experience, we are encouraged to embrace a more qualitative, subjective, impressionistic, introspective, personal, metaphorical, anecdotal -- yes, a more lyrical -- approach to our topic. Further, as we deal more with emotional content, our manner of communicating will, as always, be more effective if it reflects the nature of our subject matter. And so, whether we like it or not, we may be forced to abandon the prosaic in favor of the poetic. We may be compelled to retreat, in part, from speech into song.

[With this awakening of lyricism, incidentally, we shall overcome our semi-official aversion to the self-designating pronouns (not to mention our fondness for what Barbara Stern calls the "deadly" passive voice and for lackluster "to be" verbs), and we shall speak more often in the first-person singular. Increasingly, the pronouns "we" and even "I" will replace "you" and "they." We shall witness a diminution of "he," "she," "it," and (mercifully) "s/he." Clearly, we must applaud any trend that removes "s/he" forever from our vocabulary.]

In arguing for a more lyrical style of communication in scientific consumer research on emotions, I might cite two potential sources of support -- the first from literary criticism, the second from the philosophy of science itself.

*

First, as discussed by M. H. Abrams in *The Mirror and the Lamp* (1953), the neoclassical

literary critics (paragons of rationality) believed strongly in "the basic neo-classic unifying principle of decorum" (p. 290) that argued for "the traditional consideration of style from the point of view of its appropriateness to the subject matter" (p. 234) so as to require an "adjustment to the...matter signified, as well as the character and emotional state of the speaker depicted" (p. 290). This principle received its most famous epigrammatic articulation in Alexander Pope's apothegm from "An Essay on Criticism" (1711) urging that "The sound must seem an echo to the sense" (l. 365). In *The Rhetoric of Fiction*, Wayne Booth (1961, ed. 1983) invokes a comparable "process whereby substance and form, subject and treatment, matter and manner become fused" (p. 104). In this connection, Northrop Frye and his colleagues (1985) suggest that "the rhetorical device known as imitative harmony, or making the sound, in Pope's phrase, an echo to the sense, is most common in lyric" (p. 269). Not surprisingly, then, Andrew Welsh's *Roots of Lyric* (1978) makes much of Pope's prescription vis-a-vis the verbal dance or musical discourse that transpires in the most lyrical poetic moments:

Pope points to something that happens in the language of poetry, that sophisticated poets take the care to make happen and that readers of poetry have learned to admire. To say that sound echoes sense in a poem is to say that the poet has involved melopoeia with...logopoeia (p. 243).

More recent critics have sometimes referred to Pope's dictum and its various generalizations as "the fallacy of imitative form," which Christopher Lehmann-Haupt (1986) explains as "the error of, say, writing chaotic prose in order to convey a mood of chaos" (p. C21). However, Lehmann-Haupt admits that experts he consulted "reacted to my inquiries as if I were trying to sell them hand cranks for starting cars" (p. C21).

Adopting a less "cranky" posture, others have celebrated the wisdom of matching style to substance, form to content. For example, in a book edited by Berel Lang on *The Concept of Style*, Albert Hofstadter (1979) distinguishes among lyric, drama, and epic narrative; suggests that "the lyrical persona is directly engaged in an experience it is expressing" so that "the possibilities of emotional response...in the case of the lyric are directly embodied in the individual lyrical persona" (p. 74); and concludes that "the communicative differences" (between lyric, drama, and epic) "exist in order to express the cognitive differences, and at the same time their existence tends to generate and sustain the very possibility of such cognitive differences" (p. 76).

In short, a poet requires some conformability between substance (matter) and the style (manner) in which it is communicated so as to achieve a unity of purpose and structure, of content and form. In simpler terms, this emphasis on the matching of manner to matter appears to paraphrase a more

jargon-rich statement later in the same book by Monroe Beardsley (1979):

Distinguished, or especially admirable, style, on the other hand, consists in the harmonious adjustment of many concurrent and overlapping illocutionary actions, so that varied subordinate actions combine for richness in communication and intensity of pervasive style-quality (p. 163).

Thus, to repeat, our manner must echo our matter; our form must mirror its content; our style must convey our substance; our way of speaking must embody our message; our voice must articulate its theme.

*

A second argument for a more lyrical style of communication in consumer research on emotions comes from some newer trends in the philosophy of science and its relation to the role of semiotics, hermeneutics, and rhetoric. For example, Umberto Eco's book on *The Theory of Semiotics* (1976) tears apart the positivistic referential theory of meaning that informed the work of I. A. Richards and argues for an inextricable chain of denotation and connotation in which one *cannot* in principle remove the latter. It follows that the only honest science acknowledges its own emotional and motivational bases:

Frequently to be really "scientific" means not pretending to be more "scientific" than the situation allows.... *Ceteris paribus*, I think that it is more "scientific" not to conceal my own motivations, so as to spare my readers any "scientific" delusions (p. 29).

This point recalls the perspective of Friedrich Nietzsche, who inveighed against the *possibility* of value-free, dispassionate discourse and loaded his own style with hyperbole to serve as a constant reminder of its basis in personal interpretation:

Nietzsche uses his changing genres and styles...to prevent his readers from overlooking the fact that his views necessarily originate with him. He depends on many styles in order to suggest that there is no single, neutral language in which his views, or any others, can ever be presented. His constant stylistic presence shows...that the very distinction between the content of a view and the manner in which that view is presented is to be seriously questioned (Nehamas 1985, p. 37).

According to Allan Megill's *Prophets of Extremity* (1985), Nietzsche called his *Birth of Tragedy* "music" and felt that it should be *sung* (p. 90). Similarly, according to Roger Norrington (himself a great conductor), Nietzsche also said that "all thought that does not dance is dead" (quoted by Stearns 1989, p. 106).

Though it does not explicitly mention Nietzsche, the influential work on *Personal Knowledge* by Michael Polanyi (1958) evinces a comparable distrust of objectivism and embraces the emotional -- indeed, the passionate -- bases of both discovery *and* justification. Thus, Polanyi (1958) starts by "rejecting the ideal of scientific detachment" and replacing it with "an alternative ideal of knowledge" based on "the *personal participation* of the knower in all acts of understanding" (p. vii) where "into every act of knowing there enters a passionate contribution of the person knowing what is being known" (p. viii):

We reach here the decisive issue of the theory of knowledge. Throughout this book I have persistently followed one single endeavour. I have tried to demonstrate that into every act of knowing there enters a tacit and passionate contribution of the person knowing what is being known, and that this coefficient is no mere imperfection, but a necessary component of all knowledge (p. 312).

In this view, motivated by "intellectual desire" (p. 128) or by intuitive "heuristic craving" (p. 130), discovery moves beyond tacit skills and inarticulate connoisseurship (p. 55) -- beyond ineffable Gestalts (p. 88) -- to achieve experiences of "ecstatic communion" (p. 7). Further, despite the prevailing conception of science based on "the disjunction of subjectivity and objectivity," justification or verification or demonstration requires "forms of persuasion which can induce a conversion" (p. 151) and, therefore, *does* entail "*persuasive* passion" (p. 159) or "passionate, personal, human appraisals of theories" in which "we cannot truly account for our acceptance of such theories without endorsing our acknowledgement of a beauty that exhilarates and a profundity that entrances us" (p. 15):

The affirmation of a great scientific theory is in part an expression of delight. The theory has an inarticulate component acclaiming its beauty.... This is the kind of feeling described in the title of this chapter as 'Intellectual Passions'.... A scientific theory which calls attention to its own beauty, and partly relies on it for claiming to represent empirical reality, is akin to a work of art.... More generally, science, by virtue of its passionate note, finds its place among the great systems of utterances which try to evoke and impose correct modes of feeling (p. 133).

Thus, Polanyi adopts a view of scientific knowledge as rooted in "a fiduciary framework" (p. 266) that readily accepts its own personal and emotional components:

personal knowledge in science...commits us, passionately and far beyond our comprehension, to a vision of reality. Of

this responsibility we cannot divest ourselves by setting up objective criteria of verifiability -- or falsifiability, or testability, or what you will.... Like love, to which it is akin, this commitment is a 'shirt of flame', blazing with passion and, also like love, consumed by devotion to a universal demand (p. 64).

In this view, then, science converges with art:

The decisive part which intellectual passions have been shown to play in the several domains of natural science, engineering, and mathematics, demonstrates the ubiquity of such participation.... The arts appear then no longer as contrasted but as immediately continuous with science.... There is present a personal component, inarticulate and passionate, which declares our standards of values, drives us to fulfill them and judges our performance by these self-set standards (p. 195).

Indeed, when at last he turns his attention to the *human* sciences, Polanyi proposes a principle that sounds very much like a transported version of literary decorum:

Facts about living things are more highly personal than the facts of the inanimate world. Moreover, as we ascend to higher manifestations of life, we have to exercise ever more personal faculties -- involving a more far-reaching participation of the knower -- in order to understand life.... as we proceed to survey the ascending stages of life, our subject matter will tend to include more and more of the very faculties on which we rely for understanding it. We realize then that what we observe about the capacities of living beings must be consonant with our reliance on the same kind of capacities for observing it (p. 347).

More recently, in *Consequences of Pragmatism*, Richard Rorty (1982) recalls the Nietzschean perspective on the mistake inherent in any hope for a neutral vocabulary (p. 193), inveighs against the fetish of filtering the subjective components from one's thoughts (p. 194), and adopts a quasi-Polanyian view in which social science approaches art:

What we hope for from social scientists is that they will act as interpreters for those with whom we are not sure how to talk. This is the same thing we hope for from our poets and dramatists and novelists (p. 202).

This point gains impetus, I believe, when coupled with the relativism of Paul Feyerabend's *Against Method* (1975), recently called forcefully to our attention by Paul Peter and Jerry Olson (1983) and

by Paul Anderson (1983). (Apparently, when dealing with relativism, it helps to be named Paul.) In their cleverly titled piece -- "Is Science Marketing?" -- Peter and Olson capture the essence of Feyerabend's (1975) argument that when theories become incommensurable (Ch. 17), the only possible grounds for the justification of theoretical preferences become "aesthetic judgements, judgements of taste" (p. 285) so that, in effect, "anything goes" (p. 296) and emotional propaganda becomes part of the scientific process (p. 154). In short, scientific justification rests not on proof but on persuasion. This persuasive task calls upon the use of rhetoric. Thus, in *Science in a Free Society*, Feyerabend (1982) calls upon the rhetorical use of emotions to supplement reason in scientific argumentation:

I also favour imagination and emotion but I don't want them to *replace* reason, I want them to *limit it*, and to *supplement it* (p. 189).

This argument from the need for justification to the role of persuasion to the power of rhetoric to the use of emotional appeals parallels such earlier articulations as J. S. Mill's insistence that "eloquence" uses "feelings" to affect "beliefs" (Abrams 1953, p. 321) and F. S. C. Northrop's (1947) contention that, used properly, poetry and art can *convey* scientific truth:

the art of the future will...take the new conception of the theoretic component of reality...and...convey this conception metaphorically...in terms of the vivid aesthetic materials given in immediate intuition. Then and not until then will there be poetry...which meets the emotional, moral, aesthetic and intellectual needs of contemporary men (p. 186).

It is ours...to start afresh with the immediacy of experience as it has forced the scientist to new and more adequate theory, and, in terms of this theory to make articulate a new philosophy joining the theoretic and aesthetic components of reality, thereby defining a new meaning for human existence and hence a new morality, which it will be the privilege of some Dante of the future to express metaphorically and embody aesthetically in the feelings and emotions of men (p. 189, italics removed).

As developed in a long line of tradition traced back at least as far as the Greeks and surveyed magisterially in Perelman and Olbrechts-Tyteca's *The New Rhetoric: A Treatise on Argumentation* (1958, ed. 1969), rhetoric is "the art of persuading and of convincing, the technique of deliberation and of discussion" (p. 5) and, as such, involves "the *discursive means* of obtaining the adherence of minds" via "the technique which uses language to

persuade and convince" (p. 8). Here, the focus of the authors "constitutes a *break with a concept of reason and reasoning due to Descartes*" (p. 1) and dwells instead on "the theory of argumentation" as "the study of the discursive techniques allowing us to induce or to increase the mind's adherence to the theses presented for its assent" (p. 4):

The goal of all argumentation...is to create or increase the adherence of minds to the theses presented for their assent (p. 45).

In seeking this "adherence of minds," the authors place a strongly customer-oriented emphasis on "the essential role played by the audience" (p. 7) and repeatedly call attention to this basic principle in the marketing of ideas:

There is only one rule in this matter: adaptation of the speech to the audience, whatever its nature (p. 25).

The central principle, in this connection, is always adaptation to the audience (p. 461).

The guiding consideration...should be the needs of adaptation to the audience (p. 508).

This orientation prepares the way for an almost scornful dismissal of scientific detachment:

The authors of scientific reports and similar papers often think that if they merely report certain experiments, mention certain facts, or enunciate a certain number of truths, this is enough of itself to automatically arouse the interest of their hearers or readers. This attitude rests on the illusion, widespread in certain rationalistic and scientific circles, that facts speak for themselves and make such an indelible imprint on any human mind that the latter is forced to give its adherence regardless of its inclination (p. 17).

In place of the scientific "illusion," Perelman and Olbrechts-Tyteca repeatedly argue (contra Ogden and Richards) that one *cannot*, in principle, separate descriptive from emotive meaning (p. 140) so that "the distinction between the emotive aspect and the descriptive aspect of a concept is questionable" (p. 447) and "if it is possible to discern...some statements that relate to facts, and others that relate to values, the distinction between these two forms of statement can never be clear cut" (p. 513):

Nothing could be more arbitrary than the distinction made in textbooks between factual, neutral, descriptive speech, and sentimental, emotive speech. These distinctions have the sole advantage of drawing the student's attention to the fact that value judgments are very obviously introduced into argumentation, but they are harmful in that they imply that there are ways of

expressing oneself that are per se descriptive, that there are speeches in which only facts, with their unquestionable objectivity, find place (p. 150).

Thus, one can never remove values from scientific discourse. Rather, "values enter, at some stage or other, into every argument" (p. 75):

In reasoning of a scientific nature, they are generally confined to the beginning of the formulation of the concepts and rules that constitute the system concerned and, insofar as the reasoning aims at the truth value, to the conclusion (p. 75).

From this, it follows that even scientific arguments will include such emotional elements as "illustrations...chosen for their affective impact" (p. 360) and "feelings of the speaker" that "serve as an indication of sincerity" (p. 456):

What is required in argumentation is not so much the exactness of specific logical modalities attributed to what is asserted, as the means of obtaining the adherence of the audience through variations in the way of expressing thought (p. 163).

The version of the "new rhetoric" advanced by Richard McKeon in *Thought, Action, and Passion* (1954) and in *Rhetoric: Essays in Invention and Discovery* (ed. 1987) pursues a similar point of view. McKeon (1987) defines rhetoric as "the art of persuasion and debate" (p. 108): "As an art of communication rhetoric has been designed to make use of all means of persuasion" (p. 109). According to the introductory comments by Mark Backman, "McKeon's most important contribution" was to oppose "the arbitrary separation of rhetoric from philosophy": "The divorce of rhetoric from philosophy, of expression from content, prevents the intellectual synthesis essential to resolving the persistent problems of being, thinking, and acting" (p. xi). Thus, McKeon (1954) argued that "science, and philosophy...rhetoric, ...poetry...are not distinct in the context or in the techniques from which they arise, and...to separate them is to be guilty of unwarranted dichotomies and abstractions" (p. 13). In the more recent collection of essays, McKeon (1987) suggests that "rhetoricians...today might make rhetoric an architectonic art which relates all things by means of science and the experiences of men" and adds that "we seek to produce it in concrete experience and existence by rejoicing reason and sense, cognition and emotion" (p. 13).

These viewpoints from "the new rhetoric" have exerted considerable influence in a variety of disciplines. For example, in literary criticism, compendious works such as Wayne Booth's *The Rhetoric of Fiction* (1961, ed. 1983) see rhetoric as "the art of communicating with readers" or "the effort to help the reader grasp the work" (p. xiii) so

that, again, a strong customer-oriented emphasis attaches to the role of the audience:

The ultimate problem in the rhetoric of fiction is, then, that of deciding for whom the author should write.... And nothing the writer does can be finally understood in isolation from his effort to make it all accessible to...his audience (pp. 396-397).

From this, it follows that one cannot choose *whether* but can only choose *how* to use rhetoric:

The author cannot choose whether to use rhetorical heightening. His only choice is of the kind of rhetoric he will use (p. 116).

the author cannot choose to avoid rhetoric; he can choose only the kind of rhetoric he will employ (p. 149).

Thus, "rhetorical inquiry is universally applicable" (p. 405); or, to put the same point somewhat differently, the author cannot choose to disappear. Rather, "the author's judgment is always present, always evident to anyone who knows how to look for it" (p. 20). In this sense, "neutrality is impossible" (p. 76), and the affective evaluations of an implied author always emerge: "The emotions and judgments of the implied author are...the very stuff out of which great fiction is made" (p. 86).

Even more relevant to our present focus, a systematic view of rhetoric as the art of persuasion (p. 46) and of scientific methodology as the art of rhetoric (p. 162) appears in Kenneth Burke's *A Rhetoric of Motives* (1969). More recently, in *Modern Dogma and the Rhetoric of Assent*, Wayne Booth (1974) has developed the relevance of what he calls "emotional proof" (p. 158) -- for example, the use of arguments in which "love constitutes a good reason" (p. 162). (Here, for brevity, I neglect some important related rhetorical devices such as the use of figurative language -- for example, metaphors and other kinds of tropes. For a short review, see Abrams 1988, pp. 64-68.)

Gradually, comparable viewpoints have shone on the philosophy of science. In *The Return to Cosmology*, for example, Stephen Toulmin (1982) distinguishes early between science and poetry but nevertheless gravitates toward a postmodern view of "the need to reinsert humanity into nature" (p. 210). Thus, Toulmin focuses on the Cartesian dichotomy between subject and object and on the resulting view of science as objective versus subjective (p. 241). He views this Cartesian objectivity as "an Idol" (p. 248), pronounces that "the scientist as spectator is dead" (p. 252), and moves toward a postmodern view based on the metaphor of being "at home in the world of nature" (p. 272) -- a metaphor that he illustrates with nothing less than a quote from T. S. Eliot's "Little Gidding" (1942, ed. 1962) in which "the rose" stands for contemplation and "the fire" represents passion:

We shall not cease from exploration
And the end of all our exploring
Will be to arrive where we started
And know the place for the first time....
And all shall be well and
All manner of thing shall be well
When the tongues of flame are in-folded
Into the crowned knot of fire
And the fire and the rose are one (p. 145).

Thomas Nagel's *The View From Nowhere* (1986) pursues similar themes by expressing a concern for the absurdity of the Cartesian subject/object dichotomy (p. 220), by acknowledging the limits of objectivity (p. 87), and by seeking a possible harmony or resolution in an attitude that others have characterized as endemic to the realm of aesthetic experience:

Finally, there is an attitude which cuts through the opposition between transcendent universality and parochial self-absorption, and that is the attitude of nonegocentric respect for the particular. It is conspicuous as an element in aesthetic response, but it can be directed to all kinds of things, including aspects of one's own life. One can simply look hard at a ketchup bottle, and the question of significance from different standpoints will disappear.... the object engages us immediately and totally in a way that makes distinctions among points of view irrelevant.... such an attitude...toward the elements of everyday life...would require an immediacy of feeling and attention to what is present (pp. 222-223).

This possible mode of apprehending reality constitutes the essence of what Morris Berman (playing on Max Weber) calls *The Reenchantment of the World* (1981). Berman laments the divorce between scientists and poets and the consequent repudiation of emotion (p. 45), which he characterizes as the motto to "kill anything that moves" (p. 120). Drawing on analogies with alchemy, Berman envisions a dissolution of the subject-object dichotomy via a "participating consciousness" that merges subject and object, self and other, in a holistic worldview:

unless...participating consciousness can be restored in a way that is scientifically (or at least rationally) credible and not merely a relapse into naive animism, then what it means to be a human being will forever be lost (p. 132).

Thus, Berman hopes to overcome the Cartesian duality and to enter a world of "sensual or affective science" (p. 183) in which "eros is a fully articulated way of knowing the world" (p. 157), science is grounded in "the human experience of nature" (p. 187), and "the important thing is that affect and analysis not be differentiated" (p. 186).

Recently, we have experienced a comparable focus in the work by Russ Belk, Tom O'Guinn, John Sherry, Melanie Wallendorf, and others who describe evocatively and document carefully the role of deep meanings in possessions. [See, for example, the videotape by Wallendorf and Belk (1987), available from MSI.] In this view, a subject-object fusion enriches the psychic life of property via a consciousness of commodities that informs the essential character of the consumption experience. In profound aesthetic experience, I have argued, this fusion reaches the heights of ecstatic rapture when the subject-object dichotomy disappears (Holbrook 1980).

Other commentators have focused on similar phenomena. For example, in *Literature and Science*, the novelist Aldous Huxley (1963) describes the merger of the subjective and objective that results in *samadhi* and *satori* (p. 76). Jack Burnham (1973) points out that, in *The Raw and the Cooked*, anthropologist Claude Levi-Strauss set his chapter outlines to musical forms, thereby attempting "the reconciliation of poetry and science" (p. 16). Meanwhile, both Dudley Andrew (1984) and Jonathan Culler (1983) see Roland Barthes as progressing from the structuralism of, say, *Elements of Semiology* (1964) or *The Fashion System* (1967) to the anarchic hedonism of, say, *The Pleasure of the Text* (1973). Even as early as *Mythologies*, however, Barthes (1957) denied the Cartesian dichotomy:

I cannot countenance the traditional belief which postulates a natural dichotomy between the objectivity of the scientist and the subjectivity of the writer (p. 12).

An occasional social scientist has pursued a comparable line of thought. For example, the sociologist Richard Brown has argued persuasively for *A Poetic for Sociology* (1977). Among anthropologists, in work later collected under the title *Works and Lives: The Anthropologist as Author*, Clifford Geertz (1988) has moved some distance toward embracing the role of rhetoric at the core of scientific conviction wherein "the relation between the *ars intelligendi*, the art of understanding, and the *ars explicandi*, the art of presentation, is so intimate in anthropology as to render them at base inseparable" (p. 46). For Geertz, "ethnography...is a work of the imagination" (p. 140) that draws on rhetorical devices in a manner such that "the writing of ethnography involves telling stories, making pictures, concocting symbolism, and deploying tropes" (p. 140), all intended to produce conviction in the reader:

The ability of anthropologists to get us to take what they say seriously has less to do with either a factual look or an air of conceptual elegance than it has with their capacity to convince us that what they say is a result of their having actually

penetrated...another form of life, of having, one way or another, truly "been there." And that, persuading us that this offstage miracle has occurred, is where the writing comes in (pp. 4-5).

Influenced by this Geertzian perspective, Renato Rosaldo's essay in *The Rhetoric of the Human Sciences* (1987) calls attention to how the traditional distancing rhetoric of ethnography begins to sound like parody when applied to deep emotional experiences so that "reports cast in the normalizing ethnographic idiom trivialize the events they describe by reducing the force of intense emotions to spectacle" (p. 99). Countering this tendency to lose the phenomenon, Rosaldo proposes "a more personal, particularizing, experiential rhetoric" (p. 101).

Probably no social scientist has gone farther than Donald McCloskey in *The Rhetoric of Economics* (1985) in analyzing the scientific use of persuasive techniques. Calling on the work of Feyerabend, Booth, Polanyi, Toulmin, and Rorty -- among others -- McCloskey sees good rhetoric as enhancing the persuasiveness of the scientific "conversation" in its movement toward intersubjectivity (p. 27). Accordingly, his "Rhetoric of Economics" appears to have paved the way for a review of two books by Kenneth Boulding recently written by the Nobel Laureate Wassily Leontief for the *New York Times* (1986):

The indisputable success of Mr. Boulding's writing is probably to a considerable extent due to his truly magisterial style -- one is tempted to say, his rhetoric.... If the purpose of communication is to persuade, then oratorical discourse, which exploits to the full the emotional suggestiveness and occasional ambiguity of common language, should prove to be quite effective (p. 7).

Perhaps more than any other thinker (and sooner than most), Charles Davy captured the essence of the proposed rapprochement between science and lyrical poetics. In his book entitled *Towards a Third Culture*, Davy (1978) follows Vico and Rousseau when he suggests that the primeval languages, like those of primitive peoples still, were "more poetic" (symbolic) and "more song-like" (using variations in tone and pitch) than modern languages and that this form of expression "went with...a sense of immediate participation in...life and...nature which we have largely lost" (p. 50) so that we now find ourselves "strangers in a universe that has lost human meaning" (p. 51). Historically, "participating consciousness" has yielded to "onlooker consciousness" in which "thinking and feeling tend to fall apart" (p. 64). Aphoristically, "when imagination fails, the measurable becomes the measure of all things" (p. 71). Thus, Davy calls for a humanizing counter-current in the form of a new culture:

the third culture...will retain the particular virtues of the scientific outlook -- disciplined thinking, respect for facts, testing by experiment -- but it will use them differently.... it will be...also a religious and an artistic culture (p. 93).

Davy associates the "counter-current" of the third culture with "a humanizing influence" (p. 104) and a "new imagination" (p. 115) in which "the poet and the artist are...clairvoyant in the sense of perceiving more in the world than most of us do" (p. 116) in the way that lines of poetry "differ in meaning from a factual prose statement":

they operate differently on the mind. They bring about a temporary change in consciousness, so that something embodied in the lines -- not only in their verbal meaning but in their sound and rhythm and associated overtones and images -- is perceived (p. 135).

In short, Davy sees the progression from a participating consciousness to an onlooking consciousness as moving from an originally poetic language to a scientific discourse that has grown cold, lifeless, and empty. He envisions the birth of the "third culture" in terms that evoke the changing of the seasons:

the onlooker-consciousness...is a winter consciousness.... summer comes first: the time when nature is abundant and men in their activities and feelings go out into nature.... Evolution proceeded to autumn; the skies of consciousness darkened and men turned their thoughts to earth. We are now in winter.... We have come far from the dreamy moods of summer; our thinking is as clear and sharp as frost.... The winter experience has been indispensable; but the imagination of man has power to quicken the dry earth and bring in a new season (pp. 172-173).

*

The "new season" to which Davy tacitly refers, of course, is Spring. Here, Davy irresistibly evokes the words of another great prophet of imaginative experience, the poet Percy Bysshe Shelley, whose "Ode to the West Wind" (1820) asks what M. H. Abrams (1988) calls "the most famous rhetorical question in English" (p. 161): "If Winter comes, can Spring be far behind?" Shelley's ode implores the inspiring wind to "Make me thy lyre" (l. 57). In this, it reminds us of our "Skylark" and of Shelley's own poem, "To a Skylark" (1820). That lyric hails our bird as a "blithe Spirit" who "Pourest thy full heart/In profuse strains of unpremeditated art" (ll. 1-5). In turn, the second stanza of Carmichael and Mercer's song recalls Shelley's question to the West Wind:

O, Skylark, have you seen a valley green
with spring,
Where my heart can go a-journeying,
Over the shadows and the rain
To a blossom-covered lane?

*

This second stanza seems to celebrate a feminine point of view, concerned as it is with the fecundity and fertility of a green valley and a blossom-covered lane. And, in that, it reminds us by counterexample of how completely the field of consumer research has been dominated by the contrasting masculine orientation.

Lately, I have been reading some enlightening books that apply the perspective of feminism to the philosophy of science. For example, in her treatise on *The Flight to Objectivity*, Susan Bordo (1987) points out that our whole conventional scientific epistemology rests on a dualistic dichotomy between Self and Other. She argues that this dualism reflects a Cartesian mistrust of subjectivity that is essentially masculine in its psychological origins and that stems developmentally from the "wrenching tear" experienced in the male child's emotional separation from his mother (p. 57). In Bordo's terms, the resulting separation anxiety precipitates an anxious reaction against emotion or passion and a flight to objectivity (p. 76). This results in a masculinized psyche in which emotions become irrelevant: "Thus, the specter of infantile subjectivism is overcome by the possibility of a cool, impersonal, distanced cognitive relation to the world" (p. 99).

Bordo joins, however, in "the critical protest against the Cartesian notion that reason can and should be a 'pure' realm free from contamination by emotion, instinct, will, sentiment, and value" (p. 116). Here, she receives support from Evelyn Fox Keller's *Reflections on Gender and Science* (1985), which emphasizes that the feminine viewpoint (subjective, emotional, personal, nurturing) -- as opposed to the masculine viewpoint (objective, rational, impersonal, power-oriented) -- retains a sense of the union between mother and child and thereby permits a dissolution of the Cartesian dichotomy between subject and object (self and other), in the form of a subject-object merger. In this sense, for Keller, science "is a form of love" (p. 117) based on an empathy and intimacy in which "self and other, mind and nature survive not in mutual alienation...but in structural integrity" (p. 165).

Along similar lines, a recent book by Wendy Hollway entitled *Subjectivity and Method in Psychology: Gender, Meaning and Science* (1989) describes a masculinization of science in which "men...avoided the affective by producing it as a particularly feminine characteristic" so that "the affective was expunged simultaneously from scientific, rational and male thought" (p. 110). Hollway inveighs against what she calls "sexist regimes of truth" (p. 45) and proposes to replace these by "developing a method for interpreting texts

and working out a theory of meaning and subjectivity adequate to it" (p. 47). This method focuses on the subjectivity of meanings produced in the framework of interpersonal discourse (e.g., p. 67) -- that is, on a linguistic construction of subjective reality (p. 82) -- thereby drawing Hollway's attention to "intersubjective relations" in general and to "the part played by gender difference" in particular (p. 86). Here, she criticizes psychometric approaches to the study of androgyny (p. 99), attacks cognitive theories of sex-role stereotyping (p. 103), and proposes to replace these with a "feminist position...based on a recognition of, and celebration of, women's difference from men" (p. 105). This feminist position focuses on "women's experience" (p. 106) and on its implications for "gendered subjectivity" (p. 108). In this light, Hollway expands Keller's (and, implicitly, Bordo's) emphasis on separation anxiety and, even while recognizing the variability among people (p. 119), reaches a similar conclusion that "being a woman provides advantageous conditions for identification with the person or people participating in the research" (p. 127).

In the views of Bordo, Keller, and Hollway, the feminine aspect of science (recalling Paul Simon's "Mother and Child Reunion" and "Loves Me Like a Rock") speaks, as described by Carol Gilligan, *In a Different Voice* (1982). Gilligan characterizes feminine discourse in terms of its ability to sustain deep, caring interpersonal connections and to entertain tender, supportive feelings: "Thus women not only define themselves in a context of human relationship but also judge themselves in terms of their ability to care" (p. 17). In *Women's Ways of Knowing: The Development of Self, Voice, and Mind*, Mary Field Belenky and her colleagues (1986) point out the key importance of this metaphor for epistemological growth in which women are "gaining a voice" (p. 16). For them, this voice involves "connected" as opposed to "separate" knowing (p. 101). Connected knowing entails a trust in personal experience and a capacity for empathy (pp. 112-113). It aspires toward the "passionate" knowledge of "knowers who enter into a union with that which is to be known" (p. 141) and emerges, ultimately, in "the development of a more authentic voice" (p. 209).

According to Jean Baker Miller in *Toward a New Psychology of Women* (1976), this authentic feminine voice exerts a humanizing influence by "expressing the emotional and personal qualities that are inherent in all experience" (p. 25). Miller sees women, in comparison with men, as "trained to be involved with emotions and with the feelings occurring in the course of all activity" (p. 39). She also suggests that, as therapy, "men can also go on to enlarge their emotional experience" (p. 46). Indeed, if we (the scientists or the men) try to hang tough by denying this feminine voice, we can only succeed in falsifying the reality that confronts at least half the population -- namely, the reality described in such works as Jessie Bernard's *The Female World* (1981) and Anne Wilson Schaeff's

Women's Reality (1985). I would like to urge, therefore, that -- when the occasion calls for it, as I believe it does when we address the emotions -- both the women and the men who conduct consumer research must learn to think, to feel, and to write in a manner more feminine.

*

But I must also warn that such consumer researchers will inevitably encounter difficulties associated with the pioneering lyrical spirit and foretold in the "bridge" or B-section of "Skylark":

And, in your lonely flight,
Haven't you heard the music in the night --
Wonderful music --
Faint as the will-o'-the-wisp,
Crazy as a loon,
Sad as a gypsy serenading the moon?

*

The simple fact is that -- if you follow my advice, embark on a "lonely flight," and yield to the lyrical spirit when writing your next paper on consumer emotions -- the first reviewer will say that your logic is "faint as a will-o'-the-wisp"; the second will complain that your method is "crazy as a loon"; the third will charge that your results and conclusions are "sad (or even mad) as a gypsy serenading the moon"; and the editors will reject your manuscript (in agreement with the insuperable criticisms posed by the reviewers' many helpful comments).

This will happen, I fear, because -- as a discipline -- we have learned to deny the feminine aspects of our collective consciousness and to signal this denial by demonstrating or at least pretending that we do not care very much about each other's feelings. We adopt reviewing standards that reward authors' abilities to suppress their emotions. We excoriate any trace of self-revelation. If an occasional author dares to violate this norm, we punish this deviation by declaring the work "self-indulgent" (sometimes relying on such damning epithets as "paroxysms of self-expression"). In this, we imply that we do not care very much about each other or, ultimately, even about ourselves.

*

In short, if we were to view the discipline of consumer research metaphorically as a dwelling place in which we live, it appears (figuratively) that we have constructed a house in which there is no room for the researcher's emotions. This style of intellectual architecture violates an important principle that I believe I learned last summer.

This past June, as my friends who saw my scratched and splintered fingers can attest, I spent a good deal of time building bookcases in our apartment to accommodate my fairly large and rapidly growing collection of paperbacks and compact disks that I love dearly but that I had no place to keep. Later, I spent a happy month of July at U.B.C. in Vancouver as the guest of Rick Pollay and Carole Christopher. The moment I walked into their house, I was struck by its carefully planned use

of space. Rick is an eminent collector of relics from advertising (which he calls "advertiques") and has meticulously designed every square inch of his study at home and his office at school to store and display his collection. I felt in a profound way that Rick's example validated my own adventures in home improvement via the construction of bookshelves. And, after sensing this validation, I finally realized that it hinged on a very simple principle -- namely, that without a place to keep things that we cherish, things that move us, things that stir our emotions, things that add meaning to our lives, a house would be deeply flawed.

Yet, in consumer research, we have chosen to dwell (but perhaps not fully to live) in such a deeply flawed house -- a house with no place to put the things that matter most to many of us -- namely, a house with no room for our own feelings. Such a house may be, in the words of Graham Nash, "a very, very, very nice house." But such a house is not a home.

Apparently -- remembering the Skylark's warm, green valley and the need to build bookshelves to hold our deepest meanings -- in consumer research, we need Better Homes and Gardens. My inference, then, corresponds directly to the metaphorical content in the last stanza of Johnny Mercer's great lyrics:

Skylark, I don't know if you can find these things,
But my heart is riding on your wings;
So, if you see them anywhere,
Won't you lead me there;
O, Skylark, won't you lead me there.

In this almost prayerful conclusion, the lyricist asks for a place in which the heart can reside. Analogously, I ask for an annex to the grounds and for some new rooms with new windows and new views in the mansion where those who labor in the field of consumer research have erected their edifice. I ask for an open embrace by consumer researchers of the attempt in our work and our writings to express our emotions. I ask us, collectively, to abandon our mercilessly tough stance and to start caring profoundly about one another's deepest selves. I ask for this enlarged acceptance of poetic insights in consumer research because I believe that the lyrical resonance in which we converse will greatly facilitate our ability to interpret and to communicate the nature of the emotional phenomena that pervade the consumption experience.

Here, returning to Robert Graves and his *Greek Myths* (1981), one recalls the legend of Arion -- another great master of the lyre -- whose singing saved him from drowning in the deep when the "impassioned strains" of "his song...attracted a school of music loving dolphins, one of which took Arion on his back" and carried him to safety (p. 8).

We, too, need singing in *our* school. Perhaps only the lyricism of an impassioned song such as Arion's can rescue us from drowning in a sea of indifference.

I might illustrate what I regard as the restorative power of lyricism -- its saving grace -- with three examples drawn from music and, therefore, closely linked to singing. Here, the analogy between the scholarly activity of an academic and the creative activity of an artist becomes unmistakable. In both endeavors, I believe, lyricism may transform the mundane into the extraordinary and may encourage a transcendence from the pathetic to the exalted, from the ridiculous to the sublime.

Consider, first, the work of the great jazz saxophonist, Art Pepper. By the account found in his own autobiography -- ironically entitled *Straight Life* (1979) -- and by any reasonable standards of polite society, Pepper was for most of his life a complete scoundrel, obsessive profligate, unrepentant bum, and hardened criminal. He took drugs with reckless abandon, robbed filling stations, betrayed his friends, and spent most of his adult years in prison. Pepper was no gentle junky jazz musician -- like (say) Charlie Parker, who never hurt anyone but himself. By his own insistence, Pepper was a callous convict -- a self-proclaimed sociopath -- whose only concern for others boiled down to the fear of being caught.

Yet Pepper had one saving grace and that was his total honesty of self-expression -- found, for example, in his unfathomable ability to tell his own sordid story in the form of that amazingly candid autobiography. This honesty also permeated all his playing and revealed itself in a surprisingly lyrical temperament.

Art Pepper's alto style incorporated an almost excruciating lyricism, a vivid sense of immediate feelings and unconstrained emotions. In one of his most celebrated recordings, for example, he emerged from a drug-induced torpor, picked up a broken-down horn that he had not touched in months, and somehow blew chorus after chorus of inspired jazz melodies, wrenched not from a printed score but from the depths of his own tortured soul. In short, Art Pepper's lyrical gifts transformed this otherwise miserable creature into a poet and a prophet of emotional expression.

Paul Desmond, a second magnificent alto saxophonist, was the most lyrical player that jazz has ever known. He spun lilting musical phrases out of airy nothingness in a constantly inventive stream of sequences composed of repeated thematic ideas and their developing variations. I have enthused about Desmond's gifts elsewhere (Holbrook and Zirlin 1985) and will not repeat those effusions here, except to note the manner in which his lyricism appeared to elevate his spirit above the commonplace.

On one mournful day only a few weeks before his untimely death, in a recording made with Chet

Baker of "You Can't Go Home Again," Paul Desmond summoned all his waning strength, endured his pain, and blew one of his most beautiful solos just before collapsing from the burden of these over-exertions. His playing betrays no hint of his physical anguish. It is all tenderness, all delicacy, all lyricism. Thus does the lyrical gift raise one's spirits to heights otherwise unattainable. Thus does the force of lyricism lift one's powers of communication.

*

Interestingly, both Art Pepper and Paul Desmond recorded our emblematic song, "Skylark" -- Pepper on an early album in which he accompanied Hoagy Carmichael performing some of his own tunes, Desmond in one of his last recordings made just three years before he died. Pepper may have been uncomfortable with the unsympathetic character of Carmichael's labored singing style. For whatever reasons, his performance is dark and brooding, filled with rhythmic displacements and bent notes that suggest pain and doubt. By contrast, Desmond's rendition of this piece conjures up sweetness and light. He alters some of its chords and melody lines in ways characteristically Desmondian and toys effortlessly with melodic sequences in his typically playful pattern of implication, surprise, and reconciliation. Hence, even while Pepper's and Desmond's treatments of "Skylark" differ markedly in tone, both share an intense lyricism. Pepper sounds as if he is crying through his horn. Desmond sounds like smiling.

*

Similar stories could be told about the last concert of Sonny Stitt (who, ironically, was asked to fill in for the recently deceased Art Pepper) or about Charlie Parker's tantalizing solo on "Lover Man," which breaks off in mid-stream when the artist literally passes out and falls to the floor of the recording studio. All these evince the power of lyricism in the lives of musical geniuses. I shall end, however, on a third illustration intended to convey a somewhat more triumphant note -- namely, the achievement by the late Dinah Washington, often referred to as "the Queen."

Dinah Washington began as a gospel singer and carried the fervor of that style into her later work as a pop vocalist. Her energetic and feelingful recordings of such songs as "What a Difference a Day Made" completely mask what was for her an agonizing disability. Specifically, Dinah Washington stuttered, stuttered so badly that she could scarcely conduct a normal conversation. Hence, her ability to communicate via conventional means was severely limited. But, as often happens in cases of stuttering, her problem disappeared when she raised her voice in song. The stuttering stopped. Her lyrical gift conquered her verbal nemesis. And Dinah Washington sang like an angel.

*

As consumer researchers embarking on the study of emotion, we venture forth into a new and intellectually perilous area of inquiry. Like Art Pepper and Paul Desmond and Dinah Washington,

copied with the melodic and harmonic structure in a difficult piece of music, we face threatening risks and potential dangers. But -- also like Pepper, Desmond, and Washington -- we have the opportunity to express ourselves through the power of our lyrical gifts.

We have a choice. We can cultivate a bland form of scientific discourse that conveys little more than does a hopeless stammer. We can let our voices stammer and falter and gasp for words and have huge sighs of inarticulate helplessness. Or we can learn a lesson from Dinah Washington and the others. We can lift every voice and sing. We can let our feelings show. We can express our emotions and can welcome them in ourselves and in others for what they are -- namely, concomitants of the phenomena that we wish to understand. And, if we can follow the latter path, we may earn the contribution to be gained from the role of lyricism in research on consumer emotions.

*

The song by Carmichael and Mercer that I have been using as my text ends on what strikes me as a rather profound and even devout note in which the lyricist's heart rides on the Skylark's wings. So I, too, want to end by returning to my theme (concerning the heart) with which I began and by reminding you that today (like every day) is a very emotional day for all consumers everywhere -- and, therefore, a very emotional day for you -- and, especially, a very emotional day for me.

Perhaps, in conclusion, you might wonder what emotions I feel as I near the end of my story.

First, of course, a sense of relief that I have almost completed my task.

Second, a sense of hope that I may have encouraged us to show a little more care about one another's feelings and a little greater acceptance of each other's attempts at self-expression.

Third, a sense of pride in what we as a field of inquiry have already accomplished in the twenty short years since the first ACR conference met in Columbus during the Fall of 1969.

And fourth, abundant gratitude that leaves me full of thanks to many people. Thanks to Keith Hunt for his unswerving dedication as our Executive Secretary. Thanks to our Board of Directors -- Beth, Rich, Terry, Jack, Becky, Kent, Keith -- and the other Officers for their wise decisions. Thanks to Jerry Kernan for acting as our stalwart representative on the JCR Policy Board. Thanks to Peter Bloch and Jim Muncy for keeping our communications flowing. Thanks to Terry Shimp for his many labors of love. Thanks to Arch Woodside for his help with the local arrangements in New Orleans. Thanks to Marv Goldberg, Gerry Gorn, and Rick Pollay for serving so splendidly as chairpeople, for managing the 1989 conference with such expertise, and for putting together such a carefully designed program. Thanks to Beth Hirschman, Becky Holman, and Mike Solomon in anticipation of their efforts on our behalf next year in New York. And thanks, most of all, to all of you for listening to me express myself and for letting me be your President.

*

Skylark, I don't know if you can find these things,
 But my heart is riding on your wings;
 So, if you see them anywhere,
 Won't you lead me there.
 O, Skylark, won't you lead me there.

*

I would like to close with a reference to just one more popular song, one that I admired greatly as a youngster because some of my favorite jazz musicians used to play it -- namely, DeSylva, Brown, and Henderson's "Birth of the Blues." When I was growing up, I found the chord changes of this tune too hard to negotiate. But, since then, I have figured them out and have also noticed something else important about the song. Specifically, it seems to fuse the theme of my talk today with the location of this year's ACR conference. Thus, it again invokes the power of lyricism as represented by another singing bird (this time, a whippoorwill) and ties this bird's lyrical gift to the origins of jazz in the area around New Orleans:

From a whippoorwill,
 High on a hill,
 They took a new note;
 Pushed it through a horn
 'Til it was born
 Into a blue note.

And then they nursed it,
 Rehearsed it,
 And gave out the news
 That the Southland
 Gave birth to the blues.

Regularities, Rules and Consumer Behavior: Tangencies Between Positivist and Interpretive Approaches to Research

Eileen Fischer, York University

ABSTRACT

Positivist approaches to consumption behavior have as a goal the identification of regularities which have law-like, causal effect on the actions of individuals. Many interpretive approaches to studying consumption behavior have an analogous goal, the identification of rules, which are the tacitly understood norms and conventions underlying the behavior of individuals. Despite the profound disparities between positivist and interpretive science, the regularities/ rules which each seeks to identify constitute a point of tangency. This paper explores the relationship between positivist regularities and interpretive rules in consumer behavior and traces their implications for reconciling alternative routes to seeking knowledge.

Compelling arguments have been mounted regarding the need to consider interpretive approaches as alternatives or supplements to positivist approaches to studying consumption behavior (for instance Anderson 1986; Hudson and Ozanne 1988; Peter and Olson 1983). The challenge now facing consumer researchers is how to employ one or more research approaches in a manner of practical value for the development of the field. Hudson and Ozanne (1988) have identified four alternative strategies for coping with the diversity of research approaches. Specifically, they suggest: (1) a supremacy alternative, in which researchers attempt to resolve which scientific approach is best; (2) a synthesis alternative, in which researchers merge interpretive and positivist approaches, ignoring differing underlying assumptions; (3) a dialectic alternative, in which multiple research approaches are applied with an appreciation for their divergent philosophical foundations, but with an aim to utilize competing insights within a single analysis in the hope that an entirely new form of understanding may be generated; or (4) a relativistic alternative, in which the differing approaches are all considered acceptable so long as they are evaluated by the standards appropriate to the method of knowledge production.

Those who opt for pursuit of the latter two of these alternatives are faced with the question of how research premised on one philosophical foundation may usefully and appropriately be integrated with research from a different philosophical perspective. It is clear that those who follow the dialectic route inherently require some means for integrating the findings of divergent research streams, but it may be less evident why those who adopt the relativistic approach should share this concern. Unless relativistic researchers operating within one research tradition are content to ignore findings relevant to their topic but generated within an alternative tradition, however, they must consider how the

products generated by discrepant research approaches can be, in some sense, reconciled.

The objective of this paper is to explore one important way in which the foci of interpretive and positivist research are tangent, thereby suggesting a point of departure for researchers who attempt to draw on knowledge generated by divergent traditions. Specifically, the paper will examine the tangency between the causal regularities sought in positivist research and the hermeneutic rules sought in interpretive research. The benefits of recognizing these tangencies will be discussed. As well, limitations to the tangency between rules and regularities will be outlined. It is important to recognize that interpretive approaches are no more monolithic than positivist approaches: not all interpretive research can be said to seek interpretive rules, just as not all positivist research seeks causal regularities. Moreover, there are likely important and irreducible differences in the perspectives an interpretivist and a positivist will take on a seemingly identical phenomena: for instance, a fundamental difference in perspective occurs because interpretive researchers place much greater emphasis on the agency of actors whose behavior is studied. Given, however, that many forms of interpretive research (such as hermeneutic analysis, symbolic interactionism, and certain forms of phenomenological sociology and ethnomethodology) do generate insight into social rules, it is useful to seek tangencies between these research findings and the causal regularities which are sought in much positivist research. Even if the similarities between the perspectives taken on a phenomenon of interest is limited, it is useful to consider the nature and value of tangencies in alternative perspectives.

INCOMMENSURABILITY WITHOUT CONTRADICTION OR INCOMPARABILITY

Although the research traditions of positivism and interpretivism are incommensurable, they are not necessarily incomparable or contradictory. Tracing the implications of incommensurability, and showing that they do not include incomparability or inconsistency, will help to clarify the extent to which a rapprochement between positivism and interpretivism is possible.

The incommensurability of positivism and interpretivism stems from the differences in axiology, ontology and epistemology which characterize the two approaches. A positivist axiology entails a commitment to explanation and is based on an ontological belief that a single, multifaceted reality exists, coupled with an epistemological belief that distinct, separable facets of the one reality can be known. An interpretive axiology entails a commitment to understanding and

is based on an ontological belief that realities are mediated by the perception and comprehension of individuals, coupled with an epistemological belief that these realities can only be grasped partially, in both senses of the term (i.e. all understanding is incomplete and is conditioned by the researcher's own perspective (Packer 1985)).

Incommensurability of approaches means that "two groups of scientists see different things when they look at the same point and in the same direction" (Kuhn 1970, p. 150). That is, positivists and interpretivists may look upon the same phenomenon, but see different aspects of it. Further, they may construe the problem to be investigated in differing ways, and apply different standards to the evaluating research efforts (Bernstein 1985).

Incommensurability described in this way does not imply incompatibility. For positivist and interpretive research projects to be incompatible, the two projects would have to entail some logical contradiction. Such contradictions presuppose a shared framework of logic, a possibility upon which the incommensurability of positivism and interpretivism places severe constraints. While positivist and interpretive research programs may contain contradictions in some aspects, they are not totally contradictory simply because they are incommensurable.

In addition to being (at least partially) logically compatible, positivist and interpretive research projects may also be comparable. In fact, as Anderson (1986) demonstrates, incommensurable research programs can be compared on numerous bases. Although Anderson is contrasting incommensurable research programs that share a common cognitive aim and can all be labelled positivist, his approach is equally valid for comparing interpretive and positivist approaches. Such comparisons, it must be recognized, do not require a common, fixed grid of characteristics which is universally applicable: some comparison is possible even if one research program has characteristics without any analogue in another research program.

Comparisons between certain facets of positivist and interpretive research projects are not merely appropriate: they may also be useful. In particular, it is valuable to consider comparable -- though incommensurable -- components of positivist and interpretive research which have the potential to afford a practical linkage between projects grounded in the two research streams: the regularities sought in positivist research and the rules sought in interpretive research. Regularities and rules are analogous facets of positivism and interpretivism in that each represents the kind of knowledge sought under specific axiological commitments, as is explained below.

POSITIVIST REGULARITIES

Chief among the axiological commitments of positivism is a determination to explain causal regularities which are believed to underlie human

behavior. As described by contemporary philosophers of science, the form of argument used to assert causal regularities is characterized by the deductive-nomological model: if a number of conditions (C1, C2, etc.) are met, then any object (such as a person or system) that meets those conditions will have a certain property. That property is the outcome to be explained. For instance, consider the causal regularity posited in the relationship between a gift giver's ideal self concept and the type of gift chosen (Belk 1979). Given the task of choosing gifts for other people (the condition), gift-givers (the objects), choose gifts reflecting their own ideal self image more than their actual self image or their perceptions of the recipient (the outcome).

In positivist social science, perfect regularity is rarely if ever considered necessary for causal generalizations to be made. Probabilistic statements suffice as approximations of universal law-like statements in most instances. That is, causal regularities are often considered to exist in instances where the regularities do not hold in every instance, but do hold considerably more often than not. Causal regularities, then, may be loose regularities, but nonetheless be considered both causal and regular (Braybrooke 1987).

In some instances, casual regularities in social science may also be transitory. That is, regularities may not extend over time, or between cultures. For instance, while much research has documented as a regularity that women are more "communally" oriented and men are more "agentically" oriented (Bem 1974; Spence and Helmreich 1978), it is anticipated that it will become increasingly common for women and men to exhibit more equal degrees of communal and agentic orientations -- that is, for women and men to be relatively androgynous (see, for example, Rossi 1984). One way of explaining why a regularity may be transitory is to argue that the regularity was premised on conditions including the specific times and/or places in which the regularity was detected; the other option is to treat causal regularities as genuine even if transitory (Braybrooke 1987). The point is that positivist regularities in social science need not be immutable to qualify as causal explanations of practical value.

One other important characteristic of causal regularities is that they may express laws that apply at the individual or group level. The examples cited above refer to regularities which apply at the individual level. Consider, for example, studies of discord or unity in household purchasing decisions (such as Qualls 1987). In such studies, regularities detected in decision making patterns may be postulated to depend partially on individual differences in gender role attitudes, but they apply at the level of the couple: they cannot be construed merely as a conjunction of regularities governing individuals.

TANGENCIES BETWEEN REGULARITIES AND RULES

In contrast with the axiological commitment of positivism to explaining causal regularities is the axiological commitment of interpretivism to understanding settled social rules. Social rules may be tacitly understood or explicitly stated, but are generally amenable to verbal expressions containing a descriptive "is" or a prescriptive "ought" implication. For instance, a settled social rule detected by Caplow (1984) amongst residents of Middletown in the late 1970's was that Christmas gifts between spouses should be more valuable than any other gifts given by husband or wife, but that the husband's gift to the wife may be more expensive than the wife's to the husband (p. 1313). While Caplow explicitly uses the term "rules" to refer to his findings, it should be noted that many interpretive researchers do not. Other labels, such as "norms," "patterns," or "conventions," are common in the methodological discussions of interpretive approaches. Nonetheless, many types of interpretive research seek similar "rule-like" findings.

Ryan and Bristor (1987), following von Wright's (1971) arguments, stress that there is a symbiotic relationship between causal regularities and interpretive rules because the forms of arguments offered in support of regularities and of rules are essentially similar. They characterize the form of reasoning followed in interpretive research as a "practical syllogism," which consists of a major premise that entails some end or goal the actor has, a minor premise that is the rule or relationship comprehended by the actor as a means to that end, and a conclusion which suggests that since the actor apprehends the relationship between certain actions and specific goals or ends, the individual forms the intention to perform the action. For instance, the major premise in the example above might be that the actor wishes not to threaten the integrity of the spousal relationship. The minor premise would be the rule understood regarding the scaling of monetary expenditure to the closeness of the relationship. The conclusion would be that the actor spends more on the spouse's gift than on that for any other recipient.

The similarity between the practical syllogism of interpretive research and the deductive-nomological model of positivist research is so striking that Ryan and Bristor assert "the practical syllogism makes contact with the reasoning procedures already employed by the scientific model and is methodologically continuous with it" (p. 193). Indeed, the similarity between the logic underlying positivist regularities and the reasoning underlying interpretive rules is striking. The tangencies between rules and regularities, however, extend well beyond the logic which informs the two approaches. Other important ways in which causal regularities are tangent to interpretive rules can be gleaned from further comparison between the two.

Interpretive rules, like causal regularities, may be argued to exist despite the fact that there is

not perfect regularity or consistency observed in behaviors posited to be affected. One condition for ascribing a settled social rule to a given social unit is that, for the most part, individuals in the unit conform to the rule. However, rules may exist without widespread evidence of conformity since agents may attempt unsuccessfully to conform to social rules (Giddens 1984): for instance, the gift giving rule cited above would not be invalidated by observations that gifts were not exchanged between spouses in some families because of income constraints. Further, a rule may exist even when there are intentional lapses in conformity: evidence of the existence and persistence of a rule arises when instances of non-conformity are decried and instances of conformity rewarded. So, for instance, if an individual gave a friend of the opposite sex a gift more expensive than that given to a spouse, the persistence of the gift giving rule would be revealed by reactions of indignation on the part of the spouse.

As is true of causal regularities, interpretive rules may also be transitory over time or across geographic regions. It is a basic tenet of the philosophy underlying interpretivism that rules exist primarily as they are comprehended by actors, (though settled social rules may be codified into societal laws), and that these rules may or may not be shared by other individuals or groups. Rules are expected to vary across time and across groups, just as the laws reflecting settled social rules of one society at one point in time differ from the laws of the same society at other points in time, or from the laws of other societies. One reason rules might be transitory is that actors may come to conscious awareness of rules which underlie their behavior and choose to reject the rules or replace them. While interpretive philosophers argue about whether (or how much) conscious intention must be associated with actions presumed to be conditioned by rules, they recognize that actors may be conscious of rules, and have considerable potential for voluntary control over their rule-following behavior (Giddens 1984).

A final important similarity between positivist regularities and interpretive rules is that both may be posited to exist as either "person facts" or "group facts." While an interpretive finding may apply to the actions of individuals, it has the status of a group fact if the individual is likely to be sanctioned by other social actors for failure to follow a rule or rewarded by some reciprocal action for conformity in following the rule. Many of the rules with which interpretivists are concerned (such as the gift giving rule cited above) pertain to group facts since scientific interest often centres on understanding behaviors which are characteristic of more than one individual. Interpretive studies in marketing are particularly likely to focus on group facts because exchanges are focal behaviors, and exchanges characteristically involve understandings shared by more than one social actor.

Although settled social rules which illuminate group facts are arguably of greatest interest to

interpretivists, person facts may also be important. Biographies of important historical figures or case studies of individuals considered aberrant by society can offer insights into a particular individual's unique understanding of social rules. These types of interpretive research can illustrate how unusual or unacceptable behaviors, premised on rules not shared by a broader society, may affect or reflect on more widely shared societal rules. So, for instance, a case study of a consumer with unique rules regarding the ownership of goods offers novel insights into the nature of materialism in modern society (McCracken 1988.)

The foregoing list of similarities between rules and regularities suggests that, notwithstanding their incommensurability, there may be greater comparability and consistency between positivism and interpretivism than is typically imagined. An even stronger claim, moreover, may be advanced regarding this relationship.

MUTUAL PRESUPPOSITION OF RULES AND REGULARITIES

Braybrooke (1987) suggests it is not merely possible, but typical, that causal regularities provide a basis for inquiry into interpretive rules and that interpretive rules provide a basis for inquiry into causal regularities. He insists, in fact, that positivist and interpretive inquiry are not merely mutually supportive, but are often presupposing of one another.

Settled social rules are counterparts of causal regularities in that the rules lead to regularities for which the rule itself counts as a "cause." So, for instance, the rule about purchasing a more expensive gift for a spouse than for any other person "causes" this behavior to be an observable regularity. Note that this does not negate the fact that rules are brought into existence through the tacit understandings and interpretation of social actors, but merely asserts that while the rules exist, they act as causes of behavioral regularities. Thus it is characteristic of interpretive rules (at least settled social rules) that they will lead to regularities amenable to positivist inquiry.

At the same time, some regularities in social phenomena imply the existence of settled social rules. A causal regularity is likely to have a counterpart interpretive rule when the causal regularity applies to behaviors which an individual may voluntarily perform or not perform, and when some penalty for deviance from the regularity or reward for conforming to the regularity can be detected (Braybrooke 1987). Consider the regularity, cited by Belk (1979), that gift givers choose gifts which reflect their ideal self image more than their actual self image or their perceptions of the recipient. The degree to which gift givers choose gifts which reflect their ideal self image is, in general, under voluntary control. The reward individuals may experience as a result of conforming to the practice of choosing gifts reflecting their ideal self image is the recipient's acceptance and approval of the gift and, by

extension, of the gift giver. The deterrent associated with not choosing a gift reflective of ideal self image might be the recipient's tacit or explicit rejection of the gift. It seems reasonable to suggest that settled social rules relating to the "appropriate" symbolism for gifts are likely to be associated with this causal regularity. Moreover, it is likely that investigation of these rules could offer opportunities for further positivist inquiry into causal regularities pertaining to gift giving.

DISJUNCTIONS BETWEEN RULES AND REGULARITIES

While the foregoing discussion develops an understanding of the nature and significance of the tangency between rules and regularities, it is also important to recognize disjunctions between these facets of interpretivism and positivism. In order to proceed with due caution and sensitivity in either the dialectic or the relativistic approach to utilizing alternative means of seeking knowledge, it is critical that these disjunctions be understood and respected.

While many forms of interpretivism would focus primarily on rules which are held by a society or social group, some of the more solipsistic versions of interpretivism focus on interpreting rules so singular as to apply to only one or a few individuals (Burrell and Morgan 1979). Though they are viable forms of interpretive inquiry, such studies are not likely to yield knowledge claims about rules which are sufficiently consistent in effect to form a basis for study of positivist regularities. Thus some interpretive person facts may not be conducive to positivist inquiry regarding person facts or group facts.

A further disjunction between rules and regularities stems from the different ways in which regularities and rules are presumed to affect behavior. It appears that positivist regularities are assumed to operate in a rather mechanistic fashion. Interpretive rules are considered to affect behavior through the tacit apprehension and interpretation of social actors. Individuals are presumed to act according to rules because of their implicit assumptions about the purposes or interests an action serves within a given context (Packer 1985). An actor's assumptions regarding rules are typically tacitly held -- that is, the actor is not consciously aware of the social rules underlying a specific behavior. Thus gift-givers need not ever reflect on the "rules" affecting the amount spent on a gift to a spouse as opposed to a friend. Nonetheless, behavior occurring in conformity to rules is voluntary, since the actor has the potential to come to awareness of rules and to modify behavior or continue to follow rules.

Since interpretive inquiry is premised on the belief that individuals can modify their behavior because they become aware of and choose to modify rules, this approach has the potential to focus on situations where rules are in flux or in conflict. For instance, at a time when tacit societal rules are increasingly being seen to operate to the seeming disadvantage of women, rules relating to appropriate

behaviors for men and women are changing considerably (see, for example, Hoover-Dempsey, Plas and Strudler Wallston 1986). Interpretive inquiry into the emergence of new rules, then, is possible whereas positivist inquiry into the emergence of causes is less feasible.

On the other hand, positivist inquiry has considerably more to offer than interpretive inquiry when regularities occur which are the unintended consequences of human action or inaction. Consider, for instance, the regularity with which it happens that aggregate consumer demand for a product increases as the price of that product decreases. While an interpretive rule may underlie the behavior of independent actors who are separately seeking to make "wise" purchase decisions, it is not an intended consequence of any individual's behavior that the aggregate quantity of goods purchased should increase. In such situations, positivist science may offer more insight than interpretive inquiry.

CONCLUSIONS AND IMPLICATIONS

This discussion of points of tangency and divergence between positivist and interpretive science suggests that there is a significant relationship between the two. It demonstrates that for researchers who seek either a dialectic or a relativistic approach to dealing with divergent research streams, there is considerable potential for judicious interchange of research ideas between the streams.

The foregoing discussion also helps to clarify instances in which it is likeliest that tangencies will exist and that interpretive and positivist research streams have the greatest potential to complement one another. In cases where rules are extremely settled, are shared by groups of considerable size, and are not consciously being rejected by social agents, causal regularities are most likely to be associated with rules. In cases where regularities apply to behavior under the voluntary control of actors and where rewards or penalties are attached to conformity or nonconformity to the behavioral pattern in question, interpretive rules are likely to be associated with causal regularities.

This discussion also helps to explain the relationship between the regularities and rules which generate either person facts or group facts. It leads to an appreciation of how, for instance, positivist group facts such as might be derived from an socioeconomic study of spending habits, and a phenomenological case study of one consumer's "deviant" overspending might appropriately and fruitfully be conjoined. Greater insight into an issue noted by Anderson (1986), the examination of "the relationship between psychological/sociological explanations of behavior at an individual level and sociological/anthropological explanations at the group or cultural level" (p. 169), is also generated.

In summary, this paper lends momentum to the effort to move beyond a frustrating "either/or" debate on the merits of one research stream versus

another, and lays the foundation for a less fractious, more fruitful, search for knowledge.

Eureka! And Other Tests of Significance: A New Look at Evaluating Interpretive Research

Craig J. Thompson, University of Tennessee

ABSTRACT

The present paper discusses two broad approaches to evaluating interpretive research. The first, foundationalism, is an epistemological position motivated by the subject-object distinction. It is proposed that a foundationalist logic underlies the evaluative criteria offered by both positivists and humanists. Advantages and disadvantages of evaluating interpretive research in terms of foundationalist criteria are discussed. An evaluative approach not premised on the subject-object distinction, anti-foundationalism, is then described. The critical relativist program is noted as the major example of anti-foundationalist thought in consumer research. It is proposed that critical relativism is a hermeneutic enterprise which can not completely obviate the need for epistemic foundations. Perceptual criteria are suggested as providing non-dualistic, flexible bases for evaluating interpretive research and a description is given of one perceptually based criterion.

INTRODUCTION

Within the social sciences, there exists a vast literature discussing various methodologies and analytic procedures for conducting research. The field of consumer research is no exception as numerous books and articles have been dedicated to this topic. While discussions of applying quantitative or qualitative research methodologies are widely available, much less work has explicitly discussed *the evaluation* of research. When research evaluation has been discussed, the focus is often on the negative aspects of the journal review process. As examples, Gardner (1985) proposes that psychology's progress has been hindered by reviewers turning loose their "methodological zeal" on any new theory and Holbrook (1986) has proposed that marketing's own review process is often a sadomasochistic endeavor. The specifics of these two critiques aside, they do give some indication that research evaluation is not a straightforward, reflexive process.

With the case of qualitative research, it seems that the evaluation process (either performed by an interested reader or a journal reviewer) could become even more difficult because: 1) qualitative techniques are not staple methodologies in consumer researcher and, thus, evaluators are less likely to be familiar with relevant procedures and theoretical frameworks; 2) qualitative methodologies are not monolithic (Jacob 1987). Important methodological and philosophical differences underlie different qualitative approaches such as protocol analysis (Ericsson & Simon 1984), naturalistic inquiry (Lincoln & Guba 1985), or existential-phenomenology (Giorgi 1983; Thompson, Locander and Pollio 1989). An evaluator applying assumptions from one approach to another will, in

many cases, systematically misunderstand the research; and 3) in comparison to quantitative research, the evaluative criteria of qualitative methods often have less formalization and/or specification (Hudson & Ozanne 1988).

The present paper will discuss two broad approaches which can be taken in evaluating interpretive research: foundationalist and anti-foundationalist. This discussion has descriptive rather than critical aim. The basic tenets of the two evaluative approaches will be delineated and their respective advantages and limitations described. Finally, an evaluative approach based on perceptual criteria will be offered and a description given of what some of its properties might be.

Foundationalist Approaches

Foundationalist thought is characterized by a desire to ground human knowledge on a firm and indubitable archimedean point (Rorty 1979). The evaluative concern is primarily epistemological in seeking to identify procedures that can demarcate truth from non-truth and scientific from non-scientific knowledge. A common theme of foundationalism is an adherence to the subject-object distinction (Hekman 1986). With respect to interpretive research, foundationalism is embodied in both positivistic approaches, which emphasize "objectivity," and those versions of humanism emphasizing "subjectivity."

An explicit application of positivist criteria to qualitative research is given by Miles & Huberman's (1984) self-termed "soft-nosed positivism." In adopting a positivistic world-view, Miles & Huberman contend that knowledge must be firmly grounded on the objective side of the subject-object distinction. Their evaluative criteria are premised on the assumptions that: 1) there is an extant reality waiting to be discovered; 2) since "reality" is independent of human experience, people may have different subjective perceptions but they are perceiving the same objective entity; 3) "truth" is a correspondence between an interpretive (theoretical) term and a state of the world. This is a "soft-nosed" positivism because there is *no* requirement that the knowledge claims of qualitative research be of a hypothetico-deductive nature or validated by posthoc quantitative measures.

Miles and Huberman contend that qualitative research must address issues of verification (validity of conclusions), reliability, and generalizability. With this approach, an evaluator of qualitative research would want to see: 1) what procedures were used to assess the reliability and validity of an informant's statements. That is, did the informant express the same views over time and have sufficient knowledge to give a valid account of the phenomenon; 2) evidence of triangulation in which different sources of information are employed to

converge on the phenomenon being investigated; 3) a description of procedures used to minimize researcher biases in both data collection and interpretation; and 4) assessment of the study's generalizability, including a description of the studies sampling procedures for both informants and critical events.

Miles and Huberman's "objective" approach to evaluating qualitative research has an undeniable foundationalist logic. The need for epistemic foundations, however, is no less for researchers taking a more overtly "subjective" approach. As a case in point, Lincoln & Guba (1985) describe a naturalistic research methodology based on assumptions diametrically opposed to those of positivism. Operating on the "subjective" side of the subject-object distinction, they propose that: 1) reality is a "multiple set of *mental* constructions" for which there is no ultimate benchmark for justifying truth value; 2) these multiple mental constructions will inevitably diverge; 3) the knower and that which is known are inseparable; and 4) truth is defined by community consensus. (It should be noted that *social constructionists*, such as Berger and Luckman (1966) and Gergen (1985), avoid the subject-object distinction by viewing knowledge as product of an ongoing interpersonal discourse grounded in a socio-cultural context rather than as particular state of a private mental world).

In arguing for the efficacy of this subjectivist world-view, a lengthy and detailed critique is given of classic positivist assumptions and research criteria. In implementing naturalistic inquiry, however, opposition turns to analogy as Lincoln and Guba's evaluative criteria (credibility, dependability, transferability, and confirmability) bear a strong conceptual parallel to positivist criteria of internal validity, reliability, external validity, and construct validity (Hudson & Ozanne 1988; Thompson 1989). The major technique for establishing the confirmability of a naturalistic inquiry is a *confirmability audit* in which an independent auditor assesses the research process and the resulting interpretive results. The auditor looks for methodological procedures such as member checks, peer debriefings, triangulation, the keeping of reflexive journals (in which the researchers describe their own subjective mental processes) and then makes an evaluative judgment as to whether conclusions are logical, useful, adequate and firmly grounded in the data.

Despite their antithetical philosophical posturing, Lincoln and Guba's evaluative criteria are quite similar to those offered by Miles and Huberman. Both advocate triangulation, warn about potential sources of distortion and share a primary objective of providing foundations on which to base knowledge claims. For objectivists, the existence of epistemic foundations are simply a necessary background condition or core assumption. For subjectivists, epistemic foundations are needed to escape the philosophical quagmires of solipsism and skepticism. That is, if each person is *in* their own private subjective world (the solipsist assumption),

then there is no guarantee that a person can have any knowledge *outside* of his/her idiosyncratic realm (the skeptical conclusion). For those operating on subjective side of dualism, conventional recourses have been to seek epistemic foundations from either a theological (a supreme being guarantees consistency among private worlds), nativist (common genetic structures guarantee consistency), or methodological standpoint (adapting "objective" methodologies to "subjective" inquiries). Lincoln and Guba have taken the latter recourse.

Other, more pragmatic, benefits are gained by evaluating interpretive in terms of foundationalist criteria. These criteria are easily explicated, are based on fairly standardized methodological procedures, and provide a widely shared frame of reference for evaluating interpretive research. In sum, foundationalist criteria allow those not highly familiar with qualitative methodologies to act as competent evaluators and can be readily offered as conventionally acceptable evidence of an interpretive study's epistemological merit.

The negative consequence is that the implicit assumptions motivating foundational evaluative criteria are often inconsistent with the overt assumptions motivating interpretive research. As one example, Lincoln & Guba strongly advocate triangulation with multiple methods, sources, and, (in some cases) investigators, to "validate" information. Giving the strong argument that there exist multiple and divergent realities, it is difficult to see what purpose triangulation can serve. Why should different sources (i.e. different constructions), as a methodological principle, have to agree? In proposing that triangulated information reveals a central tendency or "consensus reality," the logic is strikingly similar to the much critiqued positivist distinction between true and error variances (Thompson 1989). As one other example, it seems inconsistent, given Lincoln and Guba's detailed arguments that understanding requires a prolonged engagement with the context being investigated, that the ultimate arbitrator of a naturalistic inquiry's trustworthiness is an "independent auditor," a disinterested party who ideally has *no* prior involvement in the study.

In sum, the evaluative criteria offered by Miles and Huberman (1984) and Lincoln and Guba (1985) are premised on dualistic assumptions, and therefore have an implicit foundationalist logic. While operating on different sides of the subject-object distinction, both seek to ground knowledge on methodological procedures and third party (objective?) verification. As increasing numbers of philosophers and social scientists are questioning the assumptions of dualism, the necessity of epistemic foundations is also being challenged. With respect to interpretive research, a very different set of evaluative criteria are offered by anti-foundationalist approaches (Rorty 1979).

Anti-foundational Approaches

Anti-foundational thought refers to philosophies rejecting the subject-object

distinction, notions of "absolute truth" and attempts to find an Archimedean point on which to ground knowledge claims (Hekman 1986; Hudson & Ozanne 1988). A common theme among anti-foundationalist philosophy is a movement away from epistemological concerns and toward ontological ones. That is, knowledge and understanding are conceived as ways of being-in-the-world and the relevant task of philosophy and/or social science is seen as describing the socio-cultural context in which knowledge is constructed (Gadamer 1976; Gergen 1985; Heidegger 1962; Wittgenstein 1953). Anti-foundationalist thought has been at the center of the "linguistic turn" occurring in philosophy, the social sciences, and the sociology of knowledge (Hekman 1986). For the major anti-foundationalist philosophers, to inquire into the nature of being is to inquire into the nature of language (Bleicher 1980). Thus, Gadamer (1976) states that "language speaks us." Heidegger (1962) describes that human beings are "thrown" into a language. Similarly, Wittgenstein (1953) discusses that language is not like a tool, which can be put down when not being used, because human forms-of-life are inherently linguistic.

For purposes of identifying evaluative criteria for interpretive research, Wittgenstein provides a sound starting point because 1) Wittgensteinian thought is central to the critical relativist program proposed for consumer research (Anderson 1986); and 2) Wittgenstein's philosophy has an explicit methodological focus in seeking to use linguistic analysis to clarify "pseudo-problems" passing as philosophical dilemmas. A prominent Wittgensteinian concept is that of *language game*. By postulating that words attain meaning from their relation in a given language game, Wittgenstein contextualized meaning. For this view, the "meaning of a word is its use in a particular situation" and it is due to a misguided "craving for generality" that philosophers seek out the one absolute meaning of a concept (Gier 1981; Wittgenstein 1953). Wittgenstein redefined philosophical problems as "grammatical fictions" arising from the assumption that a word used in different language games must have the same meaning.

With respect to consumer research, the critical relativist program is amenable to Wittgenstein's account of linguistic meaning. With language games, meaning is not simply a correspondence between word and object. With critical relativism, scientific knowledge is not simply a correspondence between a theoretical term and a state of the world but emerges from a system of metaphysical beliefs, value commitments, and cognitive aims (Anderson 1986). Thus, it can be said that what constitutes scientific knowledge depends on which language game is being employed. Just as no one ostensive definition describes the meaning of a word, no one set of methodological procedures describes the constitution of scientific knowledge. Critical relativism proposes that the evaluative criteria must vary according to the assumptions and cognitive aims underlying the

research. Researchers are required to explicitly state their assumptions, cognitive aims and also to provide appropriate evaluative criteria. The reader of the research is required to understand the study's aims and assumptions and faithfully seek to apply the relevant evaluative criteria.

Several advantages are readily seen with the critical relativist approach to evaluating interpretive research. First, and very pragmatically, the degree of explication required to specify the relevant paradigmatic assumptions, cognitive aims, and value commitments will improve the thoroughness and comprehensibility of an interpretive study. Second, the problem of applying inappropriate evaluative criteria is avoided because the researchers, themselves, provide the relevant criteria. Third, since critical relativism requires no specific set of methodological procedures, the approach facilitates methodological pluralism.

The one issue which anti-foundationalism has not fully accounted for, however, is how evaluative judgments can be made solely within the confines of a given conceptual system. Evaluation would seem to require that some criteria and beliefs transcend a specific context or conceptual system. For example, in arguing that a concept's meaning is given by its function in a language game, Wittgenstein's metaphor of *language is a game* transcended any specific linguistic usage. Similar transcendental assumptions can be seen in the works of other anti-foundationalist philosophers. Heidegger postulates the existence of "existential" categories that transcend all forms-of-being (1962). Gadamer proposes that *critical reason* can be used to distinguish between "legitimate" and "illegitimate" prejudices (1976). While anti-foundationalists made a move toward ontology (seeking only to describe the nature of being), the need for some form of an epistemological foundation was not completely obviated.

The critical relativist program also requires some foundational assumptions, albeit very broad ones. As with Gadamer, there seems to be some requirement for "critical reason." It is assumed that the evaluator, once provided with a set of criteria, will reasonably and fairly apply the criteria. Since critical relativism is devoutly non-nihilistic, the evaluator must also have some means by which to distinguish between legitimate and illegitimate cognitive aims, assumptions, and criteria. Third, it is assumed that incommensurability is not an issue in evaluation. That is, to implement the critical relativist program, the reader must be able to comprehend the intended meanings of the researcher and *use* the provided evaluative criteria in the intended fashion. The critical relativist contends that research is evaluated on the basis of the *researcher's* guiding theoretical program rather than on a "fusion of horizons" (to use Gadamer's terminology) between theoretical perspectives of reader and researcher. While arguing for the inherent theory ladenness of scientific observation, critical relativism grants an epistemic exemption to its own evaluative endeavors. The critical relativist, like the scientists

who conduct research, must adopt a perspective in evaluating research. For example, when assessing a research program's "methodological, ontological, metaphysical, axiological commitments" and its "realizable cognitive and social aims" (Anderson 1986), a hermeneutic process is being implemented. Rather than being monolithic, it would seem that critical relativism would be multi-perspectival so that disagreements might arise over the "realizability" of a given research program's cognitive aims or in specifying just what the cognitive aims are in the first place.

No charges of "self-refutation" are being levied against critical relativism or the anti-foundationalist philosophy on which it is based. The point is that the concerns of foundationalist philosophers are not so easily laid to rest. Anti-foundationalists also need some ground on which to base to their claims. The insight of critical relativism is that no one set of methodological procedures guarantees knowledge. The application of positivist criteria can be both limiting and philosophically inconsistent to interpretive research. Yet, the foundationalist insight that knowledge claims must be based on something which is, at least, *assumed* to transcend contextual variations also has descriptive merit. Out of this dialectic tension, a need can be seen for non-dualistic evaluative criteria that are not dependent on any one set of methodological procedures but that still allow for some grounding of knowledge claims.

Toward A Perceptual Approach

One foundation that might be used to ground the knowledge claims of interpretive studies, not premised on inherently dualistic notions, is perception. Perceptual experience often serves a root metaphor for anti-foundationalist, such as in Wittgenstein's contention that understanding is a process of "seeing as." The French phenomenologist Merleau-Ponty also suggests that conceptual knowledge has as its base pre-reflective perceptual experience (1962). As the following quote from the *Phenomenology of Perception* (1962) illustrates, Merleau-Ponty's view of perception is highly congruent with some of the more typical aims of interpretive research.

Our first task will be to re-discover phenomena, the level of living experience through which things and other people are given to us. We shall no longer hold that perception is an incipient science but conversely that classical science is a form of perception which loses sight of its origins and believes itself complete (p.57).

A common theme of interpretive research is to provide a thick description of lived experience, free from natural science prejudices (Belk, Sherry, & Wallendorf 1988; Hirschman 1986; Hudson & Ozanne 1988; Thompson, Locander & Pollio 1989). In this sense, evaluating interpretive research from perceptual criterion is philosophically consistent

with the aims underlying consumer research's use of interpretive methods.

Identifying an applicable set of perceptual evaluative procedures is no small task. Gestalt psychology, however, may serve as a fruitful starting point (Koffka 1935; Kohler 1947). Gestalt theory suggests that one important perceptual criterion is that the research affords insight into the phenomenon being explored. From this perspective, insight is not conceived as a mysterious, subjective experience but as a type of understanding that is-in-the-world (Kohler 1947; Merleau-Ponty 1962). For example, when a problem is solved by insight, an understanding emerges from grasping a pattern or organization (Kohler 1947). The problem and the pattern yielding a solution are not private, subjective entities but are rather public phenomena.

A demonstration of insight is provided in the following example taken from Kohler (1969). The problem is to comprehend the relationship between following three lines of integers:

- A) 0, 1, 2, 3, 4, 5, 6, 7, 8.....
- B) 0, 1, 4, 9, 16, 25, 36, 49, 64.....
- C) 1, 3, 5, 7, 9, 11, 13, 15

The solution pattern is that line A consists of a series of integers, line B consists of the squares of those integers, and line C is derived from subtracting each square from the preceding square in line B: a procedure which gives the series of odd numbers. When these relationships are grasped, one has experienced an insight.

There are at least three types of insight that interpretive research could afford:

- 1) Conceptual Gestalt- In this form of insight, the interpretation allows the evaluator to see a set of qualitative data as a coherent pattern or gestalt. What might have previously seemed a set of discrete and unrelated events becomes a good conceptual figure. As an example, Freud's interpretations allowed a wide range of neurotic behaviors to be seen as manifestations of the same general phenomena: unconscious repressions of sexual experiences and desires (van den Berg 1961).

In that conceptual gestalts are *not* dependent on empathy, the evaluator may disagree with the interpretation while still seeing how the interpretive pattern derives from the data. With a conceptual gestalt, the reader can grasp the proposed meaning of the phenomenon even if it does not directly relate to his/her own field of experience. As an example, one can comprehend Thomas and Znaniecki's (1958) ethnography of the Polish peasant without knowing what such an experience feels like. A well-known example of a conceptual gestalt is learning by insight, such as in the "Eureka" experience described in the myth of Archimedes (Pollio 1982).

2) Phenomenological Gestalt- In this form of insight, the interpretation resonates with the reader in such a way that a more personalized, first-person understanding of the phenomenon is gained. In this case, the interpretation is seen as describing a like pattern in the reader's own field of experience. The interpretation may even allow the reader to articulate some aspect of their own experience which had previously defied overt description. Phenomenological gestalts afford to the reader a heightened self-awareness and a personally relevant understanding of the phenomenon. Unlike the previous form of insight where the reader can see the interpretive pattern without necessarily agreeing with it, the reader feels there is something "right" about the interpretation in that it meaningfully relates to his/her own experience. A well-known example of a phenomenological gestalt is Dilthey's conception of "verstehen."

3) Paradigmatic Gestalt- With this form of insight, the interpretation has such a profound effect on the reader that the world is seen in an entirely new way. That is, the reader's previous world-view is replaced by a new organizational scheme. This form of insight has been described as a "paradigm shift" (Kuhn 1970). As one Kuhnian example, Einstein's theory of relativity gave rise to an entirely new understanding of space, time, and motion.

Paradigmatic gestalts have a different nature than those of the conceptual or phenomenological form. With the latter two, the interpretation affords an awareness of a novel pattern but this understanding is still within the reader's existing horizon of conceivability. With paradigmatic insight, this horizon altered in such a way that what had previously been inconceivable is now seen as a potential or actual state of the world. This is perhaps the most that could be asked of an interpretive study because it changes the horizons of what can be.

CONCLUSION

Two major approaches to evaluating interpretive research have been discussed. Foundationalism is described as a dualistically motivated epistemology seeking to ground knowledge on a firm, indubitable base. In accepting the subject-object distinction, positivist and humanist methods reveal a foundationalist logic. Anti-foundationalist approaches have a more ontological focus in seeking to describe understanding without dualistic categories. The critical relativist program is the major example of this approach in consumer research. It was noted that even anti-foundationalists cannot completely obviate the need for some epistemic ground on which to base their knowledge claims. Perceptually

based evaluative criteria were suggested as one means for a non-dualistic grounding of interpretive research's knowledge claims.

Ritual, Ritualized Behavior, and Habit: Refinements and Extensions of the Consumption Ritual Construct

Mary A. Stanfield Tetreault, George Mason University
Robert E. Kleine III, Arizona State University¹

ABSTRACT

The ritual construct offers great potential for interpreting many aspects of consumption phenomena. Ritual's potential can be best realized by a multi-layered view of the construct. We refine and clarify Rook's interpretation to provide such a perspective. We draw clear distinctions between the analytical classes of ritual, ritualized behavior, and habit. Theoretical and methodological implications are discussed.

INTRODUCTION

A number of consumer researchers have exhorted that the ritual construct affords great potential for conceptualizing and interpreting many aspects of consumption phenomena (Belk 1979; Kehret-Ward, Johnson, and Louie 1985; McCracken 1986, 1988; Rook and Levy 1983; Solomon and Anand 1985; Sherry 1983). Rook's (1984, 1985) contribution to our discipline's understanding of the ritual construct as a conceptual framework offers rich insights into the real, *experiential* lives of consumers and the types of symbolic meanings that they invest in the use of consumer products.

In this article, we attempt to build upon Rook's (1985) elaboration of the ritual construct by offering refinements, clarifications, and extensions of his work. As such, our undergirding objective is not to inculcate conceptual divisiveness or "hair splitting"; rather, we proffer a framework designed to incrementally sharpen our discipline's understanding of the ritual construct and its role in consumer behavior. Furthermore, we offer guidelines for the analytical exploration of consumption rituals and their constituent components.

RITUAL CONSTRUCT DOMAIN AND DEFINITION

We readily admit that Rook (1985) confronted a formidable analytical task in his effort to define the ritual construct in a manner most germane to the scope of consumption phenomena. Across the transdisciplinary morass of divergent interpretations of the term, Rook has abstracted a "mid-range" definition of ritual. It is not limited to the overly restrictive interpretation of ritual as "semicivilized" man's prescribed manner of comportment in religious contexts, the jingoistic Victorian-era definition predominately used until a generation ago (Kertzer 1988; Vizedom 1976). Neither does it subsume *all* forms of scripted human activity (e.g., facing forward in an elevator filled with strangers; snapping one's chewing gum). Instead, Rook's

definition of the term ritual is constructed to encapsulate the shared "structural and content elements" . . . of "both everyday, and extraordinary human experience:"

The term ritual refers to a type of expressive, symbolic activity constructed of multiple behaviors that occur in a fixed, episodic sequence, and that tend to be repeated over time. Ritual behavior is dramatically scripted and acted out and is performed with formality, seriousness, and inner intensity" (1985, p. 252).

Rook raised the question whether it is "reasonable to ask whether it is either possible or useful to derive a single definition of ritual" (1985, p. 252). We agree that it is *extremely* useful to attempt to capture a constructional domain which is appropriate for conceptualizing consumption ritual phenomena within our interdisciplinary framework. However, we believe that further refinements in a definition of ritual are necessary for crystallizing the construct's domain, and distinguishing that domain from those of the related constructs "habit" and "ritualized behavior". Although these constructs may indeed "represent overlapping sets" (Rook 1985, p. 252), greater discrimination between them may be "useful" or "appropriate" for analytical purposes. None of the constructs represent synthetic categories (Kant 1900 trans.; Bagozzi 1980); thus, there are no "right or wrong" definitions of them. Yet teasing out the distinctions between them may enhance our ability to develop a coherent framework for the different levels of symbolic meaning consumers may attach or associate with each form of behavior.

Before presenting our refined definition of ritual, we will discuss those characteristics which distinguish habit (or custom) from ritual and those which distinguish ritual from ritualized behavior (Erikson 1977, 1982).

Habit/Custom Versus Ritual

Habits or customs constitute *routinized* behavior (Howard 1979). Several characteristics best distinguish habits from rituals. First, the scripts for habitual acts may be *either* created by the individual consumer (e.g., the sequence of breakfast-making acts) or prescribed by society (rules for standing in line at the supermarket checkout counter). The second distinguishing characteristic is the level of *conscious awareness*, or cognitive processing, associated with the elicitation of the behavior sequence (Douglas and Isherwood 1979; La Fontaine 1985; Peter and Olson 1987; Turner 1985). Admittedly, this difference is a matter of *degree* rather than type, and is thus dependent upon

¹The authors would like to thank Dr. Hunter S. Thompson for his perspicacious comments on an earlier draft of this paper.

individual and/or situational characteristics. For example, arranging a place setting according to the rules of decorum may be a *completely* routinized behavior on a mundane basis, with the "rules" followed in order to save time/cognitive processing. On the other hand, one may be more cognizant of prescribed norms for place setting when preparing for an important social occasion, but engage in the *same* behavioral sequence. Thus, one's level of involvement (e.g., Celsi and Olson 1988) distinguishes habit from ritual, rather than the intricacy of the behavioral script.

The third characteristic distinguishing habit from ritual concerns their communicative function (La Fontaine 1985; Turner 1985; Lewis 1980). Analogous to language, habit or custom has been suggested to transmit (through behavioral signals) a more circumscribed message (e.g., if one offers a hand upon introduction, one has no overtly hostile intentions). Ritual, with its more intense symbolic properties and components, communicates or expresses a more condensed, multivocal and ambiguous web of meaning (Kertzer 1988; Munn 1973; Turner 1967). Therefore, participation in habitual or routinized behaviors is not likely to stimulate the same level of affective response as does participation in ritual (Warner 1959).

Finally, intransigence or resistance to change may serve to discriminate between habit and ritual. Although rituals *can* undergo procedural changes that diverge from an "ideal type" or "stereotyped script" due to either short term contingencies, or, on a more permanent basis, due to changes in the distribution of resources in society (La Fontaine 1985; Kertzer 1988), habits *in general* are more amenable to modification or extinction when they no longer fulfill their instrumental and/or expressive functions.

Ritual Versus Ritualized Behavior

In his definition of ritual, Rook (1985, p. 252) explicitly aggregates the constructs "ritual" and "ritualized behavior." This approach is attributable to Rook's sociopsychological theoretical perspective, which is founded upon Erikson's (1951, 1977, 1982) theories of intrapsychic development. According to this theoretical perspective, "*both* everyday ritualized behavior and larger public rituals" (Rook 1985, p. 257) are "energized" by the nature of the conflicts between intrapsychic and social forces uniquely associated with each of Erikson's (1951) eight universal stages of human development. Diurnal ritualized activities are seen to serve as *reinforcement* (through repetition) for status changes which are publicly "announced" by means of symbolic public ritual activities (Rook 1985, p. 257).

Although we agree that ritualized behavior may serve to *reinforce*, through mundane repetition, the role/status transitions around which many rituals are focused, we suggest that "ritualized behaviors" and "ritual" are not subsets of the identical constructional domain. Upon the basis of the socioanthropological theoretical perspective to which we subscribe, we aver that these two

constructs may be more appropriately viewed as distinct, albeit related in a nomological network. The major properties and characteristics which we believe discriminate between "ritualized behavior" and "ritual" are summarized in the Table. Our discussion will highlight those characteristics we believe are most critical for discriminating between the constructs.

Our major rationale for distinguishing between ritual and ritualized behavior concerns the notion that ritual 'instantaneously' accomplishes its purported objectives of status transition and social maintenance (Radcliffe-Brown 1952; Vizedom 1976; Turner 1985; La Fontaine 1985). This perspective is eloquently expressed by La Fontaine (1985, pp. 35-36):

Ritual is *purposive*; the participants believe that they are accomplishing their aim in what they do . . . this *cannot be ignored* . . . Day to day social life is perpetually changing; what is relatively constant in it is the part played by ideas and beliefs through which individuals both perceive events and evaluate their own and others' behavior -- what has been referred to has the moral order. To refer to it [moral order] as false, and the untidy process of living as real, is to make a judgement of value by comparing *non-comparable entities*, which cannot be helpful.

It may be tautological to state that ritual effects its purported objectives (i.e., the maintenance of, and/or change of individuals' status within the social order) because that is what the ritual process is designed to do. However, grounded in our aforementioned theoretical perspective, we aver that we (as "scientists") *must* believe this, or take this "leap of faith," because the participants of rituals espouse that *they* do so. Here we stand in contrast to Rook (1985) and Erikson (1977), who imply that mundane ritualized behaviors are *necessary* to fulfill ritual's "unfinished business." But is this is not an imposed view on the part of the "enlightened scientist"? Whose statement or interpretation should be taken as veridical: that of the "detached, objective scientist", or that of the ritual participant (the "crazy native")? We (as "crazy scientists"?) side with the perspective of the participant. Thus, we conceive of ritual and ritualized behaviors as "apples" and "oranges"; they are both in the same "angiosperm," or construct class, but are non-comparable "species."

Ritual's 'instantaneous' transitions are most evident in public events marking or celebrating either a change in an individual's or group's *status* (e.g., baptism, sorority initiation, marriage, communion, naturalization, Bastille day, Independence Day) or a transition through natural and/or "supernatural" or aesthetic cycles (e.g., the "primitive" vestiges and extant religious versions of Christmas, Easter, May Day, the Wagner "Ring" Cycle). Ritualized behaviors may be more closely associated with conditions in which roles or

TABLE
RITUALIZED BEHAVIOR CHARACTERISTICS VERSUS RITUAL CHARACTERISTICS

Ritualized Behavior	Ritual
"tidies up" ritual's "unfinished business"	accomplishes transition and maintenance objectives
'private' enactment (self and "looking glass self")	public enactment (\geq dyad)
elements intrapsychically determined	elements socially prescribed
mundane repetition across time and place	bracketed in time and space; repetition over cycle of time
role assimilation	'instantaneous' status transition
behavior-affect-cognition sequence of change	affect-cognition-behavior sequence of change
emphasizes the idiosyncratic representation	emphasizes the collective representation
occurs in self time	occurs in social time
maintain/change one's self conception	maintain/change status within a social, knowledge, or natural system
constrained by idiosyncratic tradition	constrained by social mores
confluence of actor and individual	distinction between actors and individuals

interaction patterns are *gradually* assimilated, such as divorce and other relationship disengagements (Baxter 1984; Lee 1984), landing the first post-MBA job (Solomon and Anand 1985), or 'fitting-in' as a new assistant professor on the faculty. Clearly, ritual is most closely linked to the maintenance of and/or change within systems of society, knowledge, and nature (Vizedom 1976; Van Gennep 1960 trans.; Radcliffe-Brown 1952; Durkheim 1974 trans.; Aron 1970); ritualized behaviors are more likely to be associated with the maintenance and/or change in one's self-perception (e.g., Solomon 1983; Mead 1956; Goffman 1959).

The *public* enactment of ritual requires the participation of at least two actors in a socially prescribed, standardized sequence of events (Durkheim 1974 trans.; La Fontaine 1985; Turner 1985; Kertzer 1988). The transformative, symbolic effects of ritual occur in social time (Warner 1959) which is bracketed from mundane life (Turner 1985; Wolff 1978). Turner (1985) and Vizedom (1976) view the bracketness of ritual as an essential prerequisite for affective and cognitive changes to 'instantaneously' occur; these changes permit the transition (of an individual) to a new status (within the social system).

Ritualized behavior, on the other hand, requires only a *private* enactment of a script whose elements are intrapsychically orchestrated. The sequence of events and artifacts employed may thus be guided by idiosyncratic tradition (a question

raised by Rook 1985, p. 262) as well as social norms. The mundane repetition of ritualized behavior occurs in self time (Warner 1959).

Definition of Ritual and Its Components

Our preceding summary of the qualities or characteristics of ritual *vis a vis* its related analytic constructs, habit and ritualized behavior, provides us with a foundation for abstracting a refined, interdisciplinary interpretation of the ritual construct:

Ritual is defined as an analytical class of purposive, socially standardized activity sequences. Ritual is designed to maintain and transmit both social and 'moral' order: to reaffirm social interdependency, by evoking and communicating a network of condensed, multivocal and ambiguous affective *and* cognitive meanings to which members of the collectivity may jointly subscribe. Ritual's meanings are conveyed through the use of symbolic or metaphorical artifacts (objects, language, actors, and behaviors) that are orchestrated into a structured, dramatic complex (episode or script) often repeated over time. Ritual is enacted in bracketed social time and/or place, wherein time and/or place themselves have meaning.

A cursory reading of our interpretation of ritual and its components may indicate that it varies from Rook's (1985) definition only along a few dimensions. However, these dimensions are substantial (i.e., they have important theoretical and methodological implications), and serve to recast ritual as a distinct analytical category. We highlight critical points below:

- * Ritual is an *analytic category*.
- * Ritual is *purposive behavior*; it accomplishes its objectives of transition and maintenance of both social and moral order (e.g., La Fontaine 1985; Radcliffe-Brown 1948; Gluckman 1965).
- * Ritual is *socially standardized*. Its enactment requires the organized cooperation of individuals to fulfill all necessary roles (La Fontaine 1985). Ritual is also socially standardized in that the script prescribes roles and associated rules of conduct for actor compartment (Durkheim 1974 trans.).
- * Ritual evokes and communicates *more than one specific meaning* (e.g., Kertzer 1988; Munn 1973; Turner 1967); it evokes a network of both cognitive and affective meanings. Thus, it does not evoke immediate, identical behavioral responses from *all* actors (Rook 1985, p. 253). However, consistency would be expected across actors fulfilling similar roles.
- * Ritual occurs in *bracketed social time and/or place* (Warner 1959; Turner 1985). This does not necessarily imply that ritual encompasses only "extraordinary" human experience (Rook 1985, p. 252); it encompasses human experience that celebrates *significant* social or natural transition events.
- * The socially standardized rules for ritual performance consist of both explicit and implicit conventional requirements. Implicit rules, as part of "hidden culture" (Garfinkel 1963; Hall 1977) exert an extremely powerful influence on behavior. Deviation from these rules can elicit scorn, alienation, or outright hostility, as illustrated by the following apocryphal passage:

"It was just about then that somebody noticed my 'press' tag was attached to my shirt by a blue and white McGovern button. I'd been wearing it for three days, provoking occasionally rude comments from hotheads on the convention floor and in various hotel lobbies -- but this was the first time I'd felt called on to explain myself. It was, after all, the only visible McGovern

button in Miami Beach that week -- and now I was trying to join a spontaneous Nixon Youth demonstration that was about to spill out onto the floor of the very convention that had just nominated Richard Nixon for reelection, against McGovern . . .

They seemed to feel I was mocking their efforts in some way . . . and at that point the argument became so complex and disjointed that I can't possibly run it all down here. It is enough, for now, to say that I was finally compromised: If I refused to leave without violence, then I was damn well going to have to carry a sign in the spontaneous demonstration -- and also wear a plastic red, white, and blue Nixon hat. They never came right out and said it, but I could see that they were uncomfortable at the prospect of all three network TV cameras looking down on their spontaneous Nixon Youth demonstration and zeroing in -- for their own perverse reasons -- on a weird looking, 35 year old speed freak with half his hair burned off from over-indulgence, wearing a big blue McGovern button on his chest, carrying a tall cup of 'Old Milwaukee' and shaking his fist at John Chancellor up in the NBC booth -- screaming: 'You dirty bastard!' . . . I politely dismissed all suggestions that I remove my McGovern button, but I agreed to carry a sign and wear a plastic hat like everyone else. 'Don't worry', I assured them, you'll be proud of me' . . ." (Thompson 1973, pp. 355-356).

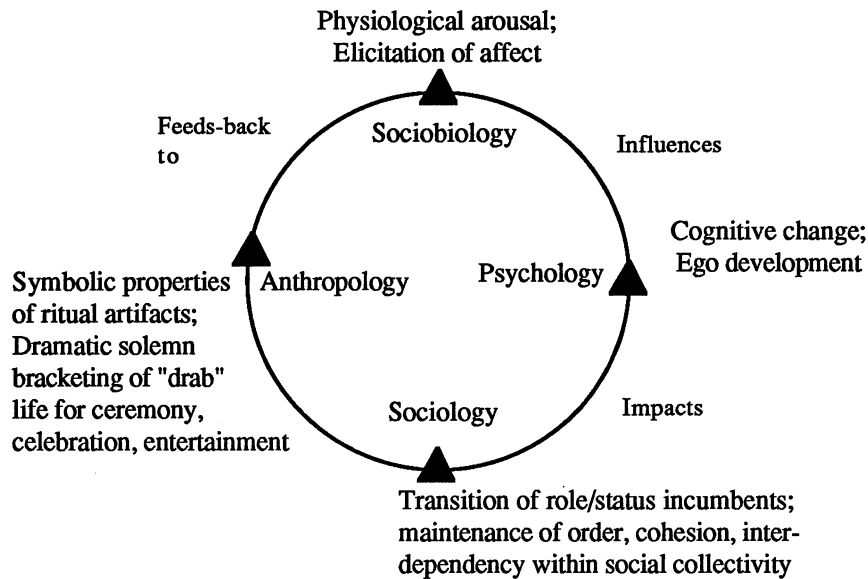

To further explore this analytical category, ritual, we next explicate threads of the interdisciplinary fabric which inculcates ritual with so much power.

THE POWER OF RITUAL: AN INTERDISCIPLINARY PERSPECTIVE

The power of ritual as an analytical category for consumer research is two-fold. First, it describes a system of which consummatory behavior is an important component. As such, ritual provides an analytically tractable microcosm within which the consumption systems of the larger culture are condensed and brought into relief -- thus facilitating their identification and analysis. Second, ritual emphasizes the integrated nature of psychological and social structural phenomena. As Kertzer (1988, p. 10) observes:

"The power of ritual stems not just from its social matrix, but also its psychological underpinnings. Indeed these two dimensions are *inextricably linked*. Participation in ritual involves physiological stimuli, the arousal of emotions; ritual works through the

FIGURE
THE POWER OF RITUAL: AN INTERDISCIPLINARY PERSPECTIVE

NOTE: This cyclical depiction of the power of ritual is most evident for those rituals celebrating social change (e.g., rites de passage, national holidays, initiation rites). However, the effects are assumed to inhere in rituals celebrating changes in the natural world (e.g., Easter, May Day, Circleville Pumpkin Festival), as the distinctions between rites de passage and calendrical rites (Gluckman 1965) is an artifact of Western ontology.

senses to structure our sense of reality and our understanding of the world around us".

This "inexorable linking" of phenomena -- generally investigated by researchers from disparate research traditions -- led us to reconceptualize Levy's (1978) typology of ritual behavior into our Figure depicting the cyclical power of ritual. This reconceptualization is in the spirit of Van Gennep's (1960 trans.; cf. Vizedom 1976) insistence that analytical power is focused, rather than diminished, by emphasizing the *similarity* among ritual's elements.

We reconceptualized Levy's (1978) five ritual types -- human biology, individual aims and emotions, group learning, cultural values, and cosmological beliefs -- into their corresponding research traditions: sociobiology, psychology, sociology, and cultural anthropology. The nonrecursive feedback loop linking these elements emphasizes that each contributes to ritual. A researcher could begin study of ritual from any of these perspectives; however, s/he should strive to capture the Gestalt (La Fontaine 1985). The study of ritualized behavior (Rook 1985) can be represented as investigation of the "slice" of the ritual cycle surrounding psychology.

For expository purposes, and to elucidate some of the myriad activities enacted within ritual, we now tour the ritual cycle one "slice" at a time. However, to analyze ritual in such a manner (i.e.,

investigate only one or two of the "slices") would strip much of the phenomenon's vitality. Sociobiology, as Barash illustrates, provides the foundation from which all ritual springs:

"Sociobiology will probably have little to tell us about why we select a blue necktie or a red one, but a great deal about why we choose to adorn our bodies in the first place; very little about why we vote Democratic or Republican, but a great deal about why we choose to have leaders in the first place; very little about the details of our lives, which are largely determined by learning, by chance, or by the whims of custom, but a great deal about why, underneath it all, we act like human beings" (Barash 1979, p. 14).

Sociobiology thus concerns the most fundamental, evolutionarily refined human tendencies which predispose humans toward not only ritual, but also certain types of ritual.

Ritual phenomena pertinent to psychological analysis include individuals' (idiosyncratic) meanings ascribed to ritual artifacts, ego development, and belief system changes which may include changes of the individual's perception of his/her environment (social or natural) and of self. Also pertinent phenomena are the content and elaboration of individuals' ritual scripts.

Sociological inquiry of ritual emphasizes not individuals, but the roles designated by a ritual's script, and the social structure within which those roles are embedded. The effects of ritual on group cohesion and status (i.e., role) transitions of ritual actors are also salient. Emphasis is placed on the role ritual serves to reaffirm the extant social order and build solidarity through the joint action of ritual participants (Durkheim as interpreted by Kertzer 1988, p. 76).

The complex texture of ritual artifacts' symbolism is of vital interest in anthropological analysis of ritual (Turner 1985; Vizedom 1975). Also emphasized are the use of ritual artifacts' symbolic properties to bracket the ritual both in time and space and to indicate social inclusiveness/exclusiveness among ritual actors.

Analytically, we can distinguish ritual phenomena characteristic of sociobiological, psychological, sociological, and anthropological modes of inquiry. However, the power of ritual resides not in the fact that this diversity of phenomena occur within the boundaries of ritual. The power of ritual emerges from the fact that traditional disciplinary boundaries dissolve. The result is the seamless interplay of individuals' emotional, cognitive and affective responses to their idiosyncratic interpretations of the enactment of socially defined roles which are demarcated one from another by cultural artifacts that become condensed symbols to facilitate ritual enactment. Consequently, ritual provides a vehicle through which consumption behavior, with all its multi-sensory, hedonic, affective, cognitive, social, and cultural qualities are fully recognized. However, the power of ritual comes not without challenges to consumer researchers. The most notable challenge is methodological, to which we now shift our attention.

METHODOLOGICAL IMPLICATIONS OF RITUAL

How does the researcher approach the challenge of understanding and capturing the meaning, power, and outcome of consumption ritual? As consumption ritual represents a complex Gestalt, embodying a multivocal latticework of manifest and implicit meanings derived from ritual actors' participation and interaction among themselves and with the ritual's symbolic set of artifacts, ritual presents the researcher with a formidable, but enticingly variegated "multivariate" analytical task.

The corpus of ritual literature is replete with expositions that disaggregate and taxonomize the outcomes and components of ritual -- e.g., Grimes' programmatic bibliography (1985); Moore and Myerhoff (1977). As we recapitulate that these phenomenal components are inexorably linked, we maintain that the exploration of consumption ritual should ideally be approached using methods of inquiry subsumed within the holistic, interpretive, hermeneutic paradigm(s) of ethnography (e.g., Denzin 1989; Geertz 1973; Goodenough 1971; Hirschman 1986; Hudson and Ozanne 1988;

O'Shaughnessy and Holbrook 1988). Approaches which proffer a continual interplay between individual actors' scripts or meaning systems (D'Andrade 1986) for particular ritual "texts" and the systemic ritual complex "text" (itself embedded within a sociocultural totality) -- a hermeneutic circle -- would provide a strong foundation of interpretive understanding of consumption ritual phenomena from the perspectives of the participants (the "crazy natives").

The consummation of interpretive modes of inquiry, although devoutly to be wished, may be difficult for many consumer scholars to achieve in the short run. The production of "thick description" (Geertz 1973) requires not only the implementation of an orchestrated set of ethnographic tools; it requires an "artistic sensibility" which our discipline's predominant patterns of "scientific" socialization neither promulgate nor invariably reward (e.g., Calder and Tybout 1987; Tetreault 1987). Furthermore, the exegistical conjoining of individual and systemic units of analysis contradicts our discipline's bias/affinity toward a reductionist, atomistic perspective.

Yet short run straits should not be bewailed. Exemplars of the use of interpretive paradigms in consumer research exist (e.g., Belk, Wallendorf, and Sherry 1989; Holbrook and Grayson 1986; Sherry and McGrath 1989), and may inspire scholars interested in consumption ritual to "take arms against a sea of troubles" (Shakespeare 1603) and rigorously journey beyond "thin description" (Ryle 1968).

Moreover, incremental insight into the "meaning" of particular consumption rituals may be gleaned through the application of extant research approaches/ techniques concerned with eliciting informants' meaning or belief systems (e.g., Fiske and Taylor 1984; Olson and Reynolds 1983; Reynolds 1983; Smith and Houston 1985). The use of field observation techniques in tandem or conjunction with the elicitation and analysis of protocol data will afford a broadened understanding of the meanings that consumers attach to rituals of consumption.

Finally, the use of sociocognitive network analysis for examining consumption rituals offers great promise for capturing both individual actors' "operating culture" and the collective "public culture" (Goodenough 1971) associated with consumption ritual events. As this set of analytical techniques addresses both individual and sociostructural units of analysis in the formation and transmission of belief systems, it is well-suited for elucidating the social interdependencies which shared networks of meanings ascribed to symbolic artifacts reaffirm and reinforce. If applied within the naturalistic context of ongoing ritual consumption activity, results from this approach may well mirror the holistic insights provided by hermeneutical paradigms of ethnography.

CONCLUSION

Rook's (1985) sociopsychological approach for conceptualizing the ritual dimension of consumption provides a strong foundation for exploring the symbolic meanings individual consumers invest in their everyday behaviors. By refining the ritual construct and recasting it into a multi-disciplinary perspective, we have illustrated that the construct weaves a multihued, complex fabric of meaning. We hope that our discussion both challenges and inspires consumer researchers to approach the examination of rituals' meaning(s) with a broader interpretation of appropriate research methodologies. We hope also that our reconceptualization of ritual focuses researcher's attention on the joint and interactive nature of consumption phenomena.

An Abstract of
"To Everything There Is a Season:" A Photoessay of a Farmers' Market
Deborah D. Heisley, U.C.L.A.
Mary Ann McGrath, Loyola University of Chicago
John F. Sherry, Jr., Northwestern University¹

THE PROJECT

On June 28, 1986, three researchers embarked upon their own Odyssey along a two block strip in a midwestern city, as they spent the first Saturday of the selling season at the Midville Farmers' Market. This first day of the market was the first step in an ethnographic journey that would last nineteen weeks. They would witness the emergence of a variety of recurring themes, the reinforcement of several theoretic constructs specific to marketing, and the development of relationships with vendors, customers, and city representatives. They constructed a richly documented natural history of the market from participant observation, directive and nondirective interviews of customers, development of key informants, reflective journal entries, audio recordings, photographs and audio/video recordings.

One thousand three hundred and seventy seven photographs were made during the project. This photoessay includes 47 of those photographs. Captions and field notes supplement these photographs to provide a richer understanding of the visual insights provided by the photographs. Due to its heavily photographic nature, only an abstract of this photoessay will be included in these proceedings.

THE PHOTOESSAY

The essay focuses on three cycles: the market day, the season, and a cycle of long term field immersion. The market day is marked by vendor, consumer and city representative's rituals. A consumer typology is developed. The growing and selling season is characterized by increasing complexity and abundance over spring, summer and fall. The third cycle is habituation, through which the researchers gain trust and access to informants and acquire deeper holistic understanding of the market and its participants.

THE CYCLE OF THE MARKET DAY

A market day's cycle, especially customer and vendor behaviors, as it proceeds from set up to close, is illustrated and documented with photographs and accompanying field notes from the first market day. The essay carries the reader

through arrival, set-up, display, vendor interaction, consumer interaction, consumer-vendor interaction, peripheral activities, stock depletion, and the end of the market. Consumer segments are differentiated by the time of day they visit the market, giving a distinctive cycle to the day.

**DIFFERING PERCEPTIONS OF
ABUNDANCE AND COMPLEXITY**

Photographs of the first market of the season document the transformation of an empty street into what may appear to be a cornucopia of abundance. While researchers perceive bounty and abundance in the marketplace, the vendors speak of anticipated bounty nearer the late summer and fall harvest time. The researchers better understand the significance of vendors' remarks through observations of abundance and more complex assortments and displays at the late summer and autumn markets. A series of photographs visually documents significant changes in assortment, abundance, and complexity of display.

**HABITUATION OF KEY INFORMANTS
TO RESEARCHERS' PRESENCE**

As the market season matured, and the vendors' wares ripened and increased in bounty and variety, the relationships between the researchers and key informants developed from cautious exchanges to comfortable, sometimes humorous and teasing, interactions. Several vendors and customers became key informants during the course of the study. Journal entries and photographs of the informants on the first day of the market are contrasted with ones made near the conclusion of the study. The comparisons reflect the levels of trust that developed between participants and researchers, that in turn led to a negotiated or collaborative interpretation of marketplace behavior.

CONCLUSIONS

While the researchers observed and recorded a myriad of happenings on June 28, true understanding and insight into these events came later, as familiarity with the Midville market became more intimate. In retrospect, the first market is exceptional in that customers and vendors appear to know and act out a script without question after an eight month hiatus. It is the researchers who do not fully understand the plot and significance of the activities unfolding. After several months of building trust in relationships with informants, the researchers are able to document and interpret this script. It is this longer term orientation that sets the ethnographic approach employed in this local study apart from the naturalistic approach of the

¹The authors are listed in alphabetical order. The first two researchers spent each Saturday, with the exception of three, from June 28 through November 1, 1986 in attendance at the Midville Farmers' Market. The third author made occasional visits to the site, served as a resource and sounding board for the ideas of the other two authors, and audited the research process.

Odyssey umbrella project. The ability to compare and contrast findings on various days, and to document findings over time, became a notable benefit of long term field immersion.

This essay illustrates how impressions formed early in an ethnographic study can, when viewed later in context, provide useful insights into the processes of interest to researchers. The changing relationships with key informants clarified and enhanced several of the initial impressions formed by the researchers. These established bonds helped produce a negotiated interpretation of marketplace behavior. That ethnographic research is a labor intensive process that emerges over time is demonstrated in this essay.

An Exploratory Study of the Effects of Imagery Processing and Consumer Experience on Expectations and Satisfaction

**Deborah J. MacInnis, University of Arizona
Linda L. Price, University of Colorado**

ABSTRACT

Research was conducted to investigate whether imagery processing and consumer experience interact to affect consumer expectations and satisfaction, and to explore some individual and situational antecedents of naturally occurring imagery processing. Results revealed the use of elaborated imagery is a prevalent part in the anticipation of vacation activities, particularly for consumers who plan to invest more time and money. As predicted, imagery processing and experience affected the positivity bias of expected outcomes. Confidence that spring vacation would turn out as expected was affected by experience, and the interaction of experience and imagery processing, but not imagery processing alone. Imagery processing and the interaction between experience and imagery processing were related to confirmation of expectations. Contrary to predictions, imagery processing had a positive effect on satisfaction and experience had a negative effect. Of all the groups, low experience individuals who engaged in imagery processing were most satisfied with their spring vacation. Finally, consumers who engaged in higher levels of elaborated imagery were more satisfied with their vacation outcomes, whether or not the event unfolded as imagined.

IMAGERY, PLANS, AND SATISFACTION

Recent theory has suggested that imagery processing may affect a wide range of outcome variables, including consumer expectations, affect, intentions and satisfaction (MacInnis and Price 1987). Despite the important implications of this processing on consumer behavior, almost no research has explored imagery effects on consumer intent (for an exception see Mitchell 1989), and no research has explored the relationship between imagery processing, consumer expectations and satisfaction.

The purpose of this research was to investigate naturally occurring imagery processing and explore its relationship to consumer expectations and satisfaction. Two questions were of substantial interest: 1) Do imagery processing and consumer experience interact to affect consumer expectations and satisfaction? 2) What are the individual and situational antecedents of naturally occurring imagery processing?

THE ROLE OF IMAGERY PROCESSING IN CONSUMER EXPECTATIONS

In their 1987 article, MacInnis and Price propose that elaborated imagery processing can have a powerful role in influencing consumer expectations

and satisfaction. Specifically, imagery processing is hypothesized to lead to systematic biases in expectations, with attendant implications for satisfaction. MacInnis and Price (1987) argue that imagery processing will affect both the probability and the valence assigned to purchase outcomes. These biased expectations, in turn, may lead to greater discrepancies between actual and imagined outcomes culminating in higher levels of consumer dissatisfaction (Anderson 1973; Oliver and DeSarbo 1988).

Some research supports that imagining future events leads to a conjunctive bias because a probability is assigned to an entire or imagined scene rather than being assigned to the individual set of elements that comprise the scene. This leads to an overestimation of the likelihood that a sequence of events will unfold as imagined (Einhorn and Hogarth 1984, Kahneman and Tversky 1982). Other research indicates that elaborated imagery not only biases probabilities assigned to contingent events, it also affects more directly consumers' expectations that imagined events will occur. The very act of creating a sensory analogue of the outcome (via imagery), makes the outcome appear more real and hence, more likely (Anderson 1983; Carroll 1978; Sherman, Cialdini, Schwartzman and Reynolds 1984). For example, Sherman et al (1984) found that students who imagined the symptoms of a given disease rated the likelihood that they would contract the disease as higher than students who did not engage in imagery.

As noted in MacInnis and Price (1987), elaborated imagery may also lead to a valence bias in imagining future events (see O'Neal 1974). Specifically, individuals are more likely to focus on positive imagined future outcomes than negative ones. Again, the sensory analogue properties of imagery processing are an important envoy for this bias. The fact that imagery provides a sensory analogue makes it natural for consumers to focus on outcomes that feel good.

The likelihood and valence biases associated with imagery processing have potentially negative implications for resultant consumption satisfaction. If consumers imagining purchase outcomes focus only on positive ones, and assess upwardly biased probabilities that the imagined event will unfold as imagined, there is a good chance that the actual purchase outcomes will fall short of the expectations formed through imagery. Disconfirmation of expectations has been noted in the satisfaction literature as a major factor influencing consumer dissatisfaction (Oliver and DeSarbo 1988; Tse and Wilton 1988). There is some suggestion that even favorable outcomes, if different than expected, may give rise to dissatisfaction (Anderson 1983). Thus, elaborated imagery, by biasing perceived

likelihoods, contingent probabilities and the positivity of future events may reduce consumers' satisfaction with the experienced event.

THE ROLE OF CONSUMER EXPERIENCE

MacInnis and Price (1987) postulate that imagery processing and consumer experience and expertise in the product category may interact to affect purchase satisfaction. In the case of discursive processing, product experience and knowledge are related to important differences in memory and cognitive structure that affect information search and processing (Alba and Hutchinson 1987). However, almost nothing is known about the effect of consumer experience on imagery processing. MacInnis and Price (1987) speculate that consumers who are product novices are likely to have a relatively modest store of information in memory from which to build scenarios of purchase outcomes. Because knowledge stores are impoverished, individuals with little or no product experience may imagine relatively few purchase outcomes. Moreover, given the positivity bias expected with imagery processing, novice consumers are likely to imagine these few scenarios as being positive in nature. Finally, because imagery processing heightens expectations that the positive events constructed from the limited storehouse will actually unfold as planned (a likelihood that is actually quite slim), there is considerable opportunity for dissatisfaction on the part of the novice consumer.

In contrast, MacInnis and Price (1987) argue that a different set of conditions may operate for more experienced consumers. Because of their richer knowledge base, experienced consumers may imagine the anticipated event as unfolding in many ways. Moreover, although experienced consumers too are likely to favor positive outcomes in their imagining, their past experiences may prompt them to consider negative outcomes as well. By imagining many different outcomes, and incorporating both favorable and unfavorable outcomes, their expectations for any one event occurring are likely to be lower than those for novices. Consequently, for experienced as compared to inexperienced consumers, there is a greater probability that at least one of the imagined events will unfold as planned (compared to the single event imagined for novices). Moreover, because experienced consumers incorporate into their imagery potentially negative outcomes, they may also engage in behaviors that reduce the probability that negative events will occur or affect their plans. Lowered expectations for a single positive event, along with imagery of negative events and risk reduction actions, may simultaneously reduce expectations for a single event, and increase ultimate satisfaction with the imagined event.

Examining the role of imagery processing and experience on consumer expectations and satisfaction suggests a main effect of imagery processing, and an interaction of imagery

processing and consumer experience on a positivity bias in expected outcomes, confidence in expectations, expectancy-disconfirmation and satisfaction. Specifically, based on extant theory, imagery processing when combined with low levels of experience should result in more positivity bias, more expectancy-disconfirmation, and less satisfaction. In contrast, imagery processing when combined with high levels of experience should result in less of a positivity bias, less expectancy-disconfirmation and more satisfaction.

ANTECEDENTS OF IMAGERY PROCESSING

The limited consumer research exploring imagery processing has generally manipulated task stimuli to induce imagery processing (see discussion MacInnis and Price 1987). This provides valuable insights into the separate effects of discursive and imagery processing, and the ability of specific variables (such as pictures, instructions to imagine, etc.) to induce imagery processing. However, such research does not provide exploratory insights into naturally occurring imagery processing and its antecedents.

Some research has supported individual differences in preferences for imagery processing and the use of imagery in everyday life (Childers, Houston and Heckler 1985; Rossiter and Percy 1978; Singer and Antrobus 1972). For example, Singer and Antrobus (1972) suggest that individuals may differ in both the level and content of their imagery. Thus, individuals will differ in their tendency to engage in vivid imagery, use imagery in anticipating the future and solving problems, and/or use imagery to fantasize.

Several characteristics of the consumption experience may also motivate imagery processing. Although the relationship of preconsumption imagery to hedonic consumption activities has not been explored, some research has suggested substantial levels of imagery when engaged in hedonic consumption activities (Hilgard 1978). Playful consumption has been proposed as a domain where imagery appears to play a particularly important value-enhancing role (Holbrook, Chestnut, Oliva, and Greenleaf 1984). In addition, stimuli high on perceived novelty may stimulate imaging of applications and outcomes (Oliver, Robertson and Mitchell 1989). Finally, large expenditures for events of limited duration (such as weddings, proms, and special vacations) may invite preconsumption imagery as a way of enhancing their valuation beyond the typically conceived duration of the event (MacInnis and Price 1987).

EXPLORATORY STUDY

Research was conducted to investigate whether imagery processing and consumer experience interact to affect consumer expectations and satisfaction in a hedonic consumption context, and to explore some individual and situational antecedents of naturally occurring imagery processing. One hundred ninety three undergraduate

n= 193

students from a large western university responded to two questionnaires about spring break. The sample was comprised almost equally of men (51%) and women (49%), with the majority (67%) between the ages of 21 and 24. Twenty three percent were between 18 and 20, and about 10% were over 24. Most of the respondents spent less than \$300 on spring break (78%), spent spring break with friends (66%), and considered it to last 6 days or more (62%).

Prior to spring break students were asked to indicate what activities they expected to engage in over spring break, and what they hoped spring break would offer (i.e., rest and relaxation, adventure, etc.). After spring break, these same students were again asked to recall what activities they planned to engage in, and also asked what activities they did engage in. A content analysis of the planned activities between the first and second questionnaires revealed very high consistency in reports of expected activities before and after spring break.

The results reported in this study focus on an analysis of the second questionnaire. This survey asked about the use of imagery prior to spring break, individual differences in imagery processing, experience with and expectations regarding the planned event, and spring break outcomes (i.e. whether it turned out as expected and satisfaction). Several descriptors of spring break were also included (i.e., amount of money spent, number of days away, activities engaged in). Finally, basic demographic information was collected.

Measures

Use of Imagery. The primary measure of imagery processing was a four item scale ($\alpha=.84$, mean= 4.54) to assess the extent to which consumers generated imagery about spring break (unless otherwise indicated, means are reported on a 1 to 7 scale). For example, "When I thought about spring break, my thoughts included the sights, smells, and/or sounds of the activities I would be engaged in." A five item scale ($\alpha=.85$, mean = 4.20) was designed to assess the extent to which they imagined many different scenarios. For

example, "In my mind, I played out many different scenarios of what I was going to do." A single item measure of time spent imagining (i.e., "I spent considerable time imagining what I would do," mean= 4.2) was also included. Standard deviations on these measures ranged from 1.27 to 1.65, indicating substantial variation between consumers in their use of imagery prior to spring break. Relationships between these measures of imagery use are provided in Table 1. As indicated, consumers who generate imagery also seem to spend a great deal of time imagining, and seem to imagine many different scenarios. Based on average levels of the primary measure of imagery processing, respondents were divided into a Low Imagery (n=99, mean=3.5) and High Imagery (n=94, mean=5.6) group.

Experience. A four item scale ($\alpha=.78$, mean = 4.4) was used to assess whether consumers were familiar with the activities and events they would be engaged in over their spring break. For example, "My spring break plans included activities I've done many times before." The standard deviation was 1.6 suggesting considerable variability. Based on the average experience level, respondents were divided into a Low Experience (n=91, mean=2.9) and High Experience group (n=102, mean= 5.7). The low and high experience groups did not differ in imagery processing (4.6, 4.5), the extent to which they imagined multiple scenarios (3.8, 3.6) or time spent imagining (4.3, 4.1).

Consumer Expectations. The item "My images of what I would do included only positive experiences," (mean= 4.20) was included to assess whether consumers considered only positive events when imagining their spring break. Confidence in expectations was assessed by a single item "How confident were you that it would happen just as expected?" (mean= 5.4). The relationship between these two items was positive (.12, $p < .05$), but small.

Spring Break Outcomes. Single items measured the extent to which spring break happened as expected (mean= 5.0), and the extent to which it included many new experiences (mean= 4.0). In

TABLE 2
Means for Expectations, Expectation-Confirmation and Satisfaction by Experience and Imagery Processing

Dependent Measure	High Imagery		Low Imagery	
	High Experience	Low Experience	High Experience	Low Experience
Positivity Bias	4.37	4.76	3.52	4.20
Confidence in Expectations	5.54	5.67	5.72	4.85
Expectation Confirmation	5.04	5.56	5.21	4.32
Satisfaction	4.47	5.63	4.07	4.53
n	52	42	50	49

addition, a seven item scale ($\alpha = .88$, mean = 4.6) asked how satisfied consumers were with their spring break. For example, "Compared to other spring breaks, my spring break was not that good." (reverse scored). Standard deviations on these measures ranged from 1.39 to 1.78. The correlations between satisfaction with spring break and both the inclusion of many new experiences (.39) and it turning out as expected (.35) were positive and significant. The relationship between spring break turning out as expected and including new experiences was non-significant (.06).

Individual Differences. The three scales developed to measure individual differences in imagery processing were based on modification of the Imaginal Process Inventory (Singer and Antrobus 1963, 1972; Huba, Singer, Aneshensel and Antrobus 1982). One was a seven item scale ($\alpha = .83$, mean = 4.7) designed to assess consumers' tendency to engage in vivid imagery. For example, "Compared to most people I believe my dreams and fantasies are more vivid." A second individual difference measure was a seven item scale ($\alpha = .78$, mean = 5.4) assessing consumers' use of imagery to plan future events/activities. For example, "I find my daydreams are useful for planning things in the near future." Finally, a five item scale ($\alpha = .56$, mean = 4.2) assessed consumers' tendency to engage in fantasy imagery. For example, "Lots of times, even in the middle of my work, I'll find myself fantasizing about something." Standard deviations for these three individual difference measures ranged from .89 to 1.1, and correlations between the three measures ranged from .31 to .57.

Results

The major purpose of this study was to test whether experience and imagery processing interact to affect a positivity bias in imagined outcomes, confidence in expectations, expectation-confirmation and satisfaction. A series of ANOVAs were performed to test the central hypothesis that experience and imagery processing interact. The results are given in Table 2. As predicted, imagery processing and experience affect the positivity bias of expected outcomes. Specifically, experience leads to less positivity bias ($F = 5.3$, $p < .05$) and imagery processing ($F = 9.0$, $p < .005$) to more. However, contrary to predictions, the interaction effect is not significant.

Confidence that spring vacation would turn out as expected was affected by experience ($F = 3.8$, $p < .05$), and the interaction of experience and imagery processing ($F = 6.6$, $p < .01$), but not imagery processing alone. Specifically, consumers with low experience who generated very little imagery about the experience were significantly less confident that things would turn out as expected, and they were right. That is, Table 2 also reports a significant interaction between experience and imagery processing on whether the vacation turned out as expected ($F = 7.6$, $p < .01$). Surprisingly, experience did not have a significant main effect on confirmed expectations, but imagery processing had a marginally significant main effect ($F = 3.9$, $p < .05$). (The belief that imagining can make it so may have some truth to it.) Finally, as indicated in Table 2 there is a significant main effect of imagery processing ($F = 15.2$, $p < .001$) and experience ($F = 18.4$, $p < .001$) on satisfaction. In addition, the interaction of imagery and experience is marginally significant ($F = 3.58$, $p < .06$). However, contrary to expectations, imagery processing had a positive

TABLE 3
Predictors of Imagery Processing

effect on satisfaction and experience had a negative effect. Thus, of all the groups, low experience individuals who engaged in imagery processing were most satisfied with their spring vacation.

One possible explanation for this finding is that, at least in this context, new experiences contribute to satisfaction and low experience individuals engaged in many more new experiences than high experience individuals. Results are consistent with this explanation. New experiences contribute to satisfaction ($F=6.6$, $p<.01$), but new experiences do not interact with experience or imagery in affecting satisfaction. However, low experience individuals reported many more new experiences (5.0) than high experience individuals (3.4) ($t= 6.3$, $d.f.= 191$).

An interesting implication of the pattern of results on the relationship between imagery processing and satisfaction is that imagery enhances satisfaction whether the break conforms to expectations or not. An analysis of variance using imagery processing and outcomes as expected or not as the independent variables, and satisfaction as the dependent variable, indicated only main effects for imagery processing ($F=12.9$, $p < .001$). The pattern of means revealed that consumers who engaged in imagery were more satisfied with the outcomes of their spring break (mean = 4.99) than consumers who did not engage in imagery (mean = 4.30), whether their break conformed to expectations or not.

A related purpose of this research was to explore the antecedents of imagery processing. Regression analyses were conducted to identify the predictors of imagery processing. The independent variables in the model included individual difference measures (use of anticipatory imagery, fantasy

imagery, vividness of imagery, gender and age), and situational variables related to spring break (prior experience with planned trip, money spent, number of days away). The results are reported in Table 3. Surprisingly, individual differences in imagery had virtually no impact on imagery processing. The novelty of the stimuli, as captured by prior experience with the planned break, also had no impact on imagery processing. However, the amount of investment (both in terms of money and time) was a significant predictor of preconsumption imagery.

DISCUSSION

We deliberately chose a hedonic consumption activity to explore naturally occurring preconsumption imagery. The present research suggests that consumers engage in imagery processing in anticipation of such activities. Moreover, individual difference variables seem to play a relatively small role in predicting imagery. Situational variables such as the duration of the vacation and money spent seem to be better predictors of imagery. The importance of these variables is consistent with the expectation that preconsumption imagery has value-enhancing properties. Such value-enhancement may be more important in the case of significant investments.

Results on the interaction of imagery and experience in affecting expectations, expectation-disconfirmation and satisfaction were interesting, but surprising. Although, as expected, imagery processing leads to a positivity bias, and leads to greater confidence that events will unfold as expected, it does not lead to greater expectancy disconfirmation, and leads to higher (rather than lower) levels of satisfaction. What's especially

provocative is that imagery has a direct effect on satisfaction, whether or not the event unfolds as imagined. This finding supports the argument that a satisfaction model based on extent of disconfirmation of a pre-experience comparison standard is too limited to capture a diversity of consumption experiences (Tse and Wilton 1988). Specifically, when learning, adventure, and novelty motives are important, a consumer may be satisfied regardless of the levels of pre-experience comparison standard and disconfirmation (Cohen and Houston 1972, Price and Fisher 1989).

Especially for low experience individuals, imagery leads to higher levels of expectancy confirmation and satisfaction. That is, despite a positivity bias, imagery appears to help low experience individuals predict what to expect. Low experience individuals were able to generate just as many scenarios as high experience individuals, and use of imagery, and time spent imagining did not differ between the two groups. Thus, contrary to predictions, imagery processing seems to be a positive decision tool for low experience consumers, helping them to play out various outcomes.

In general, experience had an unexpected relationship to satisfaction that is perhaps partially a function of the context. As expected, experience lead to less positivity bias. In addition, experience increased confidence that spring vacation would turn out as expected, although it did not lead to more expectancy confirmation. Moreover, experience contributed to lower levels of satisfaction. Perhaps because spring break is viewed as an adventure, and new experiences are highly prized, the expected relationship between experience and satisfaction was not supported.

The reported study is obviously exploratory and is perhaps most useful when viewed as an invitation to engage in further research. The study explored only one imagery domain-- one that, students would be quick to offer, invites the imagination. Although the design incorporated pre-spring break and post-spring break measures, the results of the reported study relied on retrospective reporting. Finally, measures were developed for this study. Inadequate measurement of individual differences may partially account for their poor predictive ability.

Generalization of the Market Maven's Information Provision Tendency Across Product Categories

Mark E. Slama, Utah State University
Terrell G. Williams, California State University, Northridge

ABSTRACT

Market mavens are individuals who are thought to possess and provide information about the marketplace to other consumers. Previous research has demonstrated that market mavens provide information to other consumers on nondurables. The current study shows that market mavens provide information on a broad variety of goods, services and marketplace characteristics. The potential use of market mavens as promotional targets is explored and research implications are considered.

Market maven is a term introduced to the marketing literature by Feick and Price in 1987. They state that market mavens are, "individuals who have information about many kinds of products, places to shop, and other facets of markets, and initiate discussions with consumers and respond to requests from consumers for market information." The market maven concept describes a person who has an active interest in the marketplace. The concept is consistent with previous research which has identified certain types of consumers who seem to be more generally interested in the market than average consumers.

For example, Bellenger and Krogaonker (1978) describe "recreational shoppers" as enjoying shopping and engaging in active shopping as a means of obtaining market information. Thorelli and Engledow (1980) identify "information seekers" as making up ten to twenty percent of the population and being opinion leaders, innovators and market vigilantes. Raju (1980) has shown that consumers who have high optimal stimulation levels engage in more exploratory behaviors in the marketplace than other consumers including: information seeking, interpersonal communication and innovation. In addition, Slama and Tashchian (1983; 1985) have demonstrated that certain consumers are more generally "involved" in the marketplace than others. They distinguish this type of marketplace involvement from product involvement and show that it leads to greater shopping effort. Finally, Lesser and Hughes (1986) have identified "active" information seeking consumers as being one of the most commonly appearing groups in psychographic market segmentation studies.

Thus, there is ample support for the notion of active, information seeking consumers. One type of these is the market maven. In fact, being a "smart shopper" seems to be a role played by the market maven along with the information provision role. Support for this comes from findings that market mavens are more likely than other consumers to: use shopping lists, plan grocery shopping with

advertisements, budget for groceries, and use coupons (Price, Feick and Guskey-Federouch 1988).

Some of the other characteristics of market mavens which have been documented relate to possession and provision of market place information, search activities and enjoyment of shopping. Market mavens have been shown to be more aware of new products and brands in the food and drug product categories than other consumers. They are also active providers of information on these product categories to other consumers. With regard to search activities mavens place more importance on all advertising media than other consumers and can be effectively reached through direct mail advertising and local direct mail classified papers. The tendency to be a market maven is also significantly correlated with the enjoyment of shopping (Feick and Price 1987; Higie, Feick and Price 1987).

What makes market mavens particularly interesting to marketers is their impact on other consumers through innovation and interpersonal communication. In this respect market mavens are similar to both early purchasers of products and opinion leaders, however, their influence is more general. Marketers have traditionally been interested in opinion leaders as information providers who seek information from the media and provide it to the public. An opinion leader's interest in a specific product category appears to be a major motivation for their opinion leadership (Bloch 1986; Jacoby and Hoyer 1981) and therefore opinion leadership is thought to be product specific as opposed to the market maven's information provision tendency which is thought to span many product categories. Early purchasers also provide information to the public by using and talking about new products, however, their expertise arises from early purchase of a specific product and their influence pertains primarily to that product as opposed to the more general influence of market mavens. In validating their market maven scale, Feick and Price (1987) were able to show that the tendency to be a maven, the tendency to be an opinion leader and the tendency to be an early purchaser are three related but distinct concepts.

The general influence of market mavens makes them particularly attractive promotional targets for retailers who carry many products and wish to convey information to the public about sales, low prices, product variety and other aspects of store operations in addition to information on specific products. It is unlikely that early purchasers and opinion leaders would provide much promotional leverage in delivering such a broad range of information to the public. Research has shown that market mavens are valuable in transmitting information about retailers. Mavens

talk significantly more than other consumers about the attributes of grocery stores, department stores and discount stores than do other consumers. The attributes most discussed include: special sales, usual prices, product quality and product variety (Higie, Feick and Price 1987).

The purpose of the current research is to extend on the notion that the market maven is a general provider of marketplace information by examining the market maven's tendency to provide information to other consumers for a variety of products and marketplace characteristics. Feick and Price (1987) have shown that mavens provide more information than average consumers on nondurable products (food and drug items) but it is not known how much mavens talk about an array of products including durables. In the Feick and Price (1987) study opinion leadership (operationalized as product knowledge and influence over others) was correlated with the market maven scores for nondurable goods, but, not for durable goods. This suggests that the information provision of the maven may not be even across product categories. The present study examines the market maven's information provision for: Durables, nondurables, services, and market characteristics in order to extend on previous research findings and determine the extent to which the market maven is a "general" marketplace information provider.

METHODOLOGY

In order to determine how information provision varies with a person's tendency to be a market maven a survey was conducted. The respondents in this survey were married couples chosen randomly from the telephone directory of a western city. The interviewing procedure involved the personal delivery and collection of self-administered questionnaires. This technique is a variation of the "drop off" method described by Sudman, Greeley, and Pinto (1965). The difference between this procedure and the drop-off method is that the interviewer waits for the respondent to complete the questionnaire rather than returning to pick it up at a later date.

Lovelock, et al. (1976) recommend the use of lightly trained interviewers as an effective and cost-efficient method for the personal delivery of self-administered questionnaires. The interviewers used in this research were undergraduate marketing students who underwent a two-hour training session regarding the method of data collection.

The interviewers were given a list of randomly selected respondents and asked to contact each household marked on the list. If the selected households could not or would not participate, interviewers were instructed to contact the next person on the list until a quota was obtained. Only households where both the husband and wife agreed to participate were included in the survey. If husband and wife were not both home during the initial call, the interviewer would make an appointment to return and have the couple complete the questionnaire during the return visit. A sample

of 306 couples was obtained from the sampling process. A demographic profile of the sample is presented in Table 1. The questionnaire for the survey included the market maven scale, measures of information provision and other psychographic and demographic questions.

The Market Maven Scale

The market maven scale measures a person's tendency to be a general provider of many types of market information to others on an informal basis. It is a six item, seven point, Likert Scale developed by Feick and Price (1987). In validating the scale they obtained a Cronbach's alpha of .82. They also demonstrated the nomological validity of the scale by obtaining significant correlations between its scores and measures of opinion leadership, innovativeness, possession of market information, provision of market information, and information seeking.

Measures of Information Provision

In order to determine how often respondents provide market related information to other people, five point scales were used. The stem of the scales said, "Please rate the indicated items on how often you tell others about them." The responses were rated from one (never) to five (very often). Intermediate response categories were almost never, not very often, and somewhat often. There were twenty one items including: prices, sales, product quality, store personnel, store location, new products, food products and items relating to fourteen product categories (Table 2). This method of assessing information provision is similar to that used by Feick and Price (1987). It differs from the market maven scale in that the questions address specific products, services and market characteristics while the maven scale items do not.

Design

Following the practice of Feick and Price (1987) respondents were divided into three categories based on their scores on the market maven scale. The top scoring one third of respondents were designated as market mavens or the high scoring group, the next two thirds were the medium and low scoring groups. MANOVA was used to determine whether the information provision scores differed between the low, medium and high scoring groups. Univariate F-tests were also examined. Separate analyses were made for men and women because the market maven tendency is more common among women and may have a different impact depending on gender.

RESULTS

For both men and women the overall MANOVA results indicated a statistically significant difference between the information provision score centroids for low, medium and high scorers on the market maven scale. In almost all cases the respondents who scored higher on the market maven scale also scored higher on the information

ⁿ not significant at alpha = .01 .pa

provision variables. The only exception was for medical services in the men's sample. For medical services the medium scorers on the market maven scale reported the most information provision, but the differences between groups were insignificant.

In the women's sample the most talked about aspects of the market place for market mavens were (in order from most to least talked about): sales, restaurants, product quality, clothing, prices, new products, and food products. For each of these items the mean score was above 3.5 meaning that the market mavens tended more toward talking about these "somewhat often" (coded 4) than "not very often" (coded 3).

In the men's sample the most talked about items for market mavens were (in order): product quality, restaurants, auto repairs, automobiles, prices and sales. These items all had mean scores above 3.5. The next three items were stereo & TV, new products, and food products. The new products and food products scores were relatively high on information provision in both the men's and women's samples.

The notion that information provision for durable goods and nondurable goods would be differentially related to the market maven tendency is not implied by the results. In Table 2 significant differences are reported between the male market maven groups for food products, automobiles, personal grooming aids and furniture.

These products represent a mix of durables and nondurables. In fact, in the men's sample the

only insignificant differences are for medical services. This may be due to a lack of interest, infrequency of use or knowledge. In the women's sample (Table 3) the market maven tendency is also associated with significant differences in information provision for a mix of durable and nondurable goods. For example, significant differences occur for food products, clothing, furniture and personal grooming aids.

DISCUSSION

Some of the findings of this study are remarkably consistent with the findings of previous maven studies. Feick and Price (1987) found that mavens provide greater amounts of information concerning food products to consumers other than nonmavens. Mavens were also found to possess greater amounts of information about new products. The current findings that mavens provide more information than nonmavens about new products and food products coincide with the previous findings. Higie, Feick and Price (1987) found that mavens provide more information on store prices, sales and product quality than nonmavens. These findings also emerge in the current study. Thus, the high absolute amount of information provision and the relatively large differences between mavens and nonmavens for information provision on prices, sales, product quality, food products and new products are reassuringly similar to the findings of previous studies.

The current study extends on the findings of previous studies, however, by showing the generalizability of the information provision tendency of the market maven across product classes. In the men's sample twenty out of twenty one of the information provision variables were significantly different across the high, medium and low scoring market maven groups. For the women seventeen out of twenty one were significantly different. Clearly the market maven provides information on a variety of product offerings to other consumers.

Previous research by Feick and Price (1987) left some doubt as to whether market mavens would provide information for durable goods as well as nondurable goods to other consumers. The current findings show that mavens provide information for durables, nondurables, and services.

The few insignificant differences in information provision among the market maven groups occur for products which are not often discussed including medical services for men and banks, real estate, and investments for women. The one exception to this is restaurants which are discussed a substantial amount by all of the groups of women. Given the general nature of the market maven's influence, future research should consider the interaction among market mavens, early purchasers and opinion leaders as suggested by Feick and Price (1987). It would seem that, because of their general knowledge, mavens would be more regularly sought out by information seekers than either early purchasers or opinion leaders. Perhaps for inexpensive purchases only a maven would be consulted. For more expensive purchases the maven may play an information gatekeeping role, referring others to the appropriate opinion leaders and early purchasers with more specific information.

Finally, little is known about whether market mavens provide negative as well as positive information about the marketplace. Future research should also examine the impact of market mavens on negative word of mouth advertising and complaining behavior.

An Assessment of the Moderating Effects of Market Mavenism and Value Consciousness On Price-Quality Perception Accuracy

Donald R. Lichtenstein, University of Colorado
Scot Burton, Louisiana State University

Conceptual definitions of market mavenism and value consciousness found in the consumer behavior literature suggest that consumers who possess higher levels of these two traits should be more informed regarding marketplace prices and quality than consumers who possess lower levels of these two traits. On this premise, hypotheses regarding the relationship between market mavenism, value consciousness, and price-quality perception accuracy are offered and tested. Contrary to the hypotheses, however, support was not found for the contention that consumers who possess higher levels of market mavenism (H1) or higher levels of value consciousness (H2) perceive price-quality relationships with more accuracy than consumers who possess lower levels of these two traits

A topic that has received great attention in the consumer behavior literature is the relationship between price and consumer quality perceptions. While many studies have found evidence of a positive price-perceived quality relationship (e.g., Lichtenstein, Bloch, and Black 1988; Lichtenstein and Burton 1989; Peterson and Wilson 1985), research evidence suggests that this relationship is person and product-dependent (i.e., it varies across individuals and products being judged (e.g., Lichtenstein and Burton 1989; Monroe and Krishnan 1985; Peterson and Wilson 1985; Zeithaml 1987)).

Another stream of research dealing with the topic of price and quality concerns the relationship between price and "objective" quality (i.e., quality as it "actually" exists in the marketplace). These studies have relied almost exclusively on quality ratings from *Consumer Reports* magazine for their measures of objective quality. Findings from this research suggest that the overall relationship between price and objective quality is low, but that it varies from strongly positive to strongly negative across product categories (cf. Gerstner 1985; Morris and Bronson 1969; Oxenfeldt 1950; Riesz 1978, 1979).

As part of a large data collection designed to integrate the price-perceived quality and price-objective quality research streams (i.e., assess how well consumers' price-quality perceptions correlate to price-objective quality relationships) that is reported in Lichtenstein and Burton (1989), it was of interest to ascertain if price-quality perception accuracy was moderated by the degree of market mavenism (Feick and Price 1987) and value consciousness (Lichtenstein, Netemeyer, and Burton 1989; Zeithaml 1988). Although research evidence suggests that the relationship between price and perceived quality varies across individuals (e.g., Peterson and Wilson 1985), little research has assessed if the *accuracy* of these perceptions also

varies across individuals (i.e., do the price-quality perceptions of some individuals correspond to price-objective quality relationships more strongly than the perceptions of others?) Based on conceptualizations of market mavenism (Feick and Price 1988) and value consciousness (Lichtenstein et al. 1989; Zeithaml 1988), it seems plausible to suggest that consumers who are market mavens or value conscious perceive price-objective quality relationships with greater accuracy than those consumers who are not market mavens or value conscious. Peterson and Wilson (1985) suggest that if individuals who differ on variables related to price-perceived quality relationships can be identified and segmented from one another, perhaps more of the variance in the relationship between price-perceived quality and price-objective quality can be explained. The present study represents an attempt to accomplish this goal.

Market Mavenism

Market mavens have been defined as "individuals who have information about many kinds of products, places to shop, and other facets of markets, and initiate discussions with consumers and respond to requests from consumers for market information" (Feick and Price 1987, p. 85). Feick and Price state that characteristics of market mavens include possession of a wider variety of marketplace information, more attentiveness to the marketplace in general, more engagement in generalized, as opposed to product-specific search, and a higher propensity to use a variety of sources to find out about new products in the marketplace, e.g., readership of *Consumer Reports* magazine. Because price and product quality are two of the most salient pieces of marketplace information, it seems plausible to suggest that, relative to those of lower market mavenism, *across product categories* those of higher market mavenism should possess more, and more accurate, price and quality information, and hence, be in a position to more accurately assess the relationship between the two.¹

¹Hypotheses are tested by assessing the degree to which respondents' rankings (perceptions) of the strength of individual product category price-quality relationships (across 18 product categories) correlate to the rankings of the strength of price-quality relationships across the 18 individual product categories. It is *explicitly* recognized that because market mavenism manifests itself in higher levels of *generalized* marketplace knowledge, the market maven may not hold more accurate price-quality perceptions *within* a particular product category. However, across product categories, those of high market

H1: The correlation between price-perceived quality and price-objective quality across product categories is higher for those of higher market mavenism than for those of lower market mavenism.

Value Consciousness

Definitions of value appear to focus on two factors: price and quality. For example, Monroe and Petrosius (1981) define value as the ratio of quality to price. Zeithaml (1988, p.14) defines perceived value as "the consumer's overall assessment of the utility of a product based on what is received and what is given" in a purchase transaction. If one assumes that price and product quality are the most salient "give and get" components in a purchase transaction, then Zeithaml's definition of value is consistent with that of Monroe and Petrosius in their focus on price and quality. Because of this focus on price and quality for the value conscious consumer, high value conscious consumers should be in a better position to perceive price-objective quality relationships more accurately than low value conscious consumers.

H2: The correlation between price-perceived quality and price-objective quality across product categories is higher for those of higher value consciousness than for those of lower value consciousness.

METHOD

Product Selection

One limitation of previous price-perceived quality studies is that only a limited range of products has been investigated and justification for products chosen is usually not provided (Monroe and Krishnan 1985). The present study was conducted using eighteen product categories. The product categories were chosen based on the following criteria: (1) an equal split of durable and nondurable products; (2) for both durable and nondurable product categories, three products have a positive price-objective quality correlation shown to be stable over time, three have a zero price-objective quality relationship shown to be stable over time, and three have a negative price-objective quality relationship shown to be stable over time²; and (3) substantial variation in the price range across the product categories (cf. Monroe and Krishnan 1985).

Based on these criteria, the eighteen product categories shown in the Table (column B) were selected. As indicated in column C, nine of the

product categories were durables and nine were nondurables. As can be seen in column D (ignore for the moment the values in the parentheses in column D), for both the durables and nondurables, three of the product categories had stable positive price-objective quality relationships, three had stable (essentially) zero price-objective quality relationships, and three had stable negative price-objective quality relationships.

Description of Sample and Measures Used

Respondents in the study were 152 shoppers at a supermarket in a medium-sized midwestern SMSA. Specifically, two research assistants were positioned at different exits of a large supermarket. As shoppers exited the store, they were asked to participate in a survey by taking home a questionnaire to complete and return in a postage-paid envelope. Of the 700 surveys distributed, 152 were returned (response rate = 21.7%). Sixty-four percent of the respondents were female, the median age category was 35-44, the median education category was some college, the median household size was two people, and the median income category was \$25,000-\$34,999.

For each of the eighteen product categories, respondents' price-quality perceptions were assessed by their level of agreement with the statement "The higher the price of the product, the higher the product quality" (7=strongly agree, 1=strongly disagree) (Lichtenstein and Burton 1989; Peterson and Wilson 1985). Market mavenism was operationalized using the six-item scale developed by Feick and Price (1987). Example items include "People ask me for information about products, places to shop, or sales," and "My friends think of me as a good source of information when it comes to new products or sales" (7=strongly agree, 1=strongly disagree) (scale mean=23.48, standard deviation=8.84, range=6-39, alpha=.87). Value consciousness was operationalized using the seven-item scale of Lichtenstein et al. (1989). For example, two of the items were "When purchasing a product, I always try to maximize the quality I get for the money I spend," and "I always check prices at the grocery store to be sure I get the best value for the money I spend" (7=strongly agree, 1=strongly disagree) (scale mean=41.96, standard deviation=6.43, range=19-49, alpha=.77). Finally, a single seven-place scale item was used to assess perceptions of the usefulness of information provided by *Consumer Reports* magazine ("The information provided in *Consumer Reports* magazine is useful" (7=strongly agree, 1=strongly disagree) (mean=5.5, standard deviation=1.57)). Although no hypothesis was offered concerning this item, because *Consumer Reports* magazine is considered to be among the most reliable sources for product quality and price information (Gerstner 1985), and because the measures of price and quality employed in this study were based on *Consumer Reports*, it appears plausible to suggest that those who consider this information more useful should have more accurate price-quality perceptions.

mavenism are expected to hold more accurate price-quality perceptions than those of low market mavenism.

²In order to find product categories which satisfied these criteria, correlations between price and quality ratings for over 100 product categories rated at least twice by *Consumer Reports* magazine within the last 10 years were computed.

RESULTS

Results comparing price-perceived quality relationships with price-objective quality relationships are shown in the Table. In columns A and B of the Table, the price-perceived quality rankings from highest (10-Speed Bicycle) to lowest (Club Soda) are presented. The product type, either durable or nondurable, is shown in column C. The Spearman rank-order correlation between price and objective quality (computed from *Consumer Reports* magazine data) for each of the product categories is shown in column D³. For purposes of hypothesis testing, these price-objective quality correlation values were recoded to a 3-2-1 rank-order format. Positive price-objective quality correlations were recoded to a 3, near zero correlations were recoded to a 2, and negative correlations were recoded to a 1. These recoded values are reported in the parentheses in column D. The rationale for this recoding is that many of the product categories have very similar price-objective quality correlations, and small differences in these correlations would be inappropriately accentuated given the use of rank-order correlations. Hence, the more conservative approach employing the recoded values was used. The mean perceived price-quality scores across the total sample of respondents for the eighteen product categories are reported in column E. (These mean scores in column E are the basis for the order of rankings in columns A and B.) Mean price-perceived quality ratings based on median splits of the market mavenism, value consciousness, and *Consumer Reports* perceived usefulness scales are reported in columns F, G, and H, respectively. Spearman rank-order correlations between price-objective quality (using the recoded values in column D) and price-perceived quality rankings (columns E through H) are reported in rows A, B, and C in the bottom portion of Table 1 for the total sample of respondents (under column E) and for the subsamples of respondents based on the median splits (columns F through H).

The hypotheses are tested in two different ways. First, the correlations at the bottom of the Table 1 are assessed for their consistency with the hypotheses. (Higher positive correlations mean a stronger relationship between price-objective quality rankings and price-perceived quality rankings, and, hence, more accurate price-quality perceptions.) Next, results of t-tests between mean price-quality perceptions of the subsamples produced by the median splits are examined for each individual product category to assess their consistency with the hypothesized relationships.

For the total sample of respondents, the Spearman correlations at the bottom of the Table (under column E) suggests that respondents did perceive price-quality relations with a modest degree of accuracy.⁴ Further, nondurables were perceived with a slightly higher degree of accuracy than durables.

The first hypothesis postulates that the correlation between price-perceived quality rankings and price-objective quality rankings across product categories is higher for those of higher market mavenism than for those of lower market mavenism. The correlations at the bottom of Table 1 (under row F) do not provide support for H1. To further assess H1, the direction and significance of mean differences was examined. Support for H1 is provided when those of high market mavenism have higher mean price-quality perceptions than those of low market mavenism for product categories which have a positive price-objective quality relationship, and lower mean price-quality perceptions for product categories that do not have a positive price objective-quality relationship. By looking at the consistency of direction of means with that hypothesized for the market mavenism scale (see superscript e), only 6 of the 18 mean differences were in the hypothesized direction. Upon further inspection of the direction of mean differences, those of high market mavenism perceived stronger price-quality relationships than those of low mavenism across all eighteen product categories. It appears that the only reason that 6 were in the hypothesized direction was because there were six product categories that had positive price-objective quality relationships. Contrary to expectations, these results indicate that the degree of mavenism is totally unrelated to price-quality perception accuracy.

By looking at the correlations at the bottom of the Table relevant to value consciousness (under column G), it also appears that these data offer no

³These objective price-quality correlations reported in the Table are actually average correlations based on two different years of ratings by *Consumer Reports*. The individual correlations which comprise these averages, and the years from which the correlations were calculated, are reported in Lichtenstein and Burton (1989).

⁴The correlations in Row A at the bottom of the Table represent the rank-order correlations between the mean price-quality perceptions and the price-objective quality relationships (using recoded values), and hence, are based on a sample size of 18. Consequently, the power of the statistical tests are very low, and therefore statistical significance is not used here as a criterion for testing hypotheses. Similar procedures have been followed in price-objective quality research where the number of brands tested in product categories usually ranges from about 5 to 20, and these small sample sizes normally lead to nonsignificant results. Consequently, even though significance levels associated with the correlation coefficients are sometimes provided in these studies, as a rule, researchers have not relied upon them in evaluating results (cf. Gerstner 1985; Geistfeld 1977; Morris and Bronson 1969; Oxenfeldt 1950; Riesz 1979; Sproles 1977).

TABLE

THE RELATIONSHIP BETWEEN PERCEIVED AND OBJECTIVE PRICE-QUALITY RELATIONSHIPS

Price-Perceived-Quality Rank	Product	Product Type	Price-Objective Quality Relationship	Price-Perceived Quality Relationship ^a (Total Sample)	Market Mavenism		Value Consciousness		Consumer Reports Usefulness	
					High	Low	High	Low	High	Low
A	B	C	D	E	F	G	H			
1	10-Speed Bicycle	D	.84(3)	5.36	5.44	5.31 ^e	5.30	5.43	5.44	5.23 ^e

Spearman Rank-Order Correlations Between Price-Objective Quality (Column D) and Price-Perceived Quality (Columns E-H)

(A) For all product categories (n=18)	.24	.28	.29	.34 ^d	.25	.35 ^d	.24
(B) For durable products only (n=9)	.32	.33	.29	.33	.35	.46 ^d	.16
(C) For nondurable products only (n=9)	.37	.42	.42	.45	.47 ^d	.61 ^c	.26

^a For all price-perceived quality means (column E-H), larger numbers reflect stronger price-perceived quality relationships.
^b D=durable, ND=nondurable.
^c $p < .05$.
^d $p < .10$.
^e Means in hypothesized direction (e.g., for the vanilla ice cream, which has a positive price-objective quality relationship, those of high value consciousness perceived a stronger price-quality relationship than those of low value consciousness)

support for H2. High value conscious consumers did perceive price-quality relationships across all 18 product categories slightly better than those of low value consciousness (.34 as opposed to .25), but the difference is too small to be taken as support for H2. Further, only 5 of the 18 mean differences are in the hypothesized direction (2 of these 5 differences were significant, one at the 0.05 level and one at the 0.10 level).⁵

Although no hypothesis was offered for the effect of the perceived usefulness of information provided in *Consumer Reports* magazine on price-quality perception accuracy, similar analyses to those reported above were conducted for this single-item scale (see bottom of Table under column H). From the Spearman correlations, it appears that those who perceive *Consumer Reports* magazine as providing more useful information do perceive price-quality relationships with greater accuracy than those who perceive the information as less useful. When the correlations are segmented by product type (durable vs. nondurable), support for this contention appears stronger. However, inspection of the 18 mean differences reveals that only 10 are in the hypothesized direction, a finding which can be explained by chance alone. Further, even though the correlations may suggest that those who perceive *Consumer Reports* magazine as providing more useful information do perceive price-quality relationships with more accuracy than those who perceive the information as less useful, this finding must be strongly qualified. The price-quality objective correlations were based on *Consumer Reports* data, and, hence, consumers who perceived the information as more useful may have read the information, and therefore been presensitized to the study stimuli. Had the price-objective quality ratings been taken from some other source, it is unknown how those who perceive *Consumer Reports* data as more useful would have fared vis-a-vis those who perceived it as less useful.

DISCUSSION AND LIMITATIONS

The purpose of this paper was to assess if market mavens and value conscious consumers hold more accurate perceptions of the relationship between price and quality than other consumers. Hypotheses postulating higher degrees of price-quality perception accuracy for higher levels of these two traits were not supported by the data.

To our knowledge, this is only the second study which investigates possible moderating relationships of person-related factors on price-quality perception accuracy. In the first such study,

Lichtenstein and Burton (1989) investigated whether price-quality perception accuracy varied as a function of if the respondent held a "price-perceived quality schema" or a "no price-perceived quality schema" or not, the degree of product involvement, product experience, perceived product knowledge, and a range of socioeconomic and demographic factors. Although measures of some of these variables were of unknown validity (e.g., the involvement, product experience, and perceived knowledge measures were single-item scales), none of the person-related factors showed any moderating impact on price-quality perception accuracy. Findings from the present study augment the findings of Lichtenstein and Burton (1989) by adding market mavenism and value consciousness to the list of person-related variables for which a moderating relationship on price-quality perception accuracy has been hypothesized and assessed, but with negative findings.

The failure to find a moderating relationship may be due to any of several factors. First, market mavens and value conscious consumers simply may not hold more accurate price and/or quality perceptions. While market mavens may be aware of new products and brands earlier, more apt to provide marketplace information to others, more apt to use diverse sources for providing information, more apt to enjoy shopping, more apt to pay attention to advertising, more apt to use (Feick and Price 1987) and swap coupons (Price, Feick, and Guskey-Federouch 1988), these characteristics simply may not translate into more accurate perceptions of marketplace prices and quality. Another possibility is that market mavens and value conscious consumers do hold more accurate price and quality perceptions, but they do not (or cannot) perform the cognitive algebra required to estimate product category price-quality relationships. In any event, results of this study suggests that the characterization of Price et al. (1988, p.354) of market mavens as "smart shoppers" may deserve some qualification.

Particularly interesting was the finding that market mavens perceived stronger price-quality relationships across all 18 product categories than did non-mavens. Perhaps market mavens have a higher degree of trust in the marketplace and believe in the old adage "you get what you pay for." Whatever the reason, given the preponderance of evidence which suggests that, overall, the relationship between price and quality in the marketplace is very weak (cf. Gerstner 1985), if the purchase behavior of mavens is consistent with their perceptions, there is a good chance that they will make many poor purchases.

Certain caveats are in order regarding interpretation of the findings of this study. First, as noted by many researchers (cf. Curry and Faulds 1986; Gerstner 1985; Lichtenstein and Burton 1989; Riesz 1978; 1979; Sproles 1986), to the degree that taste and preferences differences across consumers result in consumers valuing different attributes, the

⁵Because the hypotheses are directional, these significance levels reflect a one-tailed test of significance. Consequently, large differences in the means that are in the unhypothesized direction, which would normally have been significant for a two-tailed test, are not reported as significant for the present analysis.

validity of any quality rating as applicable across consumers can be questioned. However, Curry and Faulds (1986, p. 143-144) conclude that, based on a review of the objective quality ratings for 385 product categories over a six year period, "the empirical evidence presented in this article suggests that published quality scales have not been affected substantially by a particular agency's (e.g., *Consumers Reports*) choice of (attribute) weights . . . (consequently) although quality is a complex construct and its measurement is difficult, academic research should continue to integrate this construct into (its research)." Further, Gerstner (1985) notes that although there are limitations in using any measure of quality as "objective," *Consumer Reports* is the leading consumer magazine and its quality ratings are considered reliable by many people. Finally, others have argued for the validity of the measures of "objective quality" (cf. Oxenfeldt 1950; Riesz 1978) while still others have relied on *Consumer Reports* price-quality ratings for choosing products to serve as experimental stimuli (cf. John, Scott, and Bettman 1986; Rao and Monroe 1988).

Other limitations include the use of single-item measures for the price-quality perceptions measure and the use of a convenience sample. However, it should be noted that the convergent validity of the single-item price-perceived quality measure employed in this study with a very dissimilar measurement method was recently supported (cf. Burton and Lichtenstein 1989). The product classes employed in the present study were chosen from those rated by *Consumer Reports* magazine. Because *Consumer Reports* does not rate certain types of products (e.g., jewelry, perfume), the generalizability of these product categories to others is unknown. Finally, because of the possible bias brought about by presensitization of readers of *Consumer Reports* magazine to the specific product categories employed in this study, no formal hypothesis was offered for the moderating effect of the *Consumer Reports* variable. That is, it is recognized that because price-objective quality relationships used in this study were based on price and quality ratings from *Consumer Reports* magazine, to the degree that consumers who believe the information provided by *Consumer Reports* magazine perceive price-quality relationships more accurately, there is a potential confound. That is, they may only perceive price-quality relationships for the *particular products rated by Consumer Reports* more accurately, and not price-quality relationships in general (i.e., product categories not rated by *Consumer Reports* magazine). Hence, even though study results suggest that those who find *Consumer Reports* information useful perceive price-quality relationships more accurately, no generalizations are made from these data.

FUTURE RESEARCH

In summary and in light of the above noted limitations, a question that still remains is "are there certain groups of consumers who can assess price-quality relationships more accurately than

others?" If such a group exists then, relative to other consumers, these individuals should be in a position to make purchases which represent better values for the money. From a consumer welfare perspective, identification of such a group, and determination of factors underlying their greater price-quality perception accuracy, may provide insight into education programs which aid consumers in becoming better shoppers.

It is assumed that those with greater levels of product knowledge assess price-quality relationships more accurately because their assessments are based on this knowledge rather than on price level. The present study attempted to identify two groups of consumers who had higher levels of product knowledge, and thus, more accurate price-quality perceptions. The negative findings may be due to the fact that these two groups did not have higher levels of confidence knowledge (Cox 1962), or, alternatively, the negative findings may have been due to measurement problems. Regarding the former, knowledge is a complex construct. To know that a stereo has certain specs is one type of knowledge (predictive knowledge), to know how to use those specs to evaluate stereo quality requires a deeper type of knowledge (confidence knowledge). Future research should focus on differentiating these two types of knowledge in price-quality perception studies.

Regarding price-quality perception measurement, issues arise regarding the validity of measurement procedures employed in this and other price-quality perception studies. Like knowledge, quality is a very complex construct and means different things to different consumers (Zeithaml 1988). Future research may attempt to assess the basis for quality perceptions for the target population prior to investigating if these consumers believe price and quality are related. For example, we may find that variations in price-quality perceptions across segments of consumers are partially a function of the way consumers define quality. Another issue regarding price-quality perception measurement pertains to the issue of if product quality is best measured on an attribute level basis (cf. Lichtenstein, Bloch, and Black 1988), or on a global basis as done in the present paper. Taking this issue one step further, if product quality is best assessed on an attribute level basis, how should the measure be treated with respect to its relationship to price? Should the attributes be combined into a single quality score and then related to price, or should price-quality perceptions be calculated on an attribute by attribute basis. Research addressing these and similar issues should further our ability to assess the accuracy of consumers price-quality perceptions.

Opinion Leadership, Enduring Involvement and Characteristics of Opinion Leaders: A Moderating or Mediating Relationship?

Meera P. Venkatraman, Boston University¹

ABSTRACT

Recently it has been recognized that enduring involvement plays an important role in opinion leadership. However, the specific nature of this relationship has largely been ignored. Previous research suggests two different relationships; *moderating* and *mediating*, between enduring involvement and opinion leadership. This paper uses the Baron and Kenny framework to determine whether the relationship is a moderating or mediating one. Based on the movie viewing behaviors of 317 undergraduate students, it finds that opinion leadership mediates the relationship between enduring involvement and activities such as information sharing.

INTRODUCTION

A significant body of research has examined the relationship between the opinion leadership scale (Childers 1986; King and Summers 1970; Rogers and Cartano 1962) which essentially measures the trait of opinion leadership, and specific manifestations of this trait such as product class knowledge, influence, information sharing and innovative behavior (Feick and Price 1987; Robertson, Zielinski and Ward 1984). Studies have found that scores on the opinion leadership scale have significant positive relationships with characteristics of opinion leaders such as knowledge and information sharing (e.g. Summers 1970) and innovative behavior (e.g. Robertson and Myers 1969). These findings suggest that the trait of opinion leadership motivates activities such as information sharing, but the question is what drives opinion leadership?

There is growing evidence that enduring involvement which is the "on-going concern with a product that transcends situational influences" (Richins and Bloch 1986; p. 280) plays a critical role in opinion leadership (Bloch and Richins 1983; Feick and Price 1987; Richins and Root-Shaffer 1988). However, the nature of enduring involvement's relationship with opinion leadership and opinion leader characteristics is not clearly understood. On one hand, based on the involvement literature, it is argued that involvement is a *moderator* (Gatignon and Robertson 1985; Laurent and Kapferer 1985), or it is expected that the relationship between opinion leadership and its characteristics is stronger for the people who are high on enduring involvement as compared to

people who are not as enduringly involved (Refer Figure 1). On the other hand, it is argued that an opinion leader's enduring involvement with a product class may drive their desire for knowledge, information sharing and innovative behavior (Bloch and Richins 1983; Feick and Price 1987; Richins and Root-Shaffer 1988). In other words, enduring involvement may motivate opinion leadership which in turn results in information sharing and innovative behavior, which means that opinion leadership *mediates* the relationship between enduring involvement and opinion leader characteristics (Refer Figure 2).

Although moderating and mediating relationships have often been confused with each other, they are very different. According to Baron and Kenny (1986), a moderating relationship helps us understand when certain effects occur, and a mediating relationship helps us understand how and why such effects occur. If we find that the relationship between opinion leadership and its characteristics is moderated by enduring involvement and is stronger for people who are high on enduring involvement, then this finding has practical significance. It means that to effectively and efficiently influence the opinion leadership process, it is critical to identify people who are high on enduring involvement and concentrate marketing communication and information to this segment. This communication is likely to stimulate opinion leadership activities amongst those enduringly involved consumers who have opinion leader tendencies.

On the other hand, if the relationship between enduring involvement and opinion leadership is a mediating one - enduring involvement is a motivating force that drives opinion leadership activities - then we have an explanation that helps us understand why opinion leaders manifest the behaviors associated with opinion leadership. Although the practical implications of this finding are less immediate as compared to moderating relationships, it is important due to its contribution to theory building efforts in the area of opinion leadership. In summary, the moderating and mediating relationship between enduring involvement, opinion leadership and opinion leader characteristics have different implications and the objective of this paper is to determine which model, moderating or mediating, best fits the relationship.

LITERATURE REVIEW

Moderating versus Mediating Relationships

Moderating role of enduring involvement. A moderator is a variable that affects the form and/or strength of the relation between an independent or

¹I would like to acknowledge the helpful comments of Terry Childers and N. Venkatraman on an earlier version of this paper. I am also very grateful to Dick Harmer for his extensive help with measure development and data collection.

FIGURE 1
MODERATING MODEL

FIGURE 2
MEDIATING MODEL

predictor variable and a dependent or criterion variable (Arnold 1982; Baron and Kenny 1986). Moderation implies that the relation between two variables changes as a function of a moderator variable. Some research suggests that in the opinion leadership context the relationship between opinion leadership and its characteristics will be stronger for consumers who are high on enduring involvement as compared to those who are not, or enduring involvement moderates the relationship between opinion leadership and its characteristics (Bloch, Sherrell, and Ridgway 1986; Richins and Bloch 1986).

People who are high on enduring involvement for a product class seek information about this product class on an on-going basis (Richins and Bloch 1986), - their information seeking activities are not restricted to purchase related search, they are continuously seeking information from ads, magazines and friends. Due to this information seeking they gain considerable information and knowledge about the product and may also become aware of new products relatively earlier than others. Due to their ongoing concern with the product class, they are likely to buy these new products and therefore exhibit adoptive behavior

(Bloch, Sherrell and Ridgway 1986). As compared to the highly enduring involved consumers, consumers who are low on enduring involvement are less likely to: (1) seek information on an on-going basis; (2) engage in product related conversations; and (3) buy new products relatively earlier than others. Therefore, it follows that for consumers who are high on enduring involvement there may be a strong positive relationship between the trait of opinion leadership and its characteristics, while for those who are low on enduring involvement the relationship may be weaker. In other words, enduring involvement may moderate the relationship between opinion leadership and its characteristics.

Mediating role of opinion leadership. A mediator is a variable that accounts for the relationship between a predictor and a criterion variable, in other words it is a mechanism through which the independent variable is able to influence the criterion or dependent variable of interest (Baron and Kenny 1986). In the opinion leadership context, it has been suggested that enduring involvement drives opinion leadership, which in turn results in opinion leader activities such as information sharing and innovative behavior (Dichter 1966; Feick and Price 1987; Richins and Root-Shaffer 1988).

Corey (1971) proposes that the unique involvement of opinion leaders with a product class distinguishes them from non-leaders. Similarly, Ditcher (1966) argues that an opinion leader's involvement with a product category motivates product related conversations, knowledge and influence. According to Ditcher, this involvement may be product related which means that people may find themselves so pleased or so disappointed by a product that they simply must talk about it. Involvement may also be other related which means that product related conversations may be expressions of friendship, neighborliness or love. In support, Summers (1971) found that involvement with womens' clothing fashions is the strongest of five variable sets that influence opinion leadership. The other variables are demographics, sociological variables, personality, media exposure and attitudes and values. Also, in a study among women opinion leaders, Myers and Robertson (1972) found that interest in 12 product categories including entertaining at home and cosmetics is related to opinion leadership. Therefore, there is some empirical evidence that a strong interest in a product is related to opinion leadership and its characteristics, although much of this research focuses on constructs that are similar to enduring involvement and not enduring involvement per se.

METHODOLOGY

Sample

The sample consisted of 317 students at a leading northeastern university. The data was collected by students enrolled in an undergraduate Marketing Research class. At the beginning of the semester, each student was instructed to ask 10 non-class students to participate in a project which involved responding to four questionnaires over the entire semester. These questionnaires focused on opinion leadership, innovativeness and other related topics with respect to movie viewing behaviors. The objective, from the students' point of view, was to create a data base that would be useful for testing relationships using analytical techniques available in SPSSX.

Extreme care was taken to ensure data quality. The students were committed to the project both because they were interested in the results and because their grade was at stake. They impressed upon the 'panel' members their responsibility to carefully fill out the questionnaires or not do so at all. The instructor checked questionnaires for nonsense answers, systematic response patterns and any other signs of deliberate falsification. The questionnaires turned in by two students were not included due to suspect data quality.

Product Class

Movies were selected as the product class of interest for several reasons. First, undergraduates' enduring involvement with movies is expected to vary over a relatively wide range. Second, movies are inexpensive enough that the chances of income

confounding the results is reduced. Third, since new movies are released every week this provides ample opportunity for the purchase of this continuous new product. Lastly, word of mouth and interpersonal influence play very important roles in influencing movie-going behavior (Wall Street Journal 1984).

Measures

Childers' (1986) version of the opinion leadership scale was used to measure this characteristic. He revised the response format of the King and Summers (1970) opinion leadership scale and used constructs such as creativity/curiosity to examine its convergent and discriminant validity. He found that the revised scale has better reliability and construct validity properties as compared to the original scale. Psychometrically valid measures of other constructs of interest in this study such as enduring involvement and opinion leader characteristics for movies were not available. Consequently, scales were developed to measure constructs such as knowledge and information sharing with respect to movies. The items selected for the scales (refer Appendix), were based on previous theoretical and empirical research. Agreement with these items was measured on a five point response format where '1' is 'Strongly disagree' and '5' is 'Strongly agree.'

The scale developed to measure *enduring involvement* with movies is based on research by Bloch and Richins (Bloch and Richins 1983; Richins and Bloch 1986). They argue that enduring involvement is an on-going concern with a product class that transcends situational influences. This interest is deep-rooted, strong and has a hobby-like quality that sometimes is obsessional in nature. Therefore, the enduring involvement scale was designed to capture this strong interest and concern with the product class movies. The *influence* scale measures the extent to which the respondents influence other peoples' opinions about movies and their choice of movies. While the *knowledge* scale measures subjective knowledge (Brucks 1985) or a respondent's perception of their knowledge about movies and movie stars and the *information sharing* scale was designed to measure the extent to which respondents talk to friends about movies, discuss and listen to other people's opinions and share their opinions with others.

As regards *innovative behavior*, scales vary from measuring specific behaviors, such as relative time of adoption of a new product, to capturing the trait of innovativeness (Midgley and Dowling 1978). Since, this study is interested in new movie viewing behavior and not in innate innovativeness tendencies, it was decided to develop a measure that captured behavior with respect to new movies, without asking about whether or not the respondent had seen specific movies.

TABLE 1
Constructs, Sample Items and Reliability Coefficients

Construct	# of Items	Confirmatory Factor Analysis			
		Alpha	Chi-Square ^a	df	GFI ^b
Opinion Leadership	7	.77	28.36	14	.98
Enduring Involvement	10	.80	99.63	35	.94
Influence	6	.76	36.51	9	.97
Knowledge	5	.76	19.41	5	.98
Information Sharing	8	.71	101.32	20	.91
Innovative Behavior	4	.71	26.36	2	.96

^aThe p-values associated with the chi-square statistics are less than .05

^bAll individual indicators, except one, have t-values greater than 4.46

RESULTS

Reliability Analysis

Three reliability statistics were estimated for each of the scales used in this study. These are: (1) Cronbach's alpha; (2) Goodness of Fit Index (GFI) for the confirmatory factor model; and (3) the t-values associated with individual indicators of constructs for the confirmatory factor model (Bagozzi 1980; Bentler and Bonett 1980). As reported in Table 1, the alpha values range from .71 to .80, therefore all scales satisfy Nunnally's minimum alpha criterion of .70 (Nunnally 1978). The GFI values range from .91 to .98, therefore the scales also satisfy the Bentler and Bonett (1980) Goodness of Fit criterion of .90. Finally, with the exception of 2 items, the factor loadings range from .31 to .87, and only one item (item 5 for the opinion leadership scale), has a t-value less than 4.46. In summary, the scales used in this study are reliable.

The Moderating Effect of Involvement

Arnold (1982) differentiates between variables that 'moderate the degree' and those that 'moderate the form' of a relationship between two other variables. The 'degree' of a relationship is measured by the correlation coefficient and the 'form' is measured by coefficients in the regression equation. "Comparison of correlations answers the question 'does X account for as much variance in Y in group E as it does in group F?' Comparison of regression coefficients answers the question 'does a change in X make the same amount of score difference in Y in group E as it does in group F?'" (Arnold 1982; p. 146).

Accordingly, if the correlations between opinion leadership and its characteristics are different between low and high enduringly involved respondents, then enduring involvement moderates the 'degree' of the relationship (Arnold 1982; p.

151). Again, if the interaction ($x \cdot z$) between OL (x) and involvement (z) is a significant predictor of an opinion leader characteristic such as influence (y), in addition to the main effects of opinion leadership and enduring involvement, then enduring involvement moderates the 'form' of the relationship.

This analysis reveals that enduring involvement does *not* moderate the relationship between opinion leadership and each of its characteristics. As reported in Table 2, the z-statistic (Arnold 1982) that measures differences in correlation coefficients between opinion leadership and its characteristics for low and highly involved respondents is not significantly different at the $p < .05$ level of significance. Therefore, enduring involvement does not moderate the 'degree' of the relationship. Again the interaction between enduring involvement and opinion leadership is not a significant predictor of any of the characteristics, therefore, enduring involvement does not moderate the 'form' of the relationship studied here.

The Mediating Role of Opinion Leadership

According to Baron and Kenny (1986) to establish the mediation of opinion leadership between enduring involvement and opinion leader characteristics, such as influence, the following conditions must be met:

- (a) Enduring involvement should have a significant effect on opinion leadership.
- (b) Enduring involvement should have a significant effect on influence.
- (c) Opinion leadership should have a significant effect on influence over and above the effect of enduring involvement. The effect of enduring involvement on influence will be diminished as compared to condition b.

TABLE 2
TESTING FOR THE MODERATING ROLE OF ENDURING INVOLVEMENT

Testing for moderation of the 'degree' of the relationship						
Correlation between Opinion leadership and..	Enduring Involvement		z statistic			
	Low (n=164)	High (n=153)				
Influence	.58	.53	.45			
Knowledge	.43	.23	1.80			
Information Sharing	.47	.38	.81			
Innovative Behavior	.07	.26	1.72			

Testing for moderation of the 'form' of the relationship						
Dependent Variable (y)	Variable added					
	OL (x)		EI (z)		OL*EI (x*z)	
	R sq. change	F-Value	R sq. change	F-Value	R sq. change	F-Value
Influence	.38	191.86*	.10	57.06*	.00	1.03
Knowledge	.18	69.87*	.26	144.24*	.00	1.47
Information Sharing	.21	85.25*	.02	6.51	.01	3.59
Innovative Behavior	.09	30.52*	.29	144.26*	.01	3.48

* F-Value significant at p <.01

These conditions are tested for each opinion leadership characteristic separately using multiple regression analysis. Two regression equations are estimated for each mediating relationship tested. In the first, opinion leadership is regressed on enduring involvement (condition a). In the second, influence is regressed against enduring involvement and opinion leadership, which are entered in a step wise manner (condition b and c). The results of this analysis are reported in Table 3.

Condition (a) is satisfied - enduring involvement has a significant effect on opinion leadership. Condition (b) is also satisfied for all four opinion leader characteristics, - enduring involvement has a significant effect on these characteristics (p < .01). Finally, condition (c) is satisfied for influence, knowledge and information sharing, - the relationship between opinion leadership and these characteristics is significant (p < .01) when these characteristics are regressed against both enduring involvement and opinion leadership. Therefore, opinion leadership mediates the effect of enduring involvement on knowledge, influence and information sharing. However, it does not mediate the effect of enduring involvement on innovative behavior, which means that enduring involvement has a direct effect on innovative behavior.

Table 3 also reveals that as expected the effect of enduring involvement on influence,

knowledge and information sharing decreases when opinion leadership is entered in the equation, although it does not become insignificant. This indicates that while opinion leadership mediates the effect of enduring involvement on these three opinion leader characteristics, it is not the only mediator. According to Baron and Kenny (1986), "from a theoretical perspective...(this) demonstrates that a given mediator is indeed a potent, albeit not both a necessary and sufficient condition for an effect to occur" (pp. 1176).

DISCUSSION

Despite the appeal of the thesis that enduring involvement moderates the relationship between opinion leadership and its characteristics, this paper finds that the relationship between enduring involvement, opinion leadership and its characteristics is a *mediating* one. The analysis reveals that opinion leadership mediates the relationship between enduring involvement and opinion leader characteristics of influence, knowledge, and information sharing. This supports the model -Enduring involvement-> Opinion Leadership-> Opinion Leader Behaviors - that has only recently been explicitly tested (Richins and Root-Shaffer 1988). According to this model enduring involvement drives opinion leadership, which in turn accounts for behaviors such as

TABLE 3
TESTING FOR THE MEDIATING ROLE OF OPINION LEADERSHIP

		R Sq. Change	F- Value
I. OL mediates the effect of EI on Influence			
Condition a	$OL = (.44*)EI$.19	76.29*
Condition b	$Influence = (.55*)EI$.30	135.92*
Condition c	$Influence = (.34*)EI + (.46*)OL$.17	103.09*
II. OL mediates the effect of EI on Knowledge			
Condition a	$OL = (.44*)EI$.19	76.29*
Condition b	$Knowledge = (.64*)EI$.41	222.68*
Condition c	$Knowledge = (.57*)EI + (.18*)OL$.03	14.01*
III. OL mediates the effect of EI on Information Sharing			
Condition a	$OL = (.44*)EI$.19	76.29*
Condition b	$Information\ Sharing = (.32*)EI$.10	35.24*
Condition c	$Information\ Sharing = (.14*)EI + (.40*)OL$.13	52.27*
IV. OL mediates the effect of EI on Innovative Behavior			
Condition a	$OL = (.44*)EI$.19	76.29*
Condition b	$Innovative\ Behavior = (.61*)EI$.37	188.53*
Condition c	$Innovative\ Behavior = (.60*)EI + (.03*)OL$.00	.46

* F-value significant at $p < .01$.

exerting influence, gaining knowledge and sharing information and experience.

The analysis also shows that opinion leadership is not the only mediator. Other personal constructs that may mediate the relationship between enduring involvement and behaviors such as influence and knowledge are personal experience with the product, extent of information seeking activities especially ongoing information seeking behaviors, and extent of media exposure. Finally, the analysis reveals that opinion leadership does not mediate the relationship between enduring involvement and innovative behavior. This means that as suggested in the innovative behavior literature (Gatignon and Robertson 1985), enduring involvement with a product class has a strong direct effect on influencing purchase of a new product in that product class.

LIMITATIONS AND EXTENSIONS

Conclusions about the mediating role of opinion leadership must be tempered by the limitations of this study. One limitation is its use of a student sample. This study uses students due to the relatively low cost of obtaining cooperation from a relatively large sample of respondents. However, the student sample has obvious demographic differences from the general population and may also differ from it on some of the constructs used in this study such as innovative behavior. This suggests the need to replicate the study with other populations of interest.

Another limitation of the study is its use of previously unvalidated scales to measure constructs such as influence and information sharing. Consequently, this study needs to be replicated using both measures developed here and other measures in order to assess the robustness of its findings.

A third limitation is its use of a single product class to examine the moderating/mediating nature of the relationship between opinion leadership, enduring involvement and other characteristics of opinion leaders. This study should be extended to other products, both where word-of-mouth communication is important such as restaurants and where word of mouth communication is not so important such as consumer consumables.

SUMMARY AND CONCLUSIONS

This paper makes several important contributions to the research on opinion leadership. It goes beyond the direct main effect relationships that have dominated opinion leadership research, to examine more complex interactive relationships that are better models of the complicated phenomena of opinion leader activities. It does so by empirically examining the relationship of enduring involvement with opinion leadership and opinion leader activities. By exploring the role of enduring involvement it tests a relationship, which although recognized in the literature, has not been given the attention it deserves especially in empirical research. Finally, it uses the Baron and Kenny (1986) framework to distinguish between moderator

APPENDIX
Scale Items

Enduring Involvement

... Please indicate how well each of the statements below describes you.

1. If I don't go to a movie at least once a week, I feel I have missed something.
- 2.* With all of my schoolwork, movies are not high on my list of priorities.
3. Movies are more than mere entertainment to me. They are like a hobby.
4. Seeing a movie is a regular part of my schedule.
5. I will often go to see the same movie more than once.
6. I take a close interest in the technical aspects of a movie (camera work, special effects, etc.)
7. I can almost always find time to see a good movie.
8. I consider myself a movie buff.
9. I often go to movies as a treat to myself.
10. I follow the careers of specific actors and directors.

Influence

...Please indicate the extent of your agreement or disagreement with the following statements.

1. I'm usually the one in my group who suggests going to a movie.
2. I'll often steer friends away from movies I didn't like.
3. I often persuade friends to go see a movie I really liked.
4. My friends often ask me to recommend which movie they should see.
5. Friends seek information from me regarding the latest movies.
6. My friends ask me about movies that I have seen.

Knowledge

1. I generally know the showtime schedules of the theaters I go to.
2. I usually know what my favorite actors and directors are working on.
3. Among my circle of friends, I'm one of the "experts" on movies.
4. I often know quite a bit about movies before they are released.
5. I feel confident recommending movies to my friends.

Information Sharing

1. I regularly ask friends for their opinions of movies I'm thinking about seeing.
2. I usually talk to friends about a movie before I go to see it.
3. My friends and I often discuss what movies are worth seeing.
4. I often compare my opinion of movies with others.
5. I often discuss and listen to other's opinions about movies I have recently seen.
6. I often talk about movies at parties.
7. I usually rely on friends' recommendations of movies.
8. Usually before going to a movie, I'll ask my friends what they thought of it.

Innovative Behavior

1. I often try to see sneak previews of movies before they are officially released.
2. I often try to attend movie premiers.
3. I often try to see a movie during the first week after it is released.
- 4.* I usually wait to see a movie until it has been out for several weeks.

(Items marked with an * are reverse coded)

and mediator relationships in the context of opinion leadership, thereby introducing a framework which will have value for testing many different consumer behavior theories and frameworks.

The Imperial Self

Michael R. Solomon, Rutgers University

INTRODUCTION

The three papers presented in the session on The Extended Self appropriately enough attempt to extend prior work on the Self in consumer behavior to the domains of, respectively, our sense of the past (Belk 1990), our pets (Sanders 1990), and gifts we bestow on ourselves (Mick and DeMoss 1990). All three were influenced by Belk's (1988) recent paper on the Extended Self.

It is indeed heartening to witness the reemergence of the Self as a research topic. This trend represents another important acknowledgment of the need to extend our view of consumer behavior well beyond the traditional confines of the individual as a mechanistic buyer of goods. These papers help us to continue to move toward the embrace of the phenomenological individual who actively *uses* goods -- and even relies on them -- to construct and maintain his/her social reality.

Indeed, William James' discussion of the Material Self a century ago anticipated this long-overdue recognition (James 1890). As the commentator on these papers, the gift I grant to myself is the luxury of raising some issues prompted by these thoughtful papers without necessarily providing resolutions to such questions.

When is an Effect Not an Effect?

The foremost conceptual issue that emerges from these papers is a definitional one: When is an effect not an effect? While I laud the idea of extending our notion of Self beyond its corporeal confines, we run the risk of *overextending* the construct and in so doing obviating its usefulness. Some objections to the contrary (cf. Cohen 1989), there does appear to be a theoretical role for the Extended Self, but we also must acknowledge the construct's limitations.

To wit, in the present papers: When is a pet not a pet? When is a gift not a gift? And, perhaps most importantly: When is the Self not the Self?

Self Versus Not Self

In thinking about what I have termed the Imperial Self, two somewhat similar (and admittedly rather tacky) images come to mind. The first is the old macho myth of the lusty sailor who boasts of children bearing an uncanny resemblance to him in ports around the world. The second (perhaps inspired by Sanders' paper), is of the dog who "marks" his territory by leaving traces of himself along its perimeter.

These two "consumers" have in a sense expanded the empire of Self by imbuing external objects with their Selfhood. Do we do something similar as we leave a trail of significant objects in our paths? And, is this wake truly a part of the Self?

Belk's propositions about the use of objects to (re)construct the past are valid and useful. Clearly, any object is transformed

(phenomenologically and sometimes literally) from the time it leaves the "factory" to the time it is consumed -- that is the basis for the personalization process whereby a commodity is turned into a prized possession.

My concern (and one raised as well by Cohen 1989) is that in future work we try to make a distinction between objects that happen to possess some mnemonic value and those that clearly are a component of Extended Self. Belk's emphasis on such dimensions as type of attachment (functional versus emotional) and degree of control over an object (Belk 1989) is a first step in this direction, but this important issue has yet to be fully resolved.

And, as in the case when two dogs lay claim to the same territory, this distinction gets particularly dicey when an object serves as Extended Self for more than one person. A good example might be a married couple's treasured photograph of themselves in bygone days -- can an object do double duty, selfwise?

Pet Versus Not Pet

Sanders' paper provides a nice corrective to our neglect of the (non-dietary) "consumption" of animals. In providing a symbolic interactionist perspective on animal ownership, he has moved away from the notion of the animal as possession and toward the animal as companion. This raises some interesting issues about the precise relationships between people and animals. More often than not, animals appear to "own" their owners more than *vice versa*! So, when is a pet not a pet?

While the term "pet" is usually taken to refer to a domesticated animal, a secondary definition is a cherished individual (e.g., "teacher's pet"). If one adopts the interactionist notion of the Self deriving from interactions with others, the animal may be closer to a friend than to a possession. Parenthetically, the tendency of people to come to look like their pets over time provides anecdotal support for this dynamic.

So, it seems there are many instances where a pet is not a pet (in the primary sense of the word). Indeed, Sanders' preliminary delineation of "excusing tactics" implies that the Self is reflected in the conduct of the pet.

Of course, there are other domains where an animal is neither a pet nor a companion. Here we may find a relationship that more closely resembles slavery; the animal's output is harnessed to provide benefits to the owner.

Many "pets" are in fact income-generating devices, whether they are milk cows, pit bulls, fighting cocks, or racehorses. The "performance" of these animals may also help to constitute the owner's Self, much as the records of race cars or baseball teams reflect on the character of their owners. Finally, as the "animal rights" movement appears to gather momentum, it remains to be seen

to what degree (non-laboratory) animals will be treated as commodities in the future. Perhaps a litmus test of the person/animal relationship would be provided by studying owners' reactions/rationalizations when deciding to put their pets to sleep.

Gift Versus Not Gift

Mick and DeMoss' paper on self-gifts integrates the Extended Self with prior work on gift-giving. Again, the issue for future work here is to delineate what is essentially meant by a gift. There is a tautological danger here that is acknowledged by the authors. If we broadly define a gift as some creation or delivery of positive affect initiated by an individual, then virtually anything can be a gift. As noted in the paper, gifts to other people can be seen as gifts to ourselves, since we usually derive pleasure from the act of giving (whether instrumental or not). So, is doing any good act (or refraining from a bad one) targeted to ourselves and others a gift? What is not a gift?

In contrast to other-gifts which are often initiated by some structural requirement (e.g., we learn to give and expect gifts on birthdays, Christmas, etc.), self-gifts appear to often be initiated by some state of polarized affect. This can be positive (e.g., a celebration) or negative (to alleviate stress or depression). The role of affect in such gifting raises some questions:

- Can we identify differences in the type of self-gift given in "up" versus "down" situations?
- Are there differences between spontaneous and premeditated self-gifts?
- Since self-gifts often appear to occur during times of high arousal, is their receipt thus more impactful? Do they play a role as significant past markers in the manner described by Belk? Or do gifts mean less to us in the long run when we had to give them to ourselves?

THE MASS-MEDIATED SELF

The three papers (at least indirectly) raise questions about the role of society in providing input to the Extended Self. Our culture may, for example, sanction self-gifts and pampering to a greater degree now than in the past (e.g., ads that proclaim "I use it because I'm worth it"). As current values appear to be evolving somewhat away from self-indulgence and crass materialism, will this license to reward oneself change in the post-yuppie, more altruistic world some project we are headed toward?

We have also experienced an increase in fears about personal safety. As Sanders implies, this in turn appears to have accelerated the use of pets (and even *recorded pets*) as security devices; a way to fortify threatened personal space. Perhaps an analysis of the names people give to their pets or

longitudinal changes in the types of pets favored by consumers would tell us something about the qualities people have projected on to their companion animals.

Belk notes that objects are used to preserve our past. This past is, of course, more than an individual one. The "collective collecting" of past markers also creates the informal archives from which the history of popular culture is culled. In analyzing the role of objects as repositories of memories, we must also address the semiotic issue of the correspondence between the object and the actual event it is intended to memorialize. Belk, in fact, correctly notes the distortion process that frequently occurs in nostalgic behavior.

Indeed, it is not unusual to observe a sort of semiotic fraud, a "phenomenological short-cut" whereby objects can be substitutes for experience in addition to markers of it. As Belk and his colleagues have observed in their Odyssey work, museum gift shops and other purveyors of souvenirs contribute to this process.

Thus we can now purchase past markers without the bother of experiencing the past. Some examples include companies that sell college T-shirts -- removing the need to actually *visit* the college -- or collections of matchbooks from a city's restaurants that are now available in airport gift shops.

If one endorses the claim that ours is an increasingly anomic society intent on destroying its past, we can expect such manifestations of synthesized experience to escalate. For this reason, Belk's emphasis on the importance of authenticity may not always apply. Our desire to recapture the "good old days" (if these in fact existed) has fueled the acquisition of "reproductions" or even the consumption of imagery that never existed at all (or is idealized).

Thus, we can buy faded jeans without having to wait for them to be "worn in." Or, consider the fantasy WASP world created by Ralph Lauren. This designer, who was originally a poor Jewish boy from Brooklyn, has succeeded in creating an upper-class world of graceful manners and aristocratic bearing that has been internalized by many. As a result, many consumers "plug in" to common images of nostalgia and yearning -- they are acquiring the markers of someone else's imagined past.

Another illustration is in the realm of music. Certain songs function as past markers in that they often are associated with specific events or times of one's life. As a result, we often feel somewhat proprietary toward these "objects" even though they are in the public domain. However, even these experiences increasingly are synthesized and mass-mediated.

While a rendition of "Under the Boardwalk" might bring a salacious smile to one person while "My Girl" or "Feelings" might bring back precious memories to others, MTV has abrogated these unique connections. The imagery prompted by Dire Straits' "I Want My MTV" or Madonna's "Like a Prayer" is likely to be *shared* (at least by MTV viewers) rather

than idiosyncratic. Similarly, songs like "Revolution" or "I Heard It Through the Grapevine" are more likely to evoke images of sneakers or raisins than they are to initiate individual recollections.

Since some "custom-made memories" are not really customized at all, perhaps we should focus more attention on the intermediaries who create these images. For example, how does a music video director choose the images to be associated with a song? How does a museum curator decide what objects should be enshrined as part of our collective past?

THE EXTENDED SELF OR THE MEDICATING SELF?

A final issue raised by all three papers is the overlooked *therapeutic* value of objects. Because many artifacts are so tied to the Self, they can also help to stabilize the Self. Belk alludes to the importance of possessions in anchoring the Self, as in times of role transition. Objects can also be used in therapy to elicit buried responses, as when a childhood object triggers a memory. Some therapists are even developing an approach known as aromachology, where familiar smells are used to break down mnemonic barriers. The use of objects to inspire fantasy or nostalgic recollection has barely been explored.

The role of objects in regulating affect also has not been adequately addressed by consumer researchers. Sanders' work promises to tell us more about the role of animals in alleviating loneliness, teaching love, and perhaps even inspiring fear. Mick and DeMoss' study strongly implies that people use self-gifting as a form of self-medication. Ironically, popular culture has known this for a long time: A common antidote to "the blues" is the purchase of a new article of clothing, a record, etc. While this compensatory purchasing is familiar to many, we do not know much about its effectiveness: Is shopping, as some claim, superior to therapy?

THE SELF AND ITS MARKERS

The focus on the Extended Self underscores the many "empires" we build as we accumulate and distribute objects. A basic question, still to be resolved, is whether the Self is communicated or constituted through its satellites. An interactionist approach would tend to endorse the latter: Our core Selves are largely instantiated by the external symbols with which they are aligned (cf. Solomon 1983). A final, somewhat Zen-like question thus arises: Just as an Empire cannot exist without subjects, can the Self exist without its markers?

Beauty and Joy in Metaphorical Advertising: The Poetic Dimension

Barbara B. Stern, Rutgers University

The author examines "art" in advertising by micro-level focus on the single advertisement to analyze *metaphor* in terms of Aristotle's *Poetics*. Aristotelian definition of literary metaphors and three classes -- single, extended, open-ended -- are discussed. Harmony and imitation as sources of pleasure in language are analyzed, and related to consumer research. Influence of harmony on enjoyment and memorability of metaphors and influence of representational style of metaphor on inference-conclusion drawing and consumer evaluation of "goodness/badness" discussed.

But the greatest thing by far is to have a command of metaphor. This alone cannot be imparted by another; it is the mark of genius, for to make good metaphors implies an eye for resemblances (Aristotle, *Poetics*, XXII.9)

Advertising has been called an "art" by practitioners (Ogilvy 1985), marketing researchers (Holbrook 1987; Pollay 1985), and social critics (Berman 1981; Schudson 1984; Wicke 1988). Their usual focus is on the macro-level cumulative effect of the numerous messages that daily bombard consumers. This paper takes a different view, and focuses on the micro-level analysis of a single advertisement. The goal is a new approach, beginning with the question, "Why is an advertisement categorized as art?" One clue is that an advertisement may entertain as well as inform and persuade. This suggests that it may be perceived as enjoyable as a result of dimensions shared with other aesthetically satisfying works, such as poems, plays, or movies. Central to the concept of advertising as entertainment -- something to be enjoyed by the perceiver -- are literary elements as sources of beauty, joy, and pleasure. This paper thus turns to literary criticism -- the discipline specializing in "defining, classifying, analyzing, interpreting, and evaluating works of literature" (Abrams 1988, p. 38) -- for a theoretical framework to analyze an advertisement.

One enjoyable element that advertising language shares with all other verbal art is the use of *metaphor*, a figure of speech (for bib., see Shibbes 1971) analyzed by rhetorical classifiers (Connors 1984), philosophers (Black 1962; Ortony 1979; Ricoeur 1977; Searle 1979), and literary critics (Abrams 1953; Wellek and Warren 1973). Metaphor is the basis of *figurative* or "ornamental" language, fundamental not only to traditional literature, but also to other modes of discourse such as everyday speech, political propaganda, and religious sermons (Abrams 1988). Much research interest concentrates on the use of metaphor to persuade consumers, historically traceable to Aristotle's *Rhetoric*.

But advertising writers are like poets (Brooks 1947) as well as propagandists in the creation and

use of metaphors. This creativity connects advertising to literature, and allows investigation of *how* an advertisement's text relates to Aristotelian literary theory. Thus, this paper draws on Aristotle's *Poetics* (Fergusson 1961) -- the earliest *literary* theory of metaphor -- to discuss the pleasure-value of language and the concept of an advertisement as consumer entertainment. The paper proceeds as follows:

- 1: Definition of metaphor: comparison, analogy, transference of attributes
- 2: Three classes of metaphor: single, extended, open-ended
- 3: Metaphoric pleasure: harmony and imitation
- 4: Aristotelian theory and consumer research

ARISTOTELIAN DEFINITION OF METAPHOR: COMPARISON, ANALOGY, TRANSFERENCE

Metaphors are one category of *figurative language*, or *figures of speech*. These are words or phrases used in a way that departs from the standard or *literal* meaning of the words (see Searle 1979) to achieve some special effect. Aristotle regarded metaphor as the basis of poetic language, and somewhat elliptically defined it as "*the application of an alien name by transference...by analogy*, that is, proportion" (Italics mine, Fergusson 1961, p. 99). The Aristotelian metaphor thus has three elements: *comparison* ("resemblances") by *analogy* to enable *transference* of qualities to one thing (subject of the metaphor) from another (object, also called "the metaphorical term"). Another set of terminology (Richards 1936) uses "tenor" = subject, "vehicle" = object, and "grounds" = properties transferred to the subject from the object.

Comparison

The Aristotelian metaphor is an *implied indirect comparison* or similarity between a literal object and a metaphoric object, in which the reader has to supply the omitted comparative term (Brooks and Warren 1960). A frequently-used poetic example (see Barnet 1979; Brooks and Warren 1960), is Spenser's compliment from a man to his lady-love: "She is a rose." The analogy between a rose and a lady is based on transference of qualities such as beauty, softness, fragrance, and fragility (Barnet 1979). Literary critics say that it means that "the girl is fragrant; her skin is perhaps like a rose in texture and (in some measure) color; she will not keep her beauty long" (Barnet 1979, p. 181). The analogy allows the suggestions of "rose" to be transferred figuratively (rather than literally) to the lady.

In this sense, metaphor is an elliptical form of simile. A simile -- X is *like* Y -- is an *overt direct comparison*, in which two things are

associated by means of "like" or "as." Spenser's line rewritten as a simile is, "She is *like* a rose." But the metaphor leaves out the comparative word, and simply says, "X is Y." Its implicitness leaves the reader to infer that "is" means "is like in some way" rather than literally "equals" or "is identical to." The reader is expected to supply the omitted comparative word *and* understand the phrase connotatively as an analogy. The implicitness of the comparison allows metaphor to assert an *identification* of the two terms (they are not merely LIKE each other; they ARE each other). The metaphor, in sum, acts as a kind of shorthand that condenses bits of information about its subject into a single literal comparison accepted by the reader as literary, not literal, truth.

Analogy

The comparison of things that are literally unlike by finding analogical resemblances took firm root in Western literature as a result of the medieval lore of analogy in Dante's *Divine Comedy* and the voluminous body of literary criticism generated by it (Culler 1981; Spurgeon 1965). Aristotle defines comparison by *analogy* as follows (Fergusson 1961, p. 99):

Analogy or proportion is when the second term is to the first as the fourth to the third. We may then use the fourth for the second, or the second for the fourth.

An analogy of proportion requires four terms, two of which have a common factor or similarity. In notational form, this reads: 1:2::3:4, or A:B::C:D, a juxtaposition in which terms 4 and 2 can replace each other. The comparison can be stated in words as follows: If A is to B as C is to D, then B and D can be interchanged, and A can be said to be like (similar to) C. Frye illustrates the analogy using the expression "the hero was a lion," in which courage is the common factor, and the analogy is, "the hero is to human courage as the lion is to animal" (1973, p. 124). Analogical metaphors seem to control the structure of many advertisements as well, and can be analyzed on the basis of literary criticism (see Stern 1988, 1989).

An advertising example is, "Among the riches of Beverly Hills, a little gem of a hotel ... The Beverly Pavilion Hotel." This is an elliptical metaphor, for the verb "is" is omitted, but implied by the comma, often used in formal written prose to indicate ellipsis (Watkins, Dillingham, and Martin 1974). In notational form, the metaphor is shown in Figure 1. The common factor is distinctiveness: just as a little gem stands out even among many jewels, the little hotel stands out even amidst the riches of Beverly Hills dwellings.

Transference

The point of analogy is the *transference* of attributes from the object of the comparison to the subject (Brooks and Warren 1960). The subject and object are sandwiched side by side for ease of

comparison, and marketing metaphors, like poetic ones, encourage consumers to transfer characteristics of an object to the subject. In our example, the image of a small gem that stands out among an abundance of jewels is transferred to the notion of the Beverly Pavilion as the most distinctive small hotel in a geographic area remarkable for affluence. The advertisement's metaphor thus involves *the application of an alien name* [gem] to a hotel by *transference* [the quality of distinctiveness] by *analogy* [the resemblance between the gem's and the hotel's uniqueness].

THREE KINDS OF METAPHOR: SINGLE, EXTENDED, OPEN-ENDED

The concept of attribute *transference* has been further refined by post-Aristotelian literary critics into three metaphorical classes based on *number* of resemblances (attributes) and *degree of similarity* (subject and object). The classes were characteristic of various kinds of poetry popular in earlier centuries, and enter modern advertising language with differences based on historical convention. The classes are differentiated on the basis of two questions: How many attributes are shared by the items compared? and How similar are the subject and object? The three classes are single (one resemblance, dissimilar s/o); extended (many resemblances, dissimilar s/o); and open-ended (indefinite number of resemblances, similar s/o).

Single Metaphor

The *single* metaphor compares a subject and object that are quite dissimilar for the sake of emphasizing one main shared quality (Korg 1962). Single metaphors present what Samuel Johnson called "a combination of dissimilar images, or discovery of occult resemblances in things apparently unlike" (Abrams 1988, p. 31). Their ancestry is traceable to the seventeenth-century metaphysical poets (especially John Donne) who used analogy to create startling comparisons in which "the most heterogeneous ideas are yoked by violence together" (Johnson in Abrams 1988, p. 31). Transference is restricted to one limited and unambiguous -- though frequently far-fetched -- comparison that controls the text narrowly.

The metaphysical poets fell out of favor in the Romantic era, but were rediscovered by twentieth century poets, who rely even more on "occult resemblances" than did their forebears. The presence of single metaphors in advertising suggests that commercial art freely adapts whatever literary techniques are in the current cultural mainstream. An advertising example is a classified ad ("Summer Entertaining" 1989, p. 94) for a telegram-delivery service: "STRIPPER-GRAMS The only gift that unwraps itself." The specialty telegrams delivered for "bachelor parties, showers, birthdays" are compared to strip-tease artists ("gorgeous girls...great guys") based on the single quality of undressing as a form of public entertainment -- a "gift" of oneself to an audience. Although a message on paper and a live stripper are apparently quite dissimilar (in action --

FIGURE 1

Beverly Pavilion Hotel : riches of Beverly Hills :: little gem : many jewels
 A B C D

verbal vs. physical; in medium -- static vs. dynamic; in nature -- abstract vs. concrete, and so forth) they are similar in one respect: each is a "gift that unwraps itself." Hence, their comparison is a single metaphor.

Extended Metaphor

A second category also derived from metaphysical poetry is the *extended* metaphor, in which a dissimilar subject and object share *parallel points of resemblance*. The burden is on the writer to ensure that everything he says is as true of the subject as of the object (see Ciardi and Williams 1975) and to create a coherent point-by-point analogy emphasizing the one area in which two different things are alike. Extended metaphors often use comparison for shock value in that they yoke dissimilar things together as the basis for ingenious and elaborate figures, sometimes judged artificial by critics who object to a poetic straining for likenesses where none appears to exist (see Ruthven 1969).

An advertising example is Chanel's tag-line, "We don't say LIFT-SERUM is a miracle. You may think otherwise." Here, the points of resemblance between the cream and the miracle of renewed youth deal with time, place, and circumstance: [what happens] -- "up to 45% reduction in the appearance of visible lines and wrinkles"; [when] -- "after just one month's regular use"; [where] -- on a woman's face. Just as a miracle achieves instant results by means of complex simultaneous changes (Cinderella turns from a scullery maid into an aristocratic lady dressed for a ball at the stroke of midnight), so too is this cream miraculous. The parallelism among a number of resemblances linking two unlike entities makes this an extended metaphor, as elaborate a figure as any found in poetry. Interestingly, the grammatical context places it within a negative statement of fact ("we don't say it is a miracle"). It is not clear whether this is done for the sake of literary ingenuity -- to present the metaphor in a novel setting -- or in order to avoid legal problems.

Open-Ended Metaphor

A third type of metaphorical transference is *open-ended*, the heritage of the Romantic nineteenth century poets who reacted against the forced and unusual juxtapositions created by their metaphysical forefathers (see Wimsatt 1972). An open-ended metaphor entails an indefinite number of shared resemblances between two things that are more similar than dissimilar. These allow the reader to figure out the transferable qualities, alluded to rather than stated, and in so doing generate a many-sided meaning in his/her mind (Korg 1962). They give the

reader leeway to fill in numerous possible relationships between a subject and object seen as more alike than not, and to find clusters of resemblances on his/her own. The metaphors have "polysemous" meaning (see Frye 1973) and are richly ambiguous (Empson 1947) in that they permit multilayered, complex, and connotatively wide-ranging interpretation.

Open-ended metaphors are now considered the most significant and common kind, thought to evoke a strong impression precisely because they do NOT force a comparison on the reader (Korg 1962). By leaving a reader free to put in his/her own ideas, they engage his/her participation in the creative process. An example of an open-ended metaphor is found in an ad for New York's Shinbashi restaurant: "Owner Fumiko Hosoda welcomes you...Dining at Shinbashi is spending an evening in Japan." The restaurant qualities transferred are never spelled out, but merely linked by association with "an evening in Japan." The ad requires the reader to fill in the outlines of "evening in Japan" with whatever positive images s/he selects, and transfer those attributes to dining at the restaurant. Indefiniteness is thought to stimulate a reader's imagination by encouraging him/her to supply the points of resemblances that coalesce into one personally rich meaning. A reader's imagination is said to add comparisons implied by the original one (Brooks and Warren 1960), in a process itself metaphorically comparable to the widening circle of ripples (layers of meaning) that occur when a pebble is thrown into a pond.

Thus, three kinds of Aristotelian metaphor have been identified based on number of resemblances among attributes (single versus open-ended/extended) and degree of similarity between subject and object (single/extended versus open-ended).

ARISTOTELIAN METAPHOR AND PLEASURE: HARMONY AND MIMESIS

Aristotle suggested that poetry -- the "language embellished" characteristic of choral odes in the Greek tragedies -- originated in human enjoyment of language "harmony" (pleasing sounds) and "imitation" (representation of reality). "Harmony" refers to enjoyment of words and word groups as a result of their sound, rhythm, and rhyme (Fergusson 1961). Literary critics study *prosody*, the discipline of versification, to analyze metre, rhyme, and stanzaic structure (see e.g. Fussell 1979; Wimsatt 1972) as elements governing a text's musicality. Metaphorical harmony (see Crane 1953; Wellek 1963) refers to the meter, sound patterns,

FIGURE 2

/ ◡ / ◡ / ◡ / ◡
 Bombay sapphire. Pour something priceless

and rhyme scheme found in even short phrases. One way that metaphors are thought to induce pleasure, then, is by the way they sound.

Harmonious language is found in an ad for Bombay Sapphire Gin -- "Bombay Sapphire. Pour something priceless." The brand name states the metaphoric terms: Bombay is compared to a sapphire, and the qualities of blueness, icy sparkle, and costliness are transferred from object to subject. The tag-line uses alliteration (underlined "p" and "s" sounds) and rhythm (iambic, accent on the first syllable in word group) (Figure 2). The extent to which harmony positively affects enjoyment has not yet been measured (see below), but critical comments about lack of harmony suggest that sounds are important. A slogan in a recent Aetna Life & Casualty ad -- "We give new meaning to the word diligent" -- was criticized on the grounds of poor rhythm. Garfield wrote, "If ever a slogan failed to roll off the tongue, this is it. Ditto for the commercials themselves, which are full of promise but oddly out of sync" (Garfield 1989, p. 38). This implies that Aristotle's theory of harmonious sound patterns as a source of pleasure may be relevant to advertising as well as to poetry.

Imitation or *mimesis* refers to pleasure derived from meaning rather than sound. It does not imply superficial copying, but rather, a poem's representation of life by re-creating some aspect of it in the new "medium" of words. All verbal art is in this sense mimetic, for it re-creates the "real" world of human experience in word-imitations (see Nuttall 1983; Alter 1984). An advertisement, too, represents a specific kind of human action (associated with use of a product or service) in words (and also in pictures, sounds, music, and movement, although non-verbal art lies beyond the scope of this paper).

Aristotle felt that humans derive pleasure from metaphoric representations because of what they learn: "...to learn gives the liveliest pleasure....Thus the reason why men enjoy seeing a likeness is that in contemplating it they find themselves learning or inferring" (Fergusson 1961, p. 55) something about their own lives and that of others. The reader is thought to experience "a leap of the imagination, a shock of surprise" (Brooks and Warren 1960, p. 89) in apprehending a comparison that encourages fresh views of a commonplace object, idea, or event. A metaphor reveals something beautiful and new even when the domain is painful or unpleasant (as in Greek tragedy), for people are said to delight in recognizing a thing "reproduced with minute fidelity" (Fergusson 1981, p. 55). When audiences recognize the representation of an analogical transference, their satisfaction is

said to be that of enhanced understanding: they now see the subject in a new light.

Aristotle analyzed enhanced understanding in terms of the sight/blindness metaphors dominant in *Oedipus Rex*. Modern advertising also finds a similar comparison useful, as evidenced in a Kodak ad for products targeted to health care professionals. X-ray films are called "Eyes for what a doctor cannot see," in an ad that is part of the campaign's theme, "The New Vision of Kodak." The comparison of x-ray film to human eyes demonstrates how technology imitates the human body: x-rays are to medical sight as eyes are to human sight. The metaphoric play on visibility/invisibility teaches the reader that the complex and mysterious entity of diagnostic apparatus can be understood in terms of the more familiar human body. Reader pleasure, in Aristotelian terms, is thought to stem from understanding what the new technology is about as a result of its representation in terms of something already known: the bodily eye.

Thus, poetry is said to have originated in man's enjoyment of harmony and imitation, and metaphoric language said to satisfy the "natural and universal" human desire to hear pleasurable sounds and understand oneself and the world. Metaphors serve the purpose of stimulating enjoyment to the extent that they please the ear and present reality faithfully.

ARISTOTELIAN METAPHOR AND CONSUMER RESEARCH

Since advertisements create and use metaphors in ways that are traceable to Aristotelian theory, some insights may also be found there to shed light on consumer responses. The relationship of metaphorical effects to consumer responses has not yet been clearly translated from humanistic criticism to the social sciences, nor has it been extensively considered in terms of what the consumer enjoys or finds entertaining. There are many opportunities for original consumer research on the relationship of metaphors to enjoyment of advertisements, recall of messages, inference-drawing, and global evaluation.

Harmony: Enjoyment and Recall

One virtually untouched area of study is the degree to which *harmony* affects an audience's enjoyment of an ad. Prosody has barely been tapped as a useful source of antecedent variables to answer the question, "To what extent do sound and rhythmic effects influence consumer perceptions of metaphors as entertaining?" Many sound-based variables can be identified as small-unit variables (sound patterns or rhyme, for example) capable of inclusion in MacInnis and Price's processing model (1987). Other

larger-unit ones (metrical or stanzaic form) also not well-explored probably should be tested to ascertain whether and how they elicit favorable/unfavorable consumer responses. The degree to which people are entertained by pleasing sounds in advertisements is not known. It is also not clear whether different sound patterns -- "beat" -- may be appropriate for different purposes (reminder ads versus new-product introductions, for example).

In addition to pleasure, harmony is also associated with recall, for mnemonics similar to those advertisers use have long been said to enhance memorability. Since Anglo-Saxon times (see Hulbert 1961; Wrenn 1966), alliteration and assonance have been used to impress verses on non-literate mass audiences. One advertising study (Vanden Bergh, Adler, and Oliver 1987) suggests that the memorability of Coca Cola (alliterative "c" sounds, assonant "o" and "a" sounds, beginning and end rhyme) in part results from its sound-qualities. The extension of this research from brand names to metaphors seems necessary to determine whether sound effects do lead to greater recall, and if so, what the optimal combinations of sounds are. Additionally, the relationship between memorability and *displeasure* should also be investigated, for some rhythms are likely to be annoying because they are overly insistent or too regular.

Imitation: Inference-Conclusions and Evaluation

Another area of research where Aristotelian theory seems useful is inference and conclusion drawing. Literary critics say that metaphorical transference of attributes facilitates understanding in an unconscious process called by a variety of names: burst of insight (Brooks and Warren 1960) sudden perception (Ciardi and Williams 1975), vivid dramatic experience (Barnet 1979), and so forth. These descend from Aristotle's comment that humans experience a moment of truth when they perceive that one thing resembles another in a poetically created likeness. In advertisements, the transference seems designed to encourage readers to infer that the subject possesses the attributes of the object (for rev., see Sawyer 1988).

Social science research suggests that this transference may be almost automatic (Glucksberg, Gildea and Bookin 1982), but many questions remain about the process and end result. First, how does transference of attributes occur in *advertising* messages? It seems unwarranted to assume that people read ads the same way that they read literature, newspapers, or other media communications. Second, how does the transference mechanism work in single versus extended versus open-ended metaphors? There is little reason to think that the process is exactly the same, for single metaphors seem more conclusive, and may be less likely to stimulate inferences, while open-ended ones seem more *inconclusive* and place the burden of interpretation on the reader. Extended metaphors present a somewhat different mental task, in that the reader has to work out a point-by-point comparison

to understand transference of an attribute bundle from object to subject. Inference research may benefit from awareness of different kinds of metaphors analyzed by literary critics, for the process of drawing conclusions may be related not only to how much the text tells a reader, but also to how it does the "telling."

Literary critics have also expended a good deal of effort in evaluating metaphors as "good" (original, creative, expressive of universal truth and psychological insight) or "bad" (trite, incomprehensible, mixed). Consumer researchers need to capture these judgments in measurable terms, and then begin to ascertain how an advertisement (as opposed to a poem or classical tragedy) is evaluated. The definition of "good/bad" in literary metaphors is itself controversial, and it is by no means clear that even if there were agreement, it would be transferable to commercial language. Aristotle himself put forth the notion of different criteria for language appropriate to different purposes (Fergusson 1961, p. 111):

There are also many modifications of language which we concede to the poets. Add to this that the standard of correctness is not the same in poetry and politics, any more than in poetry and any other art.

Some linguists and psycholinguists measure metaphorical goodness based on the similarity or dissimilarity of the attributes compared (see e.g. Chomsky 1964; Katz, Paivio, and Marschark 1985). Others, following Richards's (1936) theory of interaction, focus on the nature of subject and object, and suggest that the best metaphors employ close resemblances between attributes of a subject and object from different categories of being (Tourangeau and Sternberg 1981). Whether consumer evaluation is based on number and similarity of attributes or relationships between the subject and object, or some combination of the two, is not yet clear. Literary criticism provides an enlarged framework for evaluation of metaphors on additional dimensions that may illuminate the nature of the transferral process. Some evaluative dimensions that seem related to advertising language are as follows (Brooks and Warren 1960, p. 272):

- degree of explicitness
- degree of ingenuity or creativeness
- shock-value in the terms compared
- degree of beauty: "unpoetic" (ugly or unpleasant comparison)
- degree of comprehensibility
- degree of economy (elaboration or condensation)

These add subtle considerations -- economy of expression, for example -- to evaluative criteria currently studied, and may lead to clearer understanding of what is meant by a "good" advertising metaphor.

Questions for consumer research concern how consumers evaluate advertising metaphors in terms of a "good/bad" rating. Do they evaluate metaphors based on the number and similarity of attributes they can transfer from object to subject? That is, do they judge by means of a quantifiable dimension of attribute transference? Or does something else occur, in which consumers experience both attribute transfer *and* the joyous feelings generated by the process (an "imaginative leap")? This comes closest to what literary critics say occurs when people read (or see) great imaginative works, but it is not clear that a "leap" or "burst of insight" can be empirically demonstrated. Nor is it clear that if it does exist (and this author thinks it does) whether and to what extent it applies to an advertisement. Little is known about perceptions of the language of commerce as entertaining or artistic in its own right. What consumers of novels or movies might consider "good" metaphors may not be the same as what consumers of advertisements think are "good," for the context may interact with the content in ways not yet understood.

Thus, additional research is necessary to understand how consumers enjoy, remember, draw inferences from, and evaluate advertising metaphors. Aristotelian theory suggests some directions this research can take. The areas of sound and meter in relation to enjoyment and memory, and analogy and transference in relation to inference-conclusion drawing and evaluation have begun to be explored. The view of advertisements as artistic creations opens up research possibilities by offering humanities theory as a source of insights for social science applications. Beauty as a quality conventionally thought to be inherent in poetic metaphors, and joy as a response may not be far removed from qualities inherent in some advertisements and consumer responses to them. It is important to keep in mind that an advertisement, like a literary work, can be viewed as a single piece of data (see Frye 1973), and examined to ascertain the nature, structure, and function of its metaphor(s). Sensitivity to within-ad elements may lead to increased understanding of the complex *gestalt* of an advertisement, similar to what Langer calls the "import" of poetry, (1951, p. 147):

Though the *material*... is verbal, its import is not the literal assertion made in the words, but *the way the assertion is made*, and this involves the sound, the tempo, the aura of associations of the words, the wealth or poverty of transient imagery that contains them, the sudden arrest of fantasy by pure fact, or of familiar fact by sudden fantasy, the suspense of literal meaning by a sustained ambiguity resolved in a long-awaited key-work, and the unifying all-embracing artifice of rhythm.

Market Metaphors for Meeting Mates
Aaron Bernard, Northwestern University
Mara B. Adelman, Northwestern University

Metaphors are linguistic systems that shape our understandings and actions even to the recesses of our most intimate lives. No where are these metaphors more apparent than in the voice of singles reflecting upon the process of meeting a mate. This paper presents findings drawn from current or former users of an introduction service for professional singles searching for a lifelong partner. Content analysis of 27 in depth (1-3 hour) interviews with adult singles reveals two dominant types of metaphors. 1) *Practical: Courtship as a Market Phenomenon*. This metaphor stresses social exchange in which each individual attempts to maximize their own utility. Exchange within romantic dyads includes both tangible assets such as financial resources, and intangible assets such as love and respect. The process of attracting a mate is seen in terms of "marketing", while the process of searching for a mate is seen in terms of "shopping" and consumption. Prospective mates are therefore seen as types of products. This contemporary market metaphor is individualistic and sees marriage solely as a means to personal fulfillment. 2) *Romantic: Love as a Physical Force*. This metaphor is similar to the classic literary conception of love as a supernatural force (e.g. magic). The contemporary metaphor however is naturalistic and sees love as "chemistry" or "electricity" between two people.

Most singles recognized the importance of both "chemistry" and exchange within their romantic relationships. Each system of metaphors was applied in a different context in order to highlight a particular aspect of the respondents relations with the opposite sex. Most respondents valued the freedom from familial or community obligations that the individualistic outlook of the market metaphor provided. However, many respondents also questioned either individualism and/or the market metaphor as an appropriate perspective for interpersonal relationships. These respondents feared that it precludes non-contingent giving and promotes adversarial attitudes. While respondents generally mentioned the importance of "chemistry" in relationship formation, several respondents expressed skepticism regarding such romantic notions as "if two people are meant to be together, they will meet without working at it". Apart from this sample, content analysis of popular press reporting on traditional dating and dating services are used to illustrate and provide a wider cultural context for the findings of the study.

Effects of Self-Reflection on Attitudes and Consumer Decisions

Timothy D. Wilson, University of Virginia

Douglas J. Lisle, University of Virginia

Dolores Kraft, University of Virginia¹

ABSTRACT

Asking people to explain their attitudes has been found to lead to temporary attitude change. In the first part of this paper, the implications of this finding for attitude theory are discussed. We argue that attitudes are best viewed as the result of a constructive process, dependent on what is currently salient to people, rather than as unitary, stable constructs. In the second part of the paper, the implications of our findings for consumer decisions are discussed. We report the results of studies showing that under some circumstances, asking people to explain why they feel the way they do about the alternatives reduces the quality of their decisions.

Traditionally, attitudes have been viewed as evaluations that are relatively stable over time. For example, Petty and Cacioppo (1981) defined an attitude as an "enduring positive or negative feeling about some person, object, or issue" (p. 7). This can be referred to as the file drawer analogy of attitudes. That is, when people are asked how they feel about something, such as George Bush, a brand of laundry detergent, or the city of New Orleans, presumably they consult some sort of mental file. After examining the contents of the file marked, "Bush" or "Tide" or "New Orleans," they report how they feel. The contents of these "files" can be changed by personal experiences, persuasive messages, and the like, but for the most part they are enduring evaluations that remain unchanged.

In contrast, some have argued that people do not have a single, fixed attitude. Instead, people's views are said to vary depending on such factors as the context in which they are asked, the situation they are in, what else they are thinking about, and the values that are currently salient to them (e.g. Shavitt 1989; Tesser 1978; Zanna and Rempel 1988). We might refer to this as the "slide rule" analogy of attitudes, where people's views slide up and down an attitude scale from time to time. This is *not* to say that people are like chameleons, changing their attitudinal colors from one extreme to the other at the spur of the moment. People are unlikely to say that they love George Bush on one occasion, only to say they hate him 10 minutes later. Instead, the "slide rule" view is similar to one espoused by social judgment theory nearly 30 years ago (Sherif and Hovland 1961). People are said to have a range of positions that they view as acceptable. People will rarely, if ever endorse positions outside of this latitude of acceptance.

Their attitude within this latitude of acceptance, however, might vary from time to time.

We will discuss a program of research that is consistent with this "slide rule" view of attitudes. Our view is similar to one proposed by Tesser (1978):

The standard paradigm . . . assumed that individuals have a *single attitude* toward the object. We have argued, however, that one's attitude at the moment is a constructive process generated from the *particular* schema tuned in. . . A different schema will make different cognitions salient and hence result in a different attitude. (p. 324; emphasis in original)

Viewing attitudes as a constructive process raises a key question: What determines the attitude people will have at any given point in time? Following Tesser (1978), we suggest that this depends largely on the thoughts about the attitude object that are salient at the time people are asked for their opinion (for a similar argument, see Salancik 1974 and Seligman, Fazio, and Zanna 1980). If someone has just seen a news conference in which George Bush was particularly effective, their attitude is likely to be at the positive end of their latitude of acceptance. If they have just seen him call September 7th Pearl Harbor Day, it is likely to be at the negative end.

Interestingly, it is not only external events such as news conferences that influence the availability of our thoughts about an attitude object. Sometimes our own self-reflections can influence this as well. For example, Tesser (1978) has demonstrated that simply asking people to think about the attitude object causes them to report a more extreme attitude (in the direction of their initial position) than they normally would. This polarization effect is especially likely to occur if people have a well-developed set of beliefs about the attitude object that are evaluatively consistent (Chaiken and Yates 1985; Millar and Tesser 1986). The reason for this appears to be that when such people spend time thinking about an attitude object, the thoughts that are likely to come to mind are those that are consistent with their initial position. Due to the increased salience of these thoughts, people's attitudes become more extreme.

It may be, however, that other kinds of thought do not necessarily bring to mind beliefs that are consistent with one's initial position. For the past several years we have been investigating a form of self-reflection that seems to fit this bill: Asking people to think about why they feel the way they do about an issue or object. We have found that asking people to explain their attitudes can

¹This work was supported by grant MH41841 from the National Institute of Mental Health.

produce attitude change, sometimes in the direction of the initial attitude and sometimes not.

We have developed the following set of arguments to explain these findings. (For a more detailed discussion, see Wilson in press and Wilson, Dunn, Kraft, and Lisle 1989.) When asked to explain an attitude, people come up with reasons that are available in memory and which seem like plausible causes of their attitude. Sometimes, however, those reasons that are available and plausible are incorrect or incomplete. One reason for this is that rational cognitions about the attitude object are, in our culture at least, viewed as the most plausible causes of attitudes, and hence are most available in memory. For example, when explaining why we like various political candidates, we are more likely to call upon such factors as their stance on the issues than such seemingly implausible things as the number of times we have seen their ads on television or whether their party affiliation is the same as our parents', even though these latter factors have been shown to influence people's attitudes. Other factors might be available in memory because they are easy to verbalize or were encountered recently, as in our earlier example of seeing George Bush look particularly effective in a news conference.

As a result of these availability effects, the reasons people bring to mind might imply a somewhat different attitude than they previously held. For example, suppose that a person has a generally favorable attitude toward Candidate X. When asked to explain why she likes this candidate, however, what comes to mind is that he looked worn and ineffective during a recent debate, and that his position on the death penalty is at variance with her own. What will happen? We have found in several studies that people adopt the attitude implied by their reasons (see Wilson, Dunn, Kraft, and Lisle 1989). Thus, if we asked this person how she felt about Candidate X she would be likely to report a somewhat negative attitude, at least more negative than if she had not focused on why she felt the way she did.

Two important points should be noted about the attitude change that results from analyzing reasons. First, unlike the results of mere thought about the attitude object (Tesser 1978), it can be difficult to predict the direction of this change. The kinds of reasons that are available in memory for one person might be primarily negative, leading to change in a negative direction. The reasons that are available to another person might be primarily positive, resulting in change in the opposite direction. We found this to be the case in a recent study of political attitudes (Wilson, Kraft, and Dunn 1989). Subjects who analyzed reasons were more likely to change their attitudes toward political candidates, but this change was not in a common direction. Subjects who listed negative reasons tended to change their attitudes in a negative direction, whereas subjects who listed positive reasons tended to change in a positive direction. (Incidentally, subjects in this study, as in most of

the ones we have conducted, were asked to list their reasons privately and anonymously to "organize their thoughts." Subjects believed that no one would ever see what they wrote, which reduces the plausibility of self-presentational or demand characteristic interpretations of the results.)

The second point is that analyzing reasons is most likely to cause attitude change in subjects who are relatively unknowledgeable about the attitude object (Wilson, Kraft, and Dunn 1989) or who have relatively inaccessible attitudes (Wilson and Pollack 1989). One reason for this, we suspect, is that unknowledgeable people often have more conflicting beliefs about the attitude object than do knowledgeable people (Lusk and Judd 1988; Wilson, Kraft, and Dunn 1989). As a result they should be more susceptible to the sort of availability effect we have described. That is, if a person's beliefs are entirely consistent, any belief that comes to mind will imply the same attitude. If their beliefs are inconsistent, however, it is more likely that the subset that come to mind will imply a new attitude.

We should note that this argument is the mirror image of Tesser's (1978) concerning the effects of thought on attitudes. He has demonstrated that mere thought will polarize attitudes when people have a set of consistent beliefs about the attitude object (see also Millar and Tesser 1986). In contrast, we have shown that asking people to *explain* their attitude causes attitude change in people with relatively *inconsistent* beliefs about the attitude object (Wilson, Kraft, and Dunn 1989).

To this point we have focused on the implications of our work for the definition of attitudes. We believe that people do not have a single attitude stored in a mental file that is the same over time. Like Tesser, Shavitt, and others, we believe that attitude reports involve a more constructive process, and depend in part on the thoughts and beliefs that are salient to people at any given time. What are the implications of this view? Is it an esoteric debate of interest only to attitude theorists, or does it have any practical implications? In the remainder of this paper we hope to show that there are some important implications of our work in the area of consumer behavior.

IMPLICATIONS FOR ATTITUDE-BEHAVIOR CONSISTENCY

One implication of viewing attitudes as a constructive process is that people can be expected to behave consistently with their attitudes only under certain conditions, namely when the same attitude is elicited when people report their attitudes as when they behave toward the attitude object. For example, if people say they prefer a certain brand of soft drink, does this necessarily mean that they are more likely to purchase that brand than others? Only if the attitude constructed at the time they reported their preference is the same attitude constructed when they are standing in the soft drink aisle of the supermarket. As seen in the papers by Shavitt and Tesser, there are a number of circumstances under which the attitude that is salient

to people when they report their feelings is different from the attitude that is salient when they behave, resulting in low attitude-behavior consistency.

One such circumstance is the kind of self-reflection we have investigated, where people are asked to explain their attitude before reporting it. We have shown in a number of studies that people who reflect about their attitudes in this way exhibit significantly lower attitude-behavior consistency than people who do not (see Wilson, Dunn, Kraft, and Lisle 1989 for a review). One reason for this finding is as follows: As argued earlier, when people analyze reasons a new attitude often becomes salient, leading to attitude change. This attitude change, however, does not appear to be particularly long lasting. Indeed, it would be rather surprising if a permanent change in people's attitudes could be brought about simply by asking them to explain why they felt the way they did. Instead, over time people's original attitude seems to "snap back."

If so, then the attitude people report after analyzing reasons is likely to be different than their behavior toward the attitude object, as long as the behavior occurs after people's original attitude has snapped back. Consistent with this hypothesis, we have found that if people behave toward the attitude object immediately after analyzing reasons, then their behavior is consistent with their new attitude. If enough time passes, however, people's behavior seems to be consistent with their original attitude and inconsistent with the attitude they reported after analyzing reasons (see Wilson, Dunn, Kraft, and Lisle 1989). These findings are of some importance to survey researchers who hope to measure people's attitudes toward a product, with the hope that these attitudes will predict their consumer behavior. People's attitudes may not predict behavior if they are asked to explain these attitudes before reporting them.

IMPLICATIONS FOR PEOPLE'S SATISFACTION WITH CONSUMER DECISIONS

Recently we have examined the implications of our work for how people make consumer decisions. As a starting point, we assume when people are left to their own devices, they often make good personal choices. People are certainly not optimal information processors, but they often manage to assign weights to the different attributes of the alternatives that produce a satisfactory choice (satisfactory to them). People often are not fully aware of how they are weighting the information, we assume, but they often use fairly optimal weights.

If this is true, what happens when people think about why they feel the way they do? Tampering with the decision process by making people introspect, we suggest, can have deleterious consequences by altering how people weight information about the alternatives. When people analyze reasons, we have argued that they focus on those attributes of the attitude object that are available in memory and which seem like plausible causes of their evaluations. As a result, people

might lose sight of which criteria of the alternatives are most important to them.

For example, consider people's preferences for a food product. When people taste the food and decide how much they like it, they might be influenced by attributes of which they are unaware (e.g., an unknown ingredient) or that are difficult to verbalize (e.g., its texture or aroma). When asked to explain their reactions, they may assign less weight to these factors because they are difficult to put into words, and as a consequence change their preferences. Assuming that their original preference was fairly optimal, this change in weights might lead to a less optimal choice.

But what do we mean by a "satisfactory" or "optimal" choice? As noted by Janis and Mann (1977), it is very difficult to evaluate how good a decision is. We have dealt with this problem by including several different measures of decision quality, including how well people's opinions of the alternatives match the opinions of experts in that domain, the correspondence between the criteria people use to make their decision and the criteria advocated by experts, and, most directly, how satisfied people say they are with their decision. We will briefly discuss some studies we have conducted to test the hypothesis that at least under some circumstances, introspecting about reasons can lead to poorer decisions.

Comparing People's Attitudes to Expert Opinion

In one study, we compared the preferences of subjects toward a food item--strawberry jams--with the opinions of sensory panelists from *Consumer Reports Magazine* (Wilson, Lisle, and Schooler 1989). Subjects tasted five different brands. Half of the subjects analyzed why they liked or disliked each alternative, whereas half did not. All subjects then rated how much they liked each brand. We suggested earlier that left to their own devices, people often make reasonably good consumer decisions. Consistent with this hypothesis, the ratings made by control subjects corresponded fairly well with the experts' ratings, resulting in a mean, within-subject correlation of .55. We have also suggested that trying to explain one's attitudes can influence the salience of certain attributes of the attitude object, causing people to change their evaluations. This prediction was also borne out, in that subjects who analyzed reasons ended up with significantly different preferences for the jams than did control subjects. Finally, consistent with our hypothesis that these preferences would be in some sense "worse," the ratings made by subjects who analyzed reasons did not correspond with the experts very well, mean correlation = .11. The difference between the mean correlations in the control and reasons conditions was significant.

Choosing College Courses

The jam study examined people's preferences, without asking them to make an actual consumer decision. In another study we examined a real-life

choice of some importance to college students: The decision of which courses to take (Wilson 1989). We evaluated students' choices in a variety of ways. For example, we compared the criteria they appeared to use to the opinions of faculty members as to what criteria *ought* to be used when choosing a course, plus we saw who was most likely to take the courses most highly rated by students: Those who introspected about the alternatives or those who did not.

A sample of introductory psychology students, who had expressed an interest in taking more psychology classes, were seen at the beginning of the week when they registered for classes for the next semester. They were given a packet of information about each of the nine sophomore level psychology classes being offered the next term. This packet contained such information as a description of the course content, student evaluations of the course, and whether or not a term paper was required. After reading through this information, some subjects were asked to describe why they might or might not take each course. To see if other kinds of reflection are equally disruptive, a second introspection condition was included: Some subjects were asked to rate each and every piece of information they received about each course according to whether it made them more or less likely to take that course. The remaining subjects were in a control condition, where they did not receive any special instructions about how to approach the course information.

The chief dependent measures were subjects' ratings of how each type of information had influenced their decision of which courses to take, their memory for the different information about the courses at the end of the session, and the courses they actually registered for and took the next semester. As predicted, introspecting about the courses seemed to change how subjects used the information about the courses (subjects who analyzed reasons and subjects who rated each piece of information responded similarly, thus for present purposes the results will be collapsed across these conditions). Subjects in the introspection conditions reported using different kinds of criteria and recalled different kinds of information about the courses than did control subjects. Further, they registered for different types of courses than control subjects.

Who is to say which group made the "right" choices? Though it is impossible to tell, there was suggestive evidence that it was control subjects and not those in the introspection conditions. First, subjects in the control condition were significantly more likely to register for and take courses that received high course evaluations (see Table 1). As another way of assessing how good subjects' choices were, we gave a list of the information our subjects received to a sample of faculty members in psychology, and asked them to rate how much students ought to weight each piece of information, in order to make the best choice. These ratings by the "experts" were then correlated with the actual

subjects' ratings of how much they had used each type of information, as well as their recall of the information. Again, it was the control subjects who came out best on these measures: Both correlations were significantly higher in the control condition than in the introspection conditions (see Table 2). What appears to have happened is that subjects who introspected lost sight of which criteria (e.g., the course evaluations) were most important, and relied more on criteria that were, at least according to faculty members, not as valuable.

Post-Choice Satisfaction With Consumer Choices

The results of the first two studies suggest that analyzing reasons changes the criteria people use to evaluate alternatives. These studies are at least suggestive of the possibility that the criteria used by people who introspect are not as "good," leading to worse decisions. But will people themselves be dissatisfied with these choices? On the one hand they might not, because several studies have found that whatever alternative people choose, they will become more favorably disposed toward it in order to reduce dissonance (e.g. Brehm 1966). On the other hand there are probably limits to this kind of dissonance reduction (to illustrate this, one need only refer to the high rate of divorce in this country!).

There are two reasons why people who introspect might regret their choices more than those who do not. First, if people who introspect end up choosing inferior alternatives, such as poorly-rated jams, then they should not be as satisfied with these choices as people who do not introspect. Second, we argued earlier that the attitude change produced by analyzing reasons is temporary, and snaps back over time. If so, people should come to regret a choice they made immediately after analyzing reasons, because their initial, pre-introspective attitude has returned.

Two studies have been performed to test these hypotheses (Wilson, Lisle, and Schooler 1989). In the first study, subjects were presented with five art posters and allowed to choose one to take home. Two of the posters were reproductions of Impressionist paintings, and were very popular with our student population, according to our pretesting. The remaining three were contemporary posters of a style we can only call "cute," such as a photograph of a cat perched on a rope with the caption, "Gimme a Break." They were considerably less popular with our pretest subjects. Half of the subjects were asked to write down why they felt the way they did about each poster, supposedly to organize their thoughts. The other half completed a filler questionnaire of equal length. All subjects then rated the posters and chose one to take home. The experimenter left the room while the subject chose a poster from bins containing several of each type; thus, in the minds of the subjects, the experimenter would not know which one they took.

As in our other studies, analyzing reasons seemed to change the criteria subjects used to

evaluate the posters. Subjects who did not analyze reasons overwhelmingly preferred the Impressionist paintings: As seen in Table 3, virtually everyone chose one of these posters to take home. Subjects who analyzed reasons, however, were significantly more likely to choose one of the contemporary posters. Having to explain their attitudes seems to have increased the salience of positive features of the contemporary posters, in that subjects listed more positive than negative attributes of these posters. What happened after people took their posters home? We telephoned them 3 weeks later to find out. As predicted, and as seen in Table 3, subjects in the reasons condition reported a lower satisfaction with their choice of poster, possibly because their initial attitude--that the Impressionist paintings were preferable--had by then returned.

According to our prediction, it should only be people who convinced themselves they liked the unpopular, contemporary posters who should come to regret this choice later. As seen in Table 3 there was a tendency in this direction, in that the

difference in post-choice satisfaction between reasons and control subjects was greater among those who chose a contemporary poster than those who chose an Impressionist poster. The interaction between condition and poster choice, however, was not significant. One reason for this might be that the control condition/contemporary poster cell was represented by one person, making this value highly unreliable. We replicated the poster study with a new stimuli, felt-tip pens, and found results that were more consistent with our hypothesis. The people who were least satisfied with their choice of a pen were those in the reasons condition who convinced themselves that they liked the one that was rather unpopular, and chose to take it home. When asked later how much they liked it, their original attitude seemed to have returned, making them relatively unhappy with their choice.

CONCLUSIONS

Viewing attitudes as the result of a constructive process, dependent on the thoughts that

^aSubjects were asked whether they still had the poster, whether they had hung it up, and whether they planned to take it home with them at the end of the semester. They received a zero if they said no to these questions and a one if they said yes. The satisfaction index is the sum of their three responses.

are salient to people at any given moment, has some interesting implications for consumer behavior. We have found that asking people to explain their attitudes changes their preferences, presumably by influencing the salience of different attributes of the attitude object. Further, we have shown that this type of self-reflection can lower the quality of people's choices. We should, however, add some caveats to our findings. First, we are not suggesting that all kinds of reflection should be avoided, or even that people should never analyze the reasons for their feelings. In most of our studies people are asked to make off-the-cuff, fairly brief explanations of their attitudes, and it is possible that a more in depth kind of reflection, such as that advocated by Janis and Mann (1977), will have very different effects on the quality of people's decisions. Further, there are times when people make decisions too impulsively, and would benefit from a more measured, reflective approach to the decision. We have just begun to explore the conditions under which people should and should not introspect about the reasons for their preferences. Perhaps the best conclusion at this point is a variation of Socrates oft-quoted statement that the "unexamined life is not worth living." We suggest that at least at times, the unexamined choice *is* worth making.

Attitudes and Behavior: The Cognitive-Affective Mismatch Hypothesis

Murray G. Millar, University of Wisconsin-Parkside
Abraham Tesser, University of Georgia

ABSTRACT

Thought about one's attitudes has inconsistent effects on the attitude-behavior relationship: Sometimes thought increases the correlation between attitudes and behaviors and sometimes thought decreases the correlation between attitudes and behaviors. One way to understand this inconsistency is to assume that the attitude reports are based on whatever aspect of the attitude is salient when the report is given. If affect is salient, then the attitude report will reflect one's feelings about the attitude object. If cognitions are salient, then one's attitude report will reflect one's beliefs about the attitude object. In short one's self-reported attitude will differ as a function of what is salient. At the same time, one's behavior may be more or less affectively or cognitively driven. Consummatory behaviors, behaviors that are engaged in for their own sake, are likely to be affectively driven. On the other hand, instrumental behaviors, behaviors intended to accomplish a goal which is independent of the attitude object, are likely to be cognitively driven. Thus, if one's affect is salient when the attitude report is given, then the attitude report will do a better job of predicting consummatory behaviors than instrumental behaviors; If one's cognitions are salient when the attitude report is given, then the attitude report will do a better job of predicting instrumental behaviors than consummatory behaviors. Evidence for these hypotheses was reviewed, and the implications of this work for a definition of attitude are discussed.

THE COGNITIVE-AFFECTIVE MISMATCH HYPOTHESIS

The effects of thought on both attitudes and the attitude-behavior relation has received considerable research attention (e.g., Carver & Scheier, 1981; Fazio, Chen, McDonel, & Sherman, 1982; Tesser, 1978; Wilson, Dunn, Kraft, & Lisle, 1989). In this research thought prior to an assessment of an attitude has produced inconsistent effects on the attitude-behavior relationship. That is, sometimes thought increases the correlation between attitudes and behaviors and sometimes thought decreases the correlation between attitudes and behaviors. In a series of recent studies, Wilson and his colleagues (e.g., Wilson & Dunn, 1986; Wilson, Dunn, Bybee, Hyman, & Rotondo, 1984; Wilson, Kraft, & Dunn, 1987), have amassed considerable evidence that thought prior to an assessment of an attitude decreases the attitude's ability to predict behavior. For example, Wilson et al. (1984) required half of his participants to analyze their reasons for liking five puzzles, and the other half were not given any instructions. The participants' attitudes expressed subsequent to this procedure were correlated with behavioral measures

of liking. The correlation between attitudes and behavior in the thought group was significantly lower ($r = .17$) than in the no-instruction group ($r = .54$).

Wilson et al. (1989) has explained this effect by suggesting that thinking about reasons causes persons to change their minds about how they feel, but does not change their behavior. Wilson's explanation suggests that when persons are asked to explain their feelings they feel compelled to generate reasonable sounding answers despite the fact they often do not know exactly the reasons for their feelings. Consequently, the reasons generated may be incorrect or only a biased subset of the actual reasons underlying their attitude, i.e., persons will tend to produce reasons easiest to verbalize or most available in memory. When persons are required to state their attitudes subsequent to this process they are influenced by this biased set of reasons and change their attitude in the direction of the biased sample. On the other hand, according to Wilson, the biased set of reasons has only a short term effect on behavior. That is, the person's behavior is initially influenced by the biased set then "snaps back" to the person's original position as the person's affective response reasserts itself.

In contrast to Wilson's findings, other research has suggested that thought about an attitude increases its ability to predict behavior. For example, Wicklund (1982) in his work on self-awareness, suggested that persons who are focused on themselves (i.e., presumably thinking about their internal feelings) have better access to their attitudes than persons who are not self-focused. Wicklund, unlike Wilson et al., predicted that highly self-focused persons should be less likely to be misled about their "true" attitude. Consequently, their attitudes should be good predictors of their behavior. Consistent with Wicklund's hypothesis Scheier, Buss, and Buss (1978) have found that persons dispositionally high in self-awareness exhibit higher attitude-behavior correlations than do persons low in self-awareness. Also Pryor, Gibbons, Wicklund, Fazio, and Hood (1977) reported higher attitude-behavior correlations for persons in the presence of a mirror (high self-awareness) than for persons in the absence of a mirror. Similarly, Snyder has argued and found evidence that instructing persons to think carefully about an attitude increases the attitudes ability to predict behavior (Snyder & Kendzierski, 1982; Snyder & Swann, 1976). Snyder suggested that thought operates to increase both the accessibility and strength of that attitude.

Even research that used a research paradigm similar to that used in Wilson's work has produced conflicting results. For example, Fazio, Zanna, and Cooper (1978), who used the same puzzles as

Wilson et al. (1984), had participants view other people performing the puzzles. One half were asked to think about how they would feel about each type of puzzle, and the other half were not given these directions. After this procedure, all of the participants were given a 15 minute play period to work on the puzzles. The attitudes of the participants who were asked to think about the puzzles were better predictors of play period behavior than were the attitudes of those not asked to think about their feelings.

Attitude Components and Thought

In order to reconcile these conflicting findings, we (Miller & Tesser, 1986, 1989) examined the relationship between thought and the different attitude components. Although, there is no universally agreed upon definition of the attitude construct, attitudes are usually conceptualized as multi-component entities (e.g., Kramer, 1949; Ostrom, 1969; Thurstone, 1928). We regard attitudes as encompassing a global evaluation based on both cognition and affect (see Zanna and Rempel (1988) for a similar conceptualization). The cognitive component is generally conceived of as containing the encoding of attributes and beliefs about the attitude object and the affective component of the attitude as containing the encoding of emotions and feelings associated with the object (Fleming, 1967). Considerable theoretical and empirical support for this dichotomy between cognition and affect has been offered by Zajonc (1980, 1984), Breckler (1984), and Breckler & Wiggins (1989)

It was our contention that attitude reports (global evaluations) are based on whatever aspect of the attitude is salient when the report is given. If affect is salient, then the attitude report will reflect one's feelings about the attitude object. If cognitions are salient, then one's attitude report will reflect one's beliefs about the attitude object. Thought prior to making an evaluation has the potential to make either the affective or cognitive component of the attitude salient and more important in the global evaluation. For example, Wilson's procedure of requiring persons to think about reasons for liking or disliking an object would tend to make the cognitive component of the attitudes salient, i.e., beliefs about the object's attributes would be salient. Alternatively, requiring persons to think about the feelings they experience in the presence of the object would make the affective component of their attitude salient. Consequently, if the affective and cognitive components of an attitude are not in perfect evaluative agreement, it is possible for thought to produce different attitude reports about the same object.

Attitude Components and Behavior

In addition, we proposed that the decision to engage in a behavior may be based more or less on the cognitive or affective component of the attitude rather than a global evaluation. That is, some

types of behavior may be more cognitively driven and other types more affectively driven. There are probably a number of dimensions that would make either the attributes of the object or the feelings the object evokes more important in directing behavior. For the present work we distinguished between instrumental and consummatory behaviors. Behaviors intended to accomplish a goal which is independent of the attitude object (instrumental behavior) are likely to be cognitively driven. For example, a person who performs a puzzle in order to develop analytic ability would primarily be interested in various attributes of the puzzle and how they affect analytic ability, not how the puzzle makes him or her feel. Alternatively, behaviors engaged in for their own sake (consummatory behavior), are likely to be affectively driven. For example, a person who performs a puzzle simply to please himself, should be primarily interested in how the puzzle makes him feel, not in the attributes of the puzzle.

Mismatch Hypothesis

Since one's global evaluations or attitude report can be more or less influenced by the affective or cognitive component and since behavior can be more or less driven by the affective and cognitive components, it was hypothesized that a match between the attitude component emphasized by thought and the attitude component driving behavior would lead to a strong attitude-behavior relation and a mismatch between components would lead to a weak attitude-behavior relation.

When the previous literature dealing with the effects of thought on the attitude-behavior relation is reexamined within this framework, many of the apparently contradictory findings can be resolved. The reasons-analysis procedure used by Wilson made the cognitive component of the attitude salient, producing global evaluations based on this component, whereas the puzzle-playing behavior in Wilson's free-play situation was probably a consummatory behavior (i.e., there was little instrumental value in playing the puzzles). The mismatch between the attitude component influencing the global evaluation and the component-driving the behavior resulted in lower attitude-behavior correlations. Alternatively, the directions of Fazio et al. (1978) to concentrate on feelings probably made the affective component salient when the global evaluation was formed, whereas the puzzle-playing behavior remained a consummatory behavior. The match between the attitude components driving the behavior resulted in higher attitude-behavior correlations.

Millar and Tesser (1986) performed a preliminary test of the mismatch hypothesis by measuring the relationship between attitudes formed after either an affective or cognitive focus procedure and behavior performed under instrumental and consummatory conditions. It was expected that attitudes formed when affect was salient would predict consummatory behavior better than instrumental behavior and alternatively attitudes

formed when cognition was salient would predict instrumental behavior better than consummatory behavior.

To test this participants were informed that the purpose of the study was to evaluate the effectiveness of five types of analytic puzzles that were designed to increase analytic ability. To create instrumental behavior conditions half the participants were informed that at the end of the study they would be receiving a test of their analytic ability. Participants in the instrumental conditions should view work on the puzzles as a way to improve their performance on the upcoming test, i.e., they had a goal independent of the attitude object. To create consummatory behavior conditions the other half of the participants were informed that they would receive an unrelated test of their social sensitivity. Participants in the consummatory conditions should not have this motive and engage in the behavior for its own sake. After five minutes to familiarize themselves with the puzzles, both groups were required to report their attitude about each of the five puzzles. During this five minute period, one half of the participants were given the reason-analysis directions that required the participants to analyze why they felt the way they did about each of the puzzles types. These directions were similar to those used by Wilson et al. (1984) and were designed to make the cognitive component of the attitude salient. The other half received affective-analysis directions that required the participants to analyze how they felt while performing each type of puzzle. These directions were designed to make the affective component of the attitude salient. Finally, all of the participants were given a seven minute free-play period to work on any of the puzzles they desired. During this period three behavioral measures were recorded: the time they spent working on the puzzles in the free-play period, the order in which they choose the puzzles, and the proportion of each type of puzzle they attempted.

The results provided strong support for the hypothesis. Three indexes of attitude-behavior consistency were constructed by computing the rank-order correlation of each participant's evaluation of the puzzles with the three behavioral measures. When these within subject correlations were analyzed within an analysis of variance framework the predicted interaction between the type of thought prior to the attitude report (affective vs. cognitive) and the type of behavior performed (instrumental vs. consummatory) was obtained. Thought emphasizing the affective component produced attitude reports that predicted consummatory behavior (affectively driven behavior) better than instrumental behavior (cognitively driven behavior). Alternatively, thought emphasizing the cognitive component produced attitude reports that predicted instrumental behavior better than consummatory behavior.

Moderating Role of Affective-Cognitive Consistency

Having obtained preliminary support for the model a further investigation was conducted to examine the moderating role of affective-cognitive consistency in the relationship between global evaluation and behavior (cf. Norman, 1975; Rosenberg, 1960). From the present perspective, if the affective and cognitive components are in good evaluative agreement then thought emphasizing either component should lead to a similar global evaluation. If this is the case, then global evaluations should relate to consummatory or instrumental behavior in the same manner regardless of what component is made salient by thought. Overall we would expect highly consistent attitudes to predict both consummatory and instrumental behavior uniformly well. On the other hand, if the cognitive and affective components are not in agreement then thought emphasizing different components would lead to different global evaluations. Consequently, if thought operates in the manner suggested by the model, the match and mismatch effects should occur when attitudes are characterized by low affective-cognitive consistency and become attenuated when there is high affective-cognitive consistency.

To test this hypothesis Millar and Tesser (1989) attempted to measure affective-cognitive consistency directly and demonstrate that the match and mismatch effects occur only under low consistency. Each participant was required to familiarize himself/herself with different types of puzzles by performing two examples of each puzzle under affective thought conditions, i.e., think about *how* the puzzle makes you feel, and two examples under cognitive thought, i.e., think about *why* you feel the way you do about the puzzle, conditions. During both the affective focus and cognitive focus, participants were required to write down their responses to the puzzles. These responses were used to produce affective and cognitive liking scores for each type of puzzle and calculate affective-cognitive consistency. In order to manipulate affective and cognitive focus the measurement of affective and cognitive components was conducted so that half the participants finished the procedure with an affective focus and half finished with a cognitive focus. Immediately after this procedure participants were required to evaluate each of the puzzles. Following the evaluation of the puzzles, participants were allowed to play with the puzzles under the instrumental or consummatory conditions described in the first study.

We expected that when affective-cognitive consistency was low there would be an interaction between Focus of Thought and Behavior Type. That is, when there is a match between the attitude component emphasized by thought and the component driving behavior, the evaluation-behavior relation should be strong; when there is a mismatch between the focus of thought and the component driving behavior the relation between evaluation and behavior should be weak.

Alternatively, when affective-cognitive consistency is high this interaction should disappear.

The results provided strong support for the predicted moderating role of affective-cognitive consistency in the attitude-behavior relation. For each participant a measure of affective-cognitive consistency was constructed by computing the rank-order correlation of his/her cognitive liking scores for each type to puzzle to his/her affective liking score for each type of puzzle. When there was low affective-cognitive consistency a match between the attitude component emphasized by thought and the component driving behavior resulted in higher evaluation-behavior correlations than a mismatch between components. Alternatively, when there was high affective-cognitive consistency the match and mismatch effects disappeared.

The results also provide support for the hypothesized relation between liking expressed by the attitude components (affective and cognitive) and behavior type (consummatory and instrumental). As we expected the liking expressed by the affective component tended to predict consummatory behaviors better than the liking expressed by the cognitive component and, alternatively, the liking expressed by the cognitive component tended to predict instrumental behavior better than consummatory behaviors.

Comparison to Cognitization Hypothesis

Wilson and his colleagues (e.g., Wilson & Dunn, 1986; Wilson, Dunn, Kraft, & Lisle, 1989) have also noted the discrepancy between their findings on the effects of thought on the attitude-behavior relation and earlier findings. Similar to our explanation Wilson and Dunn (1986) have argued that discrepancy between the thought procedures used in their work and in earlier work was responsible for the conflicting findings. That is, the reasons analysis procedure used in their work created a cognitive biased attitude whereas the thought procedures used in earlier work did not create a cognitive bias, e.g., the procedure used by Fazio, Zanna, and Cooper (1978) that required participants to think about how they feel. In Wilson's explanation if thought fails to produce a cognitive bias it will also fail to change the attitude and, consequently, the attitude and behavior will remain consistent.

This explanation brings out some important differences between our understanding and Wilson's understanding of the effects of thought on the attitude-behavior relation. Wilson's model focuses primarily on the effect of thought on affective attitudes. That is, the original attitude to be biased by cognition must be affective. Presumably attitudes based on cognition would be less susceptible to obtaining a cognitive bias than attitudes based on affect. In addition Wilson's model focuses primarily on the prediction of affectively driven behaviors. That is, except for a short time when the behavior is influenced by the cognitive bias, behavior is dependent upon the person's affect. Our model, on the other hand proposes that

thought may make salient either affective or cognitive responses to the attitude object, i.e., create either affective or cognitively based attitudes, and that behavior may either be affectively or cognitively driven. Consequently, our model allows us to integrate the effects of thought on both affectively and cognitively based attitudes and behaviors.

Having emphasized the differences it should be said that overall Wilson's and our models are not inconsistent. It seems likely that both processes occur. To distinguish the two processes future research will need to identify the type of attitudes discussed in our model (i.e., attitudes that have both affective and cognitive components) and the type of attitudes discussed in Wilson's model (i.e., attitudes that are affectively based with little or no cognition).

Conclusion

The present model not only allows us to integrate previous attitude-behavior consistency literature but also has important implications for our understanding of the attitude construct. Many researchers have conceptualized attitudes as relatively stable and lasting unitary evaluations (e.g., Ajzen, 1984). In contrast the present conceptualization suggested that at any particular moment, one has the potential for a number different attitudes toward an object. Some will be based on feelings towards the object and some based on beliefs about the object. In addition the present conceptualization emphasized the importance of immediate and changing environmental factors in determining which of the attitudes held about the object is reported. That is, different attitudes may be obtained depending on whether current environmental conditions make affect or cognition salient.

Effects of Attribute Salience on the Consistency of Product Evaluations and Purchase Predictions

Sharon Shavitt, University of Illinois
Russell H. Fazio, Indiana University¹

ABSTRACT

Previous research (e.g., Wilson & Dunn, 1986; Millar & Tesser, 1986) has demonstrated that the context for judging a product can make either affective or cognitive considerations more salient and therefore more important in evaluating that product, and in turn can affect the consistency between product judgments made in different contexts. The present research extends these findings to the specific attribute dimensions relevant to evaluating a product. Our studies examined the consistency between subjects' attitude expressions and their predictions of their purchase behaviors toward a product. The findings demonstrated that, when the attributes that were made salient at attitude expression and at purchase prediction corresponded, the consistency between those judgments was much greater than when the salient attributes did not match. The studies also identified contextual factors as well as product characteristics that heightened the salience of certain attributes when making product judgments. Finally, the results demonstrated that the effect of context on attribute salience was moderated by individuals' predispositions to be influenced by situational factors (i.e., their level of self-monitoring; Snyder, 1974). Implications of these findings for the nature of attitudes are discussed.

INTRODUCTION

Recent research by Wilson and his colleagues (e.g., Wilson & Dunn, 1986; Wilson, Dunn, Bybee, Hyman & Rotondo, 1984; Wilson, Kraft & Dunn, 1989) and by Millar and Tesser (1986, 1989), presented in this session, has demonstrated that variations in the context for judging a product can make either affective or cognitive considerations more salient and therefore more important in evaluating the product. When the evaluations implied by these cognitive and affective aspects differ, one may report differing attitudes toward the product. This in turn can affect the consistency between the product judgments one makes in different contexts.

The present research extends these findings beyond the fundamental distinction between affective and cognitive considerations. It is our contention

that these results have general implications for any attribute dimensions that underlie attitudes. The specific attributes relevant to evaluating a product (e.g., its taste, cost, sophistication) may also vary in salience as a function of the judgment context, and these variations may influence the favorability of one's attitudes. For example, one's self-reported attitude toward caviar may be somewhat unfavorable when attributes relevant to taste or cost are salient, but relatively favorable when the attribute of social sophistication is salient. This suggests that the salience of attribute dimensions should influence the consistency between people's expressed attitudes and their subsequent judgments in a manner that parallels the previous findings. Specifically, if the attribute that is salient at the time of an initial attitude report is not the same as the one that is salient at a subsequent judgment, the correspondence between these evaluative judgments may be relatively low. However, when the salient attributes correspond, consistency should increase. The present studies tested this hypothesis².

These studies also investigated some of the factors that influence which attributes are salient when evaluating a product. In addition to the contextual factors explored in the studies by Wilson, et al. and by Millar and Tesser, other factors were also thought to play a role. For example, the target of the evaluation -- the attitude object or product -- could certainly influence the attributes that are salient when evaluating it. For some items, a given attribute may spontaneously be salient when evaluating the item. When evaluating a candy bar, for example, its taste should normally be a salient attribute. Although it can certainly be evaluated along other dimensions, taste may be regarded as its most relevant attribute, and should spontaneously drive one's general evaluation of the candy bar. On

²It should be noted that mean differences in the attitudes reported in different judgment contexts were not expected in this research (and were not consistently obtained). One would only expect such differences to the extent that subjects consensually evaluated the target product more favorably in terms of one of the salient attributes than the other. If, for example, people generally agreed that the social image associated with caviar was more desirable than its taste, then the heightened salience of its social image versus its taste attribute should produce unidirectional changes in people's general evaluations of caviar. But people may differ in their relative evaluations of caviar along these dimensions, in which case mean differences in attitudes reported as a function of judgment context might not be obtained.

the other hand, when evaluating a product that is perceived to create a particular social impression (e.g., trendy clothing, a gourmet food item), attributes related to that social impression may spontaneously be salient and drive one's general evaluation.

In the absence of any contextual influences, then, evaluations of a product may spontaneously be driven by a particular attribute or set of attributes. For different products, different attributes should be salient and drive one's evaluations. Thus, products themselves can be employed as manipulations of attribute salience. (See Shavitt, 1989, in press, for a similar point regarding the attitude functions typically associated with certain attitude objects.)

The present research employed both product and context manipulations to vary independently the attributes that were salient when two different evaluative judgments were reported. These studies examined the influence of attribute salience on the relation between the attitudes that subjects initially reported toward a product and their subsequently-predicted likelihood of using the product.

STUDY 1

In the first study, 73 paid subjects (recruited through newspaper ads) reported their attitudes and predicted their behaviors toward one of two beverages.

Manipulations: The attribute that was salient at the time that subjects reported their attitudes was manipulated contextually, via an initial questionnaire intended to heighten the salience of one of two attribute dimensions, taste or social impressiveness. On the taste questionnaire, subjects rated 20 different food items (e.g., marshmallows, lima beans, chocolate milkshake) in terms of "how good they taste to you." Each item was rated on a 5-point scale, with 5 being "very good tasting" and 1 being "not at all good tasting." On the social impressiveness questionnaire, subjects rated 20 different actions (e.g., winning a tennis game, quitting your job, driving a BMW car) for "the extent to which your doing each of these things would make a good impression on others." These ratings were also made on a 5-point scale, with 5 being "will make a very good impression" and 1 being "won't make a good impression at all."

The attribute that was salient when subjects later predicted their behaviors was manipulated by varying the target product. The two beverage products used in this study, Perrier mineral water and 7-Up, were expected to differ in terms of the attributes that would spontaneously be salient when evaluating them (after the impact of the questionnaire manipulation had dissipated). 7-Up was expected to be evaluated typically on the basis of its taste. In contrast, it was thought that Perrier, because of its association with trend-conscious, upwardly-mobile consumers, was likely to be evaluated in terms of its social impressiveness.

It was predicted that the correlation between subjects' reported attitudes and their behavior predictions would be high when there was a match

between the attribute whose salience was manipulated at attitude assessment and the attribute expected spontaneously to be salient for the target beverage (i.e., Taste/7-Up or Social Impressiveness/Perrier). On the other hand, when these attributes did not correspond (Social Impressiveness/7-Up or Taste/Perrier), the correlation was expected to be low.

Procedure: Immediately after completing one of the two questionnaires (taste ratings or social impressiveness ratings), subjects reported their general attitude toward one of the two beverages on a 9-point scale (very favorable/very unfavorable). After a delay of several minutes, during which subjects filled out some other measures, they predicted their likelihood of buying or drinking the target beverage in four different situations, such as the following:

"You are having lunch at a sandwich shop that is offering a free beverage with the purchase of a sandwich. How likely would you be to order a Perrier [7-Up] as your free beverage?"

Subjects made their predictions on a 5-point scale, with 5 being "I would definitely choose it" and 1 being "I would definitely not choose it." A similar 5-point scale was used to predict one's behaviors in three other scenarios, which involved taking the beverage to the beach in a cooler, redeeming a coupon, and buying it at the supermarket.

Finally, subjects responded to checks on the types of attributes that were assumed spontaneously to underlie their evaluations of the target beverage.

Results: Subjects' responses on the attribute checks supported our assumptions about the attributes that typically underlie attitudes toward these beverages. Furthermore, as expected, when the attribute that was salient at attitude assessment (the attribute in the questionnaire) corresponded with the attribute that was salient at purchase prediction (the attribute associated with the target beverage), the correlation between subjects' attitude reports and their purchase predictions was substantially larger than when those attributes did not match (see Table 1). The interaction of questionnaire type and target beverage, representing this effect, was significant at $p < .05$ (see Steiner & Darroch, 1969, for the test of an interaction effect on correlation coefficients).

Conclusions: These findings suggest that one's evaluative judgments of a product can vary -- even within a short time frame -- as a function of what attribute is salient when the judgment is made. The results provided evidence that the salience of product attributes influenced the consistency between one's product judgments. Paralleling the studies by Wilson, et al. (1984, 1986, 1989) and by Millar and Tesser (1986, 1989) on the salience of affective versus cognitive factors, a match in the salience of specific attributes was associated with a greater correlation between attitude reports and behavioral

TABLE 1
Study 1: Correlations between Attitude and Mean Purchase Prediction

	<u>Attribute Salient at Attitude Expression</u> (Questionnaire Attribute)	
	<u>Taste</u>	<u>Social Impressiveness</u>
<u>Target Product:</u> (Attribute salient at purchase prediction)		
Seven-Up (taste)	.88 _a	.36 _b
Perrier (social impressiveness)	.46 _b	.87 _a

Note: Each correlation is based on approximately 18 cases. Correlations with the same subscript are not significantly different at $p < .05$. 2 X 2 interaction of correlations was significant at $p < .01$ (one-tailed).

Attitudes were rated on a 9-point scale with 9 being "very favorable."

The purchase prediction score was the average of subjects' predictions, over four separate situations, of their likelihood of buying or drinking the target brand. Each rating was made on a 5-point scale with 5 indicating the greatest willingness to buy or drink the brand. The four purchase predictions were highly intercorrelated ($r = .78$ to $.80$, coefficient alpha = .93).

judgments, as compared to conditions in which the salient attributes did not correspond.

The results also suggested that both contextual factors and product factors can influence the salience of product attributes. For some products, a given attribute may spontaneously be salient when a product evaluation is made. Which attribute(s) tend to be salient, and to drive one's judgments, can differ from product to product. A number of measures suggested that, as expected, such differences existed for the two beverage products employed in this study. The results also indicated that contextual factors could heighten the salience of particular attributes and temporarily increase their impact on reported attitudes toward these products.

However, one might expect the impact of such contextual factors to be moderated by other important factors. For example, certain personality characteristics, such as a high level of self-monitoring (Snyder, 1974), may predispose individuals to be affected by the contextual salience of dimensions. High self-monitors, who strive to fit into different social situations, are sensitive to situational cues, and their attitudinal and behavioral expressions are typically responsive to such cues (see Snyder and DeBono, 1989). Also, Kardes, Sanbonmatsu, Voss, and Fazio (1986) have shown

that the attitudes of high self-monitors are less accessible from memory than those of low self-monitors. All of this suggests that high self-monitors may lack strong, pre-existing attitudes to guide their responses. As a result, their responses may be more influenced than those of low self-monitors by whatever attributes are salient in a situation. Thus, the correspondence of those salient attributes may have a bigger impact on the relation between their product judgments.

Furthermore, high self-monitors may tend to be more concerned with certain attributes than with others. Recent research by Snyder and DeBono (1985, 1989) suggests that the product attitudes of high self-monitors reflect a greater concern with social image than the product attitudes of low self-monitors. This suggests that a manipulation that increases the salience of a product's social impressiveness may have stronger effects for high than for low self-monitors.

In the next study, we sought to replicate the present findings on the role of attribute salience in the consistency of product judgments, and to explore the potential moderating effects of self-monitoring.

STUDY 2

In this study, 123 introductory psychology students reported their attitudes and made purchase predictions regarding one of two powdered drink mixes.

Manipulations: The attribute that was salient at attitude assessment was manipulated via the same initial questionnaires used in the previous study (taste vs. social impressiveness ratings). There was also a control (no attribute rating) condition, in which subjects completed a filler questionnaire.

The attribute that was salient when subjects predicted their behaviors was varied by having subjects respond to one of two new target products, Wyler's Lemonade Mix or Kool-Aid Drink Mix. The attribute of taste was expected spontaneously to drive evaluations of Wyler's Lemonade Mix. In contrast, it was thought that Kool-Aid, because of its strong image as a product for young children, was more likely to be evaluated in terms of the social impressions elicited by drinking it.

Procedure: Immediately after completing one of the three questionnaires (taste vs. social impressiveness vs. control), subjects reported their general attitude toward one of the two drink mixes. After a delay of several minutes, in which subjects filled out some other measures, they predicted their likelihood of buying or drinking the target drink mix on a measure similar to the one in the first study. Finally, they responded to checks on the attributes assumed to underlie their drink mix evaluations, and completed Snyder's (1974) Self-Monitoring Scale.

Results: Overall, the correlations between expressed attitude and the average predicted likelihood of buying or drinking the target product replicated previous findings (see Table 2). When the attribute that was salient at attitude assessment (the attribute in the questionnaire) corresponded with the attribute that was salient at purchase prediction (the attribute associated with the target drink mix), the correlation between subjects' attitude reports and their purchase predictions was greater than when those attributes did not match. As in the previous study, the 2 X 2 interaction of questionnaire type and target drink mix (representing this effect) was statistically significant ($p < .05$).

How did subjects' level of self-monitoring influence this observed relation between attitude reports and purchase predictions? Table 3 shows the correlations for low and high self-monitors, based on a median-split of self-monitoring scores. As expected, it indicates that the pattern of correlations that was observed in Table 2 emerged strongly for high self-monitors (and yielded a significant 2 X 2 interaction). But, it did not emerge for low self-monitors.

Apparently, high self-monitors, who may be predisposed to be influenced by situational circumstances, were more affected by the context manipulation (questionnaire) designed to heighten the salience of product attributes. This was particularly true for the social impressiveness questionnaire, which involved an attribute that is

especially relevant to the concerns of the high self-monitor. Subjects' responses to the attribute check measures indicated that this questionnaire (rating things for the impression they make on others) was far more effective in heightening the salience of the social impressiveness attribute for high than for low self-monitors. (However, there was no evidence that high and low self-monitors differed in the extent to which either taste or social impressiveness attributes were associated with the target products.)

Conclusions: The present study replicated previous results in indicating that the product attributes that are salient at attitudinal and at behavioral expression can have a strong impact on the consistency between those judgments. When the salient attributes corresponded, the consistency between attitude reports and purchase predictions was greater than when the salient attributes did not match.

The results also provided evidence that the salience of attributes can be affected not only by contextual factors and by product factors but by individual differences, as well. Individual differences in self-monitoring apparently moderated the effects of context on attribute salience and, in turn, moderated the pattern of relations between attitudes and purchase predictions. The pattern that had been observed as a function of attribute salience emerged for high but not for low self-monitoring subjects.

It is possible that low self-monitors were less affected by the heightened salience of product attributes because they already possessed highly accessible, pre-existing attitudes that guided their responses to these products (see Kardes, et al., 1986). High self-monitors may have lacked such attitudes. Their attitudinal and behavioral judgments were perhaps more likely to be constructed in response to whatever product attributes were salient at the time.

GENERAL DISCUSSION

Attitude researchers have generally viewed attitude reports as reflecting an individual's single, global evaluation of an object. In contrast, the present findings suggest that attitude responses are not necessarily unitary and can often be somewhat unstable. These and the other studies presented in this session indicate that reports of one's attitude toward a product can vary, even within a short amount of time, as a function of whatever happens to be salient in the judgment context. Research by Wilson, et al. (1984, 1986, 1989) and by Millar and Tesser (1986, 1989) has suggested that the salience of affective versus cognitive considerations can affect the favorability of one's reported attitudes. The present studies suggest that the salience of specific attributes can do the same. This was evidenced by a substantially lower correlation between evaluative judgments that were made when different attributes were salient, compared to conditions in which the salient attributes corresponded.

Thus, attitudes may perhaps be more heuristically conceptualized as clusters of different

TABLE 2
Study 2: Correlations between Attitude and Mean Purchase Prediction

	<u>Attribute Salient at Attitude Expression</u> (Questionnaire Attribute)		
	<u>Taste</u>	<u>Social Impressiveness</u>	<u>Control (no attribute)</u>
<u>Target Product:</u> (attribute salient at purchase prediction)			
Wyler's (taste)	.61 _{ab}	.46 _a	.30 _a
Kool-Aid (social impressiveness)	.49 _{ab}	.83 _b	.56 _{ab}

Note: Each correlation is based on approximately 20 cases. Data from one subject in the Wyler's/control group condition were deleted because of the subject's extreme outlying attitude rating.

These correlations yielded a significant ($p < .05$, one-tailed) 2×2 interaction of questionnaire (taste vs. social impressiveness) and product (Wyler's vs. Kool-Aid). Correlations with the same subscript are not significantly different at $p < .05$.

Attitudes were rated on a 9-point scale with 9 being "very favorable."

The purchase prediction score was the average of subjects' predictions, over four separate situations, of their likelihood of purchasing or drinking the target brand. Each rating was made on a 5-point scale with 5 indicating the greatest willingness to purchase or drink the brand. The four ratings intercorrelated at $r = .32-.58$ (coefficient alpha = .78).

evaluations of an object (see Zanna & Rempel, 1988). Each evaluation may be specific to a representational domain (affect vs. cognition vs. behavior), a particular attribute, a goal, a setting, etc. Differences in the judgment context (e.g., differences in the goals that are salient) may lead one to access different evaluations, or to compute new ones when existing evaluations do not seem to apply.

This conceptualization of attitudes is a particularly useful approach for understanding the stability of attitudinal responses over time and across situations. It also has implications for predicting the relation between attitude reports and behavior: For example, to the extent that the considerations (e.g., attributes, goals, etc.) that are salient at attitude assessment and those that are salient in the behavioral context are likely to differ, and to the extent that those different considerations imply different evaluations of the object, attitude statements should not be good predictors of behavior. However, to the extent that the evaluations implied by different salient

considerations are consistent, attitude statements should be more predictive of behavior (see Millar & Tesser, 1989). Similarly, if the same considerations are likely to predominate and to drive one's judgments of an object regardless of context, attitude reports should provide relatively good predictions of behavior.

This view of attitudes also fits well with the nature of consumer attitudes, which are commonly formed and expressed in differing contexts and in response to different stimuli. For example, one may form some evaluations of a product based on several attributes made salient by advertisements, word-of-mouth information, past experiences, etc. Which of these evaluations is subsequently expressed (e.g., through purchase) may depend in part on which of the product attributes is salient in the decision context (e.g., in the store environment).

How these multiple evaluations are stored and structured in memory remains to be determined. In that regard, the results of the present studies are open to a number of interpretations. The present findings suggested that variations in the attribute

TABLE 3
Study 2: Correlations between Attitude and Mean Purchase Prediction for
High and Low Self-Monitoring Individuals

	<u>Attribute Salient at Attitude Expression</u> (Questionnaire Attribute)		
	<u>Taste</u>	<u>Social Impressiveness</u>	<u>Control (no attribute)</u>
<u>LOW SELF-MONITORS</u>			
Wyler's	.79 _a	.77 _a	.62 _a
Kool-Aid	.56 _a	.74 _a	.69 _a
<u>HIGH SELF-MONITORS</u>			
Wyler's	.55 _{ab}	-.22 _a	.38 _a
Kool-Aid	-.12 _a	.92 _b	.60 _{ab}

Note: Each correlation is based on approximately 10 cases. Data from one low self-monitoring subject in the Wyler's/control group condition were deleted because of the subject's extreme outlying attitude rating.

For high self-monitors, but not for low, these correlations yielded a significant 2 X 2 interaction ($p < .05$, one-tailed) of questionnaire (taste vs. social impressiveness) and product (Wyler's vs. Kool-Aid). Correlations with the same subscript (at the same level of self-monitoring) are not significantly different at $p < .05$.

rating task that subjects performed prior to attitude assessment (taste vs. social impressiveness ratings) influenced the favorability of the general attitudes they reported toward the target product. Was this because the heightened salience of particular attributes led subjects to compute new, attribute-specific evaluations of the target product on the spot? Perhaps subjects' pre-existing evaluations of the target product were not readily accessible in memory. Perhaps the salience of a certain attribute led subjects to think of the target product in a new way, and to re-evaluate it (at least temporarily) with that attribute in mind. Or perhaps the attribute rating task created a perceived demand to generate and report an attribute-specific rating of the target product.

These possibilities have relevance to the *attitude-nonattitude* distinction proposed by Converse (1970) and Hovland (1959), who observed that individuals sometimes provide attitude responses to an item on a survey (nonattitudes), even though they have no pre-existing evaluation of the attitude object. Converse (1970) noted that such nonattitudes were characterized by unreliability in their measurement. Fazio (1989) suggested that the attitude-nonattitude distinction can be viewed as a continuum, with nonattitudes at the low end, evaluations that are relatively inaccessible in

memory closer to the middle, and well-learned, highly accessible evaluations at the high end. In the context of the present research, this distinction suggests that it may be toward the lower end of the attitude-nonattitude continuum where the malleability of attitude reports observed here as a function of judgment context is most likely to emerge. This is consistent with our finding that high self-monitors, who are less likely than low self-monitors to possess highly accessible attitudes (Kardes, et al., 1986), evidenced the predicted effects of judgment context, while low self-monitors did not.

Alternatively, it is possible that the present results were obtained because multiple evaluations of the target product already existed in memory. These evaluations (or a subset of them) might have tended toward the high end of the attitude-nonattitude continuum, and been highly accessible in memory. When subjects were asked to express their attitude toward the product after performing the rating task, they may have simply retrieved and reported the evaluation that was the most accessible in that context.

Each of these possibilities can account for the present data. Determining when each of these processes is most likely to occur, however, requires a better understanding of how such multiple evaluations may be organized in memory. What

factors govern the accessibility of these evaluations? What are the links between them? How will their evaluative consistency affect the way they are organized and retrieved? When faced with new considerations regarding an object, when will a new evaluation be computed and when will an existing one be deemed adequate? What factors determine whether a newly-formed evaluation will be stored separately from the others or will be used to update an existing evaluation?

Further research is needed to investigate the implications of the present findings for the structure of attitudes. Understanding how multiple evaluations of a product are stored and organized in memory, and the conditions under which they are accessed or recomputed, is an important issue for future study.

Attitude Function: Is it Related to Attitude Structure?

Mark P. Zanna, University of Waterloo

Historically, attitudes have been conceptualized as either one component, consisting of an individual's feelings or affective responses to an attitude object, or three components, consisting of, in addition, an individual's knowledge or cognitions about and behavior towards an attitude object. With the widespread awareness that affective and evaluative responses should no longer be considered synonymous (cf. Abelson et al., 1982), a consensus seems to be emerging around a resolution to this conceptual controversy. Following Zanna and Rempel (1984, 1988) among others (e. g., Cacioppo et al., 1989; Eagly & Chaiken, in preparation), attitudes are now viewed as evaluations based on, or developed from, three general classes of information: (1) affective or emotional information, (2) cognitive information, and/or (3) information concerning past behaviors or behavioral intentions. Further, evaluations or attitudes are viewed as influencing three modes of response, including affective, cognitive and behavioral responses.

When evaluations are based primarily on (utilitarian) beliefs about the attitude object, this present view can be reduced to something like the formulation proposed by Fishbein and Ajzen (1975). When evaluations are based primarily on affects produced by or associated with the attitude object, this view can resemble the formulation proposed by Zajonc (1980). Finally, when evaluations are based on inferences from past behavior, this view can be similar to Bem's theory of self-perception (1972). Thus, this general framework or formulation not only seems to resolve the one vs. three component controversy, it suggests a way of integrating several of the most prominent theories of attitude formation. More important, perhaps, it suggests exciting new avenues of research.

Because one's overall evaluation is assumed to be a function of what evaluative-relevant information is chronically or, even, acutely salient, one of the interesting implications of this perspective is that an individual can hold more than one attitude toward a given attitude object. This notion is nicely captured by Tim Wilson's "slide rule" metaphor. Rather than having a single attitude toward the object, individuals are presumed to have a range of positions that they view as acceptable. This interesting possibility was exploited in creative ways by each of the participants in the symposium.

Wilson and his colleagues conducted a series of intriguing studies in which subjects were asked to introspect about their attitudes, explaining *why* they held particular attitudes (Wilson, Lisle, & Kraft, this symposium). To the extent that introspecting about reasons for attitudes makes salient otherwise nonsalient beliefs, attitudes temporarily change. As a consequence, individuals come to make unwise (consumer) decisions in the short run and, in the long run, behave inconsistently with these unstable

evaluations. These studies are extremely fascinating. Not only are the results generally consistent with this emerging perspective, I believe the experiments themselves make little sense without such a perspective.

Abe Tesser and Murray Millar's research is also fascinating. This research follows as well from the notion that because attitudes can be based on different sources of information, we can hold more than one attitude toward the attitude object depending upon, in Tesser and Millar's case, whether we are led to focus on our feelings or our beliefs (Tesser & Millar, this symposium). In their research, Tesser and Millar go further by suggesting, and demonstrating, that attitudes based on affect seem to influence consummatory behavior while attitudes based on cognition seem to influence instrumental behavior. Again, it would appear that this research is generally consistent with this emerging perspective and would have made little sense without it.

Finally, the research of Sharon Shavitt and Russell Fazio (Shavitt & Fazio, this symposium) capitalizes on the notion that the salience of information dimensions (e. g., taste vs. social impression) can temporarily influence one's overall attitudes, and, thus, behavior, toward consumer products, especially for individuals with high self-monitoring tendencies (i. e., individuals who tend to be more attentive to situational cues, especially cues concerning social image, and who tend to hold less accessible attitudes). Again, this research fits nicely with this emerging perspective. What is particularly impressive to me, at least, is the ease (and creativity) with which Shavitt and Fazio (as well as Wilson, Tesser and their respective colleagues) have been able to change people's attitudes, at least temporarily, by manipulating the salience of different dimensions of evaluative information.

At the University of Waterloo my students and I have also begun to explore the idea that attitudes can be based on different sources of information which may not have entirely consistent implications for an overall evaluation. For example, Megan Thompson, in her Masters thesis research (Thompson, 1989), wondered what would happen if, and when, two or more sources of information have contradictory implications for the overall evaluation. This is a state of affairs we might call attitude ambivalence, as in the case when your "mind" (i. e., cognition) tells you one thing (e. g., that exercise is good for your health) but your "heart" (i. e., affect) tells you another (e. g., that exercise is painful). To investigate the possibility that attitudes are often ambivalent, Megan induced her subjects to provide separate positive and negative evaluations of several social attitude topics (such as AIDS, euthanasia, reinstating capital punishment, and abortion) by having subjects consider separately, first, their positive beliefs and

feelings and, then, their negative beliefs and feelings for each social issue. Following Kalman Kaplan (1972), Megan defined ambivalence as "the total amount of evaluation less the degree to which the summary evaluation is polarized." For example, using four-point scales created by splitting seven-point bipolar scales (e. g., favorable-unfavorable) with the neutral point retained in each, + 2 units of positive evaluation indicated at the same time as - 3 units of negative evaluation produces 5 units of total evaluation ($+ 2 + - 3$), which can be decomposed into 1 unit of absolute polarization ($[+ 2] + [- 3]$), in this case a slight overall negative evaluation, and 4 units of ambivalence. Ambivalence is thus determined by the amount of the lesser evaluation, all of which overlaps with an equivalent amount of the stronger competing evaluation.

Using this procedure, Megan discovered first that there were strong individual differences in the ambivalence individuals seem to experience in their social attitudes. Some individuals seemed to hold ambivalent social attitudes while others did not. Next she determined that theoretically relevant dispositional variables, such as the Need for Cognition (NFC), i. e., stable differences in individuals' tendencies to engage in and enjoy effortful cognitive endeavours (Cacioppo & Petty, 1982) and the Fear of Invalidity (FOI), i. e., stable differences in individuals' concern with error in decision-making (Thompson et al., 1989), were related to this ambivalence. As expected, those high in NFC were less likely to hold ambivalent social attitudes while those high in FOI were more likely to do so. Next she determined that experts, i. e., those who possessed a great deal of knowledge concerning social issues, were less likely to be ambivalent, but, interestingly, the effect for knowledge or expertise was moderated by both personality variables. Expertise was associated with less ambivalence, but only for those high in NFC and low in FOI. In fact, there was a hint that experts high in FOI actually experienced more ambivalence. In any event, it is clear that ambivalent attitudes exist and that some people are more likely to hold ambivalent attitudes than others. The consequences of holding such attitudes will be an important topic for research in the future.

Recently some of my graduate students and I have taken the notion of attitudes being based on different sources of information one step further. Specifically, we began to wonder what it might mean if there were to be a multidimensional structure to the beliefs upon which attitudes were based. For example, in the realm of social perception it seems clear that attributes along the Social Desirability dimension (e. g., warm vs. cold) seem to influence our judgments of liking vs. disliking, while attributes along the Intellectual Desirability dimension (e. g., intelligent vs. unintelligent) seem to influence our judgments of respect vs. disrespect (cf. Lydon, Jamieson, & Zanna, 1988). If so, which judgment, liking or respect, determines our overall evaluation of or attitude toward other persons? Does this depend on the context (e. g., task-related vs.

social-emotional-related situations) in which we are asked to form (or retrieve) such attitudes? Do we experience ambivalence when we like but do not respect another (or, conversely, respect but do not like another), or, for the most part, do we compartmentalize these seemingly contradictory judgments? These and other questions will be important topics for future research in the area of impression formation. From the point of view of the consumer researcher, it might be interesting to determine whether two dimensions, similar to the Social and Intellectual Desirability dimensions of implicit personality theory, exist for consumer products, and, if so, whether two dimensions of evaluative judgment, similar to liking and respect, exist as well.

In another recent Masters thesis at the University of Waterloo, Richard Ennis explored the multidimensionality of beliefs upon which evaluations, in this case attitudes toward consumer products, were based. Rich proposed that one way to conceptualize (and operationalize) a functional approach to attitudes would be to suggest that overall evaluations based on different dimensions of beliefs might fulfill different functions (Ennis, 1989). Specifically, Ennis suggested that the Fishbein and Ajzen (1975) model of attitudes was incomplete because their belief elicitation procedure essentially "pulled" for utilitarian or instrumental beliefs about the attitude object. Following the lead of Sharon Shavitt (1989), Rich demonstrated that it was possible to elicit beliefs concerning consumer items that were more symbolic in nature, and that this was, in fact, easier for products that Shavitt suggested served more symbolic functions, such as a graduation ring or a gold neckchain, than for products that she suggested served a more instrumental function, such as an air conditioner or coffee. Interestingly, Rich was also able to demonstrate that the overall evaluations of symbolic products, such as graduation rings, were based to a greater extent on (or, at least, correlated to a greater extent with) the symbolic belief dimension (e. g., "a graduation ring is a memento of one's university years"; "a graduation ring is an item to show off your status to others") than on the utilitarian or instrumental belief dimension (e. g., "a graduation ring usually is expensive"; "a graduation ring is not terribly useful"). In contrast, overall evaluations of instrumental products, such as air conditioners, were based to a greater extent on instrumental beliefs (e. g., "an air conditioner enables you to relax comfortably") than on symbolic beliefs (e. g., "in our climate an air conditioner symbolizes extravagance"). Attitudes toward products thought to fulfill both instrumental and symbolic functions (e. g., a University of Waterloo jacket) seemed to be based on both instrumental (e. g., "a U of W jacket looks good") and symbolic (e. g., "a U of W jacket provides a feeling of status because U of W is well respected") beliefs. Future research might determine whether either individual difference variables, such as Self-Monitoring tendencies (Snyder & DeBono, 1989), or situational variables (such as social

context "primes"), for that matter, moderate the belief dimension-overall evaluation relation. Further, future research on persuasion might create communications designed to change either utilitarian or symbolic beliefs in order to test the functional hypothesis that in order to change an attitude one must change the function-relevant bases (in this formulation, informational dimensions) from which the attitude is derived.

Finally, Ennis' perspective on how to think about and operationalize a functional approach to attitudes may provide a way to conceptualize symbolic attitudes, including symbolic racism (Sears, 1988). Here the notion is simply that symbolic attitudes (e. g., symbolic racism) (in addition, perhaps, to being based to a greater extent on affect) are based upon symbolic beliefs (e. g., "Blacks are getting more than they deserve," "the streets are unsafe today," and so on) rather (or to a greater extent) than on traditional stereotypic beliefs (e. g., "Blacks are unintelligent," "lazy," and so on).

In any event, by not equating affective response with evaluation and by focusing upon the various, possibly multidimensional, sources of information upon which attitudes are based, attitude researchers (as attested to by the participants of the present symposium) will have more than enough interesting questions to pursue in the future. Most exciting, at least for me, is the possibility that, by considering attitude structure, specifically the information upon which an attitude is based, we can learn more about attitude function.

Brand Categorization and Product Involvement

Jacques E. Brisoux, Université du Québec à Trois-Rivières
Emmanuel J. Chéron, Université Laval¹

ABSTRACT

The effects of product involvement on brand categorization are examined with respect to brand set size. Data collected from 487 female users of cosmetics did not confirm the effect of product involvement on the evoked, reject, foggy, and salient set sizes. Significant effects were found for the awareness, trial and hold sets. Although the high and the low involvement groups did not differ on socio-demographic variables, high involvement seemed associated with heavier users and higher brand loyalty.

INTRODUCTION & BACKGROUND

The question of how consumers deal with the multitude of brands that are available in many product categories has attracted increasing attention by researchers in recent years. Several brand categorization models have been proposed in the marketing literature. The Brisoux and Laroche (1980) model is an expansion of earlier conceptualizations by Narayana and Markin (1975) and Howard (1963, 1977). The model suggests four stages in the consumer decision process: awareness, processing, consideration, and preference (Figure 1).

Brand Categorization

From the *available set* brands are first classified in either the *awareness set* or the *unawareness set*. The former is divided in a *processed set* and a *unprocessed* (or *foggy*) *set*. Brands in the *foggy set* are presumed to have not been processed on any of the salient attributes (the consumer has no specific brand comprehension). Brands belonging to the *processed set* are either evoked, rejected, or in a "hold" position. The *evoked set* is analogous to the Howard and Narayana & Markin conceptualizations. It includes the subset of (processed) brands that a consumer considers as acceptable purchase alternatives. The *reject set* contains those brands which the consumer considers to be unacceptable purchase alternatives. Brands in the *hold set* are not considered as purchase alternatives, and consumers may have positive, negative, or neutral attitudes towards them. For a more complete description of the basic framework and managerial implications of the brand categorization model, the reader is referred to Laroche et al. (1986).

The framework used by Brisoux and Laroche (1980), and later by Laroche et al. (1983, 1984) and Brisoux et al. (1986) differentiated the evoked, hold, reject, and foggy sets in terms of attitudes, intentions, confidence and brand evaluation, as well

as quantity of information processed. The model has been partially tested and generally supported using various product classes, in routinized response behavior (Brisoux and Laroche 1980, Laroche et al. 1983, Brisoux et al. (1986) as well as extensive (Laroche et al. 1984) and limited problem-solving situations (Church et al. 1985).

Product Involvement

The concept of involvement has been a major center of interest in consumer research literature for the past 20 years. There is no commonly accepted definition of this hypothetical construct although a (temporary) generally acceptable generic definition and a few characteristics are proposed by Rothschild: "Involvement is a state of motivation, arousal or interest. This state exists in a process. It is driven by current external variables (the situation, the product, the communications) and past internal variables (enduring; ego; central values). Its consequences are types of searching, processing and decision making" (Rothschild, 1984, p. 217). The author argues that, for the time being, the field does not need any more theoretical papers or literature reviews on the topic. We will therefore limit our presentation to the main elements necessary to the understanding of our study.

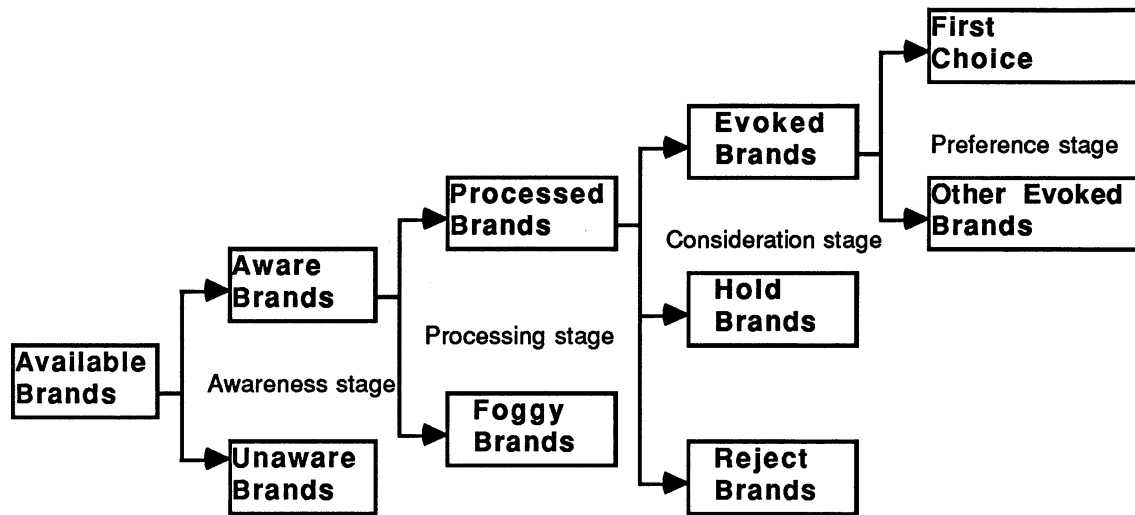

Table 1 presents a summary of the global concept of involvement. This table is based on the Houston and Rothschild (1978) paradigm which subdivides the concept into three types: situational, enduring, and response involvement. The paradigm includes a listing of the stimuli which have the ability to arouse each type of involvement, their antecedents, the hypothesized effects and the proposed measures. Other well known recent studies on the construct are cited in Table 1 (Traylor and Joseph, 1984; Laurent and Kapferer, 1985; Zaichkowsky, 1985).

Table 2 presents a comparison of three consumer involvement measuring instruments that have been recently proposed (Traylor and Joseph, 1984; Laurent and Kapferer, 1985; Zaichkowsky, 1985). The comparison is done on the prominent underlying concept, the number of product categories used for testing each measuring instrument and corresponding sample sizes, the category of respondents, the type of scale, the number of dimensions being measured, the number of items in each scale, and the observed Cronbach alphas. The table also indicates the type of validity testing conducted on each scale (concurrent, trait, discriminant, content, construct and convergent).

Rosenblatt (1985) has investigated the relationship between involvement and its effects on brand categorization but has not specifically examined the effect of involvement on brand set size and content.

¹The authors gratefully acknowledge the financial support of FCAR and the assistance of H el ene Hamel in the research project.

FIGURE 1
THE BRISOUX AND LAROCHE CONCEPTUALIZATION

RESEARCH OBJECTIVES

The aim of this research is to test the relationship between the level of product involvement and the structure of brand categorization. More specifically, the research examines differences in brand set sizes for low, medium and high involvement consumer groups.

This research can be related to the validity network schema proposed by Brinberg and Hirschman (1986). The focus of this research is first to combine the conceptual and the empirical domains to form a theory (Figure 2).

The theory is then submitted to test using specific methodological approaches. The conceptual domain comprises the construct of brand categorization and the involvement construct. The empirical domain refers to consumer characteristics and make-up products for eyes, lips and the face. The methodological domain includes the structure of brand categories proposed by Brisoux and Laroche (1980) and the measure of product involvement developed by Zaichkowsky (1985).

Since the emphasis of this research is to test a theory, greater attention will be invested in concept definitions and methodological procedures. Although every effort will be made to get a relevant sample, its convenient nature is acceptable with this type of research (Calder et al., 1981).

HYPOTHESES

Following the literature review and the research objectives, a series of specific hypotheses will be tested. The hypotheses are stated for the limited problem-solving (LPS) situation and will be supported or rejected in the empirical context of cosmetics purchase. Four hypotheses pertaining to the relationship between product involvement level and brand set structure are proposed:

- H1 Consumers with higher level of product involvement will be associated with smaller evoked sets.
- H2 Consumers with higher level of product involvement will be associated with larger reject sets.

These above hypotheses are justified by previous research confirming such relationships for other products (Brisoux, 1980; Ho, 1980; Traylor and Joseph, 1984; Rosenblatt, 1985).

- H3 Consumers with higher product involvement will be associated with smaller foggy sets.

This hypothesis is the result of the unprocessed characteristic of the foggy set, which will be associated with a low level of involvement.

- H4 Consumers with higher product involvement will be associated with larger salient (unaided awareness) sets, larger awareness sets, larger trial sets and larger hold sets.

Hypothesis 4 is proposed on since the relationship between product involvement and trial set size has been previously examined by Zaichkowsky (1985). And, as an extension, higher involvement will be tested in association with a larger salient, trial and hold sets.

Table 3 presents a detailed summary of the four hypotheses between product involvement and brand set size.

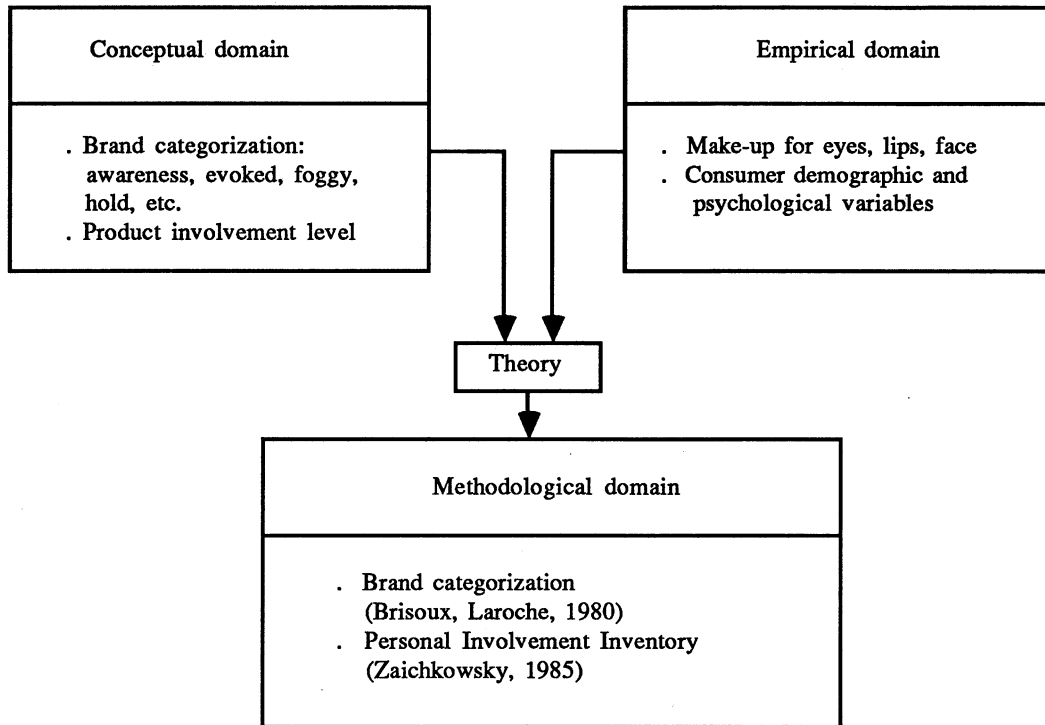

TABLE 1
THE GLOBAL CONCEPT OF INVOLVEMENT

Types	Stimuli	Antecedents	Effects	Measures
SITUATIONAL INVOLVEMENT (Houston & Rothschild, 1978)	Economic & time costs Elapsed time of consumption Complexity of the product Visibility of the product	Perceived risk (physical, financial or psychological) (Laurent and Kapferer, 1985) Self expression through product category (Laurent and Kapferer, 1985; Zaichkowsky, 1985)	Level of involvement increases with level of stimuli (or perceived consequences); as soon as the goal is reached the level of situational involvement decreases	Perceived risk (including positive and negative valences) (Laurent and Kapferer, 1985) Perceived importance of situation
ENDURING INVOLVEMENT (Houston & Rothschild, 1978)	Prior experience in purchasing or using the product Centrally held values Product importance in general (without purchase or use considerations)	Interest in the product Expected pleasure from product consumption (Laurent and Kapferer, 1985) Perception of product choice as the sign of oneself (Laurent and Kapferer, 1985; Traylor and Joseph, 1984; Zaichkowsky, 1985)	Considerable prior experience with a product related to centrally held values increases the level of enduring involvement	Perceived importance of product (Laurent and Kapferer, 1985) Level of interest in the product (Zaichkowsky, 1985) Familiarity with the product
RESPONSE INVOLVEMENT (Houston & Rothschild, 1978)	Situational involvement Enduring involvement	Desire to make an optimal purchase Functional, symbolic and experiential expectations	The nature of response involvement differs depending on the stage in the decision process Situational and enduring involvement combine to influence response involvement	Number of evaluative criteria considered important Number and type of information sources used

TABLE 2
COMPARISON OF THREE CONSUMER INVOLVEMENT MEASURING INSTRUMENTS

	TRAYLOR & JOSEPH (1984)	KAPFERER & LAURENT (1985)	ZAICHKOWSKY (1985)
Prominent concept	Self-identity	Involvement profile	Personal Involvement Inventory
Number of product categories	12	14	14
Sample size	280	207	varying from 43 to 68

Type of scale	7-point Likert scale	5-point Likert scale	7-point semantic differential scale
Number of dimensions	1	4	1
Number of items	6	3 to 5 for each of the 4 dimensions (total=17)	20
Internal consistency (Cronbach alpha level)	0.92	Between 0.72 and 0.90	Between 0.97 and 0.99
Validity testing:			
Concurrent validity	yes	no	no
Trait validity	no	yes	no
Discriminant validity	no	yes	yes
Content validity	no	no	yes
Construct validity	no	no	yes
Convergent validity	no	no	no

FIGURE 2
RESEARCH TYPE

RESEARCH METHOD

Product choice

The conceptual domain of the research specifies that the chosen product be associated with a limited problem-solving situation and that at least seven distinct brands be included in the product class (Miller, 1956). In general, make-up for women refers to a limited problem-solving situation except for a few highly brand loyal customers with routinized buying behavior. A total of 80 different brands of make-up are listed in Cosmetics (1985). The total market for cosmetics is relatively stable with a rather high competitive activity, each manufacturer fighting for his market share.

Furthermore, access to users of the product is easy, since most women are consumers of make-up products. Managers in the industry also believe that the brand is important in the buying decision (Wood, 1986). Frequent buying and using of the product make it easier for consumers to evaluate brands. According to a convenience sample of beauty consultants, *special occasions do not have an influence on the choice of products*. Therefore controlling for the buying situation was not necessary.

In this research, make-up products include all products that can be used on the eyes, the lips, or the face. To the authors' knowledge, brand

categorization has not been previously examined for this product class.

Definition of variables

This section specifies the operational definitions of the different brand sets and the product involvement variable. In addition to the four sets conceptualized in figure 1, Brisoux and Laroche (1980) measured the salient and trial sets and used the following definitions:

- Salient set:** Those brands of the product class that come to the mind of the consumer without the help of a list of brands.
- Awareness set:** Those brands that the consumer can recognize from a list of brands.
- Evoked set:** From the awareness set, those brands that the consumer would certainly consider to buy at the time of the survey.
- Reject set:** From the awareness set, those brands that the consumer would refuse to buy as they seem

TABLE 3
HYPOTHESES ON PRODUCT INVOLVEMENT IN RELATION TO BRAND SIZE

Hypothesis	Brand set	Product involvement		
		Low	Medium	High
		Brand set size		
H1	Evoked	Large	Medium	Small
H2	Reject	Small	Medium	Large
H3	Foggy	Large	Medium	Small
H4	Salient	Small	Medium	Large
H4	Awareness	Small	Medium	Large
H4	Trial	Small	Medium	Large
H4	Hold	Small	Medium	Large

unacceptable to his or her needs.

Foggy set: From the awareness set, those brands for which the consumer has not formed an opinion (no attribute processing has occurred) and which he or she is not ready to buy.

Hold set: From the awareness set, those brands for which the consumer has formed an opinion (some attribute processing has occurred) but for which he or she cannot say whether he or she would accept or reject them.

Trial set: From the awareness set, those brands that the consumer has already bought and used for him or herself.

The definition of product involvement is taken from Zaichkowsky (1985): "A person's perceived relevance of the object based on inherent needs, values and interests". This definition contains the general viewpoints of several researchers (Krugman, 1967; Clarke and Belk, 1978; Mitchell, 1979; Greenwald and Leavitt, 1984; Rotschild, 1984). The operational measurement of product involvement is derived from the Personal Involvement Inventory (PII) scale developed by Zaichkowsky (1985). A presentation of the measuring instrument follows in the next section.

Measuring instrument

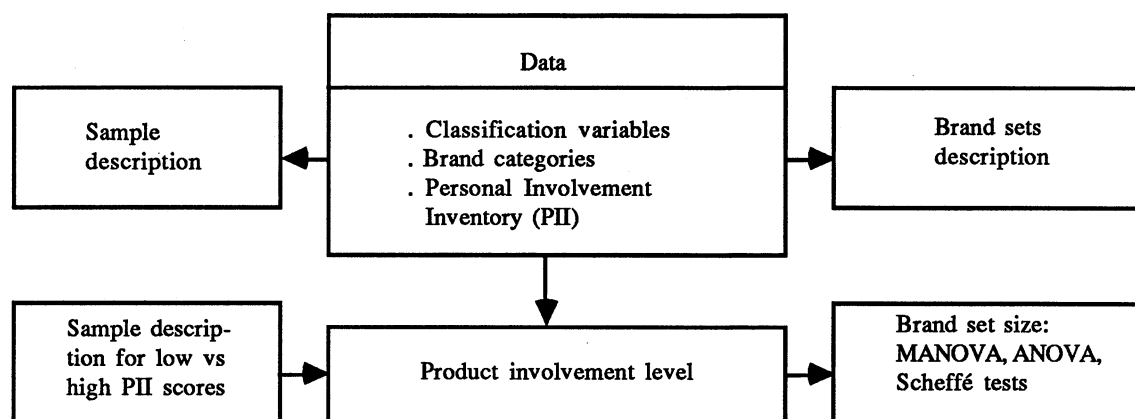

Personal interviews were used in previous research on brand categorization (Brisoux and Laroche, 1980; Rosenblatt, 1985; Brisoux, Chéron and Fernet, 1986). However for this research, a self-administered questionnaire was designed in order to obtain a fairly large sample despite a tight budget. The average time to complete the questionnaire on 45 brands was 30 minutes.

In the first part of the questionnaire respondents were asked to classify brands following the order of brand set definitions presented earlier. The second part was a French adaptation of the PII. This measuring instrument was chosen due to better consistency and validity (see Table 2). A back-translation procedure was used twice with three translators.

The French adaptation of the PII met most of the standards of the original scale. Internal reliability with a Cronbach alpha of 0.90 was comparable to results (above 0.90) reported by Zaichkowsky (1985). However, the unidimensionality of the adapted scale was not confirmed. A factor analysis produced four factors with eigenvalues above one. All factors explained up to 57.7% of variance instead of one factor accounting on the average for 70% of variance in the original study. The four factors could be interpreted as: 1) Derogative items (37.5%), 2) Product importance (8.6%), 3) Personal values (6.6%), 4) Visible appearance (5.0%). A multi-dimensional structure of the adapted scale of product involvement is supported by Kapferer and Laurent (1985).

Although with a larger mean (109 vs 90) and median (112 vs 96) the distribution of PII scores (N = 481) for cosmetics was skewed towards higher scores such as the overall distribution (N = 751) for

FIGURE 3
DATA ANALYSIS

various products obtained by Zaichkowsky (1985). The mean PII score of 109 for cosmetics was comparable to mean scores of 99 for jeans and 112 for calculators in the original study. Using the cutting points of the original study, three groups were formed with low product involvement level (PII score of 69 or below) medium level (PII score between 70 and 110) and high level (PII score of 111 or above).

The third part of the questionnaire contained classification variables related to make-up consumption such as: brand loyalty, self-designated reference group (homemaker, working woman, career woman), frequency of beauty services, allergy problems, seasonal amount spent for cosmetics and age group.

Sampling and data collection.

The target population included women 18 years or older using make-up products at the time of the survey. The observed population was limited to mothers with children in primary schools of the Quebec City metropolitan area and women listed in the Quebec Association of Business Women.

Overall, 487 completed questionnaires were obtained from a total of 696 questionnaires distributed. According to the standard definition suggested by Wiseman and Billington (1984), the response rate of eligible respondents was 70%.

Data analysis

Standard descriptive analyses were first conducted to get frequency distributions of the sample classification variables. Frequency analyses were also performed for brand sets and personal involvement scores. The sample classification variables were also examined for low versus high involvement. Figure 3 indicates the overall data analysis structure.

Three groups of personal involvement levels were formed using the 25%, 50% and 75% percentiles. The low-involvement group included PII scores of 99 or below, the medium level group

scores from 100 to 122 and the high level group scores above 122. Out of 481 valid cases, the average involvement score was 109 with a minimum value of 44 and a maximum of 139 (possible scale range is from 20 to 140).

A one-way multiple analysis of variance (MANOVA) was conducted. Although the seven dependent variables did not appear to be independent, examination of the data indicated substantial overlapping among sets. Therefore, the awareness set is not a linear combination (summation) of the evoked, reject, foggy, hold and trial sets. Hence, the assumption of independence for the MANOVA was not considered violated. Subsequently a series of ANOVA were used to test the effect of product involvement level on brand set size as specified in hypotheses 1 to 4. Multiple comparisons were examined using the Scheffé procedure, appropriate when samples are of different sizes and allowing to test for an overall significance level.

RESULTS

Since some parts of the questionnaires were not completed by all respondents, data analysis will be based upon 456 individuals. As for age groups, 58.5% of the respondents were in the 30 to 39 category. Self-ascribed reference groups were: 36.9% homemaker, 28.2% working woman and 34.6% career woman. Beauty services were "occasionally" required 47.6% of the time (vs "never", "once", and "regularly"). Some 66.4% of the respondents had no allergy problems and 73.4% purchased annually less than \$100 of make-up products.

Table 4 indicates the average brand set sizes. The average evoked set size of 4.70 is similar to the salient set size (4.57) and is comparable to 4.83 found for jeans in a previous study by Fernet (1986). The average awareness set size of 24.12 is however larger than for jeans (15.65). A previous study by Reilly and Parkinson (1985) reports average evoked

TABLE 4
AVERAGE BRAND SET SIZES AND ANOVA FOR THE EFFECT OF PRODUCT INVOLVEMENT LEVEL

Brand set	Average set size (N=456)	Product involvement			F
		Low (N=113)	Medium (N=237)	High (N=106)	
Evoked	4.70	4.24	4.81	4.99	1.98 NS
Reject	1.98	1.69	2.05	2.16	0.90 NS
Foggy	10.11	9.77	10.34	10.16	0.40 NS
Salient	4.57	4.29	4.60	4.84	1.46 NS
Awareness	24.12	<u>21.14</u>	<u>24.27</u>	<u>26.89</u>	20.54 **
Trial	10.75	<u>8.40</u>	<u>10.93</u>	<u>12.80</u>	24.01 **
Hold	12.60	<u>10.59</u>	<u>12.30</u>	<u>15.09</u>	12.86 **

Means not *linked* with a double horizontal line differ significantly at level .01 using Scheffé's test.

** Significant at level .01.

NS Non significant

set sizes of 3 to 4 (hand lotion: 3.10, toothpaste: 3.11, shampoo: 3.42, toilet soap: 4.09).

To test the effect of product involvement on the seven brand set sizes taken together as dependent variables, a one-way MANOVA was performed. Results indicated an overall significant statistical difference between the three levels of product involvement (Hotellings' approximated $F(14,892) = 14.0$ with $p = 0.000$). The F values for each univariate ANOVA to test hypotheses 1 to 4 are shown in Table 4. Significant differences are observed for the awareness, trial and hold sets. Hypotheses 1, 2, 3 and 4 (for the salient set) are not confirmed. Although not statistically significant, the hypothesized direction of brand set size is correct for the reject set and the salient set.

DISCUSSION AND CONCLUSION

The effect of product involvement on brand set size was not found to be significant for evoked, reject, foggy and salient sets. The range and skewness of observed involvement scores may account for the failure to confirm most hypotheses. Product involvement had a significant effect on awareness, trial and hold sets. Although, low and high involvement groups did not differ on socio-demographic variables, high involvement seemed associated with heavier users and higher brand loyalty.

The main contributions of this paper lie in conceptual definitions and methodological procedures. Brand categorization was measured with a self-administered questionnaire and a French adaptation of the PII scale was developed and tested.

Further research results will be presented elsewhere with the available data. Specifically, the brand categorization structure will be examined for mutually exclusive sets. Brand set contents and brand set relative position will be examined. Data were also collected on product attributes and perceived elements of the marketing mix of various

brands. Managerial results will also be presented comparing the marketing mix profiles of brands belonging to different set categories.

In Search of Brand Image: A Foundation Analysis

Dawn Dobni, University of Houston
George M. Zinkhan, University of Houston

Brand image has been an important concept in consumer behavior research since the early 1950s. Our analysis of 28 prior studies indicates that the definition of brand image has not necessarily remained stable over a 35 year time period. Similarly, there exists little consensus concerning how the construct should be operationalized. An attempt is made here to identify the essential elements of brand image.

INTRODUCTION

Since its formal introduction in the 1950s, the notion of brand image has become commonplace in consumer behavior research. Numerous studies of brand image have been reported, the phrase has been widely used in a variety of technical and casual applications, and practitioners and academics alike have embraced the concept as the embodiment of the abstract reality that people buy products or brands for something other than their physical attributes and functions.

This proliferation of brand image research has been accompanied by some drawbacks. For example, it has been suggested that over time and through overuse, or misuse, the meaning of "brand image" has evaporated and has lost much of its richness and value (Bullmore 1984). Others have similarly referred to such indiscriminate application as a debasement of the concept (Levy 1958). If these criticisms are true, then there is reason for concern.

Of primary concern is whether knowledge development has been impeded in this area due to the lack of a firm base or foundation on which to build. The way in which brand image is defined determines the nature of research questions that are posed, the methods that are used, and ultimately how findings are translated to the creative process (Reynolds and Gutman 1984). If there is no agreement at this fundamental definitional level, it is very unlikely that comparable and generalizable results will be forthcoming from this stream of research.

These issues demonstrate the importance of foundations studies to consumer behavior theorists. By tracing definitions and justifications, which is a key element of foundational research (Kerlinger 1973), those within the discipline can examine the sorts of knowledge claims that are being made and determine if a consensus is developing, both in terms of conceptualization and in terms of measurement. If it is not, the findings are likely to provide insight for forging agreement and greater precision in future work.

This paper has three objectives. First, it seeks to provide a centralized collection of definitions and conceptions of brand image, and in so doing documents the evolution of this vital behavioral concept. Second, by identifying the

major similarities and variations that exist in conceptualization, it will allow an assessment of whether there is a viable and foundationally secure definition of "brand image". And finally, some suggestions are made for guiding future research efforts in this important area.

HISTORICAL OVERVIEW

Gardner and Levy have been credited (Levy 1958) with crystallizing "brand image" in a meaningful form in their classic 1955 article. Criticizing previous research for being too superficial in its focus on stereotypical purchase reasons, they suggested that it was time to scratch beneath the surface and identify more enduring motivations for purchase. Their conception was that products had a social and psychological nature as well as a physical one, and that the sets of feelings, ideas and attitudes that consumers had about brands, their "image" of brands, were crucial to purchase choice.

While Gardner and Levy were the first to capture the essence of brand image in writing, the underlying idea of which they wrote was not entirely new. It is obvious that marketers of the late nineteenth century were increasingly concerned with a "brand's gestalt" from the progressive developments in branding, advertising and marketing techniques that took place during that era (Murphy 1987). And in 1949 James Duesenberry had observed that the act of consumption as symbolic behavior was probably more important to the individual than the functional benefits of the product.

A survey of the literature that has followed Gardner and Levy's article reveals that considerable variation exists among authors on five separate, but related, aspects of "brand image". These include (1) the names which have been ascribed to this phenomenon, (2) the formal definitions that have been offered, (3) the components of brand image, (4) the instruments that have been used to measure it, and (5) perspectives on the origin, creation, formulation and manipulability of brand image.

Despite this academic multiformity, brand image has become a vital concept for marketing managers. This has been demonstrated by findings such as those which confirm that image considerations guide purchase choice (Dolich 1969), that products are often purchased or avoided not for their functional qualities, but because of how, as symbols, they impact the buyer-user's status and self esteem (Levy 1959), and that a product is more likely to be used and enjoyed if there is congruity between its image and the actual or ideal self image of the user (Sirgy 1985).

As a point of clarification, it should be noted that in many of the works on this subject, authors have tended to use the word "product"

interchangeably with "brand". While it is acknowledged that in marketing there is normally an important difference between these two concepts, the writings on imagery have blurred this distinction by using both terms in the context of distinguishing one competitor's product from another. These terms are similarly used here (as synonyms), unless otherwise stated.

THE CRITICAL REVIEW

The Names Which Have Been Ascribed To This Phenomenon

Although the term "brand image" has become well established, there are several scholarly works that have not used the word although applying or studying very similar concepts. While these articles substantively agree that consumers discriminate among products on other than purely physical dimensions, they differ in the names which they ascribe to this phenomenon. Based on Shakespeare's principle that 'That which we call a rose by any other name would smell as sweet', it is appropriate to include these variants if a comprehensive foundational analysis is to be done.

One genre of works reflects on the symbolic nature of brands and products, adopting such labels as "symbolic utility" (Pohlman and Mudd 1973), "the symbols by which we buy" (Levy 1958) and "perceived product symbolism" (Sommers 1963) to describe the intangible aspect of consumer product evaluation.

Others have tended to emphasize human qualities and, accordingly, have coined such terms as "brand personality" (Hendon and Williams 1985), "brand character" (Hendon and Williams 1985), "personality image" (Sirgy 1985), and "the social and psychological nature of products" (Gardner and Levy 1955). As later discussion will show, this is a usage that has been welcomed by those who believe that there is an inextricable link between an individual's self concept and purchase.

Those who study this subject by focusing on the underlying meanings which consumers attribute to brands have described their object of inquiry as the "brand meaning" (Durgee and Stuart 1987), "the psychological meaning of products" (Friedmann and Lessig 1987), and "the messages communicated" by products (Swartz 1983).

THE FORMAL DEFINITIONS OF BRAND IMAGE

A collection of definitions of "brand image" is contained in Table 1. While not exhaustive, this collection does represent a good cross section of the definitions that have been offered in the past three decades. Journals have provided the source for most of these definitions, while a few were taken from textbooks, monographs or the popular press.

These definitions have been grouped into broad categories, although perhaps somewhat arbitrarily, on the basis of their principal emphasis, and within each group have been listed chronologically. This allows the major conceptual

developments and variations to be more easily identified, illustrated and traced. The five assigned categories include blanket definitions, and those which emphasize symbolism, meanings or messages, personification, and cognitive or psychological dimensions.

Blanket Definitions

Several of the definitions are so broad that they seem to contribute little to a refined understanding of the brand image concept. While it is therefore difficult to compare these to other more systematic definitions, it is important to acknowledge them because they are rather effective expressions of the general sense of brand image as an abstraction.

Those that fall within this category include such references as "the sum of the total impressions" (Herzog 1973), "everything the people associate with the brand" (Newman 1957), and "the product perception" (Runyon and Stewart 1987). In their simplicity and comprehensive totality, these usages highlight the fact that the notions that people have about a product or brand may not always coincide with its actual physical profile, and that what is important is how consumers see the product.

That the perception of reality is more important than reality itself is a theme which underlies most conceptualizations of brand image. As encapsulations of this theme, these blanket definitions are most felicitous.

Emphasis on Symbolism

Probably as an offshoot of the motivation research era, several of the definitions relate commercial objects to symbols. A symbol has been defined as a "thing which stands for or expresses something else" (Levy 1958); in casual usage it has been said to be a general term for all instances where an object, action, word, picture or complex behavior is understood to mean not only itself but also some other ideas or feelings (Levy 1958).

The definitions within this category span a wide range of detail and emphasis. The simplest (Frazer 1983) uses the term "symbol" in a purely descriptive or associative manner, merely stating that a product is a symbol and providing little or no insight into what brand image is taken to mean. Levy's (1958) elaborate conceptualization enlarges on the meaning and language of symbols, on their several dimensions, and on their relation to self concept. A more recent study (Noth 1988) has applied the concept of semiotics. From this perspective, objects of the marketplace are claimed to form semiotic systems, and commodities are studied as signs whose meaning is the consumer's "brand image".

While the reference to symbolism might ordinarily arouse connotations of the unconscious, these definitions seem generally to view this concept in a much broader and more public perspective. They imply that some personal or social meaning or value must be consciously attached to the product, and that products, as

TABLE 1
DEFINITIONS
GROUP 1A: BLANKET DEFINITIONS**1. Newman, 1957**

(a) A product is a symbol by virtue of its form, size, colour and functions. Its significance as a symbol varies according to how much it is associated with individual needs and social interaction. A product, then, is the sum of the meanings it communicates, often unconsciously, to others when they look at it or use it.

(b) A brand can be viewed as a composite image of everything people associate with it. These impressions determine how a prospective buyer feels about it and influence his selection. Brand images may have several dimensions: functional, economic, social, psychological...The limits are set by the brand image built through styling and advertisements as well as other product attributes.

2. Herzog, 1963

Brand image is the sum total of impressions the consumer receives from many sources...All these impressions amount to a sort of brand personality which is similar for the consuming public at large, although different consumer groups may have different attitudes toward it.

3. Snyder & DeBono, 1985

Practitioners of the soft sell approach typically create ads that appeal to the images

associated with the use of the product, images that one may gain and project by using the product. ...Typically the copy associated with these ads emphasizes the image of the product or, more specifically, the images associated with the use of the product.

4. Dichter, 1985

(a) The concept of image can be applied to a product ... It describes not individual traits or qualities, but the total impression an entity makes on the minds of others.

(b) An image is not anchored in just objective data and details. It is the configuration of the whole field of the object, the advertising, and more important, the customer's disposition and the attitudinal screen through which he observes.

5. Runyon and Stewart, 1987

A particular product position is also referred to as a product or brand concept if the product does not yet exist, or a brand image if the product does exist. ...A product's positioning in the market is simply the way consumers perceive that product. It reflects the language that consumers use to talk about it, their emotional responses to it, and all of the numerous factors that influence the perceptual process. The actual positioning of a product is the outcome of a complex set of factors, which are only partially understood.

GROUP 1B: EMPHASIS ON SYMBOLISM**1. Levy, 1959**

(a) People buy things not only for what they can do, but also for what they mean... The things people buy are seen to have personal and social meanings in addition to their functions.

(b) To ignore or decry the symbolism of consumer goods does not affect the importance of the fact. It will suffice to say that in casual usage symbol is a general term for all instances where experience is mediated rather than direct; where an object, action, word, picture or complex behavior is understood to mean not only itself but also some other ideas or feelings.

(c) A symbol is appropriate (and the product will be used and enjoyed) when it joins with, meshes with, adds to or reinforces the way the consumer thinks about himself.

2. Pohlman and Mudd, 1973

The purchased item is conceptualized as having two kinds of value for the owner, one for its concrete functional utility and the other for its utility as a prestige symbol. ...functional value is that which is conventionally meant by utility as a good, while symbolic value (i.e., image) is the

extent to which a purchase enhances the worth of the person in his own eyes (self esteem) and in the eyes of others (status).

3. Frazer, 1983

...the advertiser formulates a claim of superiority or distinction based on factors extrinsic to the product. Often products are associated with symbols, either socially extant or created by or for the advertiser. ...the effort to differentiate the product is psychologically rather than physically based.

4. Noth, 1988

From this perspective (i.e. semiotics) commodities are studied as signs whose meaning is the consumer's 'brand image'. Semantic components of a brand image...include technical matters, product characteristics, financial value or social suitability. Semiotically, such components constitute the signified (or content) of the product, while the material object is the signifier of the commodity as a sign.

TABLE 1 (CONTINUED)
DEFINITIONS

GROUP 1C: EMPHASIS ON MEANINGS OR MESSAGES

1. **Levy and Glick, 1973**
 - (a) The concept of brand image aptly sums up the idea that consumers buy brands not only for their physical attributes and functions, but also because of the meanings connected with the brands.
 - (b) ...imagery is a mixture of notions and deceptions, based on many things. ...At times, imagery is indeed largely an illusion.
 - (c) An image is an interpretation, a set of inferences and reactions to a symbol because it is not the object itself, but refers to it and for it.
2. **Sommers, 1963**

...the meaning that a product has
... perceived product symbolism
3. **Grubb and Grathwohl, 1967**

...the psychic or symbolic value of goods purchased in the marketplace
4. **Swartz, 1983 ("Product Message")**

In symbolic consumer behavior, interest lies in investigating the role of products as "messages" or "nonverbal communication" transmitted by the user/owner. Attention needs to be given to differentiating the message the product sends as a marketing strategy.
5. **Reynolds and Gutman, 1984**
 - (a) ...the set of meanings and associations that serve to differentiate a product or service from its competition.
 - (b) The real key to understanding image lies in understanding linkages or connections between the levels that define the perceptual lens through which the consumer views the world and subsequently develops preferences for products. Effective linkages can be established for products only when we can gain a perspective on how the product relates to the personal value systems of consumers. By viewing means-end chains as entities, we can achieve this perspective.
6. **Durgee and Stuart, 1987 ("Product Meanings")**
 - (a) what the brand connotes or means symbolically in the eyes of consumers.
 - (b)...meaning profile refers to the complex of meanings that are associated with a given product category.

GROUP 1D: EMPHASIS ON PERSONIFICATION

1. **Bettinger, Dawson and Wales, 1979**

...an "adult" image and a "child" image of the product
2. **Sirgy, 1985**

Products are assumed to have personality image, just as people do... These personality images are not determined by the physical characteristics of the product (e.g. tangible products, suppliers, and services) alone, but by a host of other factors such as advertising, price, stereotype of the generalized users, and other marketing and psychological associations.
3. **Hendon and Williams, 1985**

Also known as "brand personality" or "brand character", it involves nothing more than describing a product as if it were a human being. This is an effective way of generating interest because people favour products that match their own self interest.
4. **Debevec and Iyer, 1986**

In positioning and repositioning products, advertisers often work to create a gender image for a brand...

GROUP 1E: EMPHASIS ON COGNITIVE OR PSYCHOLOGICAL ELEMENTS

1. **Gardner and Levy, 1955**
 - (a) The sets of ideas, feelings and attitudes that consumers have about brands.
 - (b) The social and psychological nature of products.
 - (c) ...a character or personality that may be more important for the overall status (and sales) of the brand than many technical facts about the product.
2. **Martineau, 1957**

...the product or brand image is a symbol of the buyer's personality
3. **Reynolds, W.H., 1965**

...the total set of attitudes, the halo of psychological meanings, the association of feeling, the indelibly written aesthetic messages over and above the bare physical qualities.

 - (a) An image...is the mental construct developed by the consumer on the basis of a few selected impressions among the flood of total impressions; it comes into being through a creative process in which these selected impressions are elaborated, embellished and ordered.

TABLE 1 (CONTINUED)
DEFINITIONS

(b) Images are not isolated empirical beliefs about a product or brand but are systems of inferences which may have only a tenuous and indirect relationship to fact.

(c) Images are ordered wholes built by consumers from scraps of significant detail in much the same way that writers use significant detail to illumine complex totalities.

4. Bird, Channon and Ehrenberg, 1970

...(brand image is) an attitude about a given brand

5. Gensch, 1978

...brand preference is a function of the perception space associated with the alternatives. The author takes the position that perception consists of two components, the individual's ability to obtain measures of the brand attributes on factors he considers important, and the "image" of each brand. The term "image" as usually defined and discussed in the marketing literature is an abstract concept incorporating the influences of past promotion, reputation and peer evaluation of the alternative. Image connotes expectations of a consumer. The interaction of these two variables, individual attribute measurements and image, is assumed to vary across product types and across individuals.

...in marketing theory, image generally is assumed to have a more significant role in product situations in which the individual has difficulty

obtaining objective measures on the important product attributes...

6. Levy, 1978

A brand image is a constellation of pictures and ideas in people's minds that sum up their knowledge of the brand and their main attitudes towards it.

7. Bullmore, 1984

A brand's image is what people think and feel about it: and those thoughts and feelings will not - cannot - be universally identical ...The image lies in the mind of the beholder - and is conditioned at least as much by the nature of the beholder as by the nature of the object itself.

8. Park, Jaworski and MacInnis, 1986

(a) A brand image is not simply a perceptual phenomenon affected by the firm's communication activities alone. It is the understanding consumers derive from the total set of brand related activities engaged in by the firm.

(b) The image is a perception created by the marketer's management of the brand. Any product theoretically can be positioned with a functional, symbolic or experiential image.

9. Friedmann and Lessig, 1987
("Psychological Meaning")

...the consumer's understanding and evaluation of the product.

symbols, will only be used if they reinforce the consumer's self concept. These symbols are said to have several roles in that they represent personal attributes, goals, social strivings and patterns, and serve as communication devices between individuals and their significant referents.

In so implying the attachment of meaning and the matching of symbols to self concept, this group of definitions has some affiliation with those groups that focus on meaning and on personification. It is also noteworthy that conspicuous by absence are definitions which reference the Freudian symbolism of the product's design.

Emphasis on Meanings and Messages

The distinctive criterion associated with this category is a focus on the underlying meaning that consumers ascribe to a product. These definitions propose that because what each brand in a product category denotes or does may not be very different from what any other brand does, in order to differentiate itself each must rely on what it

connotes or means to the consumer. As the following discussion will show, however, what "meaning" means can vary somewhat among researchers.

Durgee and Stuart (1987) suggested that each product or brand has a "meaning profile", which they define rather circuitously as the complex of key meanings associated with the product or brand, or what the product means symbolically in the eyes of consumers. Citing the work of those who have studied the philosophy of meaning, they proposed that there are three different ways in which a product could "mean" something -- causality, context and similarity.

Swartz (1983) proposed that to the extent that functional differences between brands of the same product were minimal, "message differentiation" could be used as a viable product differentiation strategy. This was said to involve distinguishing one brand from another based on the message communicated by the use or ownership of the brand. These messages were said to generate directly from the meaning or interpretation that was

given to certain brands or products by the persons exposed to them.

Friedmann and Lessig (1987) adapt their notion of "psychological meaning" from existential-phenomenological psychology. They describe this concept as a mental position, understanding or evaluation of the product that develops in a nonrandom way from interaction between perceiver and product stimulus. Levy (1978) similarly talks about meaning as being learned or stimulated by the component experiences that people have with the product.

Reynolds and Gutman (1984) have defined product imagery in terms of the stored meanings that an individual has in memory, suggesting that what is called up from memory provides the meaning we attribute most basically to image. Still others have talked about a product as having "personal" and "social" meanings, but have provided no general framework to explain how these are derived or what they intend.

Emphasis on Personification

The personification of a brand and its image with human characteristics, a practice that has become especially popular in the 1980s, has been approached from two distinct perspectives. The first involves describing the product as if it were a human being, suggesting that the brand has a distinct personality of its own. Such "personalities" as the Kodak Kolorinks and Betty Crocker are of this ilk. The second focuses on associating the consumer's personality or self concept with the image of the product or brand. This is exemplified by the "express your individuality" appeal of Calvin Klein jeans, or the fragrance industry's correlation of perfume use with fulfilled dreams, fantasies and aspirations.

Relating brand image to personality is intuitively appealing on many grounds. Both are multidimensional, and both appear to operate at the same level of abstraction. Personality has been said by some (Kassarjian and Sheffet 1975) to be best conceived of as a dynamic whole, which is consistent with the general sense that many have about brand image. Many consumer theorists are of the view that purchase behavior is determined by the interaction of the buyer's self concept with the 'product's personality', and in this context the definitional relationship is also especially apt.

Associating brand image with personality is not, however, without difficulty. Most notably, the struggle that psychologists have had with the definition and measurement of personality likewise becomes a problem for those interested in studying brand image. It is therefore not surprising that those who define brand image by reference to personality do not attempt to define the latter concept in any detailed way. They simply suggest that products have personality images, or they focus in on some distinctly human descriptor, such as "gender" image (Debevec and Iyer 1986), "age" image (Bettinger and Dawson 1979), or "social caste" image (Levy 1958).

Emphasis on Cognitive or Psychological Elements

Such unity as exists within this group stems from the fact that each stresses a cognitive or mental process by which brand image is said to be triggered. They concentrate on mental effects by naming any one of "ideas", "feelings", "attitudes", "mental constructs", "understandings" or "expectations" as the cardinal determinant of brand image. While most of these definitions may not be directly traceable to Gardner and Levy's initial conceptualization of brand image as "a consumer's feelings, attitudes and ideas towards a brand", most seem to have been influenced by it.

The reference to "feelings" suggests a link between product and emotions (Reynolds and Gutman 1984), which is a particularly germane connection in circumstances where consumers have difficulty obtaining objective measures on product attributes, or where product clones can not be differentiated or positioned on the basis of a distinct benefit appeal. In either case, the emotional appeal of the product would seem likely to play a significant role.

Conceptualizing brand image as an "attitude" provides an orientation that is more amenable to measurement and evaluation. Perhaps because of the attitude measurement techniques that have been developed, it has been noted that definitions which employ this approach have a tendency to restrict image to a set of product characteristics (Reynolds and Gutman 1984). While such definitions might lead to the conclusion that a product's image can be approximated by the sum of its attribute values, there are surely abundant examples where two brands have the same attribute ratings but different market shares. The "attitudinal" definitions would therefore appear deficient because of their inability to explain this.

The terms "understandings", "expectations" and "mental constructs" are rather vague and noninstructive terms for capturing brand image. Nonetheless, they do form an interesting group in their restriction to intellectual or reasoned processes and in their contrast with those definitions which incorporate the "feelings" dimension.

THE COMPONENTS OF BRAND IMAGE

Because of the significance of brand image marketing, it is important to translate what we know about this concept, or think we know, into the details of what marketing practitioners should do. This is a task that has been complicated, however, by the lack of consensus concerning the components that make up brand image, and consequently, about how it should be managed.

As has been previously noted, those who conceptualize brand image as an attitude are unlikely to accept that it extends to factors beyond the physical product (Reynolds and Gutman 1984). Others, in contrast, have proposed that the "image" of a brand is composed of factors extrinsic to the product itself. Gensch (1978) made this separation clear when he proposed that product perception consisted of two components, the measures of the

brand attributes and the "image" of the brand. He defined "image" as a purely abstract concept which incorporates the influences of past promotion, reputation and peer evaluation of the product.

A more moderate view is offered by those who suggest that working only with attributes, or only with abstractions, is not the way to measure or understand image. These authors propose instead that the objective or functional product qualities, as well as the psychological qualities of both user and product, must be accounted for. In this vein, Friedmann (1986) suggests that the "psychological meaning" of products is made up of the product's attribute bundle, the consumer's dominant perceptual mode, and the context in which the perceptual process takes place.

While Reynolds and Gutman (1984) confirm this synergistic effect, they discuss the components of brand image in terms of a means-end chain, identifying an implication network which reflects memory linkages as the fundamental component of brand image. They describe a means-end chain as the connection between product attributes, consumer consequences, and personal values, and theorize that image is represented by the synthesis of these components.

Stone, Dunphy and Bernstein (1966) distinguish between three main components of an image (its theme, its image proper, and its net evaluation). Levy (1978) talks about brand image as being composed of a mixture of the physical reality of the product and the beliefs, attitudes and feelings that have come to be attached to it. And rather exquisitely, Dichter (1984) describes magic and a product's morality as two of the basic components of its image.

APPROACHES FOR MEASURING BRAND IMAGE

Given the previous discussion on the theoretical formulation of brand image, it is not unexpected that the techniques for its measurement have not been standardized. Over the past three decades, several tools, routines and methods have been used to gain insight into the content and organization of brand images. Coincidentally, wide variations have occurred in the components of brand image that have been measured, the specific types of data sought, the manner in which data have been collected, classified, coded and analyzed, and the way in which results have been presented.

There has likewise been considerable diversity in the perspective from which brand image has been assessed. Some have measured the image of individual dimensions of a brand (Pohlman and Mudd 1973), while others have arrived at a single measure for brand image overall (Dolich 1969). The brand's image has been measured in isolation, relative to its competition (Boivin 1986), in relation to consumer ideal points and advertisement images (Keon 1984), and in relation to each of a person's actual self-image, ideal self-image, the social self image, and the ideal social self image (Sirgy 1985). It has been measured as a function of

brand usage and brand conspicuousness (Bird, Channon and Ehrenberg 1970), for clarity and sharpness (Pohlman and Mudd 1973), for stability over time and for discriminating attributes (Green and Devita 1977), and has been assessed and compared from the perspective of the retailer versus that of the consumer (McClure and Ryans 1968).

While researchers have not agreed on the most appropriate tool for measuring brand image, there does appear to be a trend towards operationalizing this construct using quantitative techniques. This is not to say that the more nonstructured, qualitative methods of analysis are obsolete. In fact, a number of contemporary theorists have affirmed the conversational, projective and matching techniques that were first proposed by Gardner and Levy nearly forty years ago.

In 1986, for example, Boivin proposed a three stage 'free response' approach to brand image studies which was comprised of the collection, coding and scoring of free verbalizations. In 1987 Durgee and Stuart proposed techniques in which brand personality would be explored by asking respondents to compare their brands to people, countries, occupations, fabrics, activities, cars, animals and magazines, or to write creative descriptions of brands or stories of interesting family experiences with them. And much earlier, content analysis was used by Woodside (1972) to study the image of selected consumer goods as reflected in the mass media.

While these qualitative methods have been lauded for allowing the contents of brand image to be uncovered by permitting feelings to emerge, they have been criticized for the difficulty they present in data handling and the statistical treatment of responses. While some have adopted tools such as 'linguistic coding' to address these difficulties, most have opted for more quantitatively oriented techniques.

Based on a composite of several articles, Table 2 represents some of the 'typical' approaches and techniques that have been used in quantitative brand image studies over the past thirty years. It should be noted that several questions remain unanswered regarding which of these are the most accurate and effective, and whether the differences that are generated from the use of different tools are critical.

THE ORIGIN, CREATION, FORMULATION AND MANIPULABILITY OF BRAND IMAGE

Image building, image change, image monitoring and maintenance, product positioning, product differentiation and image segmentation are among the present generation of brand image management activities. While clearly such activities presuppose that a brand's image can be manipulated by marketing practice, the literature fails to agree on the extent to which this is possible. In fact, the debate is ongoing as to whether an image is

something that is conveyed or something that is received.

Bullmore (1984), on the one hand, emphasizes the dependence of brand image creation upon the individual psyche. He refutes the assumption that the image belongs to the brand, and ripostes that an image, like a reputation, can only reside in the minds of people. His contention is that the mind both contains and creates the image, and that it is mediated or stimulated by the consumer's experiences.

On the other hand, there are those who suggest that the consumer has a passive role where image creation is concerned. They propose that an image is projected to the consumer by the marketer, and that it can be selected, created, implemented, cultivated, and "managed" by the marketer over time. It has even been suggested that false or deceptive product images can be "ordered to be corrected", as if there is a simple transfuse between the image presented by the media and the consumer's mind (Scammon and Semenik 1983). In this context, advertisements have been regarded as a primary vehicle through which images can be imparted or "transferred" to a brand.

An amalgam of the above perspectives supports the view that product image is a function of the interaction between perceiver and product stimulus. The product's attributes, the sponsoring organization, the marketing mix, the modes through which people tend to perceive, personal values, experience, the types of people associated with use of the brand, and a number of context variables have

all been said to be among the factors that contribute to the development of a particular brand's image.

CONCLUSION

The term "brand image" is at once a label that has become somewhat impoverished because of widespread use, and a concept that has contributed richly to marketing practice. It is both a concrete and an abstract expression. Its definition and operationalization have been fairly irregular, although not without some patterns and commonalities. It is a growing, evolving term that has undergone considerable vicissitudes, some of which are enduringly useful.

This paper sought primarily to describe the shifting nuances of brand image, and therefore, has not rigorously analyzed the various shades of meaning of the definitions and conceptions under consideration. While in some cases the latter exercise may have been necessary to distinguish between substantive conceptual variations and those of form, this analysis has exposed examples of brand image usage which are polarized. These contradictions, in turn, betray the foundational integrity of this vital term.

In closing, this paper seeks to prescribe the brand image concept. This delineation is based largely on the frequency of occurrence of nuclear ideas within the definitions cited in Table 1. While admittedly there is no absolute standard of rightness, common usage is accepted as the authority for correctness, as it has been by a number of contemporary linguistic scientists and lexicographers (Bishop 1971). In this context, the

following emerge as the essential strictures of brand image:

- Brand image is the concept of a brand that is held by the consumer.
- Brand image is largely a subjective and perceptual phenomenon that is formed through consumer interpretation, whether reasoned or emotional.
- Brand image is not inherent in the technical, functional or physical concerns of the product. Rather, it is affected and molded by marketing activities, by context variables, and by the characteristics of the perceiver.
- Where brand image is concerned, the perception of reality is more important than the reality itself.

Despite conceptual deviations, it is clear that the concept of brand image has been of great significance in consumer behavior research, and there is every reason to suspect that its potential significance is even greater. As such, it is important that efforts continue to be made to more fully, completely and consensually understand this vital concept.

Consumer Evaluation of Franchise Extension Products: A Categorization Processing Perspective

Cathy L. Hartman, University of Calgary
Linda L. Price, University of Colorado
Calvin P. Duncan, University of Colorado

ABSTRACT

Although franchise extension strategies, use of familiar brand names to introduce new products, are widely used by practicing marketers, they have received limited attention from researchers. Their use is based on the belief that familiar, highly-regarded brand names will enhance response to new products. However, our understanding of consumer response is limited. This paper presents a processing model of consumer evaluation of franchise extensions using categorization theory. Conceptual and empirical findings from past studies on franchise extension are explained in the context of the model. Implications for future research are also discussed.

INTRODUCTION

A franchise extension strategy involves a company's use of an established brand name in its introduction of a product into a category that is new to the firm. The strategic importance of franchise extension is suggested by Tauber (1987) who notes that it has "become the guiding strategy of product planners in the '80s" (p.18). Almost half of all new packaged goods are franchise extensions (Tauber 1987), and in 1986, they accounted for over 35% of the total sales in the apparel and accessories industry (Kesler 1987).

The benefits promised by franchise extension strategies are based on the belief that consumers will respond more favorably to new products that carry highly-regarded, familiar rather than unfamiliar brand names. As compared against the strategy of introducing a product with a totally new brand name, franchise extension is viewed as less expensive and less risky (Tauber 1981). Advertising costs are frequently lower because expenditures to build consumer awareness of brand names are reduced. Moreover, brand name familiarity enhances trade and consumer acceptance of new offerings, thereby improving the chances of long-term market success. Placement of a popular brand name (e.g., Hershey's) on a new product (milk) helps secure retail shelf space and encourages first-time consumer trial.

Despite widespread use of franchise extension strategies by marketing managers, researchers have devoted only limited attention to uncovering factors and processes that explain consumer response to franchise extensions. Only recently has research focused on identifying factors involved in consumer evaluation of franchise extensions (Aaker and Keller 1987; Duncan and Nelson 1986). Unfortunately, these studies have been largely descriptive, and therefore provide a somewhat incomplete understanding of how, why, and when franchise extension strategies work. Fragmented and

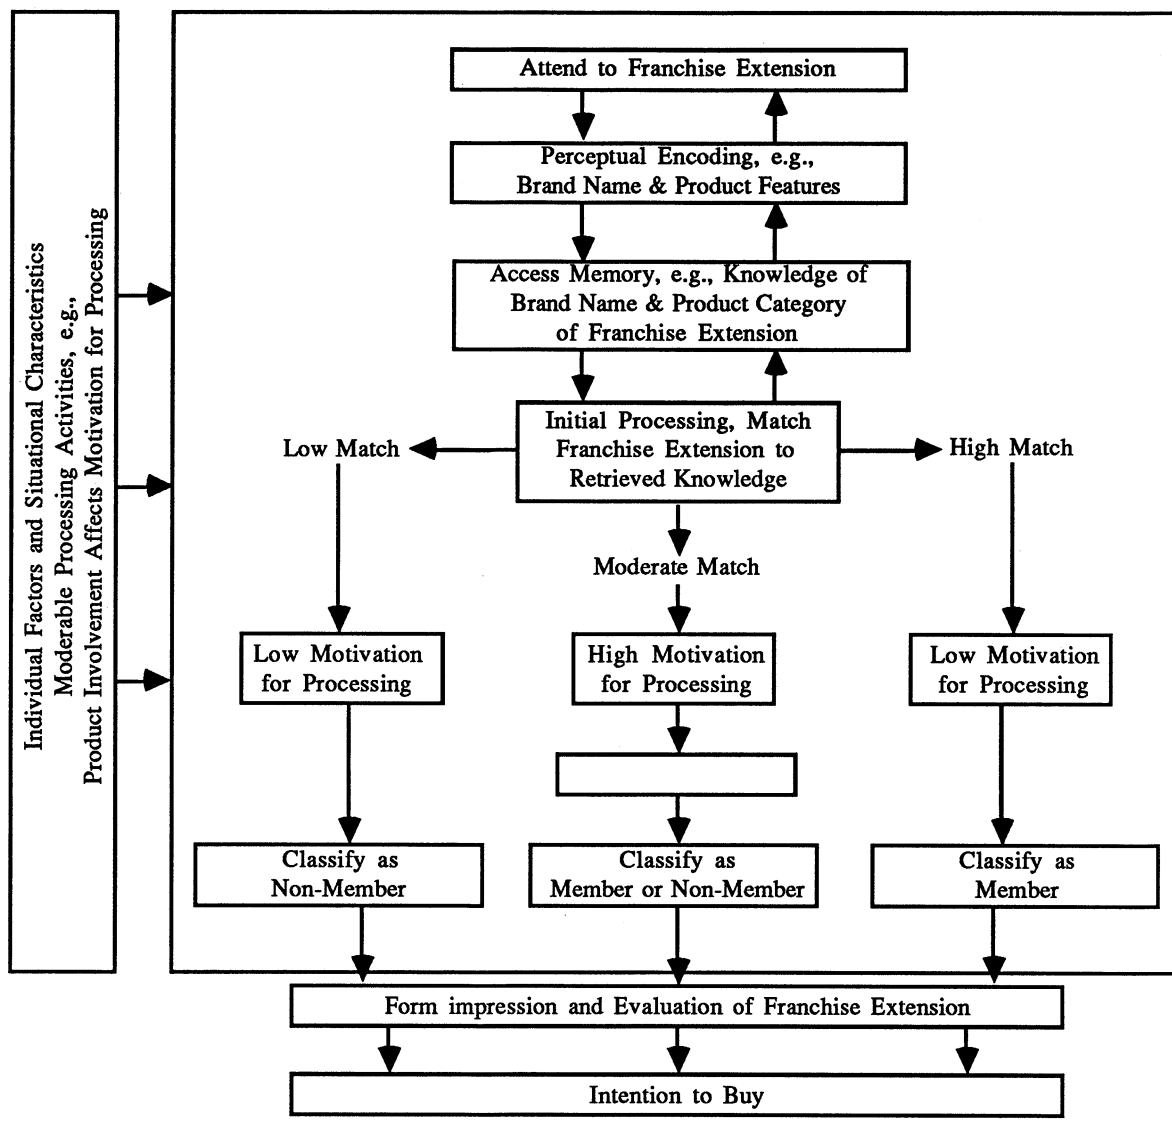

inconsistent research findings suggest the need for a unified theoretical framework to capture the complexities involved in consumer evaluation of franchise extension products (Fry 1967; Kerby 1967; Roman 1969).

This paper has three objectives. First, a conceptual model based on categorization theory is proposed to describe consumer evaluation of franchise extension products. This model demonstrates how the structure of prior knowledge interacts with the franchise extension stimulus to produce meaning given to the new product. Although previous research has found support for a relationship between prior knowledge of the brand name and consumer beliefs about franchise extensions, very little is known about the nature of the relationship. By examining the process itself, we hope to gain clearer understanding of how prior knowledge influences consumer beliefs and buying intentions. A second objective of the paper is to incorporate selected previous findings on franchise extension into the proposed model to consolidate contributions in this area. Past research has been more piecemeal than programmatic. In order to gain better understanding of franchise extensions, an attempt must be made to integrate existing conceptual and empirical findings into a framework. Finally, the paper discusses the implications of the model for further research. Categorization theory has already had a beneficial impact on theory and research in a variety of consumer research domains (e.g., Alba and Hutchinson 1987; Cohen 1982; Cohen and Basu 1987; Johnson 1984; Sujan 1985; Sujan and Deklava 1987; Sujan and Tybout 1989; Szymanski 1988). We argue that application of categorization theory to the complexities of franchise extension offers especially fertile ground for testing the assumptions and predictive qualities of the theory.

THEORETICAL MODEL

The figure illustrates the proposed model. The model assumes that a consumer's cognitive appraisal of a franchise extension depends on the way current information about the franchise extension is matched with prior knowledge of the brand name and product category of the extension. Specifically, the structure of the figure proposes five key components in franchise extension evaluation: (1) prior knowledge of the brand name and product category of the franchise extension, (2) degree of match or perceived similarity between the franchise extension and prior knowledge, (3) motivation for processing of the franchise extension, (4) extended processing and (5) moderating influences from individual factors and situational characteristics. These components represent a synthesis of findings

FIGURE
Processing Model of Franchise Evaluation

from franchise extension research with theory and research from the structure of knowledge literature. Although other components in the model are worthy of attention, this discussion focuses on those aspects that have received limited research attention and that hold promise of providing better understanding of the process itself. Subsequent sections present findings from previous research that are important to the model, provide a description of the process flow, and discuss key relationships contained in the model.

Relevant Findings from Franchise Extension Literature

A review of extant literature on franchise extension demonstrates four findings relevant to the model:

- (1) Brand name meaning represents the focal point for franchise extension strategies.
- (2) The characteristics of franchise extension products are often inferred from prior knowledge about the brand name.
- (3) The extent of meaning transfer from the brand name to the franchise extension product depends on the degree of perceived similarity between the impression of the brand name and the extension.
- (4) Individual factors influence the evaluation process for franchise extension.

Previous research pertaining to each finding is discussed.

The critical role that brand name meaning plays in franchise extension strategies is described in articles focused on managerial issues involved in franchise extension (Bengston 1982; Kane 1987a; 1987b; Karger 1981; Kennedy 1987; Tauber 1981; 1987). These articles outline guidelines for identifying extension opportunities. For example, Kane (1987a) prescribes two basic rules for developing franchise extension strategies: (1) focus on the consumer's rather than the marketer's perspective and (2) consider the total set of relations the original brand has to other products. The strongest and most consistent message in this literature is that an understanding of the total constellation of meanings that consumers associate with a brand name must be the starting point for uncovering potential product categories for extensions (Karger 1981). This contention is not substantiated with theoretical or empirical evidence, therefore, little insight is offered regarding how and why brand name meaning influences consumer response to franchise extensions.

Research on the role that brand name meaning occupies in consumer evaluation of franchise extensions has established a second finding relevant to the proposed model. Consumers often interpret characteristics of franchise extensions using knowledge stored in memory for brand names (Aaker and Keller 1987; Duncan and Nelson 1986). Duncan and Nelson (1986) define prior knowledge of the leveraged brand as the set of cognitive responses evoked by the brand name prior to exposure to the franchise extension. These authors measured prior knowledge and then instructed consumers to read concept statements for hypothetical extensions. Beliefs about the extension products were subsequently measured using a series of attribute statements. Findings suggested that consumer beliefs about and their intentions-to-buy franchise extensions were strongly influenced by prior knowledge for brand names.

An interesting aspect in this research is that consumers appear to interpret characteristics of franchise extensions using existing knowledge for brand names at different levels of abstraction. Abstraction refers to the level of generality of information and ranges from low (concrete) to high (abstract) along a continuum (Rosch 1975; Rosch, Mervis, Gray, Johnson, and Boyes-Braem 1976). Research findings indicate that consumers use concrete attributes such as taste or smell, as well as abstract attributes such as quality, to infer attributes of franchise extensions. For example, consumers expect Heineken popcorn to taste like beer (Aaker and Keller 1987) and Schwinn swing sets to be the same quality as Schwinn bicycles (Duncan and Nelson 1986). It is important to understand more about how and when consumers access and use abstract versus concrete attribute knowledge in franchise extension evaluation. For example, inferences based on concrete attributes may restrict

the range of product categories suitable for extension purposes (c.f., Johnson 1984; Johnson & Fornell 1987).

The third area of investigation relevant to the proposed model deals with the transfer of meaning from the brand name to the franchise extension. Two streams of research have studied meaning transfer: (1) semantic generalization (Fry 1967; Kerby 1967; Mazanec and Schweiger 1981; Roman 1969) and (2) cognitive-based studies (Aaker and Keller 1987; Duncan and Nelson 1986; Meyers-Levy, Louie and Curren 1988; Meyers-Levy and Tybout 1989; University of Minnesota Consumer Behavior Seminar (UMCB) 1987). Findings in each area suggest that the degree of meaning transfer depends on the level of perceived similarity between existing understanding of the brand name and the extension product.

Early research on franchise extension applied the principle of semantic generalization to investigate the transfer of response that occurs between the impression of the brand name and the franchise extension (Fry 1967; Kerby 1967; Mazanec and Schweiger 1981; Roman 1969). Semantic generalization represents a two-stage mediation model of learning. A person first transfers meaning from an object (e.g., a branded product) to signs associated with that object (e.g., a brand name), to a new object bearing the same sign (e.g., a franchise extension) (Osgood 1962). Because semantic generalization describes a stimulus/response type of learning, it reveals little about the cognitive activities that occur between the presentation of the stimulus and the overt response. This limitation has resulted in methodological problems in the application of this principle to franchise extension research and in discrepancies in the findings of published studies (Kerby 1967; Roman 1967). For example, Kerby (1967) reported limited support for semantic generalization; yet, Roman (1967) in an extension of Kerby's (1967) study found evidence that semantic generalization did occur in a franchise extension context. Roman (1967) used a methodology that separated branded product attitudes from product attitudes. She demonstrated that subjects perceived higher similarity between branded products (Cedar cleanser to Cedar bleach) than between the products themselves (cleanser to bleach). Roman interpreted differences in similarity judgments as evidence of semantic generalization. That is, products (objects) that shared a brand name (common sign) were perceived as more similar than products that did not share a brand name. These discrepancies suggest there may be important unidentified factors that influence generalization.

To address problems inherent in a semantic generalization approach, later researchers have attempted to identify the underlying cognitive variables that influence transfer of meaning from brand names to franchise extensions (Aaker and Keller 1987; Duncan and Nelson 1986; Meyers-Levy et al. 1988; Meyers-Levy and Tybout 1989; UMCB 1987). These studies have been successful in

isolating several factors of perceived similarity that may explain meaning transfer. For example, Duncan and Nelson's (1986) research indicated that logical consistency may be an important basis of perceived similarity. Logical consistency is the degree to which consumers believe the brand name makes "sense" in the context of the franchise extension. Depth interviews indicated that consumer perception of logical consistency is based on similarity in terms of production facilities and methods, attributes, prices, retail stores and packaging. Results suggest that logical consistency directly affects meaning consumers transfer from brand names to franchise extension products. It appears that perceived similarity depends on cognitive match. That is, when the cognitive structures of the brand name and franchise extension share one or more dimensions, consumers are able to transfer existing brand name impressions to franchise extensions.

Researchers have begun to explore the usefulness of knowledge structures in explaining perceived similarity (Meyers-Levy et al. 1988; Meyers-Levy and Tybout 1989; UMCB 1987). Results of these studies suggest that consumer response to franchise extensions is guided by category-based expectations. In particular, findings suggest that consumers have well-defined memory structures for products and brands that they use to process franchise extensions. When a franchise extension activates existing memory structures, evaluation of the extension depends on the degree of perceived similarity or match between the extension stimulus and activated knowledge. The level of match affects both the nature and outcome of the evaluation process. For example, Meyers-Levy and Tybout (1989) used the product category of soft drinks and varied match by including an attribute not generally associated with soft drinks. A soft drink described as being "all natural", for instance, represented moderate match. Findings indicated that when consumers perceived a moderate match, compared to either a high match or low match, they engaged in more elaborated or extended processing and reached higher overall evaluations of franchise extensions.

The final finding from previous research of relevance to our model is that individual differences among consumers can influence the evaluation process. Meyers-Levy and Tybout (1989), e.g., hypothesized and supported that nondogmatic individuals would be more willing to process franchise extensions than dogmatics. Their rationale was that because nondogmatics are more receptive of new information and change, they should be more willing to consider franchise extensions. In general, the effects of individual difference variables such as dogmatism on franchise extension processing have received limited attention. Research in other areas suggests that this is a critical topic for future study (Capon and Burke 1980; Capon and Davis 1984; Childers, Houston and Heckler 1985). For example, substantial research has suggested that consumer involvement moderates

a person's motivation to process new information (e.g., Alba and Hutchinson 1987; Celsi and Olson 1988; Petty, Cacioppo, and Schumann 1983; Greenwald and Leavitt 1984). Because involvement is a motivational state that directly affects the extent of processing, higher involvement should enhance consumer motivation for processing of franchise extensions (Celsi and Olson 1988). Research is needed to further understanding of how individual differences affect consumer evaluation of franchise extensions.

AN ILLUSTRATION OF THE PROCESSING MODEL

This section provides a discussion of key relationships between the five central components in the proposed model: (1) prior knowledge for the brand name and product category of the franchise extension, (2) degree of match or perceived similarity between the franchise extension and prior knowledge, (3) motivation for processing of the franchise extension, (4) extended processing and (5) moderating influences from individual factors and situational characteristics. Using examples of actual franchise extensions, it also describes the flow of alternative processing sequences contained in the model.

As the model indicates, consumers rely on information stored in long-term memory (LTM) to evaluate franchise extensions. The model, consistent with recent research, assumes that knowledge is stored in LTM in the form of categories or concepts. A category contains all the information for a class of objects considered to be equivalent (Rosch 1975; Mervis and Rosch 1981). Objects within a category share attributes or characteristics. People assign meaning to new objects by comparing characteristics of new objects to existing category knowledge. For example, consumers may have a knowledge category for televisions stored in LTM (Johnson 1984). Objects categorized as televisions vary from pocket-sized to big-screen, from color to black and white, but they have common attributes that are used to classify them as televisions and distinguish them from other objects such as computers and radios.

As illustrated in the figure, two categories of existing knowledge are involved in the evaluation process: (1) knowledge for the brand name and (2) knowledge for the product category of the franchise extension. Past franchise extension research establishes the importance of prior knowledge for the brand name (Aaker and Keller 1987; Duncan and Nelson 1986; Meyers-Levy et al. 1988; Meyers-Levy and Tybout 1989, UMCB 1987). Other research suggests that knowledge for the product category will also influence the evaluation process and outcome (Alba and Hutchinson 1987; Alba 1983; Lynch and Srull 1982; Sujana 1985). For example, Sujana (1985) found that when product attributes matched product knowledge, consumers did less processing of specific attributes and reached evaluations more quickly.

An important contribution of the model is in defining the role that prior knowledge plays throughout the different processing activities. This role can be illustrated by looking more specifically at the initial matching phase--the stage at which the consumer judges the degree of match between the characteristics of the franchise extension and prior knowledge. As the model depicts, consumer motivation for extended or elaborated processing depends on the level of match between existing knowledge and the new franchise extension product. Considerable research has investigated conditions that cause consumers to engage in elaborated processing and the effect that elaboration has on subsequent processing (Belmore 1987; Chaiken 1979; Petty, Cacioppo and Schumann 1983; Greenwald and Leavitt 1984; Houston, Childers and Heckler 1987; Kahle and Timmer 1984; Kahle and Homer 1985; Lynch and Srull 1982). Much of this research suggests that consumers engage in initial processing to decide whether additional cognitive effort is "worth it" (c.f., Kahle and Homer 1985). Consistent with Meyers-Levy et al.'s (1988) and Meyers-Levy and Tybout's (1989) findings, we argue that in franchise extension evaluation consumers engage in initial processing. Thus, when consumers encounter franchise extensions they perceive as extremely dissimilar or incongruent with prior knowledge, ones where they believe inconsistencies between the franchise extension and brand name knowledge are difficult or impossible to reconcile, they become frustrated. This, in turn, lessens their interest in further processing. Any additional processing then centers are inconsistencies, rather than consistencies between characteristics of the franchise extension and prior knowledge. In this case, differentiation becomes the focal point and differences may be exaggerated. Considerable research suggests that incongruent items (as compared to congruent items) receive more attention and elaboration during processing (Crocker and Weber 1983; Crocker and Vitkus 1983; Hastie 1980; Hastie and Kumar 1979).

In our model, the level of match influences consumer motivation for further processing and; thus, the likelihood of consumers to engage in extended processing. Three sequences are possible:

- (1) a low match leading to low motivation for further processing,
- (2) a high match leading to low motivation for further processing, and,
- (3) a moderate match leading to high motivation for further processing and; subsequently, extended processing.

The sequences hold different implications for franchise extension evaluation. In the first sequence of low match and low motivation, a consumer fails to find a match between the characteristics of the franchise extension and his/her understanding of the brand name. As an example, consider the recent

franchise extension of the Bic brand to sailboards. If prior knowledge is comprised of meanings associated with Bic lighters and Bic pens, a consumer's initial response to the franchise extension might be "plastic" and "disposable". The consumer may ask, "what does plastic, disposable tell me about a sailboard?" If the consumer decides these are inconsistent associations, he or she may not exert the effort to try and resolve these discrepancies. The consumer, frustrated by the large discrepancy between the brand impression and the extension product category may create a negative impression of the Bic sailboard. Some research has suggested that frustration and helplessness associated with incongruities that are unlikely to be resolved stimulates negative object evaluations (Mandler 1982; Meyers-Levy et al. 1988; Meyers-Levy and Tybout 1989). Moreover, if the consumer were motivated to resolve the problem through other incentives (e.g., through their interest in the product category), this might only enhance the negativity of the response. For example, a sailboard enthusiast may spend a few additional minutes trying to make sense of it and end with the sentiment, "What a waste of time! It doesn't make any sense".

An alternative situation is described by the high match and low motivation sequence. In this case, the consumer perceives a high degree of match between the characteristics of the franchise extension and prior knowledge. For example, an individual's first encounter with Hershey's milk probably activates thoughts of "chocolate" and "smooth" which fit with the characteristics of the franchise extension. In this case, the consumer may engage in nearly automatic transfer of his or her brand impression to the franchise extension. Consistent with stereotyping research, (e.g., Cohen 1981; Taylor, Fiske, Etoff, and Ruderman 1978), the consumer may even ignore obvious differences. If asked later about Hershey's milk, a consumer's only salient belief might be that it's milk with Hershey's chocolate in it.

The third sequence of moderate match and high motivation for processing suggests a situation where a consumer finds some degree of match between characteristics of the franchise extension and prior knowledge. Consider a Black and Decker coffee maker. Black and Decker might trigger connotations such as "trustworthy", "power tools" and "garage". Although "trustworthy" and "power" suggest the coffee maker will perform well, "garage" suggests things such as grease and dirt which are incongruent with kitchen appliances. This creates a problem for the consumer to solve, raising interest in the coffee maker. During extended processing, the consumer would try to resolve the inconsistencies, i.e., decide if the attributes that did not fit could be reconciled in some way. A moderate match creates interest in resolving the discrepancy (Hastie 1980; Meyers-Levy et al. 1988; Meyers-Levy and Tybout 1989). The elaborated processing that follows from this interest has attendant effects. For example, research suggests that it increases recall and retrievability of the moderately

incongruent object (Hastie 1980; Hastie and Kumar 1979; Meyers-Levy and Tybout 1989; Srull 1981). That is, it will be easier to remember the Black and Decker coffee maker than a new Black and Decker power screwdriver. Because the Black and Decker coffee maker spends more time in working memory, compared to the Black and Decker power screwdriver, it becomes linked to more characteristics of the brand name stored in memory (Hastie 1980).

All three processing sequences could be altered by influences such as individual differences and situational characteristics. Prior research suggests these factors would alter the nature of consumer evaluation (e.g. Batra and Ray 1986; Belk 1975; Capon and Burke 1980; Capon and Davis 1984; Childers, Houston and Heckler 1985; Park, Iyer and Smith 1989; Wright 1974). In our model, individual differences and situational characteristics are treated as moderating variables and as such alter the effects of and relationships between components (Arnold 1982). A brief discussion of potential influences from personal involvement is offered as an illustration. Involvement is defined as the level of personal relevance (Zaichkowsky 1985). Research suggests that consumer perception of the personal relevance of products affects their motivation for processing, such that at high levels of involvement their motivation is also high (Celsi and Olson 1988). In the model, motivation for processing depends on the match between characteristics of the franchise extension and prior knowledge. This relationship might be altered by consumer involvement. For example, the model suggests if match is low, a consumer has little motivation for further processing. However, if the person is at a high level of product involvement, this personal motivation may result in extended processing. As suggested, earlier this may enhance the negativity of the evaluation.

The objective of the proposed model is to describe consumer response to franchise extensions. Thus, the model ends when the consumer reaches an overall evaluation and decides on his/her intention-to-buy the franchise extension product. While processing of new information is complete at this point, there are alterations in existing knowledge that may occur that are beyond the scope of this model. In a franchise extension context, the most important change of interest would be modification of the knowledge category for the relevant brand name. New product information may alter the consumer's attitude toward the brand name. For example, a series of extension products that moderately match existing product offerings may spark interest in and enhance affect towards the brand name. Consumer acceptance of Black and Decker kitchen appliances, for instance, may have elevated the brand name to a "household" rather than just a "work-shop" brand name. Positive acceptance may also reinforce consumer overall impression of Black and Decker as a manufacturer of power tools. On the other hand, new information about extension products that mismatch existing product offerings may have deleterious effects on existing brand name

impressions. For example, consumer inability to reconcile Bic sailboards with Bic as a manufacturer of disposable products (i.e., cigarette lighters and ink pens) may create confusion about brand name meaning. This confusion may, in turn, detract from consumer regard for the Bic brand name. Thus, while changes in existing knowledge are beyond the scope of this model, they represent an important consideration for franchise extension strategies.

The proposed model provides a general framework that describes consumer evaluation of franchise extensions. It is expected that specific relationships between model components may vary according to the particular brand name that is being extended. While empirical testing of the model is necessary to uncover how relationships may change, this section presents an illustration based on theory and research in other areas to demonstrate how evaluation may change.

In light of a recent, award-winning conceptual piece by Park, Jaworski, and MacInnis (1986), perhaps the most important distinction to be made with respect to brand names is in terms of overall brand image. Park et al. (1986) hypothesize that the most critical judgment a manager must make in selecting an extension product is whether the overall impression of the extension matches the overall image of the brand name. Brand image is defined in terms of what the brand name means to the consumer and what the consumer experiences in using the brand. These researchers argue that the basis for achieving this match depends on whether the brand image is functional or symbolic; and, matching the extension product on that major type of usage outcome. Brands with functional images are those that solve consumption-related problems. Consumers think of functional brands in terms of direct, tangible, performance-outcomes that result from use of the brand, e.g., Bounty towels are absorbent. On the other hand, brands with symbolic images satisfy social and psychological needs of consumers. These brands provide intangible outcomes to consumers, e.g., a Rolex watch helps a person feel successful. Symbolic brands assist consumers in achieving role-related outcomes such as fulfillment of personal, social and professional responsibilities. Park et al. (1986) contend that functional brands should extend to performance-related products and symbolic brands to referent-based products. As an example, Park et al. (1986) suggest that the Vaseline brand possesses a functional image as a moisturizer; and therefore, the brand name is appropriate for extension to products that match this image such as bath beads, hand lotion, and baby shampoo. On the other hand, a brand such as Brooks Brothers holds a symbolic image as a manufacturer of fashion products for conservative, professional men. Extensions that match this symbolic image include shoes, cologne, and hats with a similar conservative, professional style.

While consideration of the functional/symbolic distinction represents a revolutionary idea in a franchise extension context, this distinction is

grounded in a long tradition of research on the functional/symbolic characteristics of products (e.g., Gardner and Levy 1955; Levy 1959; 1981; Solomon 1983; Hirschman 1988; Holbrook and Hirschman 1982). Research on products has demonstrated that many items such as clothing, cars and watches possess symbolic features, and that consumption of these goods may depend more on their social and psychological meaning than on their functional utility (Levy 1959; 1981; Solomon 1983; Holbrook and Hirschman 1982). The premise that consumption is often influenced by functional and symbolic qualities of products is supported by research streams involving self- and product-image congruence (e.g., Birdwell 1968; Dolich 1969; Gardner and Levy 1955; Grubb and Hupp 1968; Holman 1980; Sirgy 1982), and, social class- and product-image congruence (e.g., Bearden and Etzel 1982; Levy 1966; Martineau 1958). In line with Park et al.'s (1986) arguments and the extensive empirical evidence that substantiates the importance of the functional/symbolic distinction for products, an investigation of the effects of brand image on franchise extension evaluation would be useful for further specification of this processing model.

IMPLICATIONS FOR FUTURE RESEARCH

The figure and the discussion of the processing sequence suggests several avenues for future research. One area involves the relationship between the initial degree of match and the motivation for further processing. Based on the level of match, two different processing sequences are possible. When the match between the franchise extension and stored information is either low or high, it will result in low motivation for additional processing. And, if the degree of match between the franchise extension and stored information is moderate, it results in high motivation for processing. Research is needed to gain a clearer understanding of factors that explain the different match conditions. Related areas such as impression formation, have explored attribution theory as a possible explanatory variable (Crocker and Vitkus 1983). In this context, high apparent incongruity between brand name and the franchise extension might cause differing impressions based on what a consumer sees as the cause of the franchise extension. For example, consumers are comfortable with the brand name Coke on sweatshirts, although they see Coke as having no special expertise in making sweatshirts, because they associate Coke with fun.

Also of interest is how the nature of processing in the initial stage compares to that in the extended stage. Initial processing involves a quick check to establish some basis for relating the franchise extension to existing knowledge. This comparison could either be done automatically or with some amount of deliberation. An automatic comparison suggests that a consumer would use the first attribute that comes to mind. While a more deliberate comparison would involve the use of

attributes that are more salient or criterial than others. Thus, the extent of deliberation will influence the type of attribute comparisons made during initial processing. Research should investigate both the extent of deliberation consumers generally use during initial processing, as well as, how the level of deliberation varies across consumers and franchise extension products.

Extended processing involves a series of comparisons between characteristics of the franchise extension and stored knowledge. These attribute comparisons must eventually be integrated to reach a measure of overall similarity between the franchise extension and stored knowledge. Consumers could use alternative methods for integration. Two methods suggested by categorization research are additive and multiplicative rules (Lingle, Altom, and Medin 1985). An additive rule suggests a piecemeal process whereby attribute matches are weighted by their importance and summed to an overall measure of similarity. Consumers may proceed until some criterial level of similarity is attained. A multiplicative rule suggests a configural process in which relationships among attributes are important. Similarity coefficients might be assigned to attribute comparisons which are then multiplied together. These rules differ in their treatment of attribute relations and can lead to different measures of overall similarity for the same data. With the additive rule, a mismatch on one attribute may be compensated for by a match on another. However, for the multiplicative rule a mismatch on one attribute can reduce overall similarity to zero. Consumer preferences for the use of each of these rules when evaluating franchise extensions needs investigation.

Brand Cognitions as Determinants of Brand Attitudes: The Influence of Measurement and Processing Involvement

Randall L. Rose, University of South Carolina

Paul W. Miniard, Ohio State University

Sunil Bhatla, Case Western Reserve University

ABSTRACT

We examined the influence of brand cognitions on the formation of brand attitudes after exposure to an advertisement under conditions of higher or lower involvement. Brand cognitions were measured using both a cognitive response index and an expectancy-value measure. The strength of the brand cognitions - attitude relationship proved to be stable across involvement conditions and relatively insensitive to measurement. Further analyses using groups based on extremely high or low levels of self-reported involvement indicated the expected involvement moderation of the impact of brand cognitions on brand attitudes.

INTRODUCTION

The role of brand cognitions in the formation of post-communication brand attitudes has been well documented in research applying expectancy-value attitude theory (e.g., Fishbein and Ajzen 1975; Lutz 1975; Mitchell and Olson 1981) and cognitive response models of persuasion (e.g., Greenwald 1968; Wright 1973). More recently, researchers have begun intensive study of affective reactions to advertisements with a focus on the influence of ad attitudes (A_{ad}) on the formation of brand attitudes (A_b) (e.g., Mitchell and Olson 1981; Shimp 1981). One interesting, and somewhat surprising, observation drawn from this stream of research has been that brand cognitions, when operationalized in the form of cognitive responses, often do not affect brand attitudes in models including ad attitude as a second predictor of A_b . Both conceptual and methodological explanations have been offered for the relatively weak causal role played by brand-oriented cognitive responses. This research attempts to shed some further light on these issues.

BACKGROUND

The surprising weakness of the link between brand-oriented cognitive responses (CR_b) and brand attitudes in models including A_{ad} was first noted by Lutz, MacKenzie, and Belch (1983) and MacKenzie and Lutz (1983). Similarly, Mackenzie, Lutz, and Belch (1986) reported a non-significant relationship between CR_b and A_b in two experiments which supported their model of brand attitude formation. In a study which included affective responses as well as cognitive responses to advertisements, Batra and Ray (1986) also found that CR_b did not influence A_b when A_{ad} was included as a copredictor of brand attitudes.

At this point, the only supportive evidence of the $CR_b - A_b$ relationship when A_{ad} also serves

as a determinant of A_b has been reported by Park and Young (1986). In their study, CR_b was related to A_b when the commercial lacked music and was processed under cognitive involvement conditions. However, a change in involvement (i.e., the affective and low involvement conditions) or the presence of music under cognitive involvement reduced the relationship to non-significance.

Mackenzie et al. (1986) proposed a measurement artifact as one explanation for the lack of a significant $CR_b - A_b$ relationship. They pointed out that the cognitive response index used in their studies is inferior psychometrically to measures based on expectancy-value models. Moreover, cognitive response measures may be vulnerable to restrictions in range, especially when motivation to process message arguments is low. This line of reasoning suggests that causal relationships involving brand cognitions and attitudes should be stronger when the former is operationalized using an expectancy-value formulation instead of cognitive responses. Consistent with this, research using such measures rather than cognitive responses has reported stronger support for the causal role of brand cognitions (Gardner 1985; Mitchell 1986; Mitchell and Olson 1981). Given, however, the possibility that other inter-study differences could account for the more favorable findings involving expectancy-value measures, a more precise test of potential measurement effects would entail comparisons within the same investigation.

Such a comparison was provided by Park and Young (1986). They observed relatively little difference between cognitive response and expectancy-value measures. Both measures produced largely equivalent estimates of the relationship between brand cognitions and attitudes under all of their experimental conditions but one: affective involvement and a musical commercial. In this condition, the relationship was significant only for the expectancy-value measure. This particular finding is questionable on several grounds. First, although the regression coefficient between A_b and the expectancy-value measure was significant, the simple correlation between the two was not. Such differences typically indicate that the predictor is simply serving as a suppressor variable. It is also interesting to note that the expectancy-value measure was unrelated to A_b when subjects processed the same musical commercial but under cognitive involvement conditions. Why the measure should relate to A_b under low involvement but not cognitive involvement is not at all clear, and runs

counter to predictions about the role of involvement discussed below.

One objective of the present study was to provide a further examination of this measurement issue. In particular, we examine how changes in the operationalization of brand cognitions (i.e., expectancy-value versus cognitive response measures) influence its relationship with brand attitude.

A second explanation for the weak relationship between brand-oriented cognitive responses and brand attitude is based on the level of involvement that occurs during message processing. As suggested earlier, the ELM predicts that brand cognitive responses will play an increasingly important role in the formation of brand attitude when the person becomes more motivated and/or able to engage in a careful evaluation of a message's arguments. Consistent with this, several researchers (Batra and Ray 1986; MacKenzie et al. 1986) have argued that brand cognitions are less important contributors to the formation of A_b in typical advertising exposure settings since viewers are unlikely to be motivated to elaborate on the brand-relevant arguments presented in the ad.

Thus, the weak relationships observed in prior research may simply reflect the undermining effect of limited processing of the message claims due to weak involvement. This basic reasoning is supported by the previously discussed finding from Park and Young (1986) that CR_b was related to A_b when a non-musical ad was processed under cognitive involvement conditions, but not under low involvement conditions. Additional confirmation of involvement's moderating role is furnished by Gardner (1985). Gardner (1985) found that an expectancy-value measure was more strongly associated with A_b under brand than under non-brand processing sets. Recently, Hastak and Olson (1989) reported a similar effect of brand versus non-brand processing set on the $CR_b - A_b$ relationship.

In the present study, involvement is used to compare further the potential impact of different approaches for assessing brand cognitions. Research participants examined a print ad for a hypothetical new brand of soft drink under conditions designed to alter their involvement during processing. Consequently, it was possible to make comparisons between cognitive response and expectancy-value measures within each involvement condition. Both measurement approaches were expected to reveal the same basic pattern of stronger relationships among brand cognitions and attitude as involvement increases.

METHOD

Subjects

A total of 170 male and female students enrolled in an undergraduate business course at a midwestern university participated in the study to earn extra credit. Subjects were randomly assigned

to experimental conditions and processed in groups of five to ten.

Procedure

After subjects were seated at partitioned tables, the experimenter stated that the purpose of the study was to obtain their reactions to two new products being considered for introduction in their area. It was explained that they would look at ads for the new products and then make a choice between the two products. Subjects were told that they would receive the product of their choice as additional compensation for their participation.

The experimenter then drew subjects' attention to a set of folders in front of each subject. Starting with the top folder, subjects worked at their own pace through the set and were not allowed to return to a particular folder after they had finished with it. The first folder contained an ad for a fictitious soft drink called Sunburst. The ad heading read "Introducing the next generation of soft drinks for today's generation." Beneath the heading appeared two color pictures side-by-side: one was of the soft drink can, the other varied as explained below. The bottom half of the ad contained copy making a number of claims about the product.

The next folder held a questionnaire that assessed subjects' reactions to the ad and product. The third folder contained an ad for a fictitious soft drink called Sparkle. The fourth folder contained a form asking the subject to indicate whether they would like to receive the Sparkle or the Sunburst brand. As explained below, subjects in the low involvement condition also received a fifth folder.

Involvement Manipulation

The involvement manipulation consisted of varying the personal relevance of the Sunburst ad by telling subjects they would eventually make a choice among either soft drinks or an unrelated product category. Subjects in the higher involvement condition were told that they would be shown a print ad for each of two new soft drink brands and then make a choice between the two brands. They would then receive a six pack of the brand of their choice. This basic procedure has been used previously for enhancing involvement (cf. Petty, et al. 1983; Wright 1973). In contrast, subjects in the lower involvement condition were informed that they would be asked to choose between two disposable razor brands. It was expected that subjects would view the Sunburst ad as more personally relevant when they anticipated making a choice involving the product relative to those expecting to make a brand choice in another product category.

This manipulation necessitated some changes in the procedure and materials for low involvement subjects. First, some rationale was needed as to why they would encounter the soft drink ads. Consequently, the experimenter explained that subjects would be exposed to a couple of "warm-up" soft drink ads before seeing the critical razor ads in order to familiarize themselves with the type of print ads used in the study. It was also necessary to

make an alteration in the brand choice form within the fourth folder since subjects were not anticipating making a soft drink choice. The low involvement brand choice form stated that some of the subjects would receive a six pack of soda rather than a disposable razor. Subjects were therefore asked to indicate which brand they would prefer in the event that they received the soda. Finally, low involvement subjects received a fifth folder containing two ads for fictitious disposable razors and a razor choice form.

Claims Manipulation

This manipulation involved varying the strength of the arguments within the Sunburst ad. Common to both versions were the following claims: great taste, low in calories, thirst quenching, natural ingredients, real fruit juices, comparable price, and just the right amount of carbonation. The versions differed only in the presence and form of additional copy that attempted to substantiate these claims. One version contained information that was intended to provide stronger support for the claims (e.g., Sunburst has 50% fewer calories than the average non-diet soft drink) while a second version presented weaker support (e.g., Sunburst has 5% fewer calories than the average non-diet soft drink.). The claims and substantiation copy were placed in the bottom half of each ad used in the final experiment. Each claim was printed in bold block letters (e.g., GREAT TASTE!) which was followed by substantiation copy that comprised the claim manipulation.

Picture Manipulation

This manipulation involved altering the color picture that appeared at the top of the ad next to the picture of the Sunburst soft drink can. The favorably evaluated stimulus was a tropical beach scene with a rising sun. The disliked stimulus was a side view of five ugly iguanas facing the same direction.

Measures

Only those measures germane to the current research issues are described below. The key dependent variables consisted of thoughts, beliefs, attitudes, and purchase intentions. The thought elicitation measure, which was completed immediately after exposure to the Sunburst ad, asked subjects to list all of the thoughts, ideas, and images they had while looking at the ad. These thoughts were listed in the blank space, roughly three-fourths of a page, beneath the measure. Although a time constraint was not imposed, almost all of the subjects completed the measure in a couple of minutes.

The expectancy-value measure was operationalized in accordance with a Fishbein multi-attribute model (Fishbein and Azjen 1975). Subjects' evaluations (e_i) of the same seven soft drink attributes used in the ad (e.g., "For me, a soft drink with more real fruit juices than other brands is:") were measured on two scales (good - bad,

desirable - undesirable). Beliefs (b_j) about Sunburst (e.g., "how likely is it that Sunburst has more real fruit juices than other brands?") were assessed on two scales (likely - unlikely, probable - improbable). Responses to the two scales for each attribute evaluation and belief were summed since the correlations between them were very high (average $r = .87$ for e_i , average $r = .94$ for b_j).

Ad attitude was assessed on five scales (good - bad, effective - ineffective, interesting - uninteresting, like very much - dislike very much, not at all irritating - very irritating) which were summed ($\alpha = .92$). Attitude toward the Sunburst soft drink was represented by the sum ($\alpha = .97$) of three scales (favorable - unfavorable, positive - negative, like very much - dislike very much). Intention to purchase Sunburst when it became available was captured by two scales (likely - unlikely, probable - improbable) which were added together ($r = .98$).

The following measures were used to examine the success of the involvement manipulation. Subjects' involvement while processing the ad was assessed by asking subjects to respond to the statement "While reading the Sunburst ad, I was:" using three scales (very involved - very uninvolved, concentrating very hard - concentrating very little, paying a lot of attention - paying very little attention). Subjects also reported their agreement on an agree - disagree scale with the statement "I carefully considered the claims about Sunburst in the ad." These measures were combined to form an indicator of processing involvement ($\alpha = .91$).

Cognitive Response Coding Procedures

The coding of the cognitive response data consisted of two phases. First, each protocol was decomposed into separate thoughts by two judges blind to the experimental condition. A total of 90 disagreements occurred between the two judges which were then resolved by discussion. The total number of thoughts after resolving the disagreements was 689 or an average of four thoughts per subject. Judges therefore agreed on nearly 87 percent of the thoughts expressed by subjects.

In the second phase, the same two judges assigned each thought to categories reflecting the valence (positive, neutral, and negative) and content. The basic distinction drawn in thought content was whether it pertained to the ad versus to the product. For ad thoughts, a total of 13 categories were developed which reflected whether the thought was directed at the picture, copy, or some other ad element. One of these categories represented expressions reflecting an overall evaluation of the ad. Thirteen categories were also developed for brand thoughts. These categories represented differences in terms of whether the thought focused on product attributes, brand name, or the can/packaging. Thoughts indicating overall brand evaluation were classified separately.

Twenty-four of the 689 total responses were excluded on grounds of being either unclassifiable or irrelevant. Favorable thoughts accounted for 204 of

FIGURE
The Dual Mediation Model

the usable responses, 65 of the thoughts were neutral, and the remaining 396 thoughts were coded as unfavorable. In addition, 103 responses reflected an overall evaluation of the ad ($n=36$) or product ($n=67$). Because of concerns about such responses being indicators or overall affect (see Olson, Toy, and Dover 1982; Wright 1980), they were excluded, thus leaving 562 thoughts about various aspects of the ad ($n=217$) and product ($n=345$) for use in the analyses involving cognitive responses.

In terms of thought valence, the judges were very consistent in their ratings as reflected by an agreement rate of nearly 96 percent. For thought content, the judges agreed 81 percent of the time. While this agreement rate is lower, we believe it represents an acceptable level considering the large number of categories used to classify thought content. Disagreements for both valence and content were resolved through discussion.

RESULTS

Manipulation Checks

As expected, subjects' responses to the processing involvement measures significantly differed between high ($M=4.47$) and low ($M=.038$) involvement conditions ($F=26.3$, $p<.001$). Note that the mean for the low involvement condition was at the scale midpoint (scale ranges from +12 to -12). Consequently, this involvement condition is more appropriately viewed as inducing a moderate level rather than a truly low level of involvement.

Similar support was derived from two cognitive response indices representing (1) the total number of brand thoughts and (2) the ratio of brand thoughts to total thoughts. Higher involvement subjects reported more total brand thoughts ($M=2.03$ vs. 1.41; $F=32.9$, $p<.001$) as well as a greater proportion of brand thoughts ($M=.57$ vs. .45; $F=25.2$, $p<.001$) than those less involved.

Models

The following analyses focus on causal configurations of the relationships among brand and ad attitudes and antecedents. The dual mediation

model (Figure A) supported by MacKenzie et al. (1986) was tested using the maximum likelihood procedure for path analysis in LISREL VI (Joreskog and Sorbom 1984). We report path analysis results for models in which brand cognitions are represented by either a cognitive response index or a multi-attribute model score in three cuts of the data -- (1) pooled across treatment conditions, (2) for the higher involvement group ($n=86$), and (3) for the lower involvement group ($n=84$).

Results for CR_b

Table 1 summarizes the results of the path analyses for the dual mediation model using the cognitive response measure (cf. MacKenzie et al. 1986). An examination of the goodness-of-fit statistics indicates that all three models provide a very good description of data relationships. Two of the three chi-square statistics are non-significant and the root mean square residuals (RMSR) are small. Joreskog and Sorbom's goodness of fit estimates range from .960 to .977. The variance explained in the endogenous constructs ranges from a low of 15.1% for CR_b to a high of 58.6% for intentions. Taken together, these results indicate that the dual mediation model provides an acceptable description of data relationships in all three samples. Therefore, interpretation of the parameter estimates is appropriate. Given the focus of the present paper, discussion will center on the $CR_b - A_b$ path estimates.

Results based on the pooled data revealed a significant ($\beta_{32} = .216$, $p<.01$) path estimate between CR_b and A_b . The path estimate maintained significance ($\beta_{32} = .275$, $p<.01$) under higher involvement conditions, but becomes somewhat attenuated under lower involvement conditions ($\beta_{32} = .151$, $p<.1$). Even so, the results of a chi-square difference test did not reject the null hypothesis of equivalence in the $CR_b - A_b$ path between the higher and lower involvement conditions ($\chi^2(1) = 1.19$, $p >.1$).

TABLE 1

Degrees of Freedom		5	5	5	5	5
p-value		.036	.394	.102	.344	.502
Goodness-of-fit index		.974	.977	.960	.967	.973
Root mean square residual		.047	.050	.048	.060	.043

^a Standardized parameter estimates.

^b Estimates without superscripts are significant at $p < .01$, two-tailed tests.

^c $p < .05$, two-tailed test.

^d $p < .10$, two-tailed test.

^e $p > .10$, n.s.

This unexpected stability of the CR_b - A_b relationship prompted us to adopt another approach for testing involvement's moderating role. Based on the responses to the involvement measures, subjects were divided into three groups of roughly equal sizes. Path analyses were then performed on the two extreme groups representing either higher or lower levels of self-reported involvement for models including either the brand CR or expectancy-value indices. While this procedure sacrifices strict experimental control and runs the risk of confounding involvement with other individual difference variables, the potential for differences to emerge is also enhanced by using the two extreme groups which represent greater polarization in their level of involvement ($M=7.92$ versus -3.84 ; $n=61$ for each group) than captured by the involvement conditions ($M=4.47$ versus 0.38). Additional analyses were performed on the higher and lower self-reported involvement groups to validate presumed differences in their degree of elaboration and their responsiveness to the ad content manipulations. As expected, the higher SRI group ($M=2.38$) reported more brand-oriented cognitions

than the lower SRI group ($M=1.57$, $p < .01$). A 2 (Claim) X 2 (Picture) ANOVA was also performed on A_b for each SRI group. The higher SRI group was affected only by the claim manipulation ($F=21.8$, $p < .001$), while the lower SRI group was affected only by the picture manipulation ($F=7.5$, $p < .01$).

The results of the path analyses are reported in the last two columns of Table 1. As can be seen, the difference in the strength of the CR_b - A_b path was intensified by using the extreme self-reported involvement (SRI). Indeed, the CR_b - A_b path becomes non-significant ($p > .1$) for the lower SRI group. A chi-square difference test indicated that the influence of CR_b on A_b was significantly stronger in the high SRI group ($\chi^2(1) = 5.59$, $p < .05$).

Results for the Expectancy-Value Models

The goodness-of-fit statistics and parameter estimates for the models using the multi-attribute measure of brand cognitions are reported in Table 2. The path estimate for $\Sigma b_i e_i$ - A_b is significant ($\beta_{32} = .330$, $p < .01$) in both the pooled data analyses and as well as for the lower ($\beta_{32} = .353$, $p < .01$) and

higher ($\beta_{32} = .328$, $p < .01$) involvement conditions. These estimates did not differ between involvement conditions ($\chi^2(1) = 0.05$, $p > .1$).

In contrast, the results based on self-reported involvement revealed the anticipated difference in the strength of the $\Sigma b_i e_i - A_b$ relationships. Whereas this link is marginally significant for the lower SRI group ($\beta_{32} = .181$, $p < .1$), it achieves strong significance for the higher SRI group ($\beta_{32} = .594$, $p < .01$). A chi-square difference test confirmed the $\Sigma b_i e_i - A_b$ relationship to be stronger in the higher SRI condition ($\chi^2(1) = 7.20$, $p < .05$).

These results are essentially the same as those reported for the CR_b measure. The only substantive difference between the two measurement approaches is that the strength of the relationship between brand cognitions and attitudes is somewhat enhanced for the models using the expectancy-value measure. For example, when the analysis is based on the pooled data, the path estimate (β_{32}) based on the expectancy-value measure increases by nearly fifty percent in size relative to the same estimate based on cognitive responses.

DISCUSSION

Mackenzie et al. (1986) were disturbed by the surprising weakness of the relationship between brand cognitions as measured by a cognitive response index and brand attitudes. They provided two explanations for this finding. First, they suggested that the crudeness of the cognitive response index as an indicator of brand cognitions may have contributed to the lack of relationship with brand attitudes. Second, based on the ELM, they built an argument for the primacy of peripheral processing over central processing in brand attitude formation in a typical advertising exposure setting.

Our results indicate that the use of CR_b did reduce the apparent strength of the relationships between brand cognitions and attitude in comparison with an expectancy-value measure. However, it should be noted that this attenuation may also be attributable to the greater availability of subjects' responses to the expectancy-value measure at the time of their response to the brand attitude items (Feldman and Lynch 1988). This is possible because A_b was measured immediately after the expectancy-value measures were taken, while a number of measures separated A_b and the thought elicitation task. Nonetheless, conclusions about the

causal role of brand cognitions are essentially the same across the models. Both operationalizations yielded significant relationships between brand cognitions and attitude in the pooled data analyses. These relationships were also found to be invariant across the involvement conditions for both measurement approaches. Finally, the alternative measures produced the same pattern of differences in the significance of the brand cognitions - attitude relationship across the self-reported involvement analyses. Consequently, it would appear that prior research observing null relationships may be more indicative of the type of processing that occurred during message exposure than of any major weakness in cognitive response measures.

The results based on self-reported involvement also support the presumed moderating influence of involvement on the relationship between brand cognitions and attitude. The brand attitudes of subjects reporting lower involvement during processing were unrelated to their brand cognitions. Strong relationships, on the other hand, were observed for subjects reporting higher involvement during processing. These findings provide additional evidence for the moderating role of involvement in persuasion.

The Role of Tangible and Intangible Attributes in Similarity and Preference Judgments

Roxanne Lefkoff-Hagius, University of North Carolina at Chapel Hill
Charlotte H. Mason, University of North Carolina at Chapel Hill

ABSTRACT

Consumer judgments of both similarity and preference are widely used in marketing research. Whereas preference judgments are generally assumed to be subjective and heterogeneous across consumers, similarity judgments are commonly assumed to be objective and homogeneous. However, there is increasing evidence that, like preferences, similarity judgments may be individual specific. In this paper, the results of an experiment examining individual differences in preference and similarity judgments are reported. Using decompositional models for both judgment types, we found substantial heterogeneity across subjects. Moreover, we hypothesized that the "type of attribute" would explain some of the difference found, within subject, between preference and similarity judgments for the same object. Specifically, our results support "intangible" attributes being relatively more important in preference than similarity judgments, whereas "tangible" attributes are relatively more important in similarity judgments.

INTRODUCTION

Understanding how consumers perceive and evaluate products relative to other products is fundamental to marketing strategy. "All aspirins are the same — why pay more?" and "This car is completely different from any other car in its class" are examples of advertising campaigns that have used similarity and dissimilarity positioning strategies to influence choice (Tversky 1972).

Marketing researchers use both similarity and preference judgments to study consumer behavior. While preference judgments are viewed as individual specific, usually similarity judgments are assumed to be objective, error free, and homogeneous across subjects (Green 1975). In many multidimensional scaling applications, it is common practice to aggregate consumers' similarity judgments in order to formulate "perceptual maps" which are geometric representations of underlying perceptual dimensions. However, aggregating these judgments assumes that subjects perceive the same set of underlying dimensions, subjects make the same judgments about the extent to which objects possess particular attributes, and subjects assign the same importance weights to the attributes in determining the similarities (Jackson 1983).

To relax the last assumption, the INDSCAL multidimensional procedure (Carroll and Chang 1970, Carroll 1972) was developed. It handles individual perceptions by stretching and shrinking the axes of the spatial representation according to the importance of each dimension to the individual. For example, using INDSCAL, Wish (1971) found that subjects have different perceptions about the

similarity of various countries. Subjects classified as "hawks" tended to use the political alignment of countries (pro-western versus pro-communist) as the most important dimension, while "doves" tended to use the economic development of countries (underdeveloped versus economically developed) as the most important dimension. Likewise in marketing, INDSCAL has been used to show that consumers perceive the proximity between products differently. However, marketing variables such as familiarity with the products, personal values, and demographics have not been successful in explaining these individual differences in perceptions (Ritchie 1974).

Another common assumption that is central to joint space model configurations (Green and Carmone 1970, Green and Wind 1973) is that consumers' perceptions and preferences are based on the same underlying structural dimensions. There is evidence to suggest that this, too, is an oversimplification. Wish (1971) found that "... the dimensions of liking do not agree so well with the dimensions of similarity...subjects frequently like one and dislike the other of two countries they perceive to be quite similar. These results are somewhat counter to the frequently made assumption that preferences can be directly related to the dimensions of a space based on perceptions of the stimuli." (page 325)

In a marketing study dealing with mothers' perceptions and preferences for toys for their children, Whipple (1976) compared different data collection techniques for similarity and preference measures. He found that "solutions based on attribute ratings/rankings and directly judged proximities are not similar to preference based solutions." (pages 101-2). This led him to conclude that "... it is risky to assume that product preference is consistent with overall product similarity." (page 102).

In this study, we will *not* assume that individual perceptions are homogeneous across subjects. Instead, the purpose of this study is to attempt to understand, at the individual level, differences between what is important in similarity judgments and what is important in preference judgments. We will explore how "kind of attribute" may account for some of the difference between similarity and preference judgments

TANGIBLE AND INTANGIBLE ATTRIBUTES

Marketing researchers have used a wide variety of attribute descriptors to obtain measures of consumers' perceptions and preferences (Myers and Shocker 1981). A comprehensive summary of eleven different attribute typologies is presented by Finn (1985). What is common to all these different

approaches is that there is a distinction between the concrete, physical, objective, or TANGIBLE attributes of a product and the abstract, beneficial, subjective, or INTANGIBLE attributes of a product. For example, a car can be described as large, red and luxurious. Large and red are fundamentally tangible attributes as they describe physical properties of the car, while luxurious is primarily an intangible attribute as it describes beneficial and imagery aspects of the car.

It is believed that managers should ultimately formulate their strategies based on consumers' perceptions of the abstract benefits of products (Haley 1968). Yet, in reality, it is necessary to use concrete attributes that are "actionable" or meaningful to managers (Shocker and Srinivasan 1979). Recently there has been some concern and criticism that too much attention has been spent on tangible attributes instead of intangible attributes (Holbrook and Hirschman 1982, Hirschman 1983). In the "layers of meaning paradigm" it is proposed that "the meaning of a product stimulus is a mixture of objective properties and subjective associations" (Hirschman 1980, page 12). Thus, the perceived meaning of a product stimulus is proposed to be a joint construct of both tangible and intangible attributes. Therefore, this study considers perceptions of and preferences for product profiles described by both tangible and intangible attributes. Since attempts to categorize attributes as one or the other may result in fuzzy sets (Myers and Shocker 1981), the distinction between tangible and intangible is viewed as a continuum rather than a dichotomy.

JUDGMENTS OF PREFERENCE AND SIMILARITY

Economists and marketers theorize that consumers do not purchase goods for the goods themselves, but for the satisfaction derived from using the goods (Lancaster 1966 and 1971, Haley 1968, Ratchford 1975). Multiattribute models of consumer preferences partition product satisfaction into satisfaction for individual attributes of the product. Both compositional methods (Wilkie and Pessemier 1973) and decompositional methods (Green and Srinivasan 1978) are based on the notion that attribute utilities underlie consumer preferences. Regardless of the method, the validity of the results depends critically on the choice of appropriate attributes.

If attributes that are important to the consumer are not included, then preference predictions may be suspect. For example, when New Coke was developed, the "taste" attribute was the primary focus. However, loyal Coke drinkers responded negatively to the new product because intangible imagery attributes were probably driving their preferences more than the tangible taste attribute. In general there is a growing realization that, in many product classes, where there are few "meaningful" differences between brands and more so-called "parity" products, image and other

intangibles become more important (*Business Week*, 1983).

There have been a wide variety of approaches to model similarity judgments. These methods include multidimensional scaling, factor analysis, discriminant analysis, clustering (Hauser and Koppelman 1979), and a decompositional approach analogous to conjoint analysis typically associated with preferences (Green and DeSarbo 1978). Some of these approaches use judgments about holistic stimuli whereas others require prior identification of specific attributes. For the latter approach, just as with preference judgments, it is important to identify the appropriate attributes.

While attitude theories (Fishbein 1967, Rosenberg 1956) have provided a strong base for understanding preference judgments in applied marketing, there has not been much theoretical work to understand consumer similarity judgments. Recently there have been some empirical studies to examine how consumers perceive and compare products and product classes (Johnson 1984, Johnson and Fornell 1987, Johnson 1988). There is evidence to suggest that consumers engage in hierarchical processing when making comparison type of judgments. Johnson et al explain that consumers start out with concrete attributes and go to more abstract attributes as alternatives become more noncomparable. Using this hierarchical processing framework, we speculate that if subjects are presented with both tangible (concrete) and intangible (abstract) attributes for the same product class, the tangible attributes would receive more attention and thus be more important in similarity comparison tasks than in preference tasks. Alternatively, because preferences are driven primarily by intangible benefits, we speculate that the intangibles would receive more attention and thus be more important in preference tasks than in similarity comparison tasks.

Based on the above discussion of preference and similarity judgments, we hypothesize the following:

- H1a: Intangible attributes will receive relatively more importance weight in preference judgments than in similarity judgments.
- H1b: Tangible attributes will receive relatively more importance weight in similarity judgments than in preference judgments.

These hypotheses were tested in the following experimental setting.

METHOD

43 undergraduate business students at a major university participated in a study dealing with perceptions and preferences for jobs and cars. These product classes were familiar to the subjects and have been used in other studies (Green and Wind 1973; Green, Carroll, and DeSarbo 1981;

TABLE 1
Attributes and Levels

Jobs

Small	American	Conservative	Practical
Midsize	Foreign	Sporty	Luxurious

Montgomery and Wittink 1979). For each product category, a set of four attributes, each at two levels, was developed to form hypothetical full-profile descriptions. Each product was described by two tangible and two intangible attributes. Because the goal of this research was to examine changes in the relative role of tangible and intangible attributes between the two types of judgments, the attributes and levels selected for use in this study were based on limited pretesting. A more comprehensive and formal approach for selecting attributes (Alpert 1971) was not implemented because forecasting choices was not the primary focus of this research. Table 1 shows the attribute levels and Figures 1 and 2 show sample profiles. For both product categories, a full factorial design was used, resulting in sixteen product profiles for each product class.

Each subject completed four rank ordering tasks. These involved similarity and preference judgments for each of the two product classes. To counterbalance any order of task effects, subjects were divided into two groups and the order of the judgment tasks was reversed between the groups. Group 1 subjects (N=22):

1. rank ordered the 16 job profile cards according to their similarity to Figure 1.
2. rank ordered the 16 car profile cards according to their similarity to Figure 2.
3. rank ordered the (identical) 16 job profile cards according to personal preference.
4. rank ordered the (identical) 16 car profile cards according to personal preferences.

Likewise, Group 2 subjects (N=21) alternated between job and car profiles, but the order of similarity and preference judgments was reversed. Group 2 subjects performed tasks 3 and 4 from above and then performed tasks 1 and 2. Thus, Group 2 subjects made preference judgments first and similarity judgments second. The product classes were alternated to provide an intervening task between the similarity and preference judgments for the same product class.

Because different methods of collecting data and estimating attribute importance weights have been found to show low levels of convergence (Jaccard, Brinberg, and Ackerman 1986), this study used the same data collection technique for both similarity and preference tasks. By having subjects perform a rank ordering task for both similarity and preference judgments, differences in the resulting attribute importance weights could then be attributed to differences in the similarity and preference judgments and not be confounded with differences in methods.

Collecting rank orders of product profile cards is a common practice for obtaining preference data. Using conjoint analysis, the importance weights of the attributes and partworth utility functions can be estimated. However, determining the importance weights of the attributes in similarity judgments is not as straightforward. Whereas preferences have meaning for a single item, similarities are only meaningful between pairs of items. For example, a person may have a certain preference value or utility for a 1989 BMW. However, the similarity of the 1989 BMW is meaningful only in relation to another item, say a 1989 Honda. To obtain similarity judgments, comparisons between product profiles were necessary.

There has been limited research applying conjoint analysis to similarity data. Following the approach of Green and DeSarbo (1978) and Green, Rao, and DeSarbo (1978), data were collected to permit additive decomposition of overall similarity judgments into "part-similarity" functions, which are analogous to part-worth functions (Shocker and Srinivasan 1979). To accomplish this, each of the 16 unique profile cards were compared to one referent profile card. While Green et al asked subjects to compare profiles to imaginary, ideal products, instead we asked subjects to compare profiles to a specified, referent profile (which was the same for each subject). This was done so that similarity judgments would not be confounded by any preference insinuations suggested by the term "ideal" product. In addition, the referent profile for both product classes was identical to one of the 16 profiles to be sorted. Every subject specified the card that perfectly matched the referent as the most similar, indicating that subjects understood and followed the directions.

ANALYSIS AND RESULTS

Attribute Importance Weights

Conjoint analysis was used on both the similarity and preference data for each subject. The monotonic analysis of variance (MONANOVA) procedure was used to estimate attribute importance weights (Kruskal and Carmone 1969). Each subject rank ordered 4 sets of product profiles, so 4 MONANOVA models were computed for each subject, yielding a total of 172 models.

The MONANOVA model for the preference judgments is:

$$p_j = \sum_k f_{pk}(y_{jk})$$

p_j = preference of an individual for object j .

f_{pk} = part-worth of k^{th} attribute.

y_{jk} = level of attribute k for object j .

The MONANOVA model for the similarity judgments is:

TABLE 2
SUMMARY STATISTICS FOR ATTRIBUTE IMPORTANCE WEIGHTS ^a

Attr	Judgment	Jobs		Cars	
		Mean	Std Dev.	Mean	Std. Dev
Tan 1 ^b	Pref	18.2	23.0	19.3	23.8
Tan 1	Sim	25.7	30.0	33.1	23.9
Tan 2 ^c	Pref	23.7	19.7	21.9	28.0
Tan 2	Sim	19.5	19.3	22.0	26.5
Int 1 ^d	Pref	43.3	25.2	36.0	26.0
Int 1	Sim	34.9	25.2	28.8	21.0
Int 2 ^e	Pref	14.8	14.0	22.8	22.6
Int 2	Sim	19.9	16.7	16.1	11.1

- a Rescaled to sum to 100%
- b 1st Tangible Attribute
- c 2nd Tangible Attribute
- d 1st Intangible Attribute
- e 2nd Intangible Attribute

$$s_j = \sum_k f_{sk}(y_{jk})$$

s_j = similarity of object j to referent (according to individual).

f_{sk} = part-similarity of k^{th} attribute.

y_{jk} = level of attribute k for object j (same as above).

The estimation procedure resulted in an average stress of 10.3 % for the similarity data and 7.3 % for the preference data (0% is best fit and 100% is worse fit). Scatterplots of the best monotonic function of the estimated data values verses the original data values also showed that the preference data had a slightly better fit than the similarity data. Since subjects probably are more familiar with making preference than similarity judgments, this seems reasonable.

The output from the MONANOVA analysis was rescaled so that each set of importance weights would sum to 100 per cent. Summary descriptive statistics for the rescaled importance weights are shown in Table 2. Importance weights ranged widely and, overall, there is no indication that any particular attribute was dominant in either similarity or preference judgments. If other attributes and levels had been used, the estimated importance weights would have been different. However, this research is not concerned with the absolute value of importance weights. Instead, this research is concerned with differences in computed importance weights between the two types of judgment tasks. For the purpose of this research, it does not matter in an absolute sense whether tangibles or intangibles are more important, because this will depend on the particular product class and the particular subject. What does matter is whether importance weights change between similarity and preference judgments.

From the standard deviations of the importance weights, it is clear that the importance weights of the similarity judgments have just as much variance around their means as the importance weights of the preference judgments. This supports the notion that just as preference judgments are individual specific, so too are similarity judgments.

Multivariate Analysis of Variance

A repeated measures multivariate analysis of variance (MANOVA) procedure was implemented to test the hypotheses that the type of attribute would explain some of the difference found, within subject, between preference and similarity judgments for the same object. The between subjects factor was "order" as half the subjects made similarity judgments first, while half the subjects made preference judgments first. Within subject factors were "product" and "task". Products were jobs and cars. Tasks were preference and similarity judgments. The design was crossed because each subject made both similarity and preference judgments for both jobs and cars.

Since the hypotheses concern the weight of tangibles relative to the weight of intangibles, the absolute values of the importance weights themselves are not the focus of this study, as those values will vary from individual to individual and product class to product class. Instead, our interest centers on how the weights vary between similarity and preference judgments. Thus, to define the dependent variables, we focus on the total weight given to tangibles versus intangibles across the different judgment tasks for each of the two product classes.

Four dependent measures were computed for each subject. Each dependent variable is defined as the difference between the weights given to tangible attributes minus the weights given to intangible attributes. For example, Y1 is the sum of importance weights for tangibles in preference

TABLE 3
CELL MEANS AND STANDARD DEVIATIONS

Order		<u>Y1</u> ^a	<u>Y2</u> ^b	<u>Y3</u> ^c	<u>Y4</u> ^d
Group 1 ^e	mean	-10.78	-6.80	-18.43	14.61
	s.d.	(53.64)	(58.19)	(68.42)	(48.71)
Group 2 ^f	mean	-21.67	-12.49	-16.64	5.51
	s.d.	(49.75)	(54.91)	(59.44)	(50.78)

a Y1 = sum of tangible wts. less sum of intangible wts. for job preferences

b Y2 = sum of tangible wts. less sum of intangible wts. for job similarities

c Y3 = sum of tangible wts. less sum of intangible wts. for car preferences

d Y4 = sum of tangible wts. less sum of intangible wts. for car similarities

e Group 1 made similarity judgments first and preference judgments second

f Group 2 made preference judgments first and similarity judgments second

judgments minus the sum of importance weights for intangibles in preference judgments for the job product class. Y2 also considers jobs, but deals with the difference between tangibles and intangibles in similarity judgments. Likewise, Y3 considers the preference judgments and Y4 considers the similarity judgments for the car product class.

Since Y1, Y2, Y3, and Y4 are defined as the weights given to tangibles minus the weights given to intangibles, if the value of the variable is negative, more weight was given to intangibles. If the value is positive, more weight was given to tangibles. The means and standard deviations for Y1 through Y4 for each group are summarized in Table 3. Plots of the cell means are presented in Figure 3. Of particular interest are differences between Y1 and Y2, and between Y3 and Y4. The mean values for Y1 and Y3 which involve preferences are lower than the means for Y2 and Y4, respectively, which involve similarities. Thus, it appears that intangibles were given *relatively* more weight in preference judgments compared with similarity judgments. Or, looking at it from the other perspective, it appears that tangibles were given *relatively* more weight in similarity than preference judgments.

To test the significance of these effects, a repeated measure MANOVA was conducted. The results are presented in Table 4. The only significant factor was the "task" effect ($F(1,41) = 6.33, p < 0.016$). Thus, the results support the hypotheses. For both jobs and cars, the intangible attributes received relatively more importance weight in the preference judgments than in the similarity judgments. The tangible attributes received relatively more importance weight in the similarity judgments than in the preference judgments. This effect was significant, regardless of the order of the judgment task. None of the interactions were significant.

DISCUSSION

Although the focus of the study was on the role of attribute type in similarity and preference judgments, the results do corroborate the notion that similarity judgments are not homogeneous across people. While subjects read the same attribute information and compared it to the same referent, there was a wide range of resulting attribute importance weights. So overall, there was just as much heterogeneity in similarity judgments as in preference judgments.

Not only was there a difference between resulting attribute importance weights in similarity and preference judgments across individuals, but also within individuals there was a difference. At the individual level, the resulting attribute weights in the similarity judgments differed from the attribute weights in the preference judgments. The type of attribute was found to be a significant factor contributing to this difference. Intangible attributes received relatively more weight in preference judgments than in similarity judgments, while tangible attributes received relatively more weight in similarity than in preference judgments.

The results presented in this paper are based on an exploratory pilot study using a limited number of subjects and product classes. Further work is planned to extend the analysis by using more subjects and product classes. Another limitation of this study is that attributes were designated as tangible and intangible without verification that the specific subjects performing the tasks agreed with the labeling. A formal manipulation check is planned in future experiments. In addition, we note that since the experiment used a small number of attributes to describe alternatives, the results are not necessarily applicable to real applications involving jobs and cars. However, because the purpose of this study was to understand the relative role of tangibles and intangibles, the number of attributes was limited

Product*Task*Order	1,41	696.8	0.38	0.539

to four in order to keep the task fairly simple for the subjects and thus maximize internal validity.

The inclusion of intangible attributes into a conjoint framework is not without critics. In a survey of conjoint users in commercial settings (Cattin and Wittink 1982), some respondents reported that they did not use conjoint analyses when the attributes to define the stimulus objects tended to be "soft." While there are some unitary stimuli such as foods, scents, and aesthetic objects that cannot be easily separated into component parts (Huber 1987), many consumer products can be described in terms of both physical characteristics and intangible benefits and there are conjoint studies that do incorporate both kinds of attributes (i.e. Currim, Weinberg, and Wittink 1981). In fact, the results of the most recent survey of conjoint users (Wittink and Cattin 1989) shows there to be an increase in conjoint applications involving services, and intangibles are particularly important in services.

In many marketing applications, data from similarity and preference tasks are used interchangeably. However, the results from this study suggest that, depending on the judgment task, different kinds of information are more or less important. Since the kind of information presented to consumers is a controllable marketing variable, there are interesting methodological and managerial implications. For instance, the tangible-intangible attribute framework could explain the low convergent validity of different approaches for estimating attribute important weights (Jaccard, Brinberg, and Ackerman 1986). The tangible-intangible attribute framework could also explain the low predictive validity of some new product forecasting applications (Alter 1987). Particularly for managers formulating positioning strategies to alter how consumers perceive and evaluate their products relative to the competition, it is important to distinguish between tangible and intangible attributes. "Me too" products that copy only the tangible attributes of a brand leader's product may ultimately fail to get market share if consumer preferences are primarily driven by the intangible attributes.

Involvement and Perceived Brand Similarities/Differences: The Need for Process Oriented Models

James A. Muncy, Clemson University

The construct of consumer involvement has received a substantial amount of attention by consumer researchers in the past few years. Now, this research appears to be at a crucial point in its development. The current paper discusses the factors that have brought involvement research to this point. It further discusses how the results presented by Brisoux and Cheron (1990) could potentially provide direction in this area so as to keep it from becoming just another passing fad in consumer research. From here, the focus is turned to the area of perceived brand similarities. It is argued that this area will eventually become an important topic within consumer research. It is proposed that the results presented by Lefkoff-Hagius and Mason (1990) have the potential for providing direction to this area in a way that will avoid many of the pitfalls seen in involvement research.

INVOLVEMENT: ARE YOU GETTING OLDER OR BETTER?

Less than ten years ago, involvement was potentially the most researched topic in consumer behavior. The yearly attitude research conference focussed exclusively on involvement. There was a highly influential workshop on involvement at NYU. Every ACR conference had numerous papers on the topic and the major journals were publishing several papers per year which discussed involvement. If consumer research had "in" topics, consumer involvement was "in." If my perceptions are correct, just as fast as involvement came "in," so is it going "out." Journal editors are not as interested in involvement papers. We don't see as many papers at ACR discussing involvement. I sincerely doubt if one would get much support for having a workshop on consumer involvement.

When involvement first started out, a number of people were asking the question "what is it?" After a tremendous amount of work was done defining involvement (see for example, Antil 1984; Muncy and Hunt 1984; Stone 1984), Rothschild (1984) called for people to quit trying to define it:

We don't need more [definitions] at this time. Let's call a ten year moratorium on definitions of involvement; let's go collect data on interesting aspects of involvement and then, in ten years, see if we can (or need to) devise a better definition. (p. 217)

I did not agree with Rothschild's assessment at the time (probably because his comments came in a critical response to one of my papers defining involvement). In retrospect, however, Rothschild was accurately voicing the opinions of the majority of those working in this area: it was time for the definition stage to end and the measurement stage to begin.

And so the measures came. Numerous researchers worked diligently on measuring involvement. This resulted in several good involvement scales (see, for example, Laurent and Kapferer 1985; Slama and Tashchian 1985; and Zaichkowsky 1985). However, there are those who feel that involvement research is now at a place where better measures are not needed. For example, in the current volume, Zaichkowsky (1990) makes the following plea:

I hope the researchers continue to do work in this area, but I implore them to move on from measuring involvement to discovering relationships between consumer behavior and levels of involvement.

Perhaps Zaichkowsky is voicing the opinion of those currently working in this area: it is time for the measurement stage to end and the theory building stage to begin.

This is a crucial time for involvement research. Can we move "from measuring involvement to discovering relationships between consumer behavior and levels of involvement"? I am not sure. I do know that unless such a move is made, this area that has been studied so hard by so many talented people is destined to die a premature death. It is my perception that reviewers and editors are already writing involvement's eulogy.

Such a death is not inevitable. One need only look to the social psychology/communication literature to see that frameworks that are based in large part on involvement have maintained long and sustained interest. Social Judgement Theory (Sherif and Hovland 1961; Sherif, Sherif, and Nebergall 1965; Sherif and Cantril 1947; Sherif and Sherif 1967) was a viable stream of research for years and is still discussed today. The Elaboration Likelihood Model (Cacioppo, Petty, Kao, Rodriguez 1986; Petty and Cacioppo 1981, 1984) seems to be stronger today than it was when it was new. Thus, there is no reason why involvement-based research streams in our discipline need to end before they make substantial contributions to our understanding of the behavior of consumers. We should borrow insights from research in social psychology and communication to see how involvement research can be sustained.

What is the difference between involvement theories that have sustained interest over a long period of time (such as those in social psychology) and involvement theories in consumer research that seem to be dying on the vine? I would argue that the models in consumer behavior are *quantity oriented* whereas the models in social psychology are *process oriented*. Let me explain the difference.

In consumer research, a typical hypothesis regarding involvement has been "as the level of involvement increases, the quantity of information

search increases." Since this is simply a hypothesis about the relationship between the quantity of involvement and the quantity of information search, I would call it "quantity oriented." An example of such a quantity oriented hypothesis in social psychology and communication would be "as communication involvement increases, attention to the communication increases." The problem with these quantity oriented hypotheses is that they really are not that interesting--I would be very surprised if higher levels of involvement were not associated with higher levels of information search, attention, etc.

In contrast, the process oriented models in social psychology and communication focus on fundamentally different modes of processing based on the level of involvement. For example, the Elaboration Likelihood Model discusses two fundamentally different "routes to persuasion" based on the receiver's motivation to process the communication. Further, it shows differences in the resulting persuasion based on involvement (e.g., central route processing results in more enduring persuasion). One could see the same type of process modeling in Social Judgement Theory. Note that this type of process oriented modeling is inherently more interesting than simply postulating quantity differences based on the level of involvement.

Thus, what might keep involvement theory from dying a premature death in consumer behavior is the development of some truly interesting process oriented models. What we need is a theory that will show not just that people process more or less depending on the level of involvement, but that they process differently. This brings me to my discussion of Brisoux and Cheron (1990). As I see it, they have provided a potential starting point for a truly interesting theory of consumer involvement. I strongly disagree with their statement that "the main contributions of this paper lie in conceptual definitions and methodological procedures." Let me explain what I see as the main contribution of their paper.

Figure 1 integrates the conceptual framework of their research with their empirical findings. As indicated on this figure, some of their hypotheses are explicitly stated where as some are simply implied. Also, some of their findings imply other findings. What their model does is trace the process by which a consumer narrows down the number of brands from the whole product category all the way down to the single preferred brand. Their research shows how this varies based on level of involvement.

They found, as one might expect, that consumers who are more involved in a product category are aware of more brands than consumers who are less involved. Intuitively, this is what one would expect. Since the more involved consumers do not have fewer "foggy brands" (i.e., unprocessed brands), and since all aware brands are either foggy brands or processed brands, then these involved consumers must have more processed brands. Thus, consumers who are more involved appear to process more brands. This too is what one would expect intuitively. Thus, the

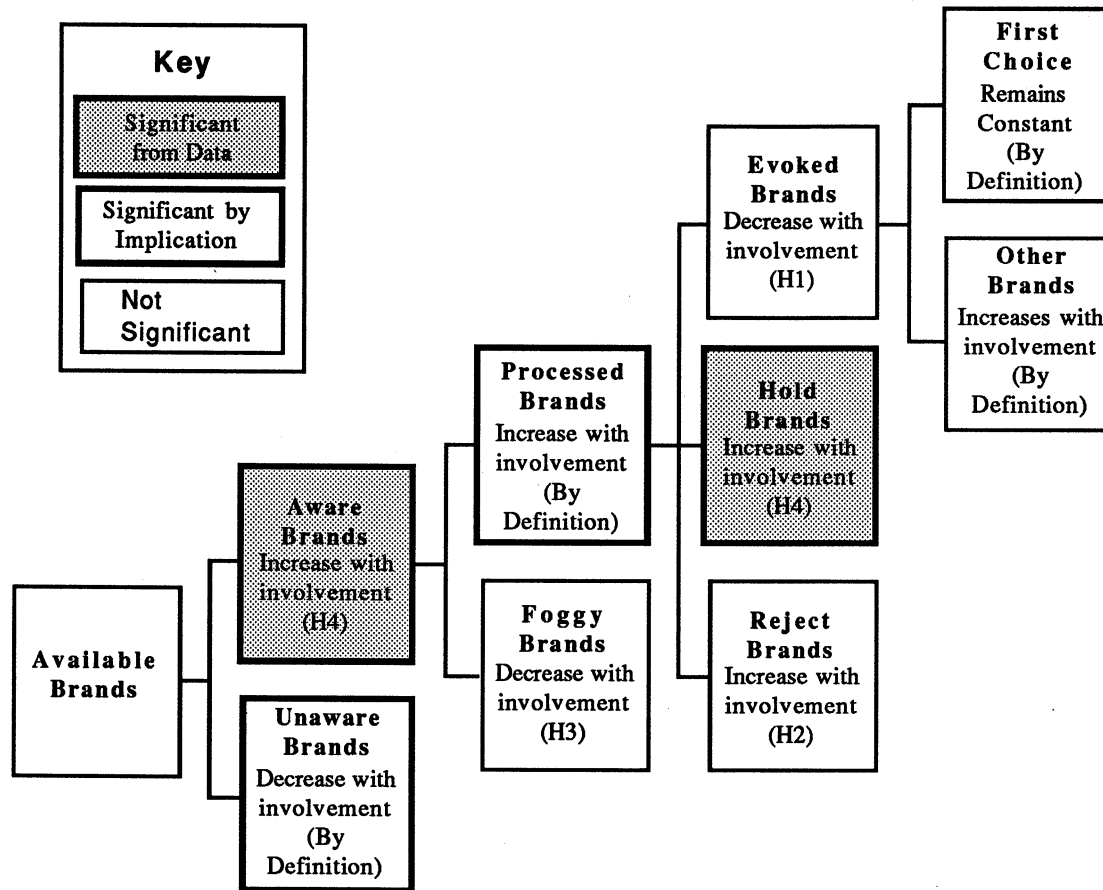

first contribution of this research is that it confirms what one would expect--that consumers who are more involved are both aware of more brands and process information about more brands. Up to this point, their findings are not particularly interesting (or even unique to their research). They are simply quantity oriented.

It is the next part of their research that provides the potential for developing a truly interesting theory of purchasing involvement. Any given brand that the consumer knows about could end up in his or her evoked set (i.e., it could become a brand that he or she considers acceptable for purchase), hold set (i.e, he or she would not have an opinion as to whether it should be accepted or rejected), or reject set (i.e, he or she would consider it unacceptable for consideration). The truly interesting question raised (and tentatively answered) by this research is: *Do highly involved consumers process their known brands differently than do low involvement consumers and if so, what are the differences?*

Here we do not have an intuitively superior expectation. If we were to simply apply Social Judgement Theory without modification to answer this question, we would expect that higher levels of involvement would cause the evoked set (analogous to latitudes of acceptance) to decrease, the hold set (analogous to latitudes of neutrality) to remain constant, and the reject set (analogous to latitudes of rejection) to increase. However, Jarvis (1972) could only find weak support for applying social judgement theory in this manner.

What Brisoux and Cheron found was that, with increased involvement, *the sizes of both the evoked set and the reject set remained relatively constant while the size of the hold set dramatically increased.* The more involved consumer is processing more brands; however, this increase in processing does not result in more acceptable brands or unacceptable brands but in more hold brands (note that this increases the probability that any *processed* brand will end up in the hold set). This raises numerous questions. Perhaps the more involved consumer sees the product category as being more complex and thus sees the process of categorizing any given brand as acceptable or unacceptable as being more difficult. Perhaps he or she does not process as much information about any given brand and thus, though he or she is processing more brands, he or she is not processing them as deep. Or perhaps the more involved consumer faces information overload and thus cannot carry out the processing needed to make brands acceptable or unacceptable. If this is so, the limitations of our processing capabilities may cause the involved consumer to be no better informed than the uninvolved consumer. Note that this is all *highly speculative*. However, it does indicate some of the interesting questions that can be addressed when the area moves away from models of quantity to models of process. I believe strongly that research like that presented Brisoux and Cheron holds tremendous promise for developing such process oriented models.

FIGURE 1
A Model of the Empirical Findings of Brisoux and Cheron (1990)

SIMILARITIES: WHAT DO YOU WANT TO BE WHEN YOU GROW UP?

This brings me to a discussion of perceived brand similarities. I believe that research on *product class* perceived similarities (or differences) is a topic that will inevitably receive the amount of attention that involvement has recently received. Let me explain why.

A few years ago, I did a study on cognitive brand loyalty. For some reason, I included a measure of perceived brand similarities across the product category. I found that, of the seven predictors that I included in my study, perceived brand similarities explained the greatest amount of variance in brand loyalty (even more than involvement). Not long after that, I did another study on information search. I included many of the same variables that I did in my brand loyalty study. To my surprise, I also found that perceived brand similarities explained the greatest amount of variance in information search (again, even more than involvement).

These findings were initially surprising to me. However, after a significant amount of reflection, it became clear to me that perceived brand similarities or

differences *across the product category* should be one of the most important variables for differentiating decision making styles. Consumers who see all the alternatives within a product category as being similar have little reason to be strongly committed to one brand over another. It is only when the consumer perceives that real and significant differences exist between the offerings in a product category that he or she has motivation to be loyal to one particular brand. In a similar way, if a consumer sees all the alternatives in a product category as being the same, why would he or she engage in significant information search? It is only when the consumer perceives that differences actually do exist that he or she is motivated to find out information about what these differences are.

Thus, there appears to be real differences in decision making styles between those instances where the alternatives are seen as being very similar and those instances where the alternatives are seen as being very different. In fact, based on the two studies mentioned above, I believe that perceived brand similarities and differences may eventually have a greater influence on consumer behavior thought than involvement.

If this area develops (as I believe it will), how can researchers avoid the disappointments that have arisen in the area of involvement. We should avoid over-defining the concept. This should not be a problem because it is not as difficult to define as involvement. We should also not spend too much time developing measures of it. This may be difficult because I believe that measuring differences across a product category will be inherently more difficult than measuring involvement. Most importantly, we should not spend too much time on models that are quantity oriented and should instead try to move towards models that are process oriented. Though it might be moderately interesting to discover that people's perceptions of the degree of similarities across a product category affect their level of brand loyalty or degree of information search, it would be more interesting to find that people have different processing styles based on the extent to which they see differences across the product category. It might also be interesting to discover differences in the way that people process similarity judgements from the way they process preference judgements.

This brings me to my discussion of the research presented by Lefkoff-Hagius and Mason (1990). Their paper focuses on the way that consumers develop similarity judgements versus the way they develop preference judgements. They found that there are differences, at least in the extent to which tangible versus intangible attributes are used in forming such judgements. Their research indicates that tangible attributes are relatively more important when making similarity judgements whereas intangible attributes are relatively more important when making preference judgements.

If consumers do use different types of attributes when making similarity judgements than when making preference judgements, then perhaps the evaluation process for similarity judgements is different from the evaluation process for preference judgements. This in turn may indicate differences in decision making strategies as the consumer progresses through the decision making process. For example, when consumers are deciding whether or not to engage in additional information search, they may simply try to discern whether or not the alternatives are similar. According to the research presented by Lefkoff-Hagius and Mason, this may involve looking at more tangible attributes. However, upon deciding that additional information is needed, they may begin looking at more intangible attributes.

Thus, this research by Lefkoff-Hagius and Mason indicates that there is at least promise in developing process oriented models which differ between consumers who perceive large differences and those who perceive small differences across a product category. The sooner this area moves through the definition, measurement, and quantity phases to get to the process oriented modeling stage, the sooner it will make a real contribution to our understanding of consumer behavior.

CONCLUSION

I admit that I have taken two relatively small research findings and have made grandiose speculations. The purpose here has not been to propose any viable framework for research in involvement or perceived similarities/differences. My purpose has been to discuss what I believe such frameworks should focus on and to show that the evidence presented by Brisoux and Cheron (1990) and Lefkoff-Hagius and Mason (1990) shows that it may be fruitful to pursue such frameworks. It is my overriding hope that the current paper will encourage consumer researchers to rethink research like that presented by Brisoux and Cheron (1990) and Lefkoff-Hagius and Mason (1990) in order to develop more interesting models of consumer decision making--ones that differentiate the processing underlying such decision making.

The Information Processing of Televised Political Advertising: Using Theory to Maximize Recall

Annie Lang, Washington State University
Patrick Lanfear, Washington State University

The point of political advertising is to get a candidate elected. In order to do so, a political advertiser must convey to the public the candidate's name, his or her stands on the issues, and a sense of liking or trust in the candidate. The advertisers who can do this can "sell" their candidates.

In some ways micro-level academic research on how television is processed by viewers seems somewhat removed from this endeavour. This paper is intended to demonstrate that specific suggestions regarding the structural aspects of television arise from that research and that these suggestions may be used to bring about significant changes in a commercial's effectiveness with only very small changes in the commercial. One might, for example, be able to create a commercial which improves viewers' memory for the candidate's name without interfering at all in the creative aspect of advertising. Further, the changes illustrated here can be done even in a fairly low budget production. It is argued that the marriage of television processing research with the real world of political advertising might be a good one.

Five variables will be considered in this paper. First, the effects on memory of visual structural complexity will be considered. (By visual structural complexity we mean the number of cuts, edits, zooms, dollies, pans, and general visual busyness that makes up an ad.) Second, the effects of visual and verbal redundancy will be considered. Third, we will look at how message difficulty affects the viewer's memory for an ad. Fourth, the order in which information is presented in a message will be considered. Last, effects of the emotional content of the commercials will be discussed.

Let's consider the political commercial shown in Figure 1. This is an ad for a fictitious politician, Charlie McGuire, who is running for Lieutenant Governor of Washington State. Charlie is relatively unknown in the state and is running for an office that does not have high salience for viewers. It is in this type of situation, when budgets are small, name recognition is low, and there is not a lot of information available about the race, that the improvement in memory resulting from the variables under discussion might make the most difference. How can we use theory to jazz up this basic ad and maximize recall for the candidate's name, what office he's running for, and his stand on the issues?

STRUCTURAL COMPLEXITY

Personal experience watching commercials suggests that visual complexity makes an ad more interesting. The question for researchers has been whether that makes the ad easier to remember or more difficult to remember. There is good evidence at this point to support the idea that visual features like cuts, edits, onsets, and movement increase

attention, in the attentive viewer, to a television advertisement by eliciting a reflexive attentive response called the orienting response (Lang, 1988; Reeves, et al., 1985). There is also evidence that audio structural features, like changes in voice, sudden silence, music, and loud noises, recall the attention of the inattentive viewer (Anderson and Levin, 1976; Thorson and Zhao, 1989). Thus, to some extent television can make you look by putting these elements of visual and audio structural complexity in the commercial.

On the other hand, there is also evidence to suggest that too much of a good thing can be bad (Berry, 1983; Gunter, 1987; Thorson and Lang, 1988; Lang and Thorson, 1989; Lang, in press). It seems that if there is too much complexity, you look but you can't think which results in high levels of attention (which is good) but low levels of memory for the contents of the ad (which is bad).

Where is the middle course and how do we get there? The research suggests, for example, that commercial onsets and scene changes within commercials elicit vigorous orienting behavior in viewers (Lang, 1988), but that information presented concurrently or during the first two seconds following scene changes and commercial onsets is remembered much more poorly than information presented more than two seconds after them (Lang, in press; Thorson and Lang, 1988). This suggests that when producing a commercial it would be wise to choose the two or three points you particularly want viewers to remember (like the candidate's name) and maximize attention to each point with a structural feature such as a scene change, loud noise, or sudden movement at least two seconds before it occurs.

In addition, there is preliminary evidence to suggest that if the structural feature used to attract the viewer's attention is visual it interferes more with information presented visually than it does with information presented verbally (Lang, in press). (Whether audio structural features interfere more with audio messages on television is not yet known, but it seems likely.) Thus, you might want to maximize memory by presenting the information verbally following a visual structural feature or visually following an audio structural feature.

In Figure 2 visual structural features are used to draw attention to Charlie McGuire's name and his stand on environmental issues. The formal feature being used here is a cut coupled with a pause in the audio track. So we have a visual cut to a new scene and a sudden silence in the audio. These should serve to increase attention in viewers who are already watching and recall the attention of those who are not looking. In addition to recalling attention, the pause in the audio track also allows the viewer time to process the new visual scene,

Commercial #2.
Timing: 30 Sec.

Scenes:

1. CLOSE-UP OF CHARLIE MCGUIRE IN FRONT OF CAPITOL BUILDING.

CHARLIE: Hello, I'm concerned about our Washington State and the entire Northwest. As a Washington state resident for fifty-five years, I've watched first-hand the devastation that pollution has wreaked upon our great state.

2. CUT TO LONG SHOT OF THE OLYMPIC PENINSULA MOUNTAINS FROM PUGET SOUND. (2 SECOND PAUSE)

CHARLIE (VOICE OVER): In the past year we've all witnessed fish kills in our streams that accounted for a ten percent decrease in migratory salmon, and oil spills that dumped 1,500 cubic barrels off the Olympic Peninsula and in the Puget Sound.

3. CUT BACK TO CLOSE-UP OF CHARLIE. (2 SECOND PAUSE)

CHARLIE: As Lieutenant Governor, I'll transform this traditionally ceremonial post into a vehicle to lead Washington and the nation in fighting for a safer and cleaner planet.

4. CUT TO FULL SCREEN SUPER. (3 SECOND PAUSE)

ANNOUNCER (DIFFERENT VOICE): Vote Charlie McGuire for Lieutenant Governor.

SUPER FULL SCREEN: CHARLIE MCGUIRE FOR LIEUTENANT GOVERNOR.

Charlie McGuire

For Lieutenant Governor.

which should lessen any interference of the orienting response with memory for the audio and video information.

AUDIO AND VISUAL REDUNDANCY

Another aspect of the structure of television messages that seems to increase recall and recognition arises when the audio and the video are well matched (Gunter, 1987; Reese, 1984). Reese has shown, for example, that memory for broadcast news is much better when the audio and video tracks carry redundant information. When they are poorly matched, memory is much worse. Figure 2 demonstrates two attempts to take advantage of this effect. In scene two a cut to a visual of the Olympic Peninsula from the Puget Sound is made when Charlie is talking about pollution on the Peninsula and in the Sound. Second, in scene four, Charlie's name and the office he is running for, arguably the two most important pieces of information in the commercial, are carried in both the visual and audio tracks of the commercial.

MESSAGE DIFFICULTY

The next aspect of a commercial to consider is how tough the message is. Are you trying to get across a dense message or a fairly simple one? Thorson and Lang (1988; Lang and Thorson, 1989), among others, have suggested that the difficulty of a televised message alters the effectiveness of the visual structural feature. They showed that when the message being presented orally was difficult or unfamiliar (which is often the case with political advertising) that visual structural features interfered with memory for the oral message both at the time that they occurred and for at least the next seven seconds. On the other hand, when the oral message was simple, visual structural features improved memory for the oral message.

This research suggests that you use appropriately placed visual structural features to improve memory for simple or expected aspects of the message, like the candidate's name, but refrain from using structural complexity during portions of the message that are more difficult, like position statements. Further, it suggests that simple messages are more easily processed than complex messages, and therefore more likely to be completely stored. Thus a balance must be struck between too simple, and therefore boring (after all it is a commercial), and too complex (i.e. attention grabbing but hard to remember). One way to strike this balance is to make sure that only one aspect of the message, either the audio or the video track, is difficult at any one time.

Figure 3 shows how this has been incorporated into Charlie McGuire's ad. In scenes one and two the verbal message has been simplified in two ways. In scene one, more familiar words have been used - "caused" instead of "wreaked" - and in scene two, the position statement has been simplified by taking out the numbers and

percentages and leaving only the descriptive statement.

These changes mean that at the start of the commercial, and just after the cut to a new visual scene (the Olympic Peninsula), which in this commercial is about as difficult as the visuals get, the audio is easier to process. When we return to Charlie's face in scene three, a familiar sight at this point, the audio track is slightly more abstract and difficult.

ORDER OF PRESENTATION OF INFORMATION

As the previous section points out, we must resist the temptation to focus only on the visual aspect of how information is presented. It is also important to consider how information is presented orally. It is the audio/visual nature of television which makes it such a compelling medium. But it is also this audio/visual nature that seems to make the process of gaining information from television a challenging cognitive task, despite its phenomenological ease. Research in both print and television suggests that information presented with a narrative structure (whether referred to as a script, story, or schema) tends to be remembered better than information presented without a narrative structure.

Of course in political advertising we may not want to tell a story all the time. But time is a great organizer, particularly during the type of episodic processing that seems to be associated with watching television (Thorson and Friestad, 1989; Ortony, 1978; Lang, in press b). Some research suggests (Lang, 1989) that to the extent simple chronological order can be maintained when presenting information on television, memory will improve. To some extent, this suggests that to the extent information is presented in your commercial in the order in which it logically occurred it will be better remembered.

Figure 4 shows how Charlie's ad has been reordered slightly to capture the chronological order associated with "meeting a politician." The new order follows the general script, "Hi, my name is ... I'm running for ... I think that ... Vote for me."

EMOTION

Having left the most interesting and complex issue until last, let's consider how emotion affects the processing of television commercials. This is a question of considerable interest and debate, especially in the context of the most recent presidential election. Does emotion help memory for commercials? Does it matter if the emotion is positive or negative? Does it affect memory for different types of information in different ways?

First, it seems fairly clear that overall memory for product commercials (Friestad and Thorson, 1985; Lang and Friestad, 1987), public service announcements (Lang, 1989; Reeves et al., 1989), and political commercials (Lang, in press; Shapiro and Rieger, 1989;) can be improved by the presence of emotion. Further, several of these

studies (Friestad and Thorson, 1985; Lang and Friestad, 1987; Shapiro and Rieger, 1989; Reeves et al, 1989; Thorson, 1988) suggest that negative commercials are remembered better than positive commercials. In some of these studies (Shapiro, 1989), the negative commercials were attack commercials; in others (Friestad and Thorson, 1985; Lang and Friestad, 1987) the commercials elicited sad or unpleasant feelings in viewers. But, in general, all of these studies and streams of research suggest that both negative and positive emotional commercials seem to be recalled better than neutral commercials.

This research suggests, as does practical experience judging from recent political advertising, which seems to be predominantly emotional, that a judicious use of emotion in a commercial can improve memory for the commercial. But exactly what part of the commercial does it improve memory for?

This is a more difficult, but perhaps more interesting, question to answer. Some of the recent research has attempted to distinguish between visual and verbal memory for commercials (Lang, in press; Lang, 1989; Lang and Friestad, 1987). This research might be of particular interest to the political advertiser who is trying to get across primarily "verbal" information, i.e., the candidate's name and his stand on an issue. Lang (in press; Lang, 1989; Lang and Friestad, 1987) has shown consistent evidence that negative emotion in commercials improves memory for the visual aspects of the messages. Thus, a commercial that is emotionally negative and has a strong visual image, like the famous revolving door ad from the Bush campaign, may be especially memorable.

In addition, some research suggests (Lang, 1987; Lang, 1988) that the emotional content of a commercial increases attention to the commercial and thereby increases memory for the commercial. Lang has reported preliminary evidence that the visual structural features in emotional commercials elicit more vigorous orienting responses than those in nonemotional commercials.

This research suggests, then, that when producing a commercial you should use emotion, as it is likely to increase both attention and memory. Further, if you use negative emotion you may want to present your main message visually. If you are using positive emotions your message can be presented either visually or verbally.

In Figure 5 negative emotion has been added to the commercial by using a strong visual image to underline Charlie's stand on environmental issues. The image of dead fish introduced in scene two carries the negative emotions associated with a fish kill (particularly salmon) in the Pacific Northwest and is a good match with the audio content. Thus visual and verbal redundancy are increased along with the introduction of emotion.

In addition, to increase attention at this point (to maximize the likelihood that the emotion will be engendered in the viewer), both an audio and a visual

structural feature are included. Visually, we have a cut to the dead fish followed by a dolly (not a zoom) forward towards the fish. Evidence suggests that putting the camera on a dolly and pushing forward, instead of zooming, increases both attention to the picture (Lang, 1987; Anderson and Levin, 1976) and memory for the scene (Kipper, 1986).

Because of the increase in arousal the still picture of the dead fish and the start of the dolly forward are accompanied by silence in the audio track. This should help recall inattentive listeners who may continue to watch the visually compelling image. In addition, it allows time to fully process the visual before the audio information begins.

This paper has shown how theory can be incorporated into the production of political, or product, commercials. While some of the specific findings relied upon in this paper are preliminary, the changes they suggest do not necessitate a major overhaul of the creative premise of an advertisement. Because of this, the advertiser can easily incorporate the findings of micro-level research into an advertisement with very little risk. It is unlikely that delaying the announcement of the candidate's name two seconds after a scene change, for example, will make a perceptible difference in the creative aspect of an advertisement, but the possible gain in memory may make it well worthwhile. The risks are low, the possible gains significant.

Further, most of the changes suggested and illustrated in this paper can be done on a relatively low budget. This is important since it is in the lower visibility campaigns or with candidates who have low name recognition that these structural changes are likely to make the most difference and these, of course, tend to be the situations where money is likely to be lacking.

Effects of Commercial Complexity, the Candidate, and Issue vs. Image Strategies in Political Ads

Joan Schleuder, University of Texas¹

In the 1940s, when the classic political communication studies were conducted, presidential campaigns would have been wise to severely limit their advertising expenses. The mass media were found to have almost no impact on attitudes, voting preferences and political knowledge. More than 80 percent of the voters decided who they would vote for before the campaign began and political party affiliation and interpersonal communication had the greatest effect on voting behavior (Lazarsfeld, Berelson & Gaudet, 1944; Berelson, Lazarsfeld & McPhee, 1954). But the "media" described by the classic studies did not include television.

Recent research indicates that many of today's voters identify themselves as people who vote for the candidate rather than the party and that the television plays a larger role in their voting decisions than interpersonal communication (Mendelsohn & Crespi, 1970; DeVries & Tarrance, 1972). Today campaign officials consider it wise to advertise, and they have been allocating ever increasing percentages of their funds to television advertising (Shyles, 1986). There's no doubt that campaigners consider television an effective means for conveying political information. Current research tends to back up this perception. Today's voters report learning about presidential candidates from television commercials, and they even say they "became better acquainted" with candidates from television advertising (O'Keefe & Sheinkopf, 1974; Mendelsohn & O'Keefe, 1976). Much research has found a high correlation between exposure to political ads and presidential candidate knowledge (Patterson & McClure, 1976; Atkin & Heald, 1976; Hofstetter & Buss, 1980). The purpose of this study is to assess whether television advertising presents political information in a way that allows viewers to learn more about candidates and store information that will be useful at the time a final voting decision is made. This work examines how different characteristics of actual 1988 presidential campaign commercials affected the way people thought about the candidates.

The first research question addresses whether commercials that emphasize issues elicit more attention and are better remembered than image-oriented ads. Next, this study asks whether the type of candidate advertised influences the effectiveness of the advertising strategy adopted and whether the

candidate type and strategy interact to affect cognitive processing. Finally, the effect of overall commercial complexity and its interaction with strategy and candidate type is assessed.

Issue vs. Image Strategy

Much political advertising research has focused on the clash between commercials that adopt the rational, issue-oriented, approach and those that adopt the image model (Hellweg, Dionisopoulos & Kugler, 1989). The results of some of these studies suggest that issue concerns are primary to voters (Rusk & Weisberg, 1972). But most studies have found image-oriented political messages more effective on measures such as perceptions of the candidate (Kraus & Smith, 1977; Dennis, Chaffee & Choe, 1979) and candidate preference (Marshall, 1983). Clark (1979) argues that to gain as many votes as possible, candidates must appear to address issues while running their campaign with an image-oriented strategy.

Natchez and Bupp (1986) found candidate image to be the best predictor of voter behavior and attributed this to the ease with which image information is processed. The authors concluded that thinking about issues is more difficult than thinking about images because issues need more information to support them. Image-oriented advertisements have also produced higher content recall scores than issue ads in an experimental setting (Kaid & Sanders, 1978). In addition, when survey respondents were asked to remember information presented in political advertisements, they most often reported image information (O'Keefe & Sheinkopf, 1974).

Few issue vs. image studies of political advertising directly address the effect strategy has on the cognitive processing of candidate information. Still, based on this review of the literature, it seems reasonable to predict overall higher attention and memory scores for image-oriented ads.

Candidate Type

The 1988 Presidential Campaign offered the unique opportunity to compare commercials for two types of candidates: A familiar national figure and a relatively unknown, novel politician. George Bush had been the Vice President of the United States for eight years prior to his election. He had spent many years in high visibility positions with the federal government. In addition, he emerged early in the campaign as the Republican Party front runner and received much more media coverage as a result than Michael Dukakis, the Democratic nominee. Dukakis may have been well-known in Massachusetts where he served as governor, but to the rest of the nation he was a political new-comer.

Generally, when a new product is introduced, a rational, information-oriented advertising

¹This research was funded by the National Political Advertising Research Project, funded by the Gannett Foundation. Thanks go to Sandra Gaiser and the fall 1988 University of Texas Journalism Research Methods class for their help in preparing stimuli, running subjects and preparing data for analysis.

campaign is used. The public needs to know what this new product has to offer. If a new political candidate is analogous to a new product, perhaps commercials advertising him (or her) should focus more on issues than on image. But for a well-known politician who has been around a long time, it's logical to assume that an image approach would work better, just as it works better for old, well established products like Coca-Cola.

People have more to learn about a novel candidate in a shorter period of time. Consequently, they may be motivated to attend to and remember more pieces of information about Dukakis than about Bush. If this is the case, highly complex Dukakis commercials -- especially if issue-oriented -- should result in better cognitive processing scores.

Commercial Complexity

Natchez & Bupp (1986) thought that image ads were less complex than issue ads and that this lack of complexity lead to better processing of image commercial information. If Natchez & Bupp (1986) are correct, overall low complexity ads should result in better cognitive processing even if Dukakis issue-oriented ads specifically benefit from high complexity executions. Bush image-oriented ads that are low in complexity should be processed more effectively than any other type of ad.

In this study, complexity is a formal characteristic of commercials and is defined by the amount of visual and verbal information present in commercials per time unit. In a program of work that has investigated complexity's effects on attention and memory, Schleuder, Thorson and Reeves found that simple product commercials have elicited more attention than complex ones (Thorson, Reeves & Schleuder, 1985; 1987; Schleuder, Thorson & Reeves, 1987; 1988; Schleuder & Gaiser, 1989). Although this finding has been rigorous with product commercials, it would be interesting to see if political ads also elicit more attention and result in better memory when they are kept simple. Beginning to examine how a commercial formal feature, such as complexity, and content features, such as the advertising strategy adopted and the candidate promoted, is important to developing an understanding of how viewers process the information contained in television commercials.

Based on past research and speculation in the issue vs. image political advertising strategy literature, overall low complexity is expected to result in higher cognitive processing scores and offer special facilitation to issue-oriented advertisements for Bush. Dukakis advertisements about issues are expected to benefit from high complexity approaches.

Attention and Memory

Attention is an on-going process that refers to how viewers allocate mental resources to information in television messages (Schleuder, Thorson & Reeves, 1988). Mental resources refer to visual and auditory sensory systems and the memory mechanisms that determine how new information

will be integrated with the old. This definition derives from Kahneman's (1973) general capacity model of attention and from multiple resources theory (Wickens, 1984) and rests on the assumption that the ability to attend to more than one simultaneous event is limited (Broadbent, 1958).

The secondary task reaction time method allows advertising and mass communication researchers to measure attention as an on-going process. In the typical secondary task experiment, viewers are told to concentrate on watching television, but to also respond as quickly as they can to periodic tones by pressing a reaction time button as quickly as possible. The assumption underlying use of the task is that performance on the secondary task decreases as attention to the primary task increases. As more attention is allocated to television viewing, less attention is left over to use in responding to the secondary task. To insure that this assumption holds, secondary task experiments should incorporate a manipulation check to assess speed-accuracy trade-offs. If subjects focus attention on the button-pressing task rather than television viewing, the reaction time measures become meaningless.

Visual and verbal recognition memory refers to the process by which information picked up from viewing commercials is stored in long-term memory and retrieved in response to a cue. Recognition is used, rather than recall because recognition methods focus on identifying the strength of the encoding process (Klatzky, 1980). The distinction between visual and verbal information retrieval is made because television is both a visual and verbal medium. In addition, as Garramone (1989) has suggested, auditory and visual processing schemes may differ in response to issue vs. image advertising strategies.

Hypotheses

The issue vs. image strategy adopted by the advertiser is a fundamental decision and, based on recent studies (O'Keefe & Sheinkopf, 1974; Kaid & Sanders, 1978; Natchez and Bupp, 1986), is expected to have an effect on attention and memory no matter how other political ad characteristics vary. Candidate type advertised also is expected to have an effect on how political information is processed. In addition, because novelty should lead to enhanced processing of ads for Dukakis (Reeves, Thorson & Schleuder, 1987), Candidate type is expected to interact with strategy and also with complexity. Commercial complexity is expected to affect how the information in political ads is processed. In addition, a low level of complexity is expected to enhance attention and memory for Bush issue strategy commercials while a high level of complexity is expected to enhance attention and memory for Dukakis ads about issues.

H1: Overall, attention as indicated by secondary task reaction time, and visual and verbal memory recognition scores are expected to be higher for Image

Strategy commercials than for Issue Strategy commercials.

- H2:* Overall, attention, and visual and verbal memory are expected to be higher for Dukakis commercials than for Bush commercials.
- H3:* Overall, Low Complexity executions of ads are expected to result in higher attention, and visual and verbal memory than High Complexity executions.
- H4:* High Complexity Dukakis ads are expected to produce higher cognitive processing scores as indicated by attention, and visual and verbal memory scores, than Low Complexity Dukakis ads.
- H5:* Low Complexity Bush ads are expected to produce higher cognitive processing scores than High Complexity Bush ads.
- H6:* High Complexity Dukakis ads, especially those about Issues, are expected to produce higher cognitive processing scores than other types of Dukakis ads.
- H7:* Low Complexity Bush ads, especially those that emphasize the candidate's Image, are expected to produce higher cognitive processing scores than other types of Bush ads.

METHOD

Subjects

A total of 44 people participated. Twenty-one adults were recruited from churches and social groups in Travis County, Texas and their organizations were paid \$5 for their participation. The 23 University of Texas undergraduate communication students participated for course credit. An additional 44 subjects (half were students and half were recruited from the community) participated as members of the secondary task manipulation check control group.

Stimuli

Eight 30-second political advertisements, four for George Bush and four for Michael Dukakis, were selected from 34 positive appeal commercials that had aired for the two candidates by October 1, 1988 (the time the experiment was run). The 34 ads were collected from the Democratic and Republican parties, from the Political Advertising Archive at The University of Oklahoma and by recording them off-air. Two commercials for Bush and two for Dukakis used issue strategies, and two for each candidate used image strategies. The Bush issue strategy ads included an ad suggesting Bush would "keep America at work," and a talking head

execution in which Bush talked about the need for American trade to become more competitive with foreign countries. The Bush image strategy ads included an ad describing Bush's government experience and a biographical ad which stressed Bush's role as a family man. The Dukakis issue strategy ads included a union member talking about the need to create more jobs and a talking head form ad in which Dukakis discussed balancing the federal budget. The Dukakis ads that stressed image included Tipp O'Neill describing Dukakis' character and a biography of Dukakis' life. Eight advertisements were used in the experiment to enhance generalizability of the effects to other political advertisements (Jackson & Jacobs, 1983).

The Bush and Dukakis ads, along with eight product commercials, were embedded in a half-hour episode of the situation comedy *Cheers*. In order to keep the viewing experience as natural as possible, each subject saw only four of the eight political ads during their half-hour viewing session. One political ad was placed in each of four 90-second commercial pods. The order in which the political commercial fell in the pod (first, second or third) and the pod order (four orders) were counterbalanced to control for practice and fatigue effects. Which four ads each group of subjects saw was determined by their random assignment to one of two strategy conditions. Clearly audible secondary task tones were triggered by four cues that were placed at random intervals in each political and product commercial. Cues were also placed in the programming so that subjects did not suspect that the experiment focused on the advertisements.

Strategy and Candidate. The 22 subjects assigned to the Issue Strategy Condition watched the two Bush and two Dukakis ads judged to be the most prototypical examples of commercials about "economic issues important to the 1988 Presidential Campaign". There was no variation in the four coders' rating scores for these commercials. The ads used were ranked first (most prototypical) or second out of 17 Bush ads, and first or second out of 17 Dukakis commercials by all four coders. The coders were graduate students in an introductory research methods course.

The ads selected for the Image Strategy Condition were those judged, by the same coders, to be the most representative of ads for Bush and Dukakis that "focus on the image of the candidate as a leader." There was little variation in the rankings for the four advertisements selected. Three of the coders rankings were identical and the fourth coder included the same ads in the top rankings for each candidate, but the Dukakis ad rankings were in reverse order.

Complexity. Prior to being coded for advertising strategy, each of the 34 political advertisements was rated for complexity following the rating procedure used in several recent attention and memory studies (see Schleuder, Thorson & Reeves, 1988). Verbal complexity was indexed by coding the presence of music, voice-overs and natural sound and by counting the number of macro-

propositions, or idea units). Messages with more types of sound and more propositions were considered more complex. Video complexity was assessed separately but combined with the verbal complexity score to determine each ad's overall complexity ranking. High video complexity scores were given to messages with many scene changes, dissolves and edits, much camera movement such as pans or zooms, much person and object movement and many superimposed images.

In addition, a group of 32 people provided subjective ratings of complexity during a pretest. These subjects were asked to view the 34 commercials and estimate on a 100-point scale the magnitude of complexity of the video, verbal or both channels. The subjective ratings provided a manipulation check on the complexity categories assigned to the political commercials and ensured that an ad rated low in complexity was perceived to be low in complexity to most viewers. Four of the eight ads used in this experiment were categorized as High Complexity and four were categorized as Low Complexity. The Bush Issue Strategy ad about keeping America working was a High Complexity ad, and his ad about foreign trade competition was Low Complexity. The Dukakis Issue Strategy ad about balancing the federal budget was High Complexity and his ad about the creation of new jobs was Low Complexity. The Bush Image Strategy ad about his life and role as a family man was High Complexity and the ad about his government experience was Low Complexity. The Dukakis Image Strategy ad about his life was High Complexity and Tip O'Neill's character appraisal was Low Complexity.

Experimental Procedure

Subjects were run one at a time after being randomly assigned to view either four Issue Strategy ads or four Image Strategy ads. Subjects were told that the purpose of the study was to see how much they could remember from watching television. They were also told to press the reaction-time button in front of them as quickly as they could whenever they heard a tone. Each subject "practiced" hitting the reaction time button in response to a tone before the experiment began so that 36 baseline simple reaction times could be collected and later used to assess individuals' basic motor speed. Then each subject viewed a brief episode of "Cheers" and a product commercial on a practice tape. They got practice responding to the tone secondary task and were given visual and verbal recognition tests about information in the practice program and in the commercial.

Subjects next viewed the one-half hour situation comedy and commercials. They were given visual and verbal recognition tests following the viewing period. The tests asked questions about "Cheers" and about product and political advertisements. Subjects then answered several questions about the upcoming presidential election including their intention to vote and their feelings about the two presidential candidates. The procedure

for the 22 subjects in the secondary task manipulation check control group was identical except there was no secondary task.

Apparatus

The subjects watched Cheers, the embedded commercials and video-frame recognition tests on a 19-inch Panasonic 2010 video monitor placed five feet from their chair. The advertisements and programming were played on a Panasonic 6500 videotape recorder. An IBM AT microcomputer, with Labpac and Timecode reader/generator cards, controlled the tone presentation and the presentation of stimuli. Reaction-time responses were collected by a button box built by university technical staff.

Design

The study was a 2 X 2 X 2 mixed-factors design. Advertising Strategy was a between-subjects factor with two conditions: Issue vs. Image Strategy. Candidate was a within-subjects factor with two conditions: Bush vs. Dukakis. Complexity was a within-subjects factor with two levels: Low vs. High. For the attention measure, there were four repetitions of reaction-time nested in each cell of the Advertising Strategy X Candidate X Complexity factorial design.

There were also two between-subjects control factors, each with three levels -- commercial pod order and political commercial position within each pod order. There was also a secondary task vs. no-secondary task between-subjects factor included in the design as a manipulation check so that speed-accuracy trade-offs on the reaction time and memory test tasks could be detected if they existed.

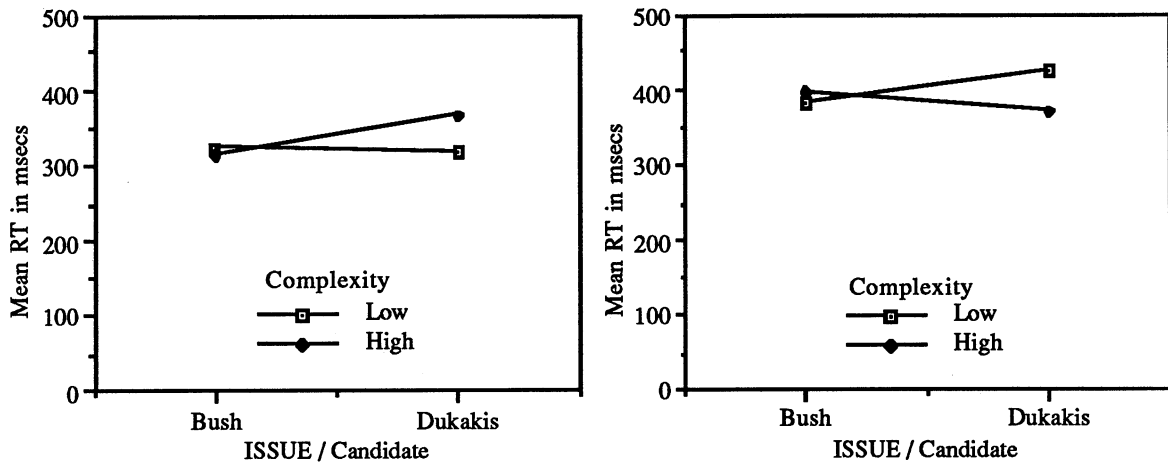

Dependent Measures

Attention. The secondary task reaction time method was used as an indicator of how intensely viewers paid attention to the political commercials. Subjects were instructed to pay primary attention to the television, but also to press a reaction time button as quickly as they could in response to periodic tones. Slower reaction time on the button pressing task indicated that subjects paid more attention to viewing. When the intensity of viewer attention to the political commercials was low, subjects had more attentional resources left over to use in hitting the reaction time button and reaction time scores were faster. Attention scores were expressed in msec. units.

Visual memory was measured for each political advertisement by frame recognition tests administered after the 30-minute program was complete. The political ad was identified and six 1/15-second frames were flashed on the screen consecutively. Some of the frames were images that subjects had seen in the political ads and some were not. The number correct out of six frame identification items was the score for each political commercial.

Verbal memory was measured by giving subjects a six-item multiple-choice test for each political commercial. This test was administered

FIGURE 1
Mean reaction time as a function of Strategy, Candidate and Complexity

Strategy x Candidate x Complexity:
($F(1,41) = 5.66, p < .05$)

after the visual recognition test. Each question offered four alternative choices. The number correct on the six-item test was the verbal recognition score for each news story.

Manipulation Check for Speed-Accuracy Trade-offs

When the pattern of memory scores for subjects in the secondary task condition were compared to those in the no-task control condition, speed-accuracy trade-offs were not apparent. If subjects were trading speed on the button-pressing task for accuracy on the memory test, the memory scores would be significantly better for the control subjects than for the secondary task subjects -- this was not the case for visual recognition tests [$F(1,84) = .00, p = .96$] or for verbal recognition scores [$F(1,84) = 3.28, p < .08$].

RESULTS

Attention

H_1 predicted that Image Strategy ads would elicit more cognitive processing than Issue Strategy ads. This hypothesis was supported by the results of the 2 (Issue v Image) X 2 (Bush v Dukakis) X 2 (Low v High Complexity) mixed-factors Analysis of Covariance for attention scores ($F(1,41) = 4.91, p < .05$). Mean reaction time in msec. was 329 for Issue ads and 392 for Images ads.

ANCOVA was used only when between-group reaction time comparisons were made. People vary tremendously in their basic motor skills. Controlling for this by collecting baseline reaction time prior to the beginning of experiments allows

the variation due only to differences in individuals' motor skills to be removed before differences due to the experimental manipulation are assessed.

There was also a three-way interaction among Strategy, Candidate and Complexity factors ($F(1,41) = 5.66, p < .05$), as shown in Figure 1. Attention paid to Bush commercials was not affected by Complexity in either Strategy condition. However, Duke commercials' ability to elicit viewer attention was facilitated by Low Complexity when ads stressed the candidate's Image, but by High Complexity for ads that stressed Dukakis' stands on economic issues, as predicted by H_6 . Support for H_2, H_3, H_4, H_5 , and H_7 was not produced by the attention data.

Visual Memory

H_1 , which predicted higher cognitive processing scores for Image Strategies, was not directly supported by the visual recognition findings. The 2 (Issue v Image) X 2 (Bush v Dukakis) X 2 (Low v High Complexity) mixed-factors Analysis of Variance did not produce a main effect for Strategy.

As predicted by H_2 , overall visual memory was better for Dukakis than for Bush commercials ($F(1,42) = 9.40, p < .005$), with a mean score of 3.81 out of 6 for Dukakis and 3.34 for Bush. The Candidate and Complexity factors interacted ($F(1,42) = 4.92, p < .05$) in the manner predicted by H_4 and H_5 (see Figure 2).

Strategy interacted with Candidate and Complexity and there was a three-way interaction. As shown in Figure 3, Issue and Image Strategies work equally well for Bush ads. But, as predicted by H_6 , the visual elements of the Dukakis Issue ads

FIGURE 2

Visual recognition number correct as a function of Candidate and Complexity

Candidate x Complexity:
(F(1,43) = 13.29, p < .001)

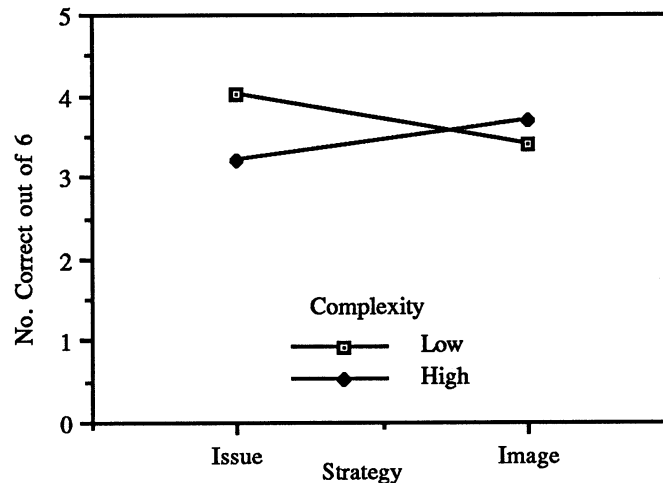

FIGURE 3

Visual recognition number correct as a function of Strategy and Candidate

Strategy x Candidate:
(F(1,42) = 10.34, p < .005)

FIGURE 4
Visual recognition number correct as a function of Strategy and Complexity

Strategy x Complexity:
($F(1,42) = 13.29, p < .001$)

were remembered better than the Image visuals ($F(1,42) = 10.34, p < .005$). Figure 4 shows the Strategy X Complexity interaction. Counter to *H4* and *H5* predictions, visual recognition scores for Image Strategy ads were not affected by Complexity level, and scores for Low Complexity Issue ads were slightly higher than for High Complexity Issue ads.

The three-way interaction ($F(1,42) = 40.26, p < .001$), shown in Figure 5, suggests that, counter to predictions, visual memory for Dukakis ads did not vary as a function of Strategy or Complexity. In addition, High Complexity Bush ads about Issues resulted in much lower visual memory scores than any other Bush ad approach.

Verbal Memory

The 2 (Issue v Image) X 2 (Bush v Dukakis) X (Low v High Complexity) mixed-factors ANOVA produced the predicted main effect for Strategy. Verbal memory for Image Strategy ads was better than for Issue Strategy ($F(1,42) = 5.89, p < .05$), with mean scores of 2.81 out of 6 for Issue and 3.43 for Image ads. Strategy did not interact with any other experimental factor, but, as predicted by *H4* and *H5*, the Candidate and Complexity factors interacted ($F(1,42) = 14.76, p < .001$). As shown in Figure 6, verbal memory scores were higher for High Complexity Dukakis ads than for Low Complexity Dukakis ads, and scores were higher for Low Complexity Bush ads than for High Complexity Bush ads.

DISCUSSION

The primary purpose of this study was to see if two important content characteristics of political

ads -- the issue vs. image strategy and the candidate type -- interacted with commercial complexity to affect information processing. In general, the moment-to-moment attention results and the visual and verbal memory scores supported the idea that strategy, candidate and complexity are important ad characteristics that can be manipulated in a manner that will result in optimal cognitive processing of political information.

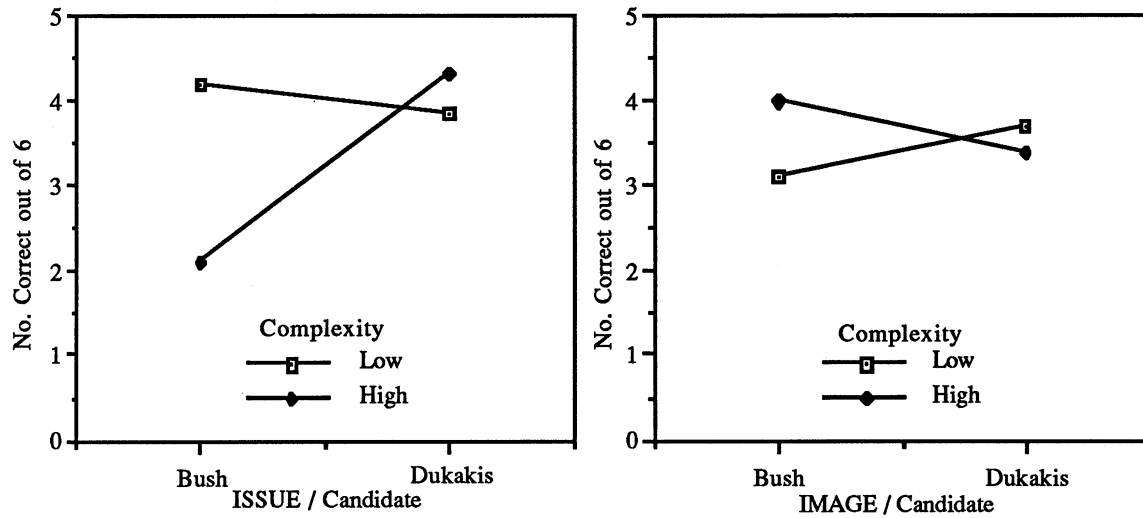

Image-oriented ads elicited more attention than issue ads. Their verbal message was also better remembered. Visual memory was better for ads about Dukakis, especially Dukakis issue ads. In general, both visual and verbal memory were better for high complexity Dukakis ads and for low complexity Bush ads.

Viewers paid more attention to high complexity issue ads for Dukakis as expected. This is probably because a novel political candidate, like a new product, benefits from a rational promotion approach and a high level of motivation on the part of the viewer to learn what the new entity has to offer. Low complexity image ads for Bush also elicited a lot of attention, probably because Bush is an old, familiar national politician. Like many familiar products, he benefited from ads that pitched his image with simple executions. This would give viewers plenty of time to devote to thinking about old memories they have about Bush (see Thorson, et al., 1985), and it's possible that this active processing of simple, familiar information is what causes the high level of attentional intensity.

Visual memory for political commercial information is highly specialized. Viewers remembered the visual information about Dukakis issue ads and Bush image ads best. Low complexity

FIGURE 5

Visual recognition number correct as a function of Strategy, Candidate and Complexity

Strategy x Candidate x Complexity:
 (F(1,42) = 40.26, p < .001)

FIGURE 6

Verbal recognition number correct as a function of Candidate and Complexity

Candidate x Complexity:
 (F(1,42) = 14.76, p < .001)

issue ads worked best. Visual memory was best for low complexity Bush ads about issues and for high complexity Bush ads about images. It appears that there is a mental trade-off process, or a time-sharing function, at work between the visual sensory system and attentional mechanisms when interactions among all three ad characteristics are examined.

This type of trade-off has been observed between auditory and visual sensory systems, between auditory and attentional systems and between visual and attentional systems (Thorson, et al, 1985; 1986; Schleuder, et al., 1987; 1988). Identifying exactly what commercial characteristics trigger the

cognitive time-sharing observed in this study should be a goal of future research.

Measuring Material Values: A Preliminary Report of Scale Development

Marsha L. Richins, University of Massachusetts, Amherst
Scott Dawson, Portland State University¹

ABSTRACT

Belk's pioneering work to develop scales measuring traits associated with materialism has facilitated numerous investigations by consumer behavior researchers. Materialism, however, is a multi-dimensional concept which includes not only traits, but attitudinal, behavioral, and value components as well. This paper reviews some of the existing knowledge about materialism and concludes that the construct is appropriately measured as a value within the constellation of a personal or cultural value system. Empirical work to develop measures of material values are reported.

INTRODUCTION

The study of the culture of consumption has become an important topic in the consumer behavior literature. One concept frequently addressed in this literature is materialism. Current measures of materialism emphasize traits associated with materialism and have greatly facilitated both theoretical development and empirical analysis. In this paper, we review key conceptualizations of materialism, suggest some additional dimensions of materialism, and report the preliminary results of research in progress to develop measures of these dimensions.

BACKGROUND

Materialism is such a complex, multifaceted concept that agreement on its meaning is only approximate. The concept has been popularized in the mass media in response to America's apparent preoccupation with consumer goods and has been variously and often loosely defined in the academic literature. Several treatises and studies that have examined materialism or related concepts form the theoretical basis for establishing the materialism dimensions and measures suggested here. For sake of discussion, we categorize these into political/historical, anthropological/sociological, and marketing orientations.

Political/Historical Orientations

Though theoretical notions about materialism have benefited from a number of historical analyses (e.g., McKendrick, Brewer, and Plumb 1982; Mukerji 1983), Inglehart's (1981) work is particularly relevant. Using a political perspective, Inglehart suggests that materialism is evident by the degree to which nations or other social groups emphasize values involving material things. Influenced by Maslow's hierarchy of needs, Inglehart posits that

Western societies have satisfied the majority of needs involving material well-being and are now primarily concerned with post-materialistic values such as family, friends, and social welfare. Perhaps because definitive data is lacking and because materialism is inferred rather than explicitly measured, his thesis has been quite controversial (Marsh 1975; Mastekaasa 1983) and difficult to accept given the consumption ethos in America during the 1980s (Yankelovich 1981). Nevertheless, Inglehart's argument that materialism is a value situated within the constellation of a value system has important implications for measure development.

Anthropological/Sociological Orientations

This genre of study has provided perhaps the richest underpinnings for understanding materialism (cf. Appadurai 1986; McCracken 1988). An especially valuable perspective is provided by Csikszentmihalyi and Rochberg-Halton (1981) who have studied attachment to and meaning associated with possessions. Broadly, these authors develop a powerful conception of materialism:

"If things attract our attention excessively, there is not enough psychic energy left to cultivate the interaction with the rest of the world. The danger of focusing attention excessively on the goal of physical consumption - or materialism - is that one does not attend enough to the cultivation of self, to the relationship with others, or to the broader purposes that affect life" (p. 53).

Among the many findings of their research, two points are particularly relevant: (1) that the types and saliency of meanings associated with objects vary over the life span, and (2) that the degree of psychic energy invested in objects appears related in a curvilinear manner with well-being and happiness. While excessive reliance on the symbolic power of objects leads to a narrow definition of self and to unhappiness, those individuals who are most adamant about the meaninglessness of objects are often the most lonely. Possessions may serve a positive function by solidifying and making concrete the ties that we develop with family and friends.

Csikszentmihalyi and Rochberg-Halton separate materialism into two components: (1) terminal materialism, in which consumption is an end of itself, there is little interaction between owner and object, and image or status associated with an object is of primary value; and (2) instrumental materialism, where objects are used in order "to make life longer, safer, more enjoyable" (Csikszentmihalyi and Rochberg-Halton 1978, p. 8).

¹Thanks to Teri Root-Shaffer for her assistance in item generation and data collection during the early phases of the project and to Russ Belk for his helpful insights during measure development.

While these distinctions in the meaning of materialism have been used as a basis for evaluating themes in advertising (Belk and Bryce 1986; Belk and Pollay 1985), psychometric work has not proceeded to develop measures of these constructs. This may be because terminal and instrumental materialism are subjective terms so pregnant with meaning that they defy unidimensional measurement. While the scales described in the current measurement effort are not designed to measure terminal and instrumental materialism, elements of both concepts are evident in their content.

Marketing Orientations

In the marketing literature, a simpler definition of materialism comes from studies of child and adolescent socialization. Ward and Wackman (1971, p. 422) defined materialism as "an orientation which views material goods and money as important for personal happiness and social progress." This definition and adaptations of their measures (Wackman, Reale, and Ward 1972) have been used in later research by Moschis and his colleagues (Churchill and Moschis 1979; Moschis and Moore 1982).

Without doubt, Belk's (1984, 1985) work on defining and measuring materialism has been the most useful to researchers working empirically in this area. According to his definition (Belk 1984, p. 291):

"Materialism reflects the importance a consumer attaches to worldly possessions. At the highest levels of materialism, such possessions assume a central place in a person's life and are believed to provide the greatest sources of satisfaction and dissatisfaction in life."

This definition is similar to others in its emphasis on degree of object attachment and an associated state of well-being. Belk developed measures of three traits associated with materialism--envy, nongenerosity, and possessiveness. These measures have been used in a number of studies (e.g., O'Guinn and Faber 1989; Wallendorf and Arnould 1988).

DEFINING THE DOMAIN OF MATERIALISM

After reviewing the conceptualizations, definitions, and operationalizations above, several issues guided the development of a new measure of materialism. First, materialism is a complex construct with multiple components that may be related or orthogonal. Second, any definition of materialism should be value neutral and not reflect some normative prescription of its authors. Material possessions do serve an important role in establishing and maintaining a positive affective state. As noted above, Csikszentmihalyi and Rochberg-Halton (1981) determined that those individuals who were the most lonely also found objects the least meaningful. Possessions serve a potent role in definition of self, and loss due to

institutionalization or theft may result in negative affective states (Belk 1989). This facet of material objects has been perhaps the greatest obstacle to clarity of semantic meaning. "Materialism" carries with it a negative connotation that is not always justified.

A third issue in deriving a measure of materialism is that it should strive to transcend cultures, subcultures, and economic systems. Better understanding of consumption culture through cross-cultural comparison (Rassuli and Hollander 1986) is facilitated when concepts such as materialism and their measures demonstrate validity and reliability across cultural systems.

Finally, a critical issue is whether materialism is best approached as a trait, an attitude, or a value. Traits are personal characteristics that (1) are formed at an early age, (2) are relatively unchanging over the life span, and (3) the underlying trait itself is generally impervious to environmental stimuli. The theoretical work reviewed above suggest that one's relationship with material items changes over time. Further, examinations of materialistic themes in advertising (Belk and Pollay 1985), brand names in novels (Friedman 1985), goals and satisfactions within societies (Inglehart 1981), and broad societal trends (Henkoff 1989; Yankelovich 1981) all suggest that materialism is affected by broader environmental stimuli. Thus, the common but approximate conception of materialism gleaned from the literature suggests that this construct does not fit the accepted characterization of trait. It seems likely, however, that some traits may be associated with materialism, as Belk (1984) has suggested.

Though many definitions of attitude exist, a favored conception is that an attitude "represents a person's favorable or unfavorable feelings toward the object in question" (Peter and Olson 1987, p. 192). Such a definition seems too narrow for approaching materialism in that it speaks to specific objects, rather than broader systems of behavior.

Materialism may be best viewed as a value. Values "are (a) concepts or beliefs, (b) about desirable end states or behaviors, (c) that transcend specific situations, (d) guide selection or evaluation of behavior and events, and (e) are ordered by relative importance" (Schwartz and Bilsky 1987, p. 551; see also Maslow 1959, Rokeach 1973). They may emphasize individualistic or collective interests and may be used to characterize individuals, small groups, and societies. Values change with social conditions and with age, two important features which appear endemic to materialism. Schwartz and Bilsky (1987) used smallest space analysis to map Rokeach's (1973) 36 instrumental and terminal values. In the resulting structure, prosocial values (e.g., equality, belief in God) and security (family and national security) were polar opposites of achievement values (social recognition, ambitious) and enjoyment values (comfortable life, pleasure) and self-direction. This structure is consistent with Inglehart's (1981) theoretical analysis of materialistic and post-materialistic values.

These findings and Belk's definition of materialism quoted above suggest that materialism may be viewed as an organizing or second-order value that incorporates both the importance placed on certain end states (achievement and enjoyment values) and beliefs that possessions are appropriate means to achieve these states. This perspective was the basis of construct definition for the measures developed here.

Building on Belk's work and the values literature, the domain of materialism for purposes of measure development was framed in terms of the motivations, expectations, and affective states that characterize individuals' values with respect to material objects. First, as a motivation, materialism has a status component which reflects the intended and actual use of material objects as a means of social recognition and to symbolize one's personal success. Second, the expectation or aspirational component of materialism concerns the extent to which an individual believes that acquisition of material objects will lead to personal happiness and enjoyment in life. Third, materialism has an affective component, represented by the degree to which an individual actually does find possessions to be a source of satisfaction. Finally, the notion of centrality is important to materialism. As noted by many writers, objects assume a central position in the lives of materialistic people. We do not posit these to be the only concepts representing materialism, and encourage the conception of additional facets.

METHODS

Exploratory Research and Item Generation

The adequacy of the materialism domain described above was examined in exploratory research. A convenience sample of 11 adult consumers was asked to describe in an open-ended format the attitudes and values of materialistic people they knew and of materialistic people in general. The sample was evenly split among males and females and spread across several age and income categories. Frequently-mentioned attitude descriptions were converted into items. In addition, the researchers constructed items designed to represent the motivation, expectation, affective, and centrality aspects of materialism described above. Another source for item generation was characterizations of materialistic people described in the literature and mentioned by social critics. Finally, a few items were adapted from earlier studies in which materialism and related constructs were measured (Belk 1985; Heslin and Johnson 1985, 1989; Richins 1987; Wackman, Reale, and Ward 1972; Yamauchi and Templer 1982). In every case, items were cast to reflect values, attitudes, and feelings about possessions rather than the more specific behaviors or traits measured by Belk's scales. Effort was also taken to avoid items that might prove specific to American culture.

During the three data collection efforts described in this study, more than 120 items were

generated. Redundant, ambiguous, leading, and other faulty items were eliminated in initial screening. Subsequent screening was based on empirical tests of reliability, validity, and social desirability bias.

Data Collection

Data were collected from students at three separate universities. In the first data collection, 50 items were administered to 448 students at Louisiana State University. The second sample consisted of 191 undergraduates at the University of Massachusetts who completed 66 potential materialism scale items. The third sample, 194 undergraduate and MBA students at Portland State University, completed 66 items. This sample was somewhat older than the other two because it included more part-time students and students in an evening MBA program; 30% were over the age of 30, 38% were married, and 35% worked 30 hours or more per week.

The materialism measures varied across data collection efforts as we revised items, deleted weak items, and added others to improve the reliability and validity of scale components. Standard scale development practices described by Nunnally (1978) and Churchill (1979) were used in item purification.

The survey instruments contained several other measures that assisted in scale refinement. Two administrations (LSU and UMass) included the Marlowe-Crowne (Crowne and Marlowe 1960) social desirability measure. While materialism seems to be more socially acceptable today than in past eras, we had some concern about the potential for social desirability bias. Twelve items from the scale were included to identify those materialism items most subject to this type of bias. The original dichotomous scaling format used by Crowne and Marlowe was changed to a five-point Likert format.

Several other measures were included for validation purposes in some or all of the data collections.

(1) Life satisfaction. Because prior research has found a negative relationship between happiness and materialism (Belk 1985; Richins 1987), satisfaction with five life domains was measured on seven-point scales in the UMass and PSU data collections: amount of fun, family life, income or standard of living, relationships with friends, and life as a whole. The LSU questionnaire included only three domains.

(2) Values. To assess the relationship of material values to other values, the List of Values scale (Kahle, Beatty, and Homer 1986; Veroff, Douvan, and Kulka 1981) was included in the questionnaire for all data collections. The scale was modified by adding two values that might be related to materialism: "financial security," and "having enough money to buy nice things." Respondents were asked to rank their four most important values.

(3) Self esteem. Several authors have argued that possessions provide a basis for self-identity (Belk 1989; James 1890) or that acquisitiveness is an effort to establish self-respect (Horney 1937). If this is the case, possessions might be more valuable

to those who have less self-respect or whose self-image is less secure. Thus, a negative relationship between materialism and self-esteem is hypothesized. Rosenberg's (1965) self-esteem measure was used in the UMass survey.

(4) Self-monitoring. This scale, developed by Snyder (1974), is designed to measure the extent to which people adjust their expressive behavior and self-presentation to different situations. While the precise latent construct measured by the self-monitoring scale is not agreed on (see Snyder and Gangestad 1986), it seems clear that high self-monitors are more concerned about self-presentation than low self-monitors. To the extent that one's possessions publicly represent the self, a positive relationship between self-monitoring and materialism is expected.

(5) Public self-consciousness. Public self-consciousness is the tendency to think about those self-aspects that are matters of public display; for example, one's overt behavior, mannerisms, and expressive qualities (Scheier and Carver 1985). Since many of one's possessions are displayed publicly, a positive relationship between public self-consciousness and materialism is expected. This scale was included in the UMass questionnaire.

RESULTS

Rather than describe in detail the analyses and results of each data collection, this section summarizes what's been learned over the course of scale development efforts.

Factor Structure

Principal components analysis of the materialism items in all data collections yielded large numbers of factors with eigenvalues greater than one. Item purification improved the parsimony of the item set, such that the analysis of the last data set was refined to 29 items with an associated set of 6 factors with eigenvalues greater than one. We have chosen to postpone further item purification until data are obtained from large consumer samples.

Scree tests on the various data sets suggested that three, four, or five factors be retained. In the first data collection effort, one of the factors had 10 items with high loadings. On further inspection, these items were all truisms, including such statements as "The desire for more things or money causes a lot of problems in our society" and "People place too much emphasis on material things." While the reliability of these items was acceptable (Cronbach's $\alpha = .76$), they had weak relationships with validating variables. The truistic statements appear to measure respondents' attitudes about materialism and society in general rather than personal values that apply to respondents themselves. Because of the general nature of these items and their low relationship with validation variables, truistic items were excluded from subsequent data collection efforts.

Four factors emerged consistently from analysis of the three data sets, interpreted as follows.

(1) Possessions as symbols of success. This factor reflects the extent to which one uses possessions to impress others or perceives possessions as indicators of success and achievement in life. This factor coincides with the motivational aspects of material values identified in the literature review. Sample items with high loadings on this factor are "The things I own say a lot about how well I'm doing in life," and "I like to own things that impress people."

(2) Possessions as a source of pleasure. This factor reflects the extent to which one derives pleasure or satisfaction from the possessions they own and corresponds with the affective component of materialism. The factor had few items with high loadings in the initial data collection, but revisions to the item set improved it considerably. Sample items with high loadings on this factor include "I have some special possessions that I care quite a lot about" and "The things I own help make me happy."

(3) Belief that more possessions lead to more happiness. Respondents scoring high on this factor believe that their lives would be better if they had more or different possessions. This factor concerns the aspirational element of materialism. Some of the items with high loadings on this factor are "My life would be better if owned certain things I don't have" and "I have all the things I really need to enjoy life" (reverse scored).

(4) Asceticism. The opposite of materialism is asceticism. The ascetic ideal involves a hostility toward luxury, a suspicion of riches, and the belief that frugality is good (Shi 1985). This factor initially consisted of items all scored in the same direction. In subsequent data collections, items scored in the reverse direction were added but were only partially successful in balancing the scale. The asceticism factor might as aptly be named anti-materialism. Items include "I try to keep my life simple, as far as possessions are concerned" and "I like a lot of luxury in my life" (reverse scored).

Because the analyses were exploratory, in early factor analyses we preferred to err on the side of over-factoring rather than under-factoring the data and retained more than four factors for rotation. Several of the later factors were coherent and interpretable, including propensity to splurge, enjoyment of shopping, and others. While these are interesting in their own right, they measure what might be outputs or consequences of materialism rather than materialism itself. Attempts were made to eliminate such factors in later data collections.

Part of the domain of materialism identified in the literature review was centrality of possessions to one's life. Items such as "I spend a lot of time thinking about the things I own" and "The things I own are an important part of my life" were included with the hope that they would form an identifiable factor. They did not. Over three data collection efforts, we were unable to generate a factor representing this domain. The centrality items

TABLE 1
Relationships with Validation Variables

Validation Variable	Factor Subscales			
	1	2	3	4
Life Satisfaction				
Overall Satisfaction			-	
With Standard of Living	-		--	
Values				
Self-Respect	-		-	
Financial security	++	+	+	
Money to buy nice things	+	+	++	-
Self esteem	--		-	
Self-monitoring				
Factor 1--social deception	+++		+	
Factor 2--social presence				-
Public self-consciousness	+++	+	++	-
+/-	Correlations generally between .20 and .29			
+ +/--	Correlations generally between .30 and .39			
+ + +/--	Correlations generally .40 or greater			

spread themselves across the factor space or had low communalities. The reason for this failure may lie with the notion of centrality. Possessions may be important for a number of reasons: they may bring pleasure (musical instruments), they may signify important events or relationships (a wedding ring), they may demonstrate the kind of person one is (Birkenstock sandals), or they might cause others to notice, admire, or envy the owner (fashion clothing or sports cars). This diversity in reasons for importance may have caused the centrality items to spread across factors rather than form one of their own.

Reliability

While a final version of the scale was not generated from the student data, preliminary subscales to measure the various domains of materialism have been formed. They vary in precise content and length across the evolution of the project, so only general statements of reliability will be made. Factor 1, possessions as symbols of success, consistently had the highest reliabilities. In the various forms, the scale performs in the range of .80 to .85 for coefficient alpha. Factor 2, possessions as a source of pleasure, started out with few items and low reliability. At the final data collection, this subscale consisted of 7 items with a reliability of .76. The subscale for the third factor, belief that more possessions lead to more happiness, generally has reliabilities between .75 and .80. The asceticism subscale has been the most difficult to construct, with reliabilities in the .59 to

.67 range. This scale needs further refinement using adult consumer samples.

Social Desirability Tests

While social desirability doesn't seem to be a serious problem with any of the subscales, there were small but significant correlations between the social desirability scale and two subscales-- asceticism ($r \approx .20$) and possessions as indicators of status ($r \approx -.25$).

Construct Validity

Results of some of the validity tests are shown in Table 1. The reported analyses are based on summed subscales that represent the factors. Analysis using factor scores produced similar results. The validity tests suggest that the materialism scales perform in the predicted manner among college students.

DISCUSSION

Analysis of the literature concerning materialism suggests that this construct is best measured as a value. Toward this end, we have embarked on a program to measure some of the relevant aspects of material values. Empirical studies conducted on student samples suggest that at least three aspects of material values can be measured reliably and with some validity: possessions valued as symbols of success, possessions as a source of pleasure, and beliefs that more possessions lead to happiness. The validity of the fourth factor emerging from data analysis

(asceticism) remains to be demonstrated. At this time, it is unclear whether this factor should be treated as a separate subscale or merely represents very low materialism across the three other subscales. Internal consistency of the asceticism items is also lower than desired.

A research program to refine the material values measures is underway. It includes collecting data from consumer samples in three separate cities of the U.S. The goals of this program are three-fold: to determine the final set of scale items, to measure the reliability of scale items in a consumer sample, and to examine the nomological network of material values by studying their relationship with other personal values, psychological constructs, and Belk's trait measures.

This research has identified some of the ways in which possessions are linked to personal values, but the possibilities extend beyond the domain identified here. The empirical study of values in consumer behavior has not been especially fruitful in the past. While values are prominently discussed in consumer behavior texts, the 1984 ten-year index for JCR doesn't even include a heading for values; the 1989 five-year index has a heading but only one article is listed. The limited empirical attention to values stems in part from measurement problems. The current measurement approaches generally involve ranking of rather abstract constructs. While these are useful in identifying the relative importance a consumer assigns to a set of values, it is difficult to use the measures for other purposes. In addition, the ordinal, ipsative nature of the resultant data is not amenable to many data analysis techniques. By providing a values measure of a more limited domain but greater depth, we hope to encourage a new approach to the study of consumption-related values.

German and Canadian Data on Motivations for Ownership: Was Pythagoras Right?

Floyd W. Rudmin, Queen's University¹

ABSTRACT

To test the Pythagorean hypothesis that women are more sharing than men, gender differences in materialism were sought in re-analyses of 1969 West German university student data and 1986 Canadian adult data. The West German data, taken from the *Multinational Student Survey*, included two questions on attitudes towards the institution of private property and six scales from Gordon's *Survey of Interpersonal Values*. Women were found to be more sharing than men, and female gender was distinguished by more favorable attitudes towards private property and by preferences for benevolence over dominance and for independence over benevolence. The Canadian data were from two samples of adults, one school teachers, the other general public. They completed Belk's scales of materialism and 10 scales from Jackson's *Personality Research Form*. In both samples, women were more generous, more nurturant, and less dominating than men. These findings are discussed in the context of a feminist materialism.

INTRODUCTION

Pythagoras was born in the sixth century B.C. on the Island of Samos in the Aegean Sea. There he studied with Thales and Anaximander, and then went to Egypt and later Babylon for further studies (Vogel, 1966). In addition to mathematics and science, Pythagoras studied Orphic mysticism. This religious philosophy, akin to modern Hinduism, emphasized that all life is a unity, sharing a common divine spirit which is isolated, trapped, and confused in the material world (Cornford, 1912). The goal of life is to rise through successive transmigrations of the soul and to transcend the irrational material world.

At the age of 40, Pythagoras began teaching in Croton, on the southeast coast of Italy. In accord with Orphism, he emphasized social harmony and the equality of all, including women, children, slaves, and animals. His school was communal since private property was seen to foster materialism. Pythagoras also gave public lectures, fragments of which are known through secondary sources (Vogel, 1966). His fourth lecture, addressed

to women, argued that women are more just, social, and sharing than men. Pythagoras said of women:

"They must not destroy the reputation they had acquired through tradition and not put the writers of myths in the wrong; on the grounds of their recognition of the justice of women, because they give away clothes and adornments without witnesses when others have need of them, without this trustfulness resulting in lawsuits or quarrels, these poets created the myth that three women had but one eye between them because there was such concord among them. If one was to apply this to men and say that one who had first obtained something could easily part with it and even willingly added something of his own, nobody would believe it. For it is not in the nature of men." (Pythagoras, in Vogel, 1966, pp. 132-133)

As suggested in this passage, that women are more sharing than men may be only a myth, or it may be an enculturated characteristic, or it may be an inherent gender difference in the psychology of property.

Although this might have been "a remarkable psychological insight", as Vogel (1966, p.133) argues, it received relatively little subsequent attention. Pythagorean philosophy strongly influenced Greek, Roman, and Western thought generally, but the question of gender differences in materialism was raised infrequently, if at all, for more than two millennia. It was not until the development of modern psychology that there began to appear incidental reports of gender differences in the materialism of young children. William James (1890) started this when he argued that the Self is created by the act of possession and materialized by the instinct for acquisition, evidence for which should be sought in the natural, unsocialized behaviors of young children.

For example, in children's collecting behaviors, Kline and France (1898) found that more girls than boys collect things. Wiltse and Hall (1891), Burk (1900), Whitley (1929) and Witty and Lehman (1931; 1933) all found that girls' collections reflected social attachments and personal achievements, while boys' collections had a more competitive quality, reflective of games, conquests, and trading. McElwain (1937) found that girls were more individualistic in their choices of possessions. In children's development of personal pronouns and possessive behavior, Cooley (1902) reported that his daughter was more advanced than had been her older brother, but attributed that to birth order rather than to gender. In a study of preschool children, Dawe (1934) found that boys quarreled more than

¹Appreciation is expressed to Dr. David Finlay for granting permission to use MSS data and to the University of British Columbia Data Library for making it available. girls and that most quarrels, particularly for boys, were about possessions.

In the past five decades, the psychology of material relations has developed extensively. However, this is not commonly recognized because the research is dispersed among isolated sub-fields and disciplines. [See bibliographies by Rudmin (1986) and Rudmin, Belk and Furby, 1987.] Gender differences in the psychology of property, ownership, and possession have yet to be the focus of much attention, despite the importance of this topic to the moral, political, and economic concerns of the feminist movement. The purpose of the present report is to explore two existing data bases for gender differences in materialism, with the hope that such re-analyses might contribute to the development of a feminist theory of materialism. The perspectives and values of both genders need representation if a coherent and useful understanding of the psychology of property is ever to be developed.

STUDY I: GERMAN DATA

The first study examined gender differences in attitudes towards the institution of private property for a sample of West German university students. The data come from the *Multinational Student Survey (MSS)*. This was a collaborative questionnaire survey of sociopolitical knowledge, attitudes, and values in 17 nations (Iversen, 1969). The target population was male university students, aged 22 to 24. However, the German researchers fortuitously collected responses from both sexes, and hence their data are suitable for an exploration of gender differences.

The respondents were 65 German students from two different universities. However, only 43 had complete data on the variables of interest here. The mean age was 23, with a range of 20 to 28. The sample was almost evenly divided between the sexes, 22 women and 21 men. Although this is admittedly a small sample, it does have the conservative virtue of making statistical significance less likely to occur. The original research questionnaire, translated into German, consisted of 190 multiple-choice questions, 14 demographic questions, and 5 open-ended interview questions. Of these, the present study examined two questions on attitudes towards the institution of private property and the 90-item *Survey of Interpersonal Values (SIV)* (Gordon, 1976).

The two property questions were separated among 47 other questions on sociopolitical values:

"The institution of private property is a sound basis on which to build a society which fulfills the needs of its members."

"The acquisition of private property is based, in the final analysis, too much on force, fraud, and violence."

Scoring was on a 7-point scale, from strongly agree (value 1) to strongly disagree (value 7). To allow

both questions to represent measures of preference for private property, the first question was reversed by subtracting its score from 8.

The SIV measures interpersonal values of Support, Conformity, Recognition, Independence, Benevolence, and Leadership. It has 30 triads and uses a forced-choice preference paradigm in which respondents must choose one of the statements in each triad as most important to themselves and one as least important. Such scales are ipsative (i.e. negatively intercorrelated) because accumulating points in one scale necessarily limits accumulation in other scales. On the positive side, the forced-choice design tends to reduce acquiescence and social desirability contamination (Mueller, 1985). Also, the SIV is considered robust for cross-cultural use (Hofstede, 1976).

On the negative side, ipsativeness confounds multivariate analyses. Therefore, an alternative scoring procedure was devised to minimize negative intercorrelations (Rudmin, 1988a). Usually, the SIV is scored by counting the number of times each scale is preferred over the other scales. In any triad, the scale item chosen as most important is scored 2 because it was preferred over the other 2 items. The scale item chosen least important is scored 0 because it was not preferred over any other scale. The undesignated item in the triad is scored 1 because it was preferred to the least important item. Because SIV scores represent preference decisions, an alternative scoring procedure is to tabulate preferences specifically for the paired options. For six scales, there are 15 preference pairs (e.g. Independence preferred to Support, Independence preferred to Benevolence, Independence preferred to Conformity, etc.), which if labelled with the SIV scale initials are: IS, IB, IC, IL, IR, SB, SC, SL, SR, BC, BL, BR, CL, CR, and LR. A preference score is incremented by one each time the first scale is preferred over the second. The total scores for each of the 15 scale pairs are divided by the number of times the preference pair is offered on the SIV. This ranges from 2 for SR to 9 for IR. The labelling of preference pairs can be reversed by using complementary scores (e.g. LC = 1 - CL). Whereas the six SIV scales have a mean intercorrelation of $r = -.20$ for random data (Hofstede, 1976), the 15 preference pair scores have a mean absolute intercorrelation of only $r = .05$ (Rudmin, 1988a).

Cronbach alpha coefficients of reliability for the SIV were: Independence .65, Support .80, Benevolence, .84, Conformity, .78, Leadership, .82, and Recognition .31. Thus, with the exception of Recognition, which was dropped from the analysis, the SIV scales represent coherent constructs, even when translated into German and administered to a small sample. Finally, because the two property questions were significantly correlated ($n=43$, $r=.38$, $p<.01$), they were summed as a two-item scale of preference for the institution of private property.

An examination of the data for gender differences found that women valued Leadership less than did men ($n=43$, $t=-2.55$, $p=.01$; $r=-.37$, $p<.01$),

and in particular, women preferred Benevolence to Leadership more than did men ($n=43$, $t=2.33$, $p<.05$; $r=.34$, $p=.01$). One of the Benevolence items directly asked whether or not it is important "to share my belongings with others", and women chose this item more frequently than did men ($n=43$, $t=2.11$, $p<.05$; $r=.31$, $p<.05$). These gender differences remained statistically significant even after partialling out any age effects.

Multiple regression showed that female gender correlated ($R=.52$, $p<.01$) with preference for Benevolence over Leadership ($\beta=.50$), with preference for private property ($\beta=.33$), and with preference for Independence over Benevolence ($\beta=.18$). As a discriminant function, these three measures alone correctly distinguished 77% of the females and 67% of the males.

These data and analyses do support the Pythagorean hypothesis. Sharing was more typical of women than of men. The reason for this appears to relate to the fact that the women more strongly preferred Benevolence to Leadership as an interpersonal value. Whereas the Benevolence scale of the SIV was defined as "doing things for other people; sharing with others; helping the unfortunate; being generous" (Gordon, 1976, p.1), the Leadership scale emphasized interpersonal dominance, "being in charge of other people; having authority over others; being in a position of leadership or power" (Gordon, 1976, p.1). Thus, in rejecting Leadership and choosing Benevolence, women prefer the care of people to the control of them.

However, it is most important to emphasize the implications of the multivariate analysis. As characteristics which reliably distinguish women from men, preferring caring to control goes along with positive attitudes towards private property and with preferring autonomy to caring. To state it most forcefully and thus set forth an hypothesis for challenge, discussion and research, it would seem that women have higher regard for the institution of private property, not for the dominance opportunities it allows, but for the benevolence and, to a lesser degree, independence opportunities.

It may seem that such interpretations are too broad for so small and so unique a sample, and for so post-hoc an analysis. However, a study of MSS data for only male university students in 15 societies found a preference for dominance to be the strongest and most replicated correlate of favoring private property (Rudmin, 1988b). Much more remote and therefore stronger support comes from the literature on gender differences in wishes. Wilson's 1939 study of U.S. university students, Wheeler's 1963 study of Australian adolescents, and Winkley's 1982 study of British school children all found that females wish less for having power and money, indicating rejection of dominance, and wish more for philanthropic activities, pets, and benefits for relatives, and for opportunities, accomplishments, and scholastic achievement, indicating preferences for benevolence and independence. That females have more of a

preference for private property gains some support from the finding by Dixon and Street (1975) that girls have a greater frequency of identifying possessions as part of themselves, and by Kline and France's (1898) and Furby's (1976) findings that, when asked, girls mention more possessions than do boys.

STUDY II: CANADIAN DATA

Further support for the Pythagorean hypothesis was sought in post-hoc analyses for gender differences in two samples of Canadian adults who had completed a questionnaire on materialism (Rudmin, 1988c;d). The first sample consisted of 102 public school teachers attending university summer session. The mean age was 34, with a range of 24 to 55; 64 were women and 38 were men. The second sample consisted of 38 men and 35 women recruited in a car ferry queue. Their mean age was 41, with a range of 21 to 76. In both samples, respondents had been eliminated if they were younger than 21 or if they had incomplete data on the variables of interest.

Both samples completed Belk's (1984; 1985) scales of materialism and 10 scales from Jackson's (1984) *Personality Research Form* (PRF). The scales of materialism consisted of Possessiveness (9 items), Nongenerosity (7 items), Envy (8 items), and a combined measure of Materialism (24 items). These were rated on a 5-point Likert scale from strongly disagree (value 1) to strongly agree (value 5). The 10 PRF scales were Abasement, Affiliation, Autonomy, Change, Defence, Dominance, Nurturance, Order, Social Recognition, and Desirability. Each of these consists of 16 true-false items.

Cronbach alpha coefficients of reliability for the materialism scales for the teachers and ferry passengers respectively were Possessiveness .26, .37; Nongenerosity .68, .54; Envy .51, .09; and the combined Materialism scale .57, .48. Alpha coefficients for the 10 PRF scales for the two samples were Abasement .39, .51; Affiliation .80, .78; Autonomy .75, .61; Change .56, .61; Defence .72, .72; Dominance .79, .84; Nurturance .61, .64; Order .89, .89; Social Recognition .69, .64; and Desirability .51, .53. Thus, with the exceptions of the Possessiveness, Envy, and Abasement scales, which were deleted from further analyses, the measures used were coherent for the two special samples under study. In both samples, Possessiveness items 8 and 9, and Envy item 2 had negative item-total correlations, suggesting that these three items should be carefully examined in future revisions of the materialism scales.

To be conservative, only those findings are reported which were statistically significant in both samples. Data on the semantic similarity of 24 verbs to the verb "own" were collected in this study (Rudmin, 1988d), but are not reported here because the analysis is too complex and the results too weak. However, the search for gender differences in the materialism and personality scales found that

females expressed less Nongenerosity in the teacher sample ($n=102$, $t=-1.98$, $p=.05$; $r=-.19$, $p<.05$) and in the ferry sample ($n=73$, $t=-3.13$, $p<.01$; $r=-.35$, $p<.01$). Females showed less Dominance in the teacher sample ($n=102$, $t=-2.81$, $p<.01$; $r=-.27$, $p<.01$) and in the ferry sample ($n=73$, $t=-3.71$, $p<.01$; $r=-.40$, $p<.01$). Females showed more Nurturance in the teacher sample ($n=102$, $t=2.97$, $p<.01$; $r=.29$, $p<.01$) and in the ferry sample ($n=73$, $t=4.66$, $p<.01$; $r=.48$, $p<.01$). Partialling out age and social desirability effects did not reduce any of these gender differences.

Multiple regression showed that female gender correlated in the teacher and ferry samples ($R=.40$, $p<.01$; $R=.60$, $p<.01$) with Nurturance ($\beta=.19$; $.39$), with Dominance ($\beta=-.29$; $-.32$), and with Nongenerosity ($\beta=-.16$; $-.14$). As a discriminant function, these three measures alone correctly distinguished the gender of 69% of the females and 68% of the males in the teacher sample, and 84% of the females and 77% of the males in the ferry sample. Autonomy was not a significant correlate of either Nongenerosity or gender.

Thus, the Pythagorean hypothesis was again supported. The women in these two samples did report themselves as more sharing than did the men. And again, it appears that this is due to the tendency for women to prefer caring to controlling. However, the weak finding in the MSS study that Independence (here Autonomy) contributed to gender differences in materialism was not replicated.

It should be noted that Belk (1984) did not find a gender difference on the Nongenerosity scale. However, other studies have reported that females are more sharing than males. For example, in a study of preschoolers in the U.S., Eisenberg, Bartlett and Haake (1983) found that girls were more likely than boys to share spontaneously and in response to requests. In another study of preschoolers, Eisenberg and Giallanza (1984) found that low dominance girls did an unusually high amount of sharing compared to other children. In a study of French preschoolers, Werebe and Baudonniere (1988) found that girls more frequently offered to share objects among themselves than did boys among themselves. In a review of the psychological literature on altruism, Krebs (1970) concluded that "adult males were found to act less altruistically toward highly (versus lowly) dependent others, especially if they seemed threatening. Altruistic females acted more altruistically toward highly dependent others" (p.298). These reports do support the Pythagorean hypothesis.

DISCUSSION

It is common to describe the institution of private property as a manifestation of dominance and an instrument of power (Schlatter, 1951). This has been well expressed by prominent men in the history of psychology:

"The idea of power is, partly at least, the foundation of our attachment to property" (Dugald Stewart, 1829, p.410).

"My power is *my* property. My power gives me property. I myself *am* my power and through it own my property" (Max Stirner, 1971, p.80).

"The feeling of possession and the exercise of power, without immediate reference to other ends, is a first-rank pleasure" (Alexander Bain, 1880, p.145).

"In abolishing private property we deprive the human love of aggression of one of its instruments" (Sigmund Freud, 1930, p.50).

"Status symbols, therefore, express a very general aspect of their owners -their power to control others" (Csikszentmihalyi and Rochberg-Halton, 1981, p.31).

That dominance is an aspect of possession and ownership, and that dominance is much more characteristic of one gender than the other, suggest that there might be other perspectives of material relationships that are being overlooked (Rudmin, 1988c). Pythagoras pointed to the easy sharing of possessions by women as an alternative to the socially divisive and defensive property ethos of men. From the evidence presented thus far, it seems that indeed women are more sharing than men, are less dominating, and yet are still favorable towards private property and possessions.

Following the lead of Gilligan (1982), it might be speculated that women's attitudes towards property and material relations are more socially contextual than men's. Whereas the social aspect of property for men is power, for women it is specific relationships. For men, property as power is socially divisive and abstract, as George Mead argued:

"Abstractness is given to the social relation involved in property through associating it with hostility. Previously property was a concrete social relation. The abstract property relation came into marriage and slavery through bringing in the outsider, one who had no rights in the group, no personality that gave him or her a place in the group . . . Abstractness always carries with it a degree of hostility. The attitude of the possession of money is an attitude of hostility toward all the rest of mankind. Money is for anyone who cares to seize and hold it. Its very abstractness puts the possessor in the attitude of defense . . . The abstractness of the relation of property always carries with it hostility just in proportion to the abstractness" (Mead, 1982, pp.87-88).

Gender differences in the possession of money are important for the proposal that female materialism is contextual. As the wish literature has

shown, for men, money is power and it is desired as such. Women do not seem to value money or seek it in the same way. Dittmar (1989) examined gender identity-related meanings of personal possessions and found that women identify with financial assets significantly less than do men. In a pilot study on Cree concepts of ownership (Rudmin, 1988c), a woman was asked about which of the things that she owns she feels least ownership; she answered, "Money". Indeed, money is property in the abstract, impersonal, decontextualized, unreal, except for its power which is most appealing to male possessiveness. Sartre (1956) aptly describes this:

"Money represents my strength; it is less a possession in itself than an instrument for possessing . . . it is evanescent, it is made to unveil the object, the concrete thing; money has only a transitive being. But to me it appears as a creative force: to buy an object is a symbolic act which amounts to creating the object. That is why money is synonymous with power" (Sartre, 1956, pp.143-144).

Rather than money and other possessions of prowess, women value and identify with property that is connected to personal and specific social relationships and events. (Csikszentmihalyi and Rochberg-Halton, 1981; Dittmar 1989). And the use of possessions for altruistic purposes, is not an abstract moral ideal but socially situated. For example, Birch and Billman (1986) found that preschool girls share food differentially, favoring friends over acquaintances, whereas boys' sharing behavior was not influenced by their personal relationships. Boys tend to share after they feel competent and in control (Staub and Noerenberg, 1981). However, Furby (1978) has argued that sharing can be an alternative means of social competence and control. Furthermore, as Dewey (1976) has argued, true altruism must be ad hoc and inadvertent, that is contextual and situated, that is, the altruism for which Pythagoras praised women:

"There is an altruistic paradox as well as a hedonistic one. The hedonistic paradox is that a man cannot secure happiness as the end unless he forgets it. He must forget it and devote himself to the thing in hand in order to be really happy. So here on the altruistic side, before he can really do good to others, he must stop thinking about the welfare of others; he must see what the situation really calls for and go ahead with that" (Dewey, 1976, p.214).

As Gilligan and Attanucci (1988) have argued, if there are gender differences in social psychological phenomena, then it is important to explore and elaborate those differences in order to truly understand the phenomena and their implications. This paper has shown that there are

gender differences in the psychology of material relations. They are not mythical. On that Pythagoras was right. Whether they are enculturated or inherent is a question that may be difficult, if not impossible, to answer.

Isolating the Effect of Non-Economic Factors on the Development of a Consumer Culture: A Comparison of Materialism in the Netherlands and the United States

Scott Dawson, Portland State University
Gary Bamossy, Vrije Universiteit

INTRODUCTION

Differences in consumption culture are quite transparent when comparing the United States to countries with significantly different economic and/or cultural systems (cf., Belk and Bryce 1986; Wallendorf and Arnould 1988). However, cross-cultural comparisons between countries of similar economic development are necessary in order to tease out other macro societal characteristics which may influence the evolution of a consumption culture (Rassuli and Hollander 1986). As such, this study uses Belk's (1985) measures of materialism to compare the consumption cultures of the Netherlands and the United States. While these countries are relatively similar in terms of economic and physical characteristics, key differences in other macro variables, namely social, religious and political structures, are proposed to lead to higher levels of materialism in The Netherlands. A synopsis of the theoretical rationale, study procedures, and analysis are provided in this paper.

A wealth of literature may be consulted concerning the importance that individuals attach to worldly possessions (cf, Csikszentmihalyi and Rochberg-Halton 1978; Douglas and Isherwood 1979), and the conception of the Belk (1984;1985) materialism scales. Briefly, Belk conceived of materialism as a complex trait which reflects the centrality of possessions in an individual's life. The measure consists of the subtraits of possessiveness ("the inclination and tendency to retain control or ownership of one's possessions"), nongenerosity ("an unwillingness to give possessions to or share possessions with others"), and envy (displeasure and ill will at the superiority of another person's happiness, success, reputation, or possession of anything desirable). The following section provides a condensed discussion of those macro differences between the Netherlands and USA which may give rise to patterns of materialism.

MACRO COMPARISONS BETWEEN THE NETHERLANDS AND USA

Economic differences between Holland and the USA on any standard indicator are negligible when compared to the advancement of either country over OECD (first world) countries such as Spain or Turkey, NIC countries such as South Korea or Brazil, or any of the third world developing economies. Both countries appear on the United Nations' list of the Ten Most Wealthy Countries, have highly industrialized economic bases, and are important players in the international trading of goods and services. When measured by 1985 GNP, Americans do have a higher per capita income than the Dutch (\$16,685 vs. \$11,404). However, ownership of

consumer durables and luxury goods are far higher in each country when compared to consumers from less developed economies.

Physically, population density in the Netherlands is significantly greater than in the USA. One theoretical perspective suggests that such population density should promote emulation and imitation of upper classes by lower classes (McKendrick, Brewer, and Plumb 1982), thereby heightening the importance of the status symbolizations associated with consumer goods. However, because the data for this study were collected in urban environments of similar population densities in both countries, this thesis is not thought to be relevant here.

The rationale for proposing that materialism will be higher in the Netherlands than in the USA is found in the political, religious and social structure of the Netherlands. Perhaps more than any other Western country, these three arenas of Dutch culture have traditionally been tightly interwoven. Until recently, Calvinist and Catholic religions permeated the political and social institutions of Dutch society. Beyond having separate political parties, these religions had their own mass media, schools, labor unions, and voluntary organizations (van Schendelen 1987). Prior to the 1970s, marriage and housing across church membership was highly unusual (Gadourek 1982). The symbolic value of material goods is heightened in such a society in order to mark these important statuses.

Calvinism itself has a complex, historical relationship with aspects of consumption culture. A modern day interpretation of Calvinism is of "individualistic business activity, sanctioned by the view that worldly prosperity is evidence of the favor of God" (McNeill 1954, p. 437). Weber (1958) argued that the Calvinist virtues of thrifty industry, honesty, and hard work would sanction the accumulation of wealth, which would serve as a sign to God and society of success in achieving God's mandates. An early but heavy Calvinistic influence may be partly responsible for the observation that the Dutch appeared to lead the world in conspicuous consumption during the 17th century (see Schama 1987).

Dutch class structure also suggests that materialism will be higher in Holland. A number of studies indicate that class consciousness and deference in the Netherlands is significantly higher than in any of nine other countries, including the USA (see Bagley 1973). Gadourek (1982) notes the multifaceted bases of deference in Dutch culture, which further suggests a rigid social structure. This rigidity is evidenced by a mobility ratio in the mid-1950s that was just half that of the USA (Tyree, Semyonov, and Hodge 1979). To sum, the more

TABLE

Life Satisfaction(a)	11.64	7.06	.02

a. Difference significant at $p < .001$.

b. Difference significant at $p < .01$, all others nonsignificant.

rigid social structure, the historical influence of Calvinism, and the prevalence of class consciousness in the Netherlands are hypothesized to increase the saliency of ownership of material goods, which should be reflected in greater levels of materialism than in the USA.

METHOD

Two Dutch nationals administered surveys to 80 households selected at random within Amsterdam and The Hague. This sample is mostly middle to lower income, high school to college educated, and evenly represented according to gender. The American data were collected in the metropolitan area of Portland, Oregon using gender and age quotas. A drop-off technique was used to place the surveys. A total of 127 questionnaires were completed. The sample profile in terms of medians was 35 to 44 years of age, \$30,000 to \$39,999 in yearly household income, and 12 to 16 years of education. Demographic comparisons of the two samples suggests that the American sample may be somewhat more upscale than the Dutch sample. Steps were taken in the ensuing data analysis to account for this difference.

Items described by Belk (1985) were used to measure envy (6 items), nongenerosity (8 items), and possessiveness (8 items). Because of its association with materialism, life satisfaction was also measured (9-point Likert scale; Very Satisfied/Very Dissatisfied) using eleven items which reflected domains such as career, community, and savings. The U.S. version of the questionnaire was back translated by two Dutch nationals and pre-tested. Tests for homogeneity of variance verified sample comparability (Bartlett's F values all nonsignificant at $p > .10$).

Both Dutch and American envy scales achieved adequate internal consistency (alphas of .81 and .76, respectively). Perhaps due to the lack of direct translation of the word "share," the Dutch

nongenerosity scale was lower in reliability (.46) than was the American scale (.63). Reliability of the Dutch possessiveness scale (.68) was higher than for the American sample (.53). Reliability of the summary Materialism scale is also somewhat low (.61 and .62 for Dutch and American). These reliabilities suggest that the results be approached cautiously. The life satisfaction measure achieved excellent reliability in the case of both Dutch (.84) and American (.80) samples.

RESULTS

Analysis of variance was performed on the three subscales and summary materialism scale in order to test for between country differences. The most significant difference in measures of materialism occurs for possessiveness (see Table) in which the Dutch sample has a higher mean than the American group ($F=5.90$, $p < .01$). However, members of the two cultures do not differ significantly in mean levels of envy, nongenerosity, or overall materialism, indicating a general lack of support for the proposed differences. Given the disparate direction of group differences in possessiveness and envy, the lack of significance of the summary materialism scale is not surprising. These differences in scale means perhaps challenge the unidimensionality of the summary materialism scale when conducting cross-cultural studies. The means for life satisfaction show that the Dutch are significantly more satisfied than are the Americans ($F=25.03$, $p < .001$).

Additional analyses were performed in order to determine if income, education, or age might be masking underlying cultural differences in materialism. No significant effects emerged involving education, while age did yield one significant relationship. As found elsewhere (Belk 1985), envy drops significantly with increasing age ($F=6.93$, $p < .001$), which may reflect success in acquiring material culture and improving quality of

life over the life span. The most interesting results involve the relationship between income and envy across the two countries. Because of the small sample of upper income respondents from the Netherlands, between country comparisons are possible only for low and middle income groups. Nevertheless, the data yield significant country (F=4.24, p<.05), income (F=6.85, p<.01), and interaction effects (F=5.96, p<.02). While lower income Americans have higher levels of envy than middle income Americans, the trend among the Dutch indicates higher levels of envy among the middle income group than the lower income group. These disparate trends can perhaps best be attributed to the greater relative level of social welfare spending in the Netherlands than in the U.S. About one-third of Dutch national income is spent on social welfare, and as far back as 1960 nearly 50% of new dwellings were built by the government (Bagley 1973). For individuals with lower incomes, such spending may improve the quality of life and lessen relative deficits in material culture. When compared to their Dutch counterparts, individuals with lower incomes in the USA may perceive greater differences in ownership of material items between themselves and others with higher levels of income.

Correlations between materialism and life satisfaction in the two cultures show that envy is the only materialism subtrait strongly and negatively related to life satisfaction. In accordance with theory, when individuals perceive a lack of ownership of material items when compared to others, the result is feelings of envy which are negatively related to evaluations of life satisfaction. Though the correlation for the Dutch sample is higher than for the American sample (-.42 versus -.31), the difference is not statistically significant.

CONCLUSIONS

Based on measures of trait materialism, the results suggest that America shares an exuberancy of consumption culture with at least one other country in the Western world. The differences in social structures between the two countries may not be great enough to produce dramatic differences in materialistic values, or such values may not be strongly affected by these social structure characteristics. The results confirm Inglehart's (1981) thesis that Western cultures share relatively similar materialistic values.

Only in the case of possessiveness did significant differences occur between the Netherlands and USA, and here the means indicate greater possessiveness among the Dutch. Americans may be less possessive since they live in a culture in which lost possessions can often be replaced with new ones which are perceived as equally if not more satisfying. McCracken (1988) has suggested that patina, or the status inferred from material items which have passed through generations, has lost the value it once had in American culture. Status in America appears easily encoded through purchase and ownership of new material goods. In contrast, individuals in the Netherlands seem less likely to

either sell or buy items in second hand markets. The phenomenon of a "garage sale" is totally absent from Dutch culture and second hand markets such as swap meets or flea markets are rare at best. Thus, while "new" more easily replaces "old" in the USA, possession seems to have a stronger, more durable meaning to the Dutch. Although possessiveness appears lower in the USA than in the Netherlands, this finding may not necessarily imply that the U.S. has a less advanced consumption culture. In fact, one could argue that the velocity of consumption is greater in the USA than in the Netherlands, and that in a world of topped-off land fills, "possessiveness" may not deserve the negative connotation often associated with "materialism".

Measuring and Comparing Materialism Cross-Culturally

Guliz Ger, Bilkent University

Russell W. Belk, University of Utah

The materialism scales developed by Belk (1985) are modified to increase appropriateness to cultures other than the US. The scales are tested by the data gathered in the United States, Turkey and France. The problems of developing and testing cross-culturally applicable scales are discussed and preliminary results of these tests and cross-cultural comparisons are presented. The Turkish sample is found to be the most materialistic, yet also the most generous. The results are discussed in terms of relative affluence levels and cultural factors.

Materialism has been defined as "the importance a consumer attaches to worldly possessions. At the highest levels of materialism, such possessions assume a central place in a person's life and are believed to provide the greatest sources of satisfaction and dissatisfaction" (Belk 1985). Materialism, or consumption-based orientation to happiness seeking, has generally been seen as a Western trait which achieved an elevated place in industrial and post-industrial life. However, consumption for the sake of pleasure existed in many different cultures and throughout the history (Belk 1988). "While high level consumer culture has existed in isolated pockets since ancient civilizations, it has become available and embraced by entire populations only over the past century" (Belk 1988, see Mason 1981).

A scale measuring materialism has been developed by Belk (1985) and three dimensions have been identified: possessiveness, envy and nongenerosity. Possessiveness is "the inclination and tendency to retain control or ownership of one's possessions" (Belk 1985). This may concern goods, experience or people. Envy is the "displeasure and ill will at the superiority of [another person] in happiness, success, reputation or the possession of anything desirable" (Schoeck 1966, in Belk 1985). This may also concern other's goods, experiences or people. Nongenerosity is "an unwillingness to give possessions to or share possessions with others" (Belk 1985).

Research by Wallendorf and Arnould (1988) and Rudmin (1988) suggests that the materialism scales developed by Belk (1985) are more appropriate to the United States than to other cultures, especially those of the Third World. The present research sought to remedy this problem by testing modified versions of these scales. Some of the original items were modified and some additional items, developed for the purposes of crosscultural appropriateness, were included. Once the scale structure was established, levels of materialism in several countries were compared.

STUDY

Sample

A convenience sample of 405 respondents was taken from among the university students in Utah, USA, Fontainebleau, France and several cities in Turkey. In France, the questionnaire was administered at INSEAD, an international institution where the student body is mostly European, the majority being French, English and German. Use of students kept some individual difference variables such as age and educational differences constant.

Questionnaire

An English version of the questionnaire was administered in USA and France (students at INSEAD are fluent in English and most courses are conducted in English), and in Turkish in Turkey. Backtranslation procedure was employed in preparing the Turkish version. The first part of the questionnaire consisted of 34 five-point Likert scale items. These are aimed at measuring materialism. They included Belk's original items, some of which were modified as well as some new items. The second part consisted of open ended questions which are not analyzed in this paper. The last part of the questionnaire listed 20 products/services (or experiences like university education, vacation, retirement) and asked the respondents to indicate whether they think the items are luxuries or necessities. The number judged to be necessities was used for validation purposes.

RESULTS

Dimensions of materialism, reliability and validity

Four dimensions emerged from factor analyses with varimax rotations. While solutions were not identical across all samples, the solution chosen was the most robust and is consistent with a factor analysis of the entire data set. The items which load on the four factors are shown in Tables 1A, B, C and D. In addition to the three dimensions, namely, possessiveness, envy and nongenerosity, identified in USA previously (Belk 1985), a fourth, named tangibility also emerged. Tangibility can be defined to be the conversion of experience into material form. Taking pictures during a vacation, keeping souvenirs, and taking slides of places visited and showing them to friends are examples. The increasing tendency towards this phenomenon has been suggested by Sherry (1987). Cronbach's alpha is used to assess reliability. In the total sample, as well as within each of the three cultures, satisfactory levels of alphas were found (Table 2). Validity is evaluated using the correlations between the number of items seen as necessities and the materialism scores as well as the subscale scores. Although the

correlations are not very high, all are significant (Table 3).

It is clear that despite the attempt to construct a cross-culturally reliable materialism scale, the resulting scale is more reliable in the United States and Europe than in Turkey. Within Turkey, reliabilities were higher in the more cosmopolitan environment of Istanbul and lower elsewhere. These findings are consistent with the view that the present conception and measures of materialism derive more from highly developed countries in Europe and North America. But this finding does not necessarily negate the application of the scales elsewhere. A primary reason is the theory that materialistic consumer culture arose in this developed world but is being emulated in the Third World at an increasing rate (Belk 1988). The pattern of the West in first developing wealth and then a consumption ethic is being superceded, in this view, by a reversed pattern in the Third World. By virtue of mass media, tourism, and multinational marketing, consumer culture is beginning to create yearning for consumer goods even before households of the Third World have adequate nutrition. Further, limited calories are sometimes sacrificed in order to afford such consumer luxuries. If so, the spread of materialism is perhaps a quintessentially developed world concept that is best measured with scales derived primarily in the same developed context. This view is strengthened by the consistent patterns of materialism scores found, as discussed in the following section.

Cross-cultural comparisons

The Turkish sample is the most materialistic of all with respect to both the scores on the materialism scale (Table 4) and the mean number of items seen as necessities (Table 5), followed by USA and then Europe (INSEAD). Among the three INSEAD subsamples Germany is the least materialistic. The scores on the subscales indicate that the Turkish sample is the most possessive, envious and tangibilizing, but at the same time, the most generous. The USA maintains its second place on envy and, along with England and France, on tangibility. It is the most nongenerous and only is behind Europe (with the exception of France) on possessiveness. Among the Europeans, Germany is the lowest on materialism, tangibility, envy and nongenerosity (although on envy and nongenerosity the differences do not reach statistical significance).

CONCLUSION AND DISCUSSION

In cross-cultural research it appears crucial that questions are decided upon by joint efforts of researchers from the cultures involved. Subtle cultural factors play in and a rigorous translation procedure is not enough to guarantee cross-cultural standardization. It is very questionable whether such a complete standardization is possible at all. The Cronbach's alphas are not very high here. The reason may be that different items are more powerful or relevant in different cultures. To have a standard instrument and overall reliability and validity, the researchers may have to sacrifice high local reliability and validity. One way to develop better

*of 20 items

instruments would be to undertake exploratory research in every culture involved and use the overlapping items. However, not only will this procedure be very difficult and possible only with huge projects, but also some of the local power may still be lost in the attempt to keep the instrument common. If local reliability and validity are emphasized, comparability across cultures may well be lost.

The results are inconsistent with a view generally held that materialism is a Western phenomenon observed in developed countries. The sample from the only nonwestern and the least developed country was the most materialistic and also highest on all subscales with the exception of nongenerosity on which they were the most generous. Furthermore, the Turkish sample was the most materialistic and the least nongenerous at the same time, although for other samples patterns of materialism were consistent for all four factors.

While it may be surprising, even shocking, to find that the Turks sampled are more materialistic than Europeans and Americans, this result is prefigured by findings measuring the Protestant Work Ethic cross-culturally (e.g., Furnham and Muhiudeen 1984, Tallman, Marotz-Baden, and Pindas 1983). These studies find that the Protestant Ethic

is now strongest in Third World countries (regardless of dominant religion) and weakest in highly developed post-industrial nations. Various authors suggest that once wealth is achieved by devotion to the Protestant Ethic, the logical imperative to use excess wealth on consumption and leisure creates the seeds for destruction of the same ethic (e.g., Albee 1977, Campbell 1987, Davis 1944, Duncan 1962, Fox, Lears, and Jackson 1983, Horowitz 1980, King 1983). Scitovsky (1976) and Hirschman (1982) carry the argument a necessary step farther and suggest that high level materialism also contains the seeds of its own destruction because such consumption is ultimately unfulfilling. That materialism is highest in the developing world is a provocative finding deserving of further research.

Why would Turks be generous and willing to share and be materialistic at the same time? One reason may be that the more traditional societies may be more collectivistic or communal- give more importance to the society and societal purposes than the individual and his/her goals. Although generally developed societies are thought to be more individualistic (independent and autonomous members) and industrialization is seen to be linked to individualism, there are arguments that individualism versus collectivism (and

interdependence) are not dependent on industrialization, but are cultural orientations. Japan provides an example of an industrialized and collectivist society (Kagitcibasi 1988). If Turks are more collectivistic, they would be expected to share. There is some evidence that Turkish university students have values that are less individualistic than the western university students (Basaran 1989).

However, it has been suggested that individualism/independence and materialism are associated such that a more individualistic person would be more materialistic: to achieve economic independence the person wants to be rich and values material goods (Furham 1984). However, the country which is probably less individualistic or independence oriented turned out to be the most materialistic. One plausible explanation may be that Turks think of the autonomous unit to be wider, the family for example, and material goods are desired for the family; what are important are the wealth status and the possessions of the family rather than those of the individual. It has been suggested that especially female Turks may think along these lines (personal communication with Ayse Oncu). So, maybe materialism does not have to be individual oriented. If materialism is linked to enhancing the material well-being of, and consumption for a unit, that unit may be a single individual in some cultures, several individuals (close friends and family members) in other cultures. Then, in cultures where the unit includes more than one person, high levels of materialism can co-occur with generosity, even if materialism is influenced by the desire for economic independence.

Why would the least affluent society in the sample be the most materialistic? Materialism has been associated with economic affluence and Western culture. The rising materialism observed in Japan has also been linked to increasing levels of affluence and Western influence (Belk 1985). Recently, it has been suggested that materialism is on the rise in underdeveloped and developing countries as well, and the present results support that suggestion. Although this may follow some sort of economic development, it may occur without accompanying or preceding widespread affluence, again as seen in the current study. The fact that materialism existed in ancient civilizations, although within isolated pockets, and that it exists in LDCs today suggests that being Western or affluent are not essential prerequisites.

Then, what factors account for materialism? A brief look at the cultural and historical factors in Turkey may provide some clues. The Ottoman empire, which survived for about 600 years, collapsed after a period of decline for about 200 years, and lost to the West during the first world war. The Turkish republic which was then formed has been trying to rebuild. A sociological account of the Turkish mentality and lifestyle of the Turkish person of the decline period (Ulgener 1981a and b), suggests that this person has been familiar to the pleasures or desire for an affluent lifestyle with high levels of consumption but is not in a hurry to get

there nor will go to great efforts to get there, and maintains his ties to tradition in setting his goals and means. Lots of and showy consumption (huge and well decorated offices, chauffeurs) is ahead of more simple and less showy service and production capacity. This person relates to material things as a means of pleasure, prestige and showing off. So, the pleasure ethic has always been there. Also, he feels close to "things", in a feeling sort of a way, rather than a good of investment or exchange value, the latter being the way an industrialized man relates to goods. Ulgener argues that religious and secular ethics reinforced consumption for pleasure, not only for the elite but also gave opportunities for similar behavior to the lower classes. Mobility existed. Lower classes as well as the elite were after the "riches", showing off and had a desire for gold and silver. Although there was public rhetoric of modesty in means, in intimate communication and advice, elders wished for a lot for their offspring.

Some of the religious influences arise from the Islamic rules that seem to have implications for materialism and generosity. For example, pilgrimage is only for the rich-- once one has enough to provide for the family and give to the poor; Muslims are required to give to the poor periodically; and when sheep are sacrificed during the holiday (to commemorate God sending sheep when Abraham was about to sacrifice his son), the meat is shared with the poor. Furthermore, there is a strong interpenetration of the religious and the commercial in Turkey, consistent with O'Guinn and Belk's (1989) findings. Artifacts which are both religious and secular include: 1. blue eye (also called "masallah" which is what is said to ward off the evil eye, although "masallah" is an Islam term whereas the evil eye is a pagan belief) hung on door or worn as jewelry, 2. prayer rug versus kilims which are linked to the nomadic tradition, 3. religious elements in many arts and crafts, such as religious writings on copper, silver and ceramic wares, and calligraphy, one of the art forms which evolved to substitute the forbidden representation of human figure in art/paintings.

Recent developments in Turkey point to possible nonreligious influences on materialism. Economic influences may include the 60-80% inflation rate of the past couple of years, and the major liberalization of the economy and encouragement of international business since 1980. The advertising industry also bloomed with foreign partnerships. For the past 20 or so years, Turkish workers in Germany have been coming back to Turkey every summer, bringing modern western goods like cars, TVs, appliances, and impressing people in their neighborhoods or villages. There has been an increase in tourism over the years with exposure to tourists and their belongings, an increase in American TV programs and films, and direct exposure, through business relations, to the lavish consumption in Saudi Arabia. There is a new class of "new rich" who like to publicize their belongings. The newspapers have pictures of the prime minister's wife in her designer clothes and of

the parties of the wealthy who serve outrageously expensive delicacies. People are crazy about Rolex watches and other brand name goods. Traveling to Europe mostly for shopping purposes created an expression: "suitcase tourism". Although these behaviors are not necessarily adopted, afforded or approved of by everyone, they still offer a sign of success. A mental picture of what the rich and famous do, and thus, is desirable, gives prominence to consumption.

Desirability of consumption can, in some cases, lead to "wrong" choices, supporting Belk's argument (1988). In a rural home, plastic plates may be hung on the wall. It is modern, it is what the city people use, and thus good. In the olden days it used to be a copper or ceramic plate. Similarly, in urban areas wall-to-wall carpeting is very "in", and some sort of plastic material covers the rural floors which previously had hand made rugs and kilims. The "doorman" and the cleaning lady purchase the latest appliances including TV and VCR (yet cutting down on food and health related expenses), the poor and the rich buy a faddish item such as stone washed jeans, and follow the latest fashions.

A lot of what is described can be thought of as "Western influence". Why is a country that has been trying to imitate the West more materialistic than the West itself? What is seen first and adopted the easiest is the tangible. Things easiest to diffuse have been the artifactual. Secondly, the "have not" feels the lack of many things, and to compensate, adopts something that is the easiest to adopt. For example, many stores and restaurants in Turkey have foreign or foreign sounding names. "We consume like they do, we have what they have, so, we now are Westerners. Why, we even have McDonalds, Pizza Hut, and Benetton." Anything "Western" is equated with "good and desirable". This feeling is widespread now, and has been since the decline of the Ottoman Empire. This may be because of the defeat of the Ottomans by the west leading to a loss of esteem/dignity accompanied by the belief that the West must know what they are doing. An analogous reasoning may account for the greater materialism in the US than Europe. Being later to industrialize than Europe, plus lacking cultural heritage may lead to lower esteem or dignity. Americans may still look up to the old land in many ways and are impressed very much by its history and culture, but not vice versa. And of course Turkey is very impressed by both USA and Europe.

With that historical and religious background, how can we interpret materialistic tendencies in Turkey now? Possessions are socially accepted and valued. People purchase things to belong. An acquaintance, who was new in a social circle, once told the first author "I realized that unless I show them that I also understand art and own it, they are going to exclude me". The value of a person increases as s/he dresses a particular way, owns certain things, and goes abroad for vacations. Young people want brand name products in order to get dates. Possessiveness and envy go along with valuing possessions. Tangibilizing may occur

because concrete things are easier to show to others and communicate something about oneself. And all may be related to a sense of lack of dignity/ esteem, maybe due to the history-- being grandchildren of a fallen empire, feeling excluded from the world, and wanting to belong. How about generosity? People still give to the poor, but not necessarily to fulfill religious rules. A lack of second hand business may also enhance such giving. They give to the poor around them quite possibly to reduce envy: people they know, like the maid and the doorman, people whom they see and are seen by. The rich and the poor are more exposed to each other, and are not as physically separated as in the USA, which may enhance envy. The blue eye is a tangible indicator of the importance of envy.

In summary, some bare minimum of economic means and communication as to available goods and how other people (in the same society or in different societies) live and consume, and a sense of affordability (I can also buy this) seem to be necessary conditions for materialism. But having the means and knowing that other people have things do not necessarily have to lead to the desire for these things or materialism. Why does that desire come about? Due to an impersonal society? Due to a desire to belong? Implicit in the above preconditions lies the notion that comparison of one's own means and possessions with those of others above oneself will push one towards materialism. The notion of comparative or relative situation seems to be an important one. This comparison may involve other aspects of life (such as constraints, lack of control and satisfaction, see Daun 1983) versus material aspects, current and historical affluence (economic and/or cultural) of others (within a country and/or across countries) versus of oneself. Both of these comparisons may be related to a latent sense of relative deprivation, esteem/dignity (related to or in self, country, society, history), and the desire to self-actualize and assert power. The sudden relative changes in means by Turkish guest workers may be a strong precipitating factor due to the relative disparities it brings about and the exposure to Western lifestyles it creates. More generally, increasing inequality in income distribution may also lead to such disparities. Finally, the relationship between materialism and affluence may be curvilinear rather than linear. In a less affluent society, people may value things they don't have, however, once these things are acquired their value may decrease. Furthermore, affluence may need to be conceptualized as a relative concept and broader in terms of its elements and time frame. That is, 1. history/recency of affluence, 2. recent comparative trends in affluence, and 3. noneconomic affluence (for example, cultural heritage) in addition to current levels of affluence, may need to be considered as the independent variables to be investigated in the future.

To undertake cross-cultural studies of interest, we have to think about causality. In order to address that issue, the nature of the phenomenon and its

dimensions must be identified. So, here we have tried to develop a measure which can assess the phenomenon in several cultures. Now, studies aimed at finding the causal relationships can be undertaken. Historical analyses and descriptive findings may provide initial ideas about causes, which then would need to be tested. Some such ideas have been suggested above.

Reducing Response Error in Consumers' Reports of Medical Expenses: Application of Cognitive Theory to the Consumer Expenditure Interview Survey

Leslie A. Miller, Bureau of Labor Statistics
Theodore Downes-Le Guin, University of Michigan¹

INTRODUCTION

Previous Analysis has suggested that the Bureau of Labor Statistics' (BLS) Consumer Expenditure Survey may underestimate consumer expenditure levels (Geiseman, 1987). Certain expenditures are prone to measurement error because of heavy demands on respondents' ability to recall and classify expenses. In response to this problem, BLS initiated a sole source contract for preliminary cognitive research to develop and evaluate improvements in the Survey's design. The following describes efforts focusing on reports of health and medical expenditures. The research design applies theories of cognitive psychology to respondents' task in an attempt to reduce burden and increase the accuracy of reports.

The Consumer Expenditure Survey program uses two instruments -- a face-to-face interview schedule and a diary -- to collect data on Americans' consumer behavior. The principle purpose of the Survey is to provide estimates of mean expenditures for the total population and for various demographic subsets of the population. The data determine the relative importance of different goods and services in consumers' budgets, which defines the "market basket" of commodities used in calculating the Consumer Price Index. Data collection is carried out by the Bureau of the Census under contract to the Bureau of Labor Statistics.

The Interview Survey employs a national probability sample of approximately 5000 Consumer Units (CUs). CUs are defined as individuals or groups in a household related by blood, marriage, adoption; or who, as individuals or as groups, are independent of all other persons in the household for payment of major expenses. Respondents are assigned to rotating panels to be interviewed quarterly for five consecutive quarters, with first quarter responses used for bounding purposes. The interview schedule is a complex, somewhat cumbersome document comprised of 22 sections for different categories of expenditures.² Unlike the Diary Survey, which collects data on smaller expenses (e.g., food and beverages, clothing, shoes and jewelry), the Interview Survey generally focuses on larger expenditures which respondents are expected to recall over a three month reference period (U.S. Department of Labor, 1988).

The Health and Medical Expenditures section of the Interview Survey attempts to determine net out-of-pocket medical expenses for sample CUs. The questions have three purposes: (1) to determine if the CU has had any payments or reimbursements for medical services or items during the reference period; (2) to elicit specific payments for medical expenses; and (3) to elicit specific reimbursements for medical expenses. For a number of questions, interviewers use an information booklet to cue respondents with various types of expenses.

STATEMENT OF PROBLEM

Collecting accurate information on health care payments is a formidable problem for survey researchers (Anderson and Frankel, 1979), involving technical terms, detailed recall and potentially embarrassing topics. Within the framework of respondents' cognitive approach to question-answering, the first two processes -- comprehension and retrieval -- pose the most problems in the Health and Medical Expenditures section of the Interview Survey. A report from the Research Triangle Institute (Lessler, 1988, 1989) on cognitive issues in the Interview Survey as a whole identified the following major problems to be addressed in redesigning the instrument:

- Lack of cues to remind respondents of the reference period and to assist in anchoring events in the reference period;
- Use of undefined terms and "hidden instructions" (instructions not read to the respondent) which modify question meanings; and
- Not defining the task adequately to respondents, resulting in under-use of records and less motivation for accurate recall.

BLS used its Collection Procedures Research Laboratory (CPRL) to investigate these problems, with the ultimate goal of revising the section to make it more cognitively "friendly". The specific objectives of the research are to:

- Improve respondent comprehension by rewording and reordering questions, making all instructions explicit and using the information booklet whenever possible; and to
- improve recall of expenditures by structuring the questions as similarly as possible to respondents' retrieval schemes, and by encouraging the use of records.

¹The views expressed herein are attributable to the authors and do not necessarily reflect those of the Bureau of Labor Statistics or the University of Michigan.

²The average time required to administer the interview schedule is about two hours.

Education	
Mean years	15
Range	12-22

RESEARCH METHODOLOGY

The research employed qualitative methods -- focus groups and personal interviews -- as primary means of data collection. Within the scope of the entire project, this research serves an exploratory purpose, leading to a quantitative field test of revisions to be conducted in the fall of 1989. As with all such qualitative designs, participants' behavior and attitudes cannot be interpreted as projectable to the populations of consumers. The research does, however, provide insight into the processes respondents use in forming answers to survey questions, processes which are difficult to investigate within the format of a sample survey.

Sixty research subjects were recruited with an attempt to balance characteristics such as age, gender, ethnicity and level of education (see Table 1). Each subject was compensated \$15 for time and travel. An experimental psychologist moderated the group discussions and conducted the personal interviews in the CPRL, resulting in a total of six groups and seven personal interviews conducted over an twelve week period.

Upon arriving at the laboratory, subjects were informed of the basic nature of the research and were asked to self-administer a questionnaire to obtain demographic information and, prior to the discussion, their interpretation of several concepts presented in the Interview Survey. The moderator then used a discussion guide to review issues of comprehension and recall relating to medical expenditures. In focus groups, participants were encouraged to express individual views as well as building consensus. Personal interview were conducted using the same discussion outline.

Data from the focus groups and interviews were analyzed with the intent of identifying consensuses which emerged among subjects, as well as individual beliefs and attitudes. Questionnaires

and transcriptions were reviewed along with the videotapes, and responses were grouped into broader categories for interpretation. Most subjects expressed similar difficulties with question wording and retrieval of expenditures; for illustrative purposes we use individual comments to represent consensuses.

RESULTS: COMPREHENSION ISSUES

The first step in the cognitive processing of a survey question, comprehension, describes respondents' understanding of the question-answering role and of the specific terms they encounter in each question. With respect to question wording, the researcher's aim should be to reduce ambiguities and abstract concepts to account for individual and cultural variations in comprehension. Reduction of these ambiguities lends more credence to the assumption that all respondents have comprehended questions similarly (standardized stimuli) and that questions are interpreted as the researcher intended (validity). Methods we used in reducing the ambiguities in the Health and Medical Expenditures section include defining the respondents' role, providing examples and definitions of frequently misinterpreted terms and using commonly-understood vocabulary.

While laboratory subjects focused on health and medical expenditures alone, these questions form only a fraction of the many expenditures respondents must recall for the Interview Survey. We identified two cognitive context effects stemming from the position of the Health and Medical Expenditures section the Survey.³

- First, no introductory information is included to aid respondents in transitioning from one category of expenditures to another. Offering respondents an introductory statement may motivate more careful consideration of the question (Cannell *et al.*, 1987) and may elicit higher levels of reporting (Laurent, 1972). Thus, we added the following introductory statement:

"Now I am going to ask you some questions about medical *payments* and *reimbursements*. We will begin with your payments."

- Second, the questions in the preceding section collect information on expenditures for hospitalization and health insurance, which predispose respondents toward reporting the *reason* they consulted a provider or the *services* they received rather than the germane payments and reimbursements. The question which

³The Health and Medical Expenditures Section is number fifteen of twenty-two sections.

originally preceded each cuing list emphasized services:

"...have you (or any members of your CU) made any payments for any of the following medical services?"

By removing the words "medical services" and skipping straight to the cuing list, we hope to discourage reports of services in place of payments.

Prior to adding the introduction, respondents were asked the following as the first question in the Health and Medical Expenditures section:

"Since the 1st of (*month, 3 months ago*), have you (or any members of your CU) made any payments for any of the following medical services? Include all payments, even those for persons who are not CU members."

Respondents were then cued with several categories of expenditures (e.g., hospital room). If respondents reported any payments for cuing items, they were asked if they had received any corresponding reimbursements from insurance companies or others. This question sequence presents an extremely complex task to respondents. Respondents (who may already have been interviewed for an hour or more) must (1) comprehend and use a reference period; (2) comprehend the difference between payments and reimbursements; (3) distinguish expenditures for CU versus non-CU members; and (4) distinguish insurance reimbursements versus other (undefined) types of reimbursements.

Perhaps the most fundamental problem we encountered in the laboratory research was ambiguity of terms and phrases central to the understanding of questions and of expenditure categories (Miller, 1988). Even the term *payments* (used throughout the Interview Survey in addition to *purchases* and *expenses*) did not present a uniform meaning to laboratory subjects. By payments, BLS means any remuneration made directly to a provider of medical services or items. Payments can be made in a variety of forms -- check, credit card, and so on -- and can be made by the sample CU for a person who does not belong to the CU. Laboratory subjects, however, applied a variety of definitions ranging from overly abstract (anything paid out for medical services, payments for non-medical expenses) to overly specific (money issued in the form of a check). In addition, several subjects wondered whether payments include expenses such as health insurance premiums, which are collected elsewhere in the Interview Survey.

The degree to which these definitions differ from the intended meaning throws doubt on the validity of the resulting data. Because the Interview Survey must be understandable to respondents with a wide range of cognitive sophistication, our solution was simply to provide respondents with an explicit

definition of payments in this context. The definition (heretofore known only to the interviewer) follows and complements the introductory sentence:

"By payments I mean any expenses paid by any members of your CU directly to a medical care provider by cash, check or credit card for a medical service or item. Include all payments, even those for persons who are not CU members."

Subjects' definitions of *reimbursements* correspond more closely to BLS's intended meaning, perhaps because the concept of reimbursement appears to be linked to health care in subjects' minds. Most subjects define reimbursement as money sent by an insurance company to cover all or part of a medical expense. Areas of confusion include insurance company payments made directly to providers, reimbursements received before payments are made and refunds or credits from providers for overpayment. Again, we attempted to reduce ambiguity by providing a definition of reimbursements as follows:

"By reimbursements I mean money received for any members of your CU from an insurance company, medical care provider or non CU member, for medical expenses which you had previously paid or will pay."

Certain categories of medical expenditures exhibit a similar lack of universal definition for laboratory subjects. In the unrevised instrument, respondents were cued with both *physician services* and *services by practitioners other than a physician*. While most laboratory subjects appear confident in their definition of a physician, virtually none could define a practitioner. Efforts to distinguish the terms produced a vague sense that practitioners are somehow "less" than physicians -- for instance, providers who do not hold M.D.s. When asked to classify a number of different providers (such as chiropractors) as physicians or practitioners subjects were unable to reach consensus.

Some of this confusion may stem from the fact that physician services previously were categorized under In-Patient Hospital Care while practitioner services were categorized under Other Medical Care Services. This categorization results from the fact that BLS analyzes physician and practitioner data separately. While the different categories appear to imply to subjects that physicians and practitioners are substantively different, however, the difference is not defined. We revised the instrument to collect expenditures for all medical professionals in the same category, and replaced practitioners with *services by medical professionals other than physicians*. This cue serves the purpose of catching expenditures for any provider which a respondent may not consider a physician, without the vague implication of a difference implied by practitioner.

RESULTS: RETRIEVAL ISSUES

Respondents' task can be especially difficult when it involves retrieving retrospective and autobiographical information rather than current attitudes. Survey researchers have acknowledged this by paying more attention to ways in which retrieval can be aided (Bradburn *et al.*, 1987; Cannell *et al.*, 1981). In the Interview Survey, the quantity and quality of recall ultimately determines the very utility of the data. The researcher's job is to encourage respondents to answer questions thoughtfully and accurately, but with minimal cognitive burden. Thus recall tasks must be structured to mimic the cognitive processes respondents use in retrieving facts. The Interview Survey uses some methods for increasing recall, such as bounding interviews, but is constrained by reference period requirements and limits on interview length. With Health and Medical Expenditures, we attempted to maximize recall by reorganizing the existing section rather than making broad changes.

Cognitive psychologists maintain that the storage, retrieval and interpretation of past experiences is managed by higher level knowledge structures, or schemata. Schema theories can serve as a valuable basis for estimating missing information and correcting inaccurate recall (Anderson, 1985). Scripts, a schema theory put forth by Schank and Abelson (1977), refer to the encoding of stereotypical or routine activities (Dippo, 1989). When describing a past activity using a script, respondents refer not to specific information about the activity in question, but to an estimate based on repeated performance of similar activities. In an oft-cited example, respondents in health surveys frequently report going to the dentist twice a year because of the common script for biannual checkups, despite the fact that they may have had intervening dental care.

Prior to revision, the Health and Medical Expenditure section was structured to collect payments made in certain expense categories, followed by reimbursements for these categories. The payment-then-reimbursement sequence is repeated on four pages until all expense categories are exhausted. While convenient for coders, the structure is awkward for respondents, requiring frequent switches between payments and reimbursements. We hypothesized that an instrument designed to mimic subjects' schemata for health care would place reimbursements after payments, the pattern familiar to most people.

In fact, most laboratory subjects said they would prefer a completely unstructured format for reporting payments and reimbursements. Given a choice of structures, however, an equal number of subjects said they would prefer (1) reporting a reimbursement after every payment and (2) reporting all reimbursements after all payments.⁴ Only a

handful of subjects said they prefer the existing category-by-category structure. Our hypothesis was partially borne out by these results. Subjects appear to consider medical reimbursements as subsequent to, and contingent upon, payments. Since the former structure is not feasible for BLS (it involves reporting reimbursements for payments made out of the reference period), we reordered the section to collect all reimbursements after payments.

One unexpected result emerged about subjects' retrieval schemes: the order of reporting payments and reimbursements may be less important than the landmarks used in retrieving them. Many subjects emphasized that, whatever the payment-reimbursement structure, they retrieve expenses by first reviewing CU members and/or the months in the reference period. This suggests that respondents may use three steps in retrieving expenses:

1. Reviewing episodes of medical care associated with self and, where applicable, each CU member.
2. Reviewing retrieved episodes to be sure they are consistent with the reference period.
3. Retrieving payments and/or reimbursements associated with the care or item.

Subjects' comments suggest that many respondents attempt to create landmarks for recall by reviewing the three-month history of CU members. Our recommendation⁵ based on this finding was to provide a calendar (displaying reference period dates and CU members) in the information booklet as a visual cue for the reference period.

CONCLUSION

Theories from cognitive psychology go beyond a simple stimulus-response description of the process respondents use in answering survey questions. By incorporating these theories into laboratory research conducted for the Health and Medical Expenditures section of the Consumer Expenditure Interview Survey, we were able to examine in-depth the reasons respondents may misunderstand questions and may have difficulty recalling expenses. This information aided in redesign of the data collection instrument to better conform to respondents' comprehension and recall processes.

The revised instrument will be field-tested in fall of 1989 using a non-probability sample of 222 households from four Census PSUs. In addition to the regular interview, both respondents and interviewers will complete a debriefing questionnaire

⁴More subjects who attained a higher education level (BA or above) said they would prefer the first structure, reporting an individual payment

followed by any reimbursement received for that payment. Less educated subjects say they would prefer to report all payments first.

⁵Unfortunately not adopted.

at the conclusion of the interview to determine if revisions have aided comprehension and recall. A portion of interviews will be audiotaped and coded for both respondent and interviewer behavior, providing another measure of the effectiveness of changes. The results should be more and better data for BLS, and a less burdensome task for respondents.

Cognitive Aspects of Proxy Reporting of Behavior

Barbara A. Bickart, University of Florida
Johnny Blair, University of Illinois
Geeta Menon, University of Illinois
Seymour Sudman, University of Illinois¹

INTRODUCTION

This paper presents some preliminary results from a study being conducted by us at the Survey Research Laboratory, University of Illinois and funded by the National Science Foundation. We are investigating the cognitive processes that underlie self and proxy reporting in surveys and their impact on data quality. We are particularly interested in the quality of data provided by proxies and explore possible ways to improve the quality of proxy reports.

In many surveys conducted by government agencies, universities, and the private sector, respondents must provide data about themselves, other household members and sometimes about the household and the community in which they live. For example, the Current Population Survey requires that one household member report about the labor force participation of all household members; in the Health Interview Survey and the National Crime Survey proxy respondents are permitted to report about other household members if they are not available. In consumer research, information about multiple family members' brand purchases and usage is often obtained using proxies because of research budget constraints.

Prior work examining the adequacy of proxy reports has usually found that self reports are more complete. However in some situations small differences are found and, in a few cases, proxy reporting is actually better. (For a review see Moore, 1988.) Many of the comparisons reported in the literature have been flawed because of possible selection biases. Typically, proxies are used only when the respondent is unavailable, thus undermining systematic comparison. In addition, earlier studies have not provided any understanding of how the cognitive processes used for proxy and self-reporting might differ. Therefore, these studies have been unable to use an understanding of processing differences to suggest methods to improve proxy reporting.

Our study addresses these limitations by studying pairs of respondents in a household and asking them to report both about themselves and another household member. We use divergent methodologies, including think-aloud interviews in a cognitive laboratory setting, telephone interviews and laboratory experiments, and our studies include survey questions on a wide range of topics, as

shown in Table 1. Our research program focuses on the following major issues:

1. The convergence between self and proxy reports of behavioral frequencies and the factors that influence convergence, particularly the joint participation of the pair in the activity and the importance of the behavior to the respondent;
2. The use of anchoring and adjustment strategies by proxies to answer both behavioral frequency and attitude questions;
3. The different processes used by self and proxy respondents to answer behavioral frequency questions.

Our current paper presents some preliminary results related to this last issue. In what follows, we give a theoretical overview of current thinking on how people respond to behavioral questions and why proxy reporting processes might be expected to differ. This is followed by a brief methodological discussion, the presentation of our results and a concluding section on the meaning of the results and plans for future research.

THEORETICAL BACKGROUND

A behavioral frequency question requires the respondent to identify the target behavior, to determine if it occurred at all during a specified time period, and if so, how often (see Schwarz, in press, for a detailed discussion of these tasks). Traditionally, it has been assumed that respondents determine the frequency of a behavior using a "recall and count" procedure. Presumably, they search memory for relevant behavioral episodes, determine the date of these episodes, and count the number of occurrences within the reference period. Unfortunately, recent research suggests that this apparently straightforward procedure is rarely used. Specifically, it is most likely to be used for rare and outstanding events, but unlikely to be used for frequent and mundane behaviors as they are usually assessed in surveys. Most importantly, frequent and mundane behaviors--such as reading the newspaper or eating out--are not represented as separate episodes in memory. Rather, these highly similar episodes tend to blend into one generic representation of the behavior, making the use of a recall and count strategy infeasible. Accordingly, frequency reports of mundane behaviors are usually based on estimation procedures in which respondents use some fragmented recall of behavioral episodes

¹This project was funded by the National Science Foundation, Grant No. SES-8821362. We would like to thank Norbert Schwarz for his useful comments on an earlier version of this paper.

along with various inferential rules to derive an appropriate estimate. Which strategy they use is likely to depend on how the information is organized in memory.

Table 2 present a heuristic framework, suggested by Geeta Menon (1989) as part of her dissertation research, that conceptualizes the impact of different memory representations on the likely use of different recall and estimation strategies. This model posits that there are two key factors that influence how information about an autobiographical event is stored in memory. The model further suggests that the specific form of the memory representation influences the strategy that respondents use to retrieve information to form a behavioral frequency judgement. The first factor pertains to whether the event occurs at regular or irregular intervals. We refer to this as the *regularity* or periodicity of the behavior. The second factor pertains to whether separate occurrences of the behavior are similar or dissimilar to one another. We refer to this factor as the *variance* of the behavioral episodes.

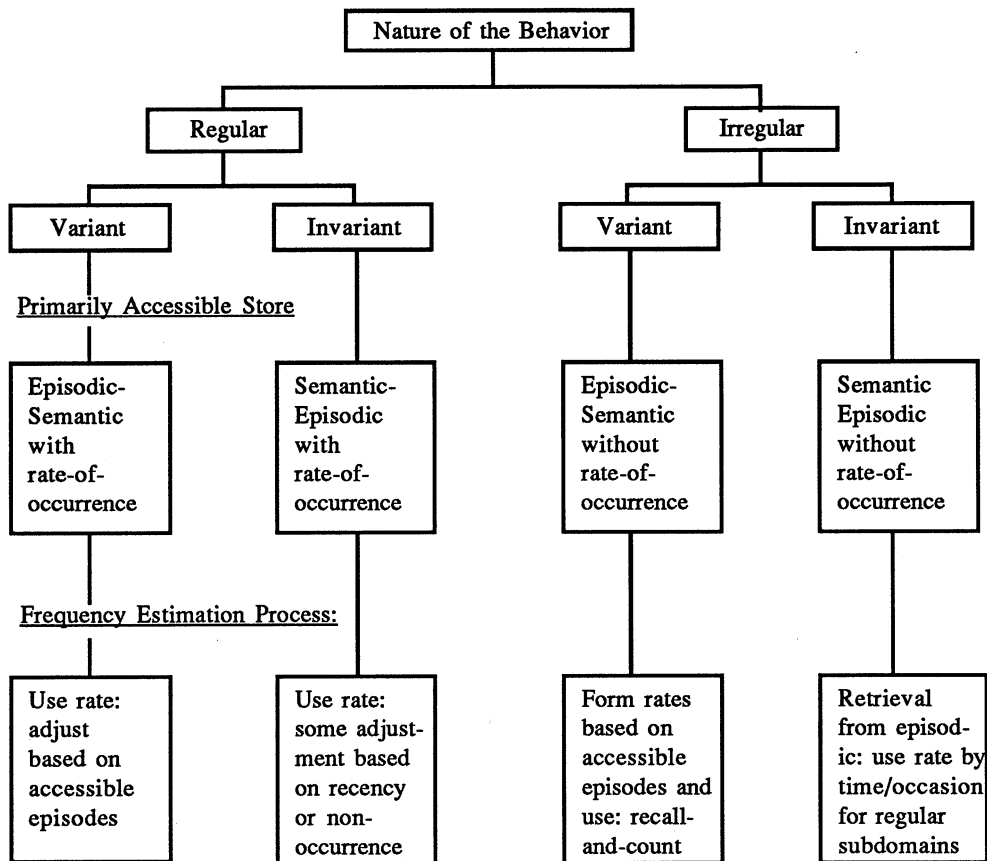

The model assumes that behaviors with a highly regular pattern of occurrences may be represented in memory in a summary form that reflects the respondent's semantic knowledge about his or her usual behavior. This representation may often have the form of a *rate-of-occurrence* (e.g., "I read the newspaper daily"). Accordingly, respondents may retrieve the rate-of-occurrence for the target behavior and may base their estimate on the rate. For example, a respondent who knows that she reads the newspaper daily would easily come up with an estimate of "seven" for the referenced period of one week, without recalling a single episodic representation of "reading the newspaper". Moreover, this initial estimate may be easily adjusted if the respondent does not read a Sunday paper, and so on.

In contrast to regularly occurring behaviors, however, behaviors with an irregular pattern of occurrence are unlikely to be represented in a summary form, such as a rate-of-occurrence. Accordingly, respondents will have to use some kind of episodic recall to compute an estimate under irregular occurrence conditions. The accessibility of individual episodes in memory, however, is likely to depend on the *variance* of the behavior. As several studies have shown, similar occurrences tend to blend into one generic representation, rendering the individual instances difficult to retrieve. Distinct occurrences, on the other hand, are represented as separate episodes, thus increasing the likelihood that they can be recalled (Linton, 1982; White, 1982; Wagenaar, 1986). Thus, the more *variant* the behavior (e.g., purchases of major household or personal items) the more likely that respondents will be able to access independent episodes. In that case, they may either count these episodes and report the frequency, or use a subset of them to form a rate on the basis of which to make a frequency judgement.

On the other hand, the more *invariant* the behavior (e.g., reading the same newspaper in the same setting, but on irregular days), the more likely that respondents will not be able to access individual episodes. Accordingly, they will have to estimate a behavioral frequency on the basis of general knowledge about their behavior. This, however, is likely to be particularly difficult because the semantic representations, such as "I sometimes read the paper", offer little frequency information over and above eliminating the possibility of a non-occurrence.

In summary, the regularity and variance of a behavior are expected to interact in determining the strategy that respondents use in providing *self reports* of behavioral frequencies. In addition to these fairly complex interactions, reporting about the behavior of others raises additional difficulties.

TABLE 2
Proposed Model for the Storage and Retrieval of Information About Frequent Behavior

"Semantic-Episodic" implies a more accessible semantic store with few accessible episodes, while "Episodic-Semantic" implies more accessible episodes with/without accessible semantic stores within subdomains. (Source: Menon, 1989)

Table 3 summarizes the major differences in the encoding and organization of information about one's own behavior as opposed to information about the behavior of others.

At the *encoding level*, it is important to note that one's own behaviors provide a rich set of experiences, including information about what we wanted to do, what we actually did, how we felt while doing it, and so on. Thus, the episodic representation is likely to include information relevant to the event, such as the location, and the emotional responses to the event (Tulving, 1972, 1983). In contrast, proxy respondents are typically answering questions about reported events, or events that are learned "second-hand." These events are likely to be represented as episodes which relate to the occasion of receiving or learning about the event. In line with this assumption, Larsen and Plunkett (1987) found that information about reported events was accessed through the memory of

the context in which the respondents learned about the event. These considerations have several implications for the strategies used to answer behavioral frequency questions.

First, cues related to the event itself should be more effective in enhancing recall for self reports than proxy reports.

Second, reported events might not be encoded in chronological order. Therefore, proxy respondents should be less likely to use a chronological pattern (i.e., forward or backward search of memory) when searching a reference period.

Finally, this suggests that the similarity between a respondent pair's episodic representation of an event should be related

TABLE 3
Information About Self and Other at Stages of Information Processing

	<u>Encoding</u>	<u>Storage</u>	<u>Retrieval</u>	<u>Response Generation</u>
Self:	<ol style="list-style-type: none"> 1. Actually experience event: <ol style="list-style-type: none"> a. Chronological b. Experienced in entirety 2. Increased elaboration. 	<ol style="list-style-type: none"> 1. If episodic, related to actual event. 2. If semantic, related to self. 	<ol style="list-style-type: none"> 1. Cues related to experience. 2. Search likely to be chronological 3. Event likely to be recently activated. 	<ol style="list-style-type: none"> 1. Self-presentation effects.
Other:	<ol style="list-style-type: none"> 1. Learn about event through: <ol style="list-style-type: none"> a. Observation b. Word-of-mouth/direct (from target) 2. Not necessarily chronological. 3. Amount of elaboration depends on social distance. 	<ol style="list-style-type: none"> 1. If episodic, related to reception situation unless joint participation in event. 2. If semantic, related to "Other" knowledge structure, presumably not as well organized. 	<ol style="list-style-type: none"> 1. Cues related to encoding situation. 2. Chronological retrieval is difficult. 3. Less frequent activation. 	<ol style="list-style-type: none"> 1. Less sensitive to demand effects. 2. May not be aware of sensitive information. 3. Social-distance will influence both (1) & (2).

to their common participation in the behavior. Therefore, the similarity of reporting strategies should be directly related to joint participation in the event.

In addition to these encoding differences, the *organization* of information stored about oneself versus others might differ for several reasons. First, self-relevant information has been shown to receive increased elaboration at encoding (e.g., Kuiper and Rogers, 1979; Rogers, Kuiper, and Kirker, 1977). This is thought to create a more elaborate memory trace for the event, resulting in enhanced recall. Thus, autobiographical events should be more likely to receive increased elaboration, and episodic representations of one's own behavior should be more accessible. Self-reports should therefore be more likely to be based on the use of a recall and count strategy than proxy reports. Moreover, the

attention that is given to the behavior of others may be a function of the other person's importance. As several studies have shown, information that is relevant to important others (e.g., one's spouse) also receives increased elaboration (Bower and Gilligan, 1979; Kuiper and Rogers, 1979). Therefore, it would be expected that the *social distance* between the self and proxy should be a major factor in determining the similarity in reporting strategies, particularly when the behavioral frequency question involves reporting of relatively variant, and/or infrequent behaviors.

The most pronounced difference in terms of self/proxy reporting may occur when answering a frequency question that requires the retrieval of a rate, as opposed to specific events. Recent research in social cognition has shown that recall of descriptive information, such as a rate, is facilitated when it pertains to the self (Klein and Kihlstrom,

1986; Klein, Loftus and Burton, 1989). This is thought to be attributable to a better organizational structure of this information in memory (Klein and Kihlstrom, 1986). Therefore, rate-based estimates should be more accurate when made about oneself than about others. For proxies, a question which requires the retrieval of a rate may be the most difficult of all to answer and the least accurate.

Finally, the impact of social desirability and self-presentation concerns should be different for self and proxy respondents. Although proxy respondents may, in general, be more willing to report about socially undesirable behaviors of others, they may lack the knowledge to do so. Again, a major factor should be the social distance between the pair. This should affect both the information which a proxy respondent has about the other, and his or her willingness to report it. However, these effects may actually counteract one another, and therefore may be difficult to detect.

These differences are summarized in Table 3. Based on this table, it is suggested that two key variables, the social distance between the pair and the extent to which the pair participated in the behavior together, will mediate the processes used by proxy respondents in answering behavioral frequency questions. Although these variables are not the focus of the analysis which follows, they play a central role in the remainder of this research project.

METHODOLOGY

The results presented today are based on twenty-five pairs of interviews conducted with husbands and wives or couples living together. The interviews were conducted by the senior project staff and covered the topics listed in Table 1. Our discussion is limited to the behavioral items.

We asked respondents the same questions about themselves as the other member of the pair and we asked them to think aloud as they responded. As other users of the think-aloud method have reported (Ericsson and Simon, 1980; Bishop, 1986), respondents vary in their ability to think aloud--some are very verbal and others much less so. If respondents did not think aloud spontaneously, they were asked immediately after answering how they arrived at their answer.

The data were coded by the senior staff using the coding scheme given in Table 4. This coding scheme underwent significant revisions as the staff coded the same interviews and attempted to reconcile differences. The coding frame is still undergoing some revision.

The major variables we examined were:

1. Whether answers were based on counting or estimation methods or a combination;
2. If based on counting, what method was used to search the reference period;

3. If based on estimation, is the estimation rate based, enumeration-based or some combination;

4. What cues were used to retrieve events?

RESULTS

Based on the literature review and the theoretical discussion, we developed four hypotheses:

1. Proxy respondents will be less likely to use chronological sequences than self reporters;
2. Proxy respondents will be less likely than self reporters to use event cues;
3. Proxy respondents will be more likely than self reporters to use estimation modes for questions of the same level of complexity;
4. Proxy respondents will be less likely to consider the reference period than will self reporters.

The comparisons between self and proxy responses are presented in Tables 5 and 6. Table 5 gives the average number of responses by method used. This is simply the total responses divided by fifty.

Overall, the obtained findings are nicely consistent with our hypotheses. As may be seen from Table 5, the use of chronological sequences is fairly low for self as well as proxy reports. However, consistent with our Hypotheses One and Two, self reporters are about 60 percent more likely to use chronological sequences and event cues than are proxy respondents.

Hypotheses Three, that proxy respondents are more likely to use estimation methods, is also supported. Table 5 shows that this is true in total, while Table 6 indicated that the same relation holds for ten of eleven specific topic areas.

Finally, Hypothesis Four, regarding the use of the reference period, also receives some weak support. Specifically, self reporters do use a specific reference period slightly more than do proxy respondents, but it is clear that this is not a widely used memory strategy by either group. These differences might have been an artifact of lower reporting by proxies and there is some indication of this. Total codes are slightly higher for self (16.22) than proxy (14.88) and if one omits the no-event-reported category, there is an average of about one more code per self than proxy.

If proxy respondents use event cues and chronological sequences to a lesser degree than self-reporters, one may wonder how they do arrive at an answer? As indicated in Table 6, proxy respondents are significantly more likely to rely on anchor and adjust strategies than self reporters. Specifically,

95	"Never..."
96	"Nowadays..."/"Usually..."

they use their own behavioral frequency as a starting point, and adjust this estimate on the basis of their knowledge about differences between self and other. However, it might be argued that this dominant use of an anchor and adjust strategy reflects the particular question order used in the present study. That is, respondents were always asked first about themselves, before being asked about others. Thus, self related information was rendered easily accessible, making the use of an anchor and adjust strategy particularly easy. This question order, however, reflects the standard procedures used in surveys, thus increasing the relevance of the present findings to current standard survey practice.

DISCUSSION

The results presented here are the first from a series of investigations that we plan about proxy reporting from a cognitive perspective. It is encouraging that the results, limited as they are, do fit the theoretical framework that we established before data collection.

It is also encouraging that our methods for obtaining think-aloud protocols and coding them seem to be generating useful data. While it can not be ruled

out that the think-aloud process itself may affect cognitive processing, we consider the present findings to provide encouraging evidence for the heuristic potential of this methodological approach (Ericsson & Simon, 1980). Given the strength and plausibility of these preliminary findings, we assume that they will hold up after completion of this study, which will involve a larger sample size and an improved coding scheme. The validity of our conclusions about the strategies of self and proxy reporters will then be the focus of our subsequent work, which will ultimately involve explicit manipulations of these strategies in tightly controlled experiments. We also plan to include the extent of joint participation of a pair in a behavior as a factor to be considered in our analyses. For the time being, we are optimistic that this research will eventually result in improved assessments of self and proxy reports.

Cognitive Models for Behavioral Frequency Survey Questions

E. Marla Felcher, Northwestern University
Bobby Calder, Northwestern University

Response Errors

How we ask a question affects how it is answered. In the course of normal conversation, a respondent is typically able to decipher a question's meaning, and the questioner is typically able to correctly interpret the response. For example, if a wife asks her husband if he "wants to see a movie", he can easily ask her to clarify what she means, by posing counter-questions to her initial question. By the close of their conversation, "see a movie" will have been defined in terms of location (home video versus theatre), type (comedy versus drama) or perhaps even in terms of a specific movie choice.

This situation becomes more complex when we are being asked a question by an unfamiliar person within an unfamiliar context, as in the case of survey research. In this situation, unlike the husband-wife interaction described above, it is much less likely that the respondent will force the questioner to specify exactly what he/she means when asking a question. Likewise, because the questioner typically does not know anything about the respondent's history, it is less likely that "wrong" or unusual answers will be detected. Consequently, response errors are likely to occur.

Throughout the past fifty years, an extensive body of research has grown out of an effort to identify types of response effects (errors in surveys caused by factors other than sampling procedures), such as respondents misinterpreting a question, intentionally misleading the researcher, or lying (see Bradburn, 1983 for review). Response effects research has demonstrated main effects such as: face-to-face interviews generally result in over-reporting of behaviors, respondents to telephone interviews under-report behaviors, closed-ended questions in self-administered questionnaires produce under-reporting of behaviors, respondents tend to give longer responses to longer questions, and respondents are likely to remember events occurring more recently than they actually did (Bradburn, 1983; Schuman and Presser, 1981). Because of its pervasiveness throughout all survey research, perhaps the most disturbing of all the response effect findings is that question wording and question order can have significant effects on the distribution of responses (Tourangeau and Rasinski, 1988).

A useful question to ask after close to fifty years of research in this area is, "What have we learned?". Basically what we have learned is that response effects do exist. However, this body of research is riddled with inconsistencies; sometimes the order of presentation of questions affects respondents' answers, while at other times order appears to be irrelevant; sometimes respondents forget events which have occurred in their lives, while at other times they seem to fabricate events which never happened. Both Bishop, et. al. (1985) and Schuman and Presser (1981) report situations in

which they have failed to replicate apparent response effects (question wording and order).

Information Processing Approaches to Response Effects

Frustrated by these seemingly unreliable findings, survey researchers have recently turned to psychology for insights into the underlying cognitive processes involved in answering questions. Initiated by researchers conducting large scale survey projects, the first of these studies attempted to identify the strategies respondents use in answering survey questions, and to apply basic principles of how we process information to questionnaire design, in the hopes of eliciting from respondents more accurate, and overall higher quality answers (Lessler, Mitzel, Salter, and Tourangeau, 1985; Lessler, Tourangeau, and Salter, 1986). Noting that a respondent's task is to understand a question, retrieve the relevant facts from memory, make a judgment, and respond, Tourangeau (1984) identifies the many opportunities in the process for error. The cognitive psychology literature on comprehension, encoding and retrieval of events, memory, and forgetting provide insights into what can go wrong in this process and the precautions researchers can take to guard against them. Most recently, Tourangeau and Rasinski (1988) apply these concepts to the measurement of attitudes, suggesting that in order to answer an attitude question, a respondent must interpret the question, retrieve the relevant beliefs and feelings from long term memory, use these beliefs and feelings to make a judgment, and use the judgment to choose a response. Applying this information processing-based model, Tourangeau and Rasinski are able to explain some of the seemingly unreplicable and inconsistent response effects found by previous researchers.

Given the importance of survey research to marketers, it seems that they would have quickly seized upon this promising new area. However, this has not been the case. To date, only one empirical study has appeared in a major marketing journal addressing this topic (Blair and Burton, 1987). The focus of this study was to identify the strategies used by respondents in answering behavioral frequency questions, and to predict the task conditions affecting strategy choice. Specifically, survey participants were asked how often they had purchased gasoline and clothing, made a long-distance telephone call, attended a movie, and dined at a restaurant within either a two-week, two-month, or six-month time frame (depending upon condition). Blair and Burton found that 28% of the respondents used an episodic enumeration strategy (recalling each specific episode of the behavior), while 56% used an estimation procedure (i.e., constructed a base rate, then converted to an

estimate of overall frequency). A negative relationship was found between question time frame and reported use of episodic enumeration. Finally, an episodic enumeration strategy was used only when reported frequencies were low; no respondents used this strategy when the number of events was greater than ten.

Blair and Burton's work was useful in indicating to marketers that they should be interested in the process-related issues of question-answering, rather than simply response distributions. However, they did not go far enough. We need to know *why* a respondent chooses to use a particular strategy, and how this choice of strategy ultimately affects response accuracy. If our ultimate goal as marketers is to increase the quality of survey research data, we must identify the factors which guide a respondent to answer in a particular way. Blair and Burton (1987) suggest that task conditions such as the time frame of interest and the number of behavioral events reported will dictate strategy choice. However, we should have learned from decades of response effects research that results such as this will simply spawn multitudes of similar studies, indicating that factors such as method of administration (telephone versus personal), length of wording of questions, question type (open versus closed-ended), etc., etc., will affect whether a respondent uses an episodic enumeration or estimation strategy in answering a behavioral frequency question. In other words, we will have simply replaced the dependent variable studied by response effect researchers, the distribution of responses, with a new dependent variable, strategy choice. And there is no reason to assume that this new research will be immune from the inconsistencies permeating the existing response effects research. Therefore, it seems that a more fruitful path to take is one briefly mentioned by Blair and Burton (1987) toward the end of their paper; "to gain an understanding, if possible, of the cognitive mechanism that controls selection of a response formulation process" (p. 288). Specifically, in order to understand how respondents answer behavioral frequency questions, we need to take a broader perspective, and look at how humans encode, store, and retrieve frequency information in general.

Is the Encoding of Frequency Information an Automatic Process?

A basic assumption in Blair and Burton's research is that frequency estimation is a conscious retrieval process. While they do note that 17% of their respondents reported using "simple direct estimates" of frequency, it is not clear whether this means the respondents had frequencies automatically encoded and stored for the categories requested, or that they were unable to describe their retrieval strategies in the protocols. It seems that an important initial question to ask, therefore, is, "Is frequency information automatically encoded and stored"?

Contrary to Blair and Burton's (1987) assumptions, Hasher and Zacks (1984) strongly contend that the encoding of frequency is an automatic process. They cite a variety of studies indicating that humans are remarkably accurate at estimating the frequency of letters, words, syllables, professions, and diseases, which are "not the sorts of events whose frequency one might be expected to learn deliberately" (p.1373). For example, after presenting subjects with lists of words on a memory drum, and not forewarning them of an upcoming frequency estimation test, Underwood, et. al. (1971) found a strong, positive, linear relationship between actual and judged frequencies of words. Furthermore, factors which have shown to strongly affect recall ability, have not been shown to affect the ability to judge frequencies. For instance, the accuracy of frequency estimates is not affected by providing subjects with feedback and additional practice, nor is it affected by individual differences such as intelligence, and age (at least between 5 and 20). (Zacks, Hasher, and Sanft, 1982). Finally, factors known to decrease cognitive capacity, such as depression, stress, arousal, and competing tasks, have been shown to decrease problem solving ability and temporarily suppress I.Q. However, these factors have no effect on frequency judgments (Hasher and Zacks, 1979). Therefore, because humans are sensitive to frequency without intending to be, training and feedback do not improve frequency estimates, there are few individual differences in the ability to provide accurate frequency estimates, and frequency judgements appear to be invariant with respect to arousal, depression, and competing task demands, Hasher and Zacks (1984) have concluded that the encoding of frequency information is an automatic process.

Contrary to Hasher and Zacks' findings, there is strong evidence suggesting that we do *not* automatically encode frequency information. For example, while Underwood et. al. (1971) demonstrated a positive correlation between actual and estimated frequencies, subjects tended to underestimate the more frequent events and overestimate the less frequent ones. Therefore, if we do automatically encode frequency information, it is not consistently accurate. Johnson, et. al. (1977, 1979) found that simply imagining that events occur increases the judged frequency of events which actually occur. This indicates that if we do automatically encode frequency information, the encoding process is unable to distinguish between actual and imagined events. Finally, numerous studies indicate that frequency judgments are not invariant across various task conditions, as was indicated by Hasher and Zacks (1984). Specifically, Rowe (1974) has shown that semantic processing of words increases the accuracy of frequency judgments, Tversky and Kahneman (1973) have shown that events which are more available are judged to be more frequent, and Greene (1986) has demonstrated that frequency estimates are sensitive to intentionality of learning. Thus, there appears to be ample evidence indicating that frequency information

is not *always* automatically encoded, and that demands posed at the time of retrieval may significantly affect frequency judgments.

Encoding of Frequency for Autobiographical Events

At this point it is useful to interpret the evidence presented thus far in relation to memory for autobiographical events. Specifically, we may ask, "Is frequency encoding automatic for real world and autobiographical events?" The answer to this question will have strong implications for survey researchers. For example, if it is found that the encoding is automatic, then research on retrieval strategies (i.e., estimation versus episodic enumeration) may be moot. Researchers investigating retrieval strategies are making an *a priori* assumption that frequencies are *not* automatically encoded. It is possible that the process of taking protocols to learn about subjects' strategies merely creates a demand effect in which respondents construct strategies in order to seem logical to the researcher and/or to themselves. If the process, or even a portion of the process is automatic, this will be extremely difficult to uncover through protocols. Finally, if frequency information is automatically encoded, is it encoded *correctly*? It may be that we automatically store *relative* frequency information, but not *absolute* frequencies. And finally, in the event that frequency data are automatically encoded correctly, is it possible that these counts get "adjusted" during the retrieval process?

Marketers have not yet directly addressed the automaticity of frequency encoding, however, it may be possible learn something about the processes involved by reassessing data from studies conducted for other purposes. For example, Burton and Blair, (unpublished manuscript) asked college student subjects to estimate how many courses they had completed outside of the college of business. The correlation between actual and judged frequencies ranged from .41 to .86, depending on condition. When the researchers did not specify how much time the subjects should take to respond, the correlation between actual and judged frequency was .41. When instructed to take 10-20 seconds, the correlation was similar, at .47. However, when told to take a full 70 seconds to answer, the correlation jumped to .86. If frequency data are automatically encoded and invariant to retrieval task, it is likely that there would not have been such a large increase in accuracy when told to take more time to answer. Therefore, these results suggest that time constraints may affect the choice of retrieval strategy. When under time pressure, it is possible that subjects respond with an automatically encoded, "rough" frequency judgment. However, when these time constraints are relaxed, they engage in more conscious, effortful strategies, perhaps adjusting the automatically encoded "rough" estimate. (While this explanation may be likely, it is not certain, as the study was not designed to test these hypotheses).

Two additional studies indicate that the judgment of frequency of autobiographical events is not a totally automatic process. In one study, subjects were queried on their frequency of visits to the dentist (Lessler, Tourangeau, and Salter, 1986). Similar to Burton and Blair (unpublished manuscript), these researchers found that the time taken to formulate a response significantly affected accuracy. Specifically, given more time to answer, subjects over-reported visits; when given less time they significantly under-reported visits. In a similar vein, Means, et. al. (1988) found that subjects consistently under-reported visits to an HMO for recurring health problems (i.e., when the patient needed to make multiple visits for the same problem). However, they discovered that prompting respondents with contextual and time-line cues (i.e., reasons they may have made the visits, times they were likely to have made the visit, etc.), significantly increased the accuracy of estimates. Again, if frequency encoding were a totally automatic process, these cues would have had no effect on frequency judgments.

The Retrieval Process

It is interesting to note that both Lessler, et. al. (1986) and Means, et. al. (1988) found that providing respondents with cues significantly increased the accuracy of their frequency judgments. Lessler, et. al. found that "reasons" cues were the most helpful in prompting more accurate estimates, while Means, et. al. found that general contextual cues worked best. In order to understand why certain cues are more beneficial than others in prompting accurate responses, it is useful to take the approach advocated by Tourangeau and Rasinski (1988), and look at the cognitive demands placed upon a respondent when asked a survey question. In this specific case, we must ask, "What cognitive processes must occur for a respondent to be able to accurately answer a behavioral frequency question?" Kolodner (1983) provides valuable insights into these processes through her theory of reconstructive memory.

Kolodner's model of memory focuses on the relationship between the structure of memory and the retrieval process. Her research is driven by the observation that while humans are experts at retrieving general autobiographical information, when they are asked details of specific episodes, this information is typically not available. Retrieval, then, is not a simple task of direct enumeration, but rather, "... a process of reconstructing what must have happened". (p. 284) The cues provided by Lessler, et. al. (1986) and Means, et. al. (1988) simply help the survey respondent reconstruct "what must have happened".

Kolodner posits that related events which occur in our lives are organized into Episodic Memory Organization Packets (E-MOP's). Each E-MOP will therefore contain multiple, related events. For example we may have an E-MOP for "Movies I Have Seen", the component parts of which are individual instances of going to the movies. When

an individual event is integrated into an existing E-MOP, it is indexed according to the features which differentiate it from other events already in the E-MOP. Differentiating features used to index these individual episodes into an existing "Movies I Have Seen" E-MOP may be people you have seen the movie with, movie types, places, times, etc. Different people may have different organizing E-MOP's, but all E-MOP's are organized according to differentiating features. Finally, events within an E-MOP will have similarities which allow for the construction of generalized episodes. For example, while the "Movies I Have Seen" E-MOP will contain different movie-watching episodes, these episodes will contain many similarities.

This E-MOP structure plays an important role in the retrieval process. In answering a behavioral frequency question, the query will typically guide the respondent to an appropriate E-MOP. For example, if asked, "How many times have you gone to the movies in the past 4 weeks?", the memory search will be directed to the "Movies I Have Seen" E-MOP. "Going to the movies" is defined as the *target event*. If the respondent has seen multiple movies, there will be multiple events stored in this E-MOP. However, the question asked in this way has failed to provide cues which will help differentiate the E-MOP's component events. Therefore, the target event must be further specified; differences between the E-MOP's component events must be specified in order for the respondent to be able to answer the question. Specifically, Kolodner theorizes that the original target event must be arrowed down through the specification of *features*. Recall that when an event is integrated into an E-MOP it is indexed according to those features which differentiate it from similar events. During retrieval, differentiating features are specified, and the events which are indexed by these features are retrieved.

The problem with behavioral frequency questions is that they are too general; they do not provide the respondent with enough features on which he/she can differentiate similar episodes. When asked the question, "How many times have you gone to the movies in the past four weeks?", a respondent may attempt to direct her memory retrieval process by thinking of the titles of the movies she has seen, the nights of the week she is likely to have gone to the movies, or people she is likely to have gone to the movies with. By doing so, she is essentially elaborating on the original question, by generating differentiating features. The original question posed to her did not specify the differentiating features which would allow the traversal process to occur through the E-MOP, therefore, she had to generate possible differentiating features herself. The cues which Lessler, et. al. (1985) and Means, et. al. (1988) found to be so effective were serving as these differentiating features, without which respondents were unable to construct an answer.

Summary

The pervasiveness of survey research in our society makes it an important topic, and one which is especially worthy of marketers' attention. Decades of response effects research has taught us that response distributions are affected by a multitude of factors, and that these effects are not always consistent. In an attempt to understand *how* survey respondents answer questions, marketers have identified typical response formulations strategies. However, it is our contention that the more fruitful path to take is that advocated by Tourangeau and Rasinski (1988) in their essay on the cognitive processes involved in answering attitude questions. Specifically, they state that an answer to an attitude question is the culmination of a four-step process. First, the respondent interprets the question, then he/she retrieves the relevant beliefs and feelings from long-term memory, and applies them to make a judgment. Finally, the judgment is used to formulate a response. The processes involved in answering a behavioral frequency question are similar; the respondent must interpret the question, retrieve the relevant information from long-term memory, and formulate a response.

Instead of focusing solely on retrieval-based strategies (i.e., Blair and Burton, 1987), we need to take a step back and look at some of the assumptions inherent in this work. First is the assumption that response formulation is a retrieval, rather than encoding process. Related to this issue is the assumption that frequency is determined consciously, rather than automatically encoded. While this issue has yet to be resolved in the cognitive psychology literature, there is ample evidence on both sides of the argument, suggesting that at least part of the process is automatic, and part is effortful. According to Jonides and Naveh-Benjamin (1987), "... it seems to us that the data concerning frequency estimation largely militate against any simple view of the coding mechanism involved. At this point, it seems a reasonable research strategy to investigate the relations among several mechanisms in the coding of frequency estimation". (p. 239) Finally, response strategy research focuses on the response formulation stage, essentially ignoring how the respondent interprets a question and determines what to retrieve from memory. Clearly, survey researchers have much to gain in understanding how these mechanisms operate as well.

The Disruptive Effects of Self-Reflection: Implications for Survey Research

Timothy D. Wilson, University of Virginia
Dolores Kraft, University of Virginia
Douglas J. Lisle, University of Virginia¹

ABSTRACT

Asking people to explain their attitudes has been found to lead to temporary attitude change. Further, these new attitudes have been found to be poor predictors of behavior. The implications of these findings for survey research are discussed. Asking "why" questions before attitude measures can be disruptive, especially for people with relatively inaccessible attitudes.

There has been a growing interest in how attitudes can be influenced by the techniques used to measure them. Such factors as question wording, question order, and the response format have been found to influence attitude reports (e.g., Hogarth 1982; Feldman and Lynch 1988; Schuman and Presser 1981; Tourangeau and Rasinski 1988). As a result, both survey and experimental researchers need to be aware of a host of potential pitfalls when assessing attitudes, such as creating an attitude where none existed before, or of altering an attitude by the way it is measured.

In the past few years we have investigated a problem with attitude measurement that has not received much attention. We have been interested in what happens when people are first asked to explain *why* they feel the way they do about an attitude object, and then are asked to report their attitude. In several studies we have found that asking people to explain an attitude can change it, at least temporarily, and can reduce the extent to which the reported attitude predicts subsequent behavior.

We have developed the following set of arguments to explain these findings. (For a more detailed discussion, see Wilson in press and Wilson, Dunn, Kraft, and Lisle 1989.) When asked to explain an attitude, people are rarely at a loss for reasons. Of the hundreds of people we have asked for reasons, almost no one has said, "I don't know," even when they were told that no one would ever look at what they wrote. Interestingly, however, there is a fair amount of evidence that people sometimes do *not* know why they feel the way they do (Nisbett and Wilson 1977; Wilson and Stone 1985). There has been some controversy over the extent of this lack of awareness (e.g., Smith and Miller 1978), though few researchers would dispute the claim that at least at times, people have difficulty knowing the exact causes of their attitudes.

Given that people are sometimes unaware of the reasons for their attitudes, what determines the reasons they will report? We suggest that people

are susceptible to a variety of availability effects (Tversky and Kahneman 1973) when reporting reasons. First, rational cognitions about the attitude object are, in our culture at least, viewed as the most plausible causes of attitudes, and hence are most available in memory. For example, when explaining why we like various political candidates, we are more likely to call upon such factors as their stance on the issues than such seemingly implausible things as the number of times we have seen their ads on television or whether their party affiliation is the same as our parents', even though these latter factors have been shown to influence people's attitudes. Other factors might be available in memory because they are easy to verbalize or were encountered recently. For example, if we happened to have just seen a televised debate where a candidate looked worn and ineffective, we might exaggerate the extent to which this contributes to our overall impression of him or her.

As a result of these availability effects, the reasons people bring to mind might imply a somewhat different attitude than they previously held. For example, suppose that a person has a generally favorable attitude toward Candidate X. When asked to explain why she likes this candidate, however, what comes to mind is that he looked worn and ineffective during a recent debate, and that his position on the death penalty is at variance with her own. What will happen? We have found in several studies that people adopt the attitude implied by their reasons (see Wilson, Dunn, Kraft, and Lisle 1989). Thus, if we asked this person how she felt about Candidate X she would be likely to report a somewhat negative attitude, at least more negative than if she had not focused on why she felt the way she did.

Two important points should be noted about the attitude change that results from analyzing reasons. First, it can be difficult to predict the direction of this change. The kinds of reasons that are available in memory for one person might be primarily negative, leading to change in a negative direction. The reasons that are available to another person might be primarily positive, resulting in change in the opposite direction. We found this to be the case in a recent study of political attitudes (Wilson, Kraft, and Dunn 1989). Subjects who analyzed reasons were more likely to change their attitudes toward political candidates, but this change was not in a common direction. Subjects who listed negative reasons tended to change their attitudes in a negative direction, whereas subjects who listed positive reasons tended to change in a positive direction. (Incidentally, subjects in this study, as in most of the ones we have conducted, were asked to list their reasons privately and anonymously to

¹This work was supported by grant MH41841 from the National Institute of Mental Health.

"organize their thoughts." Subjects believed that no one would ever see what they wrote, which reduces the plausibility of self-presentational or demand characteristic interpretations of the results.)

Second, the attitude change we have observed does not appear to be particularly long lasting. Indeed, it would be rather surprising if a permanent change in people's attitudes could be brought about simply by asking them to explain why they felt the way they did. Instead, over time people's original attitude seems to "snap back." Even though this attitude change is temporary, however, it can be consequential, in at least two respects. First, it can be consequential to researchers who are trying to predict people's behavior from their attitudes. If people report a new attitude that is only temporary, and revert back to their original position shortly thereafter, then this reported attitude will probably be a poor predictor of their behavior. Their behavior will be driven by their original position, at least if enough time has passed to allow this attitude to snap back. Consistent with this argument, Wilson, Dunn, Kraft, and Lisle (1989) reviewed 10 studies that manipulated whether subjects explained their attitudes and assessed the correlation between people's attitudes and behavior. When people did not explain why they felt the way they did, the average attitude-behavior correlation in these studies was .54. When they did explain their attitudes, the average correlation was only .17. Averaging across the studies, this difference was highly reliable. Thus, when people analyze reasons, the attitude they report is not very predictive of their later behavior.

The attitude change resulting from analyzing reasons can also be of some consequence to the person doing the analyzing. Imagine that people have to make a decision, such as a choice between different consumer goods. If they think about why they feel the way they do about each alternative, they might change their minds about which item they prefer, and make a different choice than they would have had they not analyzed reasons. If their initial attitude later snaps back, however, they might come to regret the choice they made. We have obtained results consistent with this hypothesis (Wilson, Lisle, and Schooler 1989). In one study, for example, subjects evaluated five different art posters. Those asked to explain their evaluations changed their minds about which ones they preferred, and chose different ones to take home. When telephoned a few weeks later, however, they were significantly less satisfied with their choice than were subjects who had not analyzed reasons.

Our concern has primarily been with how these processes operate in everyday life, and with the effects they have on attitude change, attitude-behavior consistency, and decision making. It is fairly common to be asked to explain why we feel the way we do about something, such as, "Why do you like or dislike George Bush?" "Why do you prefer this particular brand of laundry detergent?" "Could you explain your reaction to the movie, *Do*

the Right Thing?" Thus, there are some important implications of these processes for everyday kinds of problems.

We have also considered the implications for survey research, which is closer to the topic of this symposium. As far as we can tell it is not all that common to include "why" questions on surveys, but they are sometimes asked. To the extent that they are asked before questions assessing people's attitudes, they might cause problems. Two studies have been conducted to test this hypothesis (Wilson and Pollack 1989). In the first, all students taking introductory psychology at the University of Virginia were given an attitude questionnaire at the beginning of the semester. This questionnaire asked subjects to rate their attitudes toward the death penalty, school busing to achieve racial integration, and a national health insurance, as well several other issues, on 7-point scales.

Several weeks later a random sample of these students were telephoned and asked to participate in an ostensibly unrelated attitude survey. Of the 116 reached by phone, 97% agreed to participate. These subjects were randomly assigned to one of two conditions: In the control condition they were asked the same attitude questions they had completed earlier about the death penalty, busing, and a national health insurance. In the reasons question subjects were first asked to explain why they felt the way they did about an issue. The interviewer said that she would name an issue, and that the first thing she wanted the respondent to do was to "tell me *why* you feel the way you do about it." Subjects then answered the same attitude questions as in the control condition. The order in which the questions were asked was fully counterbalanced in both conditions.

The first question we addressed was whether the reasons manipulation changed subjects' reported attitudes in a common direction. For example, did subjects who first gave reasons become more favorable toward the death penalty, on the average? We did not expect such change to occur. As discussed earlier, the kinds of reasons that came to subjects' minds were likely to be pro for some subjects but anti for others, which would not produce a shift in attitudes in the same direction. This prediction was borne out. The mean attitudes reported in the telephone survey did not differ appreciably from the mean attitudes reported at the beginning of the semester in either condition.

We did expect attitude change to occur in the reasons condition when *bidirectional* shifts are considered. According to our hypothesis some subjects who analyzed reasons brought to mind a set of reasons that were biased in a pro direction for the issues, whereas others brought to mind a set of reasons that were biased in the anti direction, causing attitude change in different directions. If so, then the absolute value of the difference between attitudes at Times 1 and 2 should be greater in the analyze condition. This prediction was confirmed, as seen in Table 1. Though the differences in attitude change between the reasons and control

NOTE: Attitudes were measured on 7-point scales at both times.

conditions were not particularly large, averaged across the three issues these differences were reliable, $p < .05$.

It should be noted that the issues we used in Study 1 were probably not ones that most students had thought much about. In some of our other studies, we have found that there is a class of people who are immune to the effects of analyzing reasons: Those who are especially experienced with or knowledgeable about the attitude issue (Wilson, Kraft, and Dunn 1989). It was not clear from our earlier work, however, exactly why knowledgeable people are unaffected by analyzing reasons. One reason might be that knowledgeable people are more likely to know why they feel the way they do, and thus less likely to bring to mind a biased set of reasons. Another possibility, however, is that knowledgeable people simply have stronger attitudes that are less malleable than are the attitudes of unknowledgeable people.

Attitude strength is a variable that has been addressed in various guises by many attitude researchers. Such variables as attitude accessibility (Fazio 1989), affective-cognitive consistency (Rosenberg 1960), involvement (Sherif 1980), importance (Judd and Krosnick 1988), and conviction (Abelson 1988) have been discussed, but the extent to which these constructs overlap is not entirely clear. The chief purpose of Study 2 was to see which of these measures of attitude strength, if any, moderates the effects of analyzing reasons in a survey.

Study 2 was identical to Study 1, except for the following changes: Subjects participated in an initial session individually, and answered questions about only one attitude issue: How they felt about Ronald Reagan. (This issue was chosen because we

expected there to be more variance in attitude strength on this issue compared to the ones used in Study 1). In addition to giving their overall evaluation of Reagan at this session, subjects also completed a battery of measures of attitude strength, including all of those mentioned in the preceding paragraph. Attitude accessibility was measured with a procedure developed by Fazio, where the latency of subjects' response to an attitude question about Reagan was assessed (the faster the response, the more accessible the attitude). Details of how the other variables were measured can be found in Wilson and Pollack (1989). Several weeks after the initial session subjects participated in a phone survey that was identical to the one used in Study 1, except that only one attitude issue, Reagan, was included. As in Study 1, half of the subjects first explained why they felt the way they did about Reagan, whereas the others did not.

The results of Study 1 were replicated, in that subjects who analyzed reasons showed more bidirectional attitude change than subjects who did not. In this study attitudes were assessed on different scales at Times 1 and 2, thus they were converted to standard scores. The mean absolute value of the Time 2 - Time 1 difference in attitudes was .66 in the reasons condition and .51 in the control condition, a difference that was nearly significant ($p = .06$). Clearly, however, this difference is not particularly large. To see if it was larger for people with weak attitudes, subjects were divided at the median on the various measures of attitude strength that were included at Time 1. The one that moderated the effects of analyzing reasons the most was Fazio's measure of attitude accessibility. To unconfound accessibility and attitude extremity, people were divided into high and

TABLE 2
ABSOLUTE VALUES OF THE DIFFERENCE BETWEEN STANDARDIZED ATTITUDE
RESPONSES TOWARD RONALD REAGAN AT INITIAL SESSION AND TELEPHONE SURVEY
(FROM WILSON AND POLLACK, 1989, STUDY 2)

Variable	Fast Response Time		Slow Response Time	
	Control	Reasons	Control	Reasons
<u>n</u>	43	54	46	48
<u>(sd)</u>	(.53)	(.53)	(.30)	(.72)
<u>M</u>	.64	.62	.39	.71

low accessibility groups via median splits at each level of attitude response at Time 1 (see Fazio and Williams 1986). As seen in Table 2, people with relatively inaccessible attitudes (i.e., slow response times at Time 1) were susceptible to our reasons analysis effect at Time 2, $p = .004$. People who had relatively accessible attitudes (i.e., fast response times) at Time 1 were uninfluenced by analyzing reasons at Time 2. This pattern of findings resulted in a significant Reasons \times Attitude Accessibility interaction, $p = .03$. None of the other measures of attitude strength interacted significantly with the reasons analysis manipulation.

It is not entirely clear why attitude accessibility was the best moderator of the effects of analyzing reasons. One possibility is that if an attitude is highly accessible, it is unlikely that people will bring to mind reasons that are inconsistent with it. People with inaccessible attitudes may be more likely to consider reasons that conflict with their attitude, and as a result are more likely to change their minds after analyzing reasons.

IMPLICATIONS

In some respects, survey researchers might not find the present results very disconcerting. First, asking people why they feel the way they do about an attitude object appears not to be very common. Even if these questions are asked, our findings suggest that they are likely to influence the reported attitudes only of people with relatively inaccessible attitudes. Considered in another light, however, the results may have important implications. Sometimes a substantial proportion of the populace have relatively weak and inaccessible attitudes, such as people's attitudes toward a new, unfamiliar product. Further, sometimes "why" questions are asked on surveys. If they precede questions about people's attitudes, they might well produce momentary attitude change, and make the attitudes less predictive of future behavior. Thus, one clear implication of our findings is that when "why" questions are asked, they should succeed rather than precede attitude measures.

Surveys are not the only place where people are asked to explain their attitudes. It is not that uncommon to be asked by a friend or an acquaintance why we feel the way we do, thus our findings have implications for attitude change and attitude-behavior consistency in everyday life. We have discussed these implications in some detail elsewhere (Wilson in press; Wilson, Dunn, Kraft, and Lisle 1989). Suffice it to say here that there may be times when it is advisable not to spend too much introspecting about our reasons when trying to determine how we feel about something. This argument is compatible with a recent model proposed by Feldman and Lynch (1988), who suggested that "momentarily activated cognitions have disproportionate influence over judgments made about an object or on related behaviors performed shortly after their activation" (p. 421).

The Influence of Survey Format on Judgment Processes: The Case of Ideals and Perceived Similarity

Jack M. Feldman, Georgia Institute of Technology
Scott Wesley, Georgia Institute of Technology
Micael Hein, Georgia Institute of Technology
Ann Gilmore, Georgia Institute of Technology¹

Survey question format and order effects were studied in a similarity judgment context. It was expected that a series of questions requiring comparison of an object to a category ideal would cause the construction of the ideal if none existed and if overall evaluation was insufficiently diagnostic for the judgment. When questions about the attributes of an ideal were asked *before* an overall similarity judgment, a familiar asymmetry occurred: object-ideal comparisons yielded higher similarity ratings than ideal-object judgments (Tversky, 1977). With the overall rating first, the asymmetry was reversed. Object-specific and question format effects also occurred, qualifying our conclusions.

This study explores the effect of survey formats on judgment in the context of two theoretical domains: the perception of similarity (Tversky, 1977) and the concepts of value lability and response construction (Feldman and Lynch, 1988; Fischhoff, Slovic and Lichtenstein, 1980). It tests the hypothesis that variations in the format and ordering of survey questions will have predictable effects on judgments of similarity between an object or person and some hypothetical ideal, a judgment often used to evaluate the object or person in question.

The concept of the "ideal" occurs frequently in theories of attitude and satisfaction. Johnson (1971), for instance, proposed that consumers have an "ideal point" referent in some product space, and evaluate specific products in terms of their distance from that point. The product space itself is formed by product attribute dimensions (e.g., taste, price, etc.). Likewise, Locke's (1976) theory of job satisfaction proposes that one's liking for a job is determined by the perceived differences between the job itself and the job's "ideal" position on each of a set of dimensions (e.g., pay, responsibility). One widely used job satisfaction instrument (Porter, 1962) is cast in an explicitly comparative format, requiring ratings of a job's current outcome levels and the levels of those outcomes that "should" exist. In a more abstract realm Barsalou (1987) has shown that categories may be represented by, and constructed in terms of, "ideals" formed by goal-relevant properties of objects. While Barsalou's "ad hoc" categories are heterogeneous (e.g., "foods to eat on a diet"), it is not difficult to think of categories that are more homogeneous and which

may be represented by a concrete ideal (e.g., "sports cars").

The measurement models above (Johnson, 1971; Porter, 1962) implicitly assume that some ideal representation like those demonstrated by Barsalou exists within the domain of interest. This assumption may, however, be questionable. Fischhoff, et al. (1980) have discussed the concept of "value lability," making the point that people do not have well articulated values in many domains. Without a highly elaborated value structure the nature and form of questioning may in fact influence the representation of issues and concepts (Feldman and Lynch, 1988). In keeping with the principle of cognitive economy (Srull and Wyer, 1989), we assume that the judgments and associations composing a value structure are not formed in the absence of some processing goal or motive. When a motive exists, a judgment is formed based on accessible resources, according to a satisficing criterion. That is, no more elaboration is carried out than is necessary to meet a current processing demand.

Thus, in the absence of environmental contingencies (such as those provided by a particular cultural or interpersonal environment; see Triandis, 1989), it is unlikely that a highly elaborated system of beliefs (including concepts of dimensions and categories of objects) will be formed. This reasoning is consistent with the apparent absence of common ideologies in the survey research literature (e.g., Bishop, Oldendick, Tuchfarber and Bennett 1980; Schuman and Presser, 1980) and with context-dependence in the form of category representation and structure (Barsalou 1987). Only in the case of expertise (Alba and Hutchinson, 1987) and/or long-term, continuing involvement in a domain (Feldman and Lynch, 1988) would we expect to find elaborated, accessible ideal representations within a given domain. Without such representations, the act of responding to survey questionnaires of a particular form (e.g., "How far do you have to reach to adjust your car's air conditioning?" "How far *should* you have to reach?") may stimulate the creation of an ideal and its use in evaluating the object in question. This is a precondition for the phenomenon Feldman and Lynch (1988) have termed *self-generated validity*, in which the measurement operations themselves create judgment processes that seem to confirm the theory being tested.

The hypothesis that measurement operations may cause the creation of ideal representations where none had previously existed may be tested in the domain of similarity judgment, by taking advantage of a phenomenon noted by Tversky (1977).

¹Thanks are due to John Lynch for his many helpful comments.

Tversky's feature comparison model predicts asymmetrical judgments of similarity as a function of the phrasing of a comparison. In his model, the more prototypical or salient (prominent and highly elaborated) object has a larger number of accessible features than a less prototypical or salient object. In a similarity judgment more attention is directed to the features of the subject of the comparison than to the referent object. The judgment of similarity itself depends on the number of common and distinctive features of the two objects, with greater weight given to the features of the subject.

If the subject of the judgment has most of its known features in common with a more elaborated referent, it will be judged to be similar even if the referent has many features not shared by the subject. This is normally the case with category member-prototype judgments (e.g., "How similar is Poland to the USSR?"). If the order of comparison is reversed, the more elaborated object becoming the subject of the judgment, judged similarity is lower because the form of the question directs attention to the relatively large number of distinctive features of the (prototypical) subject. Thus, "How similar is the USSR to Poland?" elicits a lower judgment than does the former order.

By extension, judgments of similarity between elaborated ideal category representations and specific category members should be made in the same fashion. That is, the rated similarity between a category member and the category's ideal representation ought to be higher than the rating of similarity between the ideal and the category member.

It is important to note, however, that this prediction depends entirely on the assumptions that the ideal *exists* and that its cognitive representation *is* more elaborated than that of the object in question. For judgments in some domains, the reverse may be true.

In a variety of domains (e.g., automobiles), people may lack the knowledge or motivation necessary to form an ideal. They may, however, have constructed a relatively elaborated representation of their own possessions, either because these are an important component of the self-concept (Belk, 1988) or because daily experience and outcome dependence motivates one's construction, as occurs in the domain of person perception (Brewer, 1988; Feldman, 1988).

Thus, it is entirely plausible that under many circumstances peoples' representations of individual objects and persons are more elaborate and detailed than the corresponding category representations. Tversky's (1977) logic should dictate that, under these circumstances, a representation - exemplar comparison should yield *higher* similarity ratings than an exemplar - representation judgment, the reverse of the usual finding. If, however, the process of measurement caused the construction of a representation, by asking for ratings of the attributes an ideal category member *should* have, the usual finding would be obtained. We also expect that asking questions that specifically direct

attention to the component attributes of an ideal category representation would produce the effect more strongly than questions calling for a simple similarity judgment between the object and the ideal on the same set of attributes. The latter questions may be answered by accessing an overall evaluation of the object, without the construction of an ideal level on each attribute (Feldman and Lynch, 1988).

METHOD

Subjects

Subjects were 181 male and female students enrolled in one of four sections of introductory social or industrial psychology at a major Southeastern university. Student participation was voluntary, in exchange for course credit.

Stimulus Materials

Objects. It was decided that classroom instructors would be useful comparison objects for an exploratory study. First, classroom teacher evaluations are a near-ubiquitous form of survey, and so are of interest in their own right. Second, because of frequent interaction and outcome dependence, students are likely to form individualized or personalized representations of classroom instructors. Third, by including two instructors, each of whom taught two sections of different courses, some degree of generality could be established. Fourth, our objective in this study is to demonstrate the occurrence of a particular, hypothetical judgment process. It was felt that if the hypothesized effects did not occur in the person domain, where individualized or personalized representations seem most generally likely, they would probably not occur in nonsocial object domains (where values and involvement differ more widely across persons).

Questionnaire design. Questionnaire contents were developed using a set of behaviors from the university's standard instructor evaluation form. This form includes behaviors in several domains (e.g., "uses real-world cases to illustrate principles") and requires a Likert-type rating. For the present study, each behavior was cast into one of two forms:

- a. A similarity judgment form, requiring a rating of similarity between the present (classroom) instructor and one's ideal instructor *on that specific behavior*.
- b. An "Is-Should Be" form similar to Porter's (1962), requiring the student to rate the frequency of the behavior as performed by their instructor and as ideally performed. Twenty-one behaviors were included.

Each questionnaire also required an overall similarity rating, which was placed either before or after the 21 behavior ratings. This question required either a rating of the similarity between the present instructor and one's ideal instructor, or between one's ideal instructor and the present instructor. All

ratings were made on 20 point scales anchored by 1 (= "Not at all similar") and 20 (= "As similar as possible.")

For half the subjects, attribute (behavioral) similarity judgments were made on the same scale. For the remaining subjects, behavioral frequency (Is - Should Be) judgments were anchored by "Never" (= 1) and "Always" (= 20). Behavior ratings were always made in an order matching that of the overall similarity judgment, that is in terms of present instructor-ideal or ideal-present instructor comparisons. Additionally, when the comparison was present instructor-ideal, subjects were instructed to think of the present instructor and form a clear image of that person; when the comparison was ideal-present instructor, subjects were instructed to think of their ideal instructor in the same way.

Design and Procedures

The design was a completely crossed four-factor between subjects factorial. Manipulated variables were:

1. Comparison order (Instructor-Ideal Vs. Ideal-Instructor), intended to create asymmetrical similarity judgments.
2. Order of Global Rating (overall similarity first vs. last), intended to influence the timing of elaboration of an ideal and thus influence the direction of asymmetry in the overall similarity judgments.
3. Behavior rating Format (Similarity vs. Is - Should Be), intended to influence the relative degree of elaboration of the ideal and, thus, the relative size of the predicted asymmetry - reversal effect.
4. Instructor (Instructor 1 vs. Instructor 2), intended to increase the generality of results.

Overall similarity ratings were the dependent variable of interest.

Subjects participated in their regular classrooms, during ordinary class hours. The second, third, and fourth authors served as experimenters, presenting the study as one of judgment and evaluation processes. After a brief introduction and signing of informed consent forms, one of eight questionnaire forms was distributed at random to each participant. Participants were not told that different forms were being used. The purpose and results of the study were explained during a later class session.

RESULTS

A 2x2x2x2 ANOVA on overall similarity ratings produced the effects shown in Table 1. A main effect of Instructor accounted for 9% of the explained variance; Instructor 1 was seen as more similar to the ideal (across both comparison orders) than was Instructor 2 ($X_1 = 13.73$; $X_2 = 11.09$).

There was also a main effect for Order of Rating; rating overall similarity before any behavioral ratings resulted in lower perceived similarity than rating overall similarity after the behavioral ratings (X before = 12.09; X after = 13.54).

These effects must be considered, however, in light of the significant four-way interaction. As shown in Table 2, the effects of Order of Rating and Comparison Order differed by both Instructor and Format. For Instructor 1, ratings on the Similarity format produced no effects of rating or comparison order. The "Is-Should Be" format produced the expected pattern of ratings, however. Global similarity comparisons between the instructor and the "ideal instructor" reversed Tversky's (1977) findings when global ratings were made prior to behavior ratings (ideal/object > object/ideal), while the usual ordering (ideal/object < object/ideal) was found when global ratings were made subsequent to behavior ratings. The differences, however, did not reach conventional significance levels.

Stronger effects were observed for Instructor 2. The predicted pattern was obtained most strongly when behavior ratings were made using the similarity format. Slope differences between Order of Rating conditions are significant ($p < .05$). The "Is-Should Be" format produced a similar pattern, complicated by a higher global similarity rating in the "global rating-last" condition.

DISCUSSION

Support for the hypotheses stated earlier can be described as "moderate but encouraging." Both significant reversals and replications of Tversky's (1977) similarity judgment results were found as a result of question order and format manipulations designed to change the relative degree of elaboration of category representations vs. category members. That is, answering questions likely to cause the formation of an elaborated ideal representation led to higher overall similarity judgments when the judgments were phrased in the "object to representation" order than in the "representation to object" order. When, however, it was likely that the object was the more elaborated of the two (prior to answering the same questions), the reverse was obtained.

The results are complicated, however, by the failure to obtain differences in one instructor/format combination and the weak effects in two others. These results can, we believe, be explained by the relative accessibility and diagnosticity of overall evaluations. As discussed by Feldman and Lynch (1988), summary judgments tend to be highly accessible and, while not as diagnostic as specific judgments, may often be sufficient for the question at hand. Therefore, they are likely to be used when specific judgments are less accessible. In the present case, Instructor 1 was the more highly evaluated of the two (Instructor 2's overall similarity to the ideal being close to the scale midpoint). The more polarized affect toward Instructor 1 may have been sufficiently diagnostic for all judgments of ideal-object similarity; thus, the effect of the

TABLE 2
INTERACTION OF COMPARISON ORDER, ORDER OF RATING, SCALE FORMAT AND INSTRUCTOR

Instructor	Comparison Order:	Order of Rating			
		Global	First	Global	Last
		Ideal-Instructor	Instructor-Ideal	Ideal-Instructor	Instructor-Ideal
	<u>Scale format</u>				
Instructor 1	Similarity scale	13.56	13.38	14.88	13.33
	"Is-Should Be" scale	14.00	12.33	13.42	14.69
Instructor 2	Similarity scale	10.63	7.50	9.14	13.13
	"Is-Should Be" scale	10.75	10.20	13.13	14.25

Note: All numbers rounded to two decimal places.

similarity judgment format on the construction of an ideal would be nullified. The "Is-Should Be" format may constitute a stronger manipulation, but still not strong enough to completely overcome the greater accessibility of Instructor 1's overall evaluation. Instructor 2's overall evaluation, being more

moderate, would be less diagnostic; thus, a judgment construction process would take place as hypothesized. The less supportive results obtained using the "Is-Should Be" format may be explained by affective polarization (Tesser, 1978) produced by rehearsal in the "global rating last" condition.

Interestingly, the ratings of Instructors 1 and 2 in the "global rating last" condition of the "Is-Should Be" format are virtually identical.

This explanation is, admittedly, highly speculative. It does, however, permit unambiguous tests. For example, it predicts that over a set of objects varying in initial polarization, the size of any order of questioning effects should be negatively correlated with the absolute value of the initial polarization. Furthermore, because an ideal is not expected to be constructed when a highly polarized evaluative *object* judgment already exists, we would expect that response times to questions about the attributes of a category ideal would be longer following responses to a series of "similarity to ideal" questions about a highly polarized object than following the same questions about a more moderately evaluated object. We would also expect to find greater increases in attitude accessibility for moderately evaluated objects following questions in an "Is-Should Be" format than following questions in a straightforward similarity judgment format.

Given the qualifications above, these results are consistent with Tversky's (1977) feature-matching model of similarity judgment, and with Barsalou's (1987) concepts of category flexibility and context dependence. They further demonstrate that "ideal points" cannot be assumed to exist in every domain, contrary to earlier assumptions. Even people with substantial experience in a domain, such as college students have with instructors, may not have devoted the time and effort required to create an ideal representation. Just as the typical voter may lack a coherent political ideology and corresponding "ideal" representations of congressmen, presidents, governors, etc., so might the typical consumer lack the "implicit theories" of products such as automobiles, cameras, beers, or breakfast cereals necessary to the existence of context-independent, coherent categories and category representations (Alba and Hutchinson, 1987; Barsalou, 1987; Murphy and Medin, 1985). Without such representations, survey research guided by content models of motivation or value (as Porter's 1962 instrument was guided by Maslow's need hierarchy) may, in fact, cause the construction of ideals different from those that would otherwise have been generated. This phenomenon may have three alternative (and equally undesirable) effects:

1. Under low-involvement, "peripheral" processing conditions (Petty & Cacioppo, 1986), responses to surveys may be constructed which are unrelated to attitudes and behaviors generated later in a different context.
2. Summary judgments stored in memory may guide immediate behavior, such as voting or product choice, in a direction influenced by scale contents but contrary to other values of the respondent momentarily less accessible. The

individual may later come to regret his or her decision.

3. The individual's representation of the issue or the domain may be more or less permanently influenced by the questioning process and subsequent elaboration, producing change in values at least partially due to questioning procedures (Feldman and Lynch, 1988; Fischhoff et al., 1980; see also Lynch, Chakravarti and Mitra, 1989, for a discussion of similar effects in a different theoretical domain.)

The first of these is a methodological problem; the second and third are both methodological and ethical in nature. Both kinds of issues are best addressed by the development of methods for, first, diagnosing the presence or absence of an elaborated ideal representation and, second, developing questioning procedures that elicit multiple perspectives about a given object or issue. As Fischhoff, et al. (1980) have argued, these procedures both provide more ecologically valid responses and benefit the respondent.

Measuring and Modeling Brand Interest as an Alternative Aad Effect with Familiar Brands

Karen A. Machleit, University of Cincinnati
Thomas J. Madden, University of South Carolina
Chris T. Allen, University of Cincinnati

ABSTRACT

This study develops a measure for a new construct, brand interest, and reports exploratory modeling with the construct in a traditional Aad modeling context. The four-item brand interest scale evidences unidimensionality and discriminant validity. Structural equation modeling suggests that affecting brand interest may be a meaningful advertising objective for familiar brands.

INTRODUCTION

Since the early 1980s, many studies have demonstrated an association between attitude toward the ad (Aad) and brand attitude (e.g., Batra and Ray 1986; Edell and Burke 1986, 1989; Gardner 1985; MacKenzie, Lutz and Belch 1986; Mitchell and Olson 1981; Stayman and Aaker 1988). However, a common feature which limits the generalizability of these empirical studies is their focus on unfamiliar or hypothetical brands. On a practical level, while many new brands are continually being introduced, companies depend on mature, familiar brands for a stable base of sales. In addition, these familiar brands often utilize emotional appeals in their ads, and thus may evoke positive feelings or Aad on the part of the viewer.

It is not surprising to find that Aad affects brand attitude when the individual is unfamiliar with the brand; in this instance, the advertisement is the only basis for brand evaluation. Indeed, preliminary empirical evidence indicates that the effect of Aad on brand attitude may be important only for unfamiliar brands. For example, Gresham and Shimp (1985) found significant Aad effects on brand attitude (Ab) for only six of fifteen familiar brands, Edell and Burke (1986) found weaker Aad effects on Ab for familiar brands, and Machleit and Wilson (1988) report non-significant effects of Aad on Ab for two familiar brands.

Given it is expected that Aad will have limited effects on brand attitude for familiar consumers, additional research is needed to address the question of what happens when a consumer is exposed to an ad for a brand with which s/he is already familiar. To expect that exposure to a few ads for a brand will change brand attitude for an experienced consumer seems ambitious. It is known that attitudes of experienced individuals are typically "well-formed" and are resistant to change (cf. Fazio and Zanna 1981), and would be more likely to be affected by additional experience rather than exposure to advertising (Smith and Swinyard 1982, 1988). Thus, to consider brand attitude as the only direct effect or consequence of ad-induced emotion or Aad is limiting. For familiar brands in particular, our understanding of how advertising "works" will

need to move beyond the outcome variables traditionally examined in this research stream.

The purpose of this study is to propose and examine an additional "effect" or outcome of advertising exposure that may be affected by Aad. While research has focused on many antecedents of Aad (e.g., MacKenzie and Lutz 1989), the outcome variables examined have been limited to cognitive-structure variables such as brand cognitions (MacKenzie, Lutz, and Belch 1986), brand attribute evaluations (Burke and Edell 1989), brand attitude, and purchase intentions; all these variables are likely to be very difficult to change with familiar brands.

We propose the construct "brand interest" as an additional outcome variable. Brand interest is defined as the level of interest or intrigue the consumer has in the brand and the level of curiosity s/he has to inquire or learn more about the brand. Unlike attitude, brand interest is not a cognitive evaluation of the brand. Moreover, brand interest may be viewed as a "pre-attitudinal" construct which, when acted upon, may facilitate attitude development or change. For example, a high level of brand interest may lead the consumer to search for more brand-related information or try the brand. For familiar brands, a high level of brand interest may lead the consumer to try the brand *again* and re-evaluate his/her beliefs; as a result, brand attitude might shift (Smith and Swinyard 1988). Indeed, for uninvolved, familiar brands, generating a level of brand interest through advertising that is high enough to lead to a "re-trial" may be the most effective means of attitude change, and thus a primary objective for the advertiser.

Sustaining and/or reviving interest may be particularly challenging for familiar stimuli (Berlyne 1960; Faison 1977). As Pessemer and Handelsman (1984) conclude, familiarity can lead to variety seeking and varied purchase behavior. When the individual desires the satisfying aspects of variety, alternation among familiar brands within a set is often exhibited as a choice behavior. McAlister and Pessemer (1982) review experiments on switching tendencies and note that among somewhat familiar elements within a favored subset of stimuli, subjects' liking increased with additional exposure to the stimuli, although boredom also increased with additional exposure. By alternating among the familiar stimuli, subjects could balance the liking and the boredom.

In the situation where there are various familiar brands to choose among within a product category, the brands constantly fight the consumer's inherent desire for novelty and varied brand purchases. It is this case in particular where increasing and sustaining brand interest should be

critical for the advertiser. Additionally, it is likely that emotionally-oriented ad executions will have an impact on brand interest in this situation; for example, the positive feelings created by an ad could revive the intrigue or interest in the brand.

The question of how ad-produced feelings and Aad affect brand interest and brand attitude for familiar brands is what motivates this study. As a new construct, "brand interest" needs an empirical indicator before it can be integrated into the Aad research stream. Thus, we begin with a scale development exercise for the brand interest construct. We then present some exploratory modeling designed to illustrate the importance of considering brand interest as an alternative outcome of advertisement exposure.

METHODOLOGY

Procedure

Subjects participated in a study which was described as an evaluation of advertising campaigns. A videotape was prepared which included four different ad campaigns of three commercials each. Two campaigns were selected as the test campaigns-- Central Trust Bank (a large local bank), and Lowenbrau beer. The Central Trust campaign included humorous portrayals of the problems that one can run into with banking services. The Lowenbrau campaign included three of the emotional, "Here's to good friends" ads. Central Trust Bank and Lowenbrau beer were selected since the subjects should have at least some familiarity with both. In addition, purchasing a brand of beer versus deciding on banking services represented considerable diversity in decision making processes, thereby providing the opportunity to examine the brand interest construct in two very different contexts.

One hundred two undergraduate marketing students were exposed to the videotape during the regular class sessions of two different courses. Questionnaires were distributed after the completion of the 10 minute videotape. Half of the randomly-distributed questionnaires included the measures for Central Trust Bank as the first set of questions, while in the other half the measures for Lowenbrau came first. Thus, all subjects completed the measures for both of the test campaigns.

Measurement

The questionnaire began with the brand interest measure followed by measures of positive and negative affect, and ad evaluation, for one of the ads in the Central Trust/Lowenbrau campaigns. These measures were followed by several "filler" questions (e.g., What is the best advertising campaign you have ever seen?, Why was it your all time favorite?). The filler questions were included to reduce consistency biases on the focal measures. Finally, the subject completed brand attitude and purchase intention scales.

With the exception of the newly developed brand interest scale (discussed below), all measures

are consistent with those used in previous research. Positive/negative affect and ad evaluation were measured with the scales provided by Madden, Allen and Twible (1988). The coefficient alpha value for the positive affect measure (good, cheerful, pleased, stimulated, soothed) was .91 for Central Trust and .95 for Lowenbrau. For negative affect (insulted, irritated, repulsed), alpha values were .86 (Central Trust) and .90 (Lowenbrau). Coefficient alpha values for ad evaluation (pleasant/unpleasant, likeable/unlikeable, interesting/boring, tasteful/tasteless, artful/artless, good/bad) were .89 for Central Trust and .92 for Lowenbrau.

Brand attitude was measured with three semantic-differential items: good/bad, unfavorable/favorable, poor/excellent. The coefficient alpha values for this scale were .93 for both Central Trust and for Lowenbrau. Purchase intention was also measured with a semantic-differential scale that included the items likely/unlikely, improbable/probable, and possible/impossible with alpha values of .90 and .91 for Central Trust and Lowenbrau, respectively.

RESULTS

The Brand Interest Measure

Eleven Likert-type scale items were generated for measuring the brand interest construct (see Table 1). The items were designed to capture the curiosity that individuals have about the brand, and their interest in learning more about the brand. In addition, several of the items assessed interest in the brand that may have been influenced by specific ad exposure.

Exploratory factor analysis. Principal components analysis for both Central Trust and Lowenbrau each resulted in a two-factor solution with all scale items loading on one factor except item number 1. A principal axis factor analysis with varimax rotation produced a slightly different result. For Central Trust, two factors emerged; the second factor included scale items number 3, 6, and 11 in addition to number 1. In the same analysis for Lowenbrau, a communality of a variable exceeded 1.0, thus terminating the factor extraction. Note that for Central Trust, the three additional items loading on the second factor (see items 3, 6, and 11 in Table 1) are the ones that reflect the ability of specific ads to create some interest in the brand, rather than the general level of interest the individual has in the brand. It appears as though two "forms" of brand interest may exist: one which is the level of interest that the familiar consumer has at any point in time, and another which is "ad-induced," and represents the impact of specific ads in altering brand interest. Depending on the research context, the more specific "ad-induced" brand interest factor might be relevant to the researcher. However, here we examine further the more general brand interest factor.

Confirmatory factor analysis. Given the above exploratory analysis, seven of the eleven items were retained for confirmatory testing (items

TABLE 1
Original Brand Interest Scale Items

1. I am apathetic about _____.
2. _____ is an interesting (include name of product category).
3. These ads left me wanting to learn more about _____.
4. I see nothing really novel about _____.
5. I'd like to know more about _____.
6. These ads made _____ seem interesting.
7. _____ strikes me as dull.
8. Learning more about _____ would be useless.
9. I am intrigued by _____.
10. I'm a little curious about _____.
11. The advertiser succeeded in increasing my interest in _____.

TABLE 2
Maximum Likelihood Factor Loadings

Scale Item	Central Trust	Lowenbrau
I'd like to know more about _____.	.904	.794
Learning more about _____ would be useless.	.549	.760
I am intrigued by _____.	.727	.855
I'm a little curious about _____.	.865	.854

1, 3, 6, and 11 were eliminated). The seven items were evaluated with standard LISREL fit criteria as well as the criteria for discriminant validity (Dillon and Goldstein 1984; Fornell and Larcker 1981). Two additional scale items (4 and 7) were removed from the scale to improve the fit of the factor model. At this point, fit indices of the five remaining scale items were excellent. However, in tests of discriminant validity between brand interest and brand attitude, item number 2 of the brand interest scale had high normalized residuals with the brand attitude scale items. Indeed, by examining the wording of item 2, it appears that the respondent was being asked to make more of an evaluative judgment about the brand (consistent with the brand attitude measure) rather than making an assessment of his/her level of brand interest. Thus, item number 2 was also eliminated and the final brand interest scale was refined to include the four items shown in Table 2.

The fit values from the confirmatory analysis appear in Table 3. All of the values for Central Trust indicate an excellent fit of the four item scale to the data; the chi-square value is nonsignificant and the goodness of fit indices are very high. Additionally, the average variance extracted value is

greater than the .50 rule of thumb (Dillon and Goldstein 1984), and the coefficient alpha value for Central Trust is well within an acceptable range.

For Lowenbrau, all fit indices are within acceptable ranges with the exception of the adjusted goodness of fit index (AGFI). However, the high average variance extracted values, the high factor loadings (Table 2), and the high coefficient alpha values (Table 3), all indicate that this four item scale is internally consistent and reliable for both Central Trust and Lowenbrau.

Discriminant validity. To be construct valid (Peter 1981), the brand interest measure must show discriminant validity from other more traditional measures. Here we examine measures of brand attitude, purchase intentions, positive affect, negative affect, and ad evaluation for evidence of discrimination from brand interest.

Table 4 reports the discriminant validity checks. Consistent with the rules of thumb provided by Dillon and Goldstein (1984), the average variance extracted values are all greater than .50 and, most importantly, are all greater than the squared structural link between the pairs of constructs. This analysis provides strong support for the discriminant validity of the brand interest measure.

TABLE 3
Confirmatory Factor Analysis -- Four Item Brand Interest Measure

	chi-square	GFI	AGFI	RMSR	Av. Var. Extracted	Coeff. Alpha
Central Trust	1.25, p=.53	.99	.94	.026	.60	.82
Lowenbrau	5.65, p=.06	.95	.74	.038	.67	.87

TABLE 4
Discriminant Validity

	Average Variance Extracted	Squared Structural Link
Central Trust	Brand Interest/Brand Attitude .53 .81	.39
	Brand Interest/Purchase Intention .55 .75	.10
	Brand Interest/Positive Affect .53 .69	.04
	Brand Interest/Negative Affect .53 .68	.02
	Brand Interest/Ad Evaluation .55 .65	.12
Lowenbrau	Brand Interest/Brand Attitude .63 .83	.57
	Brand Interest/Purchase Intention .63 .80	.09
	Brand Interest/Positive Affect .63 .77	.32
	Brand Interest/Negative Affect .63 .80	.16
	Brand Interest/Ad Evaluation .63 .80	.30

Exploratory Modeling

Structural equation modeling was used to explore the relationships among affective responses to the ad (positive affect, negative affect, and ad evaluation), and brand interest, brand attitude, and purchase intentions. The model which was tested is shown in Figure 1. Note that this model includes the traditional links between positive affect, negative affect, ad evaluation and brand attitude, in addition to the brand attitude/purchase intention link. Brand interest is modeled as a potential mediator of ad exposure with effects on brand attitude and purchase intention.

Figures 2 and 3 present only the statistically significant model parameters for Central Trust and Lowenbrau. The models for Central Trust (chi-square=3.87, d.f.=3, p=.28; GFI=.99; AGFI=.91; RMSR=.03) and Lowenbrau (chi-square=.52, d.f.=3, p=.92; GFI=.99; AGFI=.99; RMSR=.01) fit the data extremely well. Note in Figures 2 and 3 that the affective responses to the ad have significant effects on brand interest and not on brand attitude. Here, brand interest appears to be mediating the effect of the Aad variables on brand attitude.

To compare the model in Figure 1 to a more traditional Aad network, an alternative model was

FIGURE 1
Structural Model

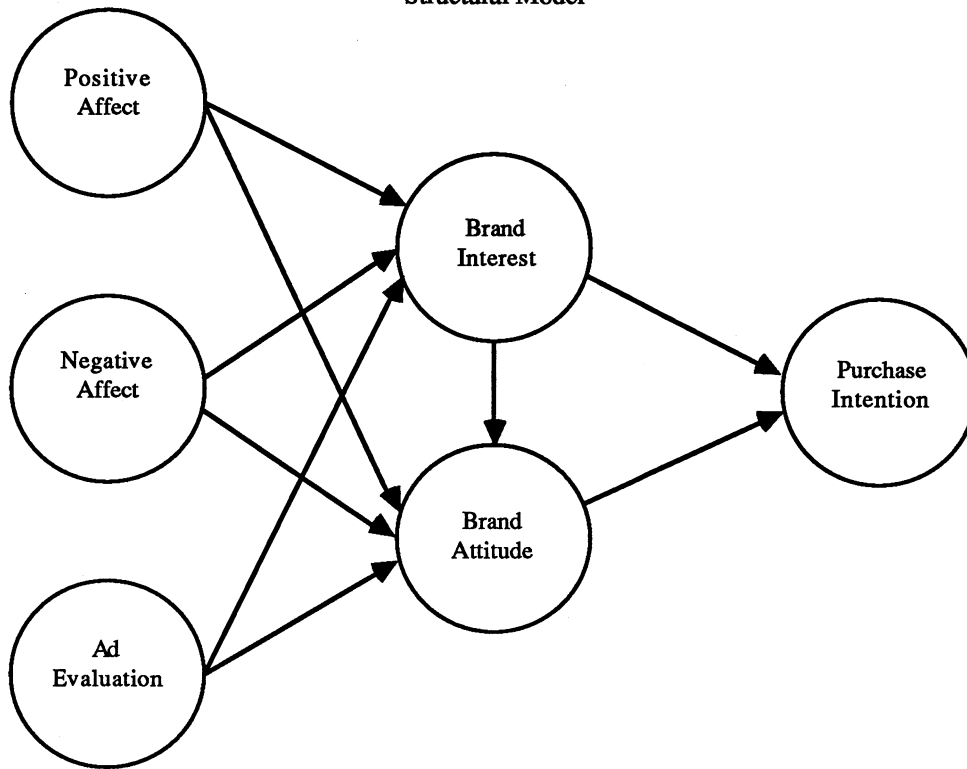

FIGURE 2
Structural Coefficients -- Central Trust Bank

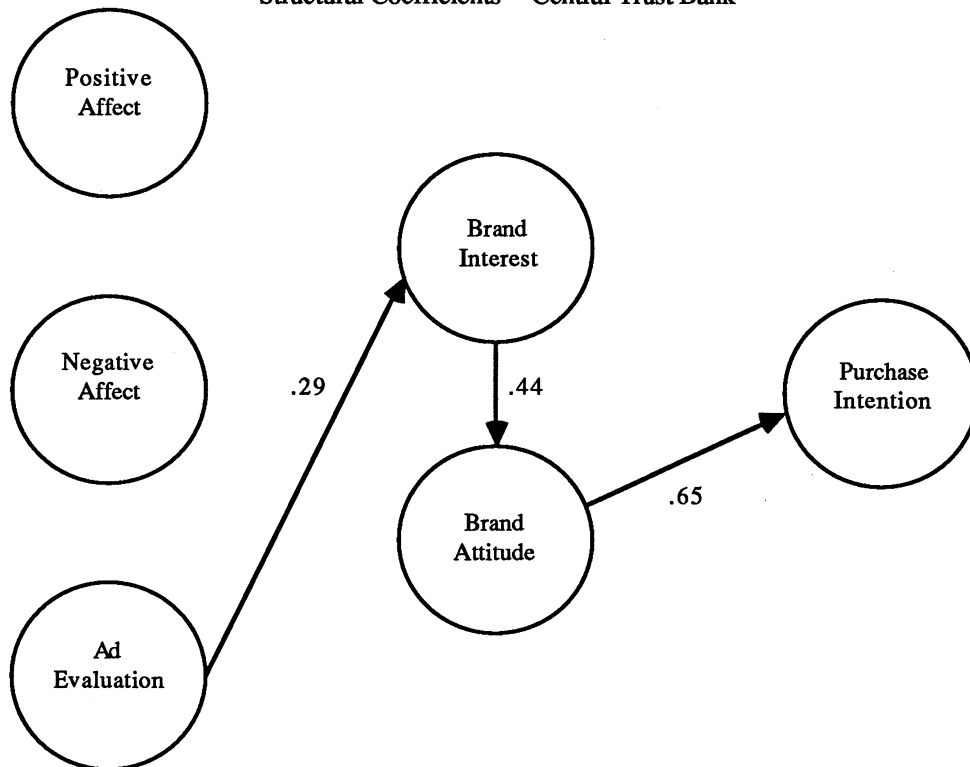

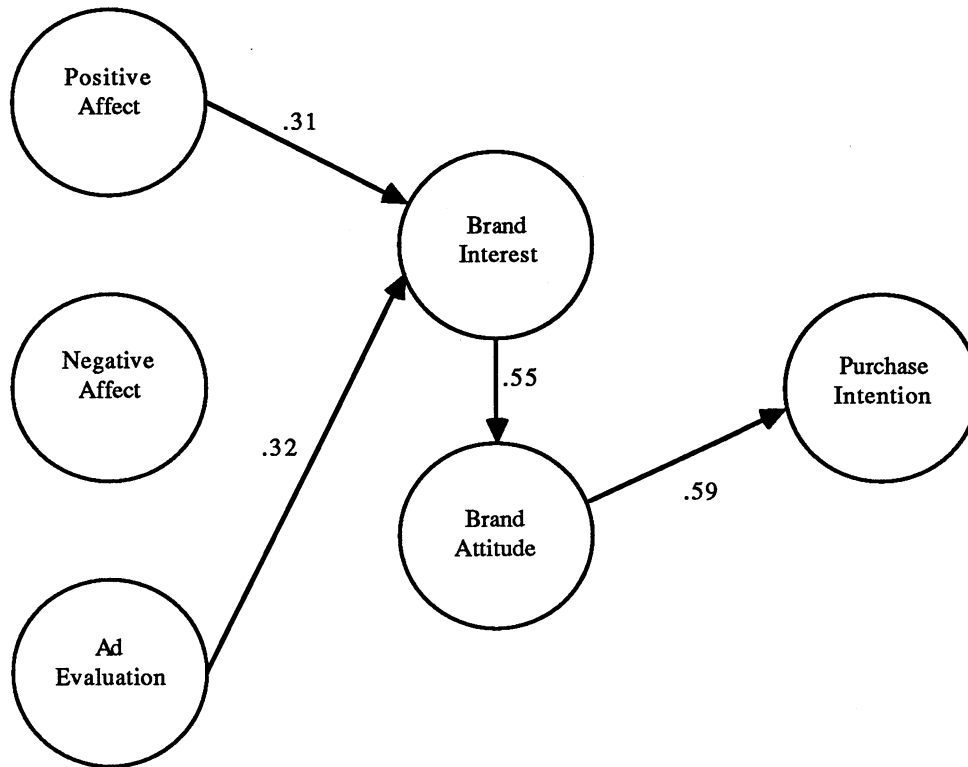

FIGURE 3
Structural Coefficients -- Lowenbrau Beer

also tested. This alternative was identical to that in Figure 1 except the brand interest construct and all corresponding links were excluded from the analysis. As a result, positive affect, negative affect, and ad evaluation all had direct links to brand attitude which, in turn, had a direct link to purchase intention. This alternate model also fit the data well for both Central Trust (chi-square=4.0, d.f.=3, $p=.262$; GFI=.98; AGFI=.92; RMSR=.03) and Lowenbrau (chi-square=.32, d.f.=3, $p=.96$; GFI=.99; AGFI=.99; RMSR=.009). For Central Trust, both positive affect and ad evaluation had significant effects on brand attitude (coefficients of .20 and .28, respectively). For Lowenbrau, only positive affect had a significant link to brand attitude (.36).

DISCUSSION

The findings of nonsignificant direct Aad effects on brand attitude (as illustrated in Figures 2 and 3) implicate the mediating potential of the brand interest construct; however, an important caution must be noted in the interpretation of this modeling. Brand interest is modeled as directly affecting brand attitude, and acting as a mediator between Aad and Ab. However, the way in which brand interest and brand attitude are related is really an open issue. For example, a heightened level of brand interest may lead to a "re-trial" of the brand, followed by a shift in attitude. In such a case, brand interest should not

be modeled as having a direct effect on brand attitude. Obviously, empirical assessment of such a process would require longitudinal data collection to disentangle the specific manner in which brand interest may ultimately impact brand attitude.

Whether Aad directly influences brand attitude for well-known brands remains an open question. The significant, direct effects of the Aad variables on brand attitudes in the alternative models is not consistent with previous studies which have shown little relationship between Aad and brand attitude for familiar brands. However, after checking familiarity levels of our subjects, we found that many were not very familiar with Central Trust and/or Lowenbrau. Familiarity was measured on a 1-7 semantic-differential scale (1=unfamiliar); mean familiarity ratings were 4.4 for Central Trust and 5.2 for Lowenbrau. Furthermore, a sizeable number of subjects were unfamiliar with the brands: 39% of the subjects had a familiarity rating of 3 or below for Central Trust, and 28% of the subjects rated Lowenbrau at a level of 3 or below. While this range of familiarity levels was desirable for developing the brand interest measure, it does not allow us to examine brand interest's role as a mediator for uniformly well-known brands, where one would expect the direct Aad/Ab relationship to be nonsignificant. Thus, a key research question remains: will brand interest serve as a mediator of advertising effects for highly-familiar brands?

Additional research is needed to resolve this important issue.

Examining various consequences of changes in brand interest can also provide interesting research opportunities. It might be expected that heightening a consumer's brand interest for a familiar brand would lead to "re-trial" of that brand; thus, one would predict that brand interest might have some direct influence on purchase intentions. However, as shown by Figures 2 and 3, the model coefficients for a brand interest effect on purchase intentions are nonsignificant. These nonsignificant parameters may have resulted from the way in which the purchase intention construct was operationalized. For Central Trust, the respondent was asked the likelihood that s/he would open a new savings account with the bank. For Lowenbrau, the respondent was asked how likely s/he would be to purchase Lowenbrau to serve at a party. Since these intention measures represent a stronger purchase commitment than simple "re-trial" of a brand, it is not surprising that the brand interest/purchase intention links are nonsignificant. Research is thus needed to evaluate brand interest effects on specific measures of "trial intention." Indeed, examining the consequences of brand interest on constructs other than brand attitude may provide a more realistic picture of the effects of advertising exposure. For example, a temporary shift in brand interest due to ad exposure may also result in changes in variables such as variety seeking tendencies, and evoked set sizes, that are less "enduring" than attitude. The consequences examined in the Aad research stream should be expanded beyond brand attitude, especially when one is attempting to understand how advertising works for mature, well-known brands.

In sum, the brand interest construct may foster research on advertising's effect for familiar brands. Research challenges await in discovering the antecedents and consequences of shifts in brand interest. By developing a scale and illustrating the relevance of the construct, this study provides a foundation for such a research program.

The Elaboration Likelihood Model (ELM): Replications, Extensions and Some Conflicting Findings

Catherine Cole, University of Iowa

Suzanne Reinke, University of Iowa
Tracy Schrader, University of Iowa

ABSTRACT

In this paper we report on three studies designed to replicate and extend the Elaboration Likelihood Model (ELM) presented in Petty, Cacioppo and Schumann's (1983) *Journal of Consumer Research* article. The reported studies were conducted with undergraduate students from two major universities using methodologies almost identical to those of Petty *et. al.* However, the results do not corroborate previous work on the ELM. We offer several possible explanations for the model's failure to generalize across products, across source manipulations and across arguments.

INTRODUCTION

In 1983, Petty, Cacioppo and Schumann published an article in the *Journal of Consumer Research* which describes an experiment and proposes the elaboration likelihood model (ELM) to explain under what conditions message cues will persuade consumers to try a new product. They argue that there are two different routes to persuasion -- central and peripheral -- and that the route taken depends on the receiver's level of involvement. According to the ELM, high involvement subjects will be motivated to process central cues such as message arguments and will be persuaded according to their quality (the central route). In contrast, low involvement subjects will focus on, and be persuaded by, peripheral cues such as source characteristics (e.g., a celebrity) and not the arguments (the peripheral route). In this paper, we report on three studies designed to replicate and extend the Petty, Cacioppo and Schumann (1983) study (hereafter, referred to as PC&S [1983]). These studies were conducted with undergraduate students from two major universities over a three year period. The methods employed in the three studies were similar, and sometimes identical, to those used by PC&S (1983). However, the results obtained are very different.

The format we use to report these studies is as follows. We first provide an overview, then describe the background, methodology and results for each study separately. Then we discuss our findings and merge them with prior research.

EXPERIMENT I

Overview

The first experiment replicates and extends PC&S (1983). We manipulate the same three variables: situation involvement, argument strength, and type of endorser. In addition, we

introduce a fourth (within subject) factor -- product involvement.

Background

The concept of involvement, the focus of much social and consumer psychology research, was a key manipulation in PC&S's (1983) test of the ELM. In that study, the researchers controlled how involved subjects felt with a print advertisement for a disposable razor by offering subjects the chance to choose a free gift for participating in the experiment; subjects selected either a disposable razor (high situation involvement) or a tube of toothpaste (low situation involvement). Involvement played a moderating role on the effects of argument quality and product endorser in influencing consumers' attitudes and purchase intentions. Based on their results, PC&S (1983) contend that the implications of ELM for advertising are that different types of messages will have different effects on different audiences.

As pointed out by Houston and Rothschild (1978) and others (Antil 1984; Stone 1984), there are different approaches to studying involvement and, more importantly, different types of involvement. These include situation involvement, issue involvement, advertisement involvement, response involvement, and product involvement. With this in mind, it may be argued that PC&S (1983) focused their efforts on manipulating "situational" involvement for a low involvement product -- a disposable razor. Attributes generally thought to characterize low involvement products include low financial and social risk, little product differentiation, and little ego involvement. As argued by Bitner and Obermiller (1985), PC&S may have ignored product involvement. For instance, it is unknown whether or not ELM would generalize and predict the route to persuasion for a high involvement product; i.e., a product that has social risk, is relatively expensive, is more ego-involving, and for which significant differences exist among available alternatives.

The present experiment examines the generalizability of ELM to high involvement products. Included in the research design are ads for a 35 mm. camera (high involvement product) and disposable razors (low involvement product). ELM predict that argument quality will have a greater effect on product attitudes under high rather than low situation involvement conditions for both cameras and razors. In addition, ELM would postulate that, for both product categories, the presence of celebrity endorsers will have a greater effect on consumers' attitudes under low rather than high situation involvement conditions.

Methods

Subjects and Design. One hundred and forty five undergraduates at a major state university participated in this first experiment. Approximately 20 subjects were randomly assigned to each of the cells in a 2 (situational involvement: high or low) x 2 (argument quality: strong or weak) x 2 (endorser: celebrity or noncelebrity) x 2 (product involvement: high or low) design. The last factor was a within subject variable; participants saw an ad for both a camera and a razor.

Procedure. Two booklets were prepared for the study. The first contains 12 product advertisements in a magazine format. The second booklet contains the dependent measures used by PC&S (1983). Included in the advertising booklet were one of four ads for a fictitious "Falka" brand 35 mm. camera, as well as one of the fictitious ads for "Edge" brand disposable razors used by PC&S (1983).

The first page of the advertising booklet explains that the study concerns the evaluation of rough newspaper and magazine ads. Consistent with PC&S (1983), it also contains the situational involvement manipulation. Half the subjects are told that for their participation they will choose a free disposable razor at the end of the study (high situational involvement for razor). The remaining half learn that they will receive a chance to win and select a brand of 35 mm. camera in a lottery at the end of the study (high situational involvement for camera). Thus, subjects in the high situational involvement condition for the razor are also assigned to the low situational involvement condition for the camera. Conversely, subjects in the high situational involvement condition for the camera are also in the low situational involvement condition for the razor.

Independent Variables

1. **Product Involvement.** The high involvement product is a 35 mm. camera; the low involvement product is the disposable razor.

2. **Situational Involvement.** As in PC&S (1983), we manipulate situational involvement in two ways. In the high involvement condition, subjects learn that they will select a free razor or have a chance to win and select a brand of 35 mm. camera. In addition, the short paragraph that precedes the razor and camera ads informs participants either that the product will soon be test marketed in the area where they live (high situation involvement), or will be test marketed in a different part of the country (low situation involvement).

3. **Source Effects.** Consistent with PC&S (1983), the celebrity source for the razors features two well-known professional male and female tennis players. For the 35 mm. camera, the celebrity source is a different well-known professional tennis player. Also consistent with PC&S, the non-celebrity source for razors is Bakersfield, California. Providence, R.I. is chosen as the non-celebrity source for the camera.

4. **Argument Strength.** The strong and weak arguments for the disposable razors are identical to those used by PC&S. To determine argument strength for the camera, a series of pretests were conducted with a different sample of undergraduates. Based on these results, the strong arguments for the camera are: auto loading, auto winding, programmed flash, print quality "superior" to competitors, and lightweight/compact. In addition, the strong arguments are preceded by the characterization "extremely simple operation." The weak arguments are preceded by the characterization "classic style and design" and include: comes in semi-hard case, adjustable neckstrap, easy access to battery chamber, print quality "similar" to competitors, and comes in several colors.

Dependent Measures

The dependent measures booklet contains the same questions used by PC&S, concerning subjects' attitudes and purchase intentions. The key responses are those toward Falka cameras and Edge razors. The attitude measures are three nine-point semantic differential scales with end points anchored bad-good, unsatisfactory-satisfactory, and unfavorable-favorable. Responses across the three scales are averaged to provide a general positive or negative attitude toward the product. Subjects also indicate their purchase intentions by rating, on a four-point scale, how likely they will be to purchase Falka cameras (and Edge razors) the next time they consider the purchase of a camera (and a razor). The descriptions for each scale value are: 1 = "I definitely would not buy it," 2 = "I might or might not buy it," 3 = "I would probably buy it," and 4 = "I would definitely buy it." To obscure the purpose of the study, similar attitude and purchase intent questions are posed for several of the legitimate products in the ad booklet. In order to check the manipulation of situational involvement, the last question asks participants to indicate the free gift they will receive (high involvement razor condition) or might win (high involvement camera condition).

Results

Manipulation Checks. Participants' responses to the last question in the dependent measures booklet indicate that the manipulation of situational involvement is successful. Ninety three percent and 97 percent of the subjects in the high involvement conditions for razors and cameras, respectively, correctly recall the free gift. Similarly, participants report recognizing the celebrity endorsers 86 percent of the time for razors and 89 percent for cameras. When the non-celebrity sources are used, over 93 percent of both groups report not recognizing the sources.

Attitudes and Purchase Intentions. 1. Razors. Separate ANOVA's are run for the attitude and purchase intention measures. Only one significant effect ($p < .05$) is found for the attitude index, such that participants like the razor more when the ad contains strong arguments than when the arguments are weak ($F[1,137] = 14.35$). Situational

involvement has a marginally significant impact ($p < .10$) on attitudes such that those in the high situational involvement condition are somewhat more favorably disposed to the razor than those in the low situational involvement condition ($F[1,137] = 3.31$). Since the present study is partly a replication of PC&S (1983), comparisons between these two studies are possible. In contrast to their results, and contrary to ELM postulates, no significant effect is found for endorser ($F < 1$), nor are any interactions found between involvement and arguments ($F < 1$) or involvement and endorser ($F < 1$).

Conflicting results are also found on the purchase intention index for razors. Unlike PC&S (1983), no significant effects are found for argument quality ($F[1,137] = 1.41$) or the interaction between involvement and argument quality ($F < 1$). In fact, no significant effects are obtained for any of the independent variables when participants rate their likelihood of purchasing the Edge disposable razor.

2.35 mm. Camera. Separate ANOVA's are also run for the attitude and purchase intention indexes for the camera. No significant effects or interactions are found for any of the factors when subjects rate how much they like the camera. For the purchase intention measures, significant effects ($p < .05$) are found for argument quality only ($F[1,137] = 4.77$); participants are more likely to purchase the Falka brand camera when the arguments are strong rather than weak. Contrary to the predictions of ELM, no significant interaction is found between involvement and either argument quality ($F < 1$) or endorser ($F < 1$).

EXPERIMENT II

Overview

The purpose of the second study is to determine if we can replicate the general findings from PC&S (1983) by substituting source attractiveness for spokesperson's celebrity status. Unlike Petty and Cacioppo (1980)'s study in which a physical feature of the spokesperson could serve as a cogent product-relevant argument (e.g., nice hair in an ad for shampoo), there is no relationship in this study between any features of the displayed female face and the product (a disposable razor).

Background

In this study we manipulate the source's physical attractiveness because prior research shows that a physically attractive source facilitates attitude change (Joseph 1982; Kahle and Homer 1985; Petty and Cacioppo 1980). However, the ELM postulates that physical attractiveness, acting as a peripheral cue, will affect attitude and purchase intentions in low involvement situations only, and that argument strength, acting as a central cue, will influence attitude and purchase intentions in high involvement situations only.

Methodology

Subjects and Design. 187 undergraduates were recruited from introductory marketing classes at a

major state university. Approximately 20 subjects were randomly assigned to one of 8 cells in a 2 (argument strength: strong or weak) x 2 (situational involvement: high or low) x 2 (source: attractive or unattractive) design.

Procedures. Eight different versions of the advertising booklets were prepared for the study. Each version has one Edge razor ad manipulating argument strength and source attractiveness. The first page of the advertising booklet, and the paragraph introducing the Edge ad, manipulate situational involvement in exactly the same way as PC&S (1983). The second booklet contains the dependent variable measures for the Edge ad as well as questions concerning other ads.

Independent Variables. As mentioned, argument strength and situational involvement are manipulated in the same way as in PC&S (1983). Source attractiveness is manipulated by using a black and white photograph of the face of either an attractive or unattractive spokeswoman. A different group of students evaluated these photographs on an attractive/unattractive scale; the differences were significant.

Dependent Measures. Attitudes toward Edge razors is assessed with the same 3 item nine-point semantic differential scale as used in PC&S (1983). Coefficient alpha for the three items is .89. Purchase intentions are assessed with the same four item scale used in Experiment I.

Results

Manipulation Checks. To determine whether or not the physical attractiveness manipulation is successful, an analysis of variance is performed on the semantic differential item included to measure spokesperson attractiveness. Subjects who see the attractive spokesperson rate her as more attractive than subjects who see the unattractive spokesperson ($F[1,175] = 29.23$, $p < .05$).

To determine whether or not we successfully manipulated argument strength, we run an ANOVA on a two item semantic differential scale (good-bad; convincing-not convincing) designed to measure argument quality. Scores are higher for subjects who see the strong arguments than for subjects who see the weak arguments ($F[1,175] = 11.57$, $p < .05$).

Participants' responses to the last question in the dependent measures booklet indicate that over 95% of the subjects correctly recall the free gift (a razor in the high situational involvement situation; a candy bar in the low situational involvement situation).

Attitude and Purchase Intentions. Argument strength is the only significant effect found on the attitude measure ($F [1, 175] = 7.08$, $p \leq .01$) and on the purchase intentions measure ($F [1,175] = 2.58$, $p \leq .05$). As expected subjects who are exposed to strong arguments like the product more and are more likely to express intentions to purchase the razor than those subjects who are exposed to weak arguments. Contrary to expectations, this result holds regardless of involvement level or spokesperson attractiveness. There are no

significant interactions involving the independent variables: involvement, attractiveness and argument strength ($F < 1$ in all cases). Consequently, in this study we do not obtain the interaction predicted by the ELM model, nor do we observe a main effect for attractiveness as has been found in other research (Kahle and Homer 1985).

EXPERIMENT III

Overview

In the third experiment, we extend the PC&S (1983) study by looking at a different source characteristic (referent or expert) and product involvement (high: MBA programs; low: root beer) in short billboard type ads. In addition, we extend the dependent variables to include attitude toward the ad itself, as well as attitude toward the brand and purchase intentions.

Background

Research has confirmed that sources holding expert power exert a large amount of influence in persuasive situations. Reinforcement theory, for example, states that communications made by experts are more readily accepted because experts are usually right and the expectation of being right is reinforcing (Maddux and Rogers 1979).

A large number of other studies have confirmed that sources holding referent power, which is here defined as similarity to the target audience, are likely to exert influence in persuasive situation. Reinforcement theory again comes into play here as it states that social approval is rewarding and people may think that agreeing with similar others will bring about social approval (Maddux and Rogers 1979). Social comparison theory and congruency theory also predict that similarity of the source would exert a positive influence on persuasion (Joseph 1982).

Consistent with the ELM, we predict an interaction between involvement and source characteristics. For high involvement products an expert source should be most persuasive because expertise is a product-relevant cue. Conversely, for low involvement products a referent source should be most persuasive, because in low involvement situations people are more likely to attend to similarity characteristics of the source, and not to expertise.

Methodology

Subjects and Design. A total of 74 male and female undergraduates business majors at a large state university participated in order to earn extra course credit. The design was a 2 (product involvement: high or low) x 2 (source: expert or referent) factorial. (Note: all subjects saw an ad for both root beer and the University's MBA program).

Procedure. Four different booklets containing five billboard-type advertisements were prepared. In each booklet, the second ad is for the school's MBA program and the fourth ad is for Lucille's root beer. A second booklet contains the dependent measures.

Independent Variables.

1. Involvement. Subjects see an ad for a high involvement product (the MBA program) and a fictitious low involvement product (Lucille's Root Beer). To increase involvement with the MBA program, subjects are also told on the cover sheet of the first booklet that they will receive a chance to participate in a lottery to receive a free guide to MBA programs.

2. Source. Two versions of each experimental advertisement are used, one with an expert endorser and one with a referent endorser. For the MBA ad, the source of a short quote is identified as either the president of IBM (Expert) or as a business student at the University (Referent). For the root beer ad, the source of a short quote is identified as the president of the American Soft Drink Association (Expert) or as a business student at a different east coast university (Referent).

Dependent Measures. For each of the experimental advertisements subjects complete a four-item semantic differential scale designed to assess impression of the ads, a four-item semantic differential scale designed to assess impression of the brand, and a single-item semantic differential purchase intentions scale. They also complete Zaichowsky's (1985) 20 item personal involvement inventory (PII) scale for each advertised product.

Results

Manipulation Checks. Subjects who see the expert source (for root beer or the MBA program) rate the source as more expert than students who see the referent source (root beer $F[1,71] = 16.97$; $p < .05$; MBA $F[1,71] = 17.10$, $p < .05$). Subjects who see the referent source (for root beer or the MBA program) tend to rate the source as more likeable than the expert source. Although this difference is in the predicted direction it is not statistically significant (root beer: $F < 1$; MBA $F(1,71) = 2.56$, $p < .11$). Finally, a paired comparison t-test on Zaichowsky's (1985) PII scale responses indicates that the MBA program is more personally involving than the root beer ($t[72] = 10.76$; $p < .05$).

Attitude toward the Ad, Attitude toward the Brand, and Purchase Intentions. For the root beer ads, there are no significant effects on attitudes toward the ad ($F[1,71] = 1.07$), attitudes toward the brand ($F < 1$), or purchase intentions ($F < 1$). Thus, the hypothesis that referent sources will have more influence in low involvement situations is not supported.

In regard to the ads for the MBA program, students who see the ad with the expert source have more favorable impressions about the ad than those who see the ad with the referent source ($F[1,70] = 11.92$; $p < .05$). Students who see the expert source also have more favorable impressions about the MBA program than those who see the referent source ($F[1,70] = 6.78$; $p < .05$). However, no significant difference is found in relation to intentions to apply to the MBA program ($F < 1.0$). In conclusion, then, we observe source effects only in the high involvement situation for a high

TABLE I
Summary of Research Results

Experiment	Independent Variables			
	Argument Quality	Source Features	Situational Involvement	Product Involvement
I	Yes	Celebrity	Yes	Yes
Major Findings:	1. For low involvement products (1) main effect of argument quality on attitudes and (2) main effect of situational involvement on attitude (marginal). 2. For high involvement products, main effect of argument quality on purchase intentions.			
II	Yes	Attractiveness	Yes	No
Major Findings:	1. Main effect of argument quality on attitudes and purchase intentions.			
III	No	Referent/Expert	Yes	Yes
Major Findings:	1. For low involvement products, no main effects. 2. For high involvement products expert source influenced attitude toward the ad, brand and behavioral intentions.			

involvement product. We do not observe source effects for a low involvement product.

DISCUSSION

In light of the predictions of the Elaboration Likelihood Model, the findings from the three experiments present some conflicting results. Table I summarizes these findings. In the first two studies, only main effects for argument quality are found. No source effects are reported and, more important, no interactions are found between involvement and any of the independent variables in either experiment. The third study, which did not manipulate argument quality, finds an expert source effect only in the high involvement situation. Thus, across three experiments designed to extend and test the generalizability of ELM, little if any support is found for the major postulates of the model. In this section, we identify reasons why our findings may diverge from those reported previously.

First, consider why we fail to replicate the critical cue by involvement interactions postulated by ELM in Experiments I and II. One possibility is that whether or not a given cue acts centrally, peripherally, as an irrelevant cue, or as a dominant cue depends to a large extent on characteristics of the product, the individual, the situation and the ad. Thus, for example, when we used slightly different products in the three studies, we necessarily had to modify the ads and some procedures. As a result, we may not have observed the expected interactions.

Nonetheless, if ELM is going to be an effective means of explaining consumer response to advertising, it should be robust enough to handle minor procedural variations.

Second, consider why we observed expertise acting as a central cue in Experiment III, while Petty, Cacioppo and Goldman (1981) found expertise acting as a peripheral cue. One difference between the two studies is that our billboard type ad provided very little product information, while Petty et al.'s message listed multiple arguments. As Bitner and Obermiller (1985) note, when no other central cues are available, a peripheral cue may act like a central cue. This result highlights a limitation of ELM; the model does not clearly specify a priori what will be a peripheral cue and what will be a central cue (Bitner and Obermiller 1985).

Another possibility, suggested by one reviewer, is that involvement should be correctly viewed as a continuous rather than a dichotomous construct. The inability to replicate the critical interaction observed in previous ELM research may reflect a failure to manipulate involvement so that subjects feel exactly the same levels of involvement as subjects in Petty and Cacioppo's (1981, 1983) research. For example, our low involvement manipulations could actually represent moderate involvement situations. Consequently, we may not observe the expected interactions. However, it should be noted that we secured the actual research materials used in PC&S (1983) and replicated the methods and procedures as closely as possible. Of

course, minor differences -- different subjects, different administrators, different surrounding ads -- may account for different levels of felt involvement, and thus the inconsistent results.

This possibility emphasizes the need for researchers to develop and report an independent measure of felt involvement. Zaichowsky's (1985) PII scale represents an important step in this direction. So that researchers can make more precise comparisons across studies, we suggest that future ELM studies report PII scores, across involvement conditions.

A final possible explanation for our finding from Experiments I and II that argument quality dominates attitude formation is that, contrary to PC&S (1983) and the predictions of ELM, consumers may base their judgments about products on the cogent reasons for purchase provided in the ad. If an ad contains both source and argument information, argument quality may be the most important determinant of attitudes and purchase intentions. Thus, the results appear to support Fishbein and Ajzen (1981) who argue that:

"...the persuasiveness of a communication can be increased much more easily and dramatically by paying careful attention to its content ... than by the manipulation of credibility, attractiveness, ... or any of the other myriad factors that have caught the fancy of investigators in the area of communication and persuasion" (p. 359).

While certain factors (e.g., extremely appropriate sources who act like product relevant arguments) may mitigate the strength of the argument quality-persuasion relationship, consumer behavior and advertising researchers will do well to approach the persuasion process as resulting from the thoughtful consideration of issue- and product-relevant information.

The Interaction of Peripheral Cues and Message Arguments On Cognitive Responses to an Advertisement

Judith E. Hennessey, California State University, Northridge
Shirley C. Anderson, California State University, Northridge

ABSTRACT

Predictions of the Elaboration Likelihood Model (ELM) as proposed by Petty and Cacioppo were tested in an experiment examining subjects' responses to some announcements. The "peripheral" cues of source context (commercial or noncommercial) and endorsement (present or absent) were systematically manipulated along with the "central" cue, argument strength (weak or strong). The effect of involvement with these variables was examined by assessing whether or not subjects had completed a university writing proficiency requirement, which served as the subject of announcements in the experiment. Results were consistent with the ELM prediction that relative use of central and peripheral cues is mediated by involvement. Both high and low involvement subjects use both central and peripheral cues in generating cognitive responses, but were affected by these cues in opposite ways. While the finding for involved subjects has been reported in earlier work and predicted by the ELM, the finding for low involvement subjects is new.

INTRODUCTION

In the literature of communication processing, the Elaboration Likelihood Model of Petty and Cacioppo (1979, 1981, 1987) is a popular explanatory theory (see Stiff, 1986). It posits that communication about a product or service occurs by one of two divergent focuses of intent: (1) *central* cognitive processing focuses on analysis of product-relevant information such as message content (arguments); alternatively (2) *peripheral* cognition focuses on the persuasive peripheral cues, (such as message length, the presence or absence of an endorsement and the background context) rather than the message content. This paper presents the results of an empirical test of a recent clarification of the model. Specifically, by controlling peripheral information and argument quality features of a message, the nature of the interactions of these features for involved and uninvolved subjects are examined.

In central cognitive processing the Elaboration-Likelihood is said to be high, and factors favor the communication recipients' motivation and ability to engage in issue-relevant thinking. These thoughts are expected to be enduring and strongly related to the message object. The second route, low elaboration-likelihood (or peripheral cognition), occurs if either motivation or ability to expend cognitive resources is low (e.g., the recipients are distracted or assess the task as unimportant). If the elaboration likelihood is low, the message "recipients adopt a strategy wherein they are more likely to attempt to derive a 'reasonable' attitude based upon a superficial

analysis of the recommendation . . . based upon various cues in the persuasion context (e.g., the more arguments for a recommendation, the better it must be)"--Cacioppo and Petty, (1981, p.74).

Factors such as involvement have been viewed as affecting people's motivation and ability to think carefully about the merits of an argument (i.e., process centrally) (Petty, Kasmer, Haugvedt and Cacioppo, 1987). The ELM predicts that low involvement recipients should be more sensitive to *peripheral cues* than to *argument* features of the advertisement (Petty and Cacioppo, 1981; Petty, Kasmer, Haugvedt and Cacioppo, 1987). Petty and Cacioppo (1984) found support for ELM predictions that the thoughts of the highly involved subject will be less influenced by peripheral cues (length of message) than quality of message. In contrast, the uninvolved subjects were found to be more influenced by the peripheral cues than by the message quality manipulations.

Petty, Kasmer, Haugvedt and Cacioppo (1987, p. 235) diagram various source effects as sample peripheral cues effecting peripheral route processors. Advertisers frequently attempt to bolster the effect of a communication by strategic control of background features. Public relations efforts focused on news releases of product information the marketer posits as news or more focused efforts on the purchase of commercial slots during news as opposed to "less serious" programs can be viewed as attempts to control peripheral qualities of the communication. Advertisers also attempt to enhance the copy points (the message itself) through the use of familiar, attractive, sexy, likeable or credible endorsers or spokespeople. Communication models typically isolate such source effects as independent from message effects (such as appeal used, order, number of items, quality of information, number and schedule of repetitions). The background or peripheral feature enhancements can be particularly costly. The relative cost to the benefit on the target audience is of strategic interest in marketing. The ELM suggests that when motivation to process is low (product has no personal relevance) the "peripheral" features should dominate persuasive influence. Alternatively, message features such as strength and quality of copy points should be the primary influence when motivation of process is high (product has high personal relevance).

In the present study, the test of the ELM involves manipulation of two peripheral cues (1) endorsement--present or absent, and (2) context--news or advertisement] and one argument feature (argument--weak or strong). From the ELM a two-way interaction between involvement and argument strength is predicted since high involvement subjects are expected to be more sensitive to variations in arguments. Likewise, two-way

interactions of involvement with context and involvement with endorsement are also predicted by the ELM.

A predicted interaction of peripheral cue variables, was reported in a study similar to the present one (Hennessey, Anderson and Bessolo, 1986). In addition to main effects on buying intention for an advertisement versus a public announcement context and for a testimonial versus a non testimonial format, these two variables interacted. In a public announcement, a testimonial was perceived as favorable, lack of testimonial was neutral. In the advertisement lack of a testimonial was neutral and presence of testimonial was perceived as negative, which lowered both perceived credibility of the message as well as intention to buy the product. Presumably the logic in the interaction was that in public announcements, endorsers always tell the truth, but in advertisements endorsers may lie. In the present study, a test will be made for this interaction effect. A two-way interaction is predicted between the two peripheral cues such that when both cues are viewed favorably by the subjects (news source and endorsement present) or negatively (advertisement source and no endorsement) the effect on thought will be more positive than when the two cues are inconsistent with one another. Should this two-way interaction be evidenced, then a three-way interaction between involvement and the two peripheral cues is also predicted since, from the ELM the low involvement subjects should be more influenced than high-involvement subjects by variations in the peripheral cues. The ELM, however does not specifically address the nature of interactions between peripheral features and argument features.

Three way interactions between the peripheral cues and argument quality as a function of involvement are predicted. Subjects with a high need or motivation to think (involved) should show the peripheral cues working most when arguments are weak. Thus an endorsement should be more effective (although its effect may take on a central character, e.g. "he should know what he is talking about") when arguments are weak. The effect of both types of variables on high involvement subjects is discussed in light of other studies in Petty, Kasmer, Haugtvedt and Cacioppo (1987). The communication literature has also reported conditions in which strong arguments are not as successful as other approaches (Psychology Today, 1975; Hadley, 1963; Hovland and Mandell, 1952). Thus we propose that low involvement may mediate the effect of arguments, such that when arguments are of high quality (strong) they could take on a peripheral character and in doing so lose their positive quality. Strong arguments, for subjects who do not need or want to think, may be perceived as a "hard sell" tactic resulting in negative effects (particularly pronounced when peripheral cues such as a strong endorsement reinforce this perception).

Since the ELM was proposed in 1979, research findings have generally supported it (Petty, Kasmer, Haugtvedt and Cacioppo, 1987; Lutz 1985;

Moore and Hutchinson, 1983; Moore, Hausknecht and Thamoderan, 1986). Lutz in 1985 extended the ELM by proposing that cognitive responses, the measure most frequently used in the ELM supportive literature, should be highly related to attitude variables. Cognitive responses are the thoughts subjects state they had as they viewed the experimental stimulus and the subsequent evaluations of such thoughts. Wright (1973) specified a method for classifying cognitive response into positive and negative categories. The frequency of the dominant cognitive response can be examined as a function of manipulated variables. More recently, Lammers (1985) investigated alternative methods of evaluating cognitive response and found this early method as appropriate as several alternative methods. Attitude, credibility of the message, cognitive response and buying intention were measured in the present study. Buying intention is expected to reflect the tendencies of attitude and cognitive response.

METHOD

Subjects

Subjects were 165 student volunteers from upper division undergraduate marketing courses. Subjects were not paid nor given course credit for participating.

Design and Stimuli

Stimuli were printed announcements of a writing proficiency course designed to help students meet a graduation requirement. The peripheral cues were (1) endorsement/no endorsement, and (2) editorial context: public announcement/advertisement. One half of the announcements had a message of four lines (four copy points) presented with an endorsement by the Dean of the School of Business. The remaining half contained the identical message, without the Dean's endorsement. Editorial context was manipulated by telling half of the subjects that the University administration was announcing a private remedial course to help students pass the Writing Proficiency Exam (WPE) required for graduation. The other half of the subjects were told that a fictitious company was advertising a course to effectively prepare students to meet the WPE requirement. The message content (argument strength) was manipulated by changing metric information in the copy (e.g. 90% or 10% of course evaluators are also University WPE evaluators) and emphasis adjectives to either strongly or weakly support the claim that the course would help in meeting the WPE requirement. This simple metric manipulation allowed the researchers to assure that there was no change in the difficulty level of the strong versus weak message. This message content manipulation was pretested and posttested for perceived strength. Finally, students were classified into a high involvement and a low involvement group depending on whether or not they had yet to meet the WPE requirement. The

FIGURE 1
INVOLVEMENT BY SOURCE INTERACTION ON CREDIBILITY

experimental design was a 2 (expert endorsement versus no endorsement) by 2 (commercial source versus non commercial source) by 2 (weak versus strong argument) by 2 (high versus low involvement) factorial design with credibility, and other attitude dimensions (such as weak-strong; like-dislike) and intention to act measured on semantic differential scales (Osgood, Suci & Tannenbaum, 1957) and with cognitive responses collected as described in Wright (1973).

Manipulation Checks

The manipulation checks indicated that subjects rated the message with weaker metric information (number of course evaluators who are also WPE evaluators, number of weeks to complete course) as a significantly weaker message [$p < .05$]. Further, subjects who had not yet taken the WPE rated the message as more meaningful and significant than subjects who had already met the requirement [$p = .05$], thus supporting the successful operationalization of involvement. Credibility judgments were examined as a function of our design to assess the intended effect of our Source Context manipulation. We expected to see source impact Credibility and possibly interact with Involvement such that the credibility judgments of involved subjects would show less of a tendency to reflect the peripheral Source manipulations. Analysis of the

variable Credibility revealed a significant interaction between Involvement and Source ($F(1,155) = 8.15, p = .005$). As can be seen from Figure 1, high involvement subjects judged the ad more credible than the news context while low involvement subjects judged news more credible than the ad context. No other main effects or interactions were significant in the analysis of credibility. Analysis of attitude components revealed that while there was a main effect for argument strength on the potency component (weak/strong), there was a main effect for endorsement on the evaluative component (like/dislike, good/bad, pleasant/unpleasant). Advertisements with the dean's endorsement were generally evaluated more favorably. No other main effects or interactions were evident in the analysis of the attitude components.

RESULTS

As described earlier in this paper, Wright (1973) indicates that the dominant type of cognitive response (negative or positive) is most sensitive to independent variable effects. Positive and negative cognitive responses were classified into categories by two independent judges as responses to cues or arguments. An independent third judge was used to resolve inconsistencies. Negative responses were dominant when thoughts were peripheral cue relevant while neither positive nor negative responses

** = marginal significance

clearly dominated when thoughts were about message arguments. The number of positive and negative cognitive responses were tabulated for each cell in our design. Table 1 provides the results of our analysis on the number of negative cognitive responses to cues and the number of positive responses to arguments. Analysis of positive cognitive responses to message arguments revealed a significant interaction between Involvement and Argument Strength ($F(1,147) = 5.21, p = .02$) (see Figure 2(a)). Further, a significant interaction between Endorsement and Argument Strength was found in this analysis ($F(1,147) = 4.32, p = .04$) (see Figure 2(b)). Analysis of the number of negative cognitive responses to message arguments mirrored these effects, although only the Argument Strength by Endorsement interaction was significant in this analysis ($F(1,147) = 4.61, p = .03$). As can be seen in Figure 2, involved subjects were relatively more positive toward strong arguments than toward weak arguments while low involvement subjects were more positive toward weak arguments than strong arguments. Earlier work supports this pattern in high involvement subjects. The pattern shown for uninvolved subjects is new, although consistent with our hypotheses. Contrary to our predictions derived from the Hennessey *et al.* (1986) study, there was no 3-way interaction between involvement and the two peripheral cues. The data indicate that the Source manipulation was relatively weak compared to the endorsement manipulation.

The 2-way interactions of these two peripheral cues were also not found.

Analysis of negative cognitive responses to peripheral cues revealed a marginally significant Involvement by Endorsement by Argument Strength interaction showing a differential advantage of no endorsement and no effect of argument strength for involved subjects. Strong arguments without an endorsement and weak argument with endorsement showed a differential advantage for low involvement subjects ($F(1,147) = 3.51, p = .06$). This finding is illustrated in Figure 3. No other main effects or interactions were evident in this analysis.

Analysis of attitude showed no significant effects for this design. However, analysis of buying intention revealed a significant main effect for Endorsement ($F(1,155) = 5.47, p = .02$) and a main effect for Involvement ($F(1,155) = 11.54, p = .001$). Both an endorsement and involvement directly stimulate buying intention. No significant interactions were found amongst the variables on buying intention.

FIGURE 3

THE INTERACTION OF INVOLVEMENT ENDORSEMENT AND ARGUMENT STRENGTH ON NEGATIVE COGNITIVE RESPONSES TO PERIPHERAL CUES

DISCUSSION

Consistent with recent clarification of ELM expectation Petty *et al* (1987), our analysis shows that involved subjects use central and peripheral elements in processing a message. These cues affect both involved and less involved subjects differently. A new finding is that cognitive responses to strong copy were more positive for involved subjects than for uninformed subjects. Although Petty *et al* (1987) emphasize the mediating role of Involvement in determining the dominant path to persuasion, they clearly leave open the possibility that Arguments may effect peripheral route processors. They further provide a summary of empirical findings that show some effect of peripheral cues on central route processors. This study is the first, however, to report an effect for argument variations on peripheral route processors (i.e. on less involved subjects).

Further, credibility was enhanced by the advertiser cue in the involved subject but dampened for low involvement subjects, who found a public announcement more credible. By classifying cognitive responses into peripheral cue comments and argument content comments, as opposed to simply examining the relative favorableness of the thoughts generated, insight was provided on why central and peripheral cues seem to affect high and low involvement subjects in opposite ways. For example, while comments on the price of the course

tended to address how "cheap" or "expensive" the course was perceived by the involved subject, price comments for less involved subjects were more like "Rip-off" or "Another attempt to get our money", indicating a more superficial use of information than was evident with involved subjects.

Buying intention was, not surprisingly, strongly affected by involvement, as well as by the presence of an endorsement. In light of findings in this study, further research might focus on differences in the way endorsement is perceived and used by both high and low involvement subjects. Further work on the circumstances likely to produce interactions in message features (both cues and arguments) is still needed.

The Effect of Background and Ambient Color on Product Attitudes and Beliefs

Susan E. Middlestadt, University of Illinois, Urbana-Champaign

ABSTRACT

The process by which attitude change occurs is a key issue in consumer research. This study addresses this theoretical question by examining the effect of background color on product attitudes and beliefs. Background color was used as the independent variable because, like music, it appears to be an aspect of the communication and exposure situation which carries little explicit information about the product. Hence, many would argue that differences in product attitude produced by background color occur via and are evidence for nonbelief-based change processes. In this study, respondents presented with a slide of a pen against a blue background exhibited a more positive attitude toward buying the product than those shown the same pen against a red background. However, beliefs as well as attitudes were measured and it was possible to demonstrate that those in the blue condition also held different beliefs about buying the product. Thus, although background color would seem, on the surface, to carry no product information, the background color affected the underlying belief structure as well as the attitude. It is argued that belief-based processes may be responsible for attitude change previously assumed to be due to affective processes.

One of the ongoing questions within the behavioral sciences concerns the nature of the processes by which attitudes, intentions and behaviors change. On the one hand, some theorists argue that attitudes, intentions and behaviors are determined by underlying beliefs and that change ultimately occurs by changing this cognitive structure. This belief-based approach has been most clearly articulated by Fishbein and Ajzen (1975). As applied to the attitude toward a behavior, these theorists propose the following compensatory expectancy-value model:

$A(\text{behavior}) = \text{fn} (\text{Sum}(B_i \times E_i))$, for i from 1 to n salient consequences of performing the behavior, where $A(\text{behavior})$ is the attitude toward the behavior, B_i is the strength of the belief that performing the behavior will lead to the i th consequence, E_i is the evaluation of this outcome and a belief times evaluation crossproduct is formed for each of n salient consequences of performing the behavior.

Notice that attitude is determined by the totality of the evaluative implications of an underlying cognitive structure, here expressed as a sum of belief times evaluation crossproducts. Furthermore, according to this model, the underlying beliefs function not merely as predictor variables, but as causal ones. Thus, a change in attitude must be mediated by a change in this sum of crossproducts

which could occur by changing the belief strengths linking the behavior to its consequences, by changing the evaluation of the outcomes, and/or by changing the set of salient outcomes.

In contrast to this highly cognitive approach, many theorists argue that it is necessary to recognize an additional process of attitude and behavior change, one which is not mediated by belief change, one which is more affective and less cognitive. This "other" process takes many forms from theory to theory. For example, Petty and Cacioppo (1981) contrast peripheral from central routes to persuasion. Zajonc and Markus (1982) argue that, under certain circumstances, affective reactions occur which precede and are independent of cognition. And, a number of researchers (Mitchell and Olson, 1981; Gresham and Shimp, 1985; Lutz, MacKenzie and Belch, 1982) suggest that the affective response to the ad might be directly transferred to the product without changing the underlying beliefs.

Evidence for an "other than belief-based" process of attitude change has come from a wide range of research. Here, it will be argued that the possible role of belief-based change as a mechanism for attitude change has frequently been neglected in this work. For example, in his study of the effect of music on choice behavior, Gorn (1982) presented a product with liked or disliked music. He found that the product associated with the liked music showed a significantly higher preference in comparison to the product associated with the disliked music. Since "minimal product information" was presented in the exposure situation and since few beliefs about the product were elicited to a free response question about the reason for choosing the product, Gorn argued that the change in behavior was accomplished via some process other than a belief-based one and that the positive affect toward the music directly transferred to the product. Gorn suggested that the effect of music on choice occurred by way of classical conditioning.

This study stimulated much debate primarily about whether, when and how classical conditioning processes occur in the advertising and consumer behavior domain (e.g., Allen and Madden, 1985; McSweeney and Bierley, 1984; Stuart, Shimp and Engle, 1987). Here, instead, the very existence of direct transfer of affect will be questioned. That is, it will be argued that music may have affected choice by changing some aspect of the underlying cognitive structure. Although the presentation of the product with background music contained no explicit verbal information about the product, it is possible that the liked music caused the respondents to form or change beliefs about the product which led to a more positive attitude in comparison to the disliked music.

Can background music during a product presentation affect the consumer's beliefs about the product? More generally, do aspects of the exposure situation which provide no explicit verbal information about the product have an effect on the cognitive structure underlying product attitudes? An answer of yes implies that belief-based change processes may be responsible for some of the changes previously assumed to be affect-based. Evidence for differences in cognitive structure as a function of these presumably "informationless" manipulations would suggest that it is premature to rule out a belief-based explanation for change. The purpose of this study is to demonstrate that aspects of the communication and exposure situation which, on the surface, do not appear to have the capacity of changing underlying cognitive structure may in fact do so. In another paper, the effect of music on beliefs has been demonstrated (Middlestadt, 1988). Here, the color associated with the product is shown to have an effect on both the attitude toward buying the product and the cognitive structure underlying this attitude.

Color is an important variable in a wide range of applied and theoretical disciplines and has been argued to produce a variety of sensory, perceptual, cognitive and affective effects. Briefly, from an applied perspective, scholars are concerned with how color affects the aesthetic experience (Ball, 1965) and with color as an element in design (Sharpe, 1974) and photocommunication. In the consumer domain, the focus is on the use of color in packaging, retail design and display (Bellizzi, Crowley, and Hasty, 1983) its impact on advertising (Warner and Franzen, 1947; Dunlap, 1950; Starch, 1959). Color is also the subject of theoretical research. For example, at the physiological level, color has been shown to affect arousal (Wilson, 1966), leg strength (Pellegrini, Schauss and Birk, 1980), performance of simple psychomotor skills (Nakshian, 1964) and perception of time (Smets, 1969). Within the learning theory tradition, there is evidence that color connotations can be conditioned to terms with which they are associated (Harbin and Williams, 1966) and that color preferences can be changed with simple learning trials (Peters, 1943). There is a long history of assumed association between color and feeling, emotionality or affectivity (Pressey, 1921; Norman and Scott, 1952). Within the psychodynamic tradition, Schachtel (1943) argues that responses to color are similar to responses to affect in that they are immediate, direct and evoked rather than deliberated or mediated. There is evidence that color affects subjects' reports of moods (Rosenshine, 1985; Levy, 1980). Furthermore, although there are cultural, developmental and individual differences, colors and color words have been shown to be consistently associated with mood-tones (Hevner, 1935; Odbert, Karwoski, and Ekerson, 1942; Wexner, 1954; Murray and Deabler, 1957; Schaie, 1961) and affective meanings (Adams and Osgood, 1973).

Two points from this varied work are relevant to the task of examining the processes by which attitude change occurs. First, like music, color would be expected to affect how people respond to products. And, like background music, background color does not convey explicit product information but seems to represent affectivity and emotion. Thus, like a music manipulation, a color manipulation would qualify as a relatively noncognitive one. Second, while the specific findings about color effects are complex and vary from study to study, red is consistently found to be different from the cool colors of blue and green. Thus, contrasting red with blue would appear to be the most effective experimental manipulation.

In the present study, three products were presented against blue and red backgrounds. It was expected that a difference in attitude toward buying the product would be found between these two color conditions. More importantly, in view of the comparison of affective and belief-based models of attitude change, it was expected that if a difference in attitude occurred, it would be accompanied by a difference in cognitive structure. Note that focus of the study is not on the effects of color per se but rather on the process by which color produces attitude change.

METHOD

The subjects in the study were 84 female undergraduate students from an introductory advertising course at a major midwestern university. These students were majors from a wide variety of departments and colleges within the university and participated in partial fulfillment of a course research requirement.

The experimental manipulation. Subjects were randomly assigned to one of two experimental conditions, red or blue. Those in the red condition viewed slides containing one of three products (a bottle of perfume, a gold and silver pen and a bottle of mineral water) against a red background and those in the blue condition viewed slides of the same products against a blue background. The light from the slide was not sufficient to read the questionnaire. Therefore, lights in a color matching the background of the slide were projected onto the ceiling at the front of the room. Thus the color manipulation was of both the background color on the slide as well as ambient color, that is, the surrounding color in the room. It should be noted that the room was kept relatively dark and that no attempt was made to control the luminance of the projected light.

The questionnaire. For each product, attitude toward buying the product was assessed directly with six bipolar semantic differential items. For example,

My buying the pen pictured in the slide is
 good ____ : ____ : ____ : ____ : ____ : ____ bad
 extrem. quite slight. neith. slight. quite extrem.

Underlying cognitive structure was measured as recommended by Ajzen and Fishbein (1980). More

** $p < .01$

specifically, belief and evaluation items were written for eight modal salient outcomes elicited in a pretest study. For the belief item, each respondent indicated on a seven-point bipolar scale, how likely or unlikely the outcome would be if they bought the product. For the evaluation item, they indicated on a seven-point bipolar scale, how good or bad the outcome was.

The procedure. The subjects arrived at the experimental room in groups of about 6 to 10. Under regular light, they read the instructions which described how to fill out the scales and indicated that the purpose of the study was to determine the effect of color on sensory processes in the eye. Then the regular room light was turned off and blank colored slides were projected on the screen and the ceiling. To allow the subjects to adjust to the color, they completed three pages of filler questions. Then the slide with the perfume on the colored background was projected on the screen and subjects indicated their attitude toward buying the perfume and completed the questions on the underlying cognitive structure. The slide was changed to the pen and subjects completed attitude and cognitive measures, this time with respect to buying the pen. Finally, the slide of the mineral water was projected and respondents answered attitude and cognitive questions with respect to buying the mineral water. Throughout the session, the color on the background of the slide and in the room was red for those in the red condition and blue for the blue condition. The session took approximately 25 minutes.

RESULTS

There were no significant effects of the color manipulation on attitudes or beliefs with respect to two of the products, the perfume and the mineral

water. Therefore, this report focuses on the effects of color on the respondents' ratings of the pen. The results for this product are presented in three sections: (1) attitude toward buying the pen; (2) overall evaluative implications of underlying cognitive structure; and (3) individual belief and evaluation aspects of the salient outcomes comprising the cognitive structure.

Effect of color on attitude toward buying the pen. The top of Table 1 presents the means within experimental condition for the six semantic differential items used as direct measures of attitude. Over the six items, the multivariate F (Approx. $F(6,77) = 3.21$) was statistically significant at beyond the .01 level. For each of the items, respondents who were exposed to the pen with the blue background and ambient color were more positive than those exposed to the pen with the red background and ambient color. The mean difference was statistically significant at beyond the .01 level for two of these items, pleasant-unpleasant and enjoyable-unenjoyable.

Thus, color had a significant effect on attitude toward buying the pen pictured in the slide. Compared to the red condition, those exposed to a pen against a blue background with blue ambient color held a more positive attitude toward buying the product. It is next reasonable to ask whether this effect could have been mediated by an effect on the underlying cognitive structure.

Effect of color on overall evaluative implications of cognitive structure. It will be recalled that cognitive structure underlying the attitude toward buying the product was assessed according to Fishbein and Ajzen (1975). That is, for each of eight salient consequences of performing the behavior, a belief item assessed the likelihood

TABLE 2
 Effect of Color on Cognitive Structure Underlying Buying Product: Mean on Beliefs and Evaluations by Condition

	Background and Ambient Color	
	Red	Blue
Likelihood that buying pen means buying something which is 1		
Elegant	.05	1.51***
Unique	-.74	.60***
Good quality	.85	1.40m
Pleasant color	.69	1.36m
Easy to use	1.59	1.36
Durable	1.23	1.20
Expensive	.92	1.40
Too large	-.64	-1.13
Evaluation of buying something which is 2		
Elegant	1.64	1.96
Unique	2.18	1.98
Good quality	2.77	2.69
Pleasant color	1.84	2.16

m p<.10

*** p<.001

that this outcome would result if the pen were bought and an evaluation item assessed the evaluation of the outcome. For each outcome, the belief and evaluation aspects were scored from +3 to -3 and multiplied to create a crossproduct. The sum of these eight belief times evaluation crossproducts provides an indirect assessment of attitude and represents the evaluative implications of the underlying cognitive structure.

First, as support for the assumption that the sum of the crossproducts represents an indirect attitude measure consider the correlations of this measure with the individual semantic differential items. These correlations range from a high of .59 for the good-bad, pleasant-unpleasant and like-dislike scales to a low of .45 for wise-foolish. These correlations are all statistically significant and about the size typically found using these types of measures.

Second, did the experimental manipulation of background color affect the overall evaluative implications of the cognitive structure underlying the attitude toward buying the product? The mean sum of crossproducts for each color group is presented at the bottom of Table 1. Again, those who were exposed to the pen in the blue condition were more positive toward buying the pen than

those exposed to the pen in the red condition. And again, this difference was significant at beyond the .01 level ($F(1,82) = 63.57$). This difference implies that the cognitive structure of those in the blue condition had significantly more positive evaluative implications than that of those in the red condition. In other words, compared to those exposed to the pen against the red background, those who viewed the pen against the blue background perceived that buying the pen was likely to lead to positive outcomes and unlikely to lead to negative ones. At this point, it is important to determine which outcomes were affected by the color manipulation.

Effect of color on belief and evaluation of individual outcomes. Multivariate analyses of variance on the individual outcomes revealed a significant effect of color over the eight beliefs (Approx. $F(8,75) = 3.14$) at beyond the .01 level, but no significant effect over the eight evaluations (Approx. $F(8,75) = 1.32$). Table 2 presents the means on these items for each color group, the beliefs at the top of the table and the evaluations at the bottom.

The background and ambient color had the strongest effect on two beliefs, buying the pen means buying something which is elegant and which

is unique. Compared to those in the red condition, those in the blue condition believed it more likely that the pen was elegant as well as unique. More specifically, those who were exposed to the pen with the blue background believed that buying the pen would quite likely lead to buying an elegant pen; whereas, those who were shown a pen against a red background perceived this outcome as neither likely nor unlikely. And, those who viewed the pen on a blue background indicated that it would be slightly likely that buying this pen would mean buying a unique pen; whereas those exposed to it against the red background believed that this outcome was slightly unlikely to occur.

Marginal effects of color are evident on two beliefs, buying the pen means buying something which is good quality and which is a pleasant color. Again, those exposed to the pen against the blue background believed that these two positive outcomes were more likely to occur than those exposed to the pen against the red background. Although not statistically significant, it is interesting to note that the pen presented in the blue condition was perceived to be more likely to be expensive (overall, a slightly negative consequence) than the pen presented in the red condition. Thus, exposure to the pen in the blue condition did not invariably lead to more positive evaluative implications.

The effect of the color manipulation on the individual evaluations is presented at the bottom of the table. Consistent with the multivariate F reported above, for none of the eight consequences did the background and ambient color significantly affect the evaluation of the outcome. That is, those exposed to the pen in the blue condition did not evaluate the outcomes significantly more or less positively than those in the red condition. The lack of significant effects on the evaluations is not surprising. One might expect that a person's favorability toward buying products with attributes, such as uniqueness, elegance and durability would be more stable and difficult to change than the beliefs about whether buying a specific product will lead to obtaining these outcomes.

CONCLUSION

In this study, it was shown that an aspect of the exposure situation, the background color, had an effect on attitude toward buying a product. Subjects exposed to a pen presented against a blue background with blue ambient color evaluated buying the pen more positively than those exposed to the same pen with a red background and ambient color.

From the perspective of understanding attitude change processes, the key issue is determining how color produced this effect on product attitudes. Since the background color did not explicitly convey any product information, it might be argued that the affect associated with the color was directly transferred to the product and thus created a positive attitude through some other than belief-based process. However, in this study, the underlying

cognitive structure was measured in detail and it was possible to show that the color affected the respondents' beliefs about buying the product. Compared to those in the red condition, those who were exposed to the pen in the blue condition believed more strongly that buying the pen would lead to two positive outcomes, buying a pen which was elegant and which was unique. This difference in beliefs resulted in a cognitive structure which was more positive for those exposed to the pen against a blue background. Thus, it could be argued that the change in attitude toward buying the pen found in this study was caused by a belief-based change process.

These data do not prove that a cognitive difference mediated the attitude and behavior effects found here or in other research. As argued by Gorn (1982), it is possible that the change in the beliefs occurred after and in justification of the change in attitude. And, disentangling the causal relations among beliefs and attitudes is unlikely to be an easy task. However, the data presented here do demonstrate that subtle differences in how a product is presented, differences which do not appear to involve product information, do produce differences in beliefs about the product. Thus, belief-based change remains a viable explanation for the observed changes in product attitude.

The Effects of Missing Information on Decision Strategy Selection

Sandra J. Burke, The University of Michigan¹

Many consumer decisions are characterized by missing information, but an understanding of how this affects decision processing is lacking. This paper proposes a framework to explain that influence. It is argued that when attribute values are missing, a consumer must infer them in order to use some preferred strategies (attribute-based comparisons). Thus, a consumer may attempt to avoid the increased inferencing effort by switching to (1) alternative-based processing, or (2) hierarchical elimination strategies. Consumer experience, task complexity, category attribute redundancy, and decision importance are all argued to influence the magnitude of the proposed strategy shifts.

Much of the available research on consumer choice strategies has implicitly assumed that experimentally available information completely describes each choice alternative. Yet, in many choice situations consumers face incomplete information or partially described alternatives. This may result from advertisements or packaging which only mention some attributes, because of imperfect attribute memory for nonpresent alternatives, or because some attributes are experiential and can only be evaluated after product use. In these situations, "missing" attribute values must be inferred from available product cues.

While the role inferences play in attribute weighting and valuation has been explored (cf Ford and Smith 1987, Meyer 1981), their role in decision strategy has not yet been researched. Missing attribute inferences may lead consumers to utilize different choice strategies than in situations of complete information. The purpose of this paper is to explore how missing information and particularly inferences may affect decision strategies.

It is proposed that as the amount of externally available attribute information for a given alternative decreases, necessary inference-making increases. In order to adapt to this situation, consumers may alter their processing. Specifically, the presence of missing information may introduce an inference stage of processing in order to perform some preferred strategy (e.g., attribute based comparisons). While, for example, attribute-based strategies are relatively easy to use in certain contexts (Tversky 1969), an added inference stage may increase their complexity. Alternative-based strategies, however, may allow more direct processing, and circumvent any added inference stage. This may result in a relative shift away from

attribute-based strategies toward alternative-based strategies as "missing" information increases.

Another way to avoid inferencing may be to continue to use an attribute-based strategy, by hierarchically eliminating alternatives based on those attributes with available values. This may be particularly appropriate when information is available on more diagnostic attributes.

Summarizing, it is proposed that in situations with missing information, consumers will attempt to avoid the effort of inferences by switching to (1) alternative-based strategies, and/or (2) hierarchical elimination strategies which focus on diagnostic, available attributes. As detailed below, these shifts may be moderated by consumer experience, decision importance, task complexity, and the category attribute redundancy.

DECISION STRATEGY USE

Decision strategies are often viewed as varying both in their level of difficulty and their ability to optimize the accuracy of a given decision (Beach and Mitchell 1978). It has been suggested that processing effort may affect the utilization of a given strategy in a given situation and that decision makers will resort to choice strategies which reduce cognitive strain (Bettman 1979; Newell and Simon 1972). The implicit assumption is that consumers trade-off accuracy and effort or consider the costs and benefits of particular strategies (Payne 1982). These costs and benefits may be influenced by aspects of the task or choice context as well as individual differences (Russo and Doshier 1983; Shugan 1980; and Wright 1975). Compensatory strategies in particular require a good deal of cognitive computations and place demands on short term memory. Using a linear compensatory strategy each alternative must be evaluated separately on each of its relevant attributes, and the resulting utility or value of each attribute must be used to arrive at an overall evaluation. In contrast, sequential elimination strategies are generally easier to apply since the alternative set is reduced and cutoffs are used, restricting attention to only part of the available information about each alternative (Payne 1976). Yet, more compensatory strategies may produce better choice alternatives.

Further, Tversky (1969) and Bettman and Jacoby (1976) suggest that attribute-based processing is easier than alternative-based processing because similar units (attributes) are being compared with one another. Slovic (1975) argues this may be due to an emphasis placed on an attribute's discriminating power. Some empirical evidence supports more widespread use of attribute-based processing (Capon and Burke 1977; Ford et al. 1989; and Russo and Rosen 1975). However, other empirical research supports equal amounts of alternative and attribute processing (Bettman and Jacoby 1976).

¹The author gratefully acknowledges comments on earlier drafts of this paper by Susan Heckler, Chris Puto, Youjae Yi, and especially Michael D. Johnson.

One reason for these conflicting findings is that a number of variables may mediate differences in the effort required to apply the different strategies. Use of the strategies varies with task complexity (see Payne 1982 for a review), information format (Bettman and Kakkar 1977; Sheluga and Jaccard 1979; and Tversky 1969), the phase of processing (Bettman and Park 1980; Biehal and Chakravarti 1986; Johnson and Meyer 1984; Lussier and Olshavsky 1979; Payne 1976), and individual differences (Bettman and Kakkar 1977; Bettman and Park 1980; Biehal and Chakravarti 1982, 1986; Capon and Burke 1980; Cohen and Basu 1987; Jacoby et al 1976; Kardes 1986; Park and Lessig 1981; Sheluga, Jaccard, and Jacoby 1979; and Sujana 1985).

Finally, paralleling the discussion here, Johnson (1984, 1988) studied the effects of noncomparability (the degree to which alternatives are described by *different* attributes) among alternatives on choice of decision strategy. These studies show that as comparability between alternatives decreases, subjects increasingly cross-over from attribute-based to more alternative-based strategies, possibly due to the increase in effort involved in attribute-based processing as comparability decreases. What these studies suggest is that on the whole, situational factors mediate the effort required to use various decision strategies and lead to shifts in strategy use. We now explore the particular role that inferences regarding missing information play in strategy selection.

MISSING INFORMATION EFFECTS ON DECISION STRATEGY USE

While the effect of missing information on decision strategy selection remains unclear, a few studies have looked at its effects on evaluation with mixed results. Slovic and MacPhillamy (1974) suggest that when making pairwise comparative judgments, an attribute is weighted more heavily if attribute values are available for both alternatives than just one alternative. They suggest that comparisons involving dimensions of complete versus missing information may demand less cognitive strain and be more appealing. In an unpublished paper discussed by Bettman (1979), Wright also looked at decisions between two alternatives each with one common and one different attribute, and found opposing results.

One reason for these conflicting results may be that the Slovic and MacPhillamy studies utilized linear models to estimate the weights assigned to the two cues without considering that different models may have been utilized in the two situations. If, as suggested here, subjects switched to more alternative-based processing when information was missing and inferencing was difficult, then simply looking at the regression weights from linear models could be problematic. The effect of missing information on decision strategy selection was not fully explored in these studies.

Following Slovic and MacPhillamy, a number of studies have suggested that missing and

subsequently inferred information is discounted or ignored (Meyer 1981; Yates, Jagacinski, and Faber 1978). Yet other studies report opposite or mixed results (Ford and Smith 1987; Johnson and Levin 1985). Overall, these studies suggest that individuals do in fact make inferences when faced with missing information, and that inferential processing requires cognitive effort (Alba and Hutchinson 1985; Meyer 1981).

However, the emphasis throughout this stream of research has been on attribute weighting and valuation and the cues used to infer missing information. Just how missing information may affect decision processing is unclear. The primary methodologies used in these studies were linear model estimates of attribute weights based on likely-to-buy indications from alternative attribute descriptions. Discounted weights, and overall decreases in satisfaction ratings on alternatives with missing information, may reflect some consumer switching from attribute-based to alternative-based processing.

If the effort required to infer the missing information is high, as when cue redundancy is low (Hagerty and Aaker 1984; Johnson and Katrichis 1988), a switch to more holistic, alternative-based processing could have led to an implicitly discounted attribute weight. However, these methods of analysis impose an additive or linear evaluation method which may not reflect how the subjects actually were evaluating the alternatives and thus may not detect a difference in evaluative procedures.

A MODEL OF INFERENCE INDUCED STRATEGY SELECTION

The basic proposition here is that missing information and the subsequent need to form inferences may result in a shift to processing strategies that avoid the inference process. In general, attribute-based comparisons are relatively easy, making attribute-based strategies (in which individual attributes are chosen and compared across alternatives one at a time) very attractive to consumers (Tversky 1969). If, however, information is missing on one or more of the attributes of comparison, inferences required to "fill-in" the missing values may require significant incremental effort (Alba and Hutchinson 1985). This additional and potentially effortful inference stage may lead consumers to shift to a simpler strategy. As the required effort necessary to utilize an attribute-based strategy increases due to the need to form inferences on individual attributes, consumers may shift to more straightforward alternative-based strategies. In such strategies, all attribute values for a given alternative are combined to provide overall alternative evaluations which can be compared to make a choice. This combining of values across attributes to form overall evaluations may circumvent the need to make attribute-based comparisons (Johnson 1984). Alternatively, consumers may use hierarchical elimination strategies on available information if this is reasonable. Such eliminations are reasonable when

based on particularly important or diagnostic attributes (Klein 1983).

The effects of missing information and subsequent inferencing should be characterized by some increase in the number of inferences used in processing in missing information situations, and a relative shift from the use of attribute-based strategies to the use of alternative-based choice strategies. This relative shift may allow attribute-based processing to continue, but decrease proportionately while the use of alternative-based strategies increases as missing information is introduced. Based on this, the following propositions are forwarded:

- P1a: As missing information increases, the number of inferences regarding attribute values used in processing should increase.
 P1b: As missing information is introduced, the use of attribute-based processing to choose among alternatives should decrease relative to alternative-based processing.
 P1c: Any attribute-based processing that does occur should involve more hierarchical eliminations based on diagnostic attributes.

THE EFFECTS OF KNOWLEDGE

The amount of effort that inferencing requires should affect the magnitude of the proposed strategy shifts. This effort should vary from consumer to consumer based on many factors. One such factor may be the consumer's level of expertise within the product category. As inferences about missing attribute values are typically assumed to be based on cues provided about the same-brand, other brand, or category (Ford, et al 1987), consumers with more expertise in the category may be able to more easily use the available cues to form inferences (Alba and Hutchinson 1987). They may already have well-formed ideas regarding the correlations between the presence and values of different attributes (Johnson and Katrichis 1988). Further, they may have previously been faced with missing information in the category and thus be familiar with using cues to form inferences. Therefore, experienced consumers may require less effort to form inferences regarding missing attribute values. As a result, their choice of a strategy may not be influenced by missing information to the same degree as novice consumers.

This idea is supported by research in the area of consumer knowledge and its effects on processing. It has been argued that over time and repeated exposures, consumers may develop a set of expectations about a product category (Sujan 1985). Further, these expectations may provide consumers with a set of hypotheses regarding which attributes go together, typical configurations of attributes, and expected performance levels of products that can be matched to these categories. Extending this view, if a consumer has such expectations, classification of a product with missing information to a category based on the available information permits one to adduce or predict the missing information (Nisbett

and Ross 1980). Therefore, experience with the product category can lead to less effortful inferencing.

Alba and Hutchinson (1987) suggest a similar consequence. They suggest that consumer knowledge has two parts; familiarity, or the number of product related experiences accumulated by the consumer; and expertise, or the ability to perform product-related tasks. They hypothesize that product familiarity increases the likelihood of analytic processing. Consequently, highly familiar consumers will be more likely to perform tasks which require analytic processing. Schema-based inferencing, as discussed above is one such task. At very low levels of knowledge, novices lack the ability to make schema-based inferences. Therefore, when inferences are required, expertise should make them easier and more likely to be generated.

Alternatively, Alba and Hutchinson (1987) and Sujan (1985) suggest that while some level of knowledge is necessary for all inferencing, experts may be more judicious in their use of nonanalytic inferencing. It has been argued that consumers with at least a rudimentary knowledge structure may prefer to use prior evaluations based on simplistic criteria to make choices (Bettman and Park 1980). They may tend to use schema-based affective processes or nonanalytic inferencing more often than consumers with very low or high levels of category knowledge (Sujan 1985).

Overall, these arguments suggest that the likelihood of inferencing increases with experience. When faced with missing information, consumers with high levels of experience in the category may have less incentive to switch to alternative-based processing since analytic inferencing may not involve significant effort. This may also occur for consumers with moderate levels of experience who may more readily engage in nonanalytic inferencing. Conversely, those with lower levels of experience will require more effort to infer missing values and should show a greater shift to alternative-based processing. Thus the following propositions are forwarded:

- P2a: The number of inferences used in processing when missing information is introduced should increase less for novices than for consumers with moderate and high levels of category experience.
 P2b: Novices should exhibit a relatively stronger shift from the use of attribute-based processing when missing information is introduced than consumers with moderate or high levels of category experience.

EFFECTS OF TASK COMPLEXITY

Another factor which may affect the effort involved in inferring missing attribute values and therefore the magnitude of the inference induced strategy shift may be the overall complexity of the decision task. Studies support the concept that task complexity can directly influence the type of

decision strategy employed by the decision maker, as discussed earlier in this paper. We extend this framework by suggesting that one way in which task complexity affects strategy use is via its mediating effect on the effort of inferencing in situations with missing information.

Consider that tasks characterized by little missing information may require that only a few attribute values be inferred, and therefore only a marginal increase in effort is needed to process by attribute. This marginal increase may not be sufficient to induce the consumer to switch to alternative-based processing. However, as the amount of missing information increases and more attribute values must be inferred to process by attribute, the effort required increases as well. Eventually, consumers may reach some threshold of missing information where inferencing effort triggers a change in processing.

Similarly, in tasks involving no time pressure, the effort and time required to infer missing attribute values may not deter the consumer from processing by attribute. However, as time pressure is introduced, the consumer may feel unable to perform the decision task while taking extra time and effort to infer missing values. Consequently, the consumer may avoid the effort and time involved in inferencing by switching to alternative-based processing.

Finally, in decision tasks involving few alternatives, the overall decision effort involved is lower than in tasks involving many alternatives. It could be argued therefore, that the extra effort involved in inferring missing values would be more likely to cause a strategy shift in situations with many alternatives particularly when the missing information is spread across alternatives. However, as discussed earlier, many studies have shown the switch to phased strategies as the number of alternatives increased, in which an elimination phase typically involving an attribute-based strategy (such as EBA) is used first to reduce the alternative set. Therefore, increases in switching to alternative-based strategies to avoid inference effort in the many alternative task versus in the few alternative task may be masked or moderated due to the increased use of elimination strategies. At the same time, any switch to elimination strategies may be enhanced.

In summary, there is evidence that task complexity may directly affect the consumers' use of decision strategies. Further, complexity may also affect decision strategy use indirectly via its mediating effect on the effort involved in inferencing. Based on these arguments, the following propositions are forwarded:

P3a: The shift from the use of attribute-based processing to alternative-based processing when missing information is introduced should be relatively stronger in decision tasks involving more missing information than in tasks involving less missing information.

P3b: The shift from the use of attribute-based processing to alternative-based when missing information is introduced should be stronger in decision tasks involving time pressure versus tasks involving no time pressure.

EFFECTS OF CATEGORY ATTRIBUTE REDUNDANCY

The last factor to be considered for its effect on the *effort* involved in inferring missing values is the natural attribute redundancy within a product class. To the extent that a consumer perceives one attribute as an accurate predictor of another they may find inferences regarding those attributes to be more straightforward. When faced with missing information on an attribute from a product category with high redundancy, the consumer is more likely to recognize another given attribute as being an accurate predictor of the missing value. While this is related to the effects of experience as discussed earlier, redundancy or covariation within the product category *itself* may influence whether or not this learning takes place. And there is evidence that consumers may enter a category perceiving redundant information (Johnson and Katrichis, 1988).

This argument rests on the assumption that the level of attribute redundancy varies between product categories. This idea was supported in a study by Johnson and Katrichis (1988) which looked at attribute level redundancy across 65 product categories. They assessed brand by attribute matrices from *Consumer Reports* and found significant levels and ranges of attribute redundancy across product categories. Redundancy varied widely both across categories, and across attribute pairs within the categories.

This argument also assumes that consumers are able to perceive covariation. Many early studies in this area suggested that prior theories or expectations may be more important to the perceptions of covariation than observed data (Chapman and Chapman 1967; Jennings, Amabile, and Ross 1980; Nisbett and Ross 1980; and Olson 1974). However, recently these assertions have been challenged. Alloy and Tabachnik (1984) argue that people are reasonably accurate estimators of covariation in situations wherein they have no strong beliefs (see also Bettman, Roedder John, and Scott 1986). If beliefs are absent and the data clear and easily processed, covariation assessment will depend more on data. Johnson and Katrichis (1988) demonstrated that consumers appear to learn attribute relationships and do not perceive redundancy in the absence of actual redundancy, suggesting that expectations do not always dominate consumer perceptions.

In summary, there exists evidence that product categories do vary in their inherent attribute redundancy, and that consumers can perceive and may use these covariation assessments to aid in inferring missing attribute values. It follows that, in highly redundant categories, inferring missing attribute values may require less effort. Further, a

consumer may then be less likely to shift to an alternative-based decision strategy to avoid inferences in highly redundant categories because the inferencing effort involved is low versus that in less redundant situations. Therefore, the following proposition is forwarded:

P4: Because inferences are easier in product categories with high attribute redundancy, the shift from attribute-based to alternative-based processing when missing information is introduced should be relatively stronger in low redundancy categories than in highly redundant categories.

Similarly, it could be argued that inherent redundancy across attribute pairs of the specific attribute with the missing value will also influence the effort a consumer is required to exert to infer that value and, therefore the likelihood of a strategy switch.

EFFECTS OF DECISION IMPORTANCE

Another factor which may affect the balance of the cost/benefit relationship involved in the proposed inference induced strategy shift is the importance of the decision. While the previously discussed factors were argued to affect the effort involved in inferencing and therefore the likelihood of a strategy shift, decision importance may affect the motivation of the consumer to strive for accuracy. If an accurate decision is more important or salient to the consumer, it may take a greater increase in effort to induce a shift to a simplifying strategy.

Decision importance may be influenced by the importance of the decision consequences to the decisionmaker (Chaiken 1980), or whether or not the decisionmaker must justify the decision in some way (Hagafors and Brehmer 1983). Thus defined, it has been argued that the higher the importance, the more analytic, systematic, formal, careful, or complete the decision process (Billings and Scherer 1988; Chaiken 1980; Gabrenya and Arkin 1979; and Hagafors and Brehmer 1983).

As previously discussed, in Beach and Mitchell's (1978) cost/benefit contingency model, the selection of a decision strategy was contingent on the relationship between the value of a correct decision and the negative feeling associated with spending the time and effort required to apply the most accurate strategy. The cost/benefit relationship was argued to be influenced by significance and accountability. As these factors are increased, the use of more formal strategies were hypothesized to increase as well, even though the cost incurred (in terms of time and effort) were also positively related to the use of the formal strategies. This relationship has since been demonstrated in studies looking at the effects of importance on time taken to make a decision (Christenson-Szylanski 1978) and on the use of more analytical decision strategies (McAllister, Mitchell, and Beach 1979).

This suggests that the more important the decision, the more likely a consumer will stick with a strategy he feels will produce a more accurate decision even in the face of increased effort. Thus, the following proposition is forwarded:

P5: The shift from the use of attribute-based to alternative-based processing when missing information is introduced should be relatively weaker in situations of high decision importance than in situations of low importance.

Similarly, it could be argued that the importance of the specific missing attribute value to the decision task will also influence the effort a decisionmaker may be willing to exert to infer that value, and consequently the likelihood of an inference effort induced strategy shift.

CONCLUSION

Given that many consumer decisions are characterized by missing information, a better understanding of its influence on consumer decision processing may be important. This paper has proposed a cost/benefit based theory which explains the influence of missing attribute value information and particularly the role of inferences on consumer decision processing. This theory argues that when attribute values are missing, in order to use some preferred strategies (e.g. attribute-based comparisons) a decisionmaker must infer the missing attribute values. If attribute value inferences require effort, a decision maker may attempt to avoid the increased effort by switching to (1) alternative-based processing which can be applied directly, or (2) hierarchical elimination strategies which use diagnostic, available information.

Further, consumer experience with the product category, task complexity in the forms of amount of missing information and time pressure, product category attribute redundancy, and decision importance were all hypothesized to influence this cost/benefit relationship, and consequently the magnitude of the proposed strategy shift.

Finally, while we have outlined a theoretical framework for the effects of missing information on decision strategies, future research will test the propositions suggested in this paper.

Knowledge and Context Effects on Typicality and Attitude Judgments

Cynthia D. Huffman, University of Minnesota

Barbara Loken, University of Minnesota

James Ward, Arizona State University

ABSTRACT

This paper examines the effects of prior knowledge and context on typicality, frequency of instantiation, and global attitude judgments made in contexts that differ in exemplar typicality. We present research that shows significant effects of context on typicality judgments and significant interaction effects of context and knowledge on typicality and frequency of instantiation judgments. In general, the findings suggest that the information available to consumers in the judgment context has effects that differ depending on the level of prior knowledge of the consumer.

Studies of judgments and attitudes in consumer behavior typically assume a constant environment; that is, the context in which the judgments are made is often neglected as a source of possible impacts on the decision process of the consumer. However, the importance of environmental effects on judgments and consumer choice has emerged in the literature as an important topic of study. Specifically, among the issues that have been investigated are the effects of context on choice processes and outcomes (Bettman 1988; Klein 1989; Payne, Bettman, and Johnson 1988), the effects of context on choice models of noncompensatory processes (Johnson and Meyer 1984), the effects of framing and reference points on consumer decision-making processes (Klein and Oglethorpe 1987, Monroe and Chapman 1987, Rowe and Puto 1987), and effects of comparative versus noncomparative advertising on judgments of similarity, distinctiveness, informativeness, and polarization of attitudes (Sujan and Dekleva 1987). These studies strongly suggest that a product may be judged differently depending on the products with which it is encountered and the situation in which it is judged, but they only begin to detail the possible implications of the effects of context on other judgments and attitudes.

One of the most well-known treatments of the effects of context arises from social judgment theory (i.e. Sherif and Hovland 1961). According to social judgment theory, the extremity of a judgment with respect to a target depends in part on the reference point available - the standard of comparison. By manipulating the standard of comparison, the judgments elicited on aspects of a stimulus may be changed. The implications of social judgment theory and context effects for product judgments are important for product positioning and, more particularly, for advertising issues. For example, companies frequently use prototypical products or brand leaders as anchors or standards in comparative advertising.

However, with the exception of Sujan and Dekleva (1987), there has been no attempt to

combine categorization judgment measures, such as typicality, with context effects. In addition, the interactions of knowledge with context have not been investigated. In this paper, we report an investigation of the effects of context and knowledge on judgments of prototypicality within a product class.

THEORY AND PRIOR RESEARCH

Contrast Theory

Sherif, Taub and Hovland (1958) found that when a person was asked to judge the heaviness of stimuli that were distributed over some range of weight with equal frequency and there was no explicit anchor or comparison stimulus in relation to which the stimuli were to be judged, the judgments tended to distribute themselves over the judgment categories approximately rectangularly. When a stimulus more extreme than any of the others was designated as the anchor stimulus from which to base judgments, other stimuli were judged to be further from the anchor stimulus than they would otherwise have been (the contrast effect). Applied to social stimuli, it has been argued that the perceiver apparently exaggerates the discrepancy between the stereotype (on a particular attribute) and the observed (Manis, Nelson, and Shedler 1988).

At least three distinct conceptualizations exist of how contrast effects might derive from some sort of comparison process (Manis, et al 1988). First, an explanation based on adaptation-level theory (e.g. Parducci, Calfee and Marshall 1960) would argue that contrast effects derive from comparison with the central tendency of the individual's internal representation of the category under evaluation. A second possibility, based on range theories, is that judgments are determined by the location of the stimulus to be evaluated within the range that is established by the most extreme of the relevant contextual stimuli. Third, a "rank-based" hypothesis argues that assessment processes are based (in part) on the rank of a target stimulus relative to other relevant stimuli (i.e. How many are more extreme?). Regardless of the particular explanation, it appears that a comparison process takes place when consumers are asked to make judgments about products. Thus, a judgment is made in relation to other contextual stimuli rather than as an absolute value (see Smith, Diener and Wedell 1989 for further elaboration of range and other comparison processes).

In addition to providing a conceptual basis for hypothesizing effects on brand judgments, the context literature suggests that attributes may be judged differently in different contexts. Tversky (1977), for example, has shown that features may be weighted differently depending on the context.

Researchers have used a variety of procedures to manipulate the context in which objects are judged. Herr, Sherman, and Fazio (1983), for example, used a priming paradigm in which the category made accessible by the prime was used as the basis for contrast. In other cases, the stimuli provided have been the context that forms the basis for range and/or rank effects (e.g. Smith et al 1989). However the context is achieved, it is in effect a standard of comparison against which to assess the target(s).

Typicality Effects

People perceive exemplars of a category to vary in the degree to which they are representative, or typical, of a category (e.g. a robin is a more typical bird than a vulture). As discussed above in relation to social judgment theory, the context in which judgments are made may have effects on the extremity of those judgments. Specifically, different collections of exemplars may differentially influence judgments on a target stimulus. For example, a moderately typical exemplar embedded in a context of atypical exemplars may be judged to be typical, while the same moderately typical exemplar may be judged to be less typical when embedded in a collection of typical exemplars. The different collections of exemplars that comprise the context for the judgments on the target exemplar serve as standards of comparison in the same way that standards of comparison were used in the contrast studies discussed above (i.e. Smith et al 1989).

It seems likely also that a "hierarchy of contrast effects" may exist, where the contrast effects are strongest for typicality, next strongest for "surrogate" measures of typicality such as frequency of instantiation (Barsalou 1985), and least strong for attitude toward the target exemplar. The more closely the independent variable of context typicality is conceptually related to the dependent measure, the greater the effect predicted. These predictions also arise from measurement studies in categorization (i.e. Mervis and Rosch 1981, Barsalou 1985), where the category representation is argued to be most nearly approximated by typicality measures, next most closely by frequency of instantiation, etc.

The above arguments lead to the following predictions:

H1: A moderately typical target exemplar will be judged to be more typical in (a) a context with all atypical exemplars than in (b) a context with all typical exemplars. In (c) a context with a range of typicality of exemplars, the typicality judgments on the target exemplar will be somewhere in between the judgments from the other two contexts (context a and context b).

H2: A "hierarchy of contrast effects" will exist such that the above context effects on the target category member

will be strongest for global typicality measures, less strong for frequency of instantiation, and least strong for attitudes toward the target category member.

Knowledge

Expertise or prior knowledge is associated with richer, more complete, and more detailed representations of a category in memory (Alba and Hutchinson 1987, Brucks 1986, Murphy and Wright 1984). Experts in a product category thus should have readily accessible knowledge about a wide range of the products in that category. Further, as Chi, Glaser and Farr (1988) argue, experts are less likely than novices to rely on less relevant surface features or literal objects stated in the problem description in making judgments. Both experts and novices use conceptual categories, but these categories are richer and more semantically-based for experts and more syntactically or surface-based for novices (Chi et al 1988; Walker, Celsi and Olson 1987).

More knowledgeable consumers are likely to know more about the various product category members and are more likely to have insight into the characteristics and criteria that differentiate one product from another. Novices should have less developed cognitive structures about specific members of a category and the characteristics that determine category structure. Thus, subjects with extensive accessible prior knowledge should be more likely than subjects with low prior knowledge to use that prior knowledge as their standard of comparison, in accordance with adaptation theory. In contrast, subjects with low prior knowledge should be more likely to use an external context for the standard of comparison, such that range theories would be appropriate in determining context effects. Since experts' perceptions of category representativeness may then be less likely to be influenced by external context than novices' perceptions, we expect to see the smallest effects of (external) context for subjects with high prior knowledge and larger effects of (external) context for subjects with low prior knowledge. That is:

H3: Subjects with low prior knowledge about the product category will show larger context effects than will subjects with high prior knowledge.

METHODOLOGY

Overview

Data collected from a laboratory study were used to test the above hypotheses. After reading through a list of 15 makes of automobiles, a sample of 81 college students completed measures of typicality, frequency of instantiation, attitude, and knowledge. The list of automobiles, which were also the ones rated on individual measures, defined the context manipulation. Each subject was

randomly assigned to one of the three context conditions.

Context Stimuli Selection

Three contexts were used in testing the hypotheses in this study. Context 1 had fourteen automobiles that represented a range of typicality, based on typicality scores from a pretest (of 35 automobiles), relevant to the category of "economy cars". Context 2 had fourteen automobiles that were all previously rated as most typical of the category of economy cars. Context 3 had fourteen automobiles that were all rated as most atypical of the category of economy cars. In addition, each context included a target economy car (referred to here as Car "X"), which had been rated as typical of economy cars. (On scales ranging from 1 to 7, with greater numbers reflecting greater amounts of the dimension, the target car was rated as 5.86 for typicality and 4.67 for representativeness in a pretest; the target car was rated as one of the 4 most typical economy cars, out of a possible 35 cars).

For each context, half of the questionnaires had a randomly determined order and half had the reverse order. In each order, for each context, the target exemplar was the fifteenth automobile listed. This ensured that the context would be fully encoded by the time the target exemplar was rated and that comparisons of the target across contexts would not be confounded by order effects.

Measures

Measures of global typicality, frequency of instantiation, attitude and knowledge were taken, in that order. All subjects rated all fifteen automobiles in one context on all measures. However, only data pertaining to the target exemplar were used in subsequent analyses. The rationale for measuring all 15 automobiles was (1) to disguise the purpose of the study and (2) to strengthen the context manipulation.

Global typicality was measured on two single-item 7-point scales. The first was a "typicality" scale ranging from "very atypical" (1) to "very typical" (7), with instructions adapted from Hampton and Gardiner (1983). The second typicality scale was a 1 to 7 scale of "representativeness", ranging from "very unrepresentative" (1) to "very representative" (7). The correlation between the typicality and representativeness scales was 0.80 for the target exemplar, so the two scales were combined to form a summary scale. However, since initial pretest data suggested that the target exemplar yielded higher scores on the typicality scale than on the representativeness scale, these two measures were also treated independently in certain analyses. As subsequent analyses indicate, the representativeness scale yielded somewhat different findings than the typicality scale.

Attitude toward the target exemplar was measured on two 1 to 7 evaluative semantic differential scales (extremely bad (1) - extremely

good (7) and extremely unfavorable (1) - extremely favorable (7)). The two scales correlated 0.90 and were summed to form the measure of attitude.

Frequency of instantiation was measured by asking subjects to rate how frequently they encountered each category member (automobile) - in store, ads, etc. - as an instance of the category "economy cars". The frequency of instantiation (FOI) measure was a 7-point scale with endpoints "not at all frequently" (1) and "very frequently" (7). Instructions were based on Barsalou (1985).

Finally, knowledge about the category was measured in two ways. First, subjective knowledge was measured by a single-item 5-point scale, asking subjects to rate how knowledgeable they were about automobiles relative to other people, on a scale from "very familiar" to "very unfamiliar". A second 30-item objective knowledge scale was developed, some items of which were open-ended and some multiple choice. The open-ended questions encompassed terminology, personal experience, and industry knowledge. For example, one question was "What does V-8 engine mean?" Another asked subjects to give an example of each of eight types of automobiles (full size pickup truck, sedan, compact, etc.). The multiple choice questions tapped specific model knowledge, and included questions such as "The ___ has a 1.8 liter fuel-injected engine" and "The Pulsar is made by ___." The objective knowledge test was pretested and refined to enhance reliability (24 items remained). Cronbach alpha for the open-ended objective questions was 0.73; for the multiple-choice questions 0.71. The two scores (open and closed-ended items) were summed for a total objective knowledge score. On the refined scale, the maximum possible score for total knowledge was 48. Subjective and objective knowledge correlated moderately high (0.74) but were analyzed separately in subsequent analyses.

RESULTS

Overview

The main hypothesis investigated was the effect of context on typicality judgments for the target exemplar (Car "X"). In addition, other measures taken were analyzed for differences across contexts to examine the hierarchy of effects proposition (hypothesis 2). Finally, the effect of prior knowledge on the other results was examined. The results of these analyses are reported below. In the analyses, all data from 7 point scales were recoded from -3 (atypical, unfavorable, not at all frequently, etc.) to +3 (typical, favorable, frequent, etc.). Data from the 5-point scales were coded from 0 (very unfamiliar) to 4 (very familiar).

To test the hypotheses, two-way analyses of variance were performed with each typicality measure separately as the dependent variable and the three levels of context as one independent variable. The second independent variable was knowledge (high or low, split at the median).

TABLE 1
MEANS FOR DEPENDENT MEASURES FOR EACH CONTEXT CONDITION

Dependent measures	All typical	Range	All atypical	F-value
Representativeness	0.96	1.04	1.31	0.461
Typicality	0.50	1.22	1.54	3.666 ^a
Typ. + Rep. (summed)	1.46	2.26	2.85	1.796
FOI	-0.32	-0.41	0.42	1.410
Attitude	-0.89	-1.33	-1.77	0.498

NOTE: N = 81 subjects, with 28 in the all typical context, 27 in the range, and 26 in the all atypical.

Effects of Context on Typicality Judgments

Results are shown in Table 1. The results for typicality show that, as predicted, judgments differ significantly ($p < 0.05$) by context. That is, in the all atypical exemplar context, the target exemplar was judged to be more typical ($M = 1.54$) than it was judged to be when it was in the context of all typical exemplars ($M = 0.50$). The mean of the typicality judgments for the target exemplar in the "range" context condition was somewhere in between the two context extremes ($M = 1.22$), as expected. The differences in means for the representativeness measure unexpectedly did not reach significance ($p = 0.63$), although the means are in the predicted direction.

Hierarchy of Contrast Effects

A hierarchy of effects of context was expected such that typicality and representativeness would show the largest effects of context, with FOI (frequency of instantiation) and attitude showing progressively smaller effects. Effects of context were not present for either FOI or attitude. However, as shown in Table 1, means were in the same direction as noted for typicality, and the F values were closer to significance for FOI than for attitude.

Effects of Knowledge on Typicality

The effects of both objective and subjective knowledge on typicality were also investigated as a function of context. As stated in hypothesis 3, an interaction between context and knowledge was expected such that subjects with low prior knowledge of automobiles would show larger effects of context than subjects with high prior knowledge. Results for typicality are shown in Table 2 and Figure A. The expected interaction effect is, indeed, significant for both objective ($F = 6.273$, $p < 0.005$) and subjective ($F = 3.252$, $p < 0.05$) knowledge, but the means are exactly opposite the predictions. As shown in Figure A, subjects with high knowledge were more likely than subjects with

low knowledge to show the predicted contrast effects (i.e. greater perceived typicality of the target exemplar as the frequency of atypical exemplars increased in the context condition). Similar interaction effects, but less pronounced, were found for frequency of instantiation for objective ($F = 7.516$, $p < 0.005$) and subjective ($F = 1.667$, $p < 0.20$) knowledge, and effects were less evident for attitudes toward the target ($F = 2.347$, $p = 0.10$ and $F = 0.227$, $p = 0.63$ for objective and subjective knowledge, respectively), as shown in Table 2 and Figures B and C.

In summary, in contrast to hypothesis 3, the effects of context were greater for high than for low knowledge subjects. A possible explanation for this effect is that only subjects with higher knowledge were able to appropriately categorize the context with respect to economy cars and use those categorizations to make typicality judgments. Further, the data seem to support the idea that the less knowledgeable subjects did not know about the characteristics of the stimuli since in the presence of the all atypical context they seemed to assume the target (typical) stimulus was atypical too, and thus their typicality rating for the target exemplar trended down. In other words, they seemed to know enough to realize that most of the stimuli in this context were atypical, but not enough to differentiate the target from this general judgment.

DISCUSSION

Summary of Findings

Several interesting results occurred, not all of which were expected. First, as predicted, we found that subjects' judgments of typicality were affected by context. In particular, when the target exemplar was presented within a list of very *atypical* exemplars, it was rated as more typical than when presented within a list of very *typical* exemplars. This finding is consistent with social judgment theory (Sherif and Hovland 1961) as well as more recent theories of contrast (Manis et al 1988) and

TABLE 2
 MEANS AND F TESTS FOR THE TARGET EXEMPLAR ON THE DEPENDENT VARIABLES FOR EACH KNOWLEDGE AND CONTEXT CONDITION

social comparison (Smith et al 1989). Not surprisingly, effects of context on frequency of instantiation (a "surrogate" measure of typicality) and attitude were less pronounced. That is, although means were in the same direction as judgments of typicality, subjects were not significantly more likely to judge the target as a familiar instance or as well-liked when the context included all atypical economy cars, than when the context included all typical economy cars.

Finally, knowledge was found to interact with context such that the above effects of context on typicality occurred for *high* knowledge but not for *low* knowledge subjects. This finding was exactly counter to predictions. However, it does suggest that higher and lower knowledge subjects have differing abilities to integrate their internal category representations with the context presented. We had predicted, in essence, that low knowledge subjects' judgments would be affected by context due to their lack of internal standard of comparison in this product category and that high knowledge subjects' judgments would not be affected because they would use their internal knowledge as a standard of comparison instead of the external context. An explanation for the results may lie in the amount of information provided and the corresponding usefulness of the information to subjects with differing levels of knowledge.

In the questionnaires, no attribute value information was given for the automobile stimuli provided to subjects. Instead, automobiles were identified only by maker and model name (e.g. Chevy Nova, Ford Tempo). Providing only a name conveys, through associations and inferences, a lot of attribute value information to high knowledge subjects, but it provides little information to subjects who are not able to make the appropriate connections of attribute values to car name, such as our low knowledge subjects. Thus the results obtained may be explained through an information provision proposition which has yet to be tested: for context effects to occur for low knowledge subjects, attribute value information must be available in the context. For high knowledge subjects, because they are able to use associations and inferences from brand names, context effects will occur even in the absence of attribute value information.

The differences in context effects between typicality and attitude judgments may be due to differences in the use of context stimuli. For attitude judgments, experts may be less likely to rely on the attributes of the other category members in making an evaluation than for typicality judgments. If in fact they had already stored an evaluation of Car "X" or "X"-type cars (recall that Car "X" was the target exemplar), their evaluation would probably be less influenced by irrelevant contextual factors than the evaluations of the novices. This is one explanation of why the experts' attitude judgments do not seem to be affected by context. Note here that the arguments

about attitude and typicality do not contradict each other if it is assumed that the typicality instructions oriented subjects more than the attitude instructions to use the category context as a reference. Finally, why were the non-experts' attitude judgments seemingly influenced by context while their typicality judgments were not? One explanation is that perhaps the non-experts did not have enough knowledge about the stimuli to form the context to influence the typicality judgment, which might require comparison on attributes, but did have enough overall evaluative knowledge (perhaps just overall stored affect about certain brands) that their attitude judgments were influenced by context.

The results found are interesting in that internal contexts (hypothesized to eliminate the contrast effects for high knowledge subjects) may not in some cases be responsible for contrast effects on judgments where an external context is available. High knowledge subjects' typicality judgments were affected by the context in which they were made. Research is needed on this question in order to clearly determine the conditions, if any, under which high knowledge subjects use their internal knowledge base as the context, or standard of comparison, against which they make their judgments. Finally, the unexpected results obtained indicate that the conclusions to be drawn are tentative. Further research is needed to test the explanations given and the conclusions drawn before any attempt to generalize is made.

CONCLUSIONS

These results, if supported by future research, have both managerial and theoretical implications. First, the results suggest that presentation of products to audiences may need to be adapted depending on the knowledge level of the targeted consumers and depending on the anticipated environment, or context, of presentation. For example, in a simple promotion presentation with minimal information given on context brands, context effects may occur only for individuals with high knowledge in the product category. Where attribute value information is available on context brands, context effects could occur for low knowledge individuals as well.

Context may be one avenue to help create a product image. On the surface, at least, it appears that if an "atypical" image is desired, the optimal context for presentation may be one with all typical brands. Of course, this assumes that the consumer will accept as credible the mix of brands presented by the advertiser. The results also suggest that much more subtle effects of context may appear with higher knowledge subjects due to their greater ability to sub-categorize context brands, with the sub-categorization subsequently affecting judgments.

Differences found between the effects of subjective and objective knowledge, or perceived and actual knowledge, although small, are interesting and may be integrated into other work in this area, such as Park, Gardner and Thukral (1989). However,

as subjective knowledge was measured with a single scale only, the conclusions to be drawn here are necessarily limited.

This research is one step in determining how prior knowledge and experience fit into the judgment process. It is suggested here that high knowledge subjects may use their internal knowledge with appropriate cues, but they may not always use their category representations as the integrating schema for presented information in some conditions. One avenue of research suggested by this study may be the conditions under which prior knowledge is used in making judgments, and the detailing of what knowledge is actually used (general category knowledge versus brand-specific information).

Inferences About Missing Attributes: Contingencies Affecting the Use of Alternative Information Sources

Carolyn J. Simmons, University of Illinois at Urbana-Champaign
Nancy H. Leonard, University of Illinois at Urbana-Champaign

ABSTRACT

We examined the use of same- and other-brand information sources in inferences about missing attributes. Subjects often used a same-brand process--probabilistic inference--when the inferred attribute was expected to be correlated with a known attribute, but they did not use an other-brand process--average-value inference--when the inferred attribute was expected to be uncorrelated with any known attribute. Subjects' inference strategies were insensitive to attribute correlations in task product sets. Feature-absent inferences were made when (a) an undescribed attribute was described for other alternatives evaluated concurrently and (b) the inferred attribute was one that could logically be absent.

Recently there has been considerable interest in models of consumers' evaluative processes which assume that consumers infer a value for salient attributes for which information is not available (Ford and Smith 1987; Gardial and Biehal 1987; Jaccard and Wood 1988; Johnson 1989; Johnson and Levin 1985; Meyer 1981; Zwick 1988). While there is some question about how broadly these models may be applied--there is evidence that such inferences are often *not* made unless explicitly prompted (Huber and McCann 1982; Lim, Olshavsky, and Kim 1988; Simmons 1988; Zwick 1988)--it is nonetheless clear that such inferences *are* sometimes made in the ordinary course of evaluating a product. In addition, there are naturally occurring situations which may be used to explicitly prompt inferences about a product--most obviously, in advertising. Therefore, it is important to understand not only the contingencies which encourage or dampen inferences about missing attributes, but also the processes by which such inferences are made.

ALTERNATIVE INFORMATION SOURCES

The literature has focused on two basic ideas about how inferred values are determined. The first is that inferences are based on some knowledge about the object of judgment. The second is that inferences are based on some knowledge or expectation about objects which are comparable to the object of judgment.

Knowledge about the Object of Judgment

Inferences based on knowledge about the object of judgment--specifically, a brand--have been labelled *same-brand* processes (Ford and Smith 1987), *attribute-based* processes (Zwick 1988), and *intra-alternative* processes (Johnson 1989). The term *same-brand* will be used in this paper. It is

generally assumed that same-brand inferences follow a rule of consistency: the missing attribute is inferred to be in some way consistent with known attributes. Two types of consistency have been posited: *evaluative consistency* and *probabilistic consistency*. *Evaluative consistency* refers to a process in which the inferred attribute is assumed to be similar in evaluative implications to known attributes. In contrast, *probabilistic consistency* refers to an inference process which is based, not on the evaluative implications of known attributes, but rather on their expected ecological correlation with the inferred attribute.

Research which has examined same-brand inference processes has generally concentrated on probabilistic inferences (Ford and Smith 1987; Huber and McCann 1982; Johnson and Levin 1985; Simmons 1988; Yamagishi and Hill 1981), although at least two studies have examined evaluatively consistent inferences (Jaccard and Wood 1988; Zwick 1988). There has been little systematic examination of the relative importance of these two types of consistency, however. Fishbein and Ajzen's (1975) review of research on trait inference suggests that probabilistic consistency is preferred as long as there is a strong correlation between a known attribute and the inferred attribute; otherwise, evaluative consistency is used. Dick, Chakravarti, and Biehal (1988) have presented results in a product evaluation study which are consistent with this conclusion.

Knowledge or Expectations about Comparable Objects

Inferences based on knowledge or expectations about comparable products have been labelled *other-brand* processes (Ford and Smith 1987), *category-based* processes (Zwick 1988), and *inter-alternative* processes (Johnson 1989). The term *other-brand* processes will be used in this paper. Other-brand processes involve the inference that an undescribed attribute has a value similar to that for comparable products. Most often, it has been assumed that such inferences are based on the expected average value for the product class or choice set.

There is evidence that alternatives are often evaluated in ways consistent with an average-value or discounted average-value inference for undescribed attributes (Ford and Smith 1987; Jaccard and Wood 1988; Meyer 1981; Slovic and MacPhillamy 1974; Yamagishi and Hill 1983; Yates, Jagacinski, and Faber 1978; Zwick 1988). It should be noted, however, that one can explain these findings without assuming that inferences are made. Using process-tracing data, Simmons (1988) found evidence that subjects treated the absence of information as a neutral or negative cue, but they did

not actually make an inference about the missing attribute. This process results in evaluations that are consistent with what would be expected if neutral or negative inferences were made, and could lead researchers to overestimate the frequency of such inferences. The distinction between treating the absence of information as a neutral or negative cue and actually making an inference about a missing attribute is not trivial. Inferences create attribute "knowledge" which may subsequently affect responses to the product in a number of ways. For example, inferring that a product is expensive may discourage a person on a tight budget from considering the product. Treating the absence of price information as a negative cue--which lowers one's evaluation, but does not create a specific belief about price--may not have the same effect.

CONTINGENCIES AFFECTING USE OF ALTERNATIVE INFORMATION SOURCES

The Best-Predictor Hypothesis

A common theme in inference research is that inferences about missing attributes are made by a very rational process. It has often been assumed that a same-brand process--probabilistic inference--is used when there is an expected correlation between a known attribute and the inferred attribute, whereas an other-brand process--average-value or discounted average-value inference--is used when the inferred attribute is expected to be uncorrelated with any known attribute (Huber and McCann 1982; Johnson 1989; Johnson and Levin 1985; Meyer 1981; Simmons 1986; Yamagishi and Hill 1981).¹ This is essentially an assumption that consumers use the best predictor available. If there is no correlation between a known attribute and the missing attribute, the expected average value is the best predictor. If there is a correlation, then prediction can be improved by using the correlation (Simmons, 1986).

Although this prediction seems straightforward, it has not been directly tested. A strong test requires both that expected correlations be varied from high positive and negative to zero, and that process-tracing data be collected. When expected correlations are varied, probabilistic inferences can be diagnosed from patterns in overall evaluations (see Johnson and Levin, 1985, for these predictions). In such outcome data, however, average-value inferences are not distinguishable from a response in which no inference is made, but the absence of information influences the evaluation. Protocol data may thus be particularly useful in detecting average-value inferences. Protocols are

also potentially useful in testing the competing hypothesis that when the inferred attribute is not expected to be correlated with a known attribute, evaluatively consistent--rather than average-value--inferences are made. Depending upon the correct model of information integration, evaluatively consistent inferences may or may not be detectable in outcome data alone.

Assessment of the Accuracy of Expectations

If the choice of an inference strategy depends upon the nature of expected correlations between the inferred attribute and known attributes, then one might expect inference makers to be sensitive to evidence about the validity of these expectations. We have evidence that consumers are able to detect attribute correlations (Bettman, John, and Scott 1986) and that decision processes may be affected by such correlations (Huber and Klein 1988). Therefore, one might expect that the probability of making a probabilistic inference decreases when the relevant attributes in the observed product set are uncorrelated, while the probability of making an average-value inference decreases when attributes in the observed product set are highly correlated. Although Simmons (1986, 1988) found no evidence that the extent to which observed correlations were consistent with expectations influenced the *frequency* of inference making, it remains possible that for those who do make inferences, the *process* is altered.

Spontaneous versus Prompted Inferences

There is some evidence that spontaneous inferences tend to be based on same-brand information, whereas inferences which have been explicitly prompted are more variable, drawing on both same- and other-brand information sources (Ford and Smith 1987; Gardial and Biehal 1987; Zwick 1988). At least one study, however, has presented conflicting evidence that spontaneous inferences are based almost exclusively on other-brand information (Jaccard and Wood 1988). This mixed evidence is not surprising because these studies have generally varied in their sensitivity to various inference processes.

There are, however, a number of reasons that one might expect prompted inferences to be more likely to draw on other-brand sources than are spontaneous inferences. First, such an effect could be caused by a *selection bias*. Huber and McCann (1982) and Hansen and Zinkham (1984) have argued that unprompted inferences are rarely made unless there is a strong expected correlation between a known attribute and the inferred attribute--it is the expected correlation which cues the inference. This implies that unprompted inferences are made primarily by those people who are likely to make a probabilistic inference. Prompting then encourages those who do not hold strong correlational expectations to make inferences, and these people are perhaps more likely to draw on other-brand information sources.

¹The models are generally more complex than this in that inferences are predicted by the linear regression between a known attribute and the inferred attribute. The intercept term can capture any systematic bias in inferences, as well as any effect of expected average values on probabilistic inferences.

If this explanation is correct, then any external cue which encourages inferences should reduce the relative frequency of probabilistic inferences. For example, if an undescribed attribute becomes salient because competitive products emphasize that attribute, this may encourage inferences even though there is no correlational expectation. These inferences may be less likely to be probabilistic than inferences which are made in the absence of any such contextual cues.

Another reason that one might expect prompted inferences to be more likely to draw on other-brand information sources is *motivational*. Prompting may increase the motivation to make a valid inference by making the inference an integral part of the task. According to this explanation, the *process* by which inferences are made is altered. Feldman and Lynch (1988) have argued that people try to achieve their processing goals using the most easily accessible inputs. Only when these inputs are insufficiently diagnostic are other more diagnostic inputs retrieved from memory or sought externally. Since the explicit goal of a judgment task is to evaluate information about the object of judgment, same-brand information sources for inferences tend to be highly accessible. Inferences are therefore likely to be based on same-brand information. When the same-brand information is insufficiently diagnostic, as when prompting increases concern about the validity of the inference, the decision maker may supplement same-brand information with the less accessible other-brand information.

If this explanation is correct, then any manipulation which increases concern for the validity of the inference should have a similar effect. For example, being asked to report one's inference may increase one's concern for validity. On the other hand, an external cue which merely focuses attention on the missing attribute may not have this effect.

These two explanations for greater variability in the informational bases of prompted inferences--selection and motivation--are not mutually exclusive. Both processes may operate concurrently.

OVERVIEW OF STUDY

Process-tracing data were collected in a series of studies which examined spontaneous inferences made during product evaluation. Although these studies were not specifically designed to examine the contingencies governing the use of alternative information sources, they provide an opportunity to test a number of hypotheses suggested by the preceding discussion.

First, the "best-predictor" hypothesis is tested:

- H1: When there is an expected correlation between a known attribute and the inferred attribute, inferences tend to be probabilistic, whereas when there is no expected correlation, inferences tend to

be based on expected average values for the product class or choice set.

Consistent with this kind of rational inference strategy, it is predicted that inference makers are sensitive to evidence about the validity of their beliefs about attribute correlations:

- H2: If there is an expected correlation between a known attribute and the inferred attribute, the frequency of probabilistic inferences decreases when the attributes in observed product sets are uncorrelated. If there is no expected correlation between a known attribute and the inferred attribute, the frequency of average-value inferences decreases when the attributes in observed product sets are highly correlated.

Finally, it was argued that prompted inferences are more likely to draw on other-brand information sources than are unprompted inferences. Two causal mechanisms were suggested: a selection bias and a motivational effect. It was argued that a selection bias effect would occur any time an external cue encourages inferences, whereas the motivational effect would occur only when concern for the validity of the inference is increased. In the current study, the selection bias effect is tested. Therefore, it is predicted that:

- H3: The overall frequency of inference making increases when an external cue encourages inferences.

- H4: The overall frequency of probabilistic inferences is not influenced by the presence of an external cue.

- H5: The relative frequency of making a probabilistic inference is lower when an external cue encourages inferences.

Hypothesis 5 follows from Hypotheses 3 and 4. However, the relative frequency of making a probabilistic inference could be lowered for reasons other than a selection bias. Hypotheses 3 and 4 test the hypothesis that a selection bias is the causal mechanism.

METHOD

The data are from three studies (Experiments I, II, and IV) which are described in detail in Simmons (1986). A brief description of the method follows.

Subjects

Subjects were undergraduate psychology or business majors who participated in partial fulfillment of a course requirement. A total of 600 subjects participated in these studies, but with the exception of the tests of hypotheses 3 and 4, the following analyses are based only on the 177

TABLE 1
Expected Correlations Between Attributes

Expected correlation ^a	Refrigerator attributes	Carpet cleaner attributes
Zero	Capacity & warranty	Area cleaned per refill & versatility
High (positive)	Capacity & shelf space	Area cleaned per refill & tank capacity
High (negative)	Capacity & energy cost	Area cleaned per refill & weight
High (negative)	Capacity & price	Area cleaned per refill & price

^ain terms of evaluative implications

Note: The greater representation of attribute pairs which are highly correlated is because these studies were designed to test hypotheses regarding the effects of varying expected correlations from positive to negative; in the following analyses, no distinction is made between positive and negative expected correlations.

subjects who spontaneously made inferences (as indicated by protocols) during the course of the evaluation task.

Pretest

Two product classes were examined: refrigerators and steam carpet cleaners. These product classes were chosen because it was possible to describe these products in terms of attributes which pretest subjects believed to be either highly correlated or uncorrelated with the undescribed attributes of interest. These attribute pairs and their expected correlations are illustrated in Table 1.

Design

The design can be thought of as a 2 x 3 between-subjects factorial, with two levels of expectations about the relationship between the known attribute and the inferred attribute (high and zero) and three levels of evidence regarding the validity of these expectations (confirming, disconfirming, and no evidence).² Embedded in this design is a third factor, the presence or absence of an external cue. As will be described below, an external cue was provided in the confirming- and disconfirming-evidence conditions, but not in the no-evidence condition.

Expectations about correlations. One-attribute descriptions of refrigerators or carpet cleaners (e.g., refrigerators described only in terms of capacity) were evaluated by some subjects in a context in which most other alternatives were described in terms of two attributes (e.g., capacity and warranty) and by other subjects in a context in which all other alternatives were also described only

in terms of one attribute (capacity in this example). Interest focuses on the process by which the one-attribute descriptions were evaluated. It was expected that in the contexts in which most alternatives were described in terms of two attributes, inferences would tend to focus on the second attribute for which information was sometimes available, and this was found to be true. In a between-subjects manipulation, the undescribed attribute made salient by the context, and therefore the inferred attribute, was either one expected to be correlated with the known attribute or one that was expected to be uncorrelated with the known attribute. For example, the no-expected-correlation condition includes four groups of subjects: those who received information about capacity and made an inference about warranty, those who knew warranty and inferred capacity, those who knew area cleaned and inferred versatility, and those who knew versatility and inferred area cleaned. The expected-correlation condition includes all subjects who received one of the remaining twelve combinations selected in the pretest (see Table 1).

The remaining subjects--who never had information about a second attribute--were classified post hoc according to whether the attribute they inferred was expected (based on the pretest) to be correlated with the known attribute.

Evidence regarding validity of expectations. In the second between-subjects manipulation, subjects who did usually have information about a second attribute saw product sets in which correlations were either consistent or inconsistent with expectations. These were the confirming- and disconfirming-evidence conditions, respectively. The no-evidence condition consisted of those subjects who never had any information about a second attribute.

Presence or absence of an external cue. Subjects in the confirming- and disconfirming-evidence conditions were cued by the context to

²With the exception of the no-expected-correlation/disconfirming-evidence condition, at least two of the original experiments (I, II, and IV) contributed subjects to each cell of this design.

think about specific undescribed attributes because information was provided about these attributes for other products being evaluated concurrently. These subjects constituted the external-cue condition. The subjects in the no-evidence condition never had any information about the inferred attribute, and thus were not cued by the context to make the inference. They constituted the no-external-cue condition.

Other design factors. In a within-subjects manipulation, product descriptions varied in attractiveness across four levels. Each subject made evaluations for a set of alternatives in each product class. As it turned out, only 10% of the subjects made inferences in both product classes. The two observations from these subjects are treated as independent observations in the following analyses.

Procedure

The task was presented as one of examining a catalog in anticipation of a purchase. A general description of the features common to all models (of refrigerators or carpet cleaners) was followed by specific information about individual models. Subjects were asked to evaluate each alternative. Following completion of this task, they were asked to retrospectively describe how they went about forming their evaluations.

Dependent Variable

Inferences revealed in the protocols were coded according to the type of inference process used. Only inferences about the attributes examined in the pretest are included in the following analyses. This is because the expected correlation between the known attribute and the inferred attribute is a variable in the design, and expected correlations were known only for the attributes from the pretest. Ninety-eight percent of these inferences were found to fall into one of the following categories: (a) probabilistic, (b) average-value, (c) feature-absent, and (d) indeterminate. An inference was coded as probabilistic if the subject stated a probabilistic inference rule (e.g., "the lower the price, the fewer cubic feet"), or if multiple inferences made by the subject varied as predicted by the expected correlation (e.g., for a low energy cost: "It's probably a small refrigerator;" for a high energy cost: "It's probably quite large").³ An inference was coded as average-value if subjects indicated assuming an average value (e.g., "I assumed [the area cleaned] was average amount"), or if the subject inferred the same value of the missing attribute for all alternatives evaluated (no examples of this category were observed).⁴ An inference was coded

³In the case of a positive expected correlation, it is possible that some subjects coded as making a probabilistic inference actually relied on evaluative consistency, but no subjects made comments which indicated such a process.

⁴This definition of an average-value inference was adopted to prevent underestimating the number of average-value inferences which would occur if

as feature-absent if subjects assumed that the product did not have the feature (e.g., "Why get one without a warranty if you can get one with one?"). If it was not possible to determine the type of inference made, the inference was coded as indeterminate.

RESULTS

Inferences were coded independently by two coders, and discrepancies were resolved by discussion. There were initially disagreements on 13% of the inferences, but 60% of these differences involved the strictness with which the rule governing the use of the indeterminate category was applied, and were resolved by coding the inferences as indeterminate type.

Eighteen percent of all inferences made were coded as indeterminate type and were not included in the following analyses. This category occurred more frequently in the expected-correlation condition than in the no-expected-correlation condition (proportions = .18 and .03, respectively, $p < .01$).⁵ Based on the intercoder discrepancies, it appears that this occurred because at least 40% of the indeterminates were apparently probabilistic inferences, which were more likely to be made in the expected-correlation condition, as will be shown below. If this is correct, then it appears unlikely, given the results of the following analyses, that inability to classify these inferences introduced any bias.

Test of Hypothesis 1

Hypothesis 1 predicts that when there is an expected correlation between the known attribute and the inferred attribute, inferences tend to be probabilistic, whereas when there is no expected correlation, inferences tend to be based on average values. The proportions of subjects making each kind of inference are presented in Table 2.

As predicted, the probability of making a probabilistic inference was higher when there was an expected correlation between the known attribute and the inferred attribute ($p < .01$). In fact, only one out of 39 subjects made a probabilistic inference in the no-expected-correlation condition, although more than three quarters of the subjects in the expected-correlation condition did. This relationship held both when there was confirming evidence ($p < .01$) and when there was disconfirming evidence ($p < .02$). When there was no evidence about the validity of the expectation, there was no difference between cells, but this result is based on a sample of 1 in the no-expected-correlation cell.

Contrary to Hypothesis 1, the probability of making an average-value inference was not higher when there was no expected correlation between the known attribute and the inferred attribute. In fact,

subjects did not use terms like "average", "typical", etc.

⁵All reported significance levels are for Fisher's exact test.

TABLE 2
Proportions of Subjects Making Various Types of Inferences

Evidence regarding validity of expectation	Correlation expected					No correlation expected				
	Cell n	Inference Type				Cell n	Inference Type			
		Prob.	Avg.	Feature absent	Other		Prob.	Avg.	Feature absent	Other
Confirming	54	.65	.00	.30	.06	29	.00	.00	1.00	.00
Disconfirming	16	.50	.06	.44	.00	9	.00	.00	1.00	.00
None	54	1.00	.00	.00	.00	1	1.00	.00	.00	.00
Total	124	.78	.01	.19	.02	39	.03	.00	.97	.00

only one subject made an average-value inference and that subject was in the expected-correlation condition. For this reason, no further tests of effects on average-value inferences were conducted.⁶

There was also no evidence that subjects in the no-expected-correlation condition made evaluatively consistent inferences. No subject made comments which suggested such an inference process, nor were probabilistic inferences--which is how an evaluatively consistent inference could be misclassified--common.

Test of Hypothesis 2

Hypothesis 2 predicts that inferences consistent with expectations about attribute correlations are more likely to be made when the observed product set confirms expectations than when it disconfirms expectations. In the expected-correlation condition, the proportions of subjects making probabilistic inferences were in the predicted direction, but the difference was nonsignificant ($p > .38$). In the no-expected-correlation condition, the hypothesis could not be tested. No average-value inferences were made at all, so they could not vary as a function of the nature of evidence. However, feature-absent inferences may also be construed as being consistent with the expectation that the inferred attribute is uncorrelated with the known attribute. Whether evidence was confirming or disconfirming had no impact on the frequency of

feature-absent inferences either; all inferences in these cells were feature-absent.

Tests of Hypotheses 3, 4 and 5

Hypothesis 3 predicts that the overall frequency of inference making increases when there is an external cue. For this test and the test of hypothesis 4, all subjects were included in the analysis, not just those who made inferences. Hypothesis 3 was supported, although the effect was small. The proportion of subjects making inferences when inferences were not cued by the context was .15 and when inferences were cued by the context was .21 ($p < .02$).⁷

Hypothesis 4 predicts that the overall frequency of making probabilistic inferences is not affected by the presence of an external cue. This hypothesis was not supported. The overall frequency of probabilistic inferences decreased when inferences were cued by the context. These proportions were .13 and .07 ($p < .02$).

Hypothesis 5 predicts that the relative frequency of probabilistic inferences is smaller when there is an external cue. This hypothesis was supported. Of the subjects who made inferences, the proportion making a probabilistic inference was 1.00 when the inference was not cued by the context and .40 when the inference was cued by the context ($p < .01$).

Taken together, these results suggest that the external cue encouraged subjects who would not have otherwise done so to make an inference, and that it either suppressed inferences by some who would have made a probabilistic inference or altered the process by which inferences were made. The second explanation perhaps seems most plausible. Almost all non-probabilistic inferences made were feature-absent inferences. These inferences were only made

⁶A feature-absent inference may be construed as an average-value inference if it is typical for members of a product class to not have a certain feature. Limitations of the design -- specifically, differential representation of attributes which can logically be absent in the expected-correlation and no-expected correlation conditions -- made it impossible for us to examine the effects of expectations about correlations on such inferences.

⁷See Simmons (1988) for detailed analyses of the effect of an external cue on inferences about individual attributes.

in the external-cue conditions, and only for three of the ten inferred attributes examined: warranty, shelves, and versatility. Based on subjects' comments, a more accurate name for the versatility dimension is "restrictions on use," as this is how they interpreted versatility information (e.g., "can only be used on synthetic carpets and rugs"). In contrast to the other inferred attributes examined (energy cost, price, capacity, and weight), it is logically possible that a warranty, shelves, and restrictions on use could be absent. Therefore, it appears that the effect of the external cue was both to increase the frequency of inferences and to encourage a particular inference process for those attributes which could in fact be absent.

DISCUSSION

When the results of this study are considered in the context of other research which has examined similar issues, we gain a number of insights into how alternative information sources may be used in inferences about missing attributes.

The "Best-Predictor" Hypothesis

As predicted, probabilistic inferences predominated when the inferred attribute was expected to be correlated with a known attribute. Contrary to prediction, average-value inferences were not made when these attributes were expected to be uncorrelated.

Many researchers have found evidence that incompletely described alternatives are evaluated in ways consistent with average-value or discounted average-value inferences about missing attributes (Jaccard and Wood 1988; Meyer 1981; Slovic and MacPhillamy 1974; Yamagishi and Hill 1983; Yates, Jagacinski and Faber 1978; Zwick 1988). In these studies, however, it is not always possible to distinguish between a strategy in which neutral or negative inferences are made about the missing attribute and one in which the absence of information is simply treated as a neutral or negative cue. This is an important distinction because inferences can create product "knowledge" which may affect subsequent behavior.

Some of the strongest support for average-value inferences comes from a study in which evidence of average-value inferences in evaluations was found only when inferences were prompted (Zwick 1988)--presumably, the difference in evaluations between the unprompted and the prompted conditions was due to inferences--and from a study in which process-tracing data showed a high rate of average-value inferences made spontaneously during a choice task (Gardial and Biehal 1987). In contrast, the current study examined spontaneous inferences in a judgment task.

It may be that average-value inferences occur more frequently in these situations--when inferences are prompted and in choice tasks--than in judgment tasks in which inferences are not prompted. It was argued above that prompting may increase average-value inferences in two ways. First, prompting may create a selection bias by increasing the likelihood

that those who do not hold correlational expectations will make inferences. Such people are perhaps more likely to make average-value inferences. Second, prompting may increase motivation to make a valid inference, and thus increase the likelihood that the decision maker will supplement same-brand information with the less accessible other-brand information--such as an expected average value--as input to the inference.

Similarly, in choice tasks, the motivation to make a valid inference, or to make an inference at all, may be higher than in judgment tasks. In evaluation, processing tends to proceed by alternative. In choice tasks, processing tends to be dimensional; alternatives are compared on each dimension (Payne 1982). The tendency to make dimensional comparisons may increase the desire to make valid inferences about attributes for which information is available for some of the alternatives, but not for others.

This is not to claim that average-value inferences are never made spontaneously in the course of evaluating a product, but rather that this and other inference processes may be influenced by variables such as prompting and processing goals. Process-tracing techniques may be especially useful for identifying other variables that encourage or dampen particular inference processes.

Some evidence suggests that evaluatively consistent inferences, rather than average-value inferences, are made when there is no expected correlation between the inferred attribute and a known attribute. In particular, Dick, Chakravarti, and Biehal (1988) found that evaluatively consistent inferences were made when information about correlated attributes was not available, but only among subjects who were prompted to make an inference. We found no evidence of such a process, but their task situation differed from ours in a number of ways. While the evidence is too limited to allow any conclusions, there is clearly a need, as with average-value inferences, to examine the task and contextual factors which lead one to the use of an evaluative consistency inference strategy.

Probabilistic Inference and Contingent Decision Behavior

Probabilistic inferences depend upon the expectation that the inferred attribute is correlated with a known attribute. One might expect, then, that a decision maker's inference strategy could be altered by varying the correlations in task product sets. We found little evidence that this occurred.

This result is consistent with a view of contingent decision behavior recently discussed by Bettman (1988). He argued that there are two distinctive ways in which decision strategies can be adaptive to environmental conditions. The first is a top-down mode in which the environment is assessed in a deliberate manner in order to select a strategy tailored to the environment. In a top-down mode, for example, an inference maker would assess attribute correlations before deciding whether to implement a probabilistic inference strategy. In a

bottom-up mode, the process of adapting strategy to the environment is not so foresightful. Instead of choosing a strategy based on a thorough assessment of the environment, the decision maker begins with a strategy which seems reasonable, and then alters this strategy in response to task feedback. For example, an inference maker might begin by making probabilistic inferences because of a belief that two attributes are correlated, but alter this strategy as disconfirming evidence accumulates.

Bettman argues that much adaptation to the environment occurs in the bottom-up mode. In this mode, adaptation occurs over time. Therefore responsiveness to contextual factors such as attribute correlations may not be apparent in the short run. Our subjects exhibited a nonsignificant tendency to make fewer probabilistic inferences in the disconfirming-evidence condition. With more experience in the task environment, they might have shown stronger evidence of an adaptive strategy. Others have also reported results consistent with a bottom-up adaptation to correlations in task product sets (Huber and Klein 1988; Klein and Yadav 1989).

Effect of an External Cue

The external-cue manipulation was intended to test the hypothesis that a selection bias occurs when inferences are cued externally, as when one is prompted to make an inference. It was expected that the cue would decrease the relative frequency of probabilistic inferences by increasing the likelihood that people who did not hold correlational expectations would make inferences.

In the external-cue condition, some alternatives were described in terms of two attributes. It was expected that when the one-attribute descriptions were evaluated, this manipulation would encourage inferences about the second attribute, and this was found to be true. This particular cue, however, not only increased the overall frequency of inference making, but it also initiated specific kinds of inferences. When it was logically possible for a feature to be absent, this is what was often inferred. As it seems unlikely that prompting would have a similar effect, these results should not be taken as evidence regarding the effects of prompting on inferences.

These results have both practical and methodological importance, however. Since consumers often encounter just such differences in the availability of attribute information, feature-absent inferences may be relatively common. In addition, it should be recognized that the manipulations we employ to encourage inferences may alter the process under study. This criticism is relevant to the current study. However, the results in our no-external-cue condition are consistent with our conclusion that probabilistic inferences predominate when there is an expected correlation, whereas spontaneous average-value inferences may be rare in these kinds of judgment tasks.

Limitations of Study

Protocols are imperfect indicators of cognitive processes. In particular, retrospective protocols may be subject to errors in encoding and retrieval. Our subjects were always shown the product descriptions during the protocol procedure to aid recall, but it is possible that they inaccurately reported how they formed their evaluations, or were perhaps more likely to articulate probabilistic inferences than average-value inferences.

Although multiple exemplars of inferred attributes expected to be correlated or uncorrelated with known attributes were examined, some of the differences in the inferences made in these two conditions could be due to the particular exemplars examined. This is more of a limitation in the no-expected-correlation condition, in which there were four exemplars, than in the expected-correlation condition, in which there were twelve.

The Effects of Familiarity on Cognitive Maps

Haim Mano, Washington University in St. Louis
Scott M. Davis, Washington University in St. Louis

ABSTRACT

This paper investigates the impact of product familiarity on consumers' cognitive structures. Using two low involvement product categories, breakfast cereals and fast food restaurants, differences in cognitive structures derived from similarity ratings and product attribute descriptions were examined. The results indicate that, for low involvement products, product familiarity has almost no impact on perceptual structure and organization but it does have an effect on the consistency (e.g., the degree of stress) of the derived structures.

INTRODUCTION

Consumer researchers often use perceptual mapping techniques as a basis for assessing the basic cognitive dimensions consumers use to evaluate alternatives within a product category or the relationships among the alternatives with respect to those dimensions (Carroll 1972). The use of these techniques is often based on the assumption that there is no significant variation across consumers in the manner in which alternatives are judged.

However, there are several sources of variations among consumers that may influence the judgmental process. Different consumers are often exposed to different types of information about the alternatives. Furthermore, consumers are sometimes exposed to a product directly through one or more usage occasions while in other cases information about a product is only available indirectly through word of mouth or advertising. Consumers also tend to vary in the frequency of exposure to the different information sources. The extent to which and the way information is processed are also likely to vary across consumers depending on their levels of involvement in a product category and their predispositions toward the alternatives within the category. Due to the fact that consumers normally vary in terms of their experiences with the judged alternatives or in terms of overall product knowledge, differences in product familiarity may influence the way judgments are made. In particular, knowledgeable consumers may exhibit superior capacities to process and integrate product-relevant information (Johnson and Russo 1984). Thus variations in product knowledge are likely to influence both the manner in which judgments are made and the consistency of the reported judgments.

Familiarity and expertise are major components of consumer knowledge and should have a considerable impact on consumer cognitive structures (Alba and Hutchinson 1987). Familiarity is defined as the number of accumulated product related experiences while expertise is the ability to perform product-related tasks. However, for low involvement, experience related, and nontechnical products--like those to be examined here--these two

components are highly interrelated and perhaps indistinguishable.

This paper presents an attempt to examine the impact of product knowledge on cognitive representations produced by perceptual mapping techniques. Recent research suggests that familiarity with a product category is likely to have an impact on these representations (cf. Srinivasan, Abeele and Butaye 1989). As consumers become more familiar and knowledgeable with a product category, there are at least two apparent consequences regarding the structure of cognitive representations. First, one would expect knowledgeable consumers to develop more clearly established criteria for making their judgments which in turn could lead to the development of different underlying dimensions for judging a product. Second, more knowledgeable consumers could apply these criteria more consistently; in that case, we would expect differences in familiarity to be a source of systematic variations in the perceptual maps produced by the various mapping techniques as well as in the measures of goodness of fit associated with them. Furthermore, since different mapping techniques require different types of judgments, we would expect the impact of product knowledge to depend on the mapping technique employed.

METHODOLOGY

This study is part of a current research program investigating the interrelationships between consumers' evaluations and product familiarity for two low involvement products, breakfast cereals and fast food restaurants. We consider the influence of product familiarity on perceptual maps generated by two different types of data: perceived similarities between product pairs and product attribute ratings.

Similarity measures are based on subjects' pairwise comparisons of stimuli (e.g., brands) and are generally analyzed by employing multidimensional scaling techniques (MDS) (e.g., INDSCAL; Carroll and Chang 1970). The results of these techniques allow one to reveal the dimensions used by consumers when evaluating the stimuli or to confirm whether a particular dimension is salient in consumers' judgments for that product category. Attribute ratings of products can also be used as a basis for deriving perceptual maps. Factor analytic techniques use correlations among attributes and products in order to determine the basic perceptual dimensions in forming product judgments.

Theoretically, if the set of attributes is relatively complete and all attribute information is adequately processed when forming similarity judgments, then maps produced by MDS and factor analytic techniques should be similar (cf. Hauser and Koppelman 1979). However, if the consistency of attribute judgments or the set of attributes in

forming judgments varies systematically as a function of familiarity with product category, then we would expect the maps produced by the various techniques also to vary with product familiarity.

The analyses to be presented here will allow us to examine three issues regarding product familiarity and cognitive structure for low involvement products: (1) whether more product-familiar subjects have more robust and consistent cognitive configurations, (2) whether the relationships between brands in these configurations will differ as a function of product familiarity, and (3) whether different perceptual mapping techniques will reveal different cognitive configurations.

In this study we will consider two low involvement, experience related, and nontechnical products, breakfast cereals and fast food restaurants, which are relevant to our surveyed population: college students. A unique feature of both product categories is the large number of available brands, their relatively frequent consumption, and the high variabilities in consumption and familiarity for our surveyed population. Furthermore, employing two different product categories allows for more extensive and convergent validation of any hypothesized contentions.

DATA

In order to generate the list of products and product attributes employed in the present study, 77 undergraduate business students were asked to list the breakfast cereals they could recall while another group of 78 students generated a similar list for fast food restaurants serving hamburgers. In addition, the students were asked to list the attributes they felt were most important in their consumption decisions of these products. From these lists, ten of the most frequently mentioned brands and product attributes were selected for use in the study.

Two weeks following the initial survey, 129 students completed questionnaires concerning perceptions and preferences with regard to alternatives and attributes of one of the two products. Based on a random assignment to one of the two product categories, 63 subjects completed questionnaires relating to breakfast cereals and 66 completed questionnaires relating to fast food restaurants. Most of these subjects were part of the initial 155 subjects used to generate the lists of products and attributes. All subjects in the study were undergraduate business students at a private midwestern university.

Questionnaires were divided into four sections which could be classified as (1) familiarity, (2) preferences, (3) perceived similarities among products, and (4) perceived attribute ratings of the products. The sequence of the sections in each questionnaire was randomized in order to minimize the impact of any learning effects that might have taken place during questionnaire completion. In addition, products and attributes were each arranged in two separate random sequences so as to minimize any effects of establishing reference points that

could be attributed to the sequence of items in the questionnaire.

The familiarity section consisted of two sets of questions. The first set asked subjects to report, based on their consumption habits over the course of the previous year, their average monthly consumption frequencies for each brand listed and for the product category as a whole. The second set of questions asked subjects to rate, on a zero to ten scale, their familiarity with each of the brands (based on personal consumption, family, friends, advertising, etc.).

The preference section consisted of five sets of questions that elicited subjects' preferences regarding products and attributes. The first two sets asked subjects for their brand preferences through ratings on zero to ten scales and rank orderings, respectively. The remaining three sets of questions asked subjects for their attribute preferences through rating the importance of the attributes on a zero to ten scale, a ranking of the ten attributes in order of their importance, and a description of their most preferred attribute levels on zero to ten scales.

The remaining two sections concerned subjects' perceptions regarding the brands tested in the study. The similarities section asked subjects to compare each product to each of the remaining nine products and rate how similar the products were on a zero to ten scale in which low ratings corresponded to an evaluation that the products were very similar while high ratings corresponded to an evaluation that the products were very different. The attribute ratings section asked the subjects to evaluate the attribute levels of each of the products on a zero to ten scale.

RESULTS

Overall Product Familiarity

Product knowledge can be assessed by subjective measures (i.e., perceptions), learned knowledge based on objective criteria, and usage experience (Brucks 1985). In the present study, product familiarity was assessed by subjective measures. Despite theoretical advantages of employing objective measures (Brucks 1985; Sujana 1985) and possible distortions due to memory errors and mental calculations, we believe that the low involvement nature of the products used here justifies the use of subjective measures of familiarity. Furthermore, for both product categories, actual brand consumption (which reflects usage experience) and brand familiarity were highly correlated. For the cereal category, the correlations ranged from .30 to .42 (all p 's < .01) with an average of .35. For the fast food category, except for the most widely known brand (McDonald's $r = .14$), correlations between brand consumption and brand familiarity ranged from .37 to .71 (all p 's < .01) with an average correlation of .45.

Given the convergence between brand consumption and reported brand familiarity, reported brand familiarities were used to operationally define product familiarity. Subjects were considered

familiar with the product category if they rated themselves as highly familiar with the individual brands in the category. Specifically, a measure which will be referred to as Product Category Familiarity was defined as the sum of the ten questions regarding the subject's degree of subjective familiarity for each brand. Theoretically, the value of this index could range from 0 (for a subject who responded 0 for all 10 products) to 100. Actual values ranged from 22 to 98 for cereals and from 26 to 90 for fast food restaurants. The mean familiarity rating for the breakfast cereal category was 68.96 with a standard deviation of 16.96; the mean for the restaurant category was 57.80 with a standard deviation of 13.68. Using the below the 33rd and above the 67th percentiles of the distribution on Product Category Familiarity, three subgroups of Low, Medium, and High Familiarity were formed.

Familiarity and preferences

Before investigating the interrelationships between familiarity and perceptual configurations, it is important to examine two issues: how brand familiarities and brand preferences were interrelated and whether preferences for the various brands differed for the different groups of overall product familiarity. The importance of these two questions stems from the particularly low involvement nature of the two products employed in the present study. For, if the group of higher product familiarity subjects shows a higher preference for particular brands, then any differences in perceptual configurations may be attributed to evaluative preferences and not solely to cognitive judgments.

We therefore anticipate that brand familiarities and brand preferences will be highly related for low involvement and frequently consumed products. Yet, at the same time, we expect to find the same patterns of brand preferences across the three levels of product category familiarity. In other words, because of the low involvement nature of the products, we do not expect substantial differences in the preference for, say, "Hardee's," between product familiar and unfamiliar subjects. It should be noted, however, that this assertion is likely to hold only for low involvement products; for higher involvement products, more knowledgeable consumers are likely to express preferences for particular (e.g., higher quality) brands.

In the cereal category, the correlations between brand familiarity and brand preference were quite high; the values for the ten correlations ranged from .33 to .57 (all $p < .01$) with an average of .47. Moreover, using univariate ANOVAs, no statistically significant differences were found in preferences for each of the ten cereals by the three subgroups of familiarity. The grand means for preferences arranged for the ten products were: Frosted Flakes, 7.19; Fruit Loops, 6.73; Cap'n Crunch, 6.34; Rice Krispies, 5.84; Post Raisin Bran, 5.71; Lucky Charms, 5.60; Cheerios, 5.07; Kellogg's Corn Flakes, 4.76; Grape Nuts, 4.04; and Total, 3.94. As with cereals, the correlations between brand familiarity and brand preference in the restaurant

category were quite high (correlations ranged from .26 to .70 with an average of .52). Except for one product (Steak N' Shake, $F(1,63)=4.74$, $p=.01$), ANOVAs did not reveal significant differences in brand preferences by the three levels of familiarity. This product was given high preference ratings by those who were familiar with it, suggesting that Steak'n Shake is a desirable product that does not have a high quality image product among uninformed subjects. In general, however, these results suggest that Product Category Familiarity did not influence brand preferences even though brand familiarity was strongly related to brand preference for specific brands.

Similarity ratings and Replicated Multidimensional Scaling

MDS analyses were conducted using two different approaches. The first approach is replicated multidimensional scaling (RMDS) which allows for a joint map of objects and individuals (Young 1975). The second approach uses the average similarities of the relevant groups to construct the multidimensional scaling maps. The difference between the approaches is that the first deals with N similarity matrices (where N = number of subjects) whereas the second deals with one matrix of average similarities.

Stress coefficients and percent of explained variance associated with RMDS analysis are presented for the various familiarity groups in Table 1.

Based on the criteria of stress and interpretability, the one dimensional solution seems to be the most appropriate for the cereal category and captures the tradeoff between artificial sweetness and naturalness. The coordinates for this dimension were: Cap'n Crunch, 1.39; Fruit Loops, 1.34; Lucky Charms, 1.24; Frosted Flakes, .86; Rice Krispies, -.59; Kellogg's Corn Flakes, -.64; Post Raisin Bran, -.87; Total, -.82; Cheerios, -.89; Grape Nuts, -1.01.

Simple correlations between the coordinates on the one dimensional solutions and canonical correlation coefficients between the coordinates of the two dimensional solutions, revealed that the four populations (whole, low, medium and high familiarity) resulted in extremely similar configurations (all simple and canonical correlations were above .99; $p < .001$).

As indicated in Table 1, in the fast food category, the one- and three-dimensional solutions for higher levels of familiarity were accompanied by lower stresses and higher levels of explained variance. However, for the two-dimensional solution, stress levels increased with familiarity; nonetheless, the percentages of explained variance remained at about the same levels. For the combined population, the two-dimensional solution seemed to be the most appropriate in terms of stress and interpretability. The first underlying dimension was interpreted as prototypicality of product offerings; the second dimension captured the perceived degree of quality of these restaurants. The whole population's two-dimensional solution is

TABLE 1

Stress coefficients and percent of explained variance (in parentheses) for the two products by degrees of overall product familiarity.

CEREALS

	Whole Population	Low Familiarity	Medium Familiarity	High Familiarity
Dimensions	N=63	N=21	N=21	N=21
1	.445 (56)	.476 (51)	.426 (57)	.422 (62)
2	.329 (60)	.335 (58)	.329 (60)	.307 (67)

FAST FOOD RESTAURANTS

	Whole Population	Low Familiarity	Medium Familiarity	High Familiarity
	N=66	N=22	N=21	N=23
1	.545 (31)	.540 (29)	.544 (31)	.527 (35)
2	.380 (48)	.357 (50)	.378 (48)	.383 (51)
3	.265 (63)	.272 (62)	.266 (63)	.263 (64)

FIGURE 1

RMDS two-dimensional solution for fast foods (whole population) based on average similarities

presented in Figure 1. The two-dimensional RMDS solutions for the four populations (whole, low, medium and high familiarity) were similar among themselves and with that of the whole population (all canonical $R^2 > .80$; $p < .01$).

In order to further investigate the relationship between familiarity and perceptual configurations of similarity, the matrices that were based on the

average similarities of the whole population and the low and high familiarity groups were also examined. For the cereal category, the one-dimensional solution seemed to be the most acceptable both in terms of stress (stress = 0.147, 94% explained variance) and interpretability. As anticipated, the stress coefficient for the low familiarity group was higher than that of the high familiarity group;

TABLE 2
Comparisons between the low and high familiarity groups on the stress coefficients and explained variance of the 10X10 matrices of average similarities (fast food restaurants)

Solution	Population	
	Low Familiarity	High Familiarity
One dimensional	.391 (53)	.276 (77)
Two dimensional	.132 (91)	.118 (94)
Three dimensional	.050 (98)	.050 (98)

TABLE 3
Cumulative variance explained by the factor solutions by three levels of overall product familiarity.

Factors	CEREALS			
	Whole Population	Low Familiarity	Medium Familiarity	High Familiarity
	N=63	N=21	N=21	N=21
1	40.2	39.2	39.6	42.5
2	70.3	69.6	72.0	70.4
	FAST FOOD			
	N=66	N=22	N=21	N=23
1	24.9	25.8	25.4	27.1
2	39.3	39.3	41.4	42.9
3	52.5	51.2	54.5	56.0

(stress = 0.184, 89% explained variance versus 0.116, 96%). As in the RMDS analysis, the underlying dimension was interpreted as Sweetness-Naturalness. The coordinates in the RMDS and present analyses had a correlation of 0.97. In the fast food restaurant category, the perceptual maps based on average similarities had stress values .284, .121 and .077 for the one, two, and three dimensional solutions respectively. As indicated in Table 2, the difference in stress between the low and high familiarity groups were in the hypothesized direction with the maps of the more familiar groups exhibiting lesser stress.

Factor Analyses: Product descriptions on performance attributes

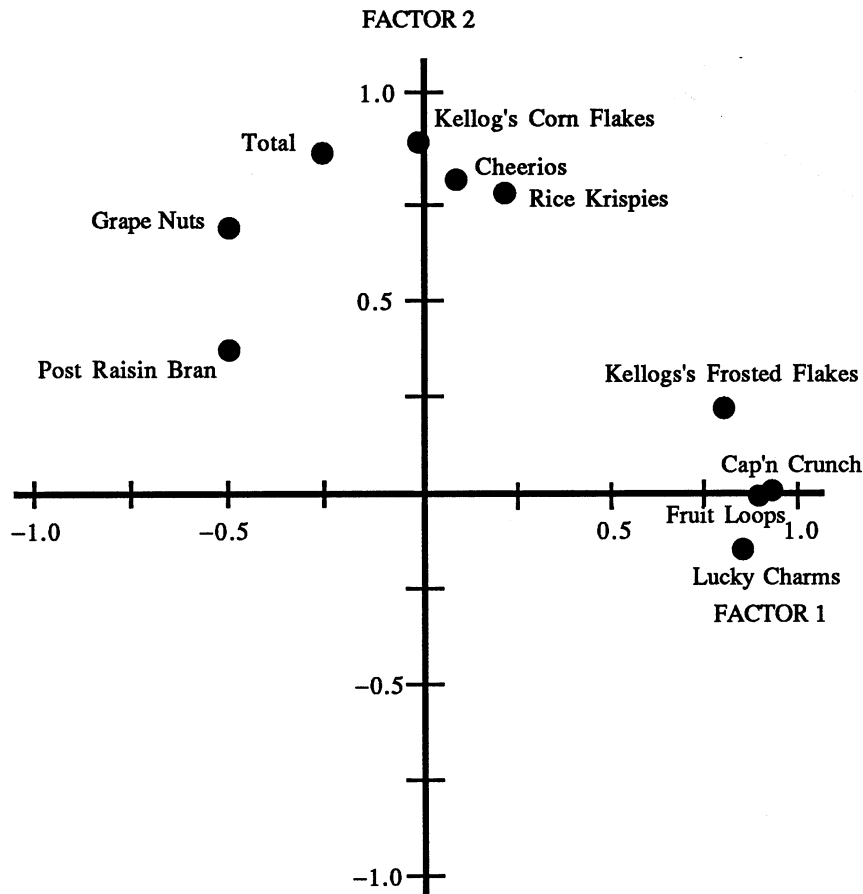

For each of the four relevant populations (whole, low, medium and high levels of familiarity), factor analyses were conducted using product descriptions on the ten attributes across subjects as observations. This analysis provides a product space whereby each brand is positioned closer to another brand if the two brands were given similar attribute descriptions.

The analyses in the cereal category for each of the four relevant populations revealed two factors with eigenvalues greater than unity. Table 3 presents the cumulative variances explained by the first two dimensions for the relevant populations.

For the one factor solution, the cumulative explained variance did increase with overall product familiarity; however, this effect was not present in the two factor solution.

The whole population and the medium and high familiarity groups, had very similar one factor solutions (r 's $>.995$; $p <.0001$). For the whole population, coordinates on that factor were similar with the sweetness-nutrition dimension obtained in the RMDS one-dimensional analysis of product similarities; the correlation between the two sets of coordinates was .672 ($p = .03$). The low familiarity group, however, resulted in a different factor configuration; the correlation between its coordinates and those of the one factor solution of the whole population was .485 (n.s.). An examination of the two factor solutions revealed that the second factor was not easily interpretable, even though it made a considerable contribution to the explained variance. Nonetheless, the three familiarity groups had highly similar two factor configurations; the canonical correlations between the two factor solutions for the three subgroups and the whole population solution were above .97 (p 's $<.01$). Figure 2 presents the two-dimensional solution for the whole population. This two factor solution was only moderately similar to the whole population's RMDS two-dimensional solution (canonical $R = .77$, $p <.20$).

FIGURE 2
Cumulative Variance explained by the factor solutions by three levels of overall product familiarity

In the fast food category, three factors with eigenvalues greater than one were revealed for all familiarity groups except for the moderate familiarity which revealed four such factors. However, the eigenvalue for the fourth factor was 1.1; therefore, due to the eigenvalue's proximity to unity and the small number of objects, this factor was excluded from further analyses. As can be seen in Table 2, the hypothesized relationship between overall familiarity and cumulative explained variance is, overall, confirmed. In particular, comparisons between the low and high familiarity groups revealed considerably higher cumulative explained variance for the high familiarity group. The two factor solution seemed the most appropriate and is presented in Figure 3. Finally, it is noteworthy that this two factor solution was only moderately similar to the whole population's RMDS two-dimensional solution (canonical $R = .90$, $p < .02$).

CONCLUSIONS

The results suggest that overall product familiarity may be an important determinant of consumer's cognitive structures, even for such low involvement products as the ones employed here. In

particular, more product-familiar subjects had more consistent cognitive configurations than those exhibited by less familiar subjects. It appears that increased product familiarity enables the consumer to differentiate brands according to more veridical criteria (Alba and Hutchinson 1987; Johnson 1984) and apply these criteria more consistently. In terms of inter-brand relationships, however, no considerable differences were revealed among the different groups of product familiarity. Thus the major difference between the lower and higher familiarity groups' maps were not as much in terms of positioning of the objects but rather on the fuzziness of the maps.

Hauser and Koppelman (1979) suggested that factor analytic techniques are superior to MDS for identifying consumer perceptions when there is variation in the way consumers perceive products in the category. In contrast, our comparisons between the two perceptual mapping techniques showed that, at the level of interpretable solutions, multidimensional and factor analytic techniques resulted in quite comparable configurations. For example, when considering the whole population for cereals, the one dimensional RMDS and the one

FIGURE 3
Two factor solution for fast foods (whole population)

factor solution were strongly correlated ($r=.672$, $p = .03$). The comparable analysis, however, for the fast-food restaurants revealed a correlation of .40 (n.s.). Nonetheless, when two dimensions and two factors were jointly examined for fast foods, the two solutions were very similar (canonical correlation .90, $p < .02$). This result suggests that the attributes contributing to the third factor were not consistently utilized by subjects when forming similarity judgments and simplifying heuristics may have been implemented when making these judgments.

Our results presented aggregate analyses of the interrelationships between perceptual configurations and familiarity. An analysis of these interrelationships on an individual level may provide useful insights into the factors influencing consumers' judgments of products. This and other related topics provide a promising field for future research.

In Search of the Elusive Consumer Inference

Sarah Fisher Gardial, University of Tennessee
David W. Schumann, University of Tennessee

ABSTRACT

A critical question raised by the papers in this session is how consumers respond to missing information. More specifically, when might we expect consumers to make inferences to fill in informational gaps in the environment? A framework is proposed which highlights the conditional nature of consumer inference making. This framework serves to 1) integrate the somewhat piecemeal research questions and methodologies which have characterized inference research to date and 2) suggest areas for future research.

INTRODUCTION

How consumers respond to informational deficiencies in the environment is a fundamental issue for those interested in consumer decision making. The number of recent studies concerning missing information, in general, and consumer inference making, in particular, attests to the amount of interest and attention which has recently been generated around the topic. However, despite the amount of research which has been forthcoming, we still seem to be grappling with some basic issues regarding inference making. How often does it occur? What types of consumers are most likely to make inferences? When is inference making a preferred decision (sub)strategy?

To some extent, researchers may be drawn to this issue because of its intuitive appeal. We all know that we can and do make inferences about all kinds of consumer products. We also know that most consumers have limited time to deal with the multitude of gaps in the informational environment, and that inference making may be an efficient way to fill in missing data. However, knowing that the phenomenon exists, and being able to actually isolate and understand it are totally different issues.

To some extent, it's like hunting an elusive jungle creature. We may see its tracks, and we may often encounter strong evidence that the beast has passed through. But we haven't been able to trap it. The scent is heavy on the trail, but the creature is too crafty or evasive to be caught. The main problem is knowing when and where the creature is going to appear. If we could only isolate some of the predictable aspects of its behavior, we could intercept it more successfully.

Such is consumer inference research. While we are sure the phenomenon exists, much of our lack of success in measuring and understanding inference making may be because we are not clear about the conditions under which it will appear. Two of the papers in this session address this issue ("The Effects of Missing Information on Decision Strategy Selection" by Sandra Burke and "Inferences About Missing Attributes: Contingencies Affecting the Use of Alternative Information Sources" by Carolyn Simmons and Nancy Leonard). These papers, as well

as other research, can be viewed within a broader framework that suggests when inference making may be used to fill in missing data in the consumer environment. The framework suggests a logical sequence of decision points which may lead the consumer toward or away from inference making. In addition, it suggests a list of potential mediating factors which must be taken into account at each decision point. Hopefully, it provides a mechanism for integrating and explaining much of what we know, and don't know, about consumer inference making to date.

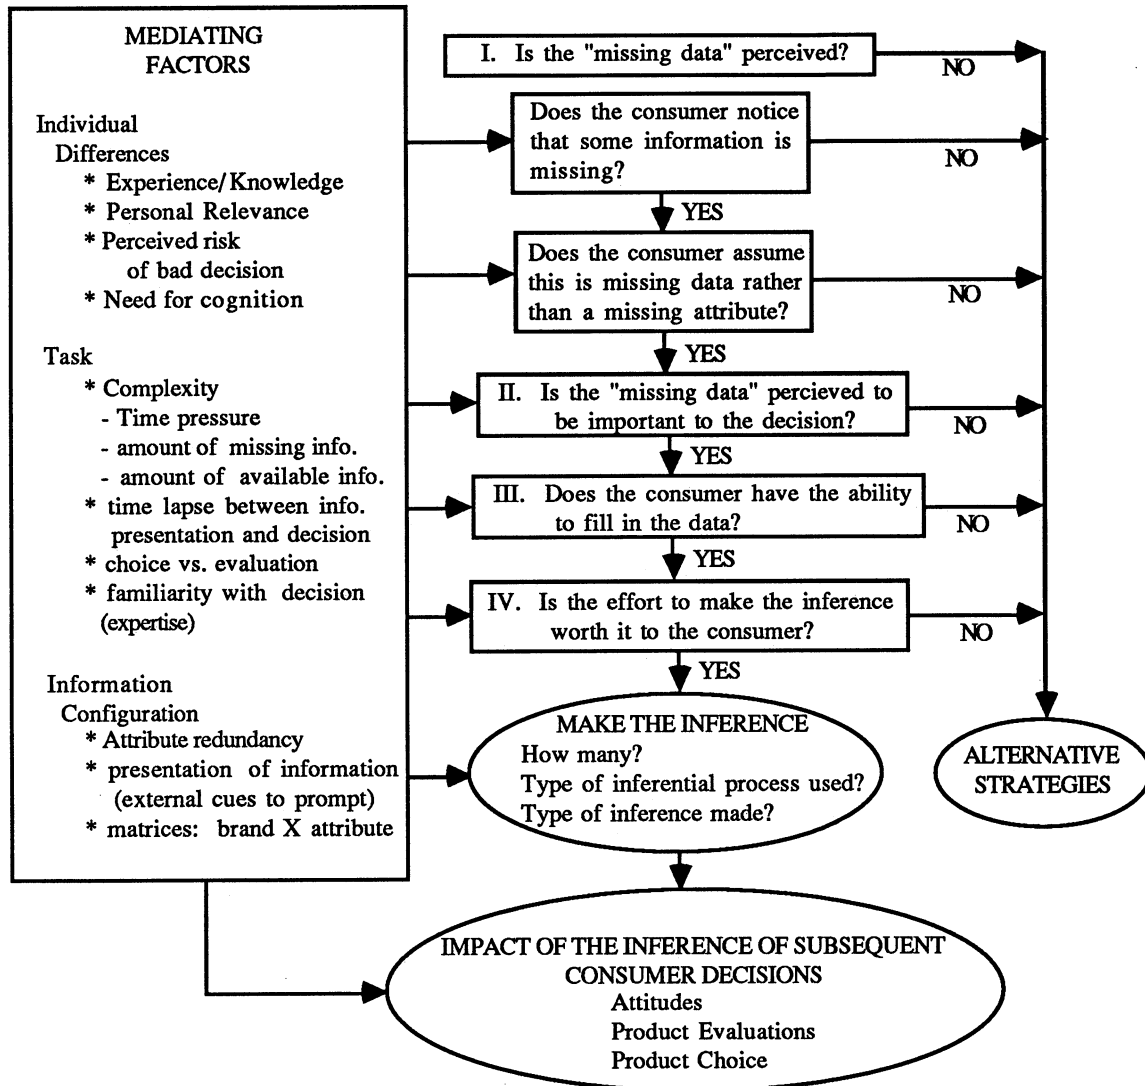

THE BASIC QUESTION

In order to address when consumers make inferences, it is necessary to identify other alternative strategies for the missing information problem. Consumers don't have to make inferences at all. It is a matter of when they choose that course of action over others which are available.

There are at least four alternative strategies which the consumer may adopt when missing information is encountered. The first option, probably more likely for high risk decisions, is that the consumer may delay the decision until the missing information is obtained. We must keep in mind that in laboratory settings consumers will be faithful subjects and follow our instructions. If they are asked to make decisions with incomplete data, they will do so. However, in the real world they have the option to defer decisions. Many types of consumer product decisions may lead to this alternative, including those with high financial or psychological costs, those for novice consumers, or those with long-term or personal consequences, e.g., buying a house or medicines. It is easy to imagine this as a viable and frequent alternative to inference making.

Second, the consumer may simply ignore missing data (Zwick 1988). That is, acknowledging that missing data can lead to a suboptimal decision, the consumer may simply decide to continue with the current decision strategy while operating within the constraints of less information. Whether the consumer is using a compensatory, hierarchical, lexicographic or other decision framework, each can be pursued using only available attribute information. Some researchers suggest that there may be some evaluative discounting due to the absence of information (Meyer 1981), but an attitude may be formed nonetheless. Given the low risk associated with many consumer decisions and possible preferences for particular decision strategies, this seems to be a plausible response. In fact, consumers may become quite good at ignoring what is not available and constraining the decision to the most accessible, least effortful information at hand.

FIGURE 1.
THE EFFECT OF MISSING DATA ON CONSUMER DECISION MAKING

The third alternative, suggested in the Burke paper, is for the consumer to actually change the decision strategy to one which better accommodates missing information. In particular, she suggests that the consumer may move away from attribute based strategies, requiring between brand comparisons, toward strategies which are 1) more alternative based (within brand) or 2) hierarchical strategies using only available information. While also a plausible alternative, it is important to note that such a change requires both that the consumer is aware of alternative strategies and is amenable to their use. In other words, the consumer must not have a strong preference for attribute based strategies.

The fourth alternative to missing information is inference making. The preceding three

alternatives (and possibly others not described) will be collectively termed "other" alternative strategies for the remainder of the discussion. The realization of "other" strategies reduces the question to a very simple one: when will consumers choose inference making over other strategies. In short, if we can isolate the conditions which would lead the consumer toward alternative four (or, conversely, toward alternatives one through three), then we will be a great deal closer to capturing inferences in our research and determining their influence on day to day consumer decisions.

THE FRAMEWORK

The following is a brief overview of the proposed framework (see Figure 1). Research will be occasionally referenced to note where previous

knowledge may be brought to bear on different parts of the framework. However, this paper will by no means attempt to provide a thorough review of the state of inference research to date. Rather, its intent to show where the two presented papers in this session may be viewed in a larger context, and to identify issues which are ripe for future research.

The central part of the framework consists of four critical questions. These four questions are those most likely to impact whether the consumer pursues an inference strategy versus whether an alternative "other" strategy is more attractive. Note that there is no attempt to indicate which alternative strategy will be used, that is another research question. Here we are only interested in identifying when inference making is the likely response.

The framework also lists some of the many possible mediating factors determining the response to the four questions. This is only a partial list, some of which have been suggested by previous research, others which are more speculative but may be fruitful areas for further study. They have been grouped into three broad categories representing individual, task and information configuration differences.

Finally, two "outcome" issues are identified: 1) how are the inferences actually made and 2) what impact do they have on subsequent consumer decisions. Each of these topics could well be expanded into sub-frameworks of equal length and complexity. For now, these issues will be relegated to others to develop. They are listed here to acknowledge that understanding the conditions under which inferences are made is only a *limited first step* in integrating our knowledge of inference making into the larger consumer decision making context.

The Four Critical Questions

The first question is the most obvious: Is the missing data perceived? Obviously, consumers must perceive that attribute information is unavailable before they can attempt to infer it. Consumers cannot be expected to know all of the potential attributes to considered in evaluating a product. Thus, the likelihood that any one particular unavailable attribute is even noticed may be small. This is certainly possible given the demands of information overload or the possibility of a novice consumer.

In fact, available evidence suggests that this may be the case. Much of the existing inference research explicitly prompted inference making (e.g., Meyer 1981, Huber and McCann 1982, Kardes 1986, Johnson and Levin 1985). However, recently some studies have found greater inference making under prompted (cued) than unprompted conditions (Zwick 1988, Ford and Smith 1987). Although it is possible that in the latter condition missing data was noted but ignored, these results also suggest that at times consumers may be unaware of missing information.

A second question, noted in the Simmon/Leonard paper, relates to this issue. That is, once noted, does the consumer assume that

information is missing or that an *attribute* is missing. For instance, a consumer may notice that warranty information is not available. In this case, s/he might assume that 1) the product has a warranty which is simply not mentioned or 2) that the product does not come with a warranty. Obviously, if the latter is assumed there will be no incentive to make an inference about the warranty. Therefore, perceiving missing information is a two-step function: it requires both that the product attribute is noted and that it is assumed to be available elsewhere.

Looking at the list of potential mediating factors, it is interesting to speculate about factors which may cause the consumer to *never* notice missing information. This may be likely for consumers with low product knowledge/experience or those with a low need for cognition. Task factors, such as time pressure or a long time lapse between information presentation and the decision may also inhibit missing information perception. Finally, the information configuration may facilitate or inhibit the perception of missing information, e.g., whether the information is presented by brand, attribute, or brand-attribute matrices (Zwick 1988) or whether realistic ad configurations are used (Gardial and Biehal 1989).

The second question is one to which very little research attention has been given. Is the missing data perceived to be important to the decision (Hansen and Zinkhan)? Typical inference research has not allowed the decision maker to select which information s/he wishes to use to evaluate the product. These studies seem to assume that all information provided to the decision maker (and none which is not provided) is important to the decision at hand. Clearly consumers come to decisions with idiosyncratic decision criteria. Those who have high product knowledge may have especially well developed schemas for brand evaluation. Thus, even if information is noted to be missing, it may not be considered critical to the decision. Because of the effort involved in inferring missing information, it is unlikely that consumers will infer missing, but relatively unimportant, attributes.

Again, mediating factors may effect this question. For instance, the higher the perceived risk associated with a decision, the more thorough a consumer might be in his/her evaluation. Under this circumstance, the list of attributes considered important may be expanded and more exhaustive than when the decision carries less risk. In addition, attribute importance may change depending on whether the consumer is choosing between brands or simply evaluating individual brands. Differences caused by between-brand (choice) versus within brand (evaluation) decisions strategies may impact the perception of attribute importance. Simmons (1986) has suggested that inference making may be more common to choice than evaluation. Also, the amount of available/missing information may impact this issue. If a great deal of information is generally available, the consumer

may be more likely to overlook the absence of even important attributes. As suggested by Burke (1989), attribute redundancy may also play a part. Even if a particularly "important" attribute is missing (e.g., repair costs over time), the availability of an attribute with redundant implications (e.g., warranty) may reduce the need for the former's inference.

The third question is perhaps the most critical of the four: does the consumer have the ability to fill in the data? Even if the motivation to make inferences is present (questions one and two), inability to do so stops the process at this point. The answer to this question may also have a significant impact on the fourth question. If a consumer has sufficient ability to make an inference, e.g., an "expert," s/he may also perceive little effort is required to do so, although this does not always have to be the case.

Several researchers have suggested that product experience is positively related to inference making ability (Sujan and Dekleva 1987, Gardial and Biehal 1989, Olson 1978, Alba and Hutchinson 1987). In the Simmons/Leonard paper in this session, it is quite possible that students were unfamiliar with purchasing refrigerators and carpet cleaners, thus hampering their ability to make inferences. Others have suggested that ability to make inferences is a function of what information is available to the consumer, and how "redundant" or how closely correlated the available and unavailable information is (Burke 1989, Ford and Smith 1987). It is also possible that the availability of visual along with verbal cues may increase consumers ability to make inferences (Smith 1988, Chattopadhyay and Alba 1988).

The final question is that posed by Burke: is the effort to make the inference worth it to the consumer? Presumably, if it is, inference making will occur. Otherwise, alternative strategies will be pursued. In her paper, Burke identifies some of the factors which might mediate the consumers' perceived effort. That list is contained within the larger list of mediating factors in this framework.

It is interesting to note how "late" in the framework the effort issue comes into play. While Burke asks an important and worthwhile question, it only becomes a consideration when the three previous preconditions (questions) have *all* been answered in the affirmative. Thus, it is important to note where her piece of the puzzle fits in to the larger context.

Other Framework Issues

Four issues relating to the interpretation and use of the framework are worth noting. First, the four questions are presented in a somewhat logical sequence, i.e., it is unlikely that the consumer would ever encounter question number two if s/he failed to answer question number one in a positive fashion. Likewise, question number four is moot unless question number three is answered in the affirmative.

Second, note that multiple mediating factors may drive the response at any level of the framework. In addition, it is perfectly possible that

one type of mediating factor may drive the response to one question (e.g., prior knowledge may have a significant impact on question three), while a completely different factor may impact another question (e.g., time constraints may impact question four). Thus, the presence of mediating factors significantly complicates the model (and may explain some of our difficulty in explaining the inference making phenomenon).

Third, inferences may only be made if *all four* of the critical questions are answered in the affirmative. If the response to any of the four is negative, then the consumer will probably resort to other alternative strategies. The complexity of the framework to this point, and the numerous potential conditions which would encourage "other" alternative strategies, may leave the impression that inference making is a relatively rare phenomenon and not worthy of our research attention. However, most consumer decisions are relatively repetitive, low risk, and familiar ones for consumers. In addition, realistic advertising constraints (cost, length and consumer attention spans) dictate that only partial product information is conveyed to the consumers. For these reasons, consumers should frequently encounter missing information *and* frequently have the ability to make inferences as a consequence. The more product experience consumers have, the more likely they are to notice missing information, to have the ability to make inferences, and to require relatively little effort to do so.

Even in a world of "cognitive misers," inference making may be so routine and effortless that consumers often create information beyond that which is available to them, while at the same time ignoring some available information. One could even posit that inference making is a simplifying strategy, i.e., a few pieces of quickly gathered product information may be expanded into a more complete profile. Thus, despite the reasons why inference might not be made, there is probably still ample opportunity for this phenomenon to affect a wide range of consumer decisions.

Finally, successfully bringing the consumer to the point of making an inference explains only part of the inference phenomenon. Several additional questions are then raised, including how many inferences are made (Gardial and Biehal 1987, Chattopadhyay and Alba 1988), what types of inferential processes are used (Simmons 1986, Zwick 1988), and the nature of the inferences that are made. In addition, once these inferences are produced, how do they impact subsequent decisions (Kardes 1986, Johnson and Levin 1985)? These questions are important in their own right, and illustrate how much more has to be learned in order to approach a complete picture of the consumer inference process.

SUMMARY

Like stalking the elusive jungle creature, researching the consumer inference making phenomenon is a challenging proposition. The

framework proposed here is one which may help researchers integrate and assimilate the sometimes disparate evidence that has been reported in the literature. In addition, it will hopefully move the research stream forward in a systematic way, highlighting what is known and unknown, and suggesting the need to understand the many and subtle complexities of this phenomenon.

AIDS Prevention Through Consumer Communication: Ideas from Past and Current Research

Elizabeth Cooper-Martin, Georgetown University
Debra Lynn Stephens, University of Maryland

ABSTRACT

The purpose of this paper is to suggest workable communication approaches to increasing heterosexuals' condom usage to protect against AIDS transmission. First we review studies of communications aimed at reducing the likelihood of AIDS transmission among heterosexuals. Then we examine literature on efforts to alter health behaviors that are similar to condom usage. Both of these sets of studies indicate that behavioral changes are difficult to achieve, especially through communications presented in the mass media. Face-to-face interactions and other non-mass media appear to hold more hope for increasing heterosexual condom consumption. Furthermore, we argue, a thorough empirical analysis of any communication effort must focus on the separate effects of message source, medium and content on the receiver.

In the early 1980s, a new and significant health care problem emerged: AIDS. It is a virulent, unforgiving disease, both incurable and fatal. Further, there is no vaccine against AIDS and there are very few effective therapies. Sexual contact and intravenous drug use are two important modes of AIDS transmission. Hence, certain changes with respect to these behaviors can reduce the risk of contracting this disease. Clearly, then, communication efforts that encourage people to make such behavioral changes are crucial to controlling this disease (Bayer 1989). This paper uses an understanding of consumer behavior to address this challenge.

This paper examines the relatively more simple problem of changing sexual behavior, rather than drug abuse. Ways to lower the risk of transmission through sexual contact include abstinence, monogamy and condom usage. Clearly, these alternatives vary in their suitability for different individuals, e.g., Catholic bishops have argued against promoting condoms as a response to AIDS (Burns 1988). However, given our interest in consumption behavior, we focus exclusively on condom usage. We will limit our discussion to heterosexuals, because they have not been studied as extensively as homosexuals.

For people who are sexually active (i.e., not abstaining) but not in a monogamous relationship, condom usage is an appropriate response to the threat of AIDS. In a national survey of 400 such adults, 67% of the women and 54% of the men said they were very likely to insist that a new partner use a condom. However, only 38% of the women and 48% of the men reported using a condom in the past year (Carter-Wallace 1988). Likewise, a national survey indicates that only 14% of sexually active unwed teenagers used a condom the last time they had intercourse (U.S. News & World Report 1988). Thus, it appears that many sexually active,

heterosexual Americans are not using condoms. Therefore, the purpose of this paper is to suggest workable approaches for communication efforts that increase condom consumption in this population to protect against AIDS transmission.

Specifically, we search two sources of suggestions for communications that affect condom consumption. The first source is research specifically on AIDS. Given the dearth of research in this area, we also review a second source: literature on efforts to change other health behaviors, with a focus on behaviors judged to be most similar to condom usage. We base our definition of similarity on key characteristics of condom usage and other health behaviors (e.g., seat belt usage, smoking cessation). Based on both sources, we present our conclusions on how to increase condom consumption. Last, we propose a future research study to test some of our conclusions.

RESEARCH ON AIDS

To answer the question of what type of communications would increase condom usage by heterosexuals to protect against AIDS, we first review research on this topic. Any communication effort involves a source, content, a medium (i.e., means of transmission), a receiver, and destination (i.e., opinion-change impact) (McGuire 1969). Because of our focus on behavior change by heterosexuals, we consider neither other groups of receivers nor destination. Rather, we examine each study for information on the effects of source, content and medium.

Of the few papers published on AIDS and heterosexual condom usage, the first we discuss examines the attitudinal and behavioral impact of a television-quality, soap opera-style videotape in which the female protagonist, with advice from her brother and girlfriend, convinces her boyfriend to use condoms (Solomon and DeJong 1989). Compared to those who did not see the videotape, clinic patients who watched it had greater knowledge and more positive attitudes toward condoms. A second group of patients who saw the videotape redeemed significantly more coupons for free condoms from the clinic. Thus, viewing the videotape affected knowledge, attitudes and behavior. The authors stress the videotape's source, i.e., members of the target audience, and several aspects of the message. The latter include portraying condoms as socially acceptable and normative, as well as sexually appealing, and focusing on interpersonal and communication skills. However, the effects of source, content and medium are confounded. In a related paper, Solomon and DeJong (1986) give a more complete list of their principles for STD and AIDS risk reduction message design. Most concern the content (e.g., develop

strategies to acknowledge and reduce the stress that AIDS causes) with fewer focusing on the medium or source (e.g., use intermediaries with access to the audience).

The Solomon and DeJong study (1989) is the only one that demonstrates that communications can affect condom usage, assuming, of course, that redemption of coupons for condoms is a good proxy for such usage. Another study finds no effect on behavior (Sherr 1987). The communication was a full page advertisement that appeared once in every national newspaper in the U.K. and presented information and advice about risk factors for AIDS and safe sex guidelines. A content analysis (performed after its appearance) found that only 24% of the population could understand the advertisement, which also used unclear terms, such as "intimate kissing" and "rectal sex". In brief, the message was weak on readability and clarity. Perhaps not surprisingly, it had no impact on self-reports of intended sexual behavior or on attitudes, desire for more information, or AIDS anxiety among its readers. Although information gaps among readers decreased, this effect was not quite significant. These findings were based on comparisons before and after the message appeared; at each time, different samples of the same populations were questioned. Unfortunately, the sexual orientation of respondents was not adequately assessed. Moreover, the study confounds the effects of source, content, and medium. However, all three differ from the Solomon and DeJong (1989) study: the source was a group of medical officials and the medium was a newspaper. The content was informational and did not address social norms, interpersonal skills, or the erotic nature of condoms.

The remaining two papers on AIDS and condom usage by heterosexuals do not examine the effects of specific communication efforts. However, they, along with Solomon and DeJong's (1986) earlier paper give good directions for message content. Siegel and Gibson (1988) discuss six barriers to heterosexuals' use of condoms to lower the risk of contracting AIDS: perceptions of low vulnerability, misperception of the efficacy of adaptive behaviors, barriers to the adoption of condoms, confusion regarding the magnitude of the threat to heterosexuals, interpersonal nature of sexual activity, and the stigma of AIDS. Based on these barriers, the authors make several recommendations, including one for wider availability of condoms. Their remaining suggestions focus on the content of communications efforts: operationalize terms such as "multiple partners" and "sexually active", destigmatize AIDS, convince people that they cannot identify AIDS carriers by their own judgments, change perceptions of condoms, and show people how to negotiate limits with sex partners. The latter two suggestions concur with Solomon and DeJong (1986, 1989).

In another study, heterosexual college students reported their reactions to two hypothetical scenarios involving condom usage (Hill and Stephens forthcoming). In the first, the student

suggests condom usage to a new partner. The students reported they would be concerned about their partner's sexual history and consequently envision a short-term relationship. They are, as one respondent stated, "pointing an accusatory finger". The students also reported their responses to a scenario in which a first-time sex partner suggests using a condom. They anticipate responding with a feeling of shared responsibility and/or favorable reactions towards the suggesting partner. Since suggesting condom usage can be other-serving as well as self-serving, a partner may interpret it as an act of "mutual consideration", as one respondent suggested.

The students' positive reactions to the partner request scenario contrast with the more negative ones from the scenario in which the student him/herself suggests using a condom. But these positive feelings are consistent with the sexual intimacy literature which suggests that self-disclosure, revealing ones' fondest dreams as well as deepest fears, is often interpreted as a sign of the other person's continuing interest (Masters, Johnson and Kolodny 1986; Millett 1970). The implications for message content are clear: portray the positive responses of a partner to the suggestion of condom usage.

Although our focus is on heterosexuals, we did examine communications about AIDS aimed at homosexuals. Bayer (1989) reports that gay groups provided information about safe sex to many members of the gay community and that subsequently, knowledge about safe sex has become widespread (e.g., 90% awareness in two samples of gay men). Further, there have been dramatic changes in sexual behavior (e.g., celibacy rose from 2% to 12% in a two-year period among a sample of 5000 men). However, many gay men continue to engage in risky behaviors (e.g., one third of the sample of 5000 do not use condoms). Bayer credits education with the changes that have been achieved, but also argues that personal knowledge and experience with those ill and dead from AIDS has had a powerful effect on behavior.

On the whole, the studies discussed above afford us little opportunity to examine the effects of communication source, content, and medium on the beliefs and behaviors of heterosexuals regarding condom usage to decrease the likelihood of AIDS transmission. However, the studies do suggest useful guideline for designing messages for more detailed empirical testing.

CHARACTERISTICS OF HEALTH CHANGE BEHAVIORS

Our goal is to identify communication efforts that are successful in encouraging heterosexuals to use condoms as protection against AIDS transmission. However, there is little past research on this problem. Therefore, we examined literature on changing other health behaviors. We focused on behaviors that are similar, i.e., have dimensions in common with using condoms to protect against AIDS transmission. In this section, we discuss

several characteristics or dimensions that describe health change behaviors. We will then review past efforts to change such health behaviors.

Frequency of Behavior

Health change behaviors can range in frequency from once in a lifetime to every day or every time a given set of conditions occurs. For example, inoculations, e.g., for hepatitis, or the installation of a smoke detector in one's home need to be done infrequently, while a seat belt must be used every time one is in a automobile. Likewise, condoms must be used every time sexual intercourse occurs. The more frequent the behavior, the more important are attention, memory, and motivation. Not only must the user pay attention to and recognize the conditions that require the behavior, but he/she must also be motivated to perform the required action.

Convenience

Convenience is a subjective belief, particular to an individual consumer. The convenience of a health change behavior depends on several dimensions: time, place, duration, pleasure, and usage situation. Note that convenience differs from repetition, i.e., a behavior can be repetitive but convenient. For example, taking a pill once a day is repetitive but convenient. However, taking AZT every four hours is repetitive and inconvenient, because of timing; the user must interrupt his sleep to take it. Most immunizations are infrequent, but a rabies or penicillin shot seems inconvenient due to unpleasant effects, unlike a hepatitis shot. Condoms are generally considered inconvenient, due to the delicacy of the usage situation, and because pleasure may be diminished (Felman and Santora 1981).

Individual versus Passive

This dimension contrasts health behaviors the individual must perform, with those that are performed *for* him/her, thus permitting the individual to remain passive (Robertson 1976). For instance, a seat belt is an individual responsibility while air bags are passive; likewise using fluoride gel is an individual responsibility while obtaining fluoridated water is passive, i.e., it requires no individual effort. The implication is that passive actions depend much less, if at all, on each person, while the motivation of each user is critical for individual actions. Clearly, condom usage is an individual responsibility, as are other changes related to preventing sexual transmission of AIDS.

Private versus Public

A public health behavior is done so that others can observe compliance, e.g., smoking cessation. However, a private behavior is observed only by the person doing it, e.g., flossing teeth. Condom usage is semi-private; two people are involved. The implication is that public behaviors have a greater opportunity for social influence than

do private ones; a semi-private one should fall between these two extremes.

Consequences

The physical consequences of performing or not performing a health behavior may be to the self only or to the self and others. For example, drinking (without driving) may be harmful only to the drinker, but drinking and then driving is harmful to the occupants of other cars and to pedestrians. Similarly, the consequences of overeating affect the eater but overfeeding one's children clearly affects others. Condom usage has consequences for one other person besides the self. When a health behavior has consequences that extend beyond the self, appeals to change the behavior can focus on protecting other people, especially loved ones.

Summary

In summary, condom usage must occur every time there is intercourse, is perceived as inconvenient, and requires responsibility and action from the individual. It is a semi-private behavior, with consequences for the self as well as others.

RESEARCH ON OTHER HEALTH CHANGE BEHAVIORS

In reviewing research on health change behaviors, we begin with work related to other sexually transmitted diseases (STDs). Among the few studies on communication efforts with regard to other STDs, even fewer look at the effects on behavior. More typically, they examine gains in knowledge. For example, a programed learning guide, an audiovisual tape and an interview all significantly increased patients' knowledge of STDs (Alkhateeb, Lukeroth and Riggs 1975). The interview was the most effective and evaluated the most favorably.

A few studies do examine effects on STD-related behaviors, such as levels of clinic use (e.g., Adler 1982) and gonorrhea patients' rate of return for test-of-cure examinations (Kroger 1980). Patients new to a clinic mentioned the media as a source of reference more often after the airing of a television program that concerned STDs and frequently mentioned the name of the clinic's hospital (Adler 1982). In this study, the effects of content, medium and source are all confounded. When nurses used "prescription" pads and simplified information sheets to communicate expected behavior, instead of verbal-only instructions and more complicated information sheets, more patients returned for test-of-cure (Kroger 1980). However, much of the improvement disappeared when the nurses were no longer monitored. Moreover, the impact of medium (pads versus verbal instructions) was confounded with content; without the pads, many times nurses did not give any instructions at all.

These findings are of limited usefulness for the problem of encouraging condom usage among sexually active heterosexuals. Both first time visits to a clinic and returns for test-of-cure are infrequent, somewhat inconvenient, and public, require

TABLE
Health Change Behaviors that are Similar and Less Similar to Condom Usage

Health Change Behavior	<u>Characteristics of Health Change Behaviors</u>				
	Frequency	Convenience	Individual/Passive	Private/Public	Consequences
Condom usage	Every time	Low	Individual	Private	Others
<i>Behaviors Similar to Condom Usage</i>					
Smoking cessation	Every time	Low	Individual	Private & Public	Others
Exercise	3-7 times/week	Low	Individual	Private	Self
Nutrition	Daily	Low-Moderate	Individual	Private	Self
<i>Behaviors Less Similar to Condom Usage</i>					
Return checkup	Once	Moderate	Individual	Public	Others
Seat belt use	Every time	Low-Moderate	Individual	Public	Self
Hepatitis shot	Once	Moderate	Individual	Public	Others
Installing air bags	Once	High	Passive	Public	Others

Note: Characteristics in bold type are similar to those for condom usage.

individual responsibility, and have consequences for others. Hence these behaviors differ from condom usage on the dimensions of frequency, convenience, and their public versus private nature (see Table for behaviors that are dissimilar and similar to condom usage). Further, there are confounded communication-related effects in both studies.

Other behaviors, even though they are not related to STDs, more closely resemble condom usage, for example cessation of smoking (see Table). Like condom usage, it must occur every time given circumstances occur (i.e., there is desire for a cigarette), is inconvenient (i.e., the smoker gives up a pleasurable activity with addictive properties), is an individual responsibility and has consequences for others. But unlike condom usage, smoking cessation occurs in public as well as in private.

There is some evidence that communications efforts encourage smoking cessation. More Australian smokers in towns with media campaigns against smoking quit, compared to a control town (Egger, Fitzgerald, Frap, Monaem, Rubinstein, Tyler and McKay 1983). The media campaigns were intensive and included television, radio, print, stickers, posters, T shirts, balloons and self help "Quit" kits. In addition to media antismoking efforts, one town had community programs, such as quit smoking groups, fact sheets, and aids to help smokers quit. In this town, declines in smoking continued past the first year of the media campaign, to the second and third years. These results suggest that face-to-face media (e.g., quit smoking groups) or "little" media (i.e., fact sheets) are more effective for long-run behavior changes than mass media (e.g., television). Unfortunately, there may be

confounds between the effects of medium and source or content.

Similar results occurred in a Finnish study of smoking (Puska, Niemensivu, Puhakka, Alhainen, Koskela, Moisio and Viri 1988). The proportion of smokers declined more in areas with both an anti-smoking media campaign (i.e., a 15-part television series) and worksite programs (i.e., opinion leaders, risk factor profiles and health education brochures) than in areas exposed only to the television series. Like those in the Australian study (Egger et al 1983), these results suggest that a mass medium (i.e., television) is less effective than other media, including face-to-face interaction (i.e., opinion leaders) and other non-mass media (i.e., brochures). However, once again, the study does not clearly control for differences in source (e.g., a known opinion leader versus unknown, albeit similar, workers in the television series) or in content (e.g., information from the risk factor profile) between different mass media, or between the various non-mass media channels.

Two other health change behaviors that resemble condom usage are exercise and diet or nutrition (see Table). Adequate nutrition and exercise both must occur frequently, require individual responsibility, and are often private. For many people trying to change their diet or increase their exercise level, these behaviors may well seem at least somewhat inconvenient. These four characteristics resemble those of condom usage; however, diet and exercise have consequences only for the self.

A study on osteoporosis prevention examined both exercise and nutrition (Rook 1986). All

subjects received one page of information about the prevalence of osteoporosis, risk factors associated with it, and actions (exercise and diet) that would help prevent it. Some subjects read the information in an abstract version, i.e., in reference to women in general, while others read a vivid version, i.e., in reference to a particular woman. Their attitudes and behavioral intentions were combined into a measure of persuasiveness. Premenopausal women (for whom osteoporosis is a distant threat) found the vivid information more persuasive. But postmenopausal women (for whom osteoporosis is a proximal threat) found both presentations equally persuasive. However, after six weeks, none of the women reported changes in exercise or diet (i.e., eating calcium rich foods). Despite the disappointing results for behavior, this study does demonstrate the impact of one message characteristic, vividness, on attitudes and intentions. This demonstration reinforces Bayer's (1989) argument that personal knowledge of individuals who have suffered (i.e., vivid information) has affected sexual behavior of homosexuals.

In sum, these studies on health change behaviors that are similar to condom usage suggest that the medium has an effect on behavior and that one aspect of the content (i.e., vividness) may have an effect. Reviews of mass media campaigns on a variety of health behaviors, including smoking, drug use, alcohol use, general health, and obesity, conclude that mass media campaigns have no lasting effects on behavior (Atkin 1979, Flay 1981, Robertson and Wortzel 1978). Typically the mass media campaigns reviewed simply involve televised public service announcements (PSAs). Clearly, a series of short (30 or 60 seconds) PSAs, often aired at off-times when the audience is small, is similar to Rook's (1986) information sheet and to the newspaper advertisement reviewed by Sherr (1987) but very different from the two anti-smoking campaigns reviewed. The Australian study used brief PSA-like announcements on TV and radio; however, they bought the time to control the amount of exposure and also used a wide variety of other channels. Although in the Finnish study only one channel (television) was used, the messages were 35-minute programs.

Thus, as Bettinghaus (1986) concludes, few mass media campaigns have lasting effects on health behavior, although weak positive effects are likely and some campaigns with special features do generate significant behavior changes. Rather, mass media communications efforts are more effective for creating awareness, affecting attitudes and beliefs, initiating information search (Schlinger 1986), and reinforcing existing behaviors (Robertson and Wortzel 1978; Schlinger 1986). Also, as demonstrated in the studies discussed here, reviews of mass media campaigns on a variety of health behaviors conclude that face-to-face interactions are more effective than mass media campaigns for inducing behavior changes (Atkin 1979, Flay 1981).

CONCLUSIONS

In sum, there is very little information on communications efforts to change condom usage by heterosexuals, to protect against AIDS. Only one study reports encouraging results for changing behavior (Solomon and DeJong 1989). Despite many recommendations about message source, content and medium, there are no definitive results on the impact of each of these communication elements, due to confounding. Hence, we argue that a thorough empirical analysis of any communication effort must focus on the separate effects of message source, medium and content on the receiver. However, for message content, Solomon and DeJong (1986) and Siegel and Gibson (1988) provide worthwhile suggestions, although they have not been rigorously tested. As for the medium, studies concerning other, but similar, health change behaviors suggest that mass media are not effective for changing behavior, but that face-to-face and other non-mass media are.

Thus the soundest suggestion is not to rely on mass media campaigns to change condom usage. Instead, channels that allow for direct interaction (e.g., in groups or between a pair of individuals) or for more detailed information which receivers can process at their own pace (e.g., brochures) seem more effective.

FUTURE RESEARCH

As the previous review illustrates, the most effective medium, source and content of communications for convincing heterosexuals to change their sexual behavior in response to AIDS is not clear. In particular, which type of non-mass media (i.e., face-to-face interactions versus printed matter such as brochures) is most effective is not clear. Further, there are no findings and few suggestions about source. Thus, work on message source and on the relative effectiveness of non-mass media seems quite crucial. We are currently developing a field study that will compare the effects of these two variables. It will take advantage of a college campus which has an important medium -- small, peer groups -- to communicate information about AIDS.

AIDS and the Arts

Ronald Paul Hill, Villanova University

ABSTRACT

Kimmelman (1989, p. 1) writes:

It would hardly be an exaggeration to describe American culture in the late 1980's as art in the era of AIDS. Art has confronted AIDS the way people confront AIDS - with fear, anger, sorrow, defiance, and confusion. In a country that idolizes youth and health, AIDS has struck at the very heart of the American self-image.

This paper explores this outlook by focusing on the images of AIDS and its victims as they are depicted in the visual and performing arts. Implications of this portrayal on opinions and attitudes within society also are presented.

INTRODUCTION

The AIDS (Acquired Immune Deficiency Syndrome) virus has captured the attention of the world and ultimately may infect more people than any other deadly disease in recent history. Since 1981, when the first case was discovered, 87,188 people in the United States have been diagnosed as carriers of the AIDS virus and 49,976 of these persons have died (Chase 1989). Once linked to homosexuals and intravenous drug users (Bayer 1988), AIDS is now viewed as a growing threat to heterosexuals worldwide (Altman 1989). The total cost due to the premature deaths of thousands of young adults in their prime years of productivity is projected to reach \$66.4 billion by 1991 (Foltz 1987). According to Dr. Andrew Moss, an epidemiologist at San Francisco General Hospital, "AIDS will be a routine sexually transmitted disease, and we have to adapt to thinking in those terms" (Altman 1989, p. A1).

A disease with such potential to destroy life might have prompted the public to demand immediate action by the U.S. government. However, the average American found it difficult to respond to an illness perceived to be "spread throughout the country mainly by anal intercourse between promiscuous homosexuals" (Lepkowski 1987, p. 59). Hospital workers nicknamed the disease "WOGS," for "wrath-of-God syndrome," and *Commentary* Editor Norman Podhoretz condemned efforts to develop a vaccine, complaining that "they are giving social sanction to what can only be described as brutish degradation" (Horn 1989, p. 62). Because of these ambivalent feelings, elected officials were slow to react to this crisis (Shilts 1988). According to Rock (1987), the Reagan administration underestimated the scope of the epidemic, played down the risk to heterosexuals, and deliberately minimized bad news in an attempt to avoid panicking an already anxious population.

One consequence of this early government neglect was the onslaught of invalid as well as valid

information available to the public from a wide variety of formal and informal sources (Hill 1988). For example, while the work of former Surgeon General Koop has raised awareness that the AIDS virus can be transmitted through sexual contact (*Associated Press* 1988), a *Washington Post-ABC News* poll found that people also believe that AIDS can be contracted through kissing, being sneezed on, donating blood, using the same drinking glass, and sitting on a toilet seat (Okie 1987). Many of these misperceptions are the result of widespread media coverage of a 1983 *Journal of the American Medical Association* editorial which suggested that AIDS could be spread through "routine household contact" (Shilts 1988). The result of this mixed information, contrary to the early expectations of the federal government, has been widespread societal confusion and anxiety (Goodman 1988).

ARTISTS' RESPONSES TO THE AIDS EPIDEMIC

No group is more aware of the deadly power of the disease than the arts community, where AIDS has taken an especially painful toll. Many artists are working to change the way the disease is portrayed by rewriting the language that positions AIDS as an act of divine retribution or as a disease of degeneracy and despair. Jan Zita Grover, curator of a show called "AIDS: The Artists' Response" at Ohio State University, asserted that "Artists have a sense of urgency, a sense that what they're producing can make a difference" (Horn 1989, p.62). Thus, the goal of much of this art work is not to produce "masterpieces" but "to save lives, by whatever means at an artist's disposal" (Kimmelman 1989, p. 6).

Consequently, work in the performing and visual arts that refers directly to the AIDS virus has grown exponentially since the syndrome was first diagnosed in 1981. Artists' examinations of AIDS range from Larry Kramer's passionate and provocative play "The Normal Heart" to the less outspoken television movie "Ryan White Story," and from the Names Project quilt, gut-wrenching in its often highly personal portrayal of thousands of dead AIDS victims, to the graphic photographs of Nicholas Nixon shown last year at the Museum of Modern Art in New York. While many of these artistic endeavors are quite painfully eye-opening, others have perpetuated harmful inaccuracies in public opinions. For example, plays like Harry Kondoleon's "Zero Positive" continue to portray AIDS as a problem confined to gay men, reinforcing the belief that AIDS is a "gay plague". Also, television movies like the "Ryan White Story" prefer to focus on "innocent victims" of AIDS (e.g., hemophiliac children) rather than on minorities who are at much greater risk.

This paper now turns to an examination of the portrayal of AIDS in a wide range of visual and

performing arts including television, photography, plays, dance, and a subset of lesser used art forms (i.e., cartoons, posters, and the Names Project quilt). The focus is on the stated purposes of the artists and, where possible, public reactions. Finally, implications for the use of these arts on societal opinions and attitudes are discussed.

Television

The television media, with few exceptions, has tended to reinforce the developing societal distinction between "innocent" and "guilty" victims. The innocent victims scenario is a well-intentioned effort by the media to make AIDS everyone's disease by producing stories of infected children and hemophiliacs. For example, ABC broadcast "The Ryan White Story," a television movie about a white hemophiliac boy who becomes ostracized by neighbors and schoolmates after developing AIDS. Another TV-movie titled "The Littlest Victims" involves infants who contract the disease through the contaminated blood supply, and focuses on heart-wrenching scenes of these children with their grief-stricken parents.

The "guilty" victims scenario is portrayed much differently. In a recent episode of the NBC program "Midnight Caller," a bisexual man with AIDS is depicted as utterly depraved as he knowingly infects women with the virus in an attempt to feed his insatiable sexual appetite. Also, a similar situation was the focus of a 1985 public television program where a documentary crew followed a black, gay man with AIDS as he wandered around the country engaging in sex with unsuspecting partners. One exception to this approach is the NBC television movie "An Early Frost". Dubbed by some critics as a "conscientious tear-jerker," this film presents a gay man with AIDS who attempts to regain the love of a disapproving father. Interestingly, while the film had high ratings and received several Emmy award nominations, the networks never attempted a project with a similar theme again.

Photography

No other visual art has attempted or achieved the graphic portrayal of AIDS and its victims as photography has, and Nicholas Nixon, well-known for his searing, sobering, and unforgettable photographs, may have produced the most powerful of these images. His subjects include gay men, a woman, and a male hemophiliac. The photographs, taken over time, show the visible signs of the destructive progress of the disease as well as the inner torment of its victims. The result is quite dramatic - the viewer sees not only the physical deterioration of the subjects but also an apparent reduction in their concern about composing themselves for the camera. In the case of one subject, the first image is of a mother and son embracing in their attempt to console each other. By the end of the sequence (and just prior to the death of the subject), the young man appears to be

ignoring the camera, gazing into infinity, and lost to his surroundings.

Robert Mapplethorpe, a well-known photographer who died of AIDS recently, also produced striking images of AIDS victims. He first gained public notoriety in the late 1970s when he chose to publicly depict the sado-masochistic subculture of male homosexuals. While many critics and members of the public found his photographs disturbing, his compulsive and unabashed portrayal of homoeroticism won him considerable fame by the late 1980s. It was the topic of AIDS, however, that led him to produce some of his most unforgettable work. After being diagnosed as having AIDS, Mapplethorpe's willingness to make his illness public helped focus attention on the disease throughout the art world. His 1988 self portraits, showing his once handsome face grim and emaciated next to a skull's head walking stick, provide a stark reminder of the personal tragedy caused by the disease.

Artist Linda Troeller provides a unique perspective on AIDS through her use of photcollage. By juxtaposing journal excerpts, family snapshots, and surreal images, she draws parallels between today's AIDS victims and the ostracism her mother faced as a tuberculosis patient in the 1930s. Using photographs taken by her mother during her isolation in a TB sanitarium in combination with pictures taken by Barbara Cleaver of her son who died recently from AIDS, Troeller shows the defiance, rage, and shame experienced by victims and their families.

One exception to the photographic portrayal of AIDS as a predominantly male and gay disease is the work of Ann Meredith. Her subjects are women with AIDS, and her pictures present these women with their children in settings from their homes to the hospital. By showing heterosexual mothers of different races and social classes infected with the disease, Meredith suggests that no individual can afford to be complacent about AIDS.

Plays

Many plays have been directly touched by the AIDS pandemic. In their wariness toward sex, "Burn This" and "Frankie and Johnnie in the Clair de Lune" could be viewed as "AIDS" plays. Also, "Eastern Standard," "The Heidi Chronicles," and "Gus and Al" are three plays recently on New York stages that make references to the disease. However, two plays - "As Is" by William Hoffman and "The Normal Heart" by Larry Kramer - directly confront the issues surrounding AIDS.

"The Normal Heart" is both a love story and a searing indictment of the indifference of New York's political and health officials to the suffering of gay men afflicted with the disease. The play covers the first three years of the AIDS crisis, and attempts to show that AIDS kills homosexuals *and* heterosexuals, men, women, and children. Though the acronym "AIDS" is never spoken, this angry play points "an accusatory finger" at all groups in society for turning away, in fear or hate, from this

common threat. In this sense, "The Normal Heart" is a "call to arms" to pressure local and national authorities to provide the necessary resources to educate society about the disease and to continue the search for a cure.

"As Is" has a more narrow focus and looks at the relationship between two gay men who were formerly lovers. After one contracts AIDS and is shunned by friends and family, his former partner invites him back into their home and comforts and takes care of him until his death. While the production contains several long, painful scenes, the use of comic blackouts rather than intermissions acts to reduce the sense of pessimism and despair inherent in other plays such as "The Normal Heart".

If "As Is" strikes a middle ground with relation to "The Normal Heart," plays such as "The AIDS Show," which is a series of mostly comic sketches staged by the Theater Rhinoceros in San Francisco, represent the other end of the spectrum. Several of the performers have AIDS, and by their presence they seem to insist that coming down with the disease does not mean giving up living or enjoyment. The humor in the production is both cathartic and inspirational.

Dance

The performing art of dance has focused attention on classic images of death in its personification of AIDS. In "21 Supported Positions," a dance performed by Bill T. Jones and Arnie Zane (who died recently from AIDS), the AIDS victim is depicted much like Christ during the crucifixion. With compassion and love, Jones lifted, caught, and carried his fragile partner through the dance. At one point, Jones held Zane in his arms as the infected man collapsed from exhaustion, evoking the image of Christ cradled in the Virgin Mary's arms. Another choreographer, Martha Clark who suffered the loss of a principle collaborator as a result of AIDS, recently produced a major production concerned with obsessive desire and death titled "Miracolo d'Amore (the Miracle of Love). In this work, which she conceived while mourning the loss of her close friend, a woman makes love to a chalky skeleton.

In a less personal but no less haunting portrayal of AIDS, choreographer Phyllis Lamhut created the dance "Man". She originally approached the topic of death in a 1980 dance called "Passing," and since then has continued to focus on the decay of modern civilization using informative cultural references. She treats the subject of AIDS with uncharacteristic and numbing reverence through the dance of solo performers. A Greek chorus of three women in dark robes opens the dance and moves through it in a way that suggests communal mourning. During each solo, the women sit quietly or lie face down at the edge of the stage framing a context of loss and death.

Lesser Used Art Forms

Besides the major performing and visual arts mentioned, the AIDS crisis has impacted other art

forms, especially cartoons, posters, and a craft project titled the "Names Project" quilt. Political and social cartoonists often have attempted to provide commentary in their work regarding current events, and the AIDS pandemic is no exception. For example, Gary Trudeau, in his comic strip "Doonesbury," has chronicled the misunderstanding and reticence regarding the disease. In one episode, a politician cannot bring herself to say the name of the disease in a public meeting: "I'd like to focus on all of these [issues] tonight in a no-holds-barred dialogue on...on...on the great unpleasantness." In another episode, Trudeau shows the same politician answering questions about the disease. A member of the audience asks what is being done to change the perception that AIDS is a "gay" disease. She responds that "... it's clearly not a gay disease. It's a perfectly ghastly one!"

Other AIDS activists use alternative art forms since they question the display of work in traditional cultural institutions where artists preach mostly to the converted. For example, the AIDS Coalition to Unleash Power (Act Up) designs and distributes posters (as well as flyers, stickers, and buttons) using the pink triangle used to identify homosexuals in World War II concentration camps with the words "Silence = Death". Also, two advocacy groups, Gran Fury and General Idea, use the format of Robert Indiana's quintessentially 60s "LOVE" painting to display the words "RIOT" and "AIDS," suggesting the spiritual distance between the 1960s and the 1980s. Another atypical visual expression involving the AIDS crisis is the Names Project quilt. Started shortly after AIDS began to devastate the gay communities in New York and San Francisco, this work of art has been described as a "giant field of cloth tombstones" since each segment of the quilt contains the name of a victim of this deadly disease. Contributors were allowed to personalize the individual squares, and many contain treasured artifacts of the deceased.

Implications

Contagious diseases and plagues tend to transform a society. Illness and mortality become communal experiences, and fear may capture the attention of healthy individuals. Further, if the group primarily stricken with the disease is disenfranchised, negative stereotypes may be reinforced, and society may attempt to ignore the afflicted rather than share their experience. In most respects, this scenario is epitomized by the AIDS pandemic. The traditional "walls" around disease and death in our society have been buttressed in recent years by an almost neurotic obsession with health and beauty. Also, the fact that AIDS has been linked primarily to gay men and intravenous drug users tends to foster an "us" versus "them" dichotomy and increase the perceptual distance between AIDS victims and healthy individuals.

Many performing and visual artists feel it is their duty to unsettle the American public through realistic and sometimes graphic portraits of AIDS and its victims in an attempt to rectify this

situation. However, these efforts often have revealed the limitations of art as a vehicle of change. Artists are constrained by their own experiences, beliefs, and needs for self-expression as well as by factors beyond their control. For example, plays like "As Is" and photographs such as those taken by Robert Mapplethorpe, while grounded in personal experience and insight, tend to reinforce perceptions of AIDS as a "gay plague" and the arts community as predominantly gay. Also, many of the most startling works, including the photographs of Nicholas Nixon, portray AIDS victims as "freaks" who are sickly and often helpless in their present condition. In combination with television programs like "Midnight Caller," which furthers the stereotype of AIDS as the disease of hedonistic excess, this representation tends to underscore the difference between "us," the uninfected onlookers, and "them," the unhealthy afflicted. Finally, television, which is the vehicle with the largest and most diverse audience, prefers to reserve empathy and compassion for "innocent" victims such as hemophiliac children in order to avoid alienating advertisers, conservative members of the public, and certain advocacy groups.

In the final analysis, little can be done to coordinate the efforts of visual and performing artists. Each work is developed individually, with an emphasis on the personal experience and motivations of the creator rather than its contribution to information dissemination or attitude formation within society. Nevertheless, the images presented by the arts of AIDS and its victims have an important effect on the way we view and respond to this deadly disease.

An Exploratory Study of Lottery Playing, Gambling Addiction and Links to Compulsive Consumption

Alvin C. Burns, Louisiana State University
Peter L. Gillett, University of Central Florida
Marc Rubinstein, University of Central Florida
James. W. Gentry, University of Nebraska-Lincoln

ABSTRACT

Little research has been devoted to lottery ticket buying. Review of the literature suggests that lottery players are distinct from nonplayers, and that addicted gamblers differ from normal gamblers. Also, excessive lottery playing may be a manifestation of a general compulsive consumption trait which is evident in other consumption areas. A telephone survey reveals that lottery players are younger and have less income and education than nonplayers. Heavy players are found to have less income and to fantasize more than light players. Very heavy lottery players share characteristics of addicted gamblers, namely they are older, higher in income, fantasize more, and engage in other forms of gambling. A subset of them also exhibits compulsive consumption in the forms of browsing and heavy buying, sensation-seeking, and risk-taking. The dream of winning the lottery seemingly accommodates the strong fantasy need found in them quite well.

INTRODUCTION

Literally millions of Americans play legal lotteries. At last count, thirty-three U.S. states have lotteries, and most not only have a weekly lottery, but also daily "pick three" or "scratch and win" varieties as well. Lottery sales in 1985 were estimated to be \$9.4 billion and increasing at 36% per year (*Business Week* 1985). A number of states who do not have lotteries are actively considering ones at this time. In the aggregate, state lotteries appear to be generating a nation of millionaires. But lottery playing is a most peculiar form of consumer behavior. It is peculiar because the odds are stacked astronomically against winning. In other words, the rational expectation of anyone buying a lottery ticket must be that the dollar will be lost. Yet lottery players persist in buying tickets week after week.

This irrationality and ethical aspects of lottery gambling give rise to interesting controversy surrounding lotteries, and this controversy is revisited practically every time a state legislature debates instituting one. Opponents claim that lotteries prey on minorities, low income families and older people (Blakey 1979, Dielman 1979, Edmondson 1986, Kallick-Kaufmann 1979). These opponents also claim that lotteries have the potential of unleashing compulsive gambling inclinations lurking in individuals who would ordinarily not be exposed to easily accessible legal gambling (Dielman 1979). Lottery proponents, on the other hand, argue that lottery gambling is socially acceptable since state revenues are enhanced

and all state residents ultimately benefit from the use of these revenues (Kallick-Kaufmann 1979). They also claim that "shallow" gambling on bingo, slot machines, or lotteries is quite dissimilar from "deep play" gambling such as casino, race track, or craps; therefore, the potential for creating compulsive lottery gamblers is minimal (Edmondson 1986).

Perhaps due to the relative newness of lottery access by large numbers of consumers, scant research exists on the phenomenon. Consequently, this paper addresses a knowledge gap and describes the results of an exploratory study on lottery playing behavior. The objectives of the paper are as follows:

1. To identify differences between lottery players and nonplayers;
2. To investigate differences between different types (e.g., light versus heavy) of lottery players
3. To determine the extent to which very heavy lottery players share characteristics of compulsive gamblers; and
4. To explore possible relationships between very heavy lottery gambling and compulsive consumer behavior.

BACKGROUND ON LOTTERY PLAYING, GAMBLING AND COMPULSIVE CONSUMPTION

Lottery Player Profile

As noted above, very little published research exists on lottery players. McConkey and Warren (1987) recently reported the results of analysis on a sample of females residing in one of sixteen lottery states. Nonplayers were found to be concentrated in retired households with college education and low income. Heavy lottery players, on the other hand, tended to come from larger families, be middle aged, and to have higher income. Light players' demographic profiles tended to fall between the nonplayers' and heavy players' characteristics. Also, nonplayers embraced conservative, traditional, and less optimistic values, while light players were optimistic and less traditional, and heavy players displayed tendencies toward excess and to experience stress. Another study cited in *American Demographics* (Edmondson 1986) reported that most lottery players were males over 35 years old with some college education and moderate to low income. Heavy players in the first 45 days of the California

lottery were found to be minorities who were less educated and poorer than the average Californian (Schreiner 1986). Understatement due to unreachables (no telephone, suspicious of poll takers) leads to the conclusion that California lottery players tended at that time to be from the low end of the socioeconomic scale (Schreiner 1986). Motivationally, lottery players are distinguished from deep-play gamblers by an overriding motive of making money rather than enjoying the excitement of gambling (Kallick-Kaufmann 1979). They are also likely to consider a lottery the means of fantasizing an escape from a dull and routine existence (*Forbes* 1986). In short, some evidence exists to support lottery opponents' claims the lotteries appeal to those least able to afford them.

Gambling and Addicted Gamblers

In contrast to the paucity of information on lottery players, there is much more research information and some theories available to explain gambling in general. Factors which have been found to differentiate gamblers from nongamblers include: childhood or previous exposure, current exposure, perceived availability, and legal status of gambling alternatives. At the same time, there is evidence that gamblers desire more stimulation in their lives than do nongamblers. Similarly, they often perceive they have better luck and greater skill than do nongamblers (Kallick-Kaufmann 1979). At least one author (Kusyszyn 1977, 1983, 1984) has developed a theory that gambling is a form of adult playland where fantasy has as important a role as does actual winnings. Kusyszyn (1983, 1984) concludes that individuals with strong tendencies toward risk-taking, sensation-seeking and fantasy more likely to be gamblers.

Interestingly, the general profile of gamblers is opposite that of lottery players on certain dimensions. That is, while more males than females gamble, gambling exhibits a positive correlation with income, and it decreases with age (Kallick-Kaufmann 1979). Moreover, important motivational differences are evident. The deep-play gambler seeks excitement while the shallow-play gambler seeks to make money (Kallick-Kaufmann 1979). The lottery or slot machine player relies primarily on luck, while the (e.g.) race track gambler or casino gambler feels that his skill is a determinant of winning. Both types are situationally enticed (Kallick-Kaufmann 1979). That is, both gamble more with larger potential winnings; however, the deep-play gambler manipulates the potential winnings with bet sizes, handicapping, or hedges, while the lottery player can only wait until the jackpot grows as a result of no one winning and the amount rolls over into the next week. Lottery players are then stimulated by the larger winnings, increased media hype (Edmondson 1986) or the possibility of instantly gaining celebrity status (*Forbes* 1986).

The vast majority of gamblers is not pathological. They place limits on their playing and live within the limits (Kusyszyn 1984).

However, about 1 percent of males and .5 percent of females are estimated to become addicted to gambling (Dielman 1979). Numerous clinical studies have been performed on addicted gamblers (See, for example, Galski 1987, Kusyszyn 1983, or Orford 1985) and have identified salient characteristics which appear to accompany this compulsion. To some degree, addicted gamblers exhibit the same qualities of gamblers in general, but these qualities are intensified. For instance, they are typically males in higher income and educational categories. Addicted gamblers have been described as energetic, impulsive, and sensation seeking. They apply their skill with a perfectionist bent, and they distort the odds of winning in their own favors. Intergenerational gambling influence is commonly found with addicted gamblers, and they often are found to be cross addicted to tobacco, alcohol, drugs, or sex. This cross-addiction trait is common for all types of addicts.

Compulsive Consumption and Hedonic Consumption

Addiction manifests itself as compulsive behavior which has recently become of interest to consumer researchers. Faber, O'Guinn and Krych (1987) provide a general description of compulsive consumption, terming it as "inappropriate, typically excessive, and clearly disruptive" of the lives of those consumers afflicted with it. These authors conclude that compulsive consumers are exhibiting a dependency much the same way a drug addict or alcoholic is dependent on a substance or someone is dependent on gambling. Further, compulsive consumers share psychological characteristics with addicts including abnormal thrill-, variety-, or sensation-seeking, impulsivity, and a need to relieve the stress of low esteem via escape or fantasy. Shopping and buying become the mechanisms for satisfying these desires. Faber, O'Guinn, and Krych (1987) contend that important public policy issues reside in compulsive consumption and recommend further study on this topic.

Further reflection on sensation-seeking, fantasy, and hedonic consumption reveals the theoretical underpinnings for some of the hypotheses addressed in this study. Hirschman and Holbrook (1982) have contended that hedonic consumption is based on what consumers desire or fantasize reality to be. They have posited a paradigm which explicitly includes the experiential aspects of consumption including fantasies, daydreams, and imagery, and they have urged researchers to address these factors in addition to information processing constructs (Holbrook and Hirschman 1982). MacInnis and Price (1987) have categorized these notions into the concept of "consumption imagery," an area they claim deserves research attention and promises managerial insight. Lottery playing obviously provides good opportunity for consumption imagery, and the fantasy aspect of lottery ticket purchases should be readily apparent. Also, since compulsive consumers are known to be high on the experiential

consumption scale, one would anticipate that heavy (possibly compulsive) lottery players would share sensation-seeking and other hedonic consumption characteristics as well.

HYPOTHESES

Given this background, there are four expectations underlying this study. First, lottery playing is affected by a myriad of personal, historical, social, and situational factors. Second, attributes exist which are useful in differentiating heavy from light lottery players. Third, very heavy lottery players may exhibit characteristics similar to compulsive gamblers. Finally, very heavy lottery playing may be related to other consumer behaviors indicative of socially-acceptable addiction, variety-seeking or compulsivity.

The descriptions above constitute the following hypotheses.

H1: Factors which will distinguish lottery players from nonplayers.

- a. Demographic (lottery playing with)
 - 1.) Males
 - 2.) Lower income
 - 3.) Lower education
 - 4.) Older
 - 5.) Minorities
- b. Historical (lottery playing with)
 - 1.) Parents as gamblers
 - 2.) Experience in another state with lottery
- c. Social (lottery playing with)
 - 1.) Socially acceptable
- d. Motivational (lottery playing with)
 - 1.) To make money
 - 2.) Need to fantasize
 - 3.) Need for escape
 - 4.) Risk-taking propensity

H2: Factors which will distinguish heavy from light lottery players.

- a. Heavy players will possess more of each characteristic listed in H1 than will light players.
- b. Situational (heavier playing with)
 - 1.) Greater amounts in jackpot
 - 2.) Purchase of some lottery book or aid
 - 3.) Previous lottery winnings

H3: Very heavy lottery players may exhibit characteristics of compulsive gamblers.

- a. Demographic
 - 1.) older
 - 2.) more income
 - 3.) more education

- b. Historical
 - 1.) Parents as gamblers
- c. Motivational
 - 1.) Sensation-Seeking
 - 2.) Impulsivity
 - 3.) Perfectionism
- d. Perceptual
 - 1.) Distortion of reality
- e. Cross-addiction with
 - 1.) Other forms of gambling
 - 2.) Alcohol
 - 3.) Smoking

H4: Very heavy lottery players may exhibit evidence of compulsive consumption

- a. Sensation-seeking
 - 1.) Browsing
 - 2.) New product trial propensity
 - 3.) Brand switching
- b. Compulsive buying
 - 1.) Heavy purchasing

METHOD

Setting

The study was performed in Florida which instituted a lottery in January of 1988. The typical weekly jackpot is approximately \$10 million, and the largest jackpot to date has been over \$40 million. In 1988, total lottery sales exceeded \$1.5 billion, and 50 percent of these revenues was awarded as winnings according to state law. Data was gathered during the month of March, 1989. Thus, it was believed that any curiosity buying or unusual playing associated with the newness of the lottery had abated.

Questionnaire and Data Collection

A questionnaire was designed for telephone administration in Orlando. Since no scales were available from previous research on the various motivational and compulsive consumption constructs (e.g. need to fantasize, heavy buying, etc.), statements were generated to be used with a 5-point agree-disagree scale. The statements were refined by having a class of marketing research students attempt to match them with descriptions of the constructs. Two statements with a minimum of 60% agreement were retained for each construct. Most had agreement levels in excess of 80%.

The questionnaire was administered by college students who were compensated for their work. Respondents were selected from the local telephone book using systematic sampling with a random starting point. Interviewers were instructed to attempt three callbacks and to alternate interviews with male and female heads of the household. A subsample of respondents was recontacted for

verification purposes, and all indicated they had participated.

RESULTS

Sample Profile

A total of 235 usable questionnaire resulted with an approximate 50-50 male-female split (48% males, 52% females). The typical respondent was 41 years old (standard deviation of 14.9), white (88%), married (66%), and had played the lottery (74%). Considerable variability in income and education levels was evident. While 23% of the sample had an annual family income before taxes of \$20,000 or less, 18% indicated income of over \$50,000, and the remainder of the sample was spread approximately evenly across the \$10,000 intervals in between these extremes. About 35% of the sample had high school or less education, 23% had some college, 28% had college degrees, and 14% either had some graduate work or a graduate degree. Lottery players in the sample bought an average of 3.6 tickets each week (standard deviation of 4.7).

Construct Measurement Reliability

Cronbach's alpha coefficients were computed for each pair of statements designed to measure the various constructs. Many failed to exhibit acceptable reliability levels. Inspection of correlations suggested considerable multicollinearity between statements intended to measure separate constructs. To control for this problem, it was decided to perform exploratory factor analysis with varimax rotation to determine underlying structure. A split-half approach was used, and nine factors identical in items with factor loadings of .60 or greater were determined for each half of the sample. The reliabilities based on the items comprising each factor were acceptable ($\alpha > .60$) except in two cases, and in two others, only one item loaded. The empirically determined constructs and the statements whose sum scores were used in subsequent analysis are described in Table 1.

Lottery Players versus Nonplayers

Table 1 also presents the results of differences tests (t-tests) and associative analyses (Chi square tests) used to test the study's various hypotheses. Because of the exploratory nature of this study, statistical significance was set at the $p < .10$ level; although, most of the statistically significant findings were at the $p < .05$ level or less.

As noted earlier, approximately one-quarter of the respondents had not played the lottery in the past. The following description parallels the categories of factors listed in HI. Compared to nonplayers, lottery players were found to be lower in family income, less well educated, and younger. No statistically significant differences were found for race or sex. Intergenerational influence was not related to playing, but experience with a lottery in another state was. Lottery playing was deemed more socially acceptable by players than nonplayers. As was expected, players tended to fantasize about

winning more than nonplayers, and they were more positive toward risk-taking. (Although not a part of HI, it was found that lottery players exhibited more heavy shopping and browsing than nonplayers.)

Light versus Heavy Lottery Players

While the average number of tickets purchased per week was 3.6, inspection of the distribution of responses, revealed that an approximate median split at 2 tickets. Consequently, those respondents who typically purchased 2 or fewer tickets per week and those who bought more than 2 were arbitrarily classified into light and heavy groups, respectively.

Heavy players were found to have less education than light players, while no other significant demographic factors (sex, income, age, or minority membership) were determined. Hypothesized historical factors such as parents gambling or lottery experience in another state also were not supported. Two motivational factors, greater fantasizing of winning and risk-taking propensity, did distinguish heavy players from light ones. (Heavy players were also more likely to browse and bargain hunt).

The situational influences aspect of the hypothesis was found to be supported by the results. Lottery players bought significantly more tickets on average (5.0 versus 2.3) if they had ever won anything in the lottery, and they bought more (7.2 versus 3.4) if they had purchased some lottery book or aid. Finally, with jackpot sizes of \$20, \$30, \$40, and \$50 million, respondents indicated they would buy 5.6, 6.7, 8.7, and 10.3 tickets, respectively.

To further understand the roles of the several factors hypothesized to be related to the amount of lottery playing, a regression analysis was performed using the number of tickets typically purchased as the dependent variable and the various demographic, historical, social, motivational, and situational factors as candidate independent variables. Six were found to have significant beta weights. Alone, they accounted for 21 percent of the variance in ticket purchases. These six were (standardized beta's in parentheses): age (.19), income (.16), education (-.20), parents gambling (-.15), won something in the lottery (-.30), and participating in other forms of gambling (-.14). Although tentative, these beta's suggest that lottery playing is not dominated by any single factor. In other words, greater lottery ticket purchasing is found with older residents who enjoy higher income but possess less education than average. Also, people who have not won anything in the lottery tend to buy more tickets, as do people who have lower participation in other types of gambling.

Very Heavy Lottery Players versus Other Players

The identification of Very Heavy lottery players was determined by inspection of the distribution of the number of tickets typically bought and facilitated by knowledge of the play slips used to select lottery numbers. The distribution revealed that 28% of the sample typically bought one ticket, while 23% normally bought five. The play slips used in this state have

TABLE 1
Factors Characterizing Various Types of Lottery Players and Nonplayers

Factor	Nonplayers	Players	Light	Heavy	Very Heavy	Possibly Compulsive
<i>Demographic Factors</i>						
Sex (Percent Males)	47%	48%	48%	46%	46%	43%

*Statistically significant at $p \leq .10$ (Refer to text)

five separate panels, allowing up to five tickets; thus, the large percentage of 5 ticket players was probably due to the play slip capacity: they simply filled one slip. It was therefore decided to use purchases of greater than five tickets to designate very heavy players; approximately 15% of the sample fell into this category.

Tests of significance were performed comparing the very heavy players group with all other lottery players. It was found that these players tended to be older and represented the second highest income group. They were also more likely to have observed gambling in their parents. They were found to fantasize about winning the lottery more than other lottery players. There was no evidence to support hypotheses of distortion of the odds of winning or cross-addiction to alcohol or drinking. But Very Heavy lottery players did report significantly more horse race, slot machine, and poker gambling in the last 12 months than did other lottery players.

Evidence of Compulsive Consumption in Very Heavy Lottery Players

Table 1 reveals that no significant differences were found between very heavy lottery players and other players on any of the three consumer behavior factors related to compulsive consumption and sensation-seeking. Realistically, one is hard pressed to argue that buying even \$10 worth of lottery tickets per week is excessive or disruptive consumer behavior: however, it was found that some respondents did report purchasing 15, 20 or even 40 tickets weekly. Exploratory analysis was performed using 7 respondents (1.7% of the sample) who purchased 15 or more tickets weekly. They are identified as "Possibly Compulsive" in Table 1. A statistically significant difference was found for this group's greater fantasizing about winning the lottery. Other statistical significance was obviously severely hampered by the very small sample size. Nonetheless, the mean response on the browser-bargain seeking dimension was higher for this group. It was higher for energetic-exciting life, impulsive and the making money motive for playing the lottery. The Possibly Compulsives were higher in risk-taking; they were older, had played lotteries in other states, and tended to engage in other forms of gambling more than other lottery players.

DISCUSSION

Some of the concerns of lottery opponents have been verified by the results of this exploratory study. That is, lottery players tend to have lower income and to be less well educated than nonplayers. However, they are younger than nonplayers. Lottery players apparently view their playing as socially acceptable risk-taking which provides them with a means of fantasizing sudden wealth and escape from their current status. Players are stimulated by situational factors, and they are likely to increase their purchases when the jackpot grows in size. There are heavy players who buy more tickets

regularly even when the jackpot is at its lowest level. These consumers have less education than the light players, and they fantasize about winning to a greater extent. Some evidence exists to suggest that the amount of tickets purchases increases with age and income; consequently, lottery playing may be less of a social problem than claimed by opponents. It appears that the vast majority of lottery players, regardless of the amount of playing, is purchasing a low cost fantasy.

There is a subset of very heavy players who are typically older and in higher income brackets. These players are more likely to have observed gambling in their parents; they fantasize of winning the lottery to a greater degree, and they participate in other forms of gambling more than other lottery players. Within the very heavy players is found a small group which appears to exhibit the characteristics of compulsive consumption. These consumers are most extreme in fantasizing, and they score high on other dimensions of compulsive consumption, namely, browsing and heavy buying, sensation-seeking, energy, and risk-taking. They are also the oldest group of lottery players and engage in other forms of gambling more. Although inconclusive, these findings do not support the claim that lotteries create addictive gamblers. Rather, excessive consumer behaviors of various types appear to be manifestations of a strong need to fantasize and perhaps to seek out sensations. Playing the lottery serves those with a strong fantasy need particularly well and holds promise of a wealth of new experiences if one should win.

A great deal of additional research must be applied to this area before definitive statements can be made. To be more specific, the measurements of the study's various constructs should be performed with greater reliability and validity tests. The sample should be broadened to provide representation in other states. Finally, a theoretical model of compulsive consumption should be developed in order to properly map out what behavioral phenomena are logically clustered together as a result of extreme sensation-seeking and fantasizing needs in consumers.

Compulsive Buying Tendencies of Adolescent Consumers

Alain d'Astous, University of Sherbrooke
Julie Maltais, University of Sherbrooke
Caroline Roberge, University of Sherbrooke

ABSTRACT

Based on the results of a qualitative study and a review of the relevant literature, research hypotheses pertaining to adolescent consumers' tendencies to buy compulsively are presented. The results of a survey of 394 adolescents support most of the hypotheses and show that teen-agers' compulsive buying tendencies are influenced by both personal and environmental factors.

INTRODUCTION

The topic of compulsive consumption, that uncontrollable urge to buy which affects a great many consumers, has received increasing attention from researchers during the past few years. This interest has been spurred by magazine articles with sensational overtones (e.g. Froom 1989; Holstrom 1985) and by some more serious research conducted by Faber and O'Guinn (1988; Faber, O'Guinn and Krych 1987; O'Guinn and Faber 1988). These researchers have reported several interesting findings about this intriguing form of addiction. Their general research strategy has been to contrast compulsive buyers from ordinary consumers on theoretically relevant variables. They have found compulsive consumers to be more materialistic but without necessarily attaching greater importance to the possession of consumer goods. They have also found them to be more envious, more likely to think that shopping is fun, less generous, more likely to feel guilty after buying things, higher on a general fantasy-imagination orientation and lower on self-esteem.

The compulsive versus normal research strategy has also been adopted in other studies. As part of the process of validating a measuring instrument, Valence, d'Astous and Fortier (1988) have found compulsive buyers to be more anxious in general and more likely to have in their family circle a parent showing an abusive consumer behavior such as alcoholism, toxicomania or bulimia. In yet another study (d'Astous and Bellemare 1989), a small number of compulsive and normal buyers matched on age, sex, income and occupation were contrasted on their reactions to print ads. The compulsive group was shown to react more favorably than the other group to image-oriented ads (e.g. "Polo Ralph Lauren. For those who have class.") as opposed to ads that emphasize product benefits (e.g. "Polo Ralph Lauren. Just quality."). The authors explain these results by arguing that compulsive consumers' buying frenzies serve as a means to improve their self-image. They prefer image-oriented advertising because it is consistent with buying as a mark of social status.

In a recent paper, d'Astous and Tremblay (1989) have taken a different approach to investigate the phenomenon of compulsive

consumption. These researchers argue that there is a generalized urge to buy characterizing all consumers at different levels and probably at different times. According to their view, compulsive buyers are at the utmost of the urge to buy continuum all the time. This leads d'Astous and Tremblay (1989) to propose that less extreme forms of compulsive buying behavior are also worth studying. So, instead of the familiar comparison research strategy, they looked at compulsive buying within the normal consumer population. They administered the compulsive buying scale developed by Valence, d'Astous and Fortier (1988) to a probabilistic sample of consumers and got results generally consistent with previous research. Thus, the higher subjects were on compulsive buying, the lower their self-esteem, the lower their age, the greater the extent of irrational use of credit cards and the greater the chance of being a woman. In addition, the authors reported some interesting relationships between compulsive buying tendencies and three items pertaining to childhood experiences: "When I was a kid, I could not help but spend immediately the money that I got" ($r = 0.2977$; $p = 0.0001$), "When I was young, I used to save the money I had in order to buy myself things that I wanted most" ($r = -0.1898$; $p = 0.0095$) and "When I was young, my parents used to buy me everything I wanted" ($r = 0.1616$; $p = 0.0279$). On the basis of these results, d'Astous and Tremblay (1989) speculated that compulsive buying tendencies might originate in early consumption experiences and therefore suggested to study the phenomenon within the teen-ager consumer population.

This paper presents the results of a research study whose objective was to follow the above suggestion and test several hypotheses related to compulsive buying tendencies in the adolescent consumer population.

GENERATING RESEARCH HYPOTHESES

Research hypotheses were developed through references to previous work on compulsive buying and on adolescent consumer behavior and by conducting a small-scale qualitative study with teen-agers. The study involved twelve adolescents, age 13 to 18, who admitted having problems with controlling their spending. The interviews were semi-structured, conducted individually and organized around three main themes: consumption habits, social and family influences, and compulsive buying tendencies. The study also allowed a pre-test of a version of the Valence, d'Astous and Fortier (1988) compulsive buying scale modified to better relate to adolescent language and interests.

The young consumers who participated in this preliminary study spend their money mostly on

TABLE 1
RESEARCH HYPOTHESES

Type of influence	Adolescents' compulsive buying tendencies are:
Mass media	H ₁ : positively associated with television viewing.
Peers	H ₂ : positively associated with peer influences.
Family	H ₃ : negatively associated with family discussion about consumption matters.
	H ₄ : positively associated with (perceptions of) their parents' compulsive buying tendencies.
	H ₅ : positively associated with family problems such as alcohol consumption, fighting, parents' absence and divorce.
Individual	H ₆ : negatively associated with self-esteem.
	H ₇ : positively associated with introversion.
	H ₈ : positively associated with generosity.
	H ₉ : negatively associated with the performance of rational consumer behaviors.
Demographic	H ₁₀ : negatively associated with age.
	H ₁₁ : negatively associated with social class.
	H ₁₂ : greater among girls.

activities like going to the movies, restaurants, disco-dancing, arcade games and on buying records and tapes. They also spend some money on clothing, garments, cosmetics and perfumes. For most of them, their parents are the main source of income. A few would sometimes borrow money to buy the things they want.

In all cases, friends appear to play a significant role in these adolescents' consumption experiences. They usually show them their purchases and sometimes ask for their opinions. We have noted however that there is a common desire to be different from peers, which leads these young people to look for products that have distinctive characteristics. On the other hand, family interactions seem minimal. A few adolescents, mostly girls, said they talk with their parents when they plan to buy something expensive.

Our young subjects said they make a lot of unplanned purchases. Many admitted being impulsive and incapable of refraining from buying things they see in stores. Budgeting is also a problem since ten of the twelve participants said their weekly or monthly allowance quickly disappears. As one teen-ager commented: "As soon as I got some money, it seems to burn my hands! You know, it's like a nervous habit, I've got to give it out!"

Two final observations are of interest. First, contrary to our expectations, we found these youngsters to be very generous with their friends. They like to please people that they appreciate by offering them, with no particular reason, gifts and treats. Second, half of the participants said they tend to isolate themselves when they have a

problem. We interpreted this as a sign of a tendency to introversion.

Table 1 presents the research hypotheses. Five of them (H₂, H₃, H₇, H₈ and H₉) are suggested by the results of the preliminary study. The others have been derived from the literature. Thus, the hypothesized relationship between compulsive buying tendencies and television viewing (H₁) follows from Moschis and Churchill (1978) who reported a positive association between TV viewing and materialism among adolescents. It is also consistent with the general belief that advertising - and by implication television advertising - contributes to reinforce the materialistic ideal among members of society (see Pollay 1986). H₄ and H₅ are simple extensions of Valence, d'Astous and Fortier's (1988) result linking compulsive buying to the presence of other dysfunctional behaviors in the family. The hypothesized negative relationship with self-esteem (H₆) comes from results obtained in studies conducted with adult consumers (d'Astous and Tremblay 1989; Faber, O'Guinn and Krych 1987; O'Guinn and Faber 1988). H₁₀, which proposes a negative relationship between age and compulsive buying tendencies, is taken from d'Astous and Tremblay (1989) who reported such a relationship with adult consumers and from Moschis and Churchill (1978) who observed a positive correlation between age and the performance by adolescents of socially desirable consumer behaviors. H₁₁, which concerns social class, follows from several studies (see the review by Moschis 1987) showing that young people from upper classes are more competent consumers and that lower class adolescents are more likely to exhibit

TABLE 2
THE MODIFIED COMPULSIVE BUYING SCALE

-
1. When I have money, I cannot help but spend part or the whole of it.
 2. I often buy something I see in a store without planning, just because I got to have it.
 3. Shopping is a way of relaxing and forgetting my problems.
 4. I sometimes feel that something inside pushes me to go shopping.
 5. There are times when I have a strong urge to buy (clothing, tapes, jewelries, etc.).
 6. At times, I have felt somewhat guilty after buying something because it seemed unreasonable.
 7. There are some things I buy that I do not show to anybody because I fear people will think I did a foolish expense or I wasted my money.
 8. I often have a real desire to go shopping and buy something.
 9. As soon as I enter a shopping center, I wish to go in a store and buy something.
 10. I have often bought a product that I did not need even when I knew I had very little money left.
 11. I like to spend money.
-

deviant consumer behaviors (e.g. shoplifting) and more susceptible to marketing stimuli. In addition, d'Astous and Tremblay (1989) have shown that compulsive buying tendencies within the adult consumer population are lower in the upper-class. Finally, H_{12} is based on d'Astous and Tremblay (1989) who found that women are significantly higher than men on compulsive buying behavior tendencies.

METHOD

A self-administered questionnaire containing all measures of interest was constructed and pre-tested to insure that the questions were clear and that there were no ambiguities. To facilitate the data collection, the researchers obtained the cooperation of school administrators and teachers. The questionnaire was distributed in student classes of four different schools: one public and one private high schools, one public and one private colleges. This was done in order to get some variability on age and social class. The final sample comprises a total of 394 French-Canadian adolescents aged between 13 and 19 years old ($\bar{x} = 15.96$). Girls are a little superior in number, since they represent about 54 percent of the total sample.

Measures

Table 2 presents the items that make up the compulsive buying scale used in the study. The scale is an adaptation of an existing instrument that has been shown to meet satisfactory levels of reliability and validity (see Valence, d'Astous and

Fortier 1988; d'Astous and Tremblay 1989). Some items were eliminated because of their irrelevance to teen-agers (e.g. "I am one of those people who respond to direct mail offers") and most items were re-worded to enhance understandability. The self-esteem measure is composed of four items (e.g. "In general, I am satisfied of myself") selected from the well-known 10-item scale of Rosenberg (1965). The other scales were developed by the authors specifically for this study. Introversion is measured with three items such as "I like to give my opinion to others" and the rational consumer behavior scale has four items such as "I rarely compare prices before I buy something". For all measures, respondents had to indicate their agreement with each item on a five-point Likert-type scale.

RESULTS

Reliability Estimates

Cronbach's alpha was computed for each scale. In spite of the important modifications to the original instruments, the compulsive buying and self-esteem scales' reliability estimates are very acceptable (0.7805 and 0.7311 respectively). The introversion and rational consumer behavior scales are less reliable (0.5900 and 0.5169 respectively), but the estimates meet the usually accepted norms for new measures (Churchill 1979).

Hypotheses Tests

Mass Media. The correlation between adolescents' estimates of the number of hours they

TABLE 3
PEER AND FAMILY INFLUENCES

	Correlations with compulsive buying score	p-value ^a
<i>Items pertaining to peer influences:</i>		
What my friends have influence what I buy	0.3439	0.0001
When I buy something, my friend's opinions are very important to me	0.2537	0.0001
I often show my purchases to my friends	0.2266	0.0001
When I buy something, I wonder what other people will think of me	0.3069	0.0001
Usually, when I want to buy something, I talk with my friends	0.2038	0.0001
When I go shopping, I often try to find things that are different from things that my friends have.	0.0953	0.0299
<i>Items pertaining to family influences:</i>		
Usually, when I want to buy something, I talk with my parents	- 0.0303	0.2742
There are products that my father (or my mother) seems unable to stop buying (shoes, tools, clothing,)	0.2538	0.0001
My father (or my mother) often buys things that he (she) doesn't need	0.1180	0.0096

^a One-tailed tests with at least 389 degrees of freedom.

watch television a day and their compulsive buying score is positive ($r = 0.1123$) and statistically significant ($p = 0.0136$; one-tailed test), which supports H_1 .

Peers. Table 3 presents the estimated correlations between the items pertaining to peer influences and compulsive buying. All correlations are positive and statistically significant, which supports H_2 . Although the tendency to compulsive-like buying behavior is positively associated with adolescents' perceived efforts to purchase distinctive products, that relationship is not strong ($r = 0.0953$).

Family. As Table 3 shows, the hypothesis of a negative relationship between compulsive buying tendencies and family discussions about consumption matters (H_3) is not supported. However, adolescents' perceptions of their parents' compulsion to buy is strongly associated with their own dispositions toward compulsive buying (H_4).

Table 4 displays results relevant to the test of H_5 which proposes a link between young consumers' tendencies to compulsive buying behavior and the presence of various problems in the family. Although compulsive buying means are consistently higher for adolescents who report such problems, the difference reaches statistical significance only in the case of divorce.

Individual. Three of the four hypotheses pertaining to individual characteristics are supported by the data. The correlation between compulsive buying tendencies and self-esteem (H_6) is, as predicted, negative ($r = -0.1270$) and highly significant ($p = 0.0058$; one-tailed test). However, adolescents who show greater dispositions to compulsive consumption are not more likely to be introverts ($r = -0.0825$; $p = 0.1031$) and H_7 is therefore rejected. The empirically-based hypothesis of an association between teen-ager's compulsion to buy and generosity (H_8) is supported, the correlation

TABLE 4
 ADOLESCENTS' COMPULSIVE BUYING TENDENCIES AND FAMILY PROBLEMS

	Compulsive Buying Means		t	p-value ^a
	Yes	No		
Alcohol problems	32.1013 (n = 79)	30.9137 (n = 313)	1.2503	0.1060
Fighting problems	31.7358 (n = 53)	31.0887 (n = 338)	0.5801	0.2311
Parents' absence	31.9455 (n = 110)	30.9100 (n = 278)	1.2157	0.1124
Divorce	32.3684 (n = 95)	30.7297 (n = 296)	1.8483	0.0327

^a One-tailed tests with at least 386 degrees of freedom.

with the item "I like to buy things to others without specific reason (gift, restaurant, ...)" being positive ($r = 0.2627$) and highly significant ($p = 0.0001$; one-tailed test). Finally, the correlation between the index of rational consumer behavior and adolescents' compulsive buying score is negative and significant ($r = -0.2897$; $p = 0.0001$; one-tailed test), which supports H_9 .

Demographics. The correlation between age and compulsive buying tendencies is negative ($r = -0.1925$) and highly significant ($p = 0.0001$; one-tailed test), as predicted by H_{10} . In order to test H_{11} , the occupation of the participants' father was transformed to a status rating using Hodges, Siegel and Rossi's (1966) index of occupational prestige. The appropriateness of this index as an estimate of the respondent's social class is questionable but no better measures were available. Still, the index appears to capture part of the social class construct since, as we expected, there is a significant mean difference between the status ratings of the fathers of public ($\bar{X} = 69.2474$) and private ($\bar{X} = 76.2733$) schools' students ($t = 6.7823$; $p = 0.0001$; two-tailed test). However, the hypothesis of higher compulsive buying scores in lower social classes has not been supported since the correlation between the occupational status index and the compulsive score is not significant ($r = -0.0612$; $p = 0.1228$; one-tailed test). Finally, in support of H_{12} , on average, girls have higher compulsive buying scores than boys (32.5667 versus 30.0670; $t = 3.2923$; d.f. = 387; $p = 0.0005$; one-tailed test).

Regression Analysis

All the results presented so far were obtained through simple bivariate analyses. In order to see if the relationships that were uncovered would hold in a multivariate context and to determine the relative

importance of the various types of influences on compulsive buying, a multiple regression analysis was conducted using the compulsive score as dependent variable and the influence measures as independent variables. The results are displayed in Table 5. In comparison with the bivariate results, there are three important changes. First, adolescents' estimates of the number of hours they watch television a day is no longer significantly related to their compulsive buying score. Second, family communication becomes now significant. That is, the more adolescents agree that they talk with their parents when they want to buy something, the less inclined to compulsive buying they are. Finally, the regression coefficient attached to the self-esteem variable is not significant, a result that is also inconsistent with the bivariate analyses.

Although they are unsatisfactory as measures of the relative contribution of the independent variables in multiple regression, the standardized regression coefficients are often used for this purpose. Table 5 shows that the largest standardized beta is that associated with peer influences. The size of this coefficient is twice that of the second largest beta weight (parents' compulsiveness). This concurs with researchers' belief that peers play a significant role in the socialization of young consumers (see Moschis 1987).

DISCUSSION

To the authors' knowledge, this study represents the first investigation of the phenomenon of compulsive buying among adolescent consumers. Conceptually, our approach has been to think of compulsive buying as a generalized urge to buy characterizing all adolescent consumers at different levels instead of an all-or-none trait attributed only to individuals affected by a totally uncontrollable

TABLE 5

and continuous craving for buying. Without denying the interest of adopting a quasi-pathological orientation to study compulsive buying behavior, we argue that our approach has much to offer to consumer research because it is driven by the belief that less excessive forms of dysfunctional consumption behavior are also important and must be studied.

The results of our study show that adolescents' compulsive buying tendencies seem to be influenced by many personal and environmental factors. Some of these results are consistent with prior compulsive buying studies involving adult consumers. Thus, higher scores on compulsive buying have been previously associated with female and younger consumers (d'Astous and Tremblay 1989). Some other results are consistent with those of studies in the area of consumer socialization. For instance, the impact of peers on compulsive buying tendencies parallels Moschis and Churchill's (1978) conclusions about these influences on adolescents' materialistic attitudes. Also, the negative relationship between age and compulsive buying is consistent with Moschis and Churchill's (1978) finding that younger adolescents are less likely to engage in socially desirable consumer behaviors. Related to the latter result is an interesting research

question: Does that imply that being a compulsive-like buyer is a stage that most adolescents pass through? Unfortunately, the cross-sectional nature of this study refrains us from providing even a partial answer to this question. Future studies using longitudinal data are needed to address the issue.

Finally, this study leads to new findings that contribute to our knowledge of the phenomenon. Thus, contrary to what Faber and O'Guinn (1988) have observed with adults, we have found that generosity is positively related to adolescents' tendency to buy compulsively. Perhaps, as some argue (see e.g. d'Astous and Bellemare 1989), compulsive buyers are generally motivated to improve their social image. For adolescents, sharing may be perceived as an appropriate means to achieve this objective. Other results of interest pertain to family influences. The positive relationship between parents' and adolescents' buyingmania for instance is intriguing. One possible explanation might be that there are modeling effects occurring. However, as noted by Faber, O'Guinn and Krych (1987), biological causes have been identified for compulsive behaviors, hence genetic inheritance is also a plausible alternative explanation. In addition, the study has brought some empirical evidence for the impact of

family problems on teen-agers' compulsive buying dispositions. Though not all family problems that were examined have a statistically significant influence, overall the pattern of results is consistent with the idea that conflicts, troubles or disorders within the family unit are potential explanatory factors for adolescents' compulsive consumption tendencies.

CONCLUSION

This study is an addition to the growing body of research on compulsive consumption. To this day, that phenomenon had not been studied with young consumers. We have shown that, while there are clear similarities between our results and those of other studies conducted with adult consumers (e.g. self-esteem), compulsive buying behavior among adolescents appears to have its own particularities (e.g. generosity). We have looked at some of the differences and tried to identify the important sources of influence. There remain many other research questions in this area and we hope that this study will stimulate some further research.

Risk-Taking Behavior: Protecting Consumers From Themselves

Jef I. Richards, University of Texas at Austin

ABSTRACT

No social system is equipped to expend unlimited resources on protecting its members. Each system must establish some level of individual self-responsibility to be required of its constituents, beyond which no systemic protection will be afforded. This paper argues that the current Federal Trade Commission deceptive advertising standard demands a level of self-responsibility analogous to that of the tort law of negligence. Then, drawing upon that analogy, it is argued that consumers' beliefs and confidence in their beliefs about a product's attributes can be applied as a screening device, to aid in determining whether a claim *should* be regulated.

INTRODUCTION

The Federal Trade Commission (FTC), even at its apex of regulatory activity, has always operated on a budget that forced its staff to be extremely selective in choosing which advertising claims it would prosecute. For example, in 1970 Eckhardt recognized:

The Federal Trade Commission currently receives about 9,000 complaints a year. It is able to investigate only one out of eight or nine of those, and of the small fraction investigated only one in ten results in a cease and desist order. (Eckhardt 1970, p. 670)

Although precise figures are unavailable, it is likely that in the recent atmosphere of deregulation (Preston and Richards 1986, p. 613-15) those percentages currently are far smaller. The simple reality is that this agency has very limited resources, and its staff must marshal those resources, arguably, to serve the best interests of the public-at-large. An ad, e.g., that deceives only the most careless consumers cannot justifiably burden those resources so long as other, more egregious, deceptive ads remain unregulated.

A few techniques have been proffered by researchers for "screening" ads or whole classes of ads to help with this resource allocation, by evaluating whether the FTC should dedicate greater attention to these ads. Most notable of these is Gardner (1975), who proposed three separate screening devices: the Normative Belief Technique, the Consumer Impression Technique, and the Expectation Screening Procedure. Each of these is designed to identify ads or types of ads which *may* be deceptive, so the FTC can concentrate its efforts on ads with the highest probability of deceptiveness rather than potentially wasting resources on ads with lower probabilities of legal violation (Gardner 1976).

Several other authors have developed typologies of deceptive ad claims (Preston 1989; Rosch 1975; Aaker 1974; Armstrong and McLennon

1973), and Grunert and Dedler (1985) developed a method for building such a typology. Typologies offer the possibility of identifying certain commonalities in deceptive claims, enabling the FTC to target types of claims with greater probability of deceptiveness.

The method suggested below takes a different approach, intended to augment rather than supplant those techniques. After an ad is identified as having a high probability of deceptiveness, this method is designed to assess whether the risk to the consumer, resulting from the potential deceptiveness, is one the consumer is willing to assume. If consumers are willing to accept the risk of loss, I suggest, there is no need to allocate further FTC resources to adjudicating the claim. In the present political atmosphere regulatory resources are much too scarce to engage in such paternalism, no matter how socially advantageous it may be.

THE NEGLIGENCE ANALOGY

Prior to creation of the FTC (FTC Act of 1914), laws regulating selling claims closely paralleled the tort law of negligence. Both bodies of law reflected changing societal views toward the individual's role in a free-market political and economic system.

Until the 1800s English and American common law affecting selling claims tightly embraced the concept of *caveat emptor*, providing consumers little or no protection from inaccurate sales promises. During the 1800s, however, significant inroads were made toward greater consumer protection (Preston 1975).

In like fashion, the concept of negligence, as an independent ground for legal liability, first began to take shape in the eighteenth and early nineteenth centuries (Baker 1979, Ch. 19). This new legal action held parties responsible for damages or injuries caused by their carelessness (James 1951). And like the laws concerning selling claims, the doctrine of negligence flourished in the 1800s as a response, in large part, to societal and judicial concerns for victims' welfare, during the rise of business enterprise through the industrial revolution (Schwartz 1981).

Both bodies of law were directly affected by economic developments of the time and concurrent reinterpretations of classical liberal political and economic philosophies regarding individual freedom of action, which were slowly recognizing the benefit of some governmental intervention as a means of promoting consumer sovereignty (Swagler 1975, Chap. 8). There came a recognized advantage to shifting some of the burden for individual welfare, from victim to purveyor, as economic power became concentrated in business entities. Within the marketplace, this meant the growth of "consumerism" (Preston 1975).

As the FTC's influence took hold in the 1900s, these two areas of law diverged from their parallel course. Under the FTC Act (1914), and later the Wheeler-Lea Amendment (1938), the Commission's authority to regulate industry was immense (Welti 1983). The eventual consequence of this vast authority was that individual protections from advertising claims far outpaced individual protections under negligence law. Where negligence standards required only that parties act *reasonably* to avoid injury to others (James 1951), the FTC held sellers responsible for the mere capacity to mislead even the "foolish or feeble-minded" (Heinz W. Kirchner 1963). Unlike negligence, advertising law permitted consumers to take virtually no responsibility for their own transactions in the marketplace, resulting in a new maxim of "caveat venditor" (Rotzoll, Haefner, and Sandage 1986, p. 123).

THE COMMISSION UNDER REAGAN

The deregulatory philosophy that characterized the Reagan administration was clearly manifest in the FTC's approach to advertising deception during the 1980s. The Commission, apparently attempting to implement administration policy, took this opportunity to completely re-define its deceptiveness standard, shifting part of the responsibility back onto consumers. Where the former standard protected essentially all consumers, even the "foolish and feeble-minded," the new standard protects only consumers acting "reasonably under the circumstances" (Cliffdale 1984). Once again we can see a parallel to negligence, which is defined as a failure to do what the reasonable person would do under the same or similar circumstances (Restatement of Torts 1986, section 283).

The analogy is not yet complete, however. Where negligence holds parties responsible when *they* act unreasonably, the FTC holds sellers responsible unless *buyers* act unreasonably. The latter is more like the standard for a legal "defense." A closer parallel, therefore, arises between the FTC standard and a defense to negligence known as "contributory negligence." With this defense a negligent defendant is liable unless the *plaintiff* was also negligent, i.e., failed to act reasonably under the circumstances (Restatement of Torts 1986, section 464). The current deceptiveness standard, consequently, is analogous to the contributory negligence defense because both require the "victims" to act reasonably, placing on those victims part of the responsibility for resulting injuries. The philosophy behind both the new deceptiveness standard and contributory negligence is that individuals should take some responsibility for themselves before the law will intercede.

ASSUMPTION OF RISK

Drawing upon that philosophy of requiring individual self-responsibility, it is an easy matter to further extend the analogy between advertising regulation and negligence. There is another defense to negligence, conceptually similar to contributory

negligence (James 1952), known as "assumption of risk." In simple terms, this defense states that when faced with a known risk a person may voluntarily proceed in a course of action, and by doing so assume the consequences of that risk, thereby releasing the creator of that risk from any potential liability. The keys to this defense are that 1) the risk must be known and understood, and 2) the party must accept that risk voluntarily (James 1952). If, for instance, you know your friend has had too many drinks, yet agree to let him drive you home, you may be said to have assumed the risk of being involved in an accident. You could be barred from suing your friend for injuries you receive. This principle is often stated by the legal maxim "volenti non fit injuria," which roughly translates as, "that to which a person assents is not esteemed in law an injury" (Edwards v. Kirk 1939).

Again, the emphasis is on requiring individuals to assume some self-responsibility. James reveals insight that supports the analogy proposed here, with the following remark about assumption of risk:

It will be apparent at once that the whole spirit of the defense and of the reasoning it employs, bears the strong imprint of *laissez faire* and its concomitant philosophy of individualism which has passed its prime. For the most part it is a product of the same climate of opinion that gave vitality, for example, to *caveat emptor* (James 1952)

I should note, however, that it is not my purpose here to pass judgment on the wisdom of current FTC policies, but merely to show that the risk assumption concept is compatible with those policies.

Applying this concept to advertising regulation, it is arguable the FTC should not expend its limited resources to protect consumers who know they may be deceived yet voluntarily purchase a product in spite of that risk. This comports with the negligence-like approach presently adopted by the FTC, as well as the philosophy of individual self-responsibility underpinning that approach. The practical difficulty, however, is identifying which claims present a risk that consumers are willing to assume.

IDENTIFYING ASSUMED-RISK CLAIMS

Negligence law offers some guidance in this determination. As mentioned earlier, the elements of assumed risk are *knowledge* and *voluntary assumption*. If we find that consumers have knowledge of the potential risk, we can safely assume any subsequent purchase of the product is voluntary, since purchase is rarely forced upon a consumer. One might argue this is controverted in the case of addictive products, but where there is addiction the consumer is intimately familiar with the product, making deception a virtual impossibility. To identify claims where risk is

voluntarily assumed, therefore, only requires evidence that the risk is known. This knowledge can be inferred by measuring both consumer beliefs about product attributes and the confidence with which they hold those beliefs.

Deceptive claims cause false beliefs.

However, there is a qualitative difference between a claim which causes consumers to hold false beliefs with confidence that they are true and one which causes uncertainty or suspicion. Where suspicion exists, consumers are aware there is an element of risk involved in purchasing the advertised product. A *reasonable* consumer faced with such suspicion will either seek out additional sources of information to confirm/disconfirm those beliefs, or will assume the risk that the belief is false (irrespective of individual factors such as category expertise or brand loyalty). Where the potential loss is substantial they might be expected to seek other information, but where the product cost is small it might be quite reasonable to assume the risk of loss. This, essentially, is the premise of the common distinction between high and low product involvement (Smith and Swinyard 1982).

Consequently, knowledge of risk can be inferred where consumers hold false beliefs but have relatively little confidence in those beliefs. By screening ad claims for resultant beliefs and belief confidence, it should be possible for the FTC to avoid prosecuting claims where consumers are willing to assume the risks.

This argument, however, is pointless if consumers never hold low levels of confidence in their beliefs, or if the FTC never prosecutes such claims. Consequently, a simple study was conducted to determine whether there are significant differences in belief confidence for claims found deceptive by the FTC. Additionally, the method used in the study is offered as an operational example of how confidence-based screening might be achieved.

METHOD

Subjects

90 undergraduate students were recruited from introductory advertising classes. Prior to participation in the study, subjects were screened to ensure they had normal or corrected-to-normal vision at typical reading distances. Because these students were in their first advertising class, and had not yet discussed regulation, there was no reason to expect their course of study to unduly bias the experiment.

Stimuli

The purpose of this study was to determine whether claims actually found deceptive by the FTC varied significantly in the confidence with which consumers held their false beliefs. A search was conducted to identify all FTC cases, in a 10-year period from 1977 to mid-1986, which ended in a Commission finding of deceptiveness. Of 23 cases identified, six were chosen that involved print ads and provided sufficient information to locate or reproduce the challenged advertisements. Those

cases were Sterling Drug (1983), Sears (1980), Kroger (1981), Thompson Medical (1984), Litton (1981), and Cliffdale (1984). Copies of the actual ads challenged by the FTC were found for two of the cases, and the remaining four were reconstructed with a computer, to as nearly resemble the original ads as possible. Each ad was used in its entirety, rather than reproducing only a single claim, because it is the impression created by the ad as a whole that is important under the law (Thompson Medical 1984, p. 790).

Questionnaires

A one page questionnaire was prepared for each ad. The cases varied in the number of claims found deceptive by the Commission, and a few claims were not tested because of their similarity to other claims being tested or because of legal technicalities involved in finding them deceptive. Consequently, the number of deceptive claims tested varied from one to four per case, for a total of 14 claims (Figure 1). To mask the purpose of the study, nondeceptive claims from each ad were also tested on the questionnaires.

Claims were evaluated on separate 13-point scales that tested first the *belief* that the claimed attribute was associated with the product or service, then the subject's *confidence* in that belief. The "materiality" (Cliffdale 1984) of each claim was also tested, but is not of concern to the present discussion.

The belief scale for each claim stated the alleged falsity on one end, and the truth about the concerned attribute at the other end. For each, subjects were asked what they believed to be true about the product. An example is depicted in Figure 2. The truth-falsity polarity of the scales was randomly assigned, to avoid demand effects.

The confidence scale immediately followed, and simply asked subjects, "How confident are you?" Their response was marked on a scale ranging from "Very Unconfident" to "Very Confident" (Figure 3).

Procedure

A total of 30 subjects participated in each of three treatment groups. In each group subjects viewed both advertisements and memoranda about ten different products/services, including two of the six advertisements which are subject of the present investigation. Each condition, therefore, saw ads for only two of the products involved in this study. Presentation sequence was randomized, so that each condition saw the ads of interest at different times during the experiment, to avoid order effects.

Subjects were each given a questionnaire booklet, consisting of a cover-sheet with instructions, followed by stimuli and questionnaires. Subjects were instructed to turn each page of the booklet only upon direction of the experimenter. They would view a stimulus on one page of the booklet, and after all in the group had completed viewing it to their satisfaction, they were permitted to turn the page and answer the corresponding

questionnaire. This was repeated until all stimuli had been viewed and evaluated

Results

The mean evaluation of each claim, for both belief and confidence, is shown in Table 1. It should be noted that this was a between-subjects design, intended only to measure the difference in belief confidence among the 14 claims. Analysis of Variance was used to test the differences between confidence levels for the claims. The difference was found to be significant ($F(13,406) = 3.215, p < 0.01$).

Mean belief for 11 of the claims (78.6%) scored above 7.0, the scale centerpoint, placing them toward the scale end labelled with the false claim. The remaining 3 claims (21.4%) fell toward the end labelled with the truth about the product attribute. Mean confidence scores for 12 claims (85.7%) fell on the "confident" side of the scale, and two (14.3%) fell on the "unconfident" side.

DISCUSSION

The results suggest not only that there is a significant difference in the confidence with which consumers hold beliefs about advertising claims, but that this difference holds true of even those claims found deceptive by the FTC. From this it is apparent that for some claims being regulated in the public interest consumers are significantly more suspicious of their own beliefs, than for other claims demanding regulatory resources. By extension we can infer that consumers are relatively more willing to assume the risk of loss in those instances, if they proceed to purchase the products in spite of those suspicions without seeking further information.

Mean confidence scores varied from 5.93 to 10.20, representing a continuum within which

consumers appear to have varying levels of suspicion about the reliability of their beliefs. From a policy standpoint, the difficulty is applying this information to determining which claims merit regulation and which do not. There is no natural dividing line, where we can confidently conclude consumers on one side will voluntarily assume the risk of loss while those on the other side will not.

It would be possible, of course, to rank-order confidence scores, and to devote regulatory attention to ad claims in order of their scores, starting with the highest score. This, however, would be unsatisfactory because the levels of belief also vary, with some claims conveying greater falsity than others. It is certainly arguable that claims conveying the greatest falsity deserve high priority by regulators.

It would also be possible to rank-order priority of the claims based on a combination of belief and confidence scores. This would account for both degree of falsity conveyed and degree of suspicion held by consumers. This approach, too, is imperfect, because it assumes the belief measure used is an accurate assessment of the claim's deceptiveness, contrary to the criticisms made by Richards (1990) of various deceptiveness measures. This belief measure is no more than a rough indicator of deceptiveness, inasmuch as this procedure was designed as a simple screening procedure and not to determine a claim's deceptiveness. It is not intended to identify which claims deserve first attention by regulators, but rather to eliminate a few claims before undue expense is incurred.

I propose, therefore, that the centerpoint of the scale be used as a cut-off point for confidence. Where a mean evaluation falls below 7.0 on the present scale, subjects on average are indicating they are "unconfident" in their beliefs, suggesting

TABLE 1

Case	Claim	\bar{X} Belief	\bar{X} Confidence
1. Cliffdale	a	11.20	5.93
	b	9.23	6.57
	c	9.93	7.93
	d	9.20	9.17
2. Litton	a	10.13	9.23

6. Thompson	a	6.83	7.30
	b	5.80	7.83
	c	10.60	10.00

that most are suspicious that their knowledge may be in error.

Though the belief measure is not a wholly accurate indicator of deceptiveness, it is arguable this is a rough indicator, not unlike Gardner's (1975, 1976) methods, which could also be used to eliminate claims with low probability of being deceptive. Where the average subject evaluates the product to fall toward the true end of the scale, the majority of them are unlikely to be deceived. And, while the claim *might* actually prove deceptive with a more rigorous test, the low probability serves as some indicator that the FTC may be wasting its money to pursue the claim further. In fact, the belief measure used here is quite similar to empirical measures frequently used by the FTC to actually determine deceptiveness, except that the typical dependent variable used in regulation is *comprehension* rather than *belief* (see discussion in Richards 1990). Arguably, belief is the superior indicator of deceptiveness (Richards 1990).

The mean evaluation for each claim used in this study is plotted in Figure 4. If the FTC staff were to adopt this simple test, using the mid-point of both scales to screen out claims unworthy of the agency's financial resources, only those claims falling in the upper right quadrant of this figure would qualify for further expenditures. Thus, 5 of the 14 claims would be excluded from consideration. Where other claims for the same product fall within the upper right quadrant there would probably be little or no savings by excluding those claims falling outside, but where the challenged claims all fall outside, substantial savings could be realized by not pursuing that case.

SUMMARY

The policy foundation for the law of negligence is functionally equivalent to that on which the present FTC deceptiveness standard is

erected. While legal decisions regarding negligence span nearly two centuries, the recent re-definition of deceptiveness raises significant questions about the utility of many decisions in the FTC's 75 year history. It is reasonable, therefore, to look to the law of negligence for help interpreting the new deceptiveness standard.

Many critics of present FTC policies may disagree with the idea of implementing a screening method which screens out not only nondeceptive claims (ala Gardner), but deceptive ones. Unfortunately, where congressional funding for the agency is insufficient to prosecute all deceptive claims, some form of regulatory triage is inevitable, with the *only* question being how it will be achieved. While the elimination process could be done on an ad hoc basis, or based on factors like the political visibility of certain advertising practices, an approach premised on theory promises much greater equity. The method presented above is such a theory-based approach.

This procedure is a simple one, because the objective was to save money, not to find new ways to spend it. It requires a very small number of subjects, though ideally they should be chosen randomly from the target market, and it takes only a few moments per ad. Because it is simple, however, it is a less-than-perfect screening tool. It would be possible to unintentionally screen out a claim that deserves regulatory attention. But, this approach is likely superior to one with no theoretical focus, and might be further improved by scholars with expertise in consumer decision-making.

Conceptualizing Argument Quality via Argument Structure

Gregory W. Boller, Memphis State University

John L. Swasy, American University

James M. Munch, University of Delaware¹

ABSTRACT

This paper discusses the construct of argument quality. It discusses the Areni and Lutz (1988) approach of using a Fishbein model of belief strength and belief valence as dimensions of the argument quality construct. This paper argues for a more specific use of the term argument, and reviews the Toulmin (1958) model of argument structure. We suggest that Toulmin's concepts of evidence, authority, and probability are important structural elements that need to be considered to better understand the concept of argument quality. Also, implications for conceptualizing argument elaboration in terms of the Toulmin structure are noted.

INTRODUCTION

The concept of argument quality is important although it has not been the direct focus of much interest by consumer researchers. Perhaps this is because the simple issue of whether strong messages are more persuasive than weak is not interesting. Nevertheless, argument quality plays an important role in research involving the Elaboration Likelihood Model (see Petty and Cacioppo 1986 for a description and review of ELM). Operationally, "argument quality" provides a reference point for assessing how other communication factors affect persuasion. For example, the persuasive effects of rhetorical questions have been inferred from the fact that in low involvement conditions, rhetorical questions enhance differences in the persuasiveness of strong and weak message versions. Under low involvement conditions, rhetorical questions encourage receivers to diligently consider the true merits of the message arguments (Petty, Cacioppo and Heesacker 1981). Integration of the logic and compellingness of the message along with activated and generated beliefs underlie acceptance of the message conclusion.

However, Areni and Lutz (1988) point out that many researchers have not been clear or consistent regarding the conceptual meaning of argument quality. Definitions of argument quality typically rely on ideosyncratic manipulations of message content that ultimately affect message valence. For example, Hunt, Smith and Kernan (1984) manipulated argument quality by defining strong arguments as statements of tangible product features and weak arguments as statements of intangible features.

The thrust of the Areni and Lutz (1988) paper centered on showing that the argument strength

manipulation employed in the often cited Petty, Cacioppo and Schuman (1983) study was confounded with manipulations of the desirability of product attributes/benefits used in the message. The weak message focused on less desirable attributes/benefits (e.g., "floats in water," and "designed for the bathroom") whereas strong messages involved more desirable product features/benefits (e.g., "blade sharpness," and "smooth shave"). In terms of the Fishbein and Ajzen (1975) model of belief structure, the valence (e_i) of the attributes/benefits presented in the strong message was more positive than that of the weak. It is clear that the distinguishing difference between the strong and weak messages was not simply their logical compellingness.

The results of the Areni and Lutz (1988) study suggest that the conceptual meaning of argument quality mostly rests in the argumentative structure contained in the persuasive message. The purpose of this paper is to continue Areni and Lutz's discussion of the argument quality construct by (1) extending their conceptualization of argument structure, and (2) considering the potential relationship between argument structure and argument elaboration.

DEFINING ARGUMENT QUALITY IN TERMS OF ARGUMENT STRUCTURE

Following the Fishbein and Ajzen perspective, Areni and Lutz (1988, p. 198) define a persuasive message as "a set of arguments concerning beliefs that link the object with positive and negative consequences and evidence in support of those arguments." They go on to say,

Of particular importance in the present situation is that each target belief has associated with it a belief strength (b_i) and a valence (e_i). That leads to the characterization of argument quality as comprised of two separate components, argument strength and argument valence. Argument strength is defined as the audience's subjective probability that the attitude object is associated with some outcome or consequence.

In their view, argument strength is defined in terms of a syllogism (McGuire 1960) created by the supporting beliefs (beliefs formed by the presentation of evidence). Areni and Lutz (1988, p. 199) write,

...Argument strength may be defined in terms of the likelihood that the conclusion of a logical syllogism is accepted. If the

¹Authors acknowledge support from the Avron B. and Robert F. Fogelman Academic Excellence Fund.

conclusion is ascribed the role of target belief in Fishbein and Ajzen's model, then Fishbein and Ajzen's support beliefs can be viewed as the premises in a syllogistic structure underlying the target belief.

In principle, we agree that the conceptual meaning of argument quality primarily resides in the structure of the argument. And in general, the syllogism provides a good starting point for examining the essence of argument structure. However, we believe that the usefulness of the syllogistic model is limited. Specifically, the syllogistic model does not provide clear distinctions between various components of a message, cannot adequately represent the complex structures found in most marketing messages, and does not provide much direction for examining potential relationships between argument structure and argument elaboration.

As an alternative, we present a different conceptualization of argument structure that overcomes the limitations associated with the syllogistic model. And as an introduction to this model, we find it instructive to first consider the intended function of argument.

The Intended Function of Argument

Willard (1979; 1981) writes that the function of argument is to provide reasons for the assertion of particular claims, positions or beliefs. Kneupper (1979) and Burleson (1979) maintain that the function of argument is to establish a relationship between an asserted claim and its supporting reasons or evidence. In other words, argument serves to support the assertion of a particular claim.

In terminology more appropriate for marketing applications, Brockriede (1975) writes that the function of argument is to provide rationale for a leap from existing beliefs to the adoption of new ones. That is, arguments give people objective and rational reasons to create a particular set of beliefs.

According to Burleson (1979), arguers first "lay claim" on existing beliefs of those toward whom the argument is directed. That is, arguers make assertions of the nature, "here is something you don't know," or "here is something that is contrary to what you already know." Next, arguers attempt to validate these asserted claims by providing a carefully structured presentation of assertions in support of those claims (Toulmin 1958; Toulmin, Reike and Janik 1984). Generally speaking then, arguments are linguistic procedures which are intended to establish the validity of an asserted claim through the presentation of a highly structured set of reasons in support of that claim.

It is important to recognize that arguments are not simple claim assertions (e.g., Petty, et al. 1983), nor are arguments statements of evidence. An argument is a type of message presentation in which one class of assertions are used *with intent to support* assertions of another class. Certain assertions are ascribed the status of "evidence"

when, and only when, they are used to support other assertions of a more general nature. Assertions which require logical support in order to be believed are ascribed the status of "claims." Specifically then, argument can ultimately be both defined and revealed by the logical relationships amongst message assertions (i.e., structure).

The Toulmin Model of Argument Structure

Instead of describing argument structure in terms of the syllogistic model (e.g., Areni and Lutz 1988; McGuire 1960), we use Toulmin's (1958) jurisprudence model. This model of argument structure is widely accepted by many argument theorists and forensic specialists, relatively simple to understand, and very applicable to marketing contexts (see Deighton 1985). Moreover, the Toulmin model offers a distinct advantage over syllogistic models of structure in that it allows one to examine the specific *types* of assertions used in an argumentative message.

Toulmin (1958) and Toulmin, Reike and Janik (1984) state that there are six crucial elements in an argument--claim assertions, grounds, warrants, backing, qualifiers, and rebuttals. For ease of discussion, we collapse these six elements into four components--*claim assertions, evidence (grounds), authority (warrants and backing), and probability (qualifiers and rebuttals).*

Claim Assertions. Perhaps the best way to understand the Toulmin model, is to work through an example. Assume that we wish to construct an argument to support the claim, "Eating Kellogg's All Bran cereal may reduce your risk of rectal cancer." This claim is an assertion about benefits of this brand that we put forth for public acceptance. Specifically, we want our target audience to *believe* this benefit claim. But suppose we simply made this assertion, and then left it at that? Although some people might believe this claim, most probably would not.

To support and validate our claim, we need to construct an argument. We need to offer *reasons why* people should believe that eating Kellogg's All Bran cereal may reduce their risk of rectal cancer. Specifically, we need to logically present evidence in support of our claim.

Evidence (grounds). In the Toulmin model, grounds are the specific facts that a communicator produces to support a claim. Stated differently, grounds are pieces of evidence which a communicator relies upon to "clarify and make good" an asserted claim (Reinard 1984). In advertisements, we often find that brand benefit claims are supported by statements about product characteristics (e.g., product attributes).

To keep our example simple, consider only one piece of evidence. For the grounding, we state that, "All Bran is made of 100% natural fiber." Thus, our argument reads: "Eating Kellogg's All Bran cereal may reduce your risk of rectal cancer because All Bran is made of 100% natural fiber."

However, this one piece of evidence may not be sufficient to validate our asserted claim. Some

people reading our argument might ask, "What does natural fiber have to do with rectal cancer?" In argument theory terms, they are asking, "On what authority are you presenting this particular piece of evidence as support for your claim?" Now we need a warrant.

Authority (warrants and backing). Warrants are statements which serve as the "rational authority" needed to logically connect the evidence with the asserted claim (Toulmin, Reike and Janik 1984). They are statements which serve as the "justification...employed by a communicator to demonstrate that the claim legitimately can be inferred from the grounds" (Reinard 1984, p. 207).

Warrants are not intended to strengthen the grounds. That is, they are not meant to change a receiver's belief that the evidence is indeed factual. Instead, they are designed to show that using particular evidence to support a specific claim is appropriate and legitimate (Toulmin 1958). In essence, warrants *specify a particular domain* of evidence that can be legitimately used to support a claim. In order for a claim to be judged as valid, the evidence presented as support must be viewed as legitimate evidence. Or, in jurisprudence terms, the evidence presented in support of a claim must be "admissible evidence."

Returning to our example, we use the following statement as our warrant. "Diets rich in fiber can help reduce the risk of rectal cancer." Logically now, our argument reads: "Diets rich in fiber can help reduce the risk of rectal cancer. Eating Kellogg's All-Bran cereal may reduce your risk of rectal cancer because All-Bran is made of 100% natural fiber." Alternatively, we might order the argument, "All-Bran is made of 100% natural fiber, and since diets rich in fiber can help reduce the risk of rectal cancer, eating Kellogg's All-Bran cereal may reduce your risk of rectal cancer."

Now, is the argument strong enough to establish the validity of our claim? Someone reading our argument could ask, "How do we know that diets rich in fiber can help reduce the risk of rectal cancer?" That is, some people may perceive our warrant to be a relatively weak "rational authority." So, to further strengthen our warrant, and consequently enhance the validity of our claim, we can provide factual evidence called *backing* that *supports the warrant*. For instance, we might use the statement: "Medical studies have proven that people who eat fiber rich foods are 60% less likely to develop rectal cancer than those people who don't."

Now, our more complex argument reads: "Medical studies have proven that people who eat fiber rich foods are 60% less likely to develop rectal cancer than those people who don't. And since diets rich in fiber can help reduce the risk of rectal cancer, eating Kellogg's All-Bran cereal may reduce your risk of rectal cancer because All-Bran is made of 100% natural fiber."

Our argument regarding the Kellogg's All-Bran claim is nearly complete at this point. We have provided reasonably strong support to

establish the validity of our claim. But there still may be some people who do not accept our claim. These people might recognize circumstances that would render our claim invalid. If we do not acknowledge, at least in part, the existence of these circumstances, some people may reject our claim because they perceive us to be untruthful by reason of omission.

Probability (qualifiers and rebuttals). The probability component of argument is not necessary to validate a claim. This component is used by communicators when they want to acknowledge that their claim assertions are not "absolute" (cf. Burleson 1979; Habermas 1979; Jaccard 1981). In essence, this third component allows a communicator to tell an audience that he/she is being "truthful." And given that most consumers view advertising as extremely partisan, the use of qualifiers and rebuttals is often recommended to enhance credibility (cf. Deighton 1985).

You may have noticed the qualification we included in the latest version of our claim. We asserted that "eating Kellogg's All-Bran cereal *may* reduce your risk of rectal cancer." By using words such as "may" and "probably," we communicate the existence of circumstances that will render our claim invalid. We could take an additional step by providing the audience with one or more of these particular circumstances. That is, we could provide a rebuttal. For instance, we might say, "Genetic tendencies, however, sometimes outweigh factors such as diet." With respect to advertisements, rebuttals are generally included at the end of the ad, or in a nonprominent place as in a footnote.

Our completed argument can now be read as follows: "Medical studies have proven that people who eat fiber rich foods are 60% less likely to develop rectal cancer than those people who don't. And since diets rich in fiber can help reduce the risk of rectal cancer, eating Kellogg's All-Bran cereal may reduce your risk of rectal cancer because All-Bran is made of 100% natural fiber. Genetic tendencies, however, sometimes outweigh factors such as diet."

To recap our example, we first asserted a claim, "Eating Kellogg's All Bran cereal may reduce your risk of rectal cancer." Recognizing that many people would not believe this claim, as it stands, we constructed an argument to support our assertion. We used evidence (one specific grounding), authority (a warrant with backing), and probability (a qualifier and a rebuttal). We used these three components of argument to support and validate our brand benefit claim.

Building arguments according to the guidelines of the Toulmin model is a relatively easy task. In fact, the model might well be used by advertising copywriters as a tool for constructing argumentative ads. However, the Toulmin model is also useful as a diagnostic device. In particular, this model of argument structure can be used to examine the nature of strong versus weak manipulations of "argument quality."

REEXAMINING MANIPULATIONS OF ARGUMENT QUALITY

Areni and Lutz (1988) convincingly argue that many manipulations of argument quality are really manipulations of claim valence. That is, many researchers who purport to manipulate argument quality actually end up manipulating the inherent desirability of brand benefit claims. For example, Petty et al. (1983) used claim assertions such as "unsurpassed sharpness" and "eliminates nicks and cuts" for their "strong arguments." In contrast, they used assertions such as "floats in water" and "designed with the bathroom in mind" for their "weak arguments." Interested viewers will most likely see these latter assertions as weak since they are not usually sought-after benefits of razors. Areni and Lutz point out that while valence manipulations produce interesting effects, manipulations of argumentative logic (i.e., structure, in our framework) are more useful within the pragmatic contexts of marketing communications. As such, Areni and Lutz present possible manipulations of argument strength, while holding claim valence both constant and positive. Their argument versions can be seen in Figures 1 and 2.

It is important to note that while Areni and Lutz primarily define argument quality in terms of the subjective probability receivers attach to a target belief, recognize that this probability is really an *outcome* of processing a particular argumentative structure. Using the Toulmin model allows us to examine the particular argumentative structures created by Areni and Lutz. The structural analysis of the arguments used to support the "unsurpassed sharpness" brand claim is pictured in Figure 1. The structural analysis of the arguments used to support the brand claims "prevents rusting" and "eliminates nicks and cuts" is pictured in Figure 2.

Diagramming these arguments with the Toulmin model reveals some interesting observations about the nature of strong versus weak arguments, as formulated by Areni and Lutz. First, Areni and Lutz used "authority assertions" to legitimize the relationship between the primary claims and the evidence, and changed the specificity of these assertions as one method of manipulating argument strength. Second, Areni and Lutz introduced additional evidence in support of their primary claims, and changed the valence of this additional evidence as a second way to manipulate argument strength. These will be explained in more detail below.

Manipulating Authority

Turning first to Figure 1, we find that the "advanced honing method"-to-"unsurpassed sharpness" relationship is authorized by several assertions. In the strong version (Panel A), the assertion "...honed more cleanly and smoothly..." serves as a warrant, while the assertion "...recent scientific breakthrough" serves as backing for the warrant. In other words, a description regarding the nature and the effects of the honing method serves to make the "advanced honing method" assertion

stand as compelling evidence in support of a sharpness claim.

Turning to the weak version (Panel B), we find that Areni and Lutz changed their authority assertions. Specifically, the assertion "...better than the others" now serves as the warrant, while the assertion "new production process..." now serves as backing for the warrant. In essence, Areni and Lutz manipulated the specificity of their "authority assertions." In the first case, their warrant and backing were detailed, and specifically related to the concept "honing method." In the latter case, the warrant and backing were vague, general and not clearly related with the concept "honing method." Examining the structural diagrams in Figure 2, the reader should note that a similar situation exists with the second set of strong and weak arguments. There is one exception however. The weak argument diagrammed in Figure 2 possesses a warrant without backing.

In general, Areni and Lutz's manipulation of "authority assertions" is consistent with Toulmin's (1958) ideas regarding argument strength. By manipulating warrants within the argument, Areni and Lutz have effectively altered the structural logic (i.e., the logical relationship between the evidence and the claim).

Manipulating Evidence

In addition to manipulating the specificity of authority assertions, Areni and Lutz also manipulated the nature of evidence offered in support of their primary claims. In Figure 1, note that Areni and Lutz introduced a second set of evidence which consists of assertions regarding Edge's sharpness in comparison to other razors, as rated by two prominent athletes. In the strong version (Panel A), the athletes rated Edge superior to Schick, Personna, Bic and Gillette. In the weak version (Panel B), the athletes rated Edge superior only to Personna. Examining the structural diagrams in Figure 2, the reader should again note that a similar situation exists with the second set of strong and weak arguments.

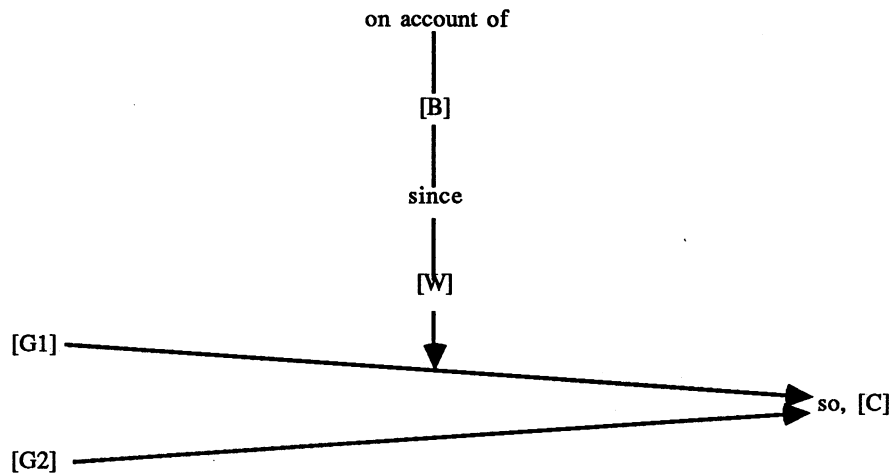

The Areni and Lutz manipulation of evidence is essentially the same type of argument strength manipulation used by Petty et al. (1983). That is, instead of manipulating claim valence, Areni and Lutz manipulate evidence valence. Because Areni and Lutz did not provide warranting assertions for the second evidence-to-primary claim relationship, their manipulation reduces to a "*positive*" versus a "*less positive* statement of fact about the brand."

Summary Contention

Based upon our structural analysis of the Areni and Lutz arguments, we offer this summary thought: Perhaps argument quality is a term better used to describe the structural integrity of an argumentative message. With this conceptualization, we can now distinguish between the outcome of argument processing (e.g., strength) from the characteristics of the argument. Defining argument quality in terms of structural integrity

allows us to avoid circular confusions such as "strength-as-believable" and "quality-as-valence." That is, we can avoid tautological definitions such as "strong arguments are anything that elicit a positive response." But more importantly, defining argument quality in terms of structural integrity forces us to consider the necessary relationships between argument structure and argument elaboration.

IMPLICATIONS FOR UNDERSTANDING ARGUMENT ELABORATION

To date, the most influential approach to understanding argument elaboration is the Elaboration Likelihood Model (Petty and Cacioppo 1981). ELM distinguishes between central and peripheral routes to attitude change. The critical feature defining the two routes is that central processing is inferred when attitude change appears to be based upon the receivers' diligent consideration of information he/she feels is central to the true merits of the message. By examining argument elaboration within the framework of argument structure, the meaning of central versus peripheral becomes clearer. For example, Bitner and Obermiller (1985) explain that when a message does not provide central cues, or the highly motivated individual does not have experience, he or she may elaborate in a "central" manner cues that would otherwise be peripheral. While there is little research describing the "central" processing of peripheral cues, Bitner and Obermiller may be suggesting that the receiver extracts his or her own "evidence" to support asserted claims (cf. Kardes 1988). As such, understanding the nature ("central" versus "peripheral") of message processing may be a matter of first describing the argumentative structure provided for the receiver, and then, that generated by the receiver.

Given the examples discussed in this paper, it is evident that structural manipulations of argument quality can take many possible forms. And a critical question that should be asked is, "Which component parts of an argument structure manipulation will influence the nature of receivers' elaboration?" It is important that any changes in structure be fully understood in terms of their relationship to elaboration measures of interest. For example, Eagly (1974) criticizes the use of broad recall indexes as measures of persuasion (i.e., elaboration) because they do not reflect what aspects of the message are actually encoded and elaborated upon. Thus if a researcher, for example, uses evidence (or lack thereof) to manipulate argument quality, then measures of evidence recalled may be more indicative of "central" argument elaboration than a more general measure of number of claims recalled (see Munch and Swasy 1988).

It is important to recognize that viewers exposed to argumentative messages must, themselves, construct a representation of the argumentative structure (Brockriede 1975, Hample

1980; 1981). That is, they must identify the evidence-via-authority and probability-to-claim relationships throughout the course of message exposure. Once these logical relationships have been identified, viewers may offer their own *qualifications*, discount the presented evidence with examples of *counter evidence*, or challenge the logical relationships between evidence and claims with their *own warrants*. If we are to better understand persuasion and argument elaboration, we need to begin to see the necessary relationships between the logical structure of the argument and the argumentative structure of receivers' processing.

Mediators of Message Sidedness Effects on Cognitive Structure for Involved and Uninvolved Audiences

Manoj Hastak, The American University
Jong-Won Park, University of Illinois

ABSTRACT

Persuasive effects due to one versus two-sided messages were examined within the framework of the Elaboration Likelihood Model (Petty and Cacioppo 1986). It was proposed that message sidedness effects on brand attitude are mediated by brand-related cognitive responses for involved audiences, and by perceptions of message/source believability for uninvolved audiences. These propositions were tested in a laboratory experiment involving a 3 (high involvement, low involvement, control) by 2 (one versus two-sided message) design. Results suggest, as expected, that involved subjects are more sensitive to manipulation of message structure. However, no effects due to message sidedness on brand beliefs or attitude were obtained for either involved or uninvolved subjects. The paper concludes with a discussion of the implications of these results for future research on message sidedness effects, and on involvement.

INTRODUCTION

Consumer and advertising researchers have for long been interested in the attitudinal effects of one versus two-sided ad message appeals. A one-sided appeal is characterized by favorable claims on all brand attributes mentioned in the message, whereas a two-sided appeal contains disclaimers or admissions of inferior performance on one or more relatively unimportant attributes. Empirical research in this area has been driven by two theoretical frameworks that focus on different mediating mechanisms in predicting more favorable attitudinal effects due to a two-sided message. Inoculation theory (McGuire 1961) suggests that two-sided appeals are likely to be more effective because presenting negative information about a brand serves to inhibit counterargumentation. Attribution theory (e.g., Jones and Davis 1965) suggests that disclaimers used in a two-sided message serve to enhance the credibility of the message and/or of the message endorser, and thus induce a more favorable attitude. Detailed reviews of these frameworks, and their implications for the study of message sidedness effects are available elsewhere (see Kamins and Assael 1987 for a recent review).

In this paper, we focus on the role of perceived message/source believability, and spontaneous cognitive responses generated in response to the ad message as alternative mediators of message sidedness effects on attitude. Although several empirical studies in the consumer behavior literature have examined message sidedness effects (Belch 1981; Settle and Golden 1974; Golden and Alpert 1978; Hunt, Domzal, and Kernan 1982; Swinyard 1981; Smith and Hunt 1978; Edgar and Goodwin 1982; Kamins and Assael 1987), evidence for mediation due to either cognitive responses or

message/source believability is very limited. For instance, two studies have shown that two-sided appeals inhibit counterargumentation and/or enhance support argumentation (Kamins and Assael 1987; Swinyard 1981). Unfortunately, measures of brand attitude were not obtained in these studies, so no tests of mediation could be conducted. Similarly, three of five studies that obtained significant effects due to message sidedness on source/message believability did not measure brand attitude (Kamins and Assael 1987; Swinyard 1981; Smith and Hunt 1978), while the two remaining studies obtained no effects on attitude (Golden and Alpert 1978; Kamins and Marks 1988).

One goal of the present study was simply to create the conditions under which mediation effects due to both mediators (cognitive responses and message/source believability) on attitude could be examined. A second, more important goal, was to investigate the conditions under which one of these mediators would likely dominate the other. The extant literature on message sidedness provides virtually no guidelines for understanding this issue. We believe that the Elaboration Likelihood Model of persuasion processes proposed by Petty and Cacioppo (1979, 1986) provides a suitable conceptual framework within which multiple mediators of message sidedness effects (such as perceived message believability, and message induced cognitive responses) can be examined. In the following sections, we first present a brief overview of the ELM model. We then derive testable implications of the model for mediation processes for message sidedness effects for involved and uninvolved audiences. Finally, we report on a laboratory experiment designed to test these implications.

THEORETICAL FRAMEWORK

The Elaboration Likelihood Model

Extensive reviews of the ELM are available elsewhere (Petty and Cacioppo 1986). Briefly, this framework suggests that the way in which recipients process a persuasive message depends on their motivation and ability to process the informational claims in the message. Individuals who are high on motivation and ability (e.g., involved and knowledgeable subjects) adopt a "central" route to persuasion. Specifically, they engage in detailed, elaborate processing of message claims en route to forming a carefully reasoned opinion about the advocacy issue. By contrast, unmotivated or unable individuals follow a "peripheral" route to persuasion. These individuals judge the advocacy issue based on a superficial assessment of readily available cues in the message. Attitudes may be formed or changed via peripheral processing either because the

communication object is associated with positive or negative cues (e.g., an attractive source), or because the individual can rely on a simple heuristic to make a quick evaluative inference about the object based on cues in the persuasive message (e.g., a product endorsed by an expert must be good). These ELM predictions have been tested in several psychology and marketing studies, and have received good empirical support (Petty and Cacioppo 1979; Petty, Cacioppo, and Goldman 1981; Petty Cacioppo and Schumann 1983). Also, several recently proposed models of advertising effects have suggested processing differences between high and low involvement audiences similar to the ELM (Batra and Ray 1985; Burnkrant and Sawyer 1983; Greenwald and Leavitt 1984; Mitchell 1986).

Message sidedness effects on involved audiences.

ELM implicates processing of message arguments, and hence the cognitive responses generated during such processing as the key mediators of message effects on attitude for involved audiences. Thus, a two-sided appeal will induce more favorable attitudinal effects to the extent it is successful in biasing the evaluative tone of message processing by either suppressing counterarguments and/or enhancing support arguments.

It is important to note here that the ELM does not predict that two-sided ad messages will result in a more favorable brand attitude than one-sided messages. All that this model asserts is that attitudinal advantage for a two-sided message (if any) will be mediated by message-related cognitive responses. However, there are several reasons why two-sided messages may produce favorable effects on attitude and cognitive responses. First, since a two-sided message explicitly admits to inferior performance on disclaimed attributes, it is likely to inhibit the recipient from generating counterarguments on those attributes. Also, these disclaimers may enhance the believability of other claims made in the message, and hence suppress counterargumentation and enhance support argumentation targeted at these claims. This logic suggests that effects of message sidedness on attitude and on beliefs for attributes not disclaimed in the message will be mediated by parallel effects on the evaluative focus of message processing as indicated by degree of counter and/or support argumentation.

Message sidedness effects on uninvolved audiences

For uninvolved audiences to be influenced by a two-sided message, they must first recognize the "two-sided" nature of the message, and then perceive this cue as being relevant to generating an overall evaluation of the advertised brand.

Since the disclaimed attributes are embedded in the verbal message of a two-sided communication, a distinct possibility is that uninvolved audiences may not even recognize the two-sided nature of the communication. This suggests that a two-sided

message may frequently have no advantage over a one-sided message in influencing brand attitude. If the two-sided nature of the message is recognized, then a two-sided message will induce a more favorable attitude to the extent that subjects rely on message sidedness as a cue to inferring source/message believability.

Note, again, that the ELM does not directly predict an attitudinal advantage for two-sided messages. It simply suggests that attitudinal effects due to message sidedness (if any) for uninvolved audiences will be mediated by a peripheral cue such as perceived message/source believability. The logic for expecting sidedness effects on believability has been clearly explicated in the attribution theory literature as applied to message sidedness effects. (see Kamins and Assael 1987 for a review). This reasoning suggests that effects of message sidedness on attitude will be mediated by perceptions of source credibility (if a source is explicitly identified) and/or message believability. Importantly, ELM predicts no effects due to message sidedness on cognitive responses (counter and support arguments). Also effects on beliefs about attributes not disclaimed (if any) should be due to halo effects, and should not be mediated by cognitive responses.

Summary

The ELM framework suggests that audience involvement with the advertised brand should influence the degree to which they recognize the message sidedness manipulation as well as the mediators of sidedness effects on attitude. Since involved audiences are expected to carefully process brand message claims in the ad, they should clearly recognize that some attributes are disclaimed in the two-sided message, and hence form distinctly inferior beliefs about these attributes. By contrast, uninvolved audiences should show much weaker effects of message sidedness on beliefs about disclaimed attributes since they are expected to process the ad in a cursory and superficial manner. Also, significant effects due to message sidedness on attitude (if any) should be mediated by brand-related cognitive responses (counter and/or support arguments) for involved audiences, and by perceptions of message/source believability for uninvolved audiences. Finally, message sidedness should produce no effects on brand-related cognitive responses for uninvolved audiences.

METHOD

Subjects and Design

130 undergraduate student subjects participated in the study in exchange for course credit. Of these, 124 provided usable responses. The design was a 3 (high involvement, low involvement, control) by 2 (one vs. two sided message) between subjects factorial. Subjects were run in groups of 12 to 15. Each session contained subjects from all six treatment conditions.

Procedure

Upon arrival, subjects were asked to read a one page description of the study. Subjects were told that they would be asked to look through a booklet containing black and white copies of several print ads. Subjects were also told that other participants would be exposed to full color versions of these ads, and that the purpose of the study was to examine the effects of color on consumer reactions to ads. This statement purpose was given for two reasons. First, it was necessary to give subjects some justification for why they were being shown black and white copies of ads. Second, we wanted to hold constant subjects' processing objectives so that natural variations in these would not weaken our involvement manipulation or mediation tests (see Hastak and Olson 1989; Wright 1980).

All subjects were exposed to a booklet containing seven black and white ads. The fifth ad in the booklet was the target ad (for a fictitious brand of ball point pen). Each ad in the booklet was preceded by a brief written description, which subjects were instructed to read carefully. After all subjects had finished examining the booklet, they were given a series of questionnaires to complete. Finally, subjects were debriefed and thanked for their participation.

Independent Variables

Involvement. Our manipulation of brand involvement closely paralleled the manipulation used by Petty, Cacioppo, and Schumann (1983). This manipulation was embedded in two places in the ad booklet. First, the one page study description for high (low) involvement subjects stated that at the end of the study they would be given an opportunity to choose one among several brands of ball point pen (pain reliever). A real ad for an unfamiliar pain reliever brand that was not locally available was included in the third position in the ad booklet. Subjects in the control condition were told nothing.

Second, the brief description that preceded the ball point pen ad for high involvement subjects stated that the pen was to be test marketed in the Champaign-Urbana area, and hence would soon be locally available for purchase. Subjects assigned to the low involvement condition were told that the pen was to be test marketed exclusively on the west coast. Also, the description for the pain reliever for low involvement subjects stated that the pain reliever brand would soon be locally introduced, while high involvement subject were told that there were no plans to introduce this brand in the local area. Control subjects were told nothing about the availability of either the pen or the pain reliever brands.

Message sidedness. The pen ad showed a picture of the pen, a photograph of a male college student, and a message that was attributed to the student. In the two-sided version, two relatively unimportant attribute (styling and color variety)

were disclaimed in the opening paragraph of the message:

Quite frankly, the Spree pen doesn't make a particularly good first impression--a rather ordinary plastic barrel that is not uniquely styled, and a limited assortment of colors to choose from. This impression changes, however, when one starts writing with the Spree.

In contrast, the one-sided message opened with the following paragraph:

The Spree pen makes a great impression right from the start--a distinctive metal barrel that reflects a unique styling in its timeless simplicity of line, and a wide assortment of colors to choose from. And this impression is further strengthened when one starts writing with the Spree.

Both messages then presented the following positive information about the pen:

This is truly one of the most consistent, smooth writing pens I have experienced in its price class. They tell me it is the tough tungsten carbide ball and the patented free flowing ink that does the trick. Whatever the reasons, the results are truly remarkable. And virtually smudge proof.

If smooth, skip free, virtually effortless writing is what you are looking for, you owe it to yourself to try the new Spree pen. You will be glad you did. I certainly am.

Dependent Measures

Cognitive responses. After subjects had viewed the ad booklet, they were asked to proceed through a series of booklets which contained the dependent measures. The first booklet asked subjects to list all the thoughts, reactions, and feelings they had while looking at the pen ad. Subjects were given three minutes to list their thoughts, but were told to stop writing whenever they had no more thoughts to report. These thoughts were subsequently classified in terms of their target (brand message, source, ad execution, other) and polarity (favorable, unfavorable, neutral).

Brand, ad, and source evaluation. These variables were all measured on 9 point rating scales. Brand attitude was measured on three scales (bad-good, unsatisfactory-satisfactory, dislike-like), purchase intention on a single scale (definitely not-definitely yes) attitude towards the ad on three scales (bad-good, dislike-like, unattractive-attractive), message believability on a single scale (unbelievable-believable), message quality on two scales (unpersuasive-persuasive, weak-strong), source credibility on three scales (unbelievable-believable, untrustworthy-trustworthy, unconvincing-convincing), and source attractiveness on two scales

(unlikable-likable, unattractive-attractive). Constructs that were measured on multiple scales were operationalized as the average of those scales.

Attribute beliefs. Beliefs about 12 attributes of the Spree pen were measured on 9 point rating scales (strongly disagree- strongly agree). Six of these attributes were claimed in the ad (variety of colors, unique styled barrel, writes smoothly, smudge proof, comfortable grip, skip free), while the other six were not (even thickness in writing, does not blotch, inexpensive, durable, does not dry out, leak proof). These latter belief measures were included to explore differences (if any) between involved and uninvolved subjects in terms of the effects of message sidedness on inferential belief formation.

RESULTS

Manipulation Checks

Involvement. Three measures intended to assess the success of this manipulation were obtained at the end of the study. Two of these paralleled measures used in the ELM literature to measure brand involvement, or personal relevance of the advertised brand (Petty, Cacioppo, and Goldman 1981; Petty, Cacioppo, and Schumann 1983). First, subjects were asked to recall the product category in which they were to be asked to choose one of several brands. As expected, 40 of 44 subjects in the high involvement condition correctly identified the ball point pen category, while 34 of 42 subjects in the low involvement condition correctly identified the pain reliever category. Importantly, only one subject in the low involvement condition incorrectly identified the pen category.

Second, subjects were asked to indicate how likely they personally thought it was that the Spree pen would be locally available in the next few months on a 9 point (very unlikely- very likely) scale. An involvement (3) by message sidedness (2) ANOVA revealed a significant main effect on this measure ($F(2,119)=10.2, p<.01$). As expected, an a priori contrast revealed that involved subjects believed that it was much more likely that the pen would be available locally (mean=5.82) than did uninvolved subjects (mean=3.62, $F(1,82)=17.15, p<.01$). The belief for control subjects on this measure (5.26) was marginally below the mean for involved subjects.

These results suggest that our manipulation successfully influenced perceived personal relevance of the pen brand. However, it could be argued that these results simply represent instructional checks (i.e., checks to confirm that subjects remembered orienting instructions) rather than evidence for successful manipulation of brand involvement. Furthermore, since the intent of the brand involvement manipulation in the ELM framework is to create differences in message response involvement (i.e., degree of brand message elaboration, see Batra and Ray 1985), we also examined the effects of this manipulation on reported levels of message response involvement, or

MRI. Message response involvement (MRI) was operationalized as the average of three 9 point scales designed to indicate how carefully subjects actually examined and processed the pen message (very uninvolved- very involved, concentrating very little- very hard, paying little- a lot of attention). A 3 by 2 (involvement by message sidedness) ANOVA on this measure revealed no main effect due to the involvement factor. The mean MRI levels for the high and low involvement groups were virtually identical (mean MRI=5.32 for high involvement, 5.34 for low involvement, 4.80 for control subjects).

In sum, these results suggest that variations in perceived personal relevance induced by our manipulation did not produce the anticipated parallel effects on brand message processing. To deal with this problem, the analyses were conducted in three ways. First, the manipulated levels of involvement (high, low, and control) were maintained in all analyses. Next, a median split on the MRI measure was used to create two groups that differed significantly on stated levels of MRI, and all analyses were repeated using this blocking factor. Finally, a median split on the number of reported brand-related thoughts (i.e., counter + support arguments) was used to create two groups of subjects that differed significantly on amount of processing related to the brand message. This final approach is discussed in Batra and Ray (1985) and has been employed in past research (e.g., see Muehling and Laczniak 1988).

The three sets of analyses produced similar results and identical conclusions. To conserve space, we report only the analyses involving the MRI blocking variable. As a result of the median split, 64 subjects were assigned to the high MRI condition (mean MRI=6.50) and 60 subjects were assigned to the low MRI condition (mean MRI=3.74). These groups differed significantly on reported MRI ($F(1, 123)=204.73, p<.01$).

Message sidedness. Effectiveness of this manipulation was checked by examining beliefs on the two attributes (variety of colors, and uniquely styled barrel) that were disclaimed in the two-sided message. Means for these beliefs are displayed in Table 1. As expected, subjects exposed to the two-sided message reported a significantly weaker belief in these attributes than did subjects exposed to the one-sided message. Thus, the message sidedness manipulation was successful. Also, the MRI by message sidedness interaction was significant or marginally significant for both beliefs. A-priori contrasts revealed that message sidedness had stronger effects on both beliefs for involved subjects ($F(1, 62)= 37.1$ for variety of colors, 11.59 for uniquely styled barrel, both $p's <.01$) compared to uninvolved subjects ($F(1, 58)= 6.69, p<.05$ for variety of colors, 0.53, $p>.4$ for uniquely styled barrel). This indicates, as expected, that high MRI subjects processed the ad message more carefully and deeply, and hence were more sensitive to a manipulation embedded in the message claims. Also note that the interaction obtained here parallels the

(message quality by involvement) interaction obtained in past ELM research (e.g., Petty, Cacioppo and Goldman 1981; Petty, Cacioppo, and Schumann 1983). Thus The median split on MRI used in this study likely created differences in brand message involvement similar to those obtained in past research.

Effects on Mediators

The ELM suggests that effects due to message sidedness on attitude are mediated by counter and support arguments for involved subjects, and by message/source believability for uninvolved subjects. Table 1 presents results of 2 (high versus low MRI) by 2 (one versus two-sided message) ANOVAs on measures of counter and support argumentation, and message quality, message believability, and source credibility. As is evident, message sidedness had no effects on any of these variables, and the two-way (MRI by message

sidedness) interaction was also not significant in each case. Also, no effects were found on measures of the proportion of counter and support arguments, or on the number/proportion of positive and negative ad and source-related thoughts produced by subjects -- these are not reported to conserve space. MRI did produce a main effect on perceptions of message quality and source credibility suggesting that involved subjects judged the ad message to be stronger, and the endorser to be more credible than uninvolved subjects. These results suggest that the message sidedness manipulation had no effects on any of the potential mediators of effects on attitude.

Effects on Belief and Attitude Measures

Results for these measures paralleled the results obtained for the mediators (see Table 1). The MRI variable produced main effects on the belief and attitude measures such that these were more positive for involved subjects. Message sidedness produced

no significant (main or interactive) effects on any of the belief measures or on brand attitude. A similar pattern of results was obtained for the six beliefs on attributes not claimed in the message (i.e., inferential beliefs) -- these are not reported to conserve space.

DISCUSSION

Summary of Results

Our results suggest that a two sided message does not produce more favorable effects on brand-related cognitive structure than does a one sided message. Although all subjects clearly recognized the message sidedness cue, and formed distinctly inferior beliefs on attributes disclaimed in the two-sided message, message sidedness had no effects on any of the brand belief and attitude measures, nor did it influence measures of message processing and message/source believability. Note that this failure to find significant effects cannot be attributed to potential problems with our manipulation of involvement, since control subjects showed an identical pattern of results.

Although disappointing, these results are not surprising in light of past research in this area. In the recent marketing literature, only one study showed clear effects due to message sidedness on brand evaluation (Etgar and Goodwin 1982), while several studies failed to show a significant attitudinal advantage due to a two-sided message (Belch 1981; Golden and Alpert 1978; Kamins and Marks 1988). These results (in conjunction with ours) seem to suggest that predicted advantages for a two-sided message are relatively weak and practically inconsequential. This conclusion seems particularly robust in light of the fact that studies in this area differ quite a bit in terms of contexts in which subjects are exposed to the ad messages, nature of the two-sided message, message modality, etc.

Our results also suggest that variations in involvement with the brand or the brand message do not alter the effects due to message sidedness. Clearly, no analyses for differential mediators of message sidedness effects under high versus low involvement could be conducted because there were no effects to be mediated. It is conceivable that weak recognition of the message sidedness cue among uninvolved subjects produced the pattern of results obtained for this group. What is surprising is that involved subjects, who strongly responded to the message sidedness manipulation, showed no effects on cognitive response or attitude measures. A possible explanation for this result may reside in the mix of counter and support arguments produced by our subjects in response to the pen ad. Past marketing research indicates that significant effects due to message sidedness on cognitive responses are usually obtained when counterargumentation is the dominant mode of message processing (e.g., Kamins and Assael 1987). Also, Inoculation theory (McGuire 1961) suggests that two-sided messages are most effective when audiences are initially negatively predisposed towards the advocacy issue, and hence

likely to predominantly counterargue with the message. Our subjects generated more support than counter arguments in response to the ad, and reported very favorable brand attitudes. Thus, a two-sided message could not have influenced attitudes through suppression of counterargumentation. Note, however, that message sidedness could still have produced attitudinal effects through enhancement of support argumentation, although this did not happen in the present study.

Manipulation and Measurement of Involvement

We manipulated brand involvement using procedures similar to those that have been successfully used in past ELM research. Also, two of the manipulation check measures we employed were identical to measures used by Petty, Cacioppo, and Goldman (1981; Petty, Cacioppo, and Schumann 1983) in their research. Interestingly, the manipulation produced significant effects on these measures, but not on a different measure of MRI. Also, attempts to examine involvement effect by using different theoretically justifiable blocking variables yielded similar results. Finally, the significant interaction effect due to MRI and message sidedness on beliefs about disclaimed attributes seems to suggest that The MRI blocking variable adjusted levels of involvement in a manner similar to past ELM studies. Nevertheless, the failure to unambiguously validate the involvement manipulation suggests that our results concerning involvement effects should be cautiously interpreted.

Although not specifically designed to do so, we believe the present study provides some interesting data on the manipulation and measurement of involvement. For instance, three sets of measures obtained in this study can be justified as measuring or partly measuring brand and/or brand message involvement. First, subject perceptions of the likelihood that the advertised brand would be locally available have been used in past ELM research as a measure of personal relevance of the brand. Second, self report measures similar to the ones we used have been used by other researchers (e.g., Laczniak, Muehling and Grossbart 1989) to measure MRI, or degree of brand message elaboration. Finally, the number of message CRs (i.e., CA + SA) has been suggested as an alternative measure of MRI (Batra and Ray 1985; Muehling and Laczniak 1988).

Table 2 shows the intercorrelations we obtained among these three sets of "involvement" measures. We find the lack of association between these measures surprising. The lack of association between the self report and cognitive response measures of message response involvement is particularly difficult to explain. Overall, our results suggest that a manipulation of involvement based on personal relevance may not produce parallel effects on self report measures of MRI, or that blocking on MRI may not create differences in degree of brand message processing as indicated by cognitive responses. Thus, future researchers should

TABLE 2
CORRELATIONS AMONG VARIOUS INVOLVEMENT MEASURES¹

	MRI ²	Availability ³	CRs ⁴
MRI	1.00	0.05	0.11
Availability		1.00	0.04
CRs			1.00

1. None of the correlations significant at $p=.05$.
2. MRI: Average of three measures of message response involvement.
3. Availability: A measure of the perceived likelihood that the pen will be available in the local market.
4. CRs: Total number of message-related thoughts.

consider employing multiple maximally different measures of "involvement" (as we did) in order to provide compelling support for the successful manipulation of this variable. This approach seems particularly useful given the fuzzy distinctions between concepts such as product class involvement, brand involvement, personal relevance of brand, and brand message response involvement.

Finally, we believe that implications derived from the ELM for message sidedness effects are useful because they reconcile the role of two competing mediators that have heretofore been independently theorized about and examined in the literature. Future research incorporating a stronger and more convincing manipulation of involvement should prove useful in developing more unambiguous tests of ELM based predictions than were achieved in the present study.

How Do Consumer Inferences Moderate the Effectiveness of Two-Sided Messages?

Cornelia (Connie) Pechmann, University of California, Irvine

ABSTRACT

This paper attempts to identify the key dimensions along which two-sided nonrefutational messages differ, and then to review empirical findings regarding how each of these dimensions moderates the effectiveness of two-sided messages. The thesis of this paper is that messages which differ on certain key dimensions elicit different consumer inferences or attributions. Consequently, these messages differ in terms of how credible they are perceived to be, and in terms of how much they enhance brand attitudes, beliefs, and purchase intentions relative to a one-sided messages. Hence, by distinguishing among different types of two-sided messages, at least some of the apparent discrepancies in the literature can be resolved.

This paper provides an organizing framework for summarizing the results of previous studies on nonrefutational two-sided messages, i.e., messages which describe potentially undesirable attributes or shortcomings of the promoted brands and yet make no attempt to refute this potentially negative information (Kamins and Assael 1987). The results of such studies seemingly are contradictory. Some studies have found that two-sided messages are more effective than one-sided messages (Goodwin and Etgar 1982; Smith and Hunt 1978), whereas other studies have found that two-sided messages are no more effective (Belch 1981; Settle and Golden 1974) or even less effective (Stayman, Hoyer and Leon 1987; Swinyard 1981) than one-sided messages.

This paper will attempt to show that two-sided messages differ on a number of key dimensions, and that messages which differ on these dimensions vary in their effectiveness because they elicit different types of consumer inferences or attributions. Therefore, by distinguishing among different types of two-sided messages, at least some of the apparent discrepancies in the literature can be resolved. Hence, this paper hopes to accomplish the following two objectives: (1) to clarify what we already know about two-sided messages, and (2) to clarify what we do not yet know, so as to stimulate and guide future research. The next section of this paper will discuss the key dimensions of two-sided messages.

THE KEY DIMENSIONS OF TWO-SIDED MESSAGES

Based on a careful review of the literature, it appears that two-sided messages differ on the following four key dimensions:

1. *How important the potentially unfavorable disclosure is perceived to be* (Stayman, Hoyer and Leon 1987). A brand can be described as having one or more undesirable attributes or shortcomings that

are either relatively unimportant or relatively important, either as perceived by all potential consumers or by a particular subgroup of consumers.

2. *The motivation underlying the potentially unfavorable disclosure.* For example, consumers might assume that a marketer is required by federal and/or state regulations to reveal its brand's potentially undesirable attributes or shortcomings. On the other hand, consumers might assume that a marketer is revealing this information voluntarily.

3. *How counter-attitudinal or pro-attitudinal the message is overall.* For example, a message might attempt to persuade consumers that a very low share brand is superior to a high share brand, in which case it would be counter-attitudinal to most consumers.

Alternatively, a message might attempt to reinforce existing favorable attitudes towards a very high share brand, in which case it would be pro-attitudinal to most consumers.

4. *How highly correlated the potentially undesirable attribute is to another potentially desirable brand attribute featured in the message.* For example, the fact that a brand has more of a potentially undesirable attribute might cause consumers to infer that it has more of a desirable attribute as well. In contrast, a brand's rating on the potentially undesirable attribute might be perceived to be unrelated to its rating on another, more desirable attribute.

The next section of this paper will discuss empirical findings regarding how these four dimensions moderate the effectiveness of two-sided messages.

A REVIEW OF FINDINGS REGARDING TWO-SIDED MESSAGES

Based on a careful scrutiny of empirical findings on two-sided messages, the following propositions have been formulated:

Proposition 1. The effectiveness of a two-sided message is moderated by the perceived importance of the potentially unfavorable disclosure. If a two-sided message discloses that the promoted brand has a potentially undesirable attribute or shortcoming that is perceived to be important by consumers, the message and message source are perceived to be more truthful or credible (Settle and Golden 1974; Smith and Hunt 1978) for the following reason. Marketers who voluntarily disclose unfavorable information about their brands do not appear to be motivated by external pressures to sell their brands. Hence, consumers apparently infer that there is a relatively high degree of

correspondence between the statements made in these two-sided messages and the brands' actual merits (Smith and Hunt 1978; Stayman, Hoyer and Leon 1987; also see Correspondence Theory e.g. Jones and Davis 1965; and Attribution Theory e.g. Kelley 1973). In contrast, marketers who use one-sided messages appear to be motivated by external pressures to sell their brands. Hence, consumers apparently infer that there is less of a correspondence between the statements made in these one-sided messages and the brands' actual merits.

Nevertheless, a two-sided message which discloses that a brand has important shortcomings does not appear to be any more effective than a one-sided message at promoting favorable brand beliefs, attitudes, or purchase intentions (Belch 1981; Settle and Golden 1974; Stayman, Hoyer and Leon 1987). Rather, it appears that the benefits gained from using this type of two-sided message (namely, the enhanced credibility) are either *equal to* or *less than* the costs incurred (namely, that unfavorable information is promulgated about the promoted brand). For example, Stayman et al. (1987) determined that a two-sided message stating that an alarm clock scored poorly on styling--a *moderately important* attribute--was perceived to be significantly more trustworthy than a one-sided message. However, consumers exposed to this two-sided message were *no more* favorably disposed towards purchasing the alarm clock than consumers exposed to the one-sided message. Apparently, the gain in credibility was offset by the costs incurred. Correspondingly, Stayman et al. determined that a two-sided message stating that an alarm clock scored poorly on accuracy--a *very important* attribute--was perceived to be significantly more trustworthy than a one-sided message. However, consumers exposed to this two-sided message were *less* favorably disposed towards purchasing the alarm clock than consumers exposed to the one-sided message. Apparently, the costs incurred were greater than the benefits gained.

There is as yet no evidence that it is possible to reduce the costs of using a two-sided message (i.e., by reducing the importance of the disclaimer made) without simultaneously reducing the benefits gained (i.e., without simultaneously reducing the credibility of the overall message). For example, Stayman et al. (1987) determined that a two-sided message stating that a record store did not sell concert tickets--an *unimportant* attribute--was *not* perceived to be any more trustworthy than a one-sided message. As a result, consumers exposed to this two-sided message were no more favorably disposed towards shopping at the record store than consumers exposed to the one-sided message.

Nevertheless, it might be advantageous to make a disclosure which is perceived by the *target* consumers to be important to *some* consumers and yet not to *them*. Such a two-sided ad might be perceived as more credible, and yet not tarnish the brand's image in the eyes of the target consumers for whom the disclosure is relatively unimportant.

Hence, it might be fruitful for researchers to explore this issue in the future.

Proposition 2. The effectiveness of a two-sided message is moderated by the perceived motivation underlying the potentially unfavorable disclosure. A marketer's perceived motivation for using a two-sided message has never been explicitly identified as being an important moderating variable, but it would also appear to moderate the effectiveness of two-sided messages. If consumers perceive that a marketer is *required* to make a potentially unfavorable disclosure, or has some other ulterior motive for doing so, they are not likely to infer that the two-sided message is any more credible than a one-sided message. For example, since most consumers realize that the health warnings on cigarette ads are required, they do not infer that cigarette advertisers are more trustworthy or truthful than other advertisers. Hence, required disclosures of any type--to the extent that they are important--almost undoubtedly are detrimental to brand attitudes and sales, which is why such disclosures are vehemently opposed by most marketers.

Proposition 3. The effectiveness of a two-sided message is moderated by how counter-attitudinal or pro-attitudinal the message is overall. This particular proposition comes from the comparative advertising literature (e.g., Swinyard 1981). Comparative ads typically claim that very low share brands are superior to very high share brands. Since such comparative ads are highly counter-attitudinal (particularly to users of the very high share brands), they are perceived to be less credible and they elicit more counterarguing than noncomparative ads (e.g., Belch 1981). Hence, it has been suggested that comparative ads be worded as two-sided messages in order to enhance their perceived credibility and to reduce counterarguing.

Based on this same logic, it would appear that the more counter-attitudinal a message, the more likely it is to benefit from a two-sided format. However, as stated previously, there is as yet no evidence that a two-sided message can enhance the credibility of a message without simultaneously reducing its overall persuasiveness because of the negative disclosures that are made. Hence, it is unclear whether counter-attitudinal messages (including comparative ads) can benefit from being two-sided. Once again, further research is sorely needed.

Proposition 4. The effectiveness of a two-sided message is moderated by how highly correlated the potentially undesirable attribute is to another potentially desirable attribute featured in the message. The correlation between the attributes featured in two-sided messages never before has been identified as being important in moderating the effectiveness of two-sided messages. However, related empirical findings on consumer inferences suggest that the relative effectiveness of a two-sided message will be contingent on the inferences consumers make when a potentially undesirable attribute is highly correlated with another desirable

attribute featured in the message (e.g., Ford and Smith 1987). Consumers can make at least two types of relevant inferences, each of which will be discussed below.

First, consider a situation in which the promoted brand's *rating* on a *desirable* attribute featured in a two-sided message is *ambiguous*. When the brand is described in a two-sided message as having an *unfavorable rating on an attribute that is highly correlated with this desirable attribute*, consumers may infer that the brand has a *more favorable rating on this desirable attribute*. Hence, a two-sided message may promote more favorable brand beliefs, attitudes, and purchase intentions than a one-sided message. However, the two-sided message probably will not be perceived as any more trustworthy or credible than the one-sided message, particularly if consumers realize that the marketer had an ulterior motive for disclosing the potentially unfavorable information. Consumers are quite accustomed to marketers discounting their brands on relatively unimportant attributes so as to more effectively position their brands as being superior on more important, highly correlated attributes.

For example, most consumers have been exposed to two-sided ads acknowledging that Loreal hair color is more expensive than other competing brands. Furthermore, consumers probably realize that the marketer of Loreal has an ulterior motive for acknowledging that Loreal is more expensive--to more effectively position it as being a superior quality hair color. Hence, consumers probably do not infer that the two-sided Loreal ad is any more trustworthy or credible than the one-sided ads for competing brands of hair color.

Prior studies of two-sided messages often used messages in which the discounted attributes were highly correlated with the other featured attributes, although probably only inadvertently. For example, Etgar and Goodwin (1982) copytested a two-sided ad stating that the advertised brand of beer was a premium beer with a full bodied taste, but was more expensive and higher in calories. The one-sided ad portrayed the advertised brand favorably on all four dimensions. It was found that the two-sided ad was not perceived to be any more believable than the one-sided ad. However, the two-sided ad was more effective at persuading respondents that the advertised beer was of higher quality, and at enhancing purchase intentions of this beer. It appears that by describing the advertised beer as being inferior on two dimensions (that is, as being higher in calories and more expensive), the two-sided ad more effectively positioned it as being superior on other, highly correlated dimensions (that is, as being a premium beer with a full bodied taste). Since respondents in the study preferred a premium beer with a full bodied taste over a less expensive or lower calorie beer (according to pretest data), the two-sided ad thereby promoted more favorable brand beliefs and purchase intentions.

Similarly, Swinyard (1981) copytested a two-sided ad stating that the advertised grocery store charged lower prices but had fewer amenities, e.g.,

consumers had to bag their own groceries. The one-sided ad simply stated that the advertised grocery store charged lower prices. It was found that the two-sided ad was more effective at persuading respondents that the advertised store actually charged lower prices. It appears that by describing the advertised store as being inferior on one dimension (that is, as having fewer amenities), the two-sided ad more effectively positioned it as being superior on another, highly correlated dimension (that is, as having low prices). However, it appears that *in the aggregate*, the respondents in the study preferred a store with amenities and somewhat higher prices over a store without amenities albeit lower prices. Hence, the two-sided ad actually was *less* effective than the one-sided ad at persuading respondents *in the aggregate* to shop at the advertised store and redeem the store coupon they had been given. However, it is possible that the two-sided ad was *more* effective than the one-sided ad at persuading respondents in the store's *target market* (i.e. respondents who considered low prices to be more important than amenities) to shop at the advertised store. Unfortunately, the data only were analyzed at the aggregate level.

Many studies also have been conducted to determine what inferences consumers make when information about a brand is missing, and in several of these studies the missing attributes were highly correlated with the known attributes. Furthermore, these "missing information" studies are related to studies of two-sided messages, although they generally have not been perceived as such. The reason why these "missing information" studies are related is that *one-sided messages essentially are messages in which the (unfavorable) information provided in two-sided messages is "missing"*.

In one such "missing information" study, Meyer (1981) exposed respondents to a two-sided message stating that a pizza parlor charged low prices but had a plain decor. The one-sided message simply stated that the pizza parlor charged lower prices. Meyer essentially replicated Swinyard's key result: it was found that the two-sided message was more effective than the one-sided message at persuading respondents that the pizza parlor actually charged low prices. Furthermore, Meyer replicated these results using a non-price attribute. He also exposed respondents to a two-sided message stating that a pizza parlor had excellent (tasting) pizza but a plain decor. The one-sided message simply stated that the pizza parlor had excellent pizza. It was found that the two-sided message was more effective than the one-sided message at persuading respondents that the pizza parlor actually had excellent pizza.

Since the two-sided messages promoted more favorable brand attitudes than the one-sided messages, Meyer concluded that consumers replace missing information with discounted average values. However, an alternative or rival explanation for why the two-sided messages promoted more favorable brand attitudes is that respondents inferred that a pizza parlor with a plain decor was more likely to

charge lower prices and to have excellent pizza, i.e., respondents perceived these attributes to be highly correlated. Hence, research should be conducted to examine the validity of this rival explanation.

There is yet another reason why the correlation between the attributes featured in two-sided messages might moderate the effectiveness of two-sided messages. Consider a second type of situation in which the promoted brand's *rating* on a *desirable* attribute featured in a two-sided message is *known with some degree of certainty*. When the brand is described as having a favorable rating on this desirable attribute, *if this desirable attribute is highly correlated with another attribute*, consumers may infer that the brand has a *less favorable rating on the other attribute if exposed to a one-sided message than if exposed to a two-sided message*. Hence, once again, a two-sided message may promote more favorable brand beliefs, attitudes, and purchase intentions than a one-sided message. However, the two-sided message probably will not be perceived as any more trustworthy or credible than the one-sided message, particularly if consumers realize that the marketer had an ulterior motive for disclosing the potentially unfavorable information. Consumers are quite accustomed to marketers reassuring them that although their brands may have shortcomings, these shortcomings are lesser in magnitude than might be expected.

For example, most consumers have been exposed to two-sided ads for certain brands of luxury cars acknowledging that such cars are quite expensive, albeit less expensive than might be expected. Furthermore, consumers probably realize that the marketers of these cars have an ulterior motive for acknowledging how expensive their cars are--to insure that consumers will not infer that these luxury cars are even more expensive than they actually are. Hence, consumers probably do not infer that these two-sided car ads are any more trustworthy or credible than one-sided car ads.

As stated earlier, many studies have been conducted to determine what inferences consumers make when information about a brand is missing, and in many of these studies the missing attributes were highly correlated with the known attributes. Furthermore, these "missing information" studies are related to studies of two-sided messages, since one-sided messages essentially are messages in which the (unfavorable) information provided in two-sided messages is "missing".

In one such "missing information" study, Huber and McCann (1982) exposed respondents to a two-sided message stating that a beer was low in price but only of average quality. The one-sided message simply stated that the beer was low in price. It was found that the two-sided message was more effective at enhancing purchase intentions for the beer than the one-sided message. A post-hoc interpretation of Huber and McCann's results is that the two-sided message was more effective than the one-sided message for following reason. Since the one-sided message described the beer as having a favorable rating on price (e.g., as being low in

price), and since price generally is perceived to be highly correlated with quality, respondents exposed to the *one-sided* message may have inferred that the beer had an *unfavorable* rating on the *missing* attribute (e.g., that it was low in quality). Hence, respondents exposed to the *two-sided* message actually may have been *reassured* by it. Even though the two-sided message acknowledged that the beer was only of average quality, at least it reassured respondents that the beer was not of even lesser quality. If so, this may explain why respondents exposed to the two-sided message evaluated the beer more favorably than respondents exposed to the one-sided message. Hence, research also should be conducted to examine the validity of this post hoc explanation of Huber and McCann's results.

It should be noted that Huber and McCann's results appear to be quite robust. For example, a study by Johnson and Levin (1985) essentially replicated Huber and McCann's (1982) results using television sets rather than beer. In addition, a follow-up study by Lim, Olshavsky and Kim (1988) was able to replicate Huber and McCann's results using non-price attributes of cars, although only when respondents' inferences were prompted. Apparently, it was necessary for Lim et al. to prompt respondents to make inferences since the correlation between the attributes Lim et al. used (i.e., comfort and gas mileage) was lower and/or less salient than the correlations between the attributes used in the earlier two studies (i.e., price and quality).

IMPLICATIONS OF THIS REVIEW

Empirical and theoretical work on two-sided messages has focused almost exclusively on one key dimension along which two-sided messages differ: the relative importance of the shortcomings or unfavorable attributes that are disclosed. Based on the review presented in this paper, this variable does appear to moderate the effectiveness of two-sided messages. The more important the shortcoming that is disclosed, the *more trustworthy or credible the message and message's source are perceived to be--* assuming that the disclosure is perceived to be made voluntarily rather than solely to comply with regulatory statutes or for some other ulterior motive. However, the more important the shortcoming that is disclosed, the *less effective the message is at enhancing favorable brand attitudes, beliefs, and purchase intentions* precisely because increasingly unfavorable information is promulgated about the brand.

What this suggests is that two-sided messages are of limited value to marketers, even for enhancing the credibility of highly counter-attitudinal messages (such a comparative ads claiming that very low share brands are superior to leading brands). One possible way to use a two-sided message effectively is to disclose a shortcoming that consumers will perceive to be important to *some consumers* and yet not important to *them personally*, and to insure that consumers will perceive that this disclosure is being made voluntarily and with no ulterior motive.

However, the relative effectiveness of this type of two-sided message must still be empirically studied.

Furthermore, much more attention probably should be focused on yet another key dimension on which two-sided messages differ: the extent to which the unfavorable and favorable attributes are perceived to be correlated. Based on the review presented in this paper, this variable also appears to moderate the effectiveness of two-sided messages. In fact, based on a post-hoc analysis of prior studies pertaining to two-sided messages, it appears that the only types of two-sided messages that appear to be effective at enhancing brand beliefs, attitudes, and purchase intentions are those in which the potentially undesirable attributes are highly correlated with other desirable brand attributes featured in these messages.

Not surprisingly, these are the only types of two-sided messages that advertisers appear to be using at the present time. One two-sided message of this type that has recently been used in Southern California is an ad for a fast food restaurant chain called Carl's Junior. The ad acknowledges that Carl's Junior is not as fast as other fast food restaurants in order to persuade consumers that its food is fresher (because it is prepared when ordered rather than in advance). Yet another recent example is the ad for Frusen Gladje ice cream which acknowledges that Frusen Gladje is fattening in order to persuade consumers that it is very rich and delicious. Other recent examples of two-sided messages are the ads for luxury cars which acknowledge the cars' high prices in order to preclude consumers from inferring that the cars are even more expensive than they really are. Given that this particular type of two-sided message appears to be the most prevalent, it is somewhat surprising that this type of two-sided message never has been explicitly studied.

Unfortunately, the conclusions made in this paper regarding the relative effectiveness of two-sided messages with correlated attributes are tentative at best. These conclusions were based primarily on post hoc analyses of empirical studies of two-sided messages as well as somewhat related "missing information" studies. Hence, these tentative conclusions must be verified by conducting additional research. It is hoped that this review will stimulate additional research on the relative effectiveness of two-sided messages, particularly those in which the desirable and undesirable attributes featured in the messages are highly correlated.

The Impact of Product-Related Announcements on Consumer Purchase Intentions

Vijay Mahajan, Southern Methodist University¹

ABSTRACT

This paper investigates the impact of brand, product, and industry announcements on consumers' intentions to purchase alternative brands of microcomputers. Results suggest that (1) negative announcements, in general, have a greater effect than positive announcements, (2) announcements regarding the entire industry tend to have a greater impact than announcements about a specific brand or set of brands, and (3) announcements are more likely to affect the evaluations of brands in the choice set than those of brands not in the choice set. Managerial implications of these results are discussed.

Product-related announcements are formal communications that provide new information to consumers about a product's availability, features, applications, defects, or its discontinuation. Such announcements may be created by design or accident, and are originated by competitors, regulatory agencies, consumer and environmental groups, and many times by manufacturers themselves. Both favorable and unfavorable in nature, product announcements may consist of (Mahajan, Muller and Kerin 1984):

- * Brand related information--such as the unintended acceleration problem with the Audi 5000 S (Manning 1987);
- * Product category related information--such as the finding that aspirin can reduce the risk of heart attack (Dallas Morning News 1988a);
- * Industry related information--such as the health and environmental effects of fluorocarbons in aerosol cans (Margolies 1976).

In many instances, product-related announcements are made or encouraged by a manufacturer as part of a marketing strategy to create a more conducive environment for the acceptance of its product in the marketplace (Wind and Mahajan 1987). For example, a manufacturer may announce a new product well before it is ready for sale, hoping to get customers to wait for this product rather than buy a competitor's product in the interim (Porter 1980, p.77; Brock 1975). On the other hand, a

competitor may announce a new technology-based product hoping to redefine the attributes that customers use to evaluate the various brands that are currently available (e.g., IBM's announcement of its Personal System 2 computers, Mitchell 1987, or NutraSweet's announcement of a new low-calorie, low-cholesterol substitute for cooking oil, Dallas Morning News 1988b). In that context, such announcements can serve as market signals to preempt other competitors from the marketplace (Porter 1980, p.76).

Little effort has been made to systematically examine the effects of product-related announcements on consumer purchase intentions. Through an understanding of this relationship, marketers can evaluate the usefulness of announcements as a strategic tool to influence consumer decisions. Eliashberg and Robertson (1988) report that a firm's expectations about consumer response to announcements are the main determinant of whether the firm will pre-announce new products. Furthermore, this information can be incorporated in consumer adoption and diffusion models to improve the prediction of consumer behavior (Midgley 1976; Mahajan, Muller, and Kerin 1984).

This paper attempts to empirically address a few basic questions about consumer response to product-related announcements. Do product-related announcements have an effect on consumers' brand purchase intentions? Does the size of this effect depend on the direction or breadth of the message? Do product-related announcements affect the evaluations of all available brands or just a select few? Are consumers more likely to change their evaluations of brands in their choice sets than those of brands that are not? The next section of the paper details the propositions associated with these questions. The study design and empirical results are then presented. The paper concludes with a discussion of the implications, limitations, and future directions of this research.

ANNOUNCEMENT CHARACTERISTICS AND CONSUMER RESPONSE

Marketing researchers have had a long tradition of examining the impact of information on consumer decision-making. Considerable research suggests that additional product information can change consumers' perceptions and evaluations of brands (e.g., Lutz 1975). By providing new information about one or a set of brands, product-related announcements would likewise be expected to affect consumers' brand perceptions and purchase intentions. Research by Farquhar and Pratkanis (1987) provides some support for this hypothesis,

¹The authors wish to thank Oliver Heil and several anonymous reviewers for their comments and suggestions.

indicating that one type of announcement, the new product pre-announcement, can influence consumer choice behavior. It is therefore proposed that:

P1: Product-related announcements affect consumers' intentions to purchase the various brands of a product.

One dimension on which announcements differ is the favorability of the message with respect to the brand. Unfavorable product-related information appears to have a much stronger influence than favorable product-related information on consumer decision-making (Arndt 1967; Burzynski and Baker 1977; Lutz 1975; Mizerski 1982; Richins 1983; Weinberger 1986; Weinberger, Allen, and Dillon 1981; Wright 1974). Individuals pay more attention to negative information (Fiske 1980), find it less ambiguous (Wyer 1973), and are more likely to recall it (Carlston 1980). Weinberger, Allen, and Dillon (1981) demonstrated that the impact of negative information persists even after the information has been refuted.

Various explanations of this "negativity bias" have been offered (see discussions by Kanouse 1984, and Kanouse and Hanson 1972). Negative information may attract more attention and be processed more extensively because it is more novel and distinctive than positive information (Fiske 1980, Kanouse 1984). In addition, since most brands are described in positive terms, negative information may be more useful for discriminating between brands at the time of choice (Kanouse and Hanson 1972). This leads to the expectation that:

P2: Negative announcements have a greater effect than positive announcements on consumers' purchase intentions.

As noted earlier, announcements also differ in terms of the breadth of the communication. Announcements about individual brands (if believed) would be expected to change consumers' brand perceptions, whereas industry announcements are more likely to change consumers' perceptions of the product category, redefining the criteria used to evaluate an entire set of brands. If industry announcements affect how consumers frame the choice decision then one would predict:

P3: Industry-level announcements have a greater effect than brand or product category announcements on consumers' intentions to purchase various brands.

Research by Biehal and Chakravarti (1982), Johnson and Russo (1978), and Tversky (1972) indicates that information is processed more extensively for chosen than for unchosen alternatives. Raj (1982) reports that increased brand advertising has a greater impact on brand loyal consumers than brand switching customers. Similarly, Petty and Cacioppo (1979) report that individuals who are highly involved in a decision

are more likely to process relevant message arguments. This suggests that consumers will be most likely to consider the implications of product-related announcements for brands that they are actively considering purchasing. It is therefore proposed that:

P4: Product-related announcements have a greater effect on the purchase intentions of brands in the choice set than on the purchase intentions of brands not in the choice set.

Finally, one would expect that when the focus of an announcement is selective, so would be its effects on purchase intentions. An announcement is expected to have the greatest impact on consumers' evaluation of its referent, although it may have a residual influence on the evaluations of other brands in the product class.

P5: Announcements have a greater effect on consumers' intentions to purchase brands and products directly referenced in the communication.

METHODOLOGY

A study was conducted to examine the effects of various types of product-related announcements on consumer purchase intentions for microcomputers. Given the competition for technological advancements and the fight for market share, manufacturers of microcomputers have been known to make announcements in order to influence consumer purchase decisions (see, e.g., Brock 1975; Mitchell 1987).

First-year MBA students enrolled in a core marketing management course at a major business school participated in the study. Before entering the MBA program, these students were required by the school to either purchase or lease an IBM-compatible computer system. Students also received computer literature from school administrators concerning various equipment options.

The volunteers from the course were asked to complete a questionnaire, requiring 30-45 minutes of their time, concerning their buying preferences for microcomputers. The questionnaire consisted of four major sections. The first section sought information on their current microcomputer equipment and usage. The second section asked for their assessment of the relative importance of the various microcomputer features. The third section was a conjoint task where they were asked to provide intention-to-buy ratings for eighteen hypothetical microcomputers in view of six different announcements. The orderings of brand profiles and announcements were randomized. The final section measured their prior familiarity with these announcements and requested some background information. Prior to its final administration, the questionnaire was given to 10 first-year MBA students to evaluate levels of comprehension and fatigue.

Respondents were screened in terms of having some familiarity with microcomputers. Students who completed the questionnaires were entered into a lottery for \$400 worth of computer software. Thirty students provided completed questionnaires. All of the students reported having used a microcomputer for job-, home-, or school-related activities within the past year. Twenty-three individuals (77% of the sample) reported that they currently owned microcomputers. The remaining 7 subjects stated that they planned to purchase or lease a computer during the academic year. Those persons who currently owned computers reported spending an average of 7.8 hours per week using this equipment.

The eighteen hypothetical brand profiles included in the third section of the questionnaire were based on seven major factors (product features) and their associated levels (listed in Table 3). The selection of these factors was done after consulting several knowledgeable MBA students and the school administrators who were directly responsible for recommending the various equipment configurations to the students. The selected levels for the various factors and their combinations were also checked with suppliers for their feasibility. The seven factors were combined into a 3^7 fractional factorial design (cf. Addelman 1962), resulting in 18 brand profiles. A fractional factorial design was used in order to reduce the number of profiles presented to a single respondent. As is common in most conjoint studies (see Cattin and Wittink 1986), interactions between brand attributes were assumed to be nonsignificant. However, the design does allow the estimation of interactions between the announcement manipulation and brand attribute factors.

Respondents were initially asked to report their likelihood of purchasing each of 18 microcomputers on a 5-point rating scale, with 1 indicating "definitely would not purchase" and 5 indicating "definitely would purchase." After completing this task, they were given six randomly-ordered product-related announcements, one at a time, and asked to provide new ratings of the same 18 profiles in view of the information conveyed by each announcement (see Table 1). While evaluating the 18 profiles for each announcement, subjects were asked to ignore any previous announcement(s) given to them. They were told that university officials were the source of these announcements.

The six announcements used in the study were taken from the actual evolution of the microcomputer industry. At the time of the study (Fall 1986), this information was relatively new and unfamiliar. The announcements were planned according to a 2×3 design where announcements were developed to convey positive or negative information about a specific brand, the product category, or the entire industry. In order to establish the perceived direction (positive or negative) and referent (brand, product, or industry) of the six announcements and to assess the announcements' effects on purchase intentions, the announcements were pretested with a group of MBA

students and industry experts. Students' prior awareness of each announcement was also measured. The pretest results confirmed the intended perception of the six announcements.

RESULTS

Overall Announcement Effects

Table 2 presents (a) means and standard deviations of subjects' purchase intentions across all brand profiles for the various types of announcements and (b) ANOVA results testing the overall effect of announcements on subjects' purchase intentions for the 18 brand profiles. The main effect of product announcement was highly significant, $p < 0.0001$. Mean purchase intentions ranged from 1.94 in the negative industry announcement condition to 2.35 in the positive product announcement condition (Table 2a). These results suggest that consumers' intentions to purchase any of the available brands of a product can be influenced by product-related announcements, supporting Proposition 1.

Direction of the Announcement

As summarized in Table 2a, relative to the no-announcement control condition, the negative announcements produced an overall downward change in evaluations of 0.21 while the positive announcements produced an upward change of only 0.06. The difference in the size of these effects is significant, $F(1,29) = 4.54$, $p < 0.05$. Individually and as a group, the brand profiles in the negative announcement conditions were rated significantly lower ($\bar{x} = 2.12$, 2.10, and 1.94, for the negative brand, product, and industry announcements, respectively) than those in the no-announcement control condition ($\bar{x} = 2.26$), $F(1,174) = 19.62$, $p < 0.0001$. On the other hand, although the mean purchase intentions in the three positive announcement conditions were higher ($\bar{x} = 2.32$, 2.35, and 2.30 for the positive brand, product, and industry announcements, respectively) than the no-announcement control condition, these differences were not significant, $F(1,174) = 1.77$, $p > 0.10$.

These results indicate that the negative product-related announcements have a greater effect than positive announcements on overall brand evaluations. This finding supports Proposition 2, and is consistent with past research showing that negative information has a greater impact on judgment than positive information.

Breadth of the Announcement

Table 2a reports the overall mean change from the no-announcement condition for the brand, product and industry announcements. The size of the announcement effect did not differ significantly across the three announcement types ($\Delta\bar{x} = 0.10$, 0.12, and 0.18, for the brand, product, and industry announcements, respectively), $F(2,58) = 1.81$, $p > 0.10$. However, there was a significant interaction between the type of announcement and its direction, $F(2,58) = 4.76$, $p < 0.02$. In the negative

TABLE 1
MICROCOMPUTER ANNOUNCEMENTS

Announcement	Referent	Direction
1. None	-	-
2. The IBM AT 20 MB hard disk is prone to "head crashes" resulting in the loss of all data and requiring the replacement of the hard disk drive. This is due to a problem with the design of the IBM hard disk controller card.	brand	negative
3. Compaq's 80286-based AT computer with 20 MB hard disk runs at least 2 MHZ (approximately 25 percent) faster than any other competitive brand.	brand	positive
4. The basic PC (base model of <i>all</i> brands) is being discontinued by suppliers. This model will continue to be sold until existing supplies are exhausted.	product	negative
5. Accelerator cards using the 80286 processor are now available for most brands of PC's and XT's. This accessory increases the speed of the computer to the performance of an AT.	product	positive
6. Intel's 80386 micro-processor will be available in the fourth quarter of 1986. This new CPU will allow multitasking in a new generation of microcomputers likely to run 2-3 times faster than the present AT's. New software developed for this environment is unlikely to run on existing 8088, 8086, and 80286 based computers such as various brands of PC's, XT's, and AT's.	industry	negative
7. The three major producers of statistical software for main-frame computers have announced microcomputer versions of their products, including advanced graphics capability and LOTUS 1-2-3 interfacing.	industry	positive

announcement conditions, the effect size depended on the focus of the announcement ($p < 0.03$), with the industry-level announcement producing greater change ($\Delta\bar{x} = 0.32$) than either the brand or product-level announcements ($\Delta\bar{x} = 0.14$ and 0.16 , respectively; $p < 0.05$). This was not the case in the positive announcement conditions ($p > 0.10$).

When compared to the no-announcement control condition, the product and industry announcement effects were both significant ($p < 0.05$). The brand announcement had only a marginally significant overall effect ($p < 0.10$). These results are consistent with Proposition 3, and suggest that product-related announcements that

relate to the entire industry tend to impact consumer purchase intentions more than the announcements that relate to a specific brand or a set of brands.

Announcement Effects On Choice-Set Brands

Given the 5-point rating scale, brand profiles rated as 4 or 5 in the no-announcement condition were considered to define the relevant choice set for each respondent (see Urban and Hauser 1980, Chapter 11). The overall mean change in brand

purchase intentions was modeled as a function of announcement type and profile grouping using ANOVA. The interaction between the type of announcement and profile grouping was highly significant, $F(6,174) = 6.05$, $p < 0.0001$. While the simple main effects of announcement were significant for both the choice-set and non-choice-set profile evaluations ($p < 0.01$), the pattern of effects for each group was different.

Profiles in the choice set were significantly affected by each of the three negative

TABLE 3
EFFECTS OF PRODUCT-RELATED ANNOUNCEMENTS ON BRAND ATTRIBUTE EVALUATIONS

announcements ($\Delta\bar{x} = -0.80, -0.58, \text{ and } -0.82$ for the negative brand, product, and industry announcements, respectively), while the remaining profiles were only affected by the negative industry announcement ($\Delta\bar{x} = -0.20$). The announcements produced considerably more absolute change in the evaluations for profiles in the choice set ($|\Delta\bar{x}| = 0.50$) than for those that were not ($|\Delta\bar{x}| = 0.17$), $F(1,29) = 24.68, p < 0.0001$. These results indicate that product-related announcements are more likely to affect consumer purchase intentions for the brands that are included in the choice set than for brands

that are not included in the choice set, as predicted by Proposition 4.

Selective Effects on Brand-Attribute Evaluations

Although the negative announcements generally tended to decrease ratings and the positive announcements generally tended to increase ratings, the effect of these announcements was very selective. The industry negative announcement (availability of Intel's 80386 micro-processor) influenced most of the brand profiles, but the effect of other announcements varied from two brand

profiles (brand positive) to four brand profiles (product negative). The selective nature of the announcement effect is supported by a significant interaction between the type of announcement and brand profile, $F(102,2958) = 10.35, p < 0.0001$. When the ratings of the brand profiles were decomposed into the evaluations of the seven brand attributes, each attribute entered into a significant interaction with the product-related announcement variable ($p < 0.0001$). The significant differences in the purchase intentions between the no-announcement control condition and the six other announcement conditions are reported in Table 3. For all of the reported pairwise contrasts, significance tests are adjusted to maintain the overall Type I error rate (Dunn 1961).

The brand-negative announcement (IBM PC/AT 20 MB hard disk crash) led respondents to decrease their evaluations of the IBM brand, the AT model, and the 20 MB hard disk. Subjects also negatively evaluated the short (3 month) warranty, the 512 KB RAM-memory, the enhanced color monitor, and the \$3,000 price. While the latter effects were not expected, they are not surprising since this particular combination of attributes was associated with the profile describing the IBM PC/AT with the 20 MB hard disk.

The product-negative announcement (PC model discontinued) caused subjects to lower their evaluations of the PC model, as well as their ratings of the IBM and Compaq brands. As with the brand-negative announcement, the product-negative announcement had a number of additional, unexpected effects on subjects' evaluations of product attributes. Once again, the combination of attributes was associated with a single brand profile which was strongly negatively evaluated.

The industry-negative announcement (Intel 80386 processor forthcoming) had a widespread negative effect on subjects' interest in purchasing any of the described brands. Consequently, each level of each attribute was rated significantly lower than in the no-announcement control condition.

As noted earlier, the positive announcements had much less of an impact on rated purchase likelihood than did the negative announcements, although a number of the effects on individual attributes were significant. The brand-positive announcement (Compaq speed enhancement) had the expected positive effect on the evaluation of the Compaq brand. The product-positive announcement (80286 accelerator board) increased the evaluation of the PC model, as expected, and also raised the evaluation of the 256 RAM-memory attribute. The industry-positive announcement (statistical package availability) had no effect on the evaluations of any of the microcomputer attributes. In general, these results support the prediction that announcements have the greatest effect on brands and products directly referenced in the communication (Proposition 5).

DISCUSSION

This research examined the impact of product-related announcements on consumers' purchase intentions for the various brands of a product. In the battle for market share, the key question is, "Can product-related announcements shift the balance of market share equilibrium? Can product-related announcements be used as a strategic tool to influence consumers' purchase intentions for the brands of a product?"

The reported results indicate that product-related announcements can be used to influence consumer behavior. The analyses further suggest that, by means of an announcement, a competitor can affect intentions to purchase a brand or a set of brands if that brand or brands are included in the consumer's choice set. Furthermore, since product-related announcements can influence certain brands more than others, they can be designed to woo customers from competitors in order to command a competitive advantage in the marketplace.

The results are also consistent with the considerable literature indicating that people tend to weight negative information more heavily than positive information in product judgments. Consumers may find negative announcements to be more novel, distinctive, and interesting than the positive information (cf. Fiske 1980, Kanouse 1984). As a result, they may pay more attention to negative announcements, using them to screen out undesirable alternatives.

Limitations

The six announcements used in this study reflect actual developments in the microcomputer industry. While this increased the external validity of the study, it may have reduced the study's internal validity. As noted earlier, a pretest was conducted with both MBA students and industry experts to establish the perceived direction and referent of the announcements. However, the announcements may have differed in strength. As a consequence, the negative and industry announcements may have produced greater effects than the positive and brand announcements because they represented more significant developments in the microcomputer industry. The present findings should therefore be replicated with a broader range of announcements, pretested and selected to be of equivalent strength. Another valuable extension would be to independently manipulate the reference object and content of the announcement, so that the separate effects of these factors can be estimated. To avoid possible carryover effects across announcements, future research should insert a distractor task between the sequence of announcements/ratings, or use a between-subjects design.

A second limitation regards the short time interval between consumers' exposure to announcements and their brand judgments. Although the results suggest that purchase intentions can be influenced by means of product-related announcements, from the competitive strategy point of view, the question is can this influence be

sustained? How does the length of effect vary by the nature of the product-related announcement defined both in terms of its direction and its referent?

A third consideration is the study's sample of MBA students. Considerable effort was made to ensure that the selected product was relevant for the sample and that the sample size was sufficient to detect the effects of the within-subject manipulations (Ferber 1977). A controlled laboratory experiment with a relatively homogeneous sample is appropriate for the evaluation of the five theoretical propositions (Calder, Phillips, and Tybout 1981). However, a field experiment with a larger, representative sample would be necessary to generalize the descriptive results on brand purchase intentions, attribute importance, and the absolute size of the announcement effects.

Future Directions

The reported study presents several opportunities for future research. This paper has examined the effects of various types of product-related announcements on consumer behavior. The source of the announcements, company reactions, and audience characteristics were not manipulated. Yet, prior research indicates that these factors may moderate the announcement effects.

The communication literature suggests that the message source will interact with message content to determine the overall impact of an announcement (cf. Eagly, Wood, and Chaiken 1978, Mizerski 1982). Spence (1974) contends that large selling organizations will acquire and maintain reputations for the accuracy of their product-related announcements. By correctly signaling forthcoming events, firms can establish high signaling credibility and thereby enhance their future abilities to communicate to and influence consumers and competitors. Conversely, manufacturers can hurt their reputations by communicating false signals. For example, some software manufacturers are noted for missing deadlines and have developed reputations for marketing "vaporware." Signaling reputations are less likely to be a factor when there are a large number of signalers and any one will not be on the market for a long period (Spence 1974, p.107).

The receiver's interpretation of and response to the announcement may also depend on the accounts or explanations offered by the firm. Some announcements put the firm in a predicament because they are embarrassing, undesirable, illegal, antisocial, or disruptive. Accounting is the firm's attempt to describe or interpret the product announcement and its consequences in desirable terms (cf. Schlenker 1978). Schlenker (1978) discusses two types of accounts: excuses and justifications. "Successful excuses allow one to escape from the predicament by minimizing personal responsibility, while successful justifications allow one to escape by minimizing the aversive consequences" (Schlenker 1978).

Likewise, if the announcement reflects positively on a firm, the firm may attempt to

increase its association with or responsibility for the announcement through acclaiming (cf. Schlenker and Schlenker 1975). Two common acclaiming tactics are "entitling," where the company attempts to increase consumers' perceptions of its responsibility for the desirable action or its consequences, and "enhancements," which involve attempts to increase the apparent positivity of the action's consequences (Schlenker 1978). These responses may increase consumers' favorability towards the firm's brands.

Finally, consumer response to product-related announcements is likely to depend on consumers' past experiences and beliefs. The higher the discrepancy between the product announcement and the receiver's prior beliefs and the higher the level of product involvement, the greater the likelihood of message rejection (Sherif and Sherif 1967). As noted earlier, consumers learn and revise their beliefs through feedback on the accuracy of market signals (Spence 1974). This will affect their future responses to product announcements.

Consumer Expertise and the Feature-Positive Effect: Implications for Judgment and Inference

Frank R. Kardes, University of Cincinnati
David M. Sanbonmatsu, University of Utah
Paul M. Herr, Indiana University

ABSTRACT

Several recent experiments have shown that people tend to overlook nonoccurrences and missing information ("out of sight, out of mind") even when such nonevents have important implications for judgment and choice. This phenomenon is known as the feature-positive effect. The present experiment indicates that consumers are more likely to overlook missing attribute information as expertise decreases. Implications of the results for consumer judgment and inference are discussed.

THE FEATURE-POSITIVE EFFECT

Time constraints and limited resources often force consumers to make product-related judgments and decisions on the basis of incomplete information. Moreover, advertisements, package labels, consumer magazines, and other sources of information typically focus on only a few product attributes. How do consumers deal with partial information? Some studies suggest that consumers form inferences about unmentioned attributes and that these inferences are integrated with judgments of known attributes to arrive at an overall evaluation (Ford and Smith, 1987; Huber and McCann 1982; Johnson and Levin 1985; Meyer 1981), whereas other studies imply that consumers fail to form inferences about unmentioned attributes (Lim, Olshavsky, and Kim 1988). The present experiment focuses on the ability of consumers to detect the absence of information about product attributes. Logically, consumers must first realize that information about an important attribute is missing before they can infer a value for that attribute.

When is missing information overlooked? Jenkins and Sainsbury (1969, 1970) found that discrimination learning in pigeons occurs much faster in the presence than in the absence of a predictive cue, even when the absence of the cue is as informative as its presence. They labeled this phenomenon the *feature-positive effect*. Newman, Wolff, and Hearst (1980) demonstrated that this effect generalizes to people. In this study subjects were shown a series of cards containing two three-letter strings, a target string and a distractor. In feature-negative conditions, the critical feature was the absence of the letter "T." Performance feedback was presented after each trial, and, as anticipated, the problem was solved in fewer trials in feature-positive than in feature-negative conditions.

Research in areas other than discrimination learning also suggests that people experience difficulty in processing nonoccurrences. For example, when attitudes are weak or nonexistent, people use their own overt behaviors to draw inferences about their attitudes (Bem 1972).

However, nonbehaviors (e.g., not laughing at a cartoon) tend to be overlooked (Fazio, Sherman, and Herr 1982; Allison and Messick 1988). Furthermore, in hypothesis testing, people tend to test cases that are expected to possess the property of interest (the *positive test strategy*) rather than on cases that are expected to lack the property (Klayman and Ha 1987). In covariation judgments, people focus on cases where the expected cause and the expected effect are both present (the *positive-positive cell*) rather than on cases where one or both events are absent (Bettman, John, and Scott 1986; John, Scott, and Bettman 1986). Finally, production and R&D departments often use checklists or fault trees to troubleshoot a system. Items that are not on the list, however, tend to be overlooked (Fischhoff, Slovic, and Lichtenstein 1978; Hirt and Castellan 1988).

THE ROLE OF EXPERTISE

When are consumers unlikely to overlook missing information? One factor that is likely to influence sensitivity to omissions is expertise. In their comprehensive review, Alba and Hutchinson (1987) defined expertise as "the ability to perform product-related tasks successfully" (p. 411) and they discussed how experts and novices differ on five important epistemological dimensions: cognitive effort, cognitive structure, analysis, elaboration, and memory. Analysis, or the extent to which attention is directed towards all and only important information, is particularly relevant to the present study. If sensitivity to important information increases as expertise increases (Brucks 1985; Furse, Punj, and Stewart 1984; Johnson and Russo 1984), then sensitivity to omitted important information should also increase with expertise.

THE PRESENT STUDY

Subjects received an incomplete description of a fictitious ten-speed bicycle. Information about two important attributes, the weight of the bicycle and the strength of the frame, was deliberately omitted. Following Sujan (1985), a subjective measure and a ten-item multiple-choice questionnaire was developed to assess expertise about bicycles. Subjects were divided into low, moderate, and high expertise groups on the basis of their scores on these measures. In addition, half of the subjects received a prompt to consider the weight of the bicycle and frame strength when evaluating the bicycle and half received no such prompt.

Evaluative judgments and confidence judgments served as the primary dependent measures. It was reasoned that if subjects spontaneously detected the absence of information about weight and

frame strength that the prompt manipulation would have no effect on these judgments. Thus, if experts have a greater ability to recognize the absence of important attribute information, their product evaluations and their confidence ratings should not differ as a function of the prompt manipulation. Moreover, because of the uncertainty generated by the lack of information about these important attributes, experts should exhibit less extreme evaluations and lower confidence ratings, relative to less expert subjects.

The prompt manipulation should have a strong impact on the judgments of moderately knowledgeable subjects. If these subjects are insensitive to important omissions, incomplete information would seem relatively complete. When people treat incomplete information as if it were complete, they are likely to form polarized evaluations and they are likely to hold these extreme judgments with a high degree of confidence. By contrast, when a prompt forces them to consider information that otherwise would have been overlooked, less extreme and less confidently-held judgments should be formed.

Finally, novices are less able to identify and use important information (Alba and Hutchinson 1987). Thus, even if a cue highlighting the absence of important information is presented, they are unlikely to see the evaluative implications of this cue. Hence, the prompt manipulation should not influence the judgments of novices. Relatively extreme and confidently-held judgments should be formed whether or not the prompt is presented.

METHOD

Procedure

One hundred thirty-one male undergraduates were asked to participate in a study concerning how people evaluate products. They were asked to read a description of a ten-speed bicycle (Brand A) that was based on a "study conducted by a popular magazine for bicycle enthusiasts." They were given two minutes to read the description and were instructed to form an impression of the bicycle. Afterwards, the description was taken away and a questionnaire was administered.

Stimuli and Measures

The description of the Brand A ten-speed bicycle contained information pertaining to six important product attributes: braking, shifting, cornering, wheels, styling, and comfort. Information about two important attributes, the weight of the bicycle and the strength of the frame, was omitted. The presented attributes were described very favorably and care was taken to present attributes that were subjectively unrelated to the other presented attributes and to the unmentioned attributes. All subjects received the exact same product description.

Product evaluations were measured on three nine-point semantic differential scales anchored at -4 and +4, with endpoints labeled bad/good,

unsatisfactory/satisfactory, and unfavorable/favorable. These ratings were averaged to form a single product evaluation index. Subjects indicated their confidence in their evaluations on a scale ranging from 1 (Not at all confident) to 9 (Highly confident).

RESULTS

Product Evaluations

Alerting subjects to the fact that important attribute information is missing should affect their evaluations only if they failed to detect the absence of this information spontaneously, and if they are knowledgeable enough to understand the implications of the missing attributes. Thus, prompting should influence only moderately knowledgeable subjects. As predicted, moderately expert subjects formed more favorable evaluations in no prompt than in prompt conditions. In contrast, prompting did not influence the evaluations of low or high expertise subjects.

Confidence Judgments

It was predicted that the prompt manipulation would influence confidence judgments as well as evaluations. Again, prompting should influence only moderately knowledgeable subjects. Consistent with this prediction, moderately knowledgeable subjects had greater confidence in their evaluations in no prompt than in prompt conditions. In contrast, prompting did not influence the confidence judgments of low or high expertise subjects. Hence, considered together, the product evaluation and confidence judgment data indicate that experts are sensitive to omissions, whereas less knowledgeable individuals overlook important missing information.

DISCUSSION

The ability to recognize the absence of important attribute information plays a key role in consumer judgment and inference. In the present study, novices and even moderately knowledgeable individuals consistently overlooked important omitted information. When important information is overlooked, extreme, confidently-held judgments are formed. Experts, on the other hand, spontaneously detect the absence of important information and form more moderate judgments.

Research in several paradigms has shown that people often overlook missing information. These paradigms include discrimination learning (Jenkins and Sainsbury 1969, 1970), concept identification (Newman et al. 1980), self-perception (Fazio et al. 1982), false consensus (Allison and Messick 1988), hypothesis testing (Klayman and Ha 1987), covariation assessment (Bettman et al. 1986, John et al. 1986), and problem solving (Fischhoff et al. 1978, Hirt and Castellan 1988).

The results of the present study suggest that expertise should moderate sensitivity to omissions within each of these paradigms. This proposition should be tested directly because other moderating

variables are also likely to be implicated. For example, some product attributes may be too important to be overlooked (e.g., price). Further, more extensive analytic processing is likely as time pressures decrease and as concern about the consequences of inferential errors increases (Kruglanski 1989, Kruglanski and Freund 1983).

Overconfidence

People are frequently overconfident about the validity of their judgments (Einhorn and Hogarth 1978; Fischhoff and Beyth-Marom 1983; Lichtenstein, Fischhoff, and Phillips 1982). Several explanations for overconfidence have been offered, including (a) people often receive incomplete feedback about the consequences of their decisions (e.g., after purchasing one brand from a set of alternatives, little is known about the performance of alternatives not chosen), (b) people tend to seek information that confirm their expectations, (c) confirmatory evidence is more accessible from memory, and (d) judgments influence and are influenced by outcomes (e.g., self-fulfilling prophecy). However, consumers are often unaware of the reciprocal relation between judgments and outcomes. Finally, our results suggest (e) that insensitivity to missing information leads consumers to treat incomplete information as if it were complete. When consumers believe they know more than they actually do, overconfidence results.

Inference Formation

The results of the present study also have implications for an apparent inconsistency in the consumer inference literature. Huber and McCann (1982) found that when explicitly presented attributes are subjectively related to omitted attributes, consumers spontaneously form inferences about omitted attributes. However, Lim et al. (1988) recently failed to replicate Huber and McCann's results. Lim et al. found that inferences were formed when consumers were explicitly asked to do so, but no evidence for spontaneous inference formation was found. The present results indicate that consumers are more likely to notice omissions as expertise increases. Because consumers must first detect omissions before they can draw inferences about these omissions, the likelihood of spontaneous inference formation should increase as expertise increases. If Huber and McCann's student subjects were more knowledgeable about their target product (beer) than Lim's et al. were about theirs (automobiles), spontaneous inference formation would be more likely in the Huber and McCann study.

To summarize, the results of the present study indicate that the ability to detect the absence of important information increases as expertise increases. Consumers who are sensitive to omissions form less extreme judgments and are less likely to exhibit overconfidence. Furthermore, the ability to detect and identify missing information is likely to serve as an important precondition for

spontaneous inference formation. Consumers must notice the gaps before they can fill them.

The Effects of Expertise on Preference and Typicality in Investment Decision Making

W. Steven Perkins, Penn State University
Valerie F. Reyna, University of Arizona

ABSTRACT

Preference is positively correlated with typicality in many product categories. As expertise increases, however, preference and typicality may change as well as the relationship between them. In this study of investment decision making, the strength of the correlation between preference and typicality decreased as subjects' expertise increased. In addition their ratings of preference and typicality differed by level of expertise. Two approaches were used to measure expertise--one cognitive measure and one experiential. This article presents an explanation of the results and a discussion of their implications.

INTRODUCTION

Alba and Hutchinson (1987) have hypothesized that, "Brand choices are less influenced by prototypicality for experts than for novices, except when prototypicality or atypicality is valued for its own sake (p. 418, hypothesis 2.9)." They suggest that as consumers gain experience the relationship between product preferences and product typicality changes. Novices' choices may be based upon whether a product is a good example of its product category while experts discriminate between products on more functional attributes.

This research builds upon two major areas in cognitive psychology that relate to decision making. The first pertains to typicality--how well an object represents its cognitive category (Rosch 1975, 1983). The second area concerns the effects of expertise. Experts think differently not only because they know more, but also because they organize and use their knowledge better (Chi 1983).

After reviewing the relevant literature, three hypotheses are proposed. An exploratory study is used to examine these hypotheses. The remainder of this article describes its results and discusses the implications, limitations, and goals for future research.

Typicality and Preference

Categorization is the process of forming classifications by which nonidentical stimuli can be treated as equivalent (Rosch and Mervis 1975). According to Rosch, objects in the same cognitive category may differ in terms of typicality (or prototypicality), meaning that some objects represent the grouping better than others. Objects in a category lie on a gradient of typicality, ranging from extremely good examples to very poor examples of the category (Barsalou 1985). Prototypical members of a category serve as reference points to which other category members can be compared (Rosch 1975, 1983) and prototypes are usually learned first (Mervis and Rosch 1981). Differences in typicality have been noted in both

natural object categories, such as fruit (Rosch and Mervis 1975), and product categories, such as snack food (Ward and Loken 1986). A competing but similar theory of categorization argues that category membership is based upon comparison to specific, retrieved instances, or exemplars, rather than abstracted prototypes (Medin 1983).

Typicality can be an important factor in product preference and choice. Nedungadi and Hutchinson (1985) asked students to rate the prototypicality of several magazines and beverages, then rate how much they liked each product. After aggregating the responses across all subjects, they found a strong positive relationship ($r > .60$) between liking and prototypicality. Loken and Ward (1987) also obtained a high positive correlation ($r = .88$) between typicality ratings and attitudes toward brands of shampoo. These results are in contrast to Rosch (1973) who found a weak relationship in natural object categories. One explanation for these differences could be that consumers construct product categories "ad hoc" in order to satisfy the goal of evaluating and purchasing a product (Barsalou 1983). Thus, affect may play a much more important role in structuring functional, product categories than natural object categories used in much of the original categorization research (Cohen 1982). Natural categories structure our perceptual experience without regard to preferences.

Effects of Expertise on Preference and Typicality

The second theoretical underpinning for this research concerns expertise. After extensive research (see Alba and Hutchinson 1987), it appears that experts organize their knowledge hierarchically by purpose as compared to novices who organize data linearly in discrete bits by attributes. Expert and novices appear to use the same types of problem solving heuristics and search methods (Chi 1983). Instead, expert performance is due to organizing their knowledge on the basis of domain relevant functionality. Novices, on the other hand, tend to organize their knowledge about a domain at a perceptual level.

As the organization of knowledge changes with increasing expertise, the relative typicality of products as well as the use of typicality in decision making may also change. Prototypical objects are learned first, but the level of perceived prototypicality for an object differs by an individual's level of familiarity with the domain (Hermann and Kay 1977). One experiment (Murphy and Wright 1984) found that as people know more about an area (in this case psychiatric diagnosis), the simple, black and white distinctions and definitions blur into fuzzier, generalities. Framed in terms of typicality, the experts based their decisions

upon factors other than stereotyped, prototypical knowledge.

Also as expertise increases, experts not only know more products they know more about efficiently and effectively choosing products. Bettman and Park (1980), for example, found that novice microwave buyers based their decisions on a brand they "had heard of," rather than evaluating brands on their attributes. Preference depended solely upon availability in memory. Novices represent objects at a superficial level as compared to a deeper structure level (Chi 1983). As noted by Alba and Hutchinson (1987), mere familiarity, the number of experiences accumulated by a consumer, is not the same as expertise, the successful performance of tasks. Expertise requires familiarity, but familiarity does not guarantee expertise.

In summary, the objects in cognitive categories differ in terms of typicality. Preference correlates positively with typicality in many product categories. As expertise increases, the organization of knowledge in memory becomes more functional, and processing becomes less superficial. Also as experience increases, atypical examples and instances are encountered and stored in memory. Thus, the influence of typicality diminishes in decision making and choice, resulting in a weaker link between preference and typicality.

THE STUDY

As expertise increases, consumer preferences are less influenced by product typicality (Alba and Hutchinson 1987). The objective of this research is to examine three aspects of that statement. Specifically, it is hypothesized that:

- H1: Product preference will differ by level of expertise.
- H2: Product typicality will differ by level of expertise.
- H3: Preference and typicality will be positively related, but the strength of the relationship will decrease with expertise.

To test these hypotheses, data were gathered from a domain in which subjects could be expected to differ in knowledge and experience: personal investments. A category such as investments is actively, even voluntarily learned, as compared to natural object categories or even common product categories. Most previous empirical research on investment decision making (Cooley 1977; Soutar and Ascui 1980) has not specifically considered the effects of expertise, though Slovic (1972) compared the decision strategies of one novice and one expert stock broker.

An overview of the tasks and derived measures follows:

Task:

1. Unaided recall of investments
2. Sort 18 investments

3. Rate 18 investments
4. Check off ones owned

Measure:

1. # recalled
2. typicality
3. preference
4. # owned

The first task asked subjects to write down all the personal investments they could recall. The remaining tasks involved a set of 18 investments given to the subject. They sorted the investments into groups of similar items, then rated their preference for each and noted whether they had ever owned each one. These 18 investments were selected based upon a previous experiment in which 60 MBA students listed all the investments they could recall. The 18 most frequent examples were used in the present experiment.

Subjects and Administration

A total of 40 people completed usable questionnaires. One half were undergraduate students, mostly seniors, in an upper division math class. They were expected to be relatively naive about investments. The other respondents had completed at least a bachelor's degree. This second group included both part-time MBA students and other non-students, many of whom worked on a day to day basis in the investment field. These financial employees included a commodities broker, international money trader, vice president of finance and others considered experienced in investments. The questionnaire was administered individually, or in small groups, to these subjects because of the difficulty of gaining access to them. Although the administration of the questionnaire varied somewhat across the groups, the study required gathering data from "real world" experts as well as novices.

Measures and Procedure

On the first page of an eight page questionnaire, subjects wrote down all the personal investments they could recall in a 2 minute time period. Subjects had no previous exposure to the stimuli and no warning as to the task, thus it required them to search their knowledge base to recall examples. This page was then returned to the experimenter. For the first measure of expertise, the total number of investments recalled was calculated, regardless of whether the example recalled was included in the target list of 18 investments. The average subject recalled 10.5 investments, with a range from 4 to 21. In previous research, the total number of factors recalled by a subject has been employed as a measure of expertise, under the assumption that it corresponds to the "richness of the cognitive process undertaken by the individual in this specific problem area (Larache and Moinpour 1983)." Also the examples recalled were later matched with the 18 investments used in the latter part of the study to ensure that the stimuli covered the majority of the investments recalled by

subjects. The 18 prespecified investments captured almost 75% of the investments mentioned during free recall. Of the 25% mentioned but not subsequently encountered in other tasks, many were redundant or unusual items.

The remaining pages of the questionnaire were then completed at each subject's own pace with most finishing in less than 15 minutes. The second page of the questionnaire gave an overview and instructions for the remaining tasks. For the second task, subjects received an envelope containing 18 pieces of paper with the name of an investment on each one. Subjects were told to sort them into separate piles based upon what they considered similar types of investments. Then within each sort group, they arranged them from the best example of that type of investment to the poorest example. Subjects recorded their sorting results on another page. The measure of typicality derived from the sorting results considered the relative position of an investment in its sort group, specifically:

$$\text{Typicality} = \frac{\text{total \# of items in the sort group} - \text{order in the group}}{\text{total \# of items in the sort group} - 1}$$

With this formula, typicality is scaled so that the first investment in a group equals 1 and the last equals 0. For example, in a group of four items the typicality scores would be 1, .66, .33, and 0. If a sort group consisted of only one investment, it was given a typicality score of 1. Sorting provides a less direct, but possibly more valid, approach to measuring typicality than the rating methods used in previous work. Subjects may find it difficult to separate product preference and typicality when asked to rate both on the same type of scale (e.g., Loken and Ward 1987; Nedungadi and Hutchinson 1985).

In the third task, subjects rated their preference for each of the same 18 investments on a scale from 0 (not preferred at all, would not invest in it) to 10 (totally preferred, my ideal investment). The question sought to measure their likelihood of investing rather than the amount of money they would invest. Ratings were later converted into z scores by individual in order to make them more comparable across subjects.

For the last task, respondents checked off which of the 18 investments they had owned or anyone in their household had owned. For the second measure of expertise, the total number of investments owned was calculated. The average subject owned (or their household owned) 7.8 of the investments with a range from 0 to 16. This measure of expertise was based on the same assumption used in previous research that expertise increases with greater frequency of purchase and use (e.g., Bettman and Park 1980).

Finally, subjects answered several demographic questions concerning their age, number of children, and annual household income. Two additional questions asked for their self-rated level of knowledge about investments and the amount of

time they spend working on investments. These two questions used a 5 point scale increasing from very little (1) to a great deal (5).

RESULTS

The four major measures are summarized in Table 1: the mean preference rating and typicality score for each investment, and the percentage recalling and owning each investment. Considering "shares of stock," for example, 88% of the subjects recalled it and 70% owned it, while it received an above average (positive) preference rating and a relatively high typicality score. "Oil and gas partnership," for instance, was much lower on every measure. At this aggregated level, mean preference and mean typicality correlated positively ($r=.57$, $p=.01$) as expected.

The first two hypotheses state that preference and typicality will differ by level of expertise. Using the total number recalled and the total number owned as measures of expertise, a multiple analysis of variance (MANOVA) was performed over the 18 preference ratings and over the 18 typicality scores. Table 1 indicates that both did differ by the number of investments recalled by a subject, typicality differing to a somewhat greater extent ($p<.01$) than preference ($p<.04$). The number of investments owned by a subject also significantly differentiated between typicality scores ($p<.04$) but not preferences ($p<.22$). Both H1 and H2 are confirmed, though the number of investments recalled was a more fruitful measure of expertise than the number owned. Because the questionnaire was administered differently to undergrads and others, the same MANOVA analyses were performed using method of administration as the explanatory variable. As expected, neither preferences ($F = 0.85$, $p<.63$) nor typicality ($F = 1.23$, $p<.32$) differed by method.

The third hypothesis suggested that preference and typicality will be positively related but that the size of that correlation will decrease as expertise increases. By individual, preference and typicality were correlated, resulting in a median Pearson coefficient of .19 indicating a positive but weak relationship. A positive coefficient occurred for 75% of the subjects, but only 23% had a positive, significant coefficient ($r>.31$, $p<.05$, $n=18$). Thus, for the majority of subjects preference and typicality correlated positively, though the coefficients ranged widely from $-.49$ to $+.62$.

To detect changes in this relationship between preference and typicality with changes in expertise, the Pearson correlation was regressed on each of the measures of expertise. As shown in Table 2, the sign of the regression coefficient for both measures of expertise is negative and significant, indicating that the size of the correlation between preference and typicality decreases as expertise increases. By both measures of expertise, H3 is confirmed. (A Fisher r to z transformation was made on each Pearson correlation coefficient before regressing on expertise).

Finally, because much of this research hinges on the concept of expertise, the validity of the two

measures of expertise should be considered. The number of investments recalled and the number owned correlated .57, signifying that the two are relatively similar. In addition, each can be correlated with the demographic and self-rating data from the end of the questionnaire as shown in Table 3. (These data were considered ordinal, necessitating a Spearman correlation.) The results have strong face validity, especially for the number of investments owned. As the number owned increased, subjects were older, had more children, had a higher income, were less likely to be undergraduates, rated themselves as more knowledgeable, and spent more time on investments. Of course, many of these factors are highly related themselves. The number recalled differentiates less well, though the results were in the same direction.

CONCLUSIONS AND IMPLICATIONS

Based upon this research in the domain of investments, it appears that both preference and typicality do change with expertise. In addition, preference and typicality were found to be positively related in the majority of subjects. This is in accord with previous research which has found a positive relationship between preference and typicality (Nedungadi and Hutchinson 1985). One aspect this current research contributes is the finding that the strength of this relationship decreases with expertise. Thus, it seems that novices' preferences are tied more closely to judgments of typicality (and/or vice versa), while experts' preferences are based upon other factors, possibly risk and return.

Limitations to this research should be addressed. First, the method for measuring typicality assumes a linear, equal-interval relationship between the objects in a sort group. Instead, the graded category structure might be non-linear, with objects clustered together according to their similarity (Barsalou 1983). The measure employed in this paper should also be compared with the results derived from a more direct rating of typicality. Second, the measures of expertise, though employed in previous research, did not perform consistently across the analyses. For example, the number of investments owned by the subject or their household did not differentiate

between preference ratings but it did correlate as expected with the demographic data. The number of investments originally recalled measures the individual's level of cognitive complexity and thus probably more closely approximates expertise. Third, though the primary purpose of the research was to investigate the changing relationship between typicality and preference, measures of investment risk propensity would also have been an interesting parallel question. Risk influences preferences for different investments, but also may influence or even be a part of typicality.

The research has implications for both marketing and decision making. Very typical objects in a category may serve as cognitive reference points in decision making. Rosch (1983) argues that judgment can be based on formal logical reasoning or on reference point reasoning. The latter type of reasoning, though relatively primitive, occurs quite often and can be valid. In a risky class of decisions, such as investments, logical thinking may play a more important role, especially for experts. In many product classes the difference between a novice and an expert is inconsequential. But in a complex product class the degree of familiarity can greatly influence an individual's ability to make reasonable decisions. First time buyers of cars, computers, and homes face an enormous amount of information. With little cognitive structure developed to hold the new information, they may rely on intuitive heuristics such as reference points in making decisions.

Future research could investigate methods for improving decision making and the resulting effects on the relationship between preference and typicality. Can we teach novices to make decisions like experts? Most research to date has concentrated on judgmental mistakes (Kahneman, Slovic, and Tversky 1982) with little said about training decision makers. The next phase of research on expertise should explore the means to improve decision making abilities.

Information Examination as a Function of Information Type and Dimension of Consumer Expertise: Some Exploratory Findings

Akshay R. Rao, University of Minnesota¹
Eric M. Olson, University of Minnesota

ABSTRACT

This paper reports on a study designed to examine information search patterns of differentially familiar subjects. The theoretical rationale predicts different patterns of search depending on whether subject familiarity is measured on terminology, attribute, or marketplace related factors and whether subjects have the option of searching for either intrinsic or extrinsic information. Using an electronic environment in which student subjects responded to personal computer based stimuli, it was found that terminology and attribute based familiarity generated "U-shaped" information search patterns for extrinsic information, while marketplace based familiarity generated a hyperbolic search pattern for intrinsic information.

INTRODUCTION

Existing theories of buyer behavior (Bettman 1979, Howard and Sheth 1969) have proposed that the degree of prior knowledge (or expertise) a consumer has about a product, product class, the marketplace and a variety of other facets of the purchasing process is likely to influence information search, examination, evaluation, and eventually, choice. This issue of consumer expertise or familiarity has recently received considerable scrutiny in the consumer behavior literature (Alba and Hutchinson 1987, Brucks 1985, Johnson and Russo 1984, Park and Lessig 1981, Punj and Staelin 1983, Rao and Monroe 1988, Sujan 1985). The principal issues of interest are a) the dimensions of consumer expertise and b) the influence of differential levels of expertise on behavior.

This paper will describe findings from an exploratory study that examines the relationship between various dimensions of expertise and consumers' information examination patterns. As the study was conducted in an electronic environment using personal computers, it was possible to use unobtrusive measures and disguise the purpose of the study quite effectively.

LITERATURE REVIEW

Expertise and Information Examination

Differentially knowledgeable consumers are expected to behave differently when searching for new information primarily because they have different amounts of information already available in memory. Studies that have examined this issue have essentially used single item measures of subjective

knowledge and examined the relationship between knowledge and degree of information search.

Two conflicting hypotheses inform the research stream. On the one hand, it has been argued and empirically validated that increased familiarity leads to enhanced search (Punj and Staelin 1983). This, the enrichment hypothesis, rests on the logic that existing knowledge facilitates the acquisition of new information -- a "rich get richer" argument. The second hypothesis predicts an "inverted U" effect, as increased familiarity results in an initial increase in information search; however exceedingly familiar individuals do not need to acquire new information as all relevant information is already available in memory (Bettman and Park 1980, Park and Lessig 1981). The essential difference in predictions between the two hypotheses is at the high familiarity level. While *low* and *moderately* familiar individuals are expected to search for low and moderate amounts of information according to both hypotheses, the *high* group is expected to search more than (or at least as much as) the moderate group according to one hypothesis (the enrichment hypothesis), while it is expected to search less than the moderate group according to the inverted U hypothesis.

To reconcile these seemingly conflicting perspectives, Rao and Monroe (1988) proposed information diagnosticity as a moderating variable. They argue that different items of information are differentially informative. Using the *extrinsic* versus *intrinsic* cue dichotomy (Cox 1962, Olson 1977) they hypothesize that differentially familiar individuals will rely on different types of information, depending on the degree to which the information is useful for the task at hand. Specifically, when assessing product quality, moderately and highly familiar consumers were expected to use intrinsic information (information directly related to product performance, e.g., nutritional content in cereal) to a greater degree than low-familiar consumers, because low-familiar consumers would be unable to interpret intrinsic information successfully. This prediction is analogous to the enrichment hypothesis. The degree to which low-familiar consumers would use extrinsic information (information not directly related to product performance, e.g., price or brand name) was hypothesized to be higher than the degree to which moderately familiar consumers would use extrinsic information. This was expected to occur because, while both groups could interpret extrinsic information successfully, the moderate group would prefer to use information already available in memory. However, whether highly familiar consumers would use extrinsic information to a greater or lesser degree than moderately familiar consumers was hypothesized to depend on whether

¹The first author gratefully acknowledges funding for this project from the Graduate School, University of Minnesota.

the item of extrinsic information was *diagnostic* for the task. In other words, in an evaluative situation, brand name or price (both extrinsic cues) may or may not be accurate indicators of quality. If they are good indicators of quality, the highly familiar consumer would know so and therefore use them, not otherwise.

In a price-quality experiment using a product that displayed a positive price-quality correlation in the marketplace, Rao and Monroe (1988) showed that as familiarity increased, reliance on extrinsic cues first reduced then increased (a "U-shaped curve") while reliance on intrinsic cues increased with increased familiarity.

The principal argument seems to be that only information that is interpretable and believed to be (or known to be) useful for the task at hand, will be examined. This argument will be revisited after an examination of the construct "expertise".

Dimensions of Consumer Expertise

According to Alba and Hutchinson (1987) and Brucks (1986), consumer expertise is comprised of multiple dimensions. Brucks (1986) developed a typology of consumer knowledge consisting of eight components. Seven of these knowledge types are declarative in nature, e.g., knowledge about concepts, objects or events. The eighth is procedural in nature and refers to those rules consumers utilize when taking action. She reduced these components into three factors which can be conveniently labelled as follows: terminology related knowledge, attribute related knowledge and marketplace related knowledge. Note that the first two factors are related to knowledge of intrinsic information, while the third factor is related to knowledge of extrinsic information. *Terminology* related knowledge can be defined as knowledge of terms related to the construction of a product (e.g., overhead cams for an automobile). *Attribute* related knowledge can be defined as knowledge of the relationship between a term and another term or the relationship between a term and a benefit (e.g., 4-wheel drive in an automobile results in better traction in snow.) *Marketplace* related knowledge can be defined as knowledge of relationships that prevail between extrinsic information and other extrinsic information (e.g., BMW automobiles are above average in price).

The multi dimensional nature of the construct calls into question whether differential degrees of familiarity on each of the dimensions will result in similar information search patterns. The argument that information examination patterns are likely to be different will be developed in the next section.

CONCEPTUAL PREDICTIONS

The existing literature suggests that differences between the low, moderate and high familiarity groups are qualitative, as well as quantitative. In other words, moderately familiar consumers are more knowledgeable than low-familiar consumers about elements that low-familiar consumers are cognizant of, as well as elements

about which low-familiar consumers are unaware. Similarly, highly familiar consumers are more knowledgeable than moderately familiar consumers about elements that moderately familiar consumers are cognizant of, as well as elements about which moderately familiar consumers are unaware. Rao and Monroe 1988 argue that the qualitative difference between the low and moderate groups is knowledge of product attributes (and how they relate to performance); and the difference between the moderate and high groups is the knowledge about market related factors (and how they relate to quality). Their argument is that, to evaluate quality, consumers must first learn what attributes are good indicators of quality. Consequently, knowledge that the number of heads on a VCR implies a better VCR has to be learned first, before a surrogate (such as brand name or price) or market related piece of information can be used to assess quality. This enhanced ability (to correlate market-based information with performance) tends to occur *after* the individual has acquired knowledge as to what constitutes quality. However, the use of extrinsic (market related) information by low-familiar consumers occurs because such information is easier to interpret than intrinsic information. In sum, information that is interpretable and informative will be sought and examined.

The argument presented above rests on an intentional learning approach to familiarity. However, if familiarity or expertise can be acquired incidentally, as well as intentionally, it is conceivable that individuals can acquire covariation information such as the relationship between extrinsic information and quality, without first acquiring information about the relationship between intrinsic information and quality. In other words, it is possible to be knowledgeable about the high quality of SONY tape players, without having any knowledge of the specific chips used in the circuitry.

In the context of Brucks's (1986) typology of knowledge content, this distinction between learning paradigms becomes particularly relevant. Clearly, attribute related knowledge (i.e., the degree to which attributes relate to each other or affect performance) cannot be acquired without terminology related knowledge (i.e., the knowledge of the terminology used to describe attributes). However, it is quite conceivable that marketplace related knowledge need not result only after attribute related knowledge is acquired, as performance judgments can be formed based on word of mouth, usage and shopping experience, under the incidental learning paradigm. Consequently, enhancements in each of the three components of familiarity may result in different patterns of examination of different types of information. The specific patterns predicted are addressed below.

When differentially familiar subjects are asked to evaluate the quality of a product (for which, extrinsic information is informative about quality):

P1a: Terminology related familiarity will display a U shaped relationship with extrinsic information examination.

P1b: No relationship is predicted between terminology related familiarity and intrinsic information examination.

Here, low-familiar consumers are expected to be able to interpret extrinsic information and thus examine it. However, as familiarity on terminology increases, reliance on intrinsic information (in memory) would supersede reliance on extrinsic information, hence examination of extrinsic information would reduce. Finally, as familiarity reaches a high level, subjects are expected to be cognizant of the relationship between extrinsic cues and quality, and thus are likely to rely on extrinsic information to a greater degree than moderately familiar subjects. For intrinsic information, the low group will spend little time given their inability to interpret it, while the moderate and high groups will spend little time, as they already have the necessary information in memory.

P2a: Attribute related familiarity will display a U shaped relationship with extrinsic information examination.

P2b: No relationship is predicted between attribute related familiarity and intrinsic information examination.

The relationship predicted in P2 (a and b) is based on the same logic as that for P1. When making quality assessments increasing familiarity on the part of the consumer initially leads to a reduction in time spent on extrinsic information examination. However, subsequent increases in familiarity lead to an enhancement in time spent on extrinsic information examination. This occurs because low-familiar subjects have the ability to interpret extrinsic information and therefore will rely on it. High-familiar subjects *know* this information to be informative and will therefore utilize it. In contrast, moderately familiar subjects do not know this information is informative and will therefore rely on other (intrinsic) information in generating quality assessments. Further, there are no anticipated differences for intrinsic information examination, for the reasons mentioned in support of P1b.

P3a: Market related familiarity will display a hyperbolic relationship with intrinsic information examination.

P3b: No relationship is predicted between marketplace related familiarity and extrinsic information examination.

Here, low-familiar subjects will not be able to interpret intrinsic information. However, moderately and highly familiar subjects *do not have*

intrinsic information in memory. Consequently, given their better developed knowledge structures, they will tend to examine intrinsic information to a greater degree than low-familiar subjects (the enrichment hypothesis). However, given their marketplace related knowledge, they would tend to spend relatively little time (like low-familiar subjects) on extrinsic information.

METHOD

To select a product that would lend itself to an examination of the issues mentioned above, a review of prior literature was undertaken. Automobiles (Johnson and Russo 1984), microwave ovens (Park and Lessig 1981) and women's blazers (Rao and Monroe 1988) are some of the products that have been used in this research stream. Given the need to use a product for which there was a subject pool that ranged in familiarity, a woman's blazer was selected as the test product. This product allowed for the use of student subjects comprising males, females, and clothing and textile majors to represent the three groups of low, moderate and high familiarity (Rao and Monroe 1988, Sujan 1985).

A seventeen item familiarity scale was constructed using the typology developed by Brucks (1985) and operationalized in Rao and Monroe (1988). The multiple indicators were representative of the three components of interest: terminology, attributes, and marketplace knowledge.

Data was collected from subjects using a personal computer based methodology (Rao 1988). Subjects responded to stimuli on a computer screen by "clicking" a pointing device on appropriate menu options. Subjects first went through a series of orienting exercises to make them comfortable with the methodology. Then, a battery of items designed to assess their level of familiarity with the product was presented to them and their responses to these items were automatically recorded. Subsequently, in a product evaluation task context, they were exposed to an advertisement comprising a picture-word combination and asked to select further information if they so desired, prior to their evaluation. Unlike Johnson and Russo (1984) who used recall as their dependent measure, and Punj and Staelin (1983) who used self reports of hours spent in search, we measured the time spent in *examining* available information as the dependent variable of interest. [The stimuli, manipulations and familiarity scales are available from the authors.]

ANALYSIS AND RESULTS

Ninety participants responded to sixteen objective questions (and one subjective, self-assessment of familiarity) pertaining to different types of knowledge of women's blazers. Participants were allowed to either immediately make an evaluation of the product, or to access additional information and then subsequently make an evaluation. Half the subjects were exposed to intrinsic information, and half the subjects were exposed to extrinsic information, when they requested more information. (Because it cannot be

determined whether those who elected not to search for more information failed to do so because of expertise and/or high self-confidence, or merely wished to conclude their obligatory time in the study as quickly as possible, their responses were treated as outliers and were not included for further analysis. This left a set of 78 usable responses.) Individual scores based on the three factors were generated and then regressed on the amount of time each individual spent examining information related to the product.

Prior to performing a regression analysis, three independent variables were created by collapsing appropriate familiarity scale items. Thus, measures for terminology related, attribute related, and marketplace related knowledge were created, based on Brucks's (1986) typology.

Regression Analysis

Our intent in this study was to identify patterns of information seeking: an exponential (the enrichment hypothesis) shape or a U-shape. Rather than set arbitrary levels of relative expertise within our study population, and then test for differences between groups, we performed a regression analysis, as our independent variable (familiarity) existed in a continuous form, not a categorical form. The dependent variable was time.

The independent variable consisted of the total value of weighted (by degree of difficulty, as determined by a Professor of Clothing and Textiles)

correct answers to questions associated with each of the three factors mentioned. A relatively high inter-item reliability ($\alpha = .7104$) was obtained.

To test for exponential and quadratic forms (U-shaped), two regression models were run on the data. For the enrichment hypothesis, the appropriate model is hyperbolic:

$$1/y = \beta_0 + \beta_1(1/x).$$

For the U-shape, the appropriate form is quadratic:

$$Y = \beta_0 - \beta_1X + \beta_2X^2 \text{ (Myers 1986).}$$

The results of the regression runs are presented in the Table.

As the results indicate, there is some marginal support for P1 (and P2), and there seems to be some support for P3. The U-shapes are evident for terminology and attribute based familiarity, when examining extrinsic information. No patterns were found for terminology and attribute based information as they related to intrinsic information examination. Similarly, a hyperbolic relationship is manifested between market based familiarity and intrinsic information examination, but no pattern was found for the relationship between this factor and extrinsic information examination. The

implications of these findings are discussed in the next section.

DISCUSSION

The results from this study are interesting, though tentative. Consumers who are differentially knowledgeable about *terminology* exhibit a "U-shaped" information search pattern for *extrinsic* information, with increasing familiarity. In other words, novices and experts tend to spend more time examining extrinsic information, than individuals who are moderately familiar. *Attribute-knowledgeable* individuals exhibit similar (though statistically weaker) results; the negative linear component of the equation suggests that increases in knowledge resulted in reduced time spent but the quadratic component of the model was not significant. *Market-knowledgeable* individuals display a hyperbolic form search pattern; an enhancement in familiarity leads to increased search and examination of *intrinsic* information (the enrichment hypothesis).

The statistical support for these findings is tenuous at best ($p < .10$). Perhaps the addition of a covariate (e.g., reading speed of subjects) would have enhanced the significance of the results. However, from a substantive, as well as methodological perspective, the results are interesting. The principal theoretical contribution of this study is that the coexistence of the inverted U and exponential hypotheses are moderated by a factor other than task (Johnson and Russo 1984) and information diagnosticity (Rao and Monroe 1988), e.g., familiarity dimension. As consumers become knowledgeable about market-based information, they tend to examine intrinsic (product related) information to an increasing degree, while consumers who become knowledgeable about product (attribute and terminology) related information tend to first reduce and then increase their examination of extrinsic information.

The rationale for the findings is theoretically defensible and has been suggested elsewhere (Johnson and Russo 1984, Rao and Monroe 1988). In essence, consumers at the low end of the familiarity continuum are unable to interpret intrinsic information, while those who are moderately and highly familiar are able to do so. Hence, information examination follows a hyperbolic function. In the context of our study, this was manifested in the market-knowledge dimension of familiarity when regressed against time spent on intrinsic information. It was not manifested in the attribute-knowledge or terminology-knowledge and intrinsic information scenarios simply because individuals possessing attribute- and terminology-knowledge would not need to spend much time on attribute- and terminology-related information (intrinsic information); hence, the absence of any trend for those two factors.

For the U-shaped trend for extrinsic information examination, the same logic prevails. Low-familiar consumers, not having much information, would tend to spend time examining

this information, given the interpretability of the information and the evaluative task being performed. However, moderately familiar consumers would tend to dismiss this information as irrelevant to the task at hand, as their better developed knowledge structure would allow for evaluation using intrinsic information in memory. However, highly familiar consumers would examine extrinsic information, if they believed it to be informative. In the case of women's blazers, extrinsic information is indeed informative (Rao and Monroe 1988). Consequently, consumers at the high end of the familiarity continuum would examine this information to a greater degree than moderately familiar consumers, who are not aware of the degree to which extrinsic information is useful in assessing quality. In other words, as consumers become increasingly familiar, they first lower their reliance on extrinsic information, and then increase their reliance on extrinsic information, if this information is useful for the task at hand (Rao and Monroe 1988). This trend would only hold if, as a consumer moves from the moderate to the high condition, his/her enhancement of knowledge results in an understanding of the existing, marketplace (or ecological) correlation between extrinsic information and quality. In other words, the distinction between low and moderate familiarity is knowledge of intrinsic attributes, while the distinction between moderate and high familiarity is knowledge of ecological correlations and marketplace phenomenon. Consequently, this trend should only be manifested for non-marketplace related dimensions of familiarity (i.e., attribute and terminology). *This trend would not be exhibited for the marketplace dimension*, because increasing knowledge on the marketplace dimension would imply increased knowledge about the relationship between extrinsic cues and quality (performance), i.e., any ecological correlations that may exist. Hence, there would be no reason for increasingly knowledgeable subjects to spend any more or less time on examination of marketplace related information.

From the methodological perspective, the use of the personal computer allowed for unobtrusive, involving and refined measurement. The presentation involved both picture and word stimuli and allowed for the development of a credible cover story regarding computerized shopping. Further, the use of a continuous variable allowed for the use of regression and trend analysis, rather than between groups analyses (e.g., Rao and Monroe 1988).

The results from this study are tentative, at best. However, this is the first attempt at testing a specific functional form that is theoretically defensible; consequently the lack of significance at the .05 level is not a source of concern. Apart from replicating this study under other scenarios using different products, it would be of interest to examine the differential reliance on the two types of information available to differentially familiar subjects. In other words, theoretically justifiable functional forms can be derived to predict changes in

relative differences of time spent on different kinds of information, as the degree of familiarity on various dimensions increase. These findings would be of considerable interest to purveyors of information (marketers, consumer advocates, public policy makers) as they attempt to determine what kinds of information their segment of interest should be provided, given their relative knowledge about various aspects of the product, product class and marketplace.

The Meaning of Custom-Made Homes: Home As A Metaphor For Living

C. B. Claiborne, Virginia Polytechnic Institute and State University
Julie L. Ozanne, Virginia Polytechnic Institute and State University

ABSTRACT

Custom-made products are products that are co-created by the consumer and the producer and, thus, offer an opportunity to study the construction of product meaning. The focus of this study is on the process of creating meaning in the building of a custom-made home and the subsequent impact of consumption on this meaning. More specifically, this study examines how consumers encode cultural and personal meaning in the specification and building of a custom-made home and how this meaning changes when they live in the home. Evidence from indepth interviews suggests that both cultural and personal categories of meaning play an important role in the creation of custom-made homes. Consumers encode cultural symbols that have widely shared meaning in the construction of their home. However, symbols that have more personal meaning are also encoded into the homes. The consumer shapes the home in the process of building and living in the home and the home, concomitantly, shapes the consumer's life. In many ways, the home is a metaphor for the consumer's life. This idea of the home as a metaphor for living is developed.

INTRODUCTION

A place need not be exotic in order to serve as a spring-board for discovery...Perhaps it is best to explore the meaning of place at our doorstep (Meyers 1989).

Throughout our lives we make choices and these choices reveal much about who we are. While the choices of love, family, and career are important opportunities for self creation, so too are our consumption choices. Consumption choices pervade almost every aspect of life and impact on the creation of one's self and life. For example, one's image of oneself as a parent may be shaped by the home that one provides for one's family.

Within the marketplace, there exists a wide variety of consumption alternatives in which consumers may express themselves. Yet, in the marketplace, researchers usually study an individual's selection of products among pre-existing alternatives. In McCracken's (1986) article, he suggests that products in the marketplace are a repository for cultural meaning and consumers unlock personal meaning from the product through consumption. Thus, studying the meaning of products selected in the marketplace is the study of the decoding of meaning by the consumer.

Yet consumers are often active and creative beings who do more than merely decode meaning. For instance, custom-made products allow for the encoding of meaning and, thus, the assertion of subjectivity. Therefore, custom-made products may

offer an opportunity to study the active creation of meaning by the consumer and the extent to which cultural or personal meaning is encoded in the product. The interaction between a producer and a consumer in the specification of a custom-made product represents an opportunity to create actively one's self and life.

CUSTOM-MADE PRODUCTS

In consumer research, no work exists that focuses directly on custom-made products or the process of creating these products. Thus, at this stage of research, it is necessary to specify the domain of this topic. While services can be custom-made, the focus of this study is on products. Custom-made products are defined as products that are co-created by a producer and a consumer. The consumer communicates, either implicitly or explicitly, with the producer prior to the creation of the product and, thus, shapes the end product. Next, each part of this definition is explained in detail.

For a product to be custom-made, both the consumer and producer must participate. Thus, a cabinet built by a woodworker for retail sale would not be a custom-made product, but a cabinet built upon the request of a consumer would be. The consumer and the producer may be either an individual or a group. For instance, the town council might commission a specific work of art from an artist. Or a person might hire a group of people to build a home: a head builder, a carpenter, a stone mason, an electrician, and a plumber.

In addition, for a product to be custom-made both the consumer and the producer must shape the product, although their respective influences may vary. The producer's influence is clear, since the producer physically creates the product. But the producer's influence can range from directing the process of co-creation to merely carrying out a consumer's well articulated specifications. The consumer can influence the product by specifying the design, the size, the materials, the process, the time, the symbols, and so forth. However, the consumer's influence may range from just selecting the producer and giving the producer a "free rein" to the consumer specifying almost every aspect of the product. Thus, a consumer buying a "tract" home is *not* an example of a custom-made product because the consumer did not participate in the creation of the home. If, however, a consumer works with an architect to create the house plans and the house is built, then this is an example of a custom-made product.

Finally, some form of explicit or implicit communication between the consumer and producer must occur, although the extent and form of communication may vary. Direct explicit communication regarding the product may occur in personal meetings, phone conversations, sketches,

or letters. But implicit communication may arise, for example, when the producer notices the consumer's previous home, how the consumer lives, how the family interacts, and so on.

In summary, a custom-made product involves a consumer and a producer who together create a product. What is unclear, though, is how meaning is created in this process. McCracken's (1986, 1988b) work offers a conceptual framework for understanding the construction of meaning in a product and is discussed next.

MCCRACKEN'S CULTURE AND CONSUMPTION MODEL

McCracken (1986, 1988b) proposes that product symbolism and consumption are related through a "flow of meaning." Here, meaning is what an object signifies. He submits that meaning originates in a culture, is encoded in products through product design and promotion, and is transferred to individuals through the consumption of these products. First, culture acts as a perceptual screen to define the set of relevant symbols. Second, culture provides a history and sets a context that gives particular symbols meaning. Symbol, context, and meaning are all aspects of the same event and cannot be interpreted independently (Peirce 1960). In other words, a symbol and its meaning depend on the context. Once meaning is encoded in a product, the product symbolizes or comes to stand for that meaning (i.e., BMWs are now synonymous with "Yuppies"). Finally, consumers decode or abstract a personal meaning through the use of products.

Thus, McCracken proposes that meaning is not static but migrates from a culture to the individual by virtue of the acquisition and consumption of consumer goods. He suggests that "ideal" meanings may be displaced from everyday life to products. In other words, goods take on meanings to allow us to bridge the gap between what is "real" and what is "ideal" in social life. For instance, a modern suburban dweller, in longing for a more ideal life style, may choose a "country" interior for her home. Her ideal life style is psychologically related to a past that is perceived as less demanding than the day to day obligations of real life. Her ideal life style is symbolized, and therefore experienced, with each purchase and use of "country" furniture or accessories. This process preserves the ideal self concept through a symbolic displacement of meaning to consumer goods, and the subsequent recovery of that meaning through consumption of those goods. Since the disparity between the real life style and an ideal life style is never resolved, the symbolic displacement of meaning drives a continuous process of consumption.

McCracken offers a theory of a one-way flow of product meaning from the culture to the individual. However, the flow of meaning may be more complex than is depicted in McCracken's model. The flow may be a two-way flow or even a multi-directional flow. For instance, product

innovators or opinion leaders often establish and interpret symbolic product values. Meaning is not always a one way flow from the culture to the individual; that is, individuals may encode meaning. Custom-made products may offer a unique opportunity to study the encoding of both personal and cultural meanings by the individual.

METHODOLOGY

Overview

The purpose of this study was to understand the meaning of custom-made homes and how this meaning is created from the perspective of the owners. Therefore, an interpretive approach was used to study the social and personal meaning of these products from the participant's point of view (Hirschman 1986; Hudson and Ozanne 1988; Lincoln and Guba 1985). In interpretive inquiry, meaning is assumed to be context dependent, thus, in-depth interviews with the owners were conducted in their own custom-made homes. To avoid the researcher imposing structure and direction, these interviews were unstructured and the interviewer took the lead from the informants. Finally, the interviews were tape recorded, transcribed, and the transcriptions were analyzed for emergent themes.

Product

Among the products recognized for their symbolic nature (Belk, Bahn, and Mayer 1982), homes are the object of surprisingly few consumer behavior studies. Consumer research using homes as a product focuses primarily on the acquisition and decision making processes (Park 1982; Munsinger, Weber, and Hansen 1975). Little research exists on the symbolic meaning of home.

As a product, a house represents the single largest purchase a person is likely to make. Similarly, to consumers, the home not only represents the motive for subsequent accompanying purchases (e.g., furniture), but it is also a continuing consumption relationship with the product itself (i.e., living in the home.) Consumption of a home is a daily process that may span decades. Thus, the home is important to the consumer and is an ideal product for examining personal meaning. The dwelling as a product has a functional, tangible part--the house--and an affective, meaningful part--the home. It is the meaning of home that is culturally bound. For example, comfort and privacy, which were 17th century European discoveries (Rybczynski 1986), are not part of the concept of "home" for 20th century Kechi Mayan farmers (Wilk 1986). To the degree that comfort and privacy determine meaning, then home has a different meaning for European and Mayan cultures. Therefore, the home as a research setting provides rich possibilities for exploring cultural symbolism.

From the literature, five categories were identified, which summarize some of the current meanings of home in our culture. These categories draw heavily on the work of Rybczynski (1986) and Csikszentmihalyi and Rochberg-Halton (1981). The

purpose of presenting these concepts was not to operationalize the concepts, as is traditional in a positivist study, but to lay out the researcher's prior beliefs upon entering the study. A goal of the present study is to suggest the relevance and meaning of these concepts for the informants. In other words, the goal was to discover if and how these cultural categories are encoded into the home. The *a priori* cultural categories used were comfort--a state of well-being, privacy--freedom from unauthorized intrusion, functionality--efficiency as an overriding rule, density--the amount placed in a room, and domesticity--the home as a place for the family. While *a priori* categories were used, the definition, the boundaries, and the meaning of these concepts were not fixed and were allowed to evolve in the study.

Selection of the Informants and the Research Setting

The informants were ten upper middle to upper class families in a small college town. All of the informants had built custom-made homes within the last one to five years. This time span was important because the process needed to be recent enough so that the informants could recall the specification process and, at the same time, long enough so that patterns of living in the house were established. Informants were identified by recommendations from architects. In addition, families were identified from interviewed families and newspaper articles. The family's willingness to participate and their involvement, in the case of uninformed recommendations, was assessed in an initial phone call.

Consistent with the definition of custom-made products, consumers were identified who had shaped their homes. Informants were considered to be involved if the home design and building was important to them and they had contributed to the creation of the home in terms of time, energy, and ideas. The family dyad, the husband and the wife, was interviewed. While the creation process may be dominated by one member of the dyad, it was assumed that the process of building a custom-made home was usually a joint process and, thus, the dyad was the appropriate unit of analysis. However, in two cases, one member of the dyad played a very dominant role and served as the sole informant. Interviews were conducted until redundancy arose (Hirschman 1986; Lincoln and Guba 1985). Given the fairly homogeneous nature of the informants, redundancy in most areas of questioning arose by the tenth interview.

The Interview Process

Since meaning is assumed to be context dependent, the interviews were conducted in the informants' home; also, the researcher could see the home and use it to stimulate discussion. The interview process was divided into two stages. Stage one involved rapport building. Informants were told the purpose of the study, how the data would be used, how confidentiality would be

maintained, and a general overview of the interview. Two broad questions, which were easy to answer, were first asked to put the informants at ease. Question one asked participants to describe the initial part of the process of building the home. Question two asked participants to describe this home relative to their "dream home?" In the second stage of the interview informants were encouraged to take the lead and discuss their home, how they built it, and any issues that were important to them. At some point during stage two, the informants gave the researcher a tour of the house.

The researcher entered the study with the intent of probing three main issues, if these issues were not raised by the informants. First, in order to understand the process of constructing meaning, informants were asked how they communicated the meaning of their home to the architect? Second, current meanings were probed by asking what does the home mean to the informants now? Third, in order to understand how the current consumption behaviors influence the meaning of home, the informants were asked about what consumption behaviors are centered around the concept of home? The five categories of home meaning, which were discussed earlier, were specifically probed: comfort, domesticity, privacy, density, and functionality. It should be noted that most of these issues and concepts were brought up by the informants during the interviews.

The interviews were conducted by one interviewer. One interview lasting from about 90 minutes to three hours was conducted with each couple or single informant. This interview was preceded by one or more telephone conversations to set the background for the study, assess suitability of informants, and schedule the interview. A total of eleven interviews were conducted and ten transcripts analyzed (one tape was discarded because of mechanical problems).

Analysis

A two-stage, hermeneutical analysis was employed based on the methods of McCracken (1988a) and Spradley (1979). As opposed to the fixed categories used in content analysis, hermeneutical analysis allows categories to evolve as the data is iteratively analyzed. The first stage was an analysis *within* each interview. The five *a priori* categories of meaning of the home were used to structure the analysis. For each of these categories, the transcribed text of each interview was analyzed for any *taxonomic terms*--words that the informant used to describe these categories, *incident statements*--comments that relate to the categories, and, finally, *relationships*. As well, categories of meaning evolved from the interviews that were not previously identified. The same analysis of taxonomical terms, incident statements, and relationships was performed for all new categories.

In the second stage, the analysis was *between* interviews and themes--relationships that occur across interviews--were identified. Two researchers analyzed the text separately. The researchers then

discussed the analysis. While the two interpretations were similar, in some cases, the researchers differed in the omission and inclusion of taxonomic terms and incident statements. Any differences were discussed and preserved in an integration of the themes. Interpretive research assumes that because of researchers' different perspectives, interpretations may diverge and these divergences should be preserved (Hirschman 1986; Hudson and Ozanne 1988; Lincoln and Guba 1985).

RESULTS AND DISCUSSIONS

Themes are relationships across the informants. Two themes occurred, which related to and expanded the *a priori* cultural categories. In fact, the *a priori* categories proved *not* to be very useful by themselves for discussing the meaning of home. Rather, the themes are more appropriately discussed in terms of two dichotomies among some of the *a priori* categories and new categories that emerged: the contrasting needs of *privacy* versus *openness* and the tradeoffs among *functionality*, *aesthetics*, *value*, and *cost*. A third theme that evolved is *the home as a process*. The results are presented according to these three topics.

The Contrast between Openness and Privacy

Openness and privacy have been issues in the western home since around 1600 A.D. when the great hall ceased to be the single space in which eating, sleeping, entertaining, and work all took place (Rybczynski 1986). In this study, openness and privacy existed simultaneously in homes because these categories have several levels of meaning. Openness and privacy have meaning relative to personal space, separation within the family, separating the family from others, and separating the inside environment from the outside environment. Also, openness and privacy refer to a cultural meaning of "psychological openness." Each informant expressed usually two or more of these levels of openness and privacy.

Openness and Privacy: Personal Space. Commonly, participants articulated the *need* for personal space. The need for personal space spoke of a need to have dominion and control over the space. But personal space also defined a special relationship to that space; that is, this space is mine. For example, one informant's personal space was a locked room over the barn to which he had the only key. Women often saw the kitchen as their personal space. Yet as houses open, new relationships must be defined to the spaces that we view as personal. Open designs mean that personal spaces are not necessarily closed off from the rest of the house. One female informant articulates best this balance between openness and personal space: "I like to think of myself as a warm individual, so I like to have small intimate spaces and open spaces for entertaining [in the same room]. That's [for example] my place for eating bon bons."

Openness and Privacy: The Family. The concept of privacy changes with the family life

cycle from separating young children from the rest of the house (e.g., "needing a space for the children") to separating the parents from the rest of the house (e.g., "wanting a space for us"). The space for family togetherness is designed into the house and driven by the functions around which the family coalesces. One family divided the space between the dining room and the living room with furniture that could be removed to accommodate large gatherings. Because the family needed space for large celebrations, the two rooms were designed without a separating wall and the space became a "great room."

Family spaces have changed from the den, previously the repository of the radio and then the T.V., to the family room, which opened up to become the great room. In this study, the great room heralds a new openness *within* the family as the wall between the kitchen and family room is removed. For example, mother in the kitchen and the kids playing in the family room are all within sight of one another. This side of the house, which is open and unstructured, tends to be reserved for the family. Some participants retained more formal rooms for "entertaining." These formal rooms were more structured and closed. Thus, the house serves to structure openness and privacy within the family and between the family and outsiders.

Openness and Privacy: Bringing the Outside In. This juxtaposition of openness and privacy extends also to nature. In one sense, the house is the protection against nature. Nevertheless, people spoke of a desire to experience nature. "I really can see the seasons and nature. In years of being interested in those things, I feel now as if I really live with them in this house." One informant found that the openness of the house had changed him, "Now I see the birds and all the other wildlife... [I] watch the sun come up. I never knew when the sun came up. I'm a city boy. Now I've found the seasons... I've never appreciated all these before."

Therefore, bringing the outside in means that the boundaries between open and private space are extended to include the surrounding environment. The house and the environment fuse:

In this house there are no curtains. The overwhelming presence in the room is that view. The view is gray and tan, and green and blue, and that's what is repeated in here to draw [the room and the outside] together. That's intentional.

Thus, home extends beyond the walls to include nature. Because the surrounding natural environment is now included in the boundaries of home, building sites are chosen that allow for privacy.

Openness and Privacy: Psychological Openness. Houses also represent a new way of being open. The following quote captures this idea of "psychological openness":

The first real entertaining we did... we hired a caterer to have a stand up buffet dinner. The caterer put food everywhere. She put smoked fish on the top of the hot tub. She had desserts in the bedroom,...There were eighty people here. It didn't seem crowded.

Thus, even spaces that are traditionally viewed as personal are opened up to guests. Houses represent a new way of contrasting the needs for openness and privacy. These new relationships are evident in how personal space, family space, formal and informal space, and environmental space are approached. These relationships are synthesized in an emergent theme of psychological openness, which stresses the breakdown of formal boundaries.

This first theme suggests that the cultural category of privacy and the competing category of openness were encoded into the informants' homes. Moreover, these cultural categories were encoded with personal meanings (e.g., "my place for eating bon bons"). Therefore, both cultural and personal meanings are intertwined in the construction of open and private spaces.

The informants in this study who sought "openness" may be compared with a group in another study who sought "homeyness" in their houses (McCracken 1987a). Homeyness, in McCracken's words, "seeks to make the occupant fully occupying of homey space and so to claim his or her full attention and affect" (p. 26). This statement is similar to the kind of openness that allows the entire house to become the "set" for a party. The group in McCracken's study, however, equated openness with coldness, formality, and unrealness. It appears that opposite terms, homeyness and openness, are used by the two groups to describe the same desirable state. Again, in McCracken's terms the house is "real," "engaging," and "informal," which makes it "riskless." Psychological openness is also a kind of riskless involvement with others, the environment, and, ultimately, with oneself.

The Trade-Off Among Costs, Functionality, Aesthetics, and Values

Homes represent the balancing of costs, functionality, value, and aesthetics. Aesthetics is recognized to be dependent on more subjective inferences, however, participants used costs and functionality in a similar subjective manner to explain why a choice was made. Trade-offs among functionality, costs, and aesthetics hinge on a concept of what is of value; that is, value is what returns the greatest benefit for a given investment. One participant summarized these ideas:

Lots of people make a mistake when they exceed their budget. They start chopping off the house. It doesn't save you anything. Also, it often destroys the concept, the way spaces are related particularly. Even if we didn't finish, if we had run out of money, we

would have built [on] this scale. We would have finished it as we had the resources.

If longevity and versatility are expected, then greater "functionality" expresses greater value and justifies the greater costs. Here, costs represent an opportunity rather than a limit. Implicit in this kind of thinking is a symbolic reference to *quality*. Metaphors to quality abound in these homes: "hand made," "custom made," and "plumb and square and level." The metaphors relate higher cost with greater value and functionality. However, at times the lowest cost is of value and is considered more functional. Here, cost is viewed as a constraint. Thus, lower costs yield greater functionality and value.

Guiding this trade off among cost, value, functionality, and aesthetics were individuals' values. The home is a symbolic expression of what the individual valued. Styles of homes often speak to such a symbolic orientation:

I wanted colonial. I didn't want a contemporary at all. I wanted something more traditional. We lived close to Williamsburg. You just don't see true Williamsburg colonial...the true, real thing.

Here, the meaning of "traditional" is cultural, but it is also personal: that is, the informant's experience of living near Williamsburg creates a personal meaning of traditional that is combined with the cultural meaning. Other examples of the expression of the role of values was more explicit and were also reflective of this joining of cultural and personal meaning.

I think people that build solar houses were hippies in the 60's. They joined the peace corps or they were professors,...there were a lot of Californians...I would bet you its people's philosophy whether they build a solar house or not.

Another informant said, "Protecting the environment [and] living in harmony with nature, that influenced our choice to build a solar house." Others expressed values of not being conspicuous consumers:

Some friends of ours recently purchased a big expensive house. Every aspect of it was built to impress people...We try to think who would live in this house, what kind of people.

In summary, informants sought to balance functionality, costs, value, and aesthetics, although the meaning of these concepts changed across and within the interviews. This balance was based on individuals' values, which were a combination of cultural and personal meaning.

Home As A Process

The home represented a process as well as an entity. This process lasted years for some of the informants. It starts with the anticipation of building, moves to learning and preparation for building, enters a period of negotiation as the house is financed, designed, and built, climaxes in the building experience, and finally extends into the living experience.

Anticipation and Learning. An important part of the process of the home is the anticipation and learning that takes place as the house is planned. "This house has been my hobby. Reading building magazines, that's where I got my ideas...I've been working on things for years and years." Sometimes learning is a cumulative process: "Actually, we built a house fifteen years ago. The things in this house are things we wanted in that house." Anticipation moves next into the process of negotiation.

Negotiation. Negotiations take place with a variety of people: financiers, architects, builders, and spouses. The basis of the relationship was important for defining the negotiations. For example, one informant describes the relationship with her builder that is based on their similar view of craftsmanship:

He wasn't in a hurry. We didn't have a deadline... Good quality [takes time]. We'd come up here and think about an hour on how to do something. He's real patient and I'm patient. I want it done right.

Thus, similarities between the negotiators led to a better relationship. Negotiation also arose between spouses. One couple resolved their differences in an innovative manner:

There were certain things she wanted and we made them mix...This is what a friend suggested, its a great idea for building a house. You can have ten "might as wells" and you've got ten of them and that's all. That window was a "might as well"...The Jacuzzi was a "might as well"...It sounds stupid but it works. We would say we will go ahead and do it for a few more bucks.

Spouses learned ways of negotiating during the process of building, which extended into the living process.

The Building and Living Process. The metaphor of the house as a process extends to the building process and, ultimately, to the living process. The house *is* how we live our lives. For example, in negotiating, some couples cooperatively made decisions, other couples partitioned off areas of responsibility, while still others reported the power struggle that took place over each decision. Examples of the house being a metaphor for how we live arose in the building process, as well. The building process was approached by "experientials" by rolling up their

sleeves and being at the site every day. "Managers" approached the building process by acting as their own general contractor. "Planners" approached the process by focusing on details and getting them right.

The building process as a living process is exemplified by the owner-builder. For the owner-builder, the major living ritual is building the house, which spans years. Since the house is continually under construction, building and living become intertwined. As one owner-builder termed it, the house is "organic" architecture, and in the sense that the house also "lives" and responds to the people that inhabit and build it. The house changes continually as they change and as their needs change:

This house has so much of our love of labor in it. We are building this thing every weekend...[Building yourself] takes incredible dedication, energy, and an incredible level of cooperation in a marriage or relationship. To make it work you are under such stress. It's really stressful, [but] it's fun. It really pulls you together. But its also stressful. Just making decisions all the time...If you contract with a builder, the house just gets build. Literally everything in this house we decided on...For us, a house is a whole lot more than a structure.

The building process is a metaphor for living. This couple was literally building their relationship and their lives each weekend. The house exerts an influence on its inhabitants, just as they create the house, the house creates them. As the house develops and solidifies, the life style that the house represents develops and solidifies. One couple said that only when the living room was completed could they move out of the social tunnel imposed by living in two unfinished rooms. The structure of the house influenced the informants' life style.

The relationship between a house and its inhabitants extends well beyond the building process. Houses are designed for a particular type of life style. In a sense, the house initially structures how a family envisions living *at a particular point in time*. In terms of process, houses are snapshots made during the learning and negotiation stages. These snapshots may emphasize the past, such as a childhood home:

As a child I always had my own room, since a very young age I had a drawing board...that general feeling for a place for my books or whatever, I've had ever since I was quite small. My study is just a big version of my room since I was a kid.

Or the snapshots may emphasize the future, such as a place to retire. Nevertheless, the house does not usually accommodate the flexibility to structure both the present life style and the changes necessary to actualize future images: "[Renovations and

additions] usually occur when people are older and the kids are gone. They don't need the space, but they want a dramatic rearrangement so it will be new." Thus, change is stimulated when the house no longer fits the inhabitants' lifestyle.

In summary, the house is a process of anticipation, learning, negotiation, building, and living. As the consumer moves deeper into this process, the consumer creates the house and the house shapes the consumer. This influence of the house on the life of the consumer is most evident in the owner-builder. When the life of the consumer does not match the house, renovations can be made or the family can move.

Limitations and Extensions

As with all studies, a number of limitations exist. For example, greater depth of information might have been gained by having additional follow-up interviews with the informants. Since the goal of this study was to *understand* this process of the co-creation of meanings, insight might be gained by interviewing the architects and builders. In other words, an area of future inquiry might be to study the dyad of the producer and the consumer. In this study, only the consumer side of the dyad was explored. Also, the process of building was recreated based on the informant's memories. An interesting study would be to examine an ongoing process of creating custom-made products.

Conclusions

The meaning of home is more clearly understood by examining the creation and consumption processes. Custom-made products offer a unique opportunity to focus on the co-creation of meaning between a producer and consumer. What is significant about the customizing process is the opportunity for meaning to be encoded into the product. Consumers are not forced to accept cultural symbols encoded by a product designer. Instead, more personal meanings--meanings that come from direct or imagined personal experiences--can replace or expand cultural meanings. Custom-made products speak for us and to us. The product speaks for us in the personal and cultural meanings that we encode. But the custom-made product may also speak to us and shape our lives, as in the case of the custom-made home.

Several participants emphasized the unexpected changes in their lives that had taken place because of their new home. The shaping process represents the development of meaning in the consumption of the home. This type of meaning is personal, experiential, and symbolic. Evidence of this influence was provided by custom-homes in which houses were envisioned with changes of life in mind. These changes represent symbolic or "displaced" meanings that feedback to shape life experience. One home builder, for example, spoke of the desire for a life with fewer responsibilities and less emphasis on work. She describe her dream home as one that would be "light" and "playful." Living in such a house would

"cultivate" those meanings in the words of Csikszentmihalyi and Rochberg-Halton (1981). Living in such a house would shape the life of this home builder so that it was light and playful.

The home is a metaphor for living because we structure our homes as we wish to structure our lives. This idea is more evident in the custom-made home where fewer constraints exist on the form the home will take. Nevertheless, the idea of structuring our home environment to reflect the way we would like to live may be applicable to home purchasers, condominium owners, and apartment dwellers. These groups are faced with more constraints in the symbols available and the encoding of these symbols. Therefore, shaping one's life in these contexts may focus more on those aspects of the home that can be changed: interior color, the carpet, the furnishings, and so on.

The idea that consumers actually shape their consumption experiences through the specification and encoding of product symbols is an extension of the culture and consumption model (McCracken 1988). In the case of custom-made products, McCracken's theory of the one way flow of meaning from culture to individuals is extended, in that the individual can create meaning by creating a product. Also, the product can shape the consumer. This relationship is a reciprocal co-creation process in which the consumer creates the product in response to symbolic needs and the product creates the individual through the structuring of experiences. Reciprocal co-creation is most apparent in custom-made products but may also operate when innovators or opinion leaders extend or interpret cultural meanings. The study of these types of consumption experiences using custom-made products may yield important insights into how we use consumption to aid our life satisfaction and ultimately insights into the role of consumption in our society.

T-Shirts as Wearable Diary: An Examination of Artifact Consumption and Garnering Related to Life Events

T. Bettina Cornwell, Memphis State University

ABSTRACT

This paper utilizes recently introduced perspectives of consumer theorists to examine the consumption of T-shirts. This artifact is examined with regard to cultural meaning, ritual behavior, primitive behavior, and consumption symbolism. Additionally, an inventory of five T-shirt diaries is made.

I sat quietly in the afternoon sun at Shultz's while Allyson, artfully decoded the complex of social symbols and wearable artifacts surrounding us. She continued:

"And that fellow there, the one with the T-shirt of Nixon that reads 'He's Tan, Rested and Ready for 1988.'"

I nodded.

"He is a biker, a bicycle biker not a motor biker, ready to have fun and at the same time very serious about his sport."

"And the one next to him, the one with the St. Paulie Girl T-shirt. He's into financial security -- I mean you can always plan on going Dutch."

"What about Mr. Executive that just hit the door?" Lee leaned over to question.

"Oh him, I don't know what he's up to today but he has an ultimate tanning machine and T-shirts from every Hard Rock Cafe he's ever been to."

INTRODUCTION

There is a considerable amount of scholarship devoted to the study of garments worn by individuals. Fortunately for those of us who would examine the consumption and rituals associated with clothing, Holman (1980) offers an excellent review of relevant literature. Holman reports that some researchers have focused on the theme of fashion cycle and aspects of economic or conspicuous consumption, while other sociopsychological researchers have studied the importance and function of clothing in the culture. It is this second approach to understanding clothing which this paper follows.

Sociopsychological researchers view clothing as more than utilitarian. Here are some conclusions about the cultural function of clothing:

-The function of clothing within the community is to designate the individual (as to sex, age, social status, occupation etc.) Yoder (1972).

-Clothing usage is an expression of personality, of self (Rosenfeld and Plax 1977).

-Dress provides a link with other individuals in festive, ceremonial and everyday activities (Roach and Eicher 1973).

T-shirt consumption and garnering is first examined with regard to recently introduced perspectives of consumer theorists. This artifact is uniquely qualified as a subject for study because of its tremendous meaning carrying capacity. It is acknowledged that other social objects (e.g., jackets and hats) can function in a similar capacity. The T-shirt is chosen as subject here because of its pervasiveness in the society and unisex nature.

This study then examines T-shirts as carriers of cultural meaning for five individual cases. The study is limited to T-shirts and sweatshirts with words or slogans and pictures that have some intention to communicate overtly. The interest here is in clothing that has communication as a primary function.

The Spirituality of T-shirts

Hirschman (1985) challenges both the stereotype of North Americans as possessed by a secular consumption ethic and the separate treatment of the natural and supernatural with regard to consuming behavior. In defending the spirituality of some American consumption patterns Hirschman turns to the work of Czikszentmihalyi and Rochberg-Halton (1982). These authors agree that consumers invest psychic energy in personal possessions and that the more that energy is invested in the objects over a lifetime, the more those objects come to transcend their mundane origins and embody personal meaning.

Czikszentmihalyi and Rochberg-Halton (1982) find that despite elevated standards of living, meaning, not material possessions is the ultimate goal of our lives. The T-shirt, as cultural artifact, serves as an illustrative example of our search for meaning. T-shirts have a very limited material value and rarely appreciate in economic value; however, they provide a unique symbol of self-definition.

Wicklund and Gollwitzer (1982) describe a person who strives for self-definition as a person who emanates or displays symbols of the self-definitional essences that are then potentially reacted to by the community. According to Wicklund and Gollwitzer, symbols can be blatant, such as the positive self-description: "I am fluent in Spanish" or they may be more subtle such as associating with Spanish speakers. Regardless of their character, the "purpose of the symbol as it has evolved is to stir up a readiness in the community to respond to the symbol" (Wicklund and Gollwitzer 1982, p. 5). This purpose is certainly true of the T-shirt.

T-shirts as Labels of Cultural Category

Contemporary North American culture has been described as having cultural categories which are more or less elective (McCracken 1986). This elective quality, as described by McCracken, means that the North American society "permits its members to declare, at their own discretion, the cultural categories they presently occupy" (1986, p.72). This self proclaiming is in contrast to other cultures where categories are more rigid and where belonging to a category is not a matter of choice. McCracken goes on to say: "Social groups can seek to change their place in the categorical scheme, while marketers can seek to establish or encourage a new cultural category of person (e.g., the teenager, the 'yuppie') in order to create a new market segment."

The T-shirt is unique in its ability to supply a label to a cultural category (e.g., "49er," "Native Floridian"). Even more importantly, individuals can, in a moments notice, change their proclamation of cultural category by changing their external symbols. This chameleon aspect of American culture is made possible in part by marketers who make you one of the group through promotional T-shirt deals and give-aways. Proclamations of cultural category may or may not be accepted by the society but the opportunity to wear symbols of choice exists nevertheless and just like the lizard, it may be discovered that one is not really part of the branch.

T-shirts in Rites of Passage

Rites of passage are rituals that center on the social observance of events that symbolically mark an individual's social status changes (Rook 1985). T-shirts in some instances have become widely accepted ritual artifacts. For example, the "class of" T-shirt which lists all the names of the graduating class of a particular high school is worn by those who will take part in the graduation rite of passage. In a society where formal events commemorating the adolescent initiation into adulthood are observed less and less often, the participation in and evidence of informal rites of passage take on greater importance. Rook (1985) recognizes the heavy metal concert as a cosmology-based ritual in that for its audience it may have a spiritually elevating effect.

Concert attendance whether heavy metal, punk rock or new age has certain norms associated with it that bridge the gap between childhood and adulthood. Some concerts require attendants to be of a certain age in order to better police restricted beverage consumption. Perhaps more importantly, music has the most unusual capacity to date an individual. Music (and the T-shirts representing the groups and individuals that produced it) "belongs" to those who came of age while that music was popular. This is not to say that one cannot enjoy the music of any period but rather that ownership of an original Woodstock T-shirt may reflect on perceptions of your age at social gatherings.

T-shirts as Trophies

As a species, humans throughout history have been fond of bringing home souvenirs of conquests. Savage warriors of the head-hunting type returned from the hunt with fragments of the human enemy and were proud of these trophies which represented prowess in war (Verrill 1946). Modern urban conquests do not depend on bringing back scalps, ribs or teeth. Sports are an established outlet for civil, non-warring competition. In the growing health conscious sector of U.S. demographics, extrusion-molded marble and golden human facsimiles are the pinnacle of amateur athletic success. However, most must settle for the perennial T-shirt as tangible proof of their participation and conquest, if not over others at least over the clock. T-shirt garnering is a serious aspect of participation in amateur athletics. Registration deadlines admonish late comers with those speed inspiring words: "T-shirts to the first 500 entrants." At the conclusion of the event the T-shirt artifact serves as a marker of the occasion and as wearable symbol of one's self-definition. For example, one can utilize the T-shirt in the ambiguous environment of a sporting goods store to establish oneself as a serious runner and a knowledgeable consumer of running shoes.

T-shirts as Poly-Cotton Pheromones

A potentially overlooked aspect of T-shirts is their ability to attract like-minded people and simultaneously repel social incompatibles. The words "Single head of household" are expected to describe 45% of United States by 1990 (Stern, Gould and Barak 1987). More importantly, the baby boom singles are characterized as being "social seekers." The singles have more leisure time, they socialize more and they also are more concerned with their social image than "marrieds." Igniting social dialogue may be an increasingly important function of the T-shirt in the future.

FIVE DIARIES

This study was limited to T-shirts (and sweatshirts) of any sleeve length and fabric construction. It included shirts with words or slogans and pictures that had some intention to communicate overtly. All clothing communicates, but the interest here was in clothing that had communication as a primary function. Patterns and florals or any image of a repeated and nonspecific nature and of course, shirts without distinction were excluded.

Inventories were conducted of the accumulated T-shirts of five individuals, one of which was the author. The procedure was to locate all T-shirts; record their symbols, slogans and other characteristics; and then group the shirts in meaningful categories. Additionally, the meanings of each shirt, the circumstances of its acquisition, and the grouping and labeling processes were discussed. Documentation was kept in the form of T-shirt lists, records of grouping and labeling activities, field notes and photographs. In seeking

participants for the study I asked for referrals (and introductions) outside the academic community. All participants had full-time jobs outside the university.

An examination of the T-shirt diaries is presented in table format and discourse. Category labels in the table are offered as prototypes so that all diaries may be presented together. Interesting and insightful category labels supplied by participants are noted in the discussion of individual diaries. Also revealed in the discussion are calibrations of myself as researcher in the unfolding of this humanistic inquiry. The incorporation of personally experienced knowledge in the rendering of research is not a new idea (see Polanyi 1962), however, in the marketing discipline, disclosure of the process is (Hirschman 1986).

The Author's Diary

After recovering from the shock that I owned 30 T-shirts of the type under study (and another 23 that were more or less generic), I recorded their symbols and began to group the shirts into meaningful categories. Several categories were readily apparent (Table 1). Seven shirts were related to past and present academic affiliations. This was

not surprising considering my line of work and many (too many) years of academic preparation. The next meaningful group to emerge was related to activities: personal participation in amateur athletic events (6 shirts), other events (5), and places where I had traveled (7). One was unique in its message of self-expression and the remaining shirts were for products or companies.

It should be noted that many of the shirts related to sports events also had some form of product or company information from the event sponsor. This fact is evidence of the expanding role of corporate America in the support of organized sports events (Oneal and Finch 1987, Taylor and Silverman 1984).

It was interesting that those shirts found in the laundry basket, the washing machine, and gym bag could be deemed most currently self expressive. For example, the shirt in the gym bag was a product shirt for an advertising text book which is expressive of a current activity: teaching advertising and promotion. Those shirts found in the bottom drawer archives were in many ways a shell of my former self. Deep in the archives was a "Gary Hart for President" shirt which had expressed loyalty to the person and the party during his first presidential

campaign. Now, stripped of its deeper meanings (or at least irrevocably altered), this shirt was reduced to functionality (to be worn under sweaters for warmth).

In the mode of self examination I found support for several of the functions of T-shirts, most notably, T-shirts as sports trophies and T-shirts as definitions of cultural category (e.g., "Texas Longhorn"). Additionally I learned that the process of inquiry took much longer than expected (nearly two hours) and that the process could be much more personally exposing than originally expected. These and other insights were helpful in developing the instructions for study participants. For example, other diarists were cautioned to look for all T-shirts before beginning the grouping and labeling process. Following are highlights from the four other diaries.

The Diaries of Others

Dee's groupings reflected her interest in amateur sports participation. Eighteen shirts were listed under her label "exercise related" and are listed in Table 1 under "Activities: sports participation." Dee explained that wearing exercise related T-shirts made her feel active. "It says: 'Look, I did a 5-K.'" Unique to Dee's diary was the special activity group that she labelled "volunteer." In this group were six T-shirts (Table 1) that were worn when organizing or officiating at some special event such as the "Run for Cancer." Dee's volunteer T-shirts seemed to reflect her history and allow her the cultural categorization of "socially concerned," whereas the sports participation T-shirts enabled her to bask in the reflected glory of accomplishment. It is important to note that a T-shirt may have different meanings for different people. For example, a T-shirt may relate to event attendance according to one person's diary but may be more specifically related to volunteerism for another person.

Also unique to Dee's diary were two fashion T-shirts. These T-shirts had no deep personal meaning. "They are just fun to wear because of the colors, in fact I organize all my T-shirts by color," she said.

Kay likewise was interested in the colors of her T-shirts, however, particular shirts had very important meanings and functions in her life. Kay's favorite was an Arkansas shirt with a Razorback on the front and a tail down the back. She gladly modeled this shirt while explaining that "It makes me feel lively, like I'm back in college again. I wear it to be obnoxious at football games." Kay also reflected that of the five T-shirts that had been given to her as gifts (Table 1) several of them reminded her of old boyfriends.

For Que (by now you may have guessed that these are not the actual names of the diarists), six T-shirts (Table 1) related to sports event participation and were grouped under the rubric of "health consciousness." Five event attendance T-shirts were either music event attendance or attendance of events unique to a particular region. These T-shirts were considered to reflect "personal taste" and an appreciation of "local color." There were life experiences of personal importance related to the

"U2 Unforgettable Fire, 1985 Tour" T-shirt and the artifactual consumption of that T-shirt served as a marker of the occasion. Whereas the "I AM A UFO" T-shirt was not related to a particular event, it was useful in defining Que's sense of humor/bizarreness and is listed in Table 1 under "Personal-Meaning--Self Expression."

A concept of meaning construction emerged from my discussion with Que. To express his sense of irony, Que wore a jacket with his "Phil Collins--No Jacket Required, Tour 1988" T-shirt. In this way Que was able to manipulate, through other articles of clothing, the meaning communicated by this T-shirt, thus constructing his own meaning.

Neither Que, nor Jay the fourth and final diarist, expressed concern for the color of their T-shirts. However, both Que and Jay utilized the concept of meaning construction. Jay emphasized the construction of meaning through a T-shirt's interaction with himself and a particular situation, activity or environment. For example, Jay's four "Impersonal: Company/Product" T-shirts (Table 1) were from sporting goods manufacturers like Nike and Reebok. Jay enjoyed the hint of irony when he wore one of these T-shirts he labeled "I'm a jock" because he was obviously not a jock (these are his own words and not a subjective opinion of the author). This meaning construction was then augmented by wearing this "I'm a jock" type T-shirt to play bridge with his oh-so-serious partner. In this way Jay constructed a personal meaning from an impersonal T-shirt.

Jay's eight "Travel/Vacation" shirts (Table 1) were thought of as evidence of conquest. According to Jay, "T-shirts are the best souvenir because they are visible and portable--better than salt and pepper shakers that just sit on a shelf." Jay had seven T-shirts which were self expressive (Table 1). Jay explained that he picked T-shirts to wear according to his mood: "There are shirts for parties that I hope will evoke a comment and T-shirts like 'Betty Boop' to wear when I feel naughty."

CONCLUSIONS

The spirituality of T-shirts, if thought of in terms of psychic energy investment, appears to vary by person. For the diarists in this study, psychic investment ranged from organizing T-shirts by color (a low psychic investment) to T-shirt coordination and integration with specific life events for the explicit intention of evoking a response from a subset of the community (a high psychic investment). T-shirts as trophies (related to sports and travel) and T-shirts as labels of cultural category were repeated themes for all diarists. The role of T-shirts in rites of passage was not emphasized by these diarists. This may be related to the fact that participants were adults and many important developmental events had long since passed. T-shirts were not cited as useful in attracting or repelling social seekers; however, T-shirts were found to be useful in self expression which may indirectly function in the same capacity.

This paper was reviewed by a peer from the communications area of a different university. The comments of that outside auditor and the comments of the two anonymous reviewers which are not already integrated into the paper are included here in the form of questions to pique the interest of researchers:

- How do we measure the effects of T-shirts on consumers as wearers or observers?
- How are T-shirt category representations expected to vary by consumer group and what does this tell us about that group?
- What is the cultural significance of oblique versus direct meanings associated with T-shirts?
- Is the function of T-shirts, as label of cultural category or declaration of group membership, different in urban, suburban and rural settings?

This study was limited to five diaries and therefore may not capture the full range of cultural functions related to T-shirts. However, for the diarist in this inquiry, T-shirts with overt intentions to communicate were unique carriers of cultural meaning for the individual who possessed the artifact. Their uniqueness stemmed from this clothing's ability to punctuate cultural categories and modify the meaning of other cultural artifacts. Furthermore, T-shirts were useful as building blocks of personal communication. Meanings were constructed by the diarists through the interplay of T-shirts, group identifiers (such as physical appearance or other elements of clothing) and situation or environment.

ABSTRACT

The development of a consumer identity is proposed to occur within the context of Erikson's life span developmental conception of the identity stage. Using Marcia's work on the development and measurement of occupational, religious, and political identity, a consumer identity interview was developed. The results of interviewing a group of undergraduates suggest that the Consumer Identity interview is measuring something distinct from occupational, religious, and political identity. The sequence of identity development suggests that a consumer identity is important for becoming an effective, productive adult.

A central issue in human development is the development of a sense of identity. The meaning and influence of one's answer to the question, "Who am I?" is sharply etched in his/her personal histories. Moreover, as a result of Erikson's (1963; 1968) descriptions of the development of identity as the primary outcome of adolescence and a significant influence on adult behavior, a wealth of research has emerged on the development and effects of identity (see Bourne 1978a; 1978b).

One of the most widely accepted operationalizations of the concept has been through a semi-structured interview developed by Marcia (Bourne 1978a, 1978b; Marcia 1976; 1980). Agreement that there is an effective measure of identity and the use of this reliable and valid interview has allowed the study of the development and effects of identity to proceed. Unfortunately, this research has been essentially limited to only those areas in which Marcia believed adolescent identity development is important. Believing that Erikson viewed occupational, political and religious identity to be the most important areas in which adolescent identity evolves, Marcia created an interview to measure identity development in those areas. Other researchers seemingly adopted those areas as the dominant areas of development, and they either studied the relationship of identity development in those areas to behavior choice in those domains or they used those areas and looked at how they relate to behavior in other domains. As in many areas of the study of human behavior, once a measuring technique is well accepted it begins to define the concept under study. Thus it appears that Marcia's interview has come to define the three areas of identity development in adolescents, as if those are the only three or most important three areas of identity development. In reality there may be other

areas of identity development of equal or greater significance to adult development and behavior than religion, politics, and occupation.

The primary purpose of this research is to develop an extension of the Marcia interview into the consumer domain. It is our contention that identity development occurs in the consumption domains as well as the occupational, religious, and political domains tapped by the Marcia technique, and may be as or more important in the development of an effective adult in a market economy and society.

Theoretical Foundations of Identity Research

Both the theoretical formulations (Erikson 1968) and reviews of empirical work (Marcia 1980) have painted identity formation as a critical building block of adulthood. According to Erikson, adolescence is a time for individuals to try out various social roles prior to making formal commitments. It is the time at which the crucial question is asked, "Who am I?"

Erikson conceptualized the adolescent conflict as one in which individuals organize and reorganize their notion of themselves. The outcome of the identity crisis is the acquisition of an ego identity. According to Erikson (1968) one's ego identity is "the awareness of the fact that there is self-sameness and continuity to the ego..." (p. 50) such that the individual forms consistent roles and beliefs. Ego identity refers to commitments to broader social goals (e.g., occupational goals, religious choice) while self-concept refers to an individual's self-perceptions and role images. According to Erikson each society provides a scheduled time for the completion of that identity.

Based on Erikson's theory, Marcia (1966) constructed a taxonomy which constitutes a four fold classification of adolescent identity development. According to this schema an adolescent forms one of four identities called identity achieved, foreclosed, moratorium, or diffuse. The following is a brief summary of the major characteristics of each identity status. Identity achieved adolescents have actively considered alternatives and have made a commitment to one of those alternatives. For example, in the case of making an occupational choice, the identity achieved individual has considered various career/job choices and has on the basis of this exploration made a firm commitment to one alternative. Identity achieved individuals have high self-acceptance, a stable self concept, and have made a commitment to a vocation, a religion, and a political ideology.

Foreclosed adolescents tend to develop identities which are isomorphic to that of one of their parents or significant other. They are happy and accepting of whatever commitments have been handed to them. Those in moratorium tend to be actively pursuing an identity. They are in the throws of the "identity crisis" and are seeking and exploring those things that may serve as their future occupation, religion, or political choice. Finally, the diffuse person has no commitment and has undergone little or no exploration. He/she lacks certainty about him/herself and has little or no commitment to occupation, religion, or political thought.

The Case for a Consumer Identity

Today's world requires a set of decisions that may go beyond occupation, religion and political identities. It is our contention that society demands that an individual address the issue of consumption. Coleman (1974; 1978) and Raphael (1979) present evidence that adolescents do not resolve identity dilemmas in occupation, politics, and religion simultaneously. They suggest that each area has meaning as a separate identity, therein opening the possibility that politics, religion, and occupational identity are three of many possible identity dimensions. Consequently, Waterman (1985) has suggested and developed an interview like Marcia's to measure sex role identity development. Learning to be an effective, productive adult consumer functioning in the marketplace is one of the social roles for which adolescents need to acquire appropriate skills, motivations, attitudes, and behaviors (Dusek 1977; Kuo 1987).

Indeed, recent research in consumer behavior has focused on the importance of and the development of adolescent consumer motivations and skills. Consumer behavior appears to undergo significant formation and change during the adolescent years, turning the child into a fairly sophisticated consumer (Moschis 1987). Unfortunately, these researchers have proceeded in a relatively atheoretical manner and either do not know of Erikson's guidance or do not think that Marcia's operationalization of Erikson into occupational, religious, and political identity is applicable or generalizable to understanding the developing consumer. It is unfortunate when such a dominant theoretical statement, such as Erikson's, has not been utilized as a guide for understanding the adolescent consumer. The objective of this research is to investigate the utility of using an Eriksonian framework to understand the adolescent consumer. The strength of this approach lies in the fact that it adopts a powerful adolescent developmental theory in studying the learning of consumer skills by adolescents with the same mechanism ("identity") by which adolescents have been said to become adults in other important developmental areas (e.g., occupational choice).

Therefore a Consumer Identity Interview was developed which patterned the interviews previously used to identify occupational, religious, political, and sex role identity areas. Identity issues have

been found to come into play and take center stage at different times in development (Coleman 1974; 1978). Research on identity has shown that individuals first assume identity development in occupational areas, next in religious areas, and last in political areas (Raphael 1979). We felt that one measure of the validity of the proposed consumer identity concept and interview was if the development of Consumer Identity would be found to occur at a different time than occupational, religious and political identities. The importance of the concept of consumer identity can be assessed from its placement/rank in the developing identities. Since occupation is an overriding concern in college, we believed like Raphael (1979) that occupational identity would be found to develop first. However, given the importance of material concerns in college, we hypothesized that consumer identity would be developed after occupational identity but before religious and political identity.

METHODOLOGY

Subjects

Forty-two freshman undergraduates volunteered for extra credit toward their final grade.

Identity Status Interview

Marcia's (1966) semi-structured interview was used to determine subjects' identity status in the areas of occupation, religion and politics. Our Consumer Identity interview was used to assess their consumer identity (see Appendix 1 - each interview lasted between 20 and 40 minutes).

The questions and procedures for administration and scoring of the Marcia interview for occupation, politics, and religion are well established and explained in manuals developed by Marcia (1966), Waterman (1982), and Grotevant et al. (1982). Since these interview schemes are well organized and tested, the translation for a consumer identity was relatively straightforward. Interviewers were trained in accordance with these procedures. Practice interviews were conducted and evaluated by a researcher experienced in the delivery and use of the Marcia interview. Each interview was coded by the interviewer and a second person other than the interviewer (each interview was recorded). The interview was coded by a person of the opposite sex to the person conducting the interview to account for possible bias identified by Matteson (1977). Agreement between judges was 87%. Any disagreement was settled by conference.

Coding procedures have become relatively objective by rating the interviewees' degree of commitment and exploration for each identity domain. A person's degree of exploration was rated on a scale of 1 to 4. A rating of 4 on exploration is given for the presence of depth and breadth. Depth of exploration involves the investigation of one option (for example, becoming a professor) by means of several different approaches (getting a PhD; attending a professional conference; reading professional journals). Breadth of exploration

APPENDIX 1
Identity Interview

Introduction:

- *What year are you in?
- *How far along did your father get in school? What does he do now?
- *How far along did your mother get in school? What does she do now?

Occupation:

- What are you going to do after college?
- Are you planning to go to college? Do you know what you will major in?*
- *What do you plan to do with it?
- *When did you come to decide on (career choice)?
- What people or experiences have been major influences on your plans for the future? (Probe re: teachers, parents, reading, etc)
- *Did you ever consider anything else? What? Anything besides that?
- *What seems attractive about _____ ?
- *Most parents have plans for their children, things they'd like them to go into or do -- do yours have any plans like that for you?
- *How do your folks feel about your plans now?
- What kinds of difficulties or problems do you see associated with your decision to _____ ? if these things were to become difficult, what would you do then?

Religion:

- *Do you have any particular religious affiliation or preference or philosophy?
- *How about your folks?
- How did you come to be a _____ ?
- What people or experiences have influenced your thinking about religion?
- *Were you ever very active in church? How about now? Do you get into many religious discussions?
- *How do your parents feel about your beliefs now?
- *Are yours any different from theirs?
- *Was there ever a time when you came to doubt any of your religious beliefs? When? How did it happen? How did you resolve your questions? How are things for you now?
- Do you anticipate that your religious beliefs will stay the same or change over the next few years?

Politics:

- *Do you have any particular political preference?
- How did you come to that decision? How long have you been a _____ ?
- *Are there any issues you feel strongly about? (Probe re: National level, state, local, or school, but DO NOT suggest specific issues to react to.)
- *Have you ever taken any kind of political action -- joined groups, signed petitions, written letters, participated in demonstrations about politics or political discussions -- anything like that?
- *How about your parents' political preferences?
- What people or experiences have influenced your thinking about politics?
- Have there been times when you have felt differently about your political affiliation (or issues)? When? What made you change?
- Do you expect your political involvement or attitudes to stay the same or change over the next few years?
- Who would you like to see elected President in 1980?

Consumer:

- How important is money to you?
- What general guidelines do you have for spending and saving your money now?
- Will your spending/savings patterns change when you get a job and make more money? Why?
- Do you plan on owning a home, a car? Why?
- Do you plan to save?
- Do you have priorities in your buying and saving? How did you arrive at these priorities?
- Do your parents have priorities in their saving and spending?
- What has influenced your thinking about your buying and saving habits?
- Do you expect these ideas to change?
- If you came into a lot of money how would your style change?
- What would you do differently/same and why?
- Just how important do you feel spending, saving, buying is for you?

TABLE 1
Proposed Scaling Sequence For Openness Across Identity Areas

Occupation	Open In			Total Open Areas
	Consumer	Religion	Politics	
+	+	+	+	4
+	+	+	-	3
+	+	-	-	2
+	-	-	-	1
-	-	-	-	0

involves the investigation of a number of different options (e.g., becoming a professor, a high school teacher, or a doctor). A rating of 3 is given if the individual has explored only 1 option in depth or a couple in very little depth. A rating of 2 is given for only superficial exploration with little depth or breadth. Finally, an individual is given a rating of 1 for exploration if he/she shows a complete absence of consideration of options in that domain. Commitment was scored on a 4 point scale, ranging from 1 (complete absence), 2 (weak or vague), 3 (moderate), to 4 (strong firm choice).

These scale ratings were used to derive identity status within each domain. In general, "identity achievers" score in the 3-4 range for both exploration and commitment, "moratoriums" score in the 3-4 range for exploration and 1-2 on commitment; "foreclosures" receive 1-2 on exploration and 3-4 on commitment; and "diffuse" score 1-2 on both exploration and commitment. For each subject, then, a set of 2 scores measuring exploration and commitment and an overall identity was derived for each content area (religion, politics, occupation, and in this study consumer identity).

RESULTS

Distribution of openness ratings. Of the 42 subjects, 37 (88.1%) were classified as "open" (having explored) in the occupation category; 17 (40.5%) in the consumerism area; 13 (31.0%) in the religion area; and 11 (26.2%) in the politics category. A McNemar Test for differences between correlated proportions indicated that differences between the number of subjects classified as open were significant ($p < .01$) between occupation and politics, consumerism and occupation, and religion and occupation. The differences between the number of open subjects were not significant between consumerism and religion, consumerism and politics, and the religion and politics categories.

Scaling of ratings. A scaling sequence was then tested for presence of open ratings. Based on Raphael (1979), the sequence predicted that an open rating in occupation was necessary before an open rating could be seen in consumerism. Likewise open ratings were necessary in both occupation and consumerism before one could be seen in religion. Finally, open ratings were required in all three of the

previous categories before one could be found in politics (see Table 1).

Analyses supported these predictions using Green's (1956) techniques for assessing the quality of Guttman scaling. Two indices of reproducibility were found. RepA = .94 and RepB = .939, both exceeding not only the traditional criterion of .85 but also the commonly used results, .89 and .91, found in other studies (Kasulis, Lusch, and Stafford 1979; Raphael 1979).

The index of reproducibility measures how successful the Guttman scale is in reproducing an individual's openness rating given only an individual's scale score. To assess the degree to which the index of reproducibility is influenced by scale item distribution, the *expected* coefficient of reproducibility is calculated. This measure calculates the coefficient that would be obtained using only item frequencies. In this study, the expected reproducibility coefficient, RepI, is .85, and is significantly different from both RepA and RepB at the $p < .05$ level.

An additional measure obtained using Green's statistical measures for Guttman analysis is the Index of Consistency. This index shows the percentage of maximum possible improvement in reproducibility that the derived scale actually obtained. As with the "Rep" measures, its range is zero to one. In this study, the indices of consistency, .42 and .43, indicate that the Guttman scale achieved 43% of the improvement in reproducibility that was theoretically possible for RepA, and 42% for RepB. Although not quite at Green's recommended measure of .5, the results account for more of the possible improvement in reproducibility than other studies that considered .30 to .40 acceptable.

Error analysis. Since both indices, reproducibility and consistency, are less than 1.0, it is obvious that the derived scale possesses some degree of error. These statistics are obtained from the number of deviations, or errors, from a perfect Guttman scale pattern.

Table 2 contains data necessary for error analysis. There are four cells containing four numbers that represent 1) rank order of category, 2) frequency, 3) number of skip errors, 4) number of category errors, and 5) error percentages.

TABLE 2
Category Rank Orders And Error Statistics By Group

	<u>Political</u>	<u>Religion</u>	<u>Consumerism</u>	<u>Occupation</u>	<u>Total Errors</u>
Rank	4	3	2	1	
Frequency	26.2%	31.0%	40.5%	88.1%	
Skip errors	0	0	7	3	10
Category errors	4	4	2	0	10
Error %	9.52%	9.52%	21.43%	7.14%	

The rank order is simply the "popularity" of each category. The skip errors occur when a respondent is not in a particular category, but was predicted to be in that category given the respondent's score. In other words, the respondent skipped a category for a higher order category. For example, an individual that was placed in both the occupation and religion categories would be given a rank of two. However, in a perfect scale, the respondent with a rank of two would have been placed in the occupation and consumerism categories, not in the religion group. When a category is "skipped," it is recorded as a skip error.

Category errors are the opposite of skip errors. A category error exists when a respondent belongs to a particular group but could not have been included in this group given a perfect scale and the score assigned to him/her. In the above example, the respondent was in the religion category when, according to his scale score, the respondent should not have belonged to this category. Therefore, a category error is assigned.

This process of skip and category error counting means that every deviation from the perfect scale is double counted. The total skip errors must equal the total category errors. As discussed by Chilton (1969), double counting is a major weakness of the Guttman techniques.

The far right numbers in the table give the total number of skip and category errors (10). This number of errors may seem to be large relative to the sample size. In error analysis of Guttman scaling, however, two points must be considered. First, errors are double counted, meaning this entire analysis has only ten errors. Additionally, the relevant error comparison is not the sample size, because any respondent can be assigned more than a single error.

The relevant comparison in a Guttman error analysis is the percentage of errors for each category in the scale. In this study there was never more than 21.43% error, meaning that only 10.71% of the respondents due to double counting of errors belonged to a category when they did not belong to all lower order groups or they did not belong to an initial category when grouped with a higher order

category. With other research claiming 12% error acceptable, a less than 11% error margin in our study would appear to be acceptable.

DISCUSSION AND IMPLICATIONS

Examination of the scaling sequence shows that an open rating in occupation was necessary before such a rating could be seen in consumer identity. An open rating in consumer identity was needed before one could be found in religion, and an open rating in religion was needed before one could be found in politics. The results suggest that society influence mandates that occupational decisions are a major concern to college age individuals. Coexisting concerns for material, and consumer issues are of less immediate priority while those of political and religious domains do exist but to a lesser degree. The present study suggests that a conceptual extension of Eriksonian ideas is warranted into consumer behavior. Instead of consumer behavior lying outside the mainstream of the human experience, consumer behavior is part of a life span developmental perspective that has been successfully used to understand and explore major areas of human development.

This study has several important implications. First, the results empirically support the existence of a consumer identity and support the validity of the interview used to assess it. The Consumer Identity Interview, modeled after Marcia's interview for identity in occupation, religion and politics, measured something distinct from the previous identity domains. The fact that the consumer identity dimension was second to occupational identity sharply etches what we think is the hypothesized importance of the consumer identity for adult functioning.

Second, while it remains to be seen whether consumer identity is related to specific forms of consumer behavior as is true with occupational identity being related to forms of occupational choice, the results of this study support its conceptual validity. The next research step is straightforward. Using what is known about identity, its development, and effects on behavior as a model, predictions between consumer identity and

consumer behavior can be made and tested. It also remains to be investigated how this approach complements the excellent work on adolescent socialization and consumer behavior by Moschis (1987).

Symbolic Interactionism: Some Implications for Consumer Self-Concept and Product Symbolism Research

Dong Hwan Lee, Indiana University¹

ABSTRACT

Research on consumer self-concept has suffered from the lack of a rigorous theoretical framework which can systematically incorporate the social dimension of self. Symbolic interactionism, a research stream in sociology, is suggested as a potentially very useful theoretical basis for advancing consumer self-concept and product symbolism research. The literature on consumer self-concept and product symbolism is first reviewed. Next, conceptual and theoretical underpinnings of the contemporary symbolic interactionist perspective are presented comprehensively and then a specific orientation of symbolic interactionism is described. Finally a model of brand choice is developed based on symbolic interactionism to illustrate its potential contributions.

INTRODUCTION

Although sociology represents an area rich in its potential for contribution to the research in consumer behavior, it has been largely neglected. This paper is intended to introduce symbolic interactionism, a research stream in sociology into the areas of consumer self-concept and product symbolism. First the literature on the self-concept and product symbolism is briefly reviewed. Next, conceptual and theoretical underpinnings of the contemporary symbolic interactionist perspective are presented comprehensively and then a specific orientation of symbolic interactionism is described. Finally, a model of brand choice is developed incorporating the situational self which is based on symbolic interactionism and the implications of the model are discussed.

LITERATURE REVIEW ON SELF-CONCEPT AND PRODUCT SYMBOLISM

Earlier Personality Research

Earlier marketing literature is replete with studies which attempted to relate purchases of product types or specific brands to personality traits of the buyers. Tucker (1957) is the first who proposed that consumers' personalities can be defined through product use. Evans (1959) in his landmark study attempted to examine the differences in personality variables between the owners of different cars. Koponen (1960) reported that cigarette smoking is related to some personality variables. Westfall (1962) found that owners of different models of cars exhibited different

personality characteristics. Claycamp (1965) reported that personality variables were better than demographic variables in predicting patronage for different financial service organizations.

These studies treated the personality traits as "enduring" characteristics of people and focused on the self-expression of the inner nature of the consumer through product use. However, they neglected the influences of others with whom a consumer interacts through social process on his choice of the product or brand. Although some of these studies found relationships between consumers' personalities and the products they consume, the overall results of this line of research are inconsistent and equivocal. Thus, it is concluded that this kind of simplistic paradigm could not properly account for product choice processes (Kassarjian and Sheffet 1975).

Self-Concept and Product Symbolism *Unidimensional Self-Concept Studies*

Later, researchers advanced the notion that consumers' buying behavior is determined by the "interaction" of the consumer's self-concept and the image of the product or brand purchased. The "symbolic property" of certain products was initially suggested by Goffman (1951) and Hall and Trager (1953). In the marketing literature, Levy (1959) initially emphasized the importance of the consumer's self-concept by proposing that the act of consumption as symbolic behavior is more important to the consumer than the functional benefits of the product. Products and services are assumed to have an image determined not only by the functional attributes but also by a host of such intangible factors as brand recognition, price, advertising, country of origin, stores, packaging, etc. Following Levy's proposition, a number of self-concept studies were undertaken. Woods (1960) asserted that where ego-involvement with the product is high, product image is important to the consumer. Birdwell (1968) empirically tested the premise that one's self image would be more congruent with the image of the chosen brand than with the images of rejected brands. Grubb and Hupp (1968) and Dolich (1969) reported similar findings.

However, it is noted that in these studies the self was treated as a "unidimensional construct" and the definitions used were referring to the "actual self," i.e., one's perception of oneself. Taken as a whole, the results of a host of empirical research following the single self construct approach were ambiguous and inconsistent.

Two Dimensional Self-Concept Studies

The confusion of those studies has led marketing researchers to conceptualize the self-concept as having more than one dimension. The central theme of these new approach to self-concept research was: "If there are differences among the

¹The author thanks Professor Richard W. Olshavsky for his helpful comments on the earlier version of this paper.

self-concepts for consumers, then which of self-concepts do they try to match with the symbolic content of available product or brand in a brand choice decision?" The "actual self" and "ideal self" were separately conceptualized and measured to match the self-concept and product image (Delozier and Tillman 1972; Dolich 1969; Gibbins 1969; Green et al. 1969). Dolich (1969) first distinguished between "actual self" and "ideal self." "Actual self" was defined as an individual's perception of what he is like, while "ideal self" was defined as the image of an individual as he would like to be. Green et al. (1969) also attempted to investigate the relationships between the two self-concepts and product ownership.

Although this stream of research broadened marketers' understanding about the consumer's self-concept, results of the studies suffered largely similar limitations to the single dimension personality research. In addition, one of these self-concepts was not demonstrated to be better than the other in predicting brand choice (Green et al. 1969; Dolich 1969; Ham and Cundiff 1969, Ross 1971). Thus, it is argued that there may be other important dimension of the self, i.e., the social dimension of the self which is not captured by the psychologically oriented self conception used in those studies.

Product Conspicuousness and Sociological Perspective

In the product symbolism study, there was a stream of research which attempted to treat the self-concept from the sociological perspective. Since Copeland's (1923) seminal work on product classification, trichotomy of convenience, shopping, and specialty goods, there have been numerous studies that tried to link consumers' behavior to various product taxonomies. However, the classification schemes, despite their intuitive appeal, fail to provide useful guideline for marketing strategy (Wind 1982). Therefore, it is argued that the static product taxonomies are of little use unless consumers' "product usage" situations are taken into consideration. One of the interesting classifications is Boune's typology (1957) which is based on the degree to which products are subject to "social influence." The main dimension of his classification is "product conspicuousness", i.e., the degree to which a product is visible. This classification is of great interest because product conspicuousness can be conceptualized in light of interpersonal relationships in social process and also links the product to the concept of self. If a product consumption is conspicuous in public and is socially visible, consumers are likely to use the visibility of the product to communicate symbolically something about themselves to the "significant others" in the consumption situation. This symbolic communication is based on the premise that there exists a commonly shared meaning and experience about the product in specific consumption situations. Boune (1957) postulated that the degree to which a product is perceived to be conspicuous will influence the degree of "perceived

social risk" associated with its usage. Social risk is one of the multiple dimensions of perceived risk which consumers subjectively have in product purchase and/or consumption situation. Initially introduced in marketing literature by Bauer (1960), the perceived risk construct has since evolved into different areas. Functional risk is defined as the risk that the product will not perform properly (Cox 1967). Performance risk is defined as the extent to which consumers think that the various products perform differently in what is important to them (Brody and Cunningham 1968). Social risk is defined as the extent to which consumers think that other people judge them on the basis of the product or a brand they use (Jacoby and Kaplan 1972). Among these perceived risks, the perceived social risk is the factor which can invoke the socially oriented self-concept (situational self; to be discussed) in consumption situations. Also many studies found that social risk is the most important component of perceived risk. Jacoby and Kaplan (1972) reported that the strongest determinant of social risk was the degree to which the product usage is socially "visible." Perry and Hamm (1969) proposed that social significance refers to how the purchase decision would affect the opinion other people hold of the individual. Their study concluded that social risk was related to product usage conspicuousness and social importance. In addition, there are some studies which attempted to connect product "conspicuousness" and "socially oriented self-concept." Witt and Bruce (1970) found that as perceived product conspicuousness increased, subjects (housewives) were more likely to use fellow members' preferences to guide their own preferences. Midgley (1983) also reported that a majority of men formed their preferences and made purchase decisions for new suits on the basis of recommendations from others (generally their wives or peers).

Taken as a whole, the research on the consumer self-concept and product symbolism has treated the self-concept from the psychological perspective and largely neglected the influence of the social structure in which people interact and products are consumed. Although the product usage typology research recognized the importance of the influence of social interaction on consumer behavior and attempted to incorporate a sociological perspective, it failed to offer a rigorous theoretical framework to aid in understanding the influence of the social interaction on the consumer and the dynamic processes involved. Thus, the research on self-concept tended to be atheoretical (Siry 1982) and become no more than empirical testing.

Social Norm in Multiattribute Attitude Model

There was an effort to incorporate the influence of social influence on an individual's behavior in social psychology. Fishbein et al. extended their multiattribute model to include the social norm (Fishbein and Ajzen 1975). Specifically, "subjective norm" refers to the person's perceptions that particular referents think the

behavior should or should not be performed and to his motivation to comply with these referents. Although the normative component conceptually incorporates the social dimension into the model, the concept is too general and broad, making operationalization and measurement very difficult. Due to such inherent limitations of the model, the effort to apply it to consumer behavior research has not been successful (see Ryan and Bonfield 1975 for a review).

SYMBOLIC INTERACTIONISM²

Introduction

Symbolic interactionism, a research stream in sociology, appears to offer a theoretical basis for conceptualizing the "socially oriented self" and its relationship with product conspicuousness. Symbolic interactionists view the basic nature of society as a system of interpersonal communication and interaction and view the basic nature of the individual (self) as the product of society. It incorporates consideration of communicational dynamics rather than focusing on a communicational participant in isolation from the others with whom he interacts (McCall and Simmons 1978). Thus, it points to the positions that underlie structural relationships among persons and to the social roles that accompany these positions as the significant sources of relevant variation in the self.

Theoretical Contributions by Key Thinkers

James (1890) viewed humans as having a variety of types of self and argued that the human being has as many "social selves" as there are distinct groups of persons about whose opinion he cares. Thus, multifaceted self is the product of a heterogeneously organized society. Cooley (1902) saw that there is no individual apart from society: personality develops from social life and from communication among those sharing that social life. Specifically, the self is the product of a process summed up in the phrase "looking glass self" which refers to an individual perceiving himself in the way others perceive him. The basic dictum of Mead's social psychology (1934) is: Start with the ongoing social interaction for it is from the social process that mind, self, and society derive. Things become stimuli (objects) only as they take on meaning for the person engaged in the social process. As do things acquire meaning that defines

them through ongoing activity, so do people. We come to know who others are by interacting with them through significant "symbols." These symbols enable people to predict their own and others' behavior and to anticipate the future courses of interaction. The self is essentially a social structure, and it develops in social experience. In other words, we come to know who and what we are through interaction with others. The self may be said to exist in the activity of viewing oneself "reflexively." That is, we become "objects" to ourselves by attaching to ourselves symbols which permit use of the standpoint of others in order to view oneself as an object. Mead viewed the self as developing through the "role taking" process (i.e., taking the standpoint of others or "generalized others").

Assumptions

Symbolic interactionism has been characterized as building on a set of assumptions.

1. Humans must be studied on their own level and efforts to infer principles of behavior from the study of nonhuman form is misguided.

This reflects the emphasis on symbolic communication. The assumption is justified by the highly developed symbolic capacities of human beings.

2. The most fruitful approach to the study of human behavior is through an analysis of society.

This assumption underlies the potentialities of human development in the social process. It argues against the views of biological nature of humans and of learning and socialization.

3. The human being is an active agent of behavior rather than simply a passive respondent to external stimuli.

This assumption is built on the notion that things become stimuli only as they take on meaning for person engaged in the social process.

Propositions

The following propositions represent central features of contemporary symbolic interactionism, identifying a fundamental approach to human behavior by modern symbolic interactionists.

1. Behavior depends on a named or classified world. The names or class terms attached to aspects of the environment carry meaning in the form of shared behavioral expectations that grow out of social interaction. From interaction with others, one learns how to classify objects and in that process also learns how one is expected to behave with reference to those objects.

²This part derives extensively on Stryker (1980), Stryker and Serpe (1982), and Manis and Meltzer (1978). Two previous studies discussed the symbolic interactionism in consumer research (Reid and Frazer 1979; Schenk and Holman 1980). However, their treatment and interpretation of the approach was partial and narrow. Thus, the intent here is to provide a broad outline of major conceptual and theoretical underpinnings of the symbolic interactionist perspective.

2. Among the class terms learned in interaction are the symbols that are used to designate "positions," which are the relatively stable, morphological components of social structure. These positions carry the shared behavioral expectations that are conventionally labeled "roles."
3. Persons acting in the social structure name one another in the sense of recognizing one another as occupants of positions. When they name one another they invoke expectations with regard to each others behavior.
4. Persons acting in the context of organized behavior apply names to themselves as well. This reflexively applied positional designations, which become part of the "self," create internalized expectations with regard to their own behavior.
5. When entering interactive situations, persons define the situation by applying names to it, to other participants in the interaction, to themselves, and to particular features within the situation, and use the resulting definition to organize their own behavior accordingly.
6. Social behavior is not, however, determined by these definitions, though early definitions may constrain the alternative definitions to emerge from interaction. Behavior is the product of a role-making process, initiated by expectations invoked in the process of defining situations, but developing through a tentative probing interchange among actors that can reshape the form and the content of interaction.
7. The degree to which roles are "made" rather than simply "played," will depend on the larger social structures in which interactive situations are embedded. Some structures are "open," others relatively "closed" with respect to novelty in roles and in role enactments of performances. All structures impose some limits on the kind of definitions that may be called into play and thus limit the possibilities for interaction.
8. To the degree roles are made rather than only played as given, changes can occur in the character of definitions, in the names and class terms those definitions use, and in the possibilities for interaction; and such changes can in turn lead to changes in the larger social structures within which interactions take place.

Thus, symbolic interactionism proposes a dynamic theory about how individuals formulate and reassess their plans of action in terms of the objects and people encountered in their social environment,

and in terms of their own assessments of themselves. A most fundamental proposition of the symbolic interactionism is that a focus on the person without a correlative focus on social structure, or vice versa, is necessarily partial and incomplete. The "self-concept" can be conceptualized as an organization (structure) of various identities and attributes, and their evaluations, developed out of the individual's reflexive, social, and symbolic activities. As such, the self-concept is an experiential, modestly cognitive phenomenon accessible to scientific inquiry. They view the self not as a dependent variable, but as a most important variable intervening between the antecedent events of the social world and the consequent actions of the individual. In this respect, the approach basically agrees with the tenets of cognitive psychology which holds that cognitive processes mediate stimuli and responses. The difference lies in the specific emphasis by symbolic interactionists on the "effects of social stimuli" on behavior in various situations.

Situated Identity Theory

Among the diverse orientations within the symbolic interactionism, situated identity theory appears to lend itself to the direct application to the study of product symbolism and the consumer's self-concept. Building on Goffman's idea about the "self presentation" in everyday life (Goffman 1963), Alexander and his associates (1971; 1977; 1981) have defined situated identities as "the dispositional imputations about an individual that are conveyed by his action in a particular social context." They argue that when a person acts, he communicates information about the kind of person he presumes to be and obliges others to regard him as being that kind of person. In Mead's terminology, behaviors are "constituted" into action, because they have implications for the creation, affirmation, or transformation of an actor's situated identity. Alexander has postulated that if there is relative consensus about the meaning of actions within a population, situations are socially defined. That is, there must be some agreement about the dispositional dimensions relevant to describe an individual's conduct, and about how a particular action is to be evaluated along those dimensions. When these conditions are met, a situation has consensual meaning or social reality. When a social situation exists by these criteria, behavior can be predicted if the situated identity that results from the choice of one action out of some alternatives is considered more socially desirable than those associated with alternative actions.

An identity is considered as a working self-meaning constructed out of the material of a particular situation. People act to create the most socially desirable situated identity available because of the "self-esteem" motive (Alexander and Wiley 1981). This argument is based on Goffman's notion that social identity attributes organize and orient social interaction (Goffman 1963). These propositions are supported in a number of

experimental studies; cognitive dissonance, risk shifting, prisoner's dilemma, and expectation studies. In dealing with Festinger and Carlsmith's dissonance study (1959), Alexander et al. conducted an interpersonal simulation, gathering data not only on estimated responses but also on the situated identities created by the "stimulus person" whose responses were observed. The results replicated the relationships found in "insufficient justification" studies and were predictable from evaluative impressions. Attempts to reconcile these results with dissonance and incentive explanations have been unsatisfactory. It was found that subjects and observers attach the same situational meaning to experimental conditions and behaviors in them. The results obtained could be explained by the "social desirability" effects. From the subjects' standpoint, experiments may include "face saving" or "image enhancing" response alternatives that are unintentional consequences of the experimental design. Their identity imputation data show that changing some elements in the social context (i.e., by creating a different situated identity set from the experimenter's point of view), changes the meaning of the situation and of actions taken in it (from subjects' perspective). The meaning of subjects' responses changes with conditional manipulations and are associated with differentially evaluated identity attributions, because of changes in the kind of person they become by choosing among available response alternatives.

To summarize, the situated identity perspective conceives of individuals as structuring complex activities and stimuli sequences in terms of their implication for participants' dispositional attributes. When members of a given population consensually invoke the same dimensions to characterize actors, their attributional process creates social situations. Behavior is predicted if there is a "most favorable" situated identity to be gained from one of the behavioral alternatives that are possible under the circumstances. People are expected to choose to become the kind of person that will be most highly valued in each condition.

SITUATED IDENTITY APPLIED TO CONSUMER BRAND CHOICE

Situational Self

Situated identity theory is expected to be used to conceptualize the socially oriented self-concept discussed in the aforementioned product symbolism studies. This symbolic interactionist perspective can explain how a consumer's purchase decision is influenced by an anticipated reactions of others and how the consumption may influence others in the social interactive processes. The "situational self" is defined as the meaning of self that the consumer wishes others to have of himself. He seeks to achieve this by means of the product or brand he owns and uses in a typical consumption situation. The situation-specific self-concept may include attitudes and perceptions that the consumer feels the need for others to form of his internal disposition.

Thus, the situational self is dependent upon the parameters of a product (symbolic meaning) and its consumption situation (social process) as suggested by situated identity theory.

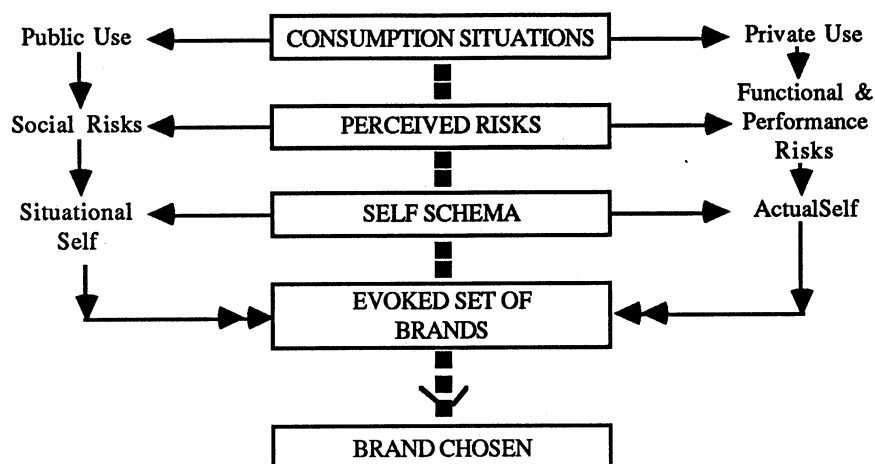

The situational self-concept is able to describe and predict the consumer's brand choice decision of the product which is used in public, and hence involves conspicuousness and visibility. In this product category alternative brands are assumed to be easily distinguishable and have well established images. It is also assumed that each brand implies a differentially desirable identity and there is relative consensus about the symbolic meaning of each brand within a population. The theoretical basis for the existence of brand images that are more or less the same for members of a social system lies in the propositions of symbolic interactionism. That is, people classify objects which they come into contact with in social processes, and in that process they also learn the symbolic meanings of the objects. Consequently, in the social process emerges the consensual meaning of the objects among all those who are interacting.

A Brand Choice Model

The situational self-concept is incorporated into a conceptual model of brand choice which is shown in Figure 1.

When a product is used in public (e.g., public luxuries such as golf clubs, snow skis, sail boat, etc.), its use involves high social visibility and conspicuousness because others are aware of one's possession and use of the product and can easily identify the brand. Thus, the consumer becomes conscious of the people in the consumption situation and is more concerned about how other people would judge him on the basis of the brand or the product he uses, which is defined as the perceived "social risk." Therefore, as the consumer subjectively assesses appropriate role behaviors and forms a meaningful evaluation of significant others to be encountered in the anticipated and/or typical consumption situation of the product (meaningful in terms of the plans of the consumer; enhancement of self-esteem motive). In this process, he establishes the "situational self" concept or draws one from his "self schema," if he has well established situation specific self concepts in relation to the product use situation. The consumer then identifies the self within the consumption situation in which the symbolic meaning of the product mediates the communication between him and others encountered as symbolic interactionists suggest. Therefore, the invoked "situational self" concept is to guide the brand choice process. He then searches through the evoked set of the brands in the product class and compares the images of brands with the situational self invoked. Each brand is to have a different degree of fit to the invoked situational self image because each has a different set of intrinsic and extrinsic values as a means of self enhancement when presented to significant others. In many product categories, alternative brands are easily

FIGURE 1
A Brand Choice Model

distinguishable and brand images are relatively well differentiated (or differentiable). Also, there is relative consensus in the market because of marketers' promotional efforts to differentiate their brand from competing brands (market segmentation and brand positioning). Each brand has a different symbolic meaning commonly shared by the majority of consumers. Therefore, the brand whose image is closest to the situational self will be selected (or will be the most preferred) for consumption in the anticipated situation. This process warrants more elaboration from the symbolic interactionist perspective to gain more insight into the dynamics involved. In this process, the consumer attributes "meaning" to the product symbolically which is to be communicated to the others encountered in the consumption situation in order to enhance his self-esteem. Goffman (1963) indicated products could serve as props to aid in communication of the situational self.

This private and individual symbolic interpretation of a brand is largely dependent upon an understanding of the symbolic meaning associated with the brand which one has learned from previous interactional experiences and/or from marketers' brand positioning efforts (e.g., image-oriented ad) to map their brand on consumers' perceptual space distinctly from other competing brands. Therefore, although the consumer may treat this process in a private manner, his evaluations of symbolic contents of the brand depend upon his "perceptions" of how other people would evaluate the brands. As the consumer attributes meaning to it, so the others interacting with the consumer in the consumption situation also attribute meaning to the symbol. This represents the symbolic interactionist perspective of how the individual and social structure maintain reciprocal relationships through symbolic communication. If a brand has a

commonly-shared meaning between the consumer and others, then the desired communication (self-enhancement) can take place and the interaction process will develop as desired by the consumer.

Meanwhile, when a product is consumed in a personal way (e.g., private necessities such as mattresses), its use does not involve conspicuousness or social visibility because almost nobody would be aware that the consumer owns or uses the product. When purchasing this kind of product, the consumer would be mainly concerned whether the product turns out to be defective or to be different from what he expected in some important physical and functional attributes. If that happens, he may be frustrated about or regret his purchasing decision. Thus, the consumer is expected to be more concerned about perceived functional and performance risks than the perceived social risk. "Functional risk" is defined as the risk that the product will not perform properly. "Performance risk" is defined as the extent to which the consumer thinks that different brands of a product perform differently in what is important to him. Therefore, in this situation, actual self-concept is expected to be invoked and guide the brand choice.

IMPLICATIONS OF THE MODEL

The model will contribute to the consumer self-concept and product symbolism research in several ways. First, it integrates the multiple dimensions of self-concepts into one construct under a symbolic interactionist framework as it applies to product symbolism. Specifically, the self concept is defined broadly enough to incorporate socially oriented self-concept (situational self) and psychologically oriented self-concept (actual self). On the other hand, the model is specific enough to suggest how to operationalize and measure the two dimensions of self. That is, the model introduced

the construct of perceived risk which has been used in many marketing studies. This compares with previous approaches which were mainly conceptual (e.g., applications of Fishbein's extended attitude model and Schenk and Holman 1980's conceptual model). Also, the proposed model is very specific in terms of the product category and consumption situation to which it can be applied.

Although the model is expected to enhance our understanding of consumer's brand choice behavior and improve the prediction of brand choice in some specific product categories, it certainly has its limitations. As an initial attempt to introduce the symbolic interactionist perspective into consumer behavior research, the focus has been on conceptualizing the "situational self" and on the application of the concept to consumer brand choice. Consequently, the model is not broad in its scope. The model does not take into account individual differences. It may well be that consumers differ in their perception of product conspicuousness. Constructs such as self-awareness (Wicklund and Frey 1980) and self-monitoring (Snyder 1979) might add additional insight if integrated into this framework in future research. Finally, the ultimate usefulness of the proposed situated self-concept in explaining or predicting behavior rests on empirical validation, which should be the next stage of this research program.

Discussant Comments - Session 5.1

Robert F. Kelly, University of British Columbia

Three of the four papers in this session are concerned with symbolic communication among consumers; an area of substantial current interest for consumer researchers generated by colleagues such as Hirschman and Holbrook, Levy, Rook, McCracken, and Belk. Of course, the study of symbolism in human behaviour has been going on much longer. Marx, Veblen, and Durkheim each considered major dimensions of symbolic behaviour. Within my professional lifetime but prior to the current surge of interest, Warner, Reisman, Gardner, Martineau, Rainwater, Coleman, and Levy (The same Levy), among others, considered the symbolic properties of objects acquired in the market place - especially in signalling status and/or social class. Even more work touching on symbolic consumption has been published outside the marketing literature (e.g., anthropology) and a substantial amount is in other than the English language (e.g., Bourdieu or Levi-Strauss in French).

Only the Lee paper among the three in this session on symbolic consumption hinted at the broader context within which this work is being conducted. This is unfortunate for a variety of reasons. First, it suggests that we are either ignorant of or ignoring a rich body of knowledge generated by scholars at least our equal in their insight into human behaviour. Second, it leads to the reinvention of the wheel; the "discovery" of classes of behaviour well documented in other disciplines. Third, it suggests a critical deficiency in the manner in which we are being prepared for our discipline.

The fourth paper seems to suffer from a tendency opposite to that discussed with respect to the "symbolism" papers. The authors seem to be ignoring a very substantial body of work by consumer researchers in their efforts to extend Erikson's work on personal identity.

After a brief commentary on each of the four papers, I would like to identify some issues with respect to symbolic consumption that were not considered in this session but that appear to me to be fundamental to an understanding of the process.

I. CLAIBORNE AND OZANNE, "THE MEANING OF CUSTOM-MADE HOMES: HOME AS A METAPHOR FOR LIVING"

The thesis, custom-made homes represent an opportunity for consumers to "create meaning" through the introduction of cultural and personal symbols ... and, subsequently, through the manner in which they live in a given house, owes much to such scholars as Edward T. Hall in both *The Silent Language* (1959) and *The Hidden Dimension* (1966), Mary Douglas in *The World of Goods* (1979), Csikzentmihalyi and Rochberg-Halton in their *The Meaning of Things* (1981), Grant McCracken in several efforts (especially *Culture and Consumption*

(1988), and earlier this year, Russ Belk's "Possessions and the Extended Self" in the *JCR*.

The idea of investigating the symbolic imprints of family units who have "custom made" their homes does constitute a new wrinkle so far as I know and certainly has intuitive appeal. Unfortunately, the work did not appear to produce empirical information markedly different from that available through studies on the selection of preexisting houses; a process much more convenient to investigate.

The investigation considered ten respondent households in a single community. In an exploratory study, the small number of households and the relative homogeneity of respondent units is not necessarily important. I had some problems with the husband-wife dyad as the "response unit", however. Both the family decision-making and the market research literature advise physical segregation and separate questionnaires for husbands and wives because of the possibility of contamination and/or dominance. Furthermore, the procedures employed make it difficult to detect sex-role specialization in the decision process even though most home-purchasing studies suggest such specialization exists.

Where Is Levi-Strauss When We Really Need Him?

Rather than pose a series of hypotheses for which the field procedures became a test, the authors employed "hermeneutical analysis;" a procedure introduced into the consumer behaviour literature by Grant McCracken. This may prove to be one of McCracken's less valuable contributions. Does it matter, given that categories are permitted to evolve as the data is analyzed, that the analysts are not trained ethnographers or structural anthropologists? Does such an analysis preclude hypotheses? If one does not know what to look for before the fact, how can one be assured the observations are sufficiently complete to establish categories afterwards?

The categories that did arise from the analysis, according to the discussion, seemed more related to functionality than to symbolism. "In summary, houses represent a new way of contrasting the needs for openness and privacy." (p.12) I felt the authors let the data lead them away from their stated purpose; in the process of defining categories on an evolutionary basis the original intent seems to have been lost.

While I am entirely sympathetic with the move away from the information-processing paradigm with its anal-retentive approach to numerical analysis, there are some restrictions that must be observed. Anarchy is no more functional in behavioural research than it is in politics. We are so inculcated with the rigidities imposed upon us by Scientism that, given license to generate and assess

data without its strictures, we behave as though no discipline at all were required.

Finally, nothing in this paper actually identified the symbols that were found to connote openness or privacy. Neither did I gain any understanding on the manner in which such symbols are transmitted through socialization, observation, or formal education. Do they form part of a system of non-verbal symbols that take on the qualities of more conventional verbal languages? If so, do these languages have structures?

II.T. BETTINA CORNWELL, "T-SHIRTS AS WEARABLE DIARY: AN EXAMINATION OF ARTIFACT CONSUMPTION AND GARNERING RELATED TO LIFE EVENTS"

Reading this paper was fun....an infrequent experience while slogging through the Consumer Research literature. Perhaps Morris Holbrook is having an impact after all.

The major premise underlying the author's work is that T-shirts with words, slogans, and pictures have communication as an overt objective *and their possessors share the values implicit in that message*. Such a maintained hypothesis concerning the symbolic content of items of dress is reasonable and was well-documented within the paper. The author cites relatively recent scholars such as Czikszentmihalyi and Rochberg-Halton (1982), Holman (1980), Hirschman (1985), and Wicklund and Gollwitzer (1982), but substantial evidence on this issue has been around at least since the turn of the century when A.L. Kroeber published his classic analysis on womens fashions over the preceding 300 years.

Some empirical evidence linking the messages on T-shirts with their possessors would have been reassuring. Most of us possess T-shirts that convey messages with which we would prefer not to be associated; not just because the sentiments are no longer apt (the Gary Hart T-shirt noted by the author) but also because we never wished to convey that message. I have received several such shirts from former students and former friends.

The choice of the T-shirt as an object of study is fortuitous for a number of reasons. As noted by the author, T-shirts are asexual and virtually universal in the subculture within which she operates. In addition, the possibility that the symbolic content of a T-shirt will be misinterpreted is minimized; the message is usually in verbal form, rarely ambiguous, and, unlike statements based upon a given style or fabric or colour combination, interpretation is not likely to vary with the taste system of the interpreter.

I was struck by the degree of self-awareness concerning the transforming qualities of T-shirts by the various diarists in the study. "Kay" in particular linked mood and attitude changes to the T-shirt she wore at a given time. Perhaps the T-shirt is the direct analog of the transformation mask. Haida friends (from the Northwest coast of Canada) report that very similar mood changes accompany the

manipulation of the masks employed in transformation rituals (in the Haida transformation mask there is a mask within a mask and one "changes" from one creature to another by pulling a string).

In the author's conclusions she avoids cosmic declarations based on five sets of observations; a restraint for which she is to be commended. She quite reasonably offers more questions than answers in her conclusions section. I would like to add one or two of my own: We know that not all persons within a given social system wear T-shirts, what qualities distinguish wearers from non-wearers? Can behaviours observed with respect to T-shirts be expected to occur with respect to other garments where the symbolic content is less obvious?

III. FEINBERG, YOON, WESTGATE, TRAPPEY, MONGER, SMITH, AND RAPHAEL. "A CONCEPTION OF CONSUMER IDENTITY."

I believe the research undertaken by the authors is both ambitious and important. It brought to mind, especially, F.B. Evans, who investigated the value of Edwards Personality Preference Profiles (i.e., "personality tests") as a predictor of product and brand preferences.(Evans 1959) Claycamp (1965) and Westfall (1962) have also done work that may prove useful. However, as in Evan's work, the question may *not* be so much whether consumption is an element of identity but, instead, whether it is important enough to have strategic or predictive significance. Alternatively, one may ask whether consumption is an independent element of personal identity or an extension of some other more basic elements. While the issue of order of development was addressed, the question of cause and effect was not.

I am surprised no use was made of the work of Ward (1972); Russ Belk, with and without associates (e.g., Belk, Bahn, and Mayer (1982); and others going back at least into the fifties on the character of the socialization process as it pertains to specific forms of consumption. The manner in which an individual "acquires" a consumer identity surely is linked to the socialization process. Just as the authors are surprised that no one has thought to extend Erikson's work so am I surprised they found so little inspiration within the marketing and consumer behaviour literature.

I must admit I have an aversion to studies conducted among university undergraduates. Arguments pro and con are familiar to most consumer researchers so I will not repeat them here. I do wish to point out that it seems particularly awkward to use students in this research since consumption styles and consumption values may be difficult to detect in individuals who are near the beginning of their consumer life cycles. Surely, yet-to-be-attained levels of education, occupation, discretionary income, and a whole host of environmental factors such as the values held by ones significant others will do much to shape the ultimate consumption element of any given "self."

The authors raised the issue of when various elements of self might evolve, but did not pursue the matter very far.

The procedures of investigation and analysis are thoroughly described - too thoroughly described for my taste - but left me hoping for more conceptual content. I would like to have seen more discussion on the bases for grafting a consumption component onto Marcia's identity interview, for example. I also hoped for conclusions more profound than "...occupational decisions are a major concern to college age individuals" or "Instead of consumer behaviour lying outside the mainstream of the human experience, (an absurd perception) consumer behaviour is part of a life span developmental perspective that has been successfully used to understand and explore major areas of human development." (p. 14, the comment in parentheses is mine)

What major areas of human development has consumer behaviour been used to explore? How does that relate to your instrument and your research? How can you hypothesize "...that consumer identity would be developed after occupational identity but before religious and political identity."(p.7) without providing a theoretical basis for such a hypothesis? You say "...the results empirically support the existence of a consumer identity..." (p.14) but do they? On what basis were those items on consumer identity chosen? How were they tested for construct validity? Does replication produce the same results? It may be that these steps fundamental to the development of any measurement instrument were completed by the authors or by others... if so, it is not evident from the paper.

Overall: This paper reads as though it were written by a committee....which, in a sense, it was. There is extraordinary detail on procedures related to analysis of the data but none on the development of the measurement instrument. The analytical procedures are very sophisticated but there is no assurance of validity for the data to which they are applied. More thought and less action is recommended. None of these comments take away from the desirability of research on consumer identity, its measurement, or implications.

IV. DONG H. LEE, "SYMBOLIC INTERACTIONISM: SOME IMPLICATIONS FOR CONSUMER SELF-CONCEPT AND PRODUCT SYMBOLISM RESEARCH"

The author is correct in observing that consumer researchers have ignored social research*lately*. But only since the beginning of our rather stifling preoccupation with the information-processing model. In the fifties and sixties, Levy, Gardner, Martineau, Rainwater, Coleman, Nicosia, Lazarfeld, Katz, Katona, Rogers, and others developed many of the principal concepts that underly our discipline. Our insights on social standing and spending behaviour, on peer and personal influence, on the two-step flow of communication, on diffusion theory, and a host of

other significant ideas came from social science researchers with at least one foot in the consumer research camp.

Among the critical conclusions from a literature review: "Social visibility" in consumption or display is a necessary condition in most instances if market objects are to carry symbolic content; and "significant others" are the principal audience to ones symbolic behaviours (an alternative hypothesis is possibleJ). Aversion to social risk (a la Bauer, Cox) is seen as an important driving mechanism. "We come to know who others are by interacting with them through 'significant symbols.' These symbols enable people to predict their own and others' behavior and to anticipate the future courses of interaction." (p.7)

I cannot agree with the author's contentions that the social visibility concept (a la Goffman) and the "social norm" as a factor in Fishbein's work lack a rigorous theoretical framework to aid in the understanding the influence of social interaction on the consumer and the dynamic processes involved. To say they were unsuccessful in application constitutes something close to heresythat does not mean it is inappropriate to look for other, more rigorous bases for explanation, however.

Questions suggested but not actually touched on in the discussion include: As social visibility increases for a given product, is it more likely that distinct, symbol-laden brand images will evolve? Are their products with little social visibility that carry high social-symbolic content?

With respect to the brand choice model which is the major focus of the paper, I cannot see that this model is any more precise or lends itself to any more rigorous empirical testing than the models the author chose to criticize. Public - private use, for example, is neither a continuum nor a dichotomy. Yet that is suggested by the manner in which the model is presented. The same comment holds for Social vs. functional risks and for situational vs. actual self. Situation is clearly an intervening variable but is not adequately provided for in the model. That, joined with individual differences (i.e., consumption style) for which the author acknowledges he has not accounted, makes the new model just as fuzzy as the old ones.

While I am pleased to have had the opportunity to read all the papers in this session - and each has contributed in some fashion to my understanding of consumer behaviour - this is the one paper from which I would actually be inclined to steal. The paper is much richer in conceptual content and requires far fewer leaps of logical faith to move from his statement of objectives to his conclusions than the others in this set. It is flawed in an editorial sense, but one can easily overlook the occasional grammatical deficiencies in the face of the quality of the thought that has gone into it.

I do not agree that he has achieved what he says he has. He has not overcome the absence of a "...rigorous theoretical framework which can systematically incorporate the social dimension of

self." But he has certainly contributed towards the development of such a framework.

SUGGESTIONS FOR ADDITIONAL RESEARCH ON SYMBOLIC CONSUMPTION.

The papers we have heard cover a range of issues on symbolic consumption. But many fundamental questions remain. Do the symbols purchased and/or displayed by consumers form non-verbal languages similar to the verbal ones (i.e., with similar structures)? To what extent must an object be involved in this symbolic process? Is it not possible that a service (e.g., an experience) could carry equally symbolic content? Some objects are denotative while others are connotative of a given meaning (e.g., status symbols). Why? How do we acquire our knowledge of symbolic languages? Do the meanings attached to those symbols change over time? If so, what factors are likely to trigger such changes? I suspect we all have ideas on how those questions should be answered. But those we will have to reserve for another year.

How Regular is Regularity? An Empirical Test of the Regularity Assumption

Thomas S. Gruca, University of Massachusetts¹

ABSTRACT

Using scanner panel data, an empirical test of the regularity assumption in the case of a new product entry is performed. Consumers with similar pre-entry purchasing patterns are assigned to segments on this basis to provide sufficient sample sizes for statistical testing.

Seven segments of the caffeinated ground coffee market of two retail markets were studied containing 6 and 4 regular brands respectively. It was found that there were no statistically significant violations of the regularity hypothesis. This result is in concert with the expectations from previous lab work which pointed to fewer violations as the choice environment increased in realism.

INTRODUCTION

An important problem for consumer researchers is the effect a new product has on consumers' preferences for the products already in the market. There is conflicting evidence from lab studies concerning possible change in preferences when a new alternative becomes available. Ryans (1974) found that the introduction of a new alternative does not change the preference orderings of the incumbent products. In contrast, Huber and Puto (1983) reported that the existence of a new alternative can greatly change the probability that one of the incumbent brands is chosen.

One thing that researchers in choice theory often agree on is: if the number of alternatives is increased from N to $N+1$ with the introduction of a new alternative, the probability of choosing any one of the original N alternatives does not increase. This assumption is called "regularity" and is a minimal condition for a large number of choice models including the Luce Choice Axiom (Luce 1959, 1977), Tversky's EBA model (Tversky 1972), market share attraction models (Bell, Keeney and Little 1975) and the ideal point model. The importance of regularity to choice models is illustrated by a comment from Luce (1977) that the "only property of general choice probabilities that has not been empirically disconfirmed has been regularity."

Despite the above conclusion, Huber, Payne and Puto (1982) and Huber and Puto (1983) present empirical evidence for violations of regularity in the choice processes of the subjects. They found that the addition of another alternative increased the probability that one of the original alternatives was

chosen. In response to these findings, some recent models have been proposed to handle situations where regularity is violated (Currim 1982, Batsell and Polking 1985).

The results of these choice experiments and the models proposed to remedy the problem of regularity violations should not be accepted uncritically. The assumption of regularity appears to be violated in the choice tasks reported in the these experiments. If these results can be generalized to other common choice situations, those marketers and academics who are interested in consumer choice may have to radically redirect their research to account for this problem. The aforementioned choice models which cannot deal with violations of regularity are among the most used models in consumer research.

Thus, the potential importance of the findings of Huber, Payne and Puto (1982) and Huber and Puto (1983) serve as motivation to critically evaluate these studies and their results. Furthermore, there are a number of limitations in these studies (and in all lab studies of this type) which may have accounted for the violations of regularity. Therefore, an empirical (field) test of the regularity assumption is performed.

CRITICAL REVIEW OF PREVIOUS RESEARCH

The main empirical evidence of violations of regularity comes from two lab studies by Huber, Payne, and Puto (1982) and Huber and Puto (1983). In both of these studies, groups of subjects were asked to make choices from sets of two alternatives and from sets of three alternatives. In the Huber, Payne, and Puto (1982) study, the new alternative was asymmetrically dominated by the existing set of products, i.e. dominated by one alternative but not the other. In the Huber and Puto (1983) study, the new alternative was extremely good on one choice dimension but poor on the others.

In the Huber, Payne and Puto (1982) study, it was found that the addition of the new alternative increased the probability of choosing one of the two original alternatives in 18 of 24 cases. This increase was taken as evidence of a violation of the regularity hypothesis. The authors concluded that the number of these violations was statistically significant; "This occurred in 18 out of 24 different cases ($p \leq 0.05$)."

The proportion of violations in the Huber and Puto (1983) paper was 15 out of 20 different cases using a similar experimental design.

The observed increases in the choice probabilities seemed large in an absolute sense (averaging 14.5% and 15.1% in the respective studies). However, using a z-test for equality of proportions, it can be shown that most of the changes in choice probabilities are not statistically significant. In fact, less than half of the reported

¹The author would like to thank John Totten of IRI, Inc. for his help in obtaining the data used in this study. This research was partly supported by a grant from Proctor and Gamble Co. to the Marketing faculty of the University of Illinois.

violations are significant ($p \leq 0.05$). Of the 18 reported violations in the earlier study, only 8 were found significant. From the data provided in the later study, it was found that only 5 of 15 reported violations were significant.

One of the major limitations of these studies may have been the construction of the experimental stimuli. Since the goal of these studies was to illustrate the change in choice probabilities when a similar new brand is introduced (similarity effects), it can be assumed that these effects - attraction or substitution - were responsible for the violations of regularity. However, a replication of these studies by Ratneshwar, Shocker and Stewart (1987) found that the similarity effects demonstrated in these two studies are moderated by stimulus meaningfulness and product familiarity. One might argue that, based on these most recent findings, the remaining cases of violations of the regularity hypothesis may be due to stimulus construction problems.

A further problem with the product choice studies lies in the assumption that the subjects' preferences were homogeneous. This assumption had to be made in order to be able to measure product choice probabilities between subjects. Otherwise, the subjects would have to make repeated choices from the same set of alternatives.

However, it is difficult to argue that consumers are homogeneous. In fact, the entire field of market segmentation is predicated on using these differences to improve the process of marketing. On the other hand, without the assumption of homogeneity, the between subject analysis in the choice experiments is incorrect.

The final limitation is one common to all laboratory studies: external validity. The question of the generalizability of lab results to the world outside is especially important in this case since the lab experiments are limited to 2 to 4 products evaluated on, at most, 3 dimensions. The importance of empirical verification is heightened by the fact that most product categories have a larger number of alternatives which can be evaluated on a wide range of bases.

Although some of these limitations are common to all laboratory research, it is important to replicate findings of this importance outside the lab regardless of the quality of the research. For this reason, a test of the regularity assumption using actual choice data is performed. The advantages of this method and the actual design is discussed in the next section.

EMPIRICAL TEST OF REGULARITY ASSUMPTION

The use of actual choice data to test for violations of the regularity assumption avoids some of the limitations of the lab studies discussed above. The main advantages are 1) less restrictive assumptions concerning homogeneity of preferences, 2) no restriction on the number of choice attributes to be used by consumers, 3) larger number of available alternatives, and 4) choice made in natural setting. The primary assumption

underlying the analysis of actual choice data is that the choice process of each consumer is zero order and stationary. A zero order choice process is one in which the choice of an alternative at time t is independent of the choice made at time $t-1$. A stationary choice process assumes that the choice probabilities are fixed over time. Under these assumptions, a Z-test for equality of two proportions (choice probabilities before and after the entry of the new product) can be used to test for violations of regularity.

There is one problem with relaxing the assumption concerning homogeneity of preferences. If the test for violations of regularity is performed at the individual level, a large number of choices must be observed. However, the longer the period of observation, the more likely that the marketplace will change leading to non-stationary choice processes. On the other hand, aggregating all of the consumers' choices might obscure possibly important consumer heterogeneity.

As a compromise, it is proposed that the market be segmented according to the choice probabilities of the consumers. A segment is defined as a group of consumers who are homogeneous with respect to the probabilities of choosing different brands in a product class. Those consumers with the same choice probabilities will be considered a segment and treated as a single unit. Since the situation examined in this paper is the introduction of a new brand into an existing market, the segmentation will be based on the pre-entry buying behavior of the consumers.

Market Segmentation Using Choice Probabilities

The market segmentation will use the pre-entry purchase patterns as a basis for market segmentation. The procedure used was developed by Grover and Srinivasan (1987) using latent class modeling using a widely available computer algorithm.

It is assumed that the probabilistic brand choice process is stationary (constant) and zero order (brand choice at time t is not affected by brand choice at time $t-1$) so that each household is characterized by its choice probabilities. If there are n brands in the market, an n -component vector of choice probabilities varies over the population. It is assumed that differences in purchase patterns observed across households can be captured by n brand loyal and m switching segments. Each household is assumed to be a member of only one of the $n+m$ segments.

A brand loyal segment will purchase only its preferred brand. This implies that for segment l , the proportion of households purchasing brand i on one occasion and brand j on another is given by: $p_{i,j,l} = 1$ if $i = j = l$, $= 0$ otherwise for all $l = 1, \dots, n$.

For the brand switching segment k , let $p_{i,k}$ be the probability of choosing brand i . In other words, $p_{i,k}$ is the brand share of brand i for segment k . It is clear that $p_{i,k} \geq 0$ and $\sum_i p_{i,k} = 1$ for all $k = 1, \dots, m$. Since the choice process is assumed to be

zero-order and stationary, the probability of buying brand i on one occasion and brand j on another is $s_{i,j,k} = P_{i,k}P_{j,k}$ for segment k .

Let the proportion of consumers who are loyal to brand l be V_l and the proportion of consumers in switching segment k be W_k . Clearly, $V_l \geq 0$, $W_k \geq 0$ and $\sum_l V_l + \sum_k W_k = 1$. Defining the theoretical proportion of consumers in the market who buy brand i on one occasion and j on another as $S_{i,j}$, then $S_{i,j}$ is given by:

$$\begin{aligned} S_{i,j} &= \sum_l V_l s_{i,j,l} + \sum_k W_k s_{i,j,k} \\ &= \sum_l V_l P_{i,l} P_{j,l} + \sum_k W_k P_{i,k} P_{j,k} \end{aligned}$$

for j not equal to i and

$$S_{i,i} = V_i + \sum_k W_k (P_{i,k})^2.$$

The latent class procedure estimates the proportion of consumers in each brand loyal segment (V_l), the proportion of customers in each switching segment (W_k), and the vector of brand choice probabilities for each switching segment ($P_{i,k}$, $i=1, \dots, n$). This is accomplished through the decomposition of the brand switching matrix $S=(S_{i,j})$.

In order to assign each household to a given segment, a maximum likelihood function was used to determine the Bayesian probability that a given household belongs to a given segment. The household is assigned to that segment for which this probability is maximized.

The likelihood function used the purchase frequency vector for each household in addition to the estimates from the latent class procedure. Let r_i (for $i=1, \dots, n$) denote the number of purchases of brand i for a given household. The likelihood of (r_1, \dots, r_n) given segment h ($1, \dots, n+m$) is given by the formula:

$$\begin{aligned} L_h &= [(\sum_i r_i)! / \pi_i(r_i)!] \\ &\quad * (P_{1,h}^{r_1} P_{2,h}^{r_2} \dots P_{n,h}^{r_n}). \end{aligned}$$

The prior probability of belonging to segment h is V_l for $h=1, \dots, n$ and W_k for $k=n+1, \dots, n+m$ and will be denoted by B_h . The posterior probability of belonging to segment h is given by Bayes' Rule:

$$P_h = B_h L_h / \sum_j B_j L_j, \quad j=1, \dots, n+m.$$

From this market segmentation procedure, those consumers with the same pre-entry purchase patterns will be identified. This segmentation will be used to test whether the introduction of a new brand changes the choice probabilities of those consumers who do not buy the new product.

EMPIRICAL INVESTIGATION

The empirical tests of the regularity hypothesis reported here will try to replicate the

violations observed in the lab. The situation studied is the change in choice probabilities with the introduction of a new brand into an existing market. The study will consider the choice probabilities of only those consumers who *do not* purchase the new brand. Since the empirical test compares the pre-entry and post-entry purchase probabilities, only those consumers who do not try the new brand can be assumed to have a choice process is stationary and zero order.

This restriction of the sample is similar to those experiments in which none of the subjects chose the new, added alternative. There were 9 such experiments in Huber and Puto (1983).

In the previous laboratory experiments, the added alternative was inferior in some respect at least one member of the original choice set. In the data used in this paper, however, the new alternative was sampled (and repurchased) by a large number of consumers in the two markets under study. Since many consumers felt that the new brand was sufficiently similar to existing brands to warrant trial, it will be assumed that the perception of similarity of the new brand to existing offerings is widely shared. The new brand is therefore assumed to be similar to existing offerings and not an inferior substitute. In that case, there may be effects of attraction or substitution (which caused the violations of regularity in the lab experiments). Although there is no way to determine if the non-triers perceived the new brand as being similar, if these effects are as strong as demonstrated in the lab, violations of regularity should occur in the purchase patterns of those who not try the new brand.

The database used is the IRI Academic Research Database of coffee purchases. The markets under study are the retail ground coffee markets of Pittsfield, MA and Marion, IN. The new product entry being studied is the entry of Master Blend, a General Foods brand, in March, 1981. After the brand was introduced, it was available in all grinds in all stores tracked by the IRI data.

The study is limited to ground caffeinated coffee purchases since it has been found that regular ground coffee and instant or decaffeinated coffee are used for different usage situations rather than being substitutes (Urban, Johnson and Hauser, 1983).

Those brand-grind combinations which accounted for at least 1% of the purchases in the pre-entry period were retained for analysis. The brand-grind combinations used in the study are listed in Table 1. The eight brands retained accounted for 94.8% of the pre-entry purchases in Pittsfield. The six brands retained for the Marion market accounted for 95.7% of the pre-entry purchases. It is clear that these brands account for most of the purchases in these markets.

In addition to choosing which brands to include in the study, which households to include must also be decided. The households included in the study have purchased ground coffee at least 8 times before and after the entry of the new brand.

TABLE 1
Brand-Grinds Used in the Study

Pre-entry Purchase Share		
Brand	Pittsfield	Marion
A Hills Bros.	7.5	---
B Folgers	23.5	30.8
C Folgers Flaked	3.4	19.2
D Chase and Sandborn	3.5	4.6
E Maxwell House	28.7	24.8
F Brim - Decaffeinated	3.1	7.4
G Sanka - Decaffeinated	1.4	8.9
H Chock Full O'Nuts	23.0	---
Total	94.8	95.7

Note: (---) indicates that the brand-grind combination was unavailable in the market indicated.

Lighter buyers were excluded since, due to the small number of purchases observed, it is very difficult to accurately measure their purchase probabilities. Including the light buyers might lead to their misassignment to a segment simply because not enough purchases were observed.

Segmentation Results

In these markets, there are a large number of households who purchase both regular and decaffeinated coffee, presumably for different purposes. Those households which purchase both types of coffee will be excluded since changes in the decaffeinated brands (for example, a price hike) might affect purchasing of regular coffee. Therefore, only households loyal to caffeinated brands will be studied.

To determine which households were loyal to which brands, the segmentation procedure described above was applied to all eligible households (those with at least 8 pre-entry purchases). In the interest of brevity of presentation, only the final segmentation results will be presented (for the estimation details, see Grover and Srinivasan, 1987).

In order to obtain these results, the data were split by markets into two subsamples for model identification and then estimation. The chi-square test for the assumption of a zero-order, stationary choice process performed on the brand switching matrices showed no significant deviations. The m+n solution was identified for m = 1,5 switching segments. It was determined that the four switching

segment solution for Pittsfield and the two switching segment solution for Marion were the best fitting (based on the recommended \bar{R}^2 measure) without overfitting the data. The final model parameters were estimated from the second subsample. These estimation results are in Table 2.

Tests for Violations of Regularity

Each consumer was assigned to a single segment based on his pre-entry purchase behavior (total segment size in Table 3). Those consumers who did not purchase the new product at least once in the first year of availability were the subjects of the tests for regularity violations (sample size in Table 3).

The purchase frequency vectors of the consumers in each segment were converted to purchase probabilities by dividing each element of the vector by the total number of purchases made by the consumer. The segment choice probability vector was then computed by aggregating the individual probabilities by segment for both the pre-entry and post-entry time periods. This yields an unweighted "average" choice probability vector.

Without the conversion to probabilities at the individual level, those consumers with a large number of purchases would have a great effect on the segment purchase probability vector. A small change in the buying patterns of a single, high volume user could be magnified, leading to a possibly erroneous conclusion that regularity had been violated.

2	10/0	2	73/0
3	38/0		
4	65/0		

The Z-statistic requires that the number of observations of a choice from a set be supplied. Since the segment choice probability vector is based on the "average" member of the segment, the average number of purchases by a member of a segment will be used as the number of observations.

To determine if regularity has been violated, the pre and post entry purchase vectors will be compared. If there is any increase in the probability

of choosing some brand in the post-entry observations, the statistical significance of this increase will be determined using a Z-test for the equality of proportions.

The changes in the post-entry purchasing patterns may be due to factors other than the entry of a new brand and these factors may even be unobservable. However, the procedures used to choose the brands and households for the study

attempted to reduce these effects (like spurious changes due to sampling error) and are the same ones used by practitioners using these analysis procedures to study actual market behavior.

Statistical Notation

The hypotheses are:

$$H_0 = P(x|A) \geq P(x|B) \text{ and}$$

$$H_1 = P(x|A) < P(x|B).$$

If N_1 , N_2 are the number of observations and R_1 , R_2 are the number of times that x was chosen, then define:

$$p^* = (R_1 + R_2) / (N_1 + N_2).$$

The Z-statistic is:

$$Z = [(R_1/N_1) - (R_2/N_2)] \\ + \sqrt{[p^*(1-p^*)(1/N_1 + 1/N_2)]}.$$

Previous work has used McNemar's test, Fisher's exact test or the chi-square statistic. These are all proper tests for violations of the assumption of zero-order choice process or stationary choice process since they take into account all choice probabilities. However, the concern in this paper is only for violations of regularity. In addition, since the data have not been collected in the lab, there is no way to insure that the assumptions of cell size can be fulfilled. This leads to using the Z-statistic to test for violations of regularity.

RESULTS

There were three and four segments in the Pittsfield and Marion markets respectively which had a sufficient number of consumers who did not try the new product. The Z-tests reported in Table 4 do not indicate any significant violations of the regularity hypothesis. Although the largest increases in choice probabilities for each segment averaged over 6%, none of them were statistically significant.

DISCUSSION AND CONCLUSIONS

It would be very surprising if there were a large number of significant violations found in the data presented here. However, the situation observed in this study is as close to the previous lab experiments one could hope for in the real world. How could the results be so different from the lab studies? The real question is: Are the results different?

Recall that Huber, Payne and Puto (1982) and Huber and Puto (1983) reported a large number of violations of regularity but that only a few of these violations were significant. Recall further that the work of Rameshwar, Shocker, and Stewart (1987) showed that the similarity effects (which lead to violations of regularity) may be mitigated by product familiarity and meaningfulness of the lab

stimuli. Since at least 8 choices of coffee by each household were observed in the supermarket, it is reasonable to assume that the consumer was familiar with the product (ground coffee).

The progression of work from the original lab studies to the Rameshwar, Shocker, and Stewart (1987) paper to this study show a definite reduction in the incidence and severity of violations of the regularity assumption. It is not an accident that each of the succeeding studies attempted to be more realistic. It is hoped that the corresponding drop in regularity is also not an accident.

The study does not have the dramatic implications for marketers and scholars that it would if the results were different. The validation of the results of Ryans (1974) is still important since his study involved a durable good and the product preference measure was a ranking. The product in this study is a grocery item whose implied preference is indicated by a probability. This news should give some comfort to those who use choice models which require the regularity assumption, like the ideal point, attraction models and the others mentioned above.

There are obviously a large number of limitations to this study. The lack of regularity violations in this entry episode does not mean that it cannot or will not happen in other situations. There may be question of the aggregation of consumers into segments since previous work relied exclusively on pooled or individual level data. Furthermore, there may have been some higher order or non-stationary choice processes at work in this market. Even with these potential problems (and all of the others not mentioned), the results do not seem to be exceptionally out of line with previous research.

Effects of the Mass Media News on Trends in the Consumption of Caffeine-Free Colas

David P. Fan, University of Minnesota
Carol L. Shaffer, University of Minnesota¹

ABSTRACT

The influence of the news media on consumer behavior is explored using an extension of procedures employed successfully in the past to predict public opinion from the press. For the current caffeine and cola study, texts of news articles were retrieved from the NEXIS computer database and scored by computer. The story scores were used to project expected time trends in overall consumption of caffeine-free colas. The projections show a dramatic increase in expected sales of the caffeine-free product in the early 1980s accompanying the introduction of the colas. Then the model predicts a plateau of little change in market share in good agreement with overall sales of caffeine-free colas.

INTRODUCTION

Prior studies have already shown that the news media plays a significant role in influencing public opinion (Dearing and Rogers, 1988; Fan, 1988; Iyengar and Kinder, 1987; Page, Shapiro, and Dempsey, 1987). Since purchase patterns are related to opinions, the news media should also affect consumer behavior, especially for products such as caffeine-free colas since prices are the same regardless of caffeine content, since caffeine has minimal effect on taste, and since all products of the same company are physically displayed together for easy customer choice. Therefore, advertising and news coverage are likely to be the major influences on the purchase of caffeine-free colas. Of the two, the news was likely to be dominant force since there was no incentive to produce such colas without messages about caffeine's effects.

METHODOLOGY

Four main steps were used to study the news and market share of caffeine-free colas: (1) retrieval of the texts of relevant news articles from an electronic database, (2) performance of a computer content analysis of the articles, (3) calculation of mathematical projections of consumption trends, and (4) comparisons of the calculated trends with actual opinion values or sales figures. The analysis follows other studies demonstrating that time trends of public opinion could be predicted from computer content analysis scores of news stories from the Associated Press (AP) wire service. Topics of previous studies have included consumer sentiment (Fan, 1988; Tims, Fan, and Freeman, in press) and the 1987 - 1988 presidential contest between George Bush and Michael Dukakis where the time trend calculated from 2603 AP stories was within 2.7

percent, on average, of 120 actual published poll values (Fan and Tims, 1989).

RESULTS

Stories mentioning both "caffeine" and "soft drinks" or "colas" were retrieved from the AP because this news wire had already been used successfully for opinion calculations (see references in previous section) and because this news wire is relied upon by most written and electronic news organizations in the United States. The analysis ran from January 1, 1977, well before the discussion of caffeine-free colas, to August 7, 1989 when the analysis was begun. All text within 50 words of the words "caffeine," "cola," or "soft drink" was retrieved into the investigators' computer from all 238 identified stories (650,000 characters of text). Text at a greater distance from any of these words was usually irrelevant and was therefore not harvested.

This text was then analyzed by computer for its support of various positions pertinent to caffeine in colas. A reading of a random sample of the retrieved stories showed that their overall sense could be captured by examining only paragraphs containing the word "caffeine." Therefore, the computer was used to "filter" the text keeping only such paragraphs. The yield was 230,000 characters or 36 percent of the original retrieval. The paragraph was chosen as the unit of analysis because the beginnings of paragraphs are easy for the computer to identify and because AP paragraphs tend to be short, typically discussing one idea in one or two sentences.

The caffeine containing paragraphs were read by human analysts to determine the extent to which the paragraphs supported different positions. Four referred to disadvantages of caffeine consumption: harm to the central nervous system, causation of diseases (such as hypertension or heart disease), impediment to the development of fetuses or young children, and harm for unspecified reasons. The fifth position was that caffeine provided a positive benefit or at least did not constitute a health hazard.

The human analysts then constructed a dictionary and a corresponding set of rules to score the paragraphs for their support of the five positions. The scoring used the fact that the filtered paragraphs were all about caffeine since they all contained the word. Consequently, the mere presence of words mentioning children or pregnancy (e.g. "baby," "conception," "fetus," or "mother") implied that the drug was discussed in an unfavorable light. Most paragraphs mentioning these terms described caffeine's ill effects.

Similarly, words like "cancer" and "illness" led to paragraph scores linking caffeine with diseases; words like "addict" and "anxiety" suggested

¹Supported in part by Public Health Service Research Grant MH-39610.

that caffeine was bad for the nervous system; and words like "avoid" and "problem" meant a score unfavorable to caffeine for nonspecific reasons. Scores for nonspecific disadvantages were also implied by phrases such as "caffeine-free," "no caffeine" and "not ... drink caffeine containing." This latter set of conditions meant that the mere mention of caffeine-free products was scored as adding to the available information claiming that caffeine-free colas were better than their caffeine containing counterparts. Words such as "alert," "benefit," and "analgesic" or "pain killer" resulted in a paragraph being scored as favorable to caffeine.

The dictionary also included negation words like "insufficient," "not," and "without." Rules were written so that a negation word close to a word in the "children" class would lead to a paragraph score favorable to caffeine. Thus, for example, a paragraph with the phrase "does not affect fetuses" was scored as favorable to caffeine. In the reverse case, a negation word close to a clause favoring caffeine resulted in a score unfavorable to caffeine for nonspecific reasons.

Doubt and ambiguity were also coded. If a paragraph had a favorable and/or unfavorable mention of caffeine, the computer was instructed to score the paragraph as half pro- and half anti-caffeine if that paragraph also had a conditional word like "disputed" or "inconclusive." Each paragraph had a total possible score of 1.0 with partial scores summing to this value. If a paragraph had phrases scored as being harmful for different reasons, the paragraph score was split between the reasons.

In developing the dictionary and rules described above, two different human analysts compared the computer decisions with impressions obtained by reading the text. The dictionary and corresponding rules were changed and refined until the computer decisions gave good approximations with human evaluations based on about 200,000 characters from stories selected at random. Then, the computer scored the entire text uniformly and consistently without further human interference. The broad applicability of the computer instructions is seen in the fact that 217 of the 238 retrieved stories had a score supporting at least one of the five chosen positions.

Since each score also had a date, it was convenient to plot all the scores as a function of time (Fig. 1). For this plot, each paragraph was given its scored value on the day of the AP dispatch. With each passing day, the score from each paragraph was decreased by one-half because the mathematical model of ideodynamics (Fan, 1988) has found that this rapid decrease in score value reflects the memory loss of the public. With a one day half-life, a paragraph effectively loses all its persuasive ability within a week.

The data in Fig. 1 show that there was relatively little news about caffeine in the cola context before 1979. In late 1978, the Food and Drug Administration (FDA) began reviewing studies implicating the substance as a possible cause of

birth defects. In September 1980, the FDA added caffeine to a list of substances that pregnant women should avoid or use sparingly. By December, an FDA review panel recommended removing the drug from the list of substances Generally Regarded as Safe (GRAS) and placing it in a category of substances requiring additional study. In 1981, evidence challenging the FDA's warnings against caffeine began to appear in the news. From 1982 to the beginning of 1984, the press carried many reports debating caffeine's potential health hazards, primarily in the area of fetal development. By late 1984, discussion on the possible harms of caffeine had diminished (Fig. 1).

In addition to discussion about the health aspects of the drug, Fig. 1 also included substantial coverage of the soft drink manufacturers' introduction of caffeine-free colas in response to the caffeine controversy. Royal Crown introduced the first caffeine-free sugarless cola in March 1980. At that time the FDA required caffeine in sugared colas. In mid-October, the FDA proposed changing its regulations so that regular colas need not include caffeine. In March 1982 7UP shook the soft drink industry with an anti-caffeine advertising campaign and the introduction of its caffeine-free cola, Like. PepsiCo and Coca-Cola decried the 7UP campaign, but four months later, in July 1982, PepsiCo introduced its own caffeine-free colas, Pepsi Free and Sugar Free Pepsi Free (these were renamed Caffeine-free Pepsi and Caffeine-free Diet Pepsi in 1988). Coca-Cola followed suit in April 1983, introducing caffeine-free versions of Coke, Diet Coke, and Tab.

The history of the market share for Coca-Cola and PepsiCo's caffeine-free colas is plotted in Fig. 2 beginning with the first full calendar year after their introduction (Maxwell, 1989). Only Caffeine-free Diet Coke has shown an increase in recent years. However, the overall market share of Diet Coke is so large that the increase in its caffeine-free version alone was enough to cause a small rise in the share of all colas without caffeine in 1987 and 1988 (Fig. 2, bottom frame).

The scores from the 238 AP stories on caffeine and soft drinks or colas (Fig. 1) were used in the mathematical model of ideodynamics to calculate expected purchases of caffeine-free colas. This model is consistent with previous reports noting that consumers respond positively to increasing amounts of information, although not necessarily in a linear fashion (Keller and Staelin, 1989; Meyer and Johnson, 1989; Alba and Marmorstein, 1987).

Ideodynamics argues that people change their purchasing patterns only in response to information favoring another product or opposing their current product choice. Information reinforcing preferences might cause greater product or brand loyalty but will cause no alterations in buying habits. Using these arguments, a fraction of the public currently purchasing a caffeine containing soft drink should switch to the caffeine-free product by persuasive information noting the dangers of this drug. If C_F describes the number of consumers of caffeine-free

FIGURE 1
 Informational pressures relevant to the problems of caffeine in stories mentioning both soft drink or cola and caffeine

The vertical scale is in paragraphs. Top frame: Paragraphs supporting the position that caffeine harms the central nervous system. Second frame: Paragraphs supporting the position that caffeine causes diseases such as hypertension and heart disease. Third frame: Paragraphs supporting the position that caffeine hinders the development of fetuses and children. Fourth frame: Paragraphs supporting the position that caffeine is harmful without reasons being given. Fifth frame: Combination of all above paragraphs supporting the position that caffeine is harmful. Bottom frame: Paragraphs supporting the position that caffeine is not harmful.

colas in the population, and C_C represents the number of purchasers of the caffeine containing variety at a particular initial time t_1 , then $C_F + C_C = 100$ percent at all times t_n if the population of cola consumers does not change composition significantly during the study. It should be possible to compute time trends for both C_F and C_C from t_1 to t_n if the C values at t_1 and all intervening changes are known.

In any time interval t , the number of caffeine-free consumers C_F is postulated to increase in proportion to the strength G_F of the persuasive paragraphs describing problems with caffeine (Fig. 1, next to bottom frame). However, the increase should also be proportional to C_C , the population still consuming the caffeine containing product since that is the population of potential converts. The more the potential converts, the larger should be the number of people whose habits are changed given the same persuasive information. There is also a constant of proportionality k incorporating the attention being paid to caffeine information and the natural resistance to switching buying patterns.

The reverse transition is also hypothesized in which G_C , information about caffeine not being a problem (Fig. 1, bottom frame), would convert the caffeine-free drinkers C_F to return to the caffeinated product. However, caffeine has always been in colas and it is conceivable that there is a residual preference for the caffeinated variety, perhaps due to a small taste difference or a desire to be kept awake by caffeine. In this case, there might be an additional persuasive force encouraging the drinkers of caffeine-free colas to return to the caffeine containing soft drink. This persuasive information could be modeled as being proportional to the amount of caffeine containing colas available. That is, the more colas sold with caffeine, the more the consumer would feel that it was permissible to consume the soft drink with the drug. In other words, the persuasive pressure favoring more caffeine would include not only G_C from news messages saying that caffeine was beneficial or at least not harmful but also an added component proportional to C_C , the number of drinkers of caffeinated colas. If the proportionality constant is c for C_C , then the ideodynamic expressions for the numbers of consumers of caffeinated and caffeine-free colas at time t are

$$(Eq. 1) \quad C_{F,t} = C_{F,t-1} + k \cdot G_{F,t} \cdot C_{C,t-1} - k \cdot (G_{C,t} + c \cdot C_{C,t-1}) \cdot C_{F,t-1}$$

$$C_{C,t} = C_{C,t-1} - k \cdot G_{F,t} \cdot C_{C,t-1} + k \cdot (G_{C,t} + c \cdot C_{C,t-1}) \cdot C_{F,t-1}$$

(see Fan, 1988 for additional details for derivation of these equations). In the first equation, the positive term reflects the recruitment of caffeine-free drinkers from the caffeine consuming group and the

negative term is due to the loss of caffeine-free buyers due to return to the caffeine purchasing population. The same terms are also found in the second equation and keep the total population size at 100 percent.

The initial condition for equations 1 was that the entire population drank caffeine containing colas, the only kind in existence, on January 1, 1977 when the AP retrievals and calculations started. Then computations were made at $t = 24$ hour intervals with the newly calculated C values after each day being used for the computation on the subsequent day. The only two unknown parameters in this equation are constants k and c . These parameters were optimized to fit the actual consumption pattern for the overall consumption of caffeine-free colas beginning in 1984, the first year in which both Coke and Pepsi caffeine-free colas were sold during the entire calendar year (Fig. 2, bottom frame).

Comparison with Fig. 1 explains the shape of this projected time trend. Before 1980, there was relatively little information about caffeine, so there should be no change with 100 percent consumption of the caffeinated variety (Fig. 2). Then from 1980 to the beginning of 1984 there was a notable increase in anti-caffeine information (Fig. 1, next to bottom frame) with a much smaller corresponding increase in pro-caffeine news (Fig. 1, bottom frame). This rise in anti-caffeine coverage caused the rapid increase in the projected preference for caffeine-free colas from 1980 to early 1984. Then, the anti-caffeine news decreased sharply (Fig. 1). At this time, the $c \cdot C_C$ term began to be important leading to a plateau or even a slight decrease in the consumption of the caffeine-free product.

If parameter c in the $c \cdot C_C$ term is increased, there will be a more pronounced drop in the caffeine-free market share as was found for all colas except Diet Coke. The $c \cdot C_C$ term was justified on the grounds that some people might prefer to have caffeine in their cola for reasons other than those given in the mass media. Obviously, the reverse could also be true, other persons might not like the effects of caffeine, such as inhibiting sleep. Simple substitution into equations 1 of the original condition that $C_C + C_F = 100$ percent yields the conclusion that, if both C_C and C_F have different constant multipliers, then only one term is needed, in this case $c \cdot C_C$, reflecting the extent to which the constant for C_C is larger than the one for C_F .

For the studies described above, only AP stories discussing both caffeine and soft drink or cola were used. To account for the public using all information about caffeine and not just that in soft drink stories, another NEXIS retrieval was made, this time for all stories mentioning the word "caffeine." This retrieval included not only the AP but also the United Press International wire service, the *New York Times* and *Washington Post* newspapers, and *U.S. News & World Report* and *Newsweek* magazines. This analysis ran from September 26,

Caffeine-Free Market Share: Real and Calculated

Top frame is for Coca-Cola brand products: Squares: $(\text{Caffeine-free Diet Coke}) / (\text{Caffeine-free Diet Coke} + \text{Diet Coke})$. Triangles: $(\text{Caffeine-free Coke}) / (\text{Caffeine-free Coke} + \text{Coke Classic} + \text{Coke})$. Diamonds: $(\text{Caffeine-free Tab}) / (\text{Caffeine-free Tab} + \text{Tab})$. Dotted line: $(\text{Sum of all three caffeine-free colas in numerators of previous three plots}) / (\text{Sum of all denominators in three previous plots})$. Center frame is for PepsiCo brand products: Squares: $(\text{Caffeine-free Diet Pepsi}) / (\text{Caffeine-free Diet Pepsi} + \text{Diet Pepsi})$. Diamonds: $(\text{Caffeine-free Pepsi}) / (\text{Caffeine-free Pepsi} + \text{Pepsi})$. Dotted line: $(\text{Sum of both caffeine-free colas in numerators of previous two plots}) / (\text{Sum of all corresponding denominators})$. Bottom frame: Dotted line: Overall market share of caffeine-free colas from $(\text{Sum of all numerators in plots by brands in previous frames}) / (\text{Sum of all corresponding denominators})$. Solid line: Ideodynamic prediction of market share based on paragraph scores in the bottom two frames of Fig. 1.

1980, the earliest date for which all the sources were present in the database, to July 27, 1989. With this larger number of data sources and the lack of requirement for the word caffeine, 1782 stories were identified and text was retrieved from all within 50 words of the word "caffeine" (2,500,000 characters of text). The same content analysis was applied as described above leading to the paragraph plots of Fig. 3. The first filtration to retain only paragraphs mentioning "caffeine" resulted in 1,400,000 characters or 56 percent of the retrieved text. The computer gave a score for at least one of the six scored positions for 1479 of the original 1782 retrieved stories.

The paragraph plots in both Figs. 1 and 3 show that caffeine was discussed more often in the context of problems than as being desirable, regardless of whether colas were mentioned. The complexion of the positive and negative information could be explored by calculating likely public opinion using equations 1 without the $c.C_C$ term. These simpler equations were consistently used in the past for studies relating the mass media with opinion (Fan, 1988; Tims, Fan, and Freeman, in press; Fan and Tims, 1989; Fan and McAvoy, 1989). Using the CWC method of Fan and McAvoy (1989) it was possible to estimate that the projected opinion -- and hence the information structure -- was fairly constant and overwhelmingly against the consumption of caffeine (Fig. 4). The anti-caffeine messages were consistently higher (Fig. 4) for Fig. 3, being closer to 90 percent than the 80 percent for the AP stories for Fig. 1. The differences between the two lines could either be due to the requirement of cola mentions in Fig. 1 or the fact that the AP is systematically slightly less sympathetic to caffeine than the other news sources.

Besides including an extra $c.C_C$ term, the projection in Fig. 2 uses the same AP story scores but a different constant k . The value was $k = 0.037$ per AP paragraph per day for purchases (Fig. 2) and $k = 1.0$ per AP paragraph per day for opinion (Fig. 4). The much larger value in Fig. 4 suggests that people are much more ready to start thinking that caffeine is bad than to start purchasing caffeine-free drinks.

An additional question is whether the decreased discussion of caffeine in colas after 1984 is due to less discussion of colas and soft drinks in general. To explore this possibility, another retrieval was made in which 2000 out of 7306 AP stories on soft drinks or colas were retrieved at random from January 1, 1977 to August 7, 1989. All text within 50 words of one of these key words was retrieved (2,600,000 characters of text) and scored for the number of paragraphs discussing soft drinks or colas regardless whether caffeine was also present. The caffeine stories were ignored because they only constituted 3 percent of the total. Fig. 5 shows that the peak of caffeine discussion from 1982 - 1984 did not correspond to the major peaks of soft drink discussion in 1985 - 1987 when other issues were discussed, such as the introduction of

new Coke and lawsuits involving the major manufacturers.

DISCUSSION

This study has examined the effect of the news media on consumer behavior and was greatly facilitated by the ability to retrieve large amounts of relevant information from electronic databases. Such retrievals are more complete than is possible using manual searches because the computer, with no loss of attention, can easily scan for words appearing within the contents of a story instead of merely in the headline. For this analysis, 4020 stories containing 4,700,000 characters of text were retrieved and analyzed by computer, the only practical method for evaluating such a large quantity of text. The new method of successive filtrations is highly flexible since the user can enter customized dictionaries and rules for individual studies. Using a fixed set of instructions, the computer has the advantage of consistency and uniformity, an advantage which compensates for its inability to detect some subtleties in language usage that only a human can catch.

The computer content scores were entered into the mathematical model of ideodynamics to give consumption time trends which are close to actual market shares. The data from Fig. 1 used for the calculations included both exogenous reports on the desirability of caffeine and endogenous stories on the public's own behavior in terms of purchases of caffeine-free colas. The computations were made every 24-hours, thereby avoiding aggregation errors when data are pooled into quarters or years. The calculations can be performed throughout a time period when information important to the consumer is available.

The ideodynamic model includes only two parameters and is therefore suitable for rigorous testing using a reasonable number of data points. In fact, since both parameters have already been fixed, a good test would involve retrieving more stories into the future and seeing if the computer text analysis can yield scores which still give accurate market shares without altering either constant.

Even for the data in this paper, no changes in the parameters can change the time at which the public should initially have become interested in caffeine-free colas. With little news prior to 1980, the model only permitted public preference for the caffeinated variety.

Then, with the increase in cola news in 1980 - 1984, the model insists on an increase in interest in caffeine-free colas. The only question is how much. After 1984, news coverage relevant to colas diminished so the main question is the extent to which caffeine-free consumers have inherent preferences which will push them back to drinking the caffeinated drink. Depending on this pressure governed by constant c , the decrease in cola consumption will be more or less great.

The model uses three important assumptions which merit some discussion. In the first place, the

FIGURE 3
Informational pressures relevant to the problems of caffeine in all stories on caffeine

Caffeine Bad for Nervous System (All Caf. Stories)

Caffeine Causes Disease (All Caf. Stories)

Caffeine Bad for Children (All Caf. Stories)

Unspecified Caffeine Problems (All Caf. Stories)

Caffeine Not a Problem (All Caf. Stories)

Same as Fig. 1 except that the retrieval was for all stories on caffeine instead of caffeine in the context of soft drinks and the retrieval began on September 2, 1980 instead of January 1, 1977 and used six news sources (see text) instead of just the AP.

FIGURE 4

Opinion that caffeine is bad predicted from soft drink stories (solid line) or from all caffeine stories (dotted line)

Solid line predicted from paragraph scores in Fig. 1 and dotted line from paragraph scores in Fig. 3.

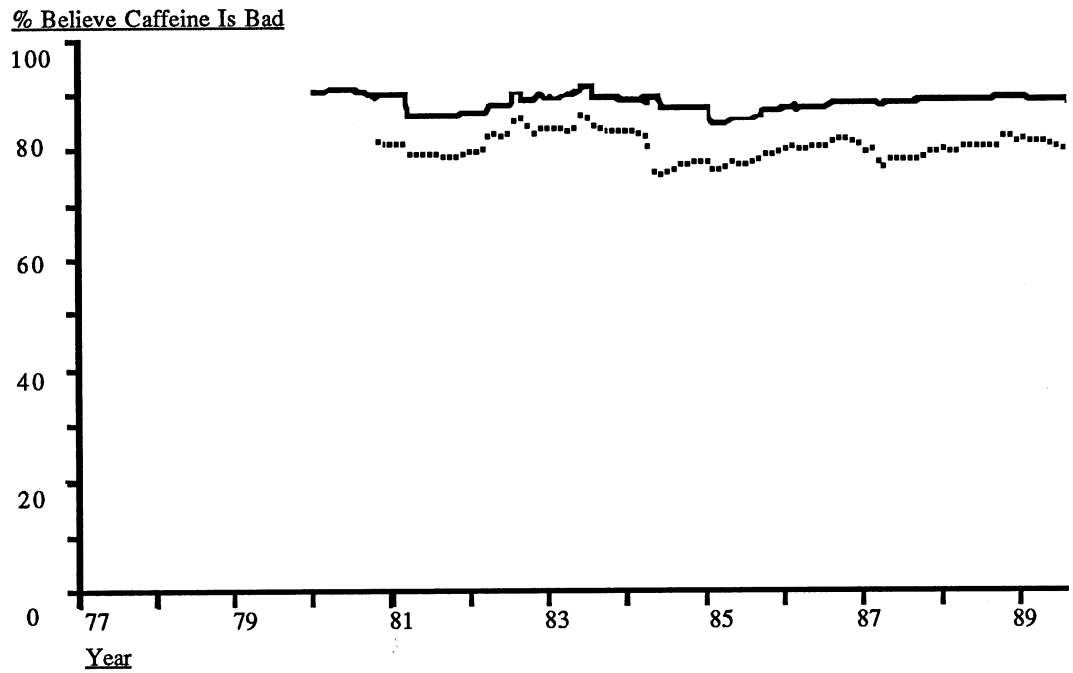

FIGURE 5

Paragraphs discussing soft drinks and colas regardless of whether caffeine is mentioned.

model should only work if most of the important persuasive information is used in the calculation. Thus a more accurate calculation would require inclusion of persuasive information from marketing and advertising.

Another important assumption was that the same people were studied for the entire 12 years from 1977 to 1989 and that they only chose between the caffeinated and caffeine-free versions of a cola. However, from 1981 to 1988, there has been a continual increase in the sales of colas so the question is whether there are substantial numbers of new drinkers and, if so, how they make their choices. Also, a cola consumer might switch not to a diet variety but to an alternative drink like a lemon-lime soft drink. The estimates in this paper will be inaccurate if these other factors are very important.

Finally, it is assumed that caffeine-free colas are as readily available as the caffeinated variety.

A Structural Examination of Two Optimal Stimulation Level Measurement Models

Russell G. Wahlers, Ball State University
Michael J. Etzel, University of Notre Dame

ABSTRACT

The study examines the internal structure of two measurement models used to operationalize the optimal stimulation level (OSL) construct in consumer research. Using a causal modeling approach, the structure of Zuckerman's Sensation Seeking Scale was confirmed. However, the analysis raises questions regarding the internal specification of Mehrabian and Russell's Arousal Seeking Tendency instrument. The need for a theory-based definition of OSL in consumer behavior is identified. Implications for future OSL scale refinement research are offered.

INTRODUCTION

The OSL Construct and Adaptive Behavior

Behavioral scientists' interest in the concept of stimulation dates back at least a century. In the field of psychology, the concept has been incorporated in several frameworks that describe the link between one's psychological state and his/her reaction to environmental stimuli (Hebb 1955; Leuba 1955). A summary of the OSL literature can be found in Rogers (1979). A generally accepted conceptual treatment of the stimulation construct is that each individual has a uniquely determined, homeostatic degree of stimulation or an "optimal stimulation level" (OSL) with which he/she is comfortable. When the environment is deficient in providing stimulation at this level, one tends to seek complexity or novelty. Conversely, when the environment provides more stimulation than the desired, optimal level, the individual will engage in behavior to reduce stimulation. Thus, the individual is viewed as adapting to his/her environment so as to maintain a balance between actual and optimal levels of stimulation. This adaptive behavior will involve either stimulation seeking or avoidance depending on the individual's OSL and present profile of environmental input. Thus, three factors must be considered in the analysis of stimulation adaptive behavior: (a) the individual's OSL, (b) the stimulating or arousal potential of the object, person, or event within the environment which is confronting the individual, and (c) one's state at the time of exposure to the stimulus in question (Berlyne 1960).

Several alternative theoretical frameworks incorporating the OSL construct have been developed by psychologists to explain stimulation-related exploratory behavior in a clinical research setting (Berlyne 1960, 1963; Driver and Streufert 1965; Fiske and Maddi 1961; Hunt 1963). More pragmatically, the construct has obvious significance in a consumer behavior context as OSL may contribute to an explanation of differences across consumers relative to a range of diverse

behaviors including brand switching, acceptance of innovations, shopping behavior, and response to advertising repetition as summarized by Raju (1980).

OSL Measurement Models in Consumer Research

Stimulation seeking as an influence on consumer behavior has been addressed in the marketing literature both conceptually (Faison 1977; Hirschman 1984; Howard and Sheth 1969; Kirby 1975; Markin 1974; Raju 1981; Raju and Venkatesan 1980; Venkatesan 1974) and empirically (Etzel and Wahlers 1984; Goodwin 1980; Grossbart, Mittelstaedt, and Devere 1976; Joachimsthaler and Lastovicka 1984; Mittelstaedt, Grossbart, Curtis, and Devere 1976; Raju 1980; Venkatraman and MacInnis 1985; Wahlers and Etzel 1985; Wahlers, Dunn, and Etzel 1986). The evidence provided by prior studies suggests that the tendency to seek stimulation is a significant behavioral influence that is manifest in varying degrees across a number of consumer activities. Research in marketing thus far has dealt with arousal seeking and has not focused specifically on stimulation avoidance behavior.

In terms of measuring the OSL construct, Raju (1980) has identified several paper-and-pencil instruments found in the psychology literature as potential OSL operationalizations. Among these are the Sensation Seeking scale (Zuckerman 1979; Zuckerman, Kolin, Price, and Zoob 1964), the Arousal Seeking Tendency scale (Mehrabian and Russell 1974), the Change Seeker Index (Garlington and Shimota 1964), the Stimulus Variation Seeking scale (Penney and Reinhr 1966), and the Similes Preference Inventory (Pearson and Maddi 1966). The Sensation Seeking (SS) scale and the Arousal Seeking Tendency (AST) scale have been the two predominant instruments employed in consumer behavior studies. The principal studies involving an empirical treatment of OSL in a marketing context are chronologically summarized in Table 1.

An inspection of the Sensation Seeking scale and the Arousal Seeking Tendency scale and their respective subscales proposed by the scale developers suggests that these two instruments tap somewhat different aspects of OSL. The SS instrument consists of forty pairs of statements in a forced-choice format. Zuckerman (1979) has identified four components which underlie SS: (a) Thrill and Adventure Seeking, (b) Experience Seeking, (c) Boredom Susceptibility, and (d) Disinhibition. Alternatively, the AST scale consists of forty items combined with nine-point Likert agreement-disagreement scales. Mehrabian and Russell (1974) assert that the instrument taps five underlying factors relating to OSL: arousal associated with (a) Change, (b) Unusual Stimuli, (c) Risk, (d) Sensuality, and (e) New Environments.

TABLE 1
MEASUREMENT OF OSL IN SELECTED CONSUMER BEHAVIOR STUDIES

Study	Year	Scale Used	Focus of Investigation	Findings
Grossbart, et al.	1975	SS	Relationship between OSL and perceptions of retail shopping environment	Environmental adjectives and SS in combination better predicted behavior than either the adjectives or SS alone
Grossbart, et al.	1976	SS	Relationship of OSL to adoption process for nontraditional retail outlets	SS positively associated with consumers acceptance of nontraditional urban retail outlets
Mittelstaedt, et al.	1976	SS	Relationship of OSL to adoption process for new products and services	SS directly linked to awareness and trial of new products and retail outlets negatively linked to awareness-trial timing and rejection of products and outlets under consideration
Goodwin	1980	AST	OSL treated as covariate in responses to stimulus characteristics such as complexity, blurredness, and incompleteness	AST found to influence advertising attentiveness and impact of the various message components studied
Raju	1980	AST	Relationship of OSL to other aspects of personality, demographics, and general exploratory tendencies in a consumer context	AST associated with tolerance for ambiguity and education and inversely linked with rigidity and age. AST found to be positively related to selected exploratory behavior tendencies.
Etzel & Wahlers	1984	AST	Relationship of OSL to vacation travel preferences	AST positively related to vacation preferences described as different, and offering change - and negatively linked with those described as restful, rejuvenating, and traditional.
Joachimsthaler & Lastovicka	1984	AST	Relationship of OSL to selected personality traits and exploratory behavior tendencies involving information search and innovativeness	Rather than acting as a mediator, AST and selected personality traits exerted direct influence on subjects' exploratory behavior proneness.
Wahlers & Etzel	1985	SS	Differences between experienced and optimal stimulation related to preference for activity	OSL satiation related to preferences for tranquil, passive vacations. OSL deprivation linked to preferences for action, activity-oriented vacations.
Venkatraman MacInnis	1985	SS & AST	Relationship of OSL to epistemic and sensory exploration and product perceptions	SS in combination with other & personality traits defined four types of consumers exhibiting different product perception and exploratory behavior pattern

TABLE 1 (CONTINUED)
MEASUREMENT OF OSL IN SELECTED CONSUMER BEHAVIOR STUDIES

Study	Year	Scale Used	Focus of Investigation	Findings
Wahlers, Dunn & Etzel	1986	SS & AST	Comparison of alternative OSL measures with Raju's exploratory tendencies classifications	SS and AST positively linked to innovativeness, risk taking, shopping and brand switching, and information seeking - while negatively related to repetitive behavior proneness.

While it appears intuitively obvious that these factors are related both internally and across scales, the two scales have not been compared in a consumer behavior study. In addition, the degree of interscale congruence with respect to scale components is unclear. Thus far these two scaling approaches have been used interchangeably in consumer research.

Research Objective

Prompted by the observation that Sensation Seeking and Arousal Seeking Tendency have been the scaling methods of choice to operationalize OSL in the consumer behavior literature -- and noting that the scales have different subscale descriptions, the present study was conducted to examine both the measurement congruence between the scales and to assess the dimensionality of the measures. The results should provide consumer behavior researchers some direction in OSL scale selection -- particularly when dimensionality is relevant..

THE STUDY

Method

To examine the Sensation Seeking and Arousal Seeking Tendency as alternative measures of OSL, data were collected via mail questionnaire from a Midwestern consumer panel. The questionnaire contained Form V of the Sensation Seeking scale (Zuckerman 1979) and the Arousal Seeking Tendency instrument (Mehrabian and Russell 1974). A pretest of the questionnaire found no item order bias (either between or within the two OSL instruments). Thus, the two instruments included in the final questionnaire were presented in the same form that they appear in the psychology literature. The results reported in this paper are based upon 697 usable responses to the questionnaire.

In an initial examination of the data, SS and AST scores were calculated for each respondent after making the appropriate item scale reversals described in the literature. In addition, subscale scores for SS and AST were generated for each subject. The subscale structure of the Sensation Seeking scale is fully detailed by Zuckerman (1979).

However, since the Arousal Seeking Tendency instrument's item-to-subscale pairings are only partially disclosed in the literature (Mehrabian and Russell 1974, pp. 42-43), the complete structure (see Figure 2) was reconstructed with the assistance of the scale developers.

Reliability estimates for SS (0.851 overall) and each of the four SS subscales were calculated in addition to between-subscale correlations. Both reliabilities and correlation coefficients associated with the SS scale were found to be in agreement with parallel statistics reported in previous studies by Zuckerman (1979, pp. 110-113) and Ridgeway and Russell (1980, p. 663). Similarly, reliability estimates and between-subscale correlations were calculated for AST. While no previous reports of subscale reliabilities were found in the literature, the reliability estimates for the total scale (0.853) was consistent with AST reliability (0.881) reported earlier by Wahlers, Dunn, and Etzel (1986). In addition, between-subscale correlations were judged to be in reasonable agreement with those disclosed by Mehrabian and Russell (1974). Thus, the consistency in the measurement models' reliabilities and subscale intercorrelations observed between the present study's subjects and other previous samples used by the scale developers and other researchers was interpreted as evidence of sample adequacy.

Correlation Between SS and AST

The first objective of the study was to determine the overall comparability of the two scales. To do that a simple correlation between SS and AST was computed. The results ($r=.951$) indicate that the scales produce very similar scores. Thus researchers interested in an overall, general OSL measure could feel comfortable with either scale.

TESTING THE INTERNAL STRUCTURE OF SS AND AST

Sensation Seeking as a Measure of OSL

The internal structure of the SS measurement model was examined using a second-order factor model shown in Figure 1. The items comprising each of the four subscales are identified by number

for the sake of brevity using the numbering scheme consistent with Zuckerman's item list (1979, pp. 397-401).

Parameters were estimated using LISREL (Jöreskog and Sörbom 1978). In an initial analysis, the model produced unsatisfactory fit. (Because of the large sample size and model complexity, absolute fit in terms of the X^2 statistic was not expected (Burt 1973, p. 148).) Therefore in order to continue the analysis, the model's fit was adjusted by sequential modifications indicated by the modification indices. It is important to note that our goal was to minimize unnecessary modifications so as to preserve the structural integrity of the SS measurement model relative to the form specified by the developers and used in past consumer behavior studies. Hence, modifications were continued only to a point at which the X^2 statistic was approximately equal to twice the number of degrees of freedom (Carmines and McIver 1981, p. 80). The fit statistics for the SS measurement model were $X^2(731)=1508.61$, GFI=0.883, AGFI=0.868, and RMSR=0.050. Parameters are included in Tables 2 and 3.

With the exception of Item 6 which cross-loaded on the first subscale (Thrill and Adventure Seeking), the remaining thirty-nine items exhibited the hypothesized loadings structure described by Zuckerman. In addition, only four correlated error terms were uncovered in the analysis which is not unexpected given the total number of indicators

comprising the SS model. Thus, given the large sample size and small number of data-based modifications required to achieve approximate fit (i.e., $X^2 \approx 2(df)$), one can conclude that the SS model is reasonably specified both conceptually and empirically.

Arousal Seeking Tendency as a Measure of OSL

The second-order factor model associated with the Arousal Seeking Tendency framework is shown in Figure 2. Again, items comprising each of the five AST subscales are identified by number consistent with the item numbering scheme used by Mehrabian and Russell (1974, pp. 218-219).

Parameters were estimated using LISREL adjusting the model to fit the same X^2 criterion described above. The fit statistics for the AST measurement model were $X^2(707)=1693.19$, GFI=0.859, AGFI=0.837, RMSR=0.054. Parameters are included in Tables 4 and 5.

Results of this analysis point to several problems. First, the third subfactor (η_3) purportedly representing Risk exhibited an unsatisfactory parameter estimate (standardized $\gamma_3=0.042$, $p>0.05$). An inspection of the item loadings included in Table 5 further shows sixteen items specified for subscales one (Change), two (Unusual Stimuli), four (Sensuality), and five (New

Environments) incorrectly cross loaded on the third subscale (Risk); and one item specified on the third subscale incorrectly cross loaded on subfactor one. In addition, seven items were found to exhibit parameters having nonsignificant t-values on their respective hypothesized subscales. A total of eight statistically significant intercorrelated error terms were further uncovered. Thus, although the overall goodness-of-fit statistics are encouraging, the abundance of cross loadings, nonsignificant parameter estimates, and a fair number of intercorrelated error terms leads to questions regarding the internal specification of the AST measurement model's structure.

CONCLUSIONS

A second-order causal model analysis of the Sensation Seeking measurement model confirmed that its framework appears to be conceptually and empirically well specified. In contrast, however, a similar examination of Arousal Seeking Tendency uncovered serious problems in the structure of the paradigm's subfactors. Specifically, seventeen items were inappropriately cross loaded, seven items failed to load on their respective hypothesized subfactors, and eight statistically significant correlated error terms were discovered. These results suggest that

researchers interested in selecting a measurement model to investigate the dimensions of the OSL construct would be advised to employ Sensation Seeking rather than Arousal Seeking Tendency. While both scales have been developed to tap a similar aggregate conceptualization of OSL, on a subscale level the two scales not only are comprised of somewhat different dimensions in terms of numbers and meaning, but additionally the AST structure could not be empirically confirmed using the present panel data.

Thus far the SS and AST paradigms have been used interchangeably in consumer research to represent a unidimensional, summed-scale measure of OSL. On this aggregate basis the two measurement models may tap a similar conceptualization of OSL. However, in cases in which the dimensionality of stimulation seeking is of interest, the structural differences between SS and AST may produce inconsistent findings.

Future research needs to address several issues. First, given the inability of the present data to confirm the structure of AST, this model requires further scrutiny before it is widely used in an applied marketing research context. Additionally, opportunity exists to compare the dimensional differences and similarities of SS and AST with

respect to a range of actual behaviors reflecting stimulation seeking and/or avoidance. Finally, noting that both the SS and AST instruments were developed in a clinical context, there is an opportunity to develop a measurement instrument more directly representing the OSL construct in a consumer context. Given the apparent relevance of exploratory consumer behavior, this would be a logical research priority.

Specifying Measurement Error in Structural Equation Models: Are Congeneric Measurement Models Appropriate?

Joseph A. Cote, Washington State University
Robert Greenberg, Washington State University

ABSTRACT

It is well known that misspecification of structural equation models leads to biased estimates. It is also widely known that systematic measurement errors are ubiquitous. In spite of these two well known facts, researchers using structural equations (LISREL) usually specify congeneric measurement models. This paper outlines why congeneric measurement models may lead to biased estimates of the structural relationships which consequently can affect theoretical conclusions in empirical research. Several alternative techniques for modelling measurement error are presented.

Congeneric measures are the most commonly used approach for specifying structural equation models (Anderson and Gerbing 1982; Darden, Carlson, and Hampton 1984). Congeneric measurement models assume measures are composed of a single underlying construct (true score represented by ξ 's and η 's) and random measurement error (δ 's and ϵ 's) as illustrated in Figure 1.

However, it is quite likely that measures tap more than one underlying construct. In this case, the true score contains both valid and invalid components (Gerbing and Anderson 1984, Smith 1974). The valid component is the construct we are trying to measure. The invalid component is other trait and method components which are "... part of the true portion of variance because they contribute to the covariance of the variable with other variables..." (Smith 1974, p 492). For example, measures of satisfaction might contain variance from product satisfaction, method effects, general life satisfaction, and random error.

When present, invalid components (hereafter referred to as systematic measurement errors) constitute additional constructs whose variance cannot be properly subsumed under random error. As shown in Figure 2, when systematic measurement error exists, a measure contains variance from random error (ϵ 's) and at least *two* underlying constructs, the construct of interest ($\eta_1, \eta_2, \text{ or } \eta_3$) and a second, invalid or confounding component ($\eta_4, \eta_5, \text{ or } \eta_6$).

The use of congeneric measurement models, as in Figure 1, is only appropriate if measures do not contain systematic error. Unfortunately, systematic measurement errors are commonly found in behavioral research (Peter and Churchill 1986, Cote and Buckley 1987). Measures often contain invalid components, most notably method effects. It has been suggested that method effects are omnipresent (Fiske 1982, Peter 1981). Cote and Buckley (1987) provided empirical support for this claim and found that, on average, 26.3% of the

variance in measures is due to method effects. In addition to method effects, it is quite possible that measures tap multiple constructs (Cattell 1978), a problem that is rarely addressed in consumer behavior (Churchill 1979, Anderson and Gerbing 1982).

In summary, it appears quite likely that measures contain systematic measurement error. Systematic measurement error can be either method effects or some other type of invalid measurement component. This raises questions about how consumer researchers specify measures in structural equation models. Simply put, Figure 2 probably represents measurement reality, yet we commonly specify Figure 1 when fitting structural equation models.

EFFECTS OF MISSPECIFYING MEASUREMENT CONDITIONS

Proper interpretation of structural estimates is possible only when the measurement model is correctly specified (Anderson and Gerbing 1982, Gerbing and Anderson 1984). Failing to model systematic measurement error can lead to biased and inconsistent parameter estimates which may confound theoretical conclusions (Anderson and Gerbing 1982, Burt 1976, Gerbing and Anderson 1984, Kumar and Dillon 1987, Phillips 1981). While it is impossible to determine the effect of misspecification on any *single* parameter estimate, failure to model existing systematic measurement error will, on average, inflate estimates of structural relationships. This can be seen by considering the model in Figure 1. Suppose that the first indicator for each construct ($x_1, y_1, \text{ and } y_4$) has been measured using method 1, the second indicator with method 2 and the third indicator with method 3. Since they are not modeled, the shared method variance must be accounted for in some other way. The model allows for shared method variance only through the structural relationships (γ 's and β 's). For example, the shared method variance between x_1 and y_4 can only be accounted for through γ_{21} . Since the structural estimates contain both trait variance *and* method variance, they may overestimate the effect of one trait on another. Moreover, this bias may make a relationship appear statistically significant when it is actually zero.

MODELLING SYSTEMATIC MEASUREMENT ERROR

Three methods for modelling systematic measurement error have been suggested; 1) create separate factors to explicitly model invalid components, 2) use second order factor analysis to implicitly model invalid components, or 3) use a correlated errors model. The separate factors

FIGURE 1
How Measurement Error is Commonly Specified

FIGURE 2
True Measurement Conditions

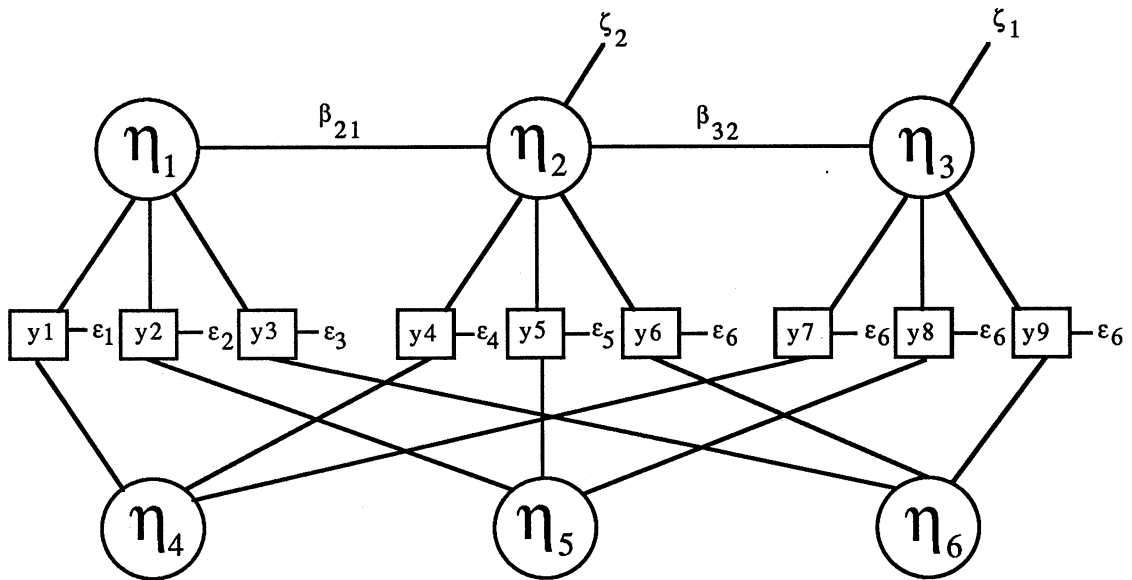

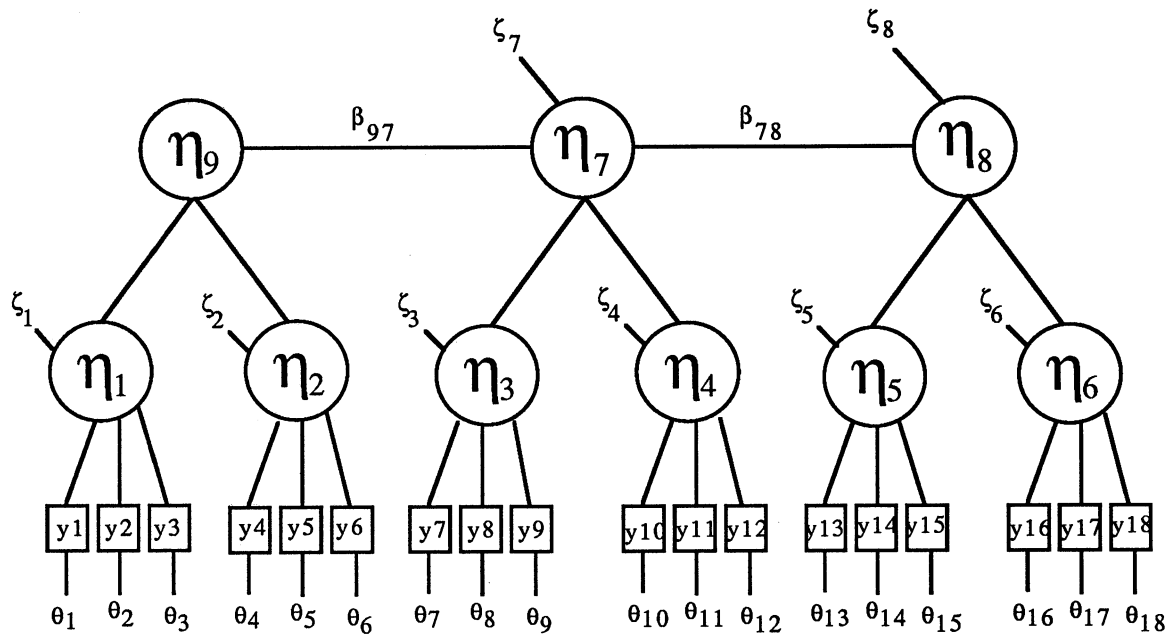

FIGURE 3
Second Order Factor Model (Gerbing and Anderson)

approach is exemplified by multitrait-multimethod analysis. As shown in Figure 2, valid components are modeled as separate factors, with the structural relationships specified among the constructs of interest. Invalid components are also modeled as separate factors. These invalid components can either be correlated or uncorrelated with one another, but must be uncorrelated with the valid components (due to identification problems). Systematic error will not confound the estimated relationships among the valid factors since they are separated out.

Second order factor models are an alternative way to account for systematic error (Gerbing and Anderson 1984, Marsh and Hocevar 1988). A traditional measurement model is used to specify first order factors which contain both valid and invalid components (η_1 to η_6 in Figure 3). For example, η_6 contains variance from trait 3 (η_8) and invalid component 6 (ζ_6). Second order factors are then specified as a common component (valid component) in the first order factors (η_7 to η_9 in

Figure 3). The invalid components are separated out in ζ_1 to ζ_6 .

Marsh and Hocevar (1988) recommend combining the traditional MTMM model and the second order factor model presented above. This combination results in a model with both explicitly and implicitly modeled invalid components (see Figure 4). As with the second order factor model discussed above, first order factors include both valid and invalid components (η_1 to η_6). Second order factors for both the valid components (η_7 to η_9) and *known* invalid components (η_{10} to η_{11}) are then specified. Finally, the unique variance for the first order factors (ζ_1 to ζ_9) model any additional invalid components the researcher can not identify.

The third alternative is to model the invalid component using correlated measurement errors (John and Reve 1982, Marsh 1988). Model identification is ensured by constraining correlations among errors to be equal. For the model in Figure

FIGURE 4
Second Order Factor Model (Marsh and Hocevar)

1, the constraints could be specified such that only six correlated error parameters are estimated¹ (John

¹The specification for method effects in Figure 2 can be replaced with the following correlated error specifications.

$$\sigma_A = \sigma_{1,4} = \sigma_{1,7} = \sigma_{4,7}$$

$$\sigma_B = \sigma_{2,5} = \sigma_{2,8} = \sigma_{5,8}$$

$$\sigma_C = \sigma_{3,6} = \sigma_{3,9} = \sigma_{6,9}$$

$$\sigma_D = \sigma_{1,2} = \sigma_{1,5} = \sigma_{1,8} = \sigma_{4,2} = \sigma_{4,5} = \sigma_{4,8} = \sigma_{7,2} = \sigma_{7,5} = \sigma_{7,8}$$

$$\sigma_E = \sigma_{1,3} = \sigma_{1,6} = \sigma_{1,9} = \sigma_{4,3} = \sigma_{4,5,6} = \sigma_{4,9} = \sigma_{7,3} = \sigma_{7,5,6} = \sigma_{7,9}$$

$$\sigma_F = \sigma_{2,3} = \sigma_{2,6} = \sigma_{2,9} = \sigma_{5,3} = \sigma_{5,6} = \sigma_{3,9} = \sigma_{8,3} = \sigma_{8,6} = \sigma_{8,9}$$

Where

σ_A = correlation among measures containing method 1.

σ_B = correlation among measures containing method 2.

and Reve 1982). Assuming simple method effects, all the error terms for measures using method 1 (ϵ_1 , ϵ_4 , and δ_1 in Figure 1) would be correlated with the correlations constrained as equal (With LISREL this can only be done by making Ksi 1 an endogenous factor and converting all the δ 's to ϵ 's as was done in Figure 2). This is repeated for all other methods and intercorrelations among different methods. Unlike the models discussed above, the correlated errors model does not include additional factors to control for invalid components, rather, correlated error terms account for the correlation between invalid components.

σ_C = correlation among measures containing method 3.

σ_D = correlation among measures containing method 1 and those containing method 2.

σ_E = correlation among measures containing method 1 and those containing method 3.

σ_F = correlation among measures containing method 2 and those containing method 3.

It has been argued that using correlated errors is theoretically inelegant and makes actual theoretical relationships unclear (Gerbing and Anderson 1984). This is true only when correlated errors are specified in an atheoretical, post hoc basis. Theoretically supportable correlated errors have been used to model method effects in an multitrait-multimethod model (Arora 1982) and are extensively used with longitudinal data (Alwin and Jackson 1979).

When using correlated errors models, there is no requirement that all constructs be measured using the same invalid components (as with multitrait multimethod data). For example, some constructs can be measured with a single method component while others have some combination of methods. Finally, correlated error models may even be superior to traditional MTMM factor models (Widaman 1985), since they are not plagued by Heywood cases and provide more intuitively reasonable estimates (Marsh 1987).

AN EXAMPLE

Modelling invalid components is common when assessing validity with confirmatory factor analysis, but is much less frequently used when structural relationships are specified (exceptions include: Allen and Taylor 1985; Anderson 1987; Arora, 1982; Bielby, Hauser and Featherman 1977; Campbell 1983; Wolfle and Robertshaw 1982). Wolfle and Robertshaw present a good example of how systematic measurement error affects structural estimates. The effect of locus of control in period 1 on locus of control in period 2 dropped from 0.445 to 0.335 when method effects were accounted for using a correlated errors model. Reanalysis of Churchill and Surprenant (1982) data will further highlight the drastic difference in theoretical conclusions that may result when a model incorporating an invalid component rather than a congeneric measurement model is examined.

Churchill and Surprenant examined the effect of expectation and performance on disconfirmation and satisfaction using a video disk player and a plant. Churchill and Surprenant express concern about the inconsistent results between the two models, and suggest this may be due to differences in the measures used for each data set and the possibility of shared method variance. The pair-wise correlations reported in their study were reexamined using EQS to analyze both of these possibilities.

To test the effect of using different measures for the two data sets, a model using all the measures except 13 was fit to *both* data sets. This adjustment did effect the magnitude of the estimates but not the theoretical conclusion. Most notably, the plant data indicated disconfirmation affected satisfaction while the video disk player data still indicated it did not (see $\beta_{4,3}$ in Table 1). The video disk player data also indicated a much larger effect for perceived performance on disconfirmation and satisfaction (see $\beta_{3,2}$ and $\beta_{4,2}$ in Table 1).

To test the possible effect of shared method variance, correlated errors were added to Churchill and Surprenant's (see Figure 2, Churchill and Surprenant 1982). Although not identical, the measurement methods used by Churchill and Surprenant for each question were very similar, except for the faces scale (measure 12). A model was specified with the error terms for measures 1 thru 11 correlated with one another and constrained equal (only one method effect for measures 1 thru 11). Accounting for method effects resulted in models with similar estimates for both data sets (see Table 1). While some minor differences in the size of the estimates still exist, the theoretical conclusions for the two models are identical. Both models now indicate; disconfirmation affects satisfaction ($\beta_{4,3}$), perceived performance has a minimal effect on satisfaction ($\beta_{3,2}$), and perceived performance has a large effect on disconfirmation ($\beta_{4,2}$).

In summary, as Churchill and Surprenant suggest, not accounting for systematic measurement error appears to have effected theoretical conclusions. In particular, the conclusion that, "the effects of expectation, disconfirmation, and performance on satisfaction may differ for durable and nondurable products," was not supported when shared method variance is modeled. In addition, their conclusion that, ". . . both researchers and managers must direct much more attention to the impact of performance levels (on satisfaction)," may have been overstated.

LIMITATIONS

The researcher faces a dilemma when confronted with systematic measurement error. One alternative is to ignore systematic measurement error and use a model that is known to be misspecified. The other alternative is equally unattractive because data requirement may be excessive or restrictive assumptions about the nature of the systematic measurement error may be needed.

The ability of the researcher to explicitly model systematic measurement error will be limited for several reasons. First, the multiple measures necessary for this approach are often not available. Either multiple methods have not been developed (e.g. behavior intentions) or the researcher is unable to include multiple measures (data already collected or cost/length constraints). Even when multiple measures are available, the model may not be identified. MTMM models with more than three traits and three methods are considered identified, even with all traits and methods specified as correlated. However, replacing the correlation specifications with causal relationships may cause identification problems for subcomponents of the model. For example, a standard MTMM model is identified for the Arora data (1979), but when trait intercorrelations are replaced with structural relationships suggested by Arora, LISREL indicates the model is not identified. Determining model

identification must be handled on a case by case basis.

A final limitation is that the researcher must be able to identify and correctly model the invalid component(s). This may be difficult if the invalid component is not method based, or more than one invalid component exists. If more than one invalid component exists, then it is unlikely that the researcher can explicitly model all the relevant factors and still have an identified model. Identifying relevant systematic error may also prove difficult. Even when multitrait-multimethod data is used, simply modelling method effects does not insure proper specification. There may be other types of systematic error which are improperly modeled. To help minimize the existence of systematic measurement error (other than method effects), scales should be constructed using the procedures outlined by Churchill (1979) and Gerbing and Anderson (1988).

The second order factor models bypass the need to explicitly identify and model the invalid component. The advantage to this approach is its ability to account for multiple invalid components which do not have to be explicitly identified and modeled. The major problem associated with this approach is model identification (Gerbing and Anderson 1984). As with the explicit modelling approach, the identification problem must be handled on a case by case basis.

A problem with the second order factor model in Figure 3 is that systematic errors are uncorrelated. This may be inappropriate in some cases such as when there are shared method effects. When these correlations are not modeled, the second order factor will contain part of the invalid component. The problem becomes more serious the higher the correlation among the invalid components. This can be overcome by including correlations among the invalid components, however, empirical identification is difficult to achieve if a large percentage of the invalid components are correlated. Finally, the second order factor model not only requires multiple methods, but also requires the use of multi-item rather than single item scales. This is more restrictive than the traditional MTMM approach which only requires a single item for each method/trait combination.

The second order factor model in Figure 4 allows the researcher to explicitly model invalid components that may be correlated while simultaneously accounting for any unknown systematic error. This approach is the most powerful approach and makes the least restrictive assumptions about measurement conditions. As with the two approaches discussed above, identification can be a major problem. For example, Marsh and Hocevar (1988) present a three trait, three method model with three measures for each trait-method combination. This model was identified when correlations among the traits and methods was specified. However, changing the correlations to causal links will cause the model to be unidentified since certain subcomponents of the model are not

identified. In addition, the data requirements for complex models can be quite formidable, not only are multi-item, multiple method scales required, but there must be a large number of them since the number of specified relationships is also large.

Correlated error models have the most restrictive assumptions about the systematic errors. Restricting correlated errors to be equal implies that the percentage of measurement error, due to a specific systematic error, is identical for all measures. This assumption is violated if interactions between traits and methods exist. By definition, trait-method interactions indicate that the method variance differs across traits. The prevalence of trait-method interactions is unknown because they are difficult to assess. However, Widaman (1985) argues that these interactions should not exist and that they may be safely ignored in empirical work (commonly practiced in multitrait-multimethod analysis). The appropriateness of the equality constraints can be examined using first-order derivatives and modification indices. If these indicate that particular equality constraints are unreasonable (i.e., significantly reduce fit), the offending constraints can be relaxed. If only a few constraints require removal, the model may still be identified and the problems associated with the equality constraints will be reduced.

The correlated errors model will require that a correlation, rather than a covariance matrix, be analyzed. A covariance matrix cannot be analyzed since it is unlikely that the constraint of equal covariance between errors is reasonable if the measures have significantly different variances. Analyzing a correlation matrix is a compromise, however, because of the scale invariance problem. Analyzing a correlation matrix can lead to questionable estimates of the χ^2 value and the standard errors. For example, Bentler and Lee (1983) found the χ^2 value was optimistic by about 15%, and the correct standard errors were up to three times less efficient when a correlation matrix is analyzed. Nevertheless, dealing with scale invariance may be preferable to using a model that is known to be misspecified. Bentler and Lee (1982) found the parameter estimates were very similar no matter which matrix was analyzed. In addition, Lee (1985) has suggested an estimation procedure which is scale invariant, although programs using this procedure are not yet readily available.

DISCUSSION AND CONCLUSIONS

The pervasiveness of systematic measurement error, such as method effects, is widely recognized, yet researchers frequently do not model these invalid components (Darden, Carlson, and Hampton 1984). Commonly used congeneric measurement models may be inappropriate since they ignore the existence of systematic error and may often lead to inflated estimates of the structural relationships. However, the problem can be remedied by properly modelling systematic error in one of three ways, explicitly model the invalid components, second

TABLE 2
DATA REQUIREMENTS AND DISADVANTAGES OF ALTERNATIVE APPROACHES FOR
MODELLING SYSTEMATIC MEASUREMENT ERROR

Approach	Data Requirements	Disadvantages
Explicit modelling of invalid component	Matched measures which contain identical invalid components, need minimum of three different valid and three different invalid components	Data requirements may be restrictive, identification may be difficult to achieve, must be able to identify systematic errors
Simple second order factor models	Multi-item scales for each valid/invalid factor, multiple invalid components for each valid component	Data requirements may be restrictive, identification may be difficult to achieve, invalid components can not be correlated
Complex second order factor models	Multi-item scales for each valid/invalid factor, multiple invalid components for each valid component, matched measures which contain identical invalid components, minimum of three different valid and three different invalid components	Data requirements may be very restrictive, identification may be difficult to achieve
Correlated error model	Some factors must have more than one invalid component, some factors must have multiple measures	Percentage of systematic measurement error must be equal for all correlated error terms constrained equal, must analyze correlation matrix (scale invariance problem)

order factor analysis, or theoretical use of correlated errors. The results of this study underscore the importance of assessing and properly modelling measurement error before testing theory. Models ignoring systematic measurement error and using similar measures for all variables make it impossible to determine whether results are theoretically important or simply statistical artifacts.

Measurement quality must be carefully considered when using structural equation models. Without careful consideration of the possible presence of systematic measurement error, interpretation of the structural relationships is confounded. When selecting an approach to model systematic measurement errors, there is a tradeoff between the data requirements and assumptions about the nature of systematic error. If multi-item measures using multiple methods is available, complex modelling of the invalid components can be accomplished. If such data is unavailable, then a correlated errors model with the associated restrictive assumptions must be used. Table 2 summarizes the data requirements and disadvantages of the approaches for including systematic measurement error. Preferably, multiple methods should be used to measure each construct but the possibility of systematic error must be assessed and properly modeled even when a single method is used.

Varying Approaches to Data Analysis Discussant's Remarks

Stephen J. Arnold, Queen's University

The title of this session reflects the diversity of the four papers. One paper models choice of ground coffee. The second paper models market share as a function of number of newspaper stories. The third paper compares two optimal stimulation level scales. The fourth paper prescribes alternatives for accounting for systematic measurement error in structural equation models.

Unable to establish a common theme among these papers, I decided to focus upon the Wahlers and Etzel paper. It raises an important issue--whether or not a scale can be multidimensional. After commenting on this paper, I will make brief remarks about the other three papers.

WAHLERS AND ETZEL

The paper by Wahlers and Etzel examines the "internal structure of two measurement models used to operationalize the optimal stimulation level (OSL) construct in consumer research." Specifically, they consider two forty-item scales, the Sensation Seeking (SS) scale and the Arousal Seeking Tendency (AST) scale. They hypothesize four and five dimensions underlie the SS scale and the AST scale, respectively.

Wahlers and Etzel attempt to confirm the expected dimensionality of each scale using a second-order factor model. In this model, OSL is the second order construct, the four or five dimensions are the first-order constructs and the indicators are single-item measures. The research objective is "to examine both the measurement congruence between the scales and to assess the dimensionality of the measures. The results should provide consumer behavior researchers some direction in OSL scale selection--particularly when dimensionality is relevant."

Although initial analyses of the SS scale produced "unsatisfactory fit," Wahlers and Etzel make modifications until they are able to show that thirty-nine of forty items load as per the underlying four-dimensional structure. In the AST scale, however, they find seventeen items in the AST scale are inappropriately cross-loaded on the five-dimensional structure and that seven items fail to load on their respective hypothesized dimensions. They conclude by saying "researchers interested in selecting a measurement model to investigate the dimensions of the OSL construct would be advised to employ Sensation Seeking rather than Arousal Seeking Tendency."

I question whether these results "provide consumer behavior researchers some direction in OSL scale selection." Specifically, I believe that finding multidimensionality in a scale is an undesirable result. Since the AST results show more unidimensionality, I conclude researchers would be advised to employ the AST rather than the SS scale.

Several arguments can be made against pursuing and finding multidimensionality in scales. One argument is that it is contrary to the unidimensionality thesis advanced by Gerbing and Anderson (1988) and others. Anderson and Gerbing (1988), for example, state:

"that the computation of this composite score is meaningful only if each of the measures is acceptably unidimensional.

Unidimensionality refers to the existence of a single trait or construct underlying a set of measures" p.186

Other things being equal, a scale exhibiting multidimensionality will have a lower coefficient alpha, a measure of reliability, than will a unidimensional scale. The structure displayed in Figure 1 of the Wahlers and Etzel paper implies items associated with a specific first-order construct will be highly correlated with each other. However, these same items will be less correlated with items representing the other first-order constructs. Thus, the average intercorrelation among all items is less than it would be under unidimensionality. A lower average intercorrelation in turn drives down coefficient alpha. It is not surprising that reliability estimates are 0.851 for the SS scale and 0.853 for the AST scale. With a forty-item unidimensional scale, it would seem reasonable to expect reliabilities in the 0.9 range.

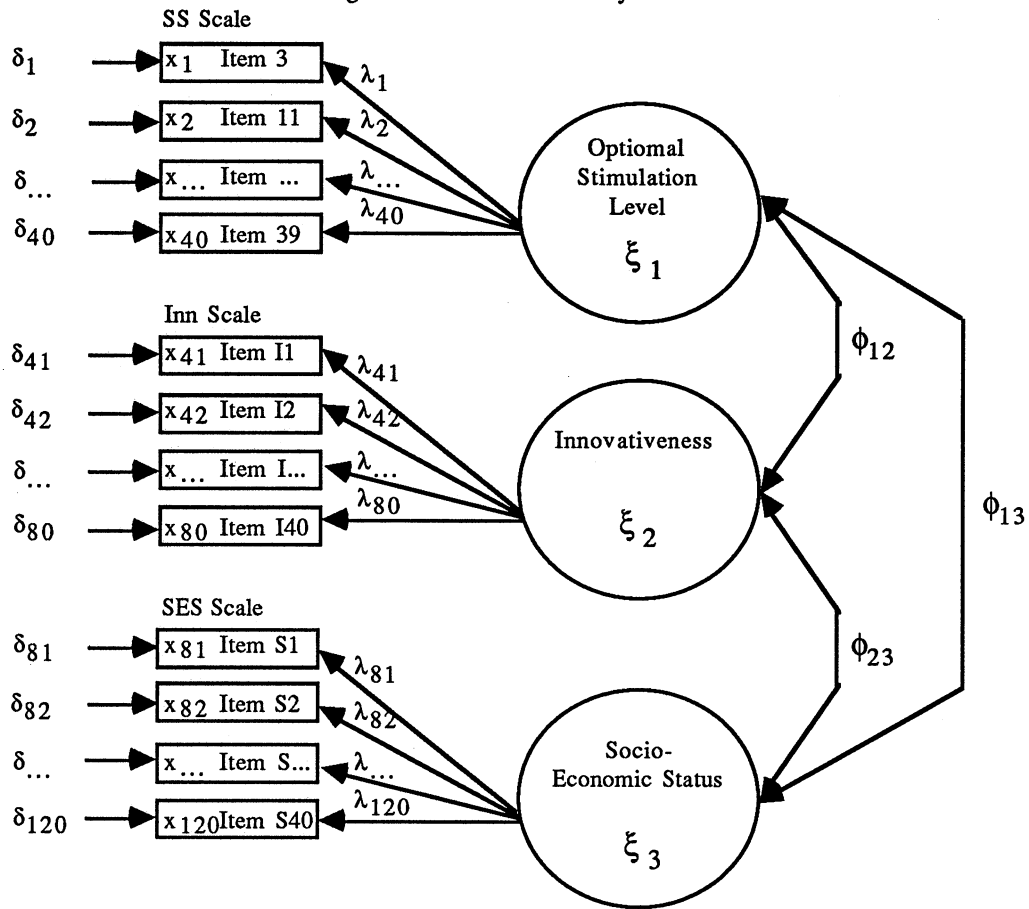

There are inherent contradictions in the concept of a multidimensional scale. For example, each of the forty items are stated to be indicative of the one second-order OSL construct. This implies all of the items are related to each other. At the same time, each of the forty items are posited to be indicative of one and only one of the four or five dimensional OSL constructs. This implies the items not indicative of the same construct are unrelated.

The clear factor pattern and "good fit" of the SS multiple construct model underlying Table 3 in Wahlers and Etzel means the four first order scales exhibit discriminant validity. In fact, these reputedly alternative OSL scales should exhibit convergent validity.

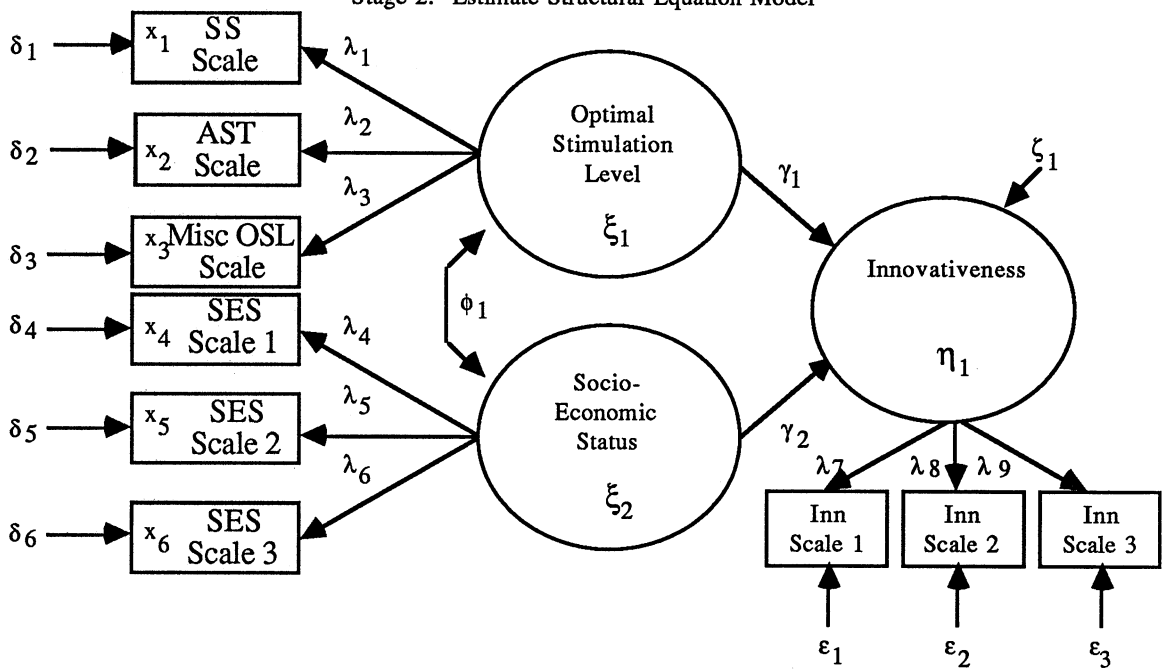

The unclear factor pattern and "several problems" of the AST results in Table 4 suggest at least some degree of convergence among the five alternative OSL scales. This provides some evidence of convergent validity for the AST scale. Thus, if the objective is to assess the construct validity of the SS and AST scales, the AST scale gives better results. This conclusion is opposite to that drawn by Wahlers and Etzel.

In general, a unidimensional set of items representative of the OSL construct should be resistant to demonstrating any stable underlying factor structure. As a consequence, any attempt to fit

FIGURE 1
Two-Stage Scale Assessment
Stage 1: Estimate Item Analysis Model

Stage 2: Estimate Structural Equation Model

a model which expresses the items as a function of multidimensional constructs should result in a poor fit.

Substituting four or five constructs for one construct defeats the criterion of parsimony in a theoretical model. A simple structure has been made more complex without any apparent gain.

Nomological validity is also not demonstrated when variations of the OSL construct, e.g., Thrill and Adventure Seeking, Experience Seeking, etc., are expressed as functions of the OSL construct. Nomological validity is demonstrated in a structural context when either a. the OSL construct is confirmed to be a function of two or more antecedents, e.g., situation characteristics, personality traits, or, b. the OSL construct is confirmed to have certain hypothesized consequences, e.g., innovative behaviour, risk taking.

Having raised questions about the Wahlers and Etzel approach to scale assessment, I feel obliged to present an alternative. Following Cronbach and Meehl, Campbell and Fiske, Nunnally, Heeler and Ray, Churchill, Bagozzi, and Peter among others, scaling research should work to establish construct validity of the scale. Construct validity, in turn, means finding evidence of convergent validity (scales indicative of the same construct are highly related), discriminant validity (scales indicative of different constructs are not related to each other) and nomological validity (expected relationships between constructs are confirmed).

To evaluate these three forms of validity, scale assessment appears to require estimation of two models rather than one, contrary to Wahlers and Etzel. Estimation of an "item analysis model" indicates discriminant validity. Estimation of a "structural model" demonstrates convergent validity and nomological validity.

The item analysis model is illustrated in Figure 1. Note that it is a confirmatory factor analysis model where only one construct is OSL-related. The other constructs are unrelated to OSL. This is a second fundamental difference from the Wahlers and Etzel approach.

The indicators in the item analysis model are groups of single-item measures indicative of each construct. The set of indicators associated with the OSL construct will be the group of single-item measures under investigation, e.g., the forty-item SS scale. Each of the other groups of single-items represent each of the other constructs, e.g., a group of innovativeness items represent the innovativeness construct.

When this model is estimated, the λ 's are indicative of the relationship between each item and its corresponding scale. High λ 's are desired. Anderson and Gerbing (1988) show that a function of the λ 's also provides an expression for computing the reliability of the scale.

The ϕ 's between the OSL construct and the other constructs are indicative of the discriminant validity of the SS scale (Widaman 1985).

The structural model to be estimated for scale assessment is also illustrated in Figure 1. In this model, the construct related to the scale under investigation is expressed as either an antecedent to, or consequence of, the other constructs. The indicators of the construct of interest are three alternative multiple-item scales (the SS scale, the AST scale and another OSL scale). Single-item measures are not used.

When this model is estimated, the cross-product of the λ 's for the SS and AST indicators demonstrate the degree of convergent validity (Widaman 1985). The γ 's between the OSL and other constructs demonstrate the existence of nomological validity.

GRUCA

Imagine a new supermarket is built in your neighbourhood. What happens to your chances of shopping at each of the existing supermarkets? It seems they would either stay the same or fall. It doesn't seem logical they would rise. This is the regularity assumption which is tested in the Gruca paper. Instead of supermarket data, however, he uses the ubiquitous coffee data.

I believe Gruca understates how well his results support the regularity assumption. Table 4 gives the share changes for the seven brand loyal segments. The percentage change to focus on in each segment is obviously the one for the brand to which the segment is loyal. In seven out of the seven segments, the portion loyal to the brand drops after entry of the new brand.

The small number of households used in the estimation (52 in Pittsfield and 44 in Marion) raises questions of external validity. Systematically excluded are the light users and those who purchase beans, instant coffee, decaffeinated coffee, minor brands or the new brand. Also excluded are coffee purchasers who are not on either of the two panels.

Obviously, no one test of an assumption can be definitive. Continued testing is justified and the validity of the assumption at any point in time depends on the accumulated evidence.

FAN AND SHAFFER

In marketing communications courses, we always refer to the potential influence of public relations activities in addition to the effects of advertising and personal selling. However, I can't recall any empirical advertising/sales or market share models which included measures of this form of unpaid media presence or "information pressure" as it is referred to by Fan and Shaffer. Drawing our attention to this variable and describing a measurement approach is a contribution made by these authors. They also highlight the use of electronic databases which I think is an underutilized resource in marketing research.

Whether or not information pressure will explain additional variance in measures of sales and market share after accounting for the other major variables--advertising spending, distribution and pricing--is another question. I can anticipate a high correlation between advertising spending and unpaid media presence. If this was the case, unpaid presence would not have a significant effect once the effects of advertising spending were partialled out.

This question in turn leads to a more general question--how valid are these results? What we see is a significant relationship between information pressure and market share when the data for one measure is related to the data for one other measure. However, any series of data with up to one inflection point can be fitted quite well with a two-parameter model. A spurious relationship is another possibility. Thus, obtaining measures for the other major variables and including them in the model is an obvious and important next step.

If obtaining these other measures is a problem, establishing predictive rather than nomological validity is an alternative. This could be done using a holdout sample. The model would be estimated on the first half of the data and tested on the second.

Consistency in formulation is also important which applies to the current effort as well as to any future models which might be estimated. By this I mean that the dependent variable, market share, is a relative or proportionate measure. The specification for the independent measures should be the same. Thus, information pressure should be specified as share of new stories rather than absolute number of news stories.

COTE AND GREENBERG

This paper is an important followup to Cote and Buckley's 1987 paper which alerted us to the potential magnitude of method variance. The current paper outlines alternative techniques for accounting for method variance as well as other forms of potential measurement error.

I have only one observation and it is to emphasize a disadvantage which was acknowledged for the first three alternative techniques: "identification may be difficult to achieve." With a few exceptions, I believe identification will be *extremely* difficult to achieve. This only emphasizes the importance of the correlated errors model alternative. It may also point to the utility of a fifth alternative technique which is not mentioned: Perhaps we will have to revert to inspection of the multitrait, multimethod correlation matrices. For example, an inspection of the correlation matrix for the eighteen measures should reveal that y_1 , y_2 and y_3 correlate more with y_4 , y_5 and y_6 than with y_7 through y_{18} .

In any case, determining whether or whether not there is method variance is dealing only with nomological validity. It will still be necessary to consider the convergent and discriminant validities as I discussed earlier when commenting on the Wahlers and Etzel paper.

Repetition, Social Settings, Perceived Humor, and Wearout

George M. Zinkhan, University of Houston

Betsy D. Gelb, University of Houston

ABSTRACT

Humor has been examined from various perspectives in consumer behavior research. As E.B. White (1941) has asserted, "humor can be dissected, as a frog can, but the thing dies in the process." Here, we continue this dissection tradition by examining two variables which may significantly influence perceived humor: social settings and wearout. A theoretical model is developed to predict when commercials will be perceived as humorous and when they will die (under the knife).

INTRODUCTION

The history of advertising and the history of humor have only recently intersected. In the early days of American journalism, ads were serious business, literally called "tombstone" ads by journalism historians because they were print notices which resembled the terse wording found memorializing the dead.

With the advent of broadcast media--radio and television--humor has blossomed, and it can be argued that the association is more than coincidental. Broadcast introduces into the advertising communication process three elements absent from print advertising. One is unsought repetition of a commercial message. The other is the possibility of communication to an audience greater than one, whose members are aware that others are sharing with them receipt of the advertiser's message. The third, of course, is the possibility of enhancing perceived humor through voice inflection, accent, and music.

The influence of the first two factors--unsought repetition and multi-person audiences--on response to humor in advertising is the focus of the discussion to be presented here. We will first outline the argument that humorous ads may flourish because of these two factors. Then we will review literature suggesting that repetition of a humorous ad leads to a particular type of "wearout," where a commercial message may lose its perceived humor. However, we will also suggest that in social settings, wearout of humor can be mitigated by the presence of a multi-person audience which supplements the humor in the commercial with its own shared meanings.

WHY COMMERCIALS NEED HUMOR

Literature linking attitude toward an ad to its effectiveness provides one managerial rationale for humor in advertising (Gelb and Pickett 1983). Another rationale is the association of humor with attention getting (Sternthal and Craig 1973, Madden and Weinberger 1984). These arguments appear to support the value of humor in advertising in any medium, print or broadcast.

In fact, however, humor appears relatively more rarely in print ads than in broadcast

commercials. When Sears sends out a direct mail piece for its McKids stores directing the reader to "fill out the name and address coupon if your label was eaten by a large creature with teeth," the piece stands out conspicuously from the vast majority of humorless direct advertising. Similarly, a reader may page through a daily paper or magazine in vain seeking a light touch in display or classified ads. It seems reasonable to ask, then, why humor has made greater headway in radio and television.

It will be argued here that humor is related to the purpose of advertising and humor is the advertiser's response to anticipated audience unhappiness with unsought repetition in commercials. However, humor may "wear out" even sooner than other commercials do--possibly because it commands more attention. On the other hand it appears that the capacity of broadcast commercial messages to achieve exposure to audiences of more than one person, consciously sharing the experience, mitigates some wearout of humorous messages. Each of these will be discussed in turn.

BROADCAST MEDIA: HOME OF HUMOR

Our first proposition is that commercial messages in broadcast media are more likely to at least attempt to evoke humor than are print ads. Two explanations, which are not contradictory, may be offered.

First, Puto and Wells (1984) suggest that good advertising either transforms the experience of using a product (e.g., a musical cola commercial) or informs the consumer. Broadcast media appear particularly appropriate for "transforming," due to the availability of music and other sound. Humor is a more likely approach for transformational than for informational advertising, one may surmise. If so, the link between broadcast media and humor is indirect, but plausible.

Second, the advertiser's desire to prevent or delay "wearout" is another explanation. If a print ad would be boring upon rereading, it will presumably not be reread. A radio or TV spot, by contrast is less likely to be encountered only once. The advertiser, aware of the problem, uses humor to bribe the viewer or listener to tolerate the repetition.

HUMOR AND REPETITION

Whether either or both of the previous explanations are indeed the factors linking humor to broadcast media, the reality is that humor may actually speed wearout (Gelb and Zinkhan 1985). The phenomenon of "wearout" refers to the fact that advertisements lose effectiveness after repeated exposures. There is evidence that this effect occurs for a variety of dependent measures, including: humor (Gelb and Zinkhan 1985), persuasion, recall,

and sales (Blair 1988). It is generally assumed that advertising messages achieve their peak effect after three exposures. After that point, the persuasive or selling power of an ad declines with repeated exposures.

Investigating the potential wearout of humorous appeals, a McCollum/Spielman study ("Repeating ..." 1978) concluded that a humorous or off-beat commercial will lose its effectiveness sooner than a straight selling message. More recently, however, this result was unsupported in a study by Belch and Belch (1984). In their laboratory study, they embedded in a half-hour television program either humorous or serious Federal Express commercials shown one, three, or five times during the program. Unaided message recall scores showed no significant effect for humorous vs. serious message or for number of exposures. Intention to use Federal Express, designed as a measure of persuasion, likewise did not vary significantly based on humor, number of exposures, or the interaction between the two.

An earlier study by Ray and Sawyer (1971) did not consider humor specifically, but explored the repetition effect of "grabber" ads (those with intrusive and unique qualities). Such ads, which might or might not seek to evoke humor, were found to outperform "non-grabbers" on recall but to underperform them on purchase intention. Blair (1988) similarly investigated the proposition that certain "world class" ads do not wear out over time. She found that such commercials do build in the sense that persuasive ads increase sales over time (related to advertising spending). However, in the process, these ads also wear out (Blair 1988).

Various models have been proposed for explaining and investigating advertising response. Here we discuss two models:

- 1) A cognitive model, in which some element (e.g., humor) elicits attention for the substance of a message. This subsequently produces belief, then conviction, then brand preference.
- 2) A classical conditioning model, in which some element (e.g., humor) makes the advertisement attractive, and that attractiveness is transferred to the brand.

These two models are adapted from theories developed in the speech literature which link humor to persuasion. In general, we feel that a promising method for comparing these two, competing models is to examine their predicted effects on various measures of advertising response (e.g., recall, persuasion). That is, these two models can be used to derive predictions about the expected effects which humor will have on alternative measures of advertising effectiveness. To the extent to which these predictions are confirmed, the relative power of the two models can be assessed.

If an individual is exposed several times to the same humorous commercial, which exposure will

have the greatest influence on that individual's subsequent evaluation of the advertised product? In other words, which will be more influential: the level of perceived humor following the first exposure or the level of perceived humor after the final exposure?

The two proposed models have differing predictions concerning this question. Under situations where the cognitive model is appropriate, the better predictor of advertising response (e.g., recall, persuasion) would be the humor perceived following the first advertising exposure. In situations where the classical conditioning model applies, the better predictor would be the humor perceived in the final (pre-purchase) advertising exposure.

These different predictions result from the function of humor in the advertisement. Madden and Weinberger (1982) found a significant association between humor and Starch "noted" scores, suggesting that humor draws attention to an ad. Using the cognitive model, it then appears that a sequential process of first knowing and second believing the substance of the message is set in motion. Thus, if the humor fades on subsequent exposures, there should be no associated drop in conviction, which presumably has already been developed. Perceived humor and recall should be positively associated if this model applies.

By contrast, humor would have a different function in the "transfer of affect" model (Shimp 1982). Presumably its function would be to make the advertisement attractive, and by classical conditioning to make the brand attractive. If so, and if humor then fades with repeated exposures, it would be expected that the impact of the initial perception of humor would be superseded by later perception. Thus, a level of perceived humor in the advertising exposure closest to the purchase decision would be a better predictor of brand choice than would the initial level of perceived humor. Perceived humor and recall need not be positively associated for this model to apply, since brand choice is presumed to stem from advertising attractiveness, not from the substance of the message.

To explore whether the cognitive model does explain wearout, Craig, Sternthal and Leavitt (1976) forced attention to repeated messages, and by doing so postponed wearout, a result supporting the attention-belief-persuasion path. However, Calder and Sternthal (1980) found that wearout can occur in spite of advertising strategies designed to enhance attention. They expected message repetition to lead to counterargumentation, a hypothesis which would appear to support the classical conditioning model, if some element which provides positive feelings about a message (humor, perhaps) declines over time and permits a clearer-eyed consumer to begin evaluating the message. Specifically, the researchers measured the effect of successive exposures on the arousal value of commercials and also the evaluation of those commercials. Results showed, for one of two products, a lower evaluation

with a higher number of exposures and a non-monotonic effect on arousal, which increased up to three exposures and then decreased with six exposures. However, the study failed to find the expected increase in negative thoughts processed by audience members after several exposures. Thus, the findings were equivocal.

The above discussion of the literature suggests the overall proposition that perceived humor will decline with repetition. The cognitive and classical conditioning models provide alternative explanations for this effect. Since these models provide contrasting predictions about the relationship between humor and advertising effectiveness, carefully designed experiments should be able to identify the circumstances under which one model is superior or preferable to the other in terms of explaining this humor wearout effect.

THE INFLUENCE OF SOCIAL SETTINGS

The discussion so far has offered a contradictory picture. Humorous messages are placed on TV or radio because humor is deemed useful, but humor "wears out" with repetition. The final proposition to be presented here concerns the effect of social settings. Specifically, if more than one person is listening to or watching a commercial message, then this social dimension increases the likelihood that a message will be perceived as humorous, *even* after repetition.

Three studies suggest the merits of the case. Butcher and Whissell (1984) instructed experimental groups of two, four, or 10 subjects to view a humorous short film and taped their laughter. They found that, as group size increased, there were more laughs per person, longer laughs, and louder laughs. The trend in all cases was for greatest responding to occur in the 10-person audience and least responding in the 2-person audience (p. 950). An explanation for this relationship may be found in research by Alello et al. (1983) who found that "high spatial density" (more people per square foot) enhanced subjects' enjoyment of humor.

The third relevant study (Brown et al. 1982), building on the effect of "laugh tracks" in TV shows, showed print cartoons to individuals and measured laughter and smiling. A pre-coached "model" looked at the cartoons first, and then left the room; results showed that when the model had laughed, a subject laughed more than when the no-longer-present model had not laughed.

These studies support previous research which has found laughter to be contagious--or as the second study shows, even the recollection of laughter.

Here, then, may be a clue to the common-sense observation that not all humorous commercials (or comedy acts) "wear out" with repetition; some seem to get better, as *anticipation* of what will be presented evokes an anticipatory humorous response. If, in fact, a listener or viewer laughs because others do or have, the fact that broadcast commercials may have audiences of a size

greater than one allows for the possibility that wearout of humor may at least be postponed. In a similar way, certain television commercials appear to become "funnier" over time as their punch lines enter the language of popular culture and are repeated by professional comedians, as well as the general public. One example of this sort of "world altering" commercial is Wendy's "where's the beef?" campaign, which even became an integral part of the 1980 Presidential election.

DISCUSSION

This paper has offered three propositions:

1. Humorous commercials are disproportionately placed in broadcast media.
2. The unavoidable multiple exposures of radio and TV audience members to humorous broadcast messages diminishes perceived humor as exposures increase. The classical conditioning and cognitive response models provide competing explanations for this effect.
3. The contagious quality of laughter suggests that wearout can be greatly delayed under some circumstances, if commercial messages are seen/heard by someone in a social setting.

Taken together, these propositions suggest specific research directions.

First, it would be useful to examine the effect of group vs. individual responses to humor in radio commercials. The appeal of Jack Benny's "Well..." indicates the likelihood that a family gathered around the radio *circa* 1945 did indeed enjoy a group response to humor. For the 1990s, an appropriate project might be to test the perceived humor in drive-time radio messages heard by carpoolers vs. solo drivers, for example.

Second, it would be valuable to analyze elements of broadcast/telecast messages to determine which ones evoke group responses, with the idea of employing these elements in prime-time dayparts where group listening or viewing is most likely. Is "visual humor," for instance, more evocative of group response than is clever dialogue?

Third, we need to examine the fundamental issue of whether laughter and reports of perceived humor measure the same response, and/or to what extent they do so. The study where a laughing or non-laughing model left the room before the research subjects were exposed to a humorous stimulus obviously tried to reduce the likelihood of laughing because others were doing so, rather than laughing because the stimulus was perceived as funny. But one study can never be definitive.

Finally, we need to probe further the effects of "successful" humorous messages. Which are most likely to achieve which advertising objectives?

Only if humor "works" with considerable reliability is it useful to know the extent to which it wanes with repetition and/or waxes as the group sitting in front of the TV set enlarges. Basic questions in this whole area continue to challenge consumer behavior researchers, no matter how carefully or reliably we hone our dissecting knife.

Does Brand Attitude Moderate the Persuasiveness of Humor in Advertising

Amitava Chattopadhyay, McGill University
Kunal Basu, McGill University

INTRODUCTION

Though the use of humor in advertising has been growing with widespread support among practitioners (Kelly and Solomon 1975; Markiewicz 1974; Lubalin 1977; Madden and Weinberger 1984), academic research in the area has over the years yielded equivocal conclusions. In research studies, humorous treatments of ads have failed to evoke systematic and superior persuasive effects, either by themselves, or in comparison with serious versions of the same messages (Sternthal and Craig 1973; Duncan 1979). Both methodological as well as conceptual critiques have been directed at the above research, particularly with increasing emphasis on the role of contingencies that might moderate the impact of humor in advertising. It has been pointed out (Murray 1987) that with the exception of a few audience characteristics, such as race, sex, etc., systematic and theoretically driven investigations are missing in the literature.
